This conceptual study marks the beginning of the exploration of instances in which servicescapes can be said to be exerting an influence on the service 'recipient' that cannot be fully accounted for by understanding the value provision of the service. We provide an alternative view where the servicescape provides a milieu that is never politically innocent. For instance, servicescapes are often constructed to attract a particular clientele, either implicitly or explicitly, on account of their age, gender or appearance (Rosenbaum 2005). Nor are servicescapes always directed towards individuals that would be consumers of the service by virtue of their own volition. Often when travelling, for instance, consumers have little option other than to traverse a commercialized servicescape to reach an exit (Pütz 2012).

We shift our gaze to service encounters that have run amok – servicescapes that continue to add service components that exceed control and organize not in accordance with mutually co-created benefits but in monstrous forms, where organizing is not assumed to tend towards harmony but rather its opposite (Thanem 2006). These perspectives, which draw from non-representational literatures (Hill, Canniford, and Mol 2014), offer novel conceptual tools for theorizing consumption in servicescapes that question the individualism (Thompson, Arnould, and Giesler 2013) that manifests methodologically as the *emic* voice that assumes active cognitive meaning-makings by the consumer. This allows for theorizing on questions of collective domination, injustice, and inequality (Peñaloza and Venkatesh 2006) – all possible affective relations of the service encounter. We conceptualize the airport servicescape as an exemplar of a service encounter with a machinic logic where consumption is not sufficiently explained by the notion of meaningful experiences of value co-creation.

THE AIRPORT SERVICESCAPE

As sites of travel departure and arrival, airports serve many functions that directly facilitate consumption. They offer spatial possibilities for consumers to engage with airline services and constitute consumption environments created and shaped to a large extend by retailers (Folkes, Koletsky, and Graham 1987; Rowley and Slack 1999). Beginning with duty-free tobacco and liquor sold to trans-Atlantic travellers in Shannon, Ireland in 1947, the airport context of consumerism thereafter emerged worldwide (Newman and Lloyd-Jones 1999). Latterly, airports have emerged into 'airports-as-firms', offering "an array of different value propositions: attractions for tourists and aviation enthusiasts, congressional and logistics facilities, shopping venues and consulting services" (Jarach 2001, 119).

Akin to other servicescapes, airports are sites of a wide array of consumption instances, posing either favorable or adverse outcomes that vary in their degree of controllability and predictability. Crawford and Melewar (2003) describe airports as sites of heightened consumer anxiety, fear, and excitement, accentuated by travel stress. While this is conducive to heighted impulse purchasing, such consumption can only be facilitated by stress-reducing design – thus airports should be both aesthetically pleasing and functional (Bowes 2002). Fodness and Murray (2007) describe the airport as "an elaborate servicescape … similar to a hospital, with many corridors, queues, signs and complex interactions" (p. 493). Rowley and Slack (1999) note that airports, due to consumers' experiences of global travel, facilitate a sense of "timelessness and placelessness" (p. 363) for consumers in transit. Similarly to hospitals, supermarkets and motorways, airports thus reflect what Augé (1995) terms 'non-places' and Castells (2000) 'places of flow'. Both lack a history and sense of identity and are judged primarily on their capacity to transfer users from one point to another in as smooth and error free a fashion as possible. Airports are also often the first and last points of traveler contact from the perspective of tourism consumption, and thus airport experience has a strong bearing on travellers' future expectations and intentions (Martín-Cejas 2006).

Consumption in airports often consists in frustrating and problematic experiences (Crawford and Melewar 2003; Pütz 2012; Rowley and Slack 1999). In the extreme, it has been noted that airport 'security theatre' (as opposed to 'security reality'), elaborated in the wake of 2001, has played no role in thwarting recent attacks (The Economist, 2015). Highly visible security rituals have not been able

to guarantee passenger safety against 'inside' jobs (Metrojet Flight 9268), external attacks (Malaysian Airlines Flight 17), or technological malfunction (Malaysian Airlines Flight 17). However, airport service contexts continue to prosper (Crawford and Melewar 2003; Rowley and Slack 1999), indicating that any straightforward notion of benign value co-creation fails to capture the emergence of these consumption contexts and the performative ways they become reenacted through their mundane repetition.

While the airport consumption experience has many unique characteristics, a recurring theme in the literature is the idea of its manageability and its value generating potential. We will now offer an alternative logic of machinic becoming to provide a new way of describing and problematizing the airport consumer experience – a view that questions the manageable and foregrounds the 'monstrous'.

PHILOSOPHICAL REFOLDING – BECOMING-MACHINIC, BECOMING-MONSTROUS

Gilles Deleuze and Félix Guattari (1977, 1987), in addition to their various single-authored works, collaboratively wrote some of the most influential non-representational accounts in the recent tradition of French philosophy. While it is impossible to construct any comprehensive account of their approaches here, their project firmly centered upon constructing a new image of thought that would be of 'emergence'. Their work has had little impact upon consumer research (Hietanen, Rokka, and Schouten 2014), but their ideas, which foreground an ontology of incessant change rather than assuming that nature (or thought) aims for a harmonious systemic order or equilibrium, have received greater recognition in organization theory (Thanem 2006). We believe adapting their ontology can bring forth a new perspective to services research sharing a threshold with consumer culture theory (Arnould 2006; Peñaloza and Venkatesh 2006).

In contrast to most marketing and consumer research accounts that base their ontology on human rationality and individual agency, for Deleuze and Guattari all relations (both human and nonhuman) are in becoming; a production of intensities that attract or repulse. This is affect that is beyond the representational; a form of surplus of raw desire that is in constant excess of rationalistic accounts (Thanem 2004). Thus, while a conventional account of services would see problematic situations as merely faulty or as epiphenomenal hindrances to the intended service (Grönroos and Voima 2013; Morgan and Hunt 1994; Ravald and Grönroos 1996), in this view the 'problematic' is purely productive (Genesko 2014). It produces an excess of relational affect. All relations are in mutual becoming, and thus also it is the tendency for humans to become-machinic when thrust into relational becoming with machinic emergence (Deleuze and Guattari 1977, 1987).

In its view of the machinic, the Deleuzoguattarian approach breaks from rationalistic aspirations of humanity by postulating that oppression and subjugation are not emotive states which desire avoids. Quite the opposite, we desire to be controlled by a structuralist logic we embody from a very early age (Deleuze and Guattari 1977, 1987). Moreover, a Deleuziguattarian perspective of becoming one with the environment is not a matter of Aristotelian distinctions of the external and the internal (Deleuze 1994). We do not walk into a space as external things. Rather, we construct the space itself through presence in space and social interactions. It is not mimesis (Marks 2000), but rather the idea that space cannot occur without embodied participation in it.

Next, we argue that the airport servicescape, through its tensions and performative events (security checks, pronounced distinctions between the have-nots and the privileged, unpredictability of service

encounters and the like), is best described as a machinic becoming where technologies, operators and consumers become engulfed in a systemic becoming that has long since escaped any conceivable form of rational service provision.

MACHINIC ENCOUNTERS IN THE AIRPORT

We identify three machinic performances of the airport servicescape which we term (1) conspicuous stratification, (2) the contradiction of unpredictability and linearity, and (3) security theatre. These collectively manifesting performances invite all participants to submit and enter into a relationship of becoming with and within them.

Processes of stratification both implicitly and explicitly segregate passengers by way of wealth, physical ability, and sexuality within the airport context. In an implicit sense, luxury boutiques and high-end restaurants housed in airport terminals constitute restrictive zones whose services cater to affluent travelers but actively discourage those less privileged. In an explicit sense, business and first class passengers are granted privileged access to lounges and fast track queues from which economy passengers are formally excluded (Wu 2014). On the flight itself, it is often only a conspicuous curtain that separates economy from business and first class. The curtain, usually left open during take off and landing, is tantalizingly drawn closed during the flight itself, during which time higher-paying passengers enjoy superior meals and entertainment than lower-paying passengers (The Economist 2016). One could argue that nowhere else in contemporary western society is social class distinction as visible as in the airport servicescape.

Physical disabilities, accentuated within the context of the security check, constitute a second form of stratification. Upon entering the metal detectors, for instance, travelers are processed before spectating passengers and airport employees. Pütz (2012) notes the manner by which this temporary isolation poses a challenge for travellers walking unaided, but constitutes an "insurmountable barrier for others" (p. 15), such as infants and the disabled. By virtue of their wide thoroughfares, disability ramps, and support vehicles, airports are constructed to accommodate disabled passengers. However, these very same provisions also draw attention towards these disabilities. Another form of stratification is evident in the observable limit on equality that lies in the function of the physical security check (Mann 2011). Primarily as an organizational response to issues of privacy, travelers are instructed by security personnel to divide into males and females before being patted down (Pütz 2012). That this form of screening is embraced by the majority of passengers and practiced in airports universally is indicative of the human desire to, in some fashion, submit to its machinic order. In all, the airport is machinic insofar as stratification occurs and segregating insofar as that stratification is conspicuous.

A second machinic property of the airport servicescape lies in the contradiction of linearity and unpredictability. Put simply, though airports constitute a near universally defined set of practices, arranged in a specific order, which seasoned travellers can negotiate with ease, they also engender a high degree of unpredictability. Delays are all too common, hour-long stopovers can suddenly extend to full days, and random drug and explosives checks can be sprung upon unsuspecting travellers (Pütz 2012). Professional security continually monitors passengers; and passengers consciously and unconsciously surveil one another (Foucault 1977). As a result, inappropriate behaviors, like drunkenness, are treated with greater severity than in analogous service encounters. Airport servicescapes possess a linear quality consistent with Lovelock and Wright's (1999) notion of being 'in the factory'. Whereas consumers can voluntarily leave

most service encounters, airports reflect an extreme of the 'in the factory' metaphor with no obvious provision for passengers to turn back. Once on the plane, that plane will continue to its predefined destination and passengers only emerge at the end of the assembly line. Recognition of the gravity of entering the airport machinery is visible in passenger body language as they enter the security check. As Pütz (2012) notes, on stepping through the metal detector "travelers duck while passing it … other travelers take a deep breath before stepping through the metal detector. Some pause right in front of it and take one large step, as if passing a point of no return" (p. 18).

A third machinic property of the airport servicescape is security theatre. This term, referenced in previous studies of airport and border security encounters (Amoore and Hall 2010; Walsh 2015), describes the irrational fashion in which security checks are conducted. High technology and staffing costs expend supplier resources and protracted queuing wastes the time of travellers. This takes place despite little evidence security checks increase overall passenger safety, for safety is an illusion conferred in the iterative practice of security checking rather any measurable outcome (Walsh 2015). In addition to this, airport security machinery primes users to enact the persona of 'the passenger' as deemed desirable by airport staff, airlines and other passengers. In their study of borders, for instance, Amoore and Hall (2010) emphasize how assemblages of technologies and calculations that form the sequence of the securitized border serve to authorize its actions. By differentiating bodies that must wait, stop, pass or turn back, travellers are disciplined to understand they must adopt prescribed behaviors to ensure timely passage. Since most seek only hassle-free travel, passengers strive to avoid potential conflicts, as inconsequential as they may be. This further guides desire to comply with the machinic. Passengers, for instance, often remove watches, sunglasses, and other accessories in imitation of others further ahead in the queue, rather than wait to be instructed to do so themselves by security personnel (Pollner 1979).

The capacity consumers display to render themselves compatible with machinic assemblages has been explored within the servicescape literature. Studies have shown humans are highly sensitive to environmental cues: for instance talking softly and slower when lights are slow and the service environment is perceived as formal (Nilsson and Ballantyne (2014). By contrast brightly lit service encounters tend to be louder and communication exchange is more frequent and fast paced (Lewison 1991; Hoffman and Bateson 2002). In similar fashion, Pütz (2012) notes that the closer travelers come to the checkpoint itself and to the perceived sense of formal observation and security scrutiny, the quieter they become. Passengers avoid looking directly at travellers who are patted down, but nevertheless seek to take cues from the exchange as to how they should behave once their turn comes. When it does, travelers avoid direct eye contact with the security official but also avoid staring dreamily into space: "they are able to observe the situation out of the corner of their eye and stay cooperative" (Pütz 2012, 174).

AN ONTOLOGY OF THE
MACHINIC SERVICE ENCOUNTER

The purpose of this conceptual study has been to open novel ontological avenues for theorizing the consumer experience of a service encounter. Employing a Deleuzoguattarian perspective that emphasizes the relational emergence of affect, we have attempted to introduce an alternative conceptual space to how 1) servicescapes have been written as manageable wholes that assume an equilibrium-logic (Ezeh and Harris 2007; Grönroos 2011; Vargo, Maglio, and Akaka 2008), and 2) to the view that privileges consumers' individualism and cognitive meaning-making prevalent in consumer culture theory

(Thompson et al. 2013). While we posit that the service encounter in servicescapes such as the airport emerge as assemblages where the consumers enter into a collective mode that can be described as becoming-machinic, our approach is not devoid of humanism in the sense that we remain conceptually interested in how the airport is a primary exhibit of how consumption manifests under the (1) conspicuous stratification, (2) the contradiction of unpredictability and linearity, and (3) security theatre. The airport, as a service encounter is an example of monstrous organizing (Thanem 2006) *par excellance*, and in all its machinic tendencies is a site where discipline is performed both as a condition of its own systemic properties and collectively between consumers themselves.

The idea of machinic becoming is marked by a certain precognitive condition, the sense through which humans are affectively drawn to, or repulsed from, becoming constitutive of and embodying the contexts and socially and technologically unfolding performances. A Deleuzoguattarian logic of desiring has the tendency to actively seek its own repression and subjugation, which is embodied when one 'becomes' a machinic part of the spatial organization itself (Deleuze and Guattari 1977, 1987). We argue for a novel logic in culturally oriented consumer research that questions the capabilities of the individual to maintain a cognitive distinction with him/herself and the performative context s/he encounters. This is how the airport has a systemic tendency that evolves by centripetally feeding the system itself for itself. If conventional theorizing on services would hold, it should be straightforward to rectify the inconsistencies and contradictions of how the airport service encounter unfolds. Thus, we are faced with the idea that airports are, as they manifest now, either supposedly approaching something deemed the managerial optimum, or then there may well be a relational space of becoming not well addressed by the extant literature. Neither alternative seems to have received adequate attention.

We thus postulate that, with the particularities of the airport consumption experience nothwithstanding, the monstrous (Thanem 2006) is inherent in all events of sociotechnological organizing. An airport as a service encounter seems to be a fitting example of this, but similar emergent relationality could potentially take place in all servicescapes where the consumer is required to pass through and adhere to a market logic. Additionally, the airport offers an illustrative example of an ultra disciplined urban space. This is not a simple idea of surveillance, but rather a collective policing that goes on among people going through the 'system' ("doesn't she know what she is doing in the security check? Why would you bring your family with you as a nuisance to all other travellers?"). Yet, we are not attempting to dissect the machinic encounter of the airport-scape. Rather, we see it *in toto*, as a totalizing system without limit, a holistic desiring-machine, inhabited by desiring-technologies and desiring-consumption.

This is one reason why passengers display a willingness to give themselves over to the machine: only through compliance with the airport apparatus can passengers secure a swifter passage. This compliance is reinforced by what Pütz (2012) defines as architectural design and procedural rules. The former is reflected in permanent fixtures (i.e. walls and gates) and impermanent fixtures (ropes and other movable elements that channel passengers into forming a queue) engineered to narrow the possible actions that could happen at any given checkpoint. The latter manifests in unambiguous written and unwritten rules that reduce the many imaginable behavioral patterns at a security point to those few deemed acceptable and desirable. To return to the machine metaphor, this process is akin to (1) priming subjects as they enter the machine and (2) sifting out inappropriate, contaminated, perhaps even dangerous, subjects before they enter the machine (Pütz 2012).

In addition, there is a future call to pay increasing attention to the breaks in the machinic code of the servicescape. While its logic remains totalizing, it is unlikely that it can 'be total'. Every act of subversion by the servicescape consumers or operators (removing the temporary barriers so as to not have to zig-zag lengthily in the queuing apparatus, the officer cracking a joke during the security check ritual) pierces the machinic and renders it visible. Under different logics, such phenomena have been called ludic agency (Kozinets et al. 2004), microemancipation (Brownlie 2006), or the molecular tendency within every system that operates to produce molar or structural rigidities (Deleuze and Guattari 1977, 1987; Guattari 2007; Thanem 2006). Nevertheless, these subversive acts of resistance seem to hardly contest the overall functioning of the airport servicescape and its repetitious performative unfolding.

If non-representational theorizing continues to gain ground in consumer research (Canniford and Shankar 2013; Hill et al. 2014; Hietanen and Rokka 2015) there is also another pressing issue that the Deleuzoguattarian logic of machinic becoming of social relations can inform us about. This is the problem of subjectivity. Unlike practice-based theorizing and actor-network perspectives that generally stress the surface level of human and technological interactions (Latour 2005; Warde 2005), Deleuze and Guattari (1977, 1987) make human desire for subjectivity one of their central focuses, even if this subjectivity is inherently always fleeting, elusive and incomplete. Thus Deleuze and Guattari foreground the politics of the human who continues to incessantly desire subjectivity (Genosko 2009). In the airport servicescape, the potential for such desire may seem bleak. The question in consumer research thus becomes: what kinds of subjectivities are we able to imagine in the machinic orders of commercialized and stratifying servicescapes? In line with Denzin (2001), it calls for research that incites and informs action or what could, even if only conditionally, bring about possibilities for 'revolutionary consciousness' (Bogue 2003).

Why Negative Political Ads Don't Work on Gen Y

Andrew Hughes, Research School of Management, Australian National University, Australia

ABSTRACT

This study demonstrates that televised political negative advertising generates high levels of negative emotions and emotional intensity upon Gen Y consumers. These responses are developing negative attitudes towards political advertising and brands that may have far reaching generational societal and political impacts long past the end of the campaign.

INTRODUCTION

Televised political advertising is the workhorse of the political marketing campaign. From the moment of the election date announcement through to the close of polls, television remains the dominant platform for message delivery for politics. Campaigns are traditionally waged on the visual and visceral levels against opponents, with an emphasis on messages that encourage the rejection of opponents through negativity. Conventional trade wisdom indicates that attacking, discrediting and creating fear of the alternative party offerings has been the effective platform for campaigning (Garramone 1984; Lau, Sigelman and Rovner 2007; Merritt 1984).

However, the rise of the media savvy Generation Y and Generation Z may present an opportunity to return to pitching claims to governance by a positive value proposition, offers of polity and policy. With the rise in social media, ease of access to fact checking of negative claims, and an inoculation to attack rhetoric born of growing up in the internet era, the Gen Y and Gen Z vote may not be vulnerable to the message strategies of the older generations.

This paper studies the emotive reaction of Generation Y voters to political advertising campaigns. It tests the responsiveness and resonance of the campaign messages on a cohort of both potential voters (locals) and non-voters (outsiders) to examine how the content elements of the message result in emotive responses.

LITERATURE REVIEW

Political Marketing

Political marketing is a combination of rules of thumb, heavily documented statistically designed interventions and folk wisdom. Formally, political marketing is defined by Hughes and Dann (2009) as:

"…a set of activities, processes or political institutions used by political organisations, candidates and individuals to create, communicate, deliver and exchange promises of value with voter-consumers, political party stakeholders and society at large."

Of interest to this paper is the requirement for political marketers to communicate a promise of value to the voter-consumer, stakeholders and society at large. As such, the literature review examines the value creation in political advertising messages, the process of political advertising delivery and the sub-elements of advertising linked to the political value creation.

Promises of Value

Promises of value within political communications divide on the axis of positive messages to sell of promise of gain in voting for the branded party, and, negative imagery that implies potential for loss involved in the success of opposing political parties (Hughes and Dann 2006). It should also be noted that the value offering is also different in politics, as commercial campaigns can operate entirely without stated or implied identification of loss in their communication of a value offering to targeted markets. Whereas as a commercial product such as funeral insurance may pitch on the out-of-pocket costs to the family, it still emphasizes the personal cost of leaving the loved ones unprotected. In contrast, negative political campaigns can be broader statements of "Don't risk X" where X is an abstract concept such as the natural environment, industry, or economic conditions (Hughes & Dann 2010).

Political Advertising: Communicating the Promise

Advertising is the dominant method used to create awareness, and subsequently, one of the most costly items in the campaign. In the 2014 US mid-term elections, $1 billion was spent on advertising (Wesleyan 2014). The 2012 United States elections, inclusive of the Presidential election, federal, state and local elections was over $US 3 billion (Fowler and Ridout 2013). Fowler and Ridout (2013) and Ridout, Franz and Fowler (2014) work emphasized the development of targeted television advertising for audience specific reactions - generation of specific short responses rather than long-term relationship building (Goldstein and Ridout 2004). This identifies an increasing problem for political campaigns of needing to operate within a short-term results focus that overemphasizes short term promises tailored to the nearest election result, but one that comes at the expense of brand building and relationship development with key market segments.

At the same time, Blumenthal (1982), Goldstein and Ridout (2004) and Needham (2005) discuss the era of the permanent campaign whereby parties are constantly in a campaign mode, but do their persuasion of undecided voters in the short election campaign period. The perpetual campaign, fatigued by the need to constantly move message and market, often resorts to short term "sales" strategies near elections to create the desired result. As with commercial marketing, aggressive discounting, sales orientations and short termism has a detrimental impact on the value of the brand in the eyes of the consumer. Yet the perceived efficacy of the negative message in downselling an opponent, or discounting cost of adopting the less scary alternative is taken as a marketing truism in much of the political practitioner's playbook.

Consumer Engagement with Voting

Voting in the political process is surprisingly viewed as a low involvement product based on consumers having a high level of distrust in political brands and political messages, and perceived limited engagement post-purchase decision (Dann & Hughes 2008). As a low involvement, low commitment product, political marketers often focus on the brand switching behaviour of the swinging voters, and tailor message strategies around short term promises of loss or gain (Dann & Hughes 2008). This approach assumes that there will be a fast transformation of voters from low involvement state to high involvement decision making through messages based on arousal states (Bradley, Angelini and Lee 2007; Rossiter and Bellman 2005). As a low involvement product (Rothschild & Ray 1974), political advertising has become largely dependent on generating brand decisions through emotive responses to advertising stimuli. Prior advertising studies on Generation X and Baby Boomers have found negative images tended to create higher levels of arousal and recall than positive images (Cacioppo, Tassinary and Berntson 2007; Lang 1991; Lang et.al. 1996, 1999, 2000).

Politics and Generation Y

As generational change takes effect in the voter blocs, marketers find themselves pitching to a media savvy audience of Gen Y

consumers who have grown up on a diet of media awareness. The consequence of the changing of the guard of the youth vote represents a significant opportunity to re-examine message strategies developed for passive audiences (Boomers, Gen X) who were captive in limited media channels, and with restricted avenues of response against the attitudes of a Generation Y cohort. As young voters have been regarded as having higher levels of cynicism and mistrust in political brands than other voters, the conventional call to action through negative advertising may not be the most effective message strategy for the Generation Y market. The question for this study then is whether negative imagery has a similar impact on the Generation Y cohort, which leads to the formulation of the hypotheses:

> *Hypothesis 1:* *Respondents will have higher levels of arousal for negative messages than for positive messages*

> *Hypothesis 2:* *Negative messages will generate higher overall levels of emotive response than positive messages*

Arousal will be measured using Self-Assessment Manikin scale (Russell and Mehrabian 1977; Lang 1985; Rossiter and Bellman 2005). Emotive response in this exercise is measured by the volume and nature of emotions captured from the Geneva Emotion Wheel. Details of the measure are outlined in the methodology.

INSTRUMENT AND MEASURES

Data was collected on each advert using 2 specific measures. Respondents filled out Morris's (1995) Self-Assessment Manikin (SAM), followed by Scherer (2005) Geneva Emotional Wheel (GEW).

Self-Assessment Manikin (SAM)

The Self-Assessment Manikin is a non-gender specific graphic character that measures the type 1 emotions of pleasure, arousal and dominance (Russell and Mehrabian 1977; Lang 1985; Rossiter and Bellman 2005). Hypothesis 1 is tested using P-A-D element of Arousal, with Pleasure used as a secondary measure of advertising content. The advantage of the SAM measure as a correlating item in the study is the speed of response to non-verbal measures (Lang 1985; Morris 1995). SAM allows for the specific emotional measurement of each advertisement shown to the respondent and can be used across dynamic advertisements studies (Lang 1985; Morris 1995).

Geneva Emotion Wheel (GEW)

Scherer's (2005) Geneva Emotion Wheel is the core of the data collection protocol. Using a visual and verbal scale, the GEW measures a range of 20 different type 2 emotions in a quick response method similar to SAM instrument. Figure 1 illustrates the Geneva Emotion Wheel as used in the study. The spokes of the GEW relate each to the family of emotions, with a modified five point scale used to measure level of intensity of that emotion. Further, the wheel is quadrant based on two axis of control (high-low), and the valence running from negative (left) to positive (right). Hypotheses 2 of this study are resolved from the data sourced from the GEW measures.

Advert selection: pacing & content

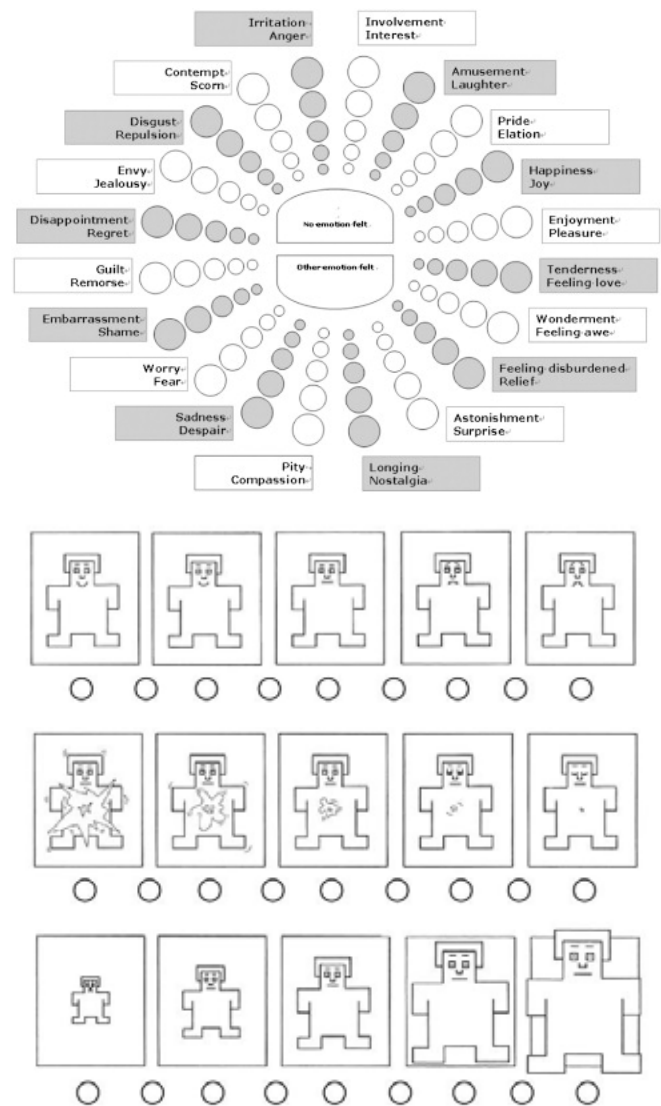
Political advertisements were selected from a range of online sources to represent a broad spectrum of political views. Each advert was rated for pace based on the established metrics of Bolls, Mueh-


Figure 1: Self Assessment Mannikin and Geneva Emotion Wheel

ling and Yoon (2003) and Lang et.al. (1999,2004). Slow adverts were classified as using between 0 and 3 cuts, medium pace ranged from 4 to 10 cuts, and fast adverts involved 11 or more cuts. Messages were selected from a range of political parties that encompassed the broad spectrum of political views. Eighteen advertisements were selected from an initial pool of 30 possible cases. Advertising content was classified on the basis of the overall message, in line with prior studies (Hughes 2003; Kaid 2012; Jamieson, Waldman and Sherr 2000; Johnson-Cartee and Copeland 1991; Lau et al. 1999). Three considerations were used in advert selection. First, the cohort of adverts needed to represent the current political atmosphere, thus providing coverage for the three primary political parties who account for 90% of the vote, and incorporating minor parties and independents. Second, a mixture of message types were required to create an effect 3x2x2 (primary party x fast/slow x positive/negative) design for the major party adverts, and allocating 6 adverts to non-major parties (others x fast/slow x positive/negative). Finally, all adverts were confirmed to have been screened on prime time, mainstream television in Australia and were not subject to regulatory complaints.

METHODOLOGY

This study used a hybrid methodology of SAM and GEW pictorial research forms. This was chosen based on similar prior studies conducted in the area and the need to capture as quickly and as effectively as possible the emotional response to the stimuli the participants were exposed to. This is one of the major advantages of both the SAM and GEW tools as they allow for rapid collection and measurement of emotional responses as the pictorial tools allow for a more rapid processing and familiarisation of the research instrument, without participants suffering from noticeable survey fatigue. Responses were captured in 5 sessions of 15 respondents. Advertisement presentation order was randomised between groups. Ten minutes was allocated to set up the capture, provide information and instructions. Respondents were shown the first sample advertisement, always numbered 1, and given 60 seconds to complete the first survey page. At the conclusions of the minute mark, a 5 second count in to the next ad would commence, displaying the identification number of the next advert. Respondents were shown 18 political advertisements across the political spectrum and asked to rate the speed of the advert (slow, medium, fast) and the overall tone of the message (positive, neutral, negative) as per the design discussed above. Participants were 71 undergraduate students from a large Australian university who were undertaking second year coursework in a field unrelated to politics or communication. The cohort consisted of 25 male and 33 female respondents, and inclusive of 13 respondents who did not identify a gender. All participants were Generation Y, with the age range from 19 to 32, and a mean age of 22 years. Voting experience was divided with 34 (47.9%) indicating that they had voted in a previous election, and 21 (29.6%) indicating that they were registered as voters for the local state election. Only 32% had prior voting experience with any of the candidates or parties shown in the advertisements.

RESULTS

The results of the study do not support this hypothesis. Advert 10, perceived to be the most negative advert in the study evoked a neutral response in the pleasure score (mean 6.38, SD=1.8) and similarly neutral position in Arousal (mean 6.52, SD=1.77). In contrast, Advert02, which was seen to be relatively negative with a wider range of reactions (mean 4.14, SD 2.05), also created the most excited in Arousal (4.43, SD=1.99) and the most happiness on the Pleasure score (3.81, SD=1.67). Negative adverts did not evoke the expected responses – adverts with the highest sadness ratings in the Pleasure score (Adverts 06, 04, 10 ,16) also evoked some of the calmest responses in the Arousal score. However, adverts with high happiness levels (Adverts 02, 18 11) were not consistent in their responses. Even with Arousal, the most evocative adverts (02, 08, 05) did sit towards the Happiness end of the Pleasure spectrum. Negative advertising did not resonate with the Gen Y audience according to theoretical expectations, and this opens an area of future research and study.

Arousal in this exercise is measured by the volume and nature of emotions captured from the Geneva Emotion Wheel. Two measures are reported to examine Hypothesis 2 – Emotive Intensity and Normalised Emotive Response. Emotive Intensity is the sum of responses in the Geneva Emotion Wheel, where adverts have a greater emotive resonance; more items of the Geneva Emotion Wheel will be recorded by the respondents. Results from the study are outlined in Table 5. As illustrated by Table 1, Positive advertisements had greater emotional intensity, with the highest emotive intensity occurring in Advert 13 (338), Advert 11 (338) and Advert 02 (312). Notably, Adverts 11 and 13 are rated as highly positive by the re-

Table 1: Reactions to Advertising (Summary)

SAM Findings

Advert	Content (negative to positive)	SD	Pleasure (happy to sad)	SD	Arousal (excited to calm)	SD
02Advert	4.14	2.05	**3.81**	1.67	**4.34**	1.99
03Advert	4.36	1.86	4.97	1.37	**6.68**	1.89

17Advert	5.69	1.71	4.71	1.49	6.52	1.97
18Advert	**6.92**	1.46	4.18	1.63	5.70	2.22
19Advert	5.20	2.10	4.89	1.67	5.68	2.09

GEW Findings (Summary)

Ad number	Emotive Intensity (n total responses to GEW)	Pleasure (happy to sad)	Arousal (excited to calm)	Speed (slow to fast)	Content (negative to positive)
10Advert	262	6.38	6.52	4.36	3.00
16Advert	234	5.81	6.44	4.24	3.19
04Advert	286	6.58	6.58	4.53	3.23
06Advert	282	6.91	5.98	4.34	3.34
15Advert	242	5.80	6.31	4.27	3.37
09Advert	240	5.09	5.55	5.30	3.50
14Advert	251	5.69	6.52	4.14	3.56
08Advert	274	4.49	5.00	6.77	4.09
02Advert	312	3.81	4.34	6.42	4.14
03Advert	271	4.97	6.68	4.25	4.36
12Advert	177	5.21	6.60	4.61	4.95
19Advert	262	4.89	5.68	4.97	5.20
05Advert	298	4.47	5.45	6.35	5.64
17Advert	211	4.71	6.52	4.25	5.69
07Advert	242	4.52	5.61	5.17	6.08
13Advert	338	5.31	6.33	3.98	6.27
11Advert	333	4.24	6.33	4.77	6.75

spondents, whereas Advert 2 is towards the negative end of the neutrality rating. Similarly, Adverts with Pleasure scores rated towards Happiness have higher emotive response rates (Advert 02, Advert 18, advert 11) than those rated for Sadness (Advert 06, Advert 04, Advert 10). Finally, Arousal did not reflect emotive response levels with the most exciting advert (Advert 02, Advert 08, Advert 05) not having the highest emotive responses.

Similarly, there is no consistency between the emotive response level, and the content of the advertisement as perceived by the respondents. Given the unexpected reaction of the respondents to the advertising stimulus, further examination of the 3 most negative and positive adverts was undertaken, to look specifically at the emotion generated by the adverts. For consistency, each GEW outcome was converted to a normalized score, enabling graphing on a consistent base line. Advert 10 evoked a strong Irritation-Anger (n 37, mean 3.4, SD1.14) followed by Disgust-Repulsion reaction (n 29, mean 3, SD 1.14) which is possibly indicative of a rejection of this advert by the audience. Advert 04 evoked Worry-Fear (n 32, mean 3.2, SD 1.26) as the strongest response with Irritation-Anger (n 31, mean 2.8, SD1.17) as the next most powerful reaction. This may indicate the effective delivery of a negative message, but the continued rejection of the negative advertising platform. Finally, Advert 16 evoked a strong Irritation-Anger (n 29, mean 3.31, SD 1.16) response, followed by a Worry-Fear (n 24, mean 2.54, SD 1.21). With only two of the three adverts creating Worry-Fear results, and all three having a high level of Irritation-Anger, the Generation Y cohort did react negatively to a negative message. By way of contrast, the top three positive advertisements were examined using a similar normalisation process. Advert 11 had a strong engagement with the audience with a high Involvement-Interest measure (n 37, mean 2.8 SD 1.08), and a positive Happiness-Joy measure (n 35, mean 2.7, SD 1.08).

Similarly, Advert 13 also brought a resounding Involvement-Interest score (n 4, mean 3.7 SD 1.019) and, surprisingly for a positive advert, a powerful Pity-Compassion (n 30, mean 3.4, SD 1.27). Finally, Advert 18 continued the engagement trend with a strong Involvement-Interest (n 34, mean 3.2, SD 1.18) score, and a positive Happiness-Joy measure (n 30, mean 3.1, SD 1.07). Overall, the engagement levels with the positive adverts are very high, and the Involvement-Interest score was consistently either the top or second rate item across the positive advert spectrum. Finally, across all advertisements, the most consistent emotional reaction from the Generation Y cohort was Involvement-Interest (Figure X). From the study, Generation Y respondents are engaged in politics, are interested by political content, and want access to political content – however, they are rejecting the negative messaging strategy, and the so-called "disengagement of the youth" may come from the lack of resonance the attack adverts are finding with an audience seeking substance over bile.

KEY FINDINGS

Implications for Political Advertising Practitioners

There is growing evidence (Bradley, Angelini and Lee 2007) that negative advertising is not as effective in generating an emotional response that creates a behavioural response in favour of the sponsored brand as practitioners are led to believe. The results are notable as they demonstrate that emotional responses to political advertising are far higher for positive advertisements than for negative advertisements. This is especially so for slow paced positive advertisements. This would suggest that Gen Y voters have more resource capacity to process these advertisements than they would for fast paced advertisements that might reach their capacity for message

processing (Lang 2000). This would mean that a Gen Y voter would have more likelihood of recalling the advertisement in a positive way and developing a more positive attitude towards the sponsoring brand, and their advertisements, than a negative advertisement. These results do suggest that brands that want to be successful in creating memorable and highly effective emotionally responsive advertisements with Gen Y need to use negative messages only sparingly in a campaign. This research also supported that structural elements can influence emotional responses to political advertisements. Fast paced messages, as predicted by Lang (2000) and confirmed by Bradley, Angelini and Lee (2007), do indeed make voters feel more negative emotionally, even where the advertisement is positive. As Gen Y is only in the early stages of political brand experience it is highly questionable whether fast paced messages have any place in a brand's political communication strategy if they actually want to influence these voter's behaviour.

Implication for Governance

As practitioners, reformers and interested parties discuss campaign spending limits, campaign financial reforms and donation declarations, an unusual area of reform may be possible for political marketers. Whereas campaign finance reforms in some democracies are limiting spending on advertising in campaigns, there are no limits proposed on the nature of the advertisement content. If so desired, parties currently can spend their entire political advertising budget on negative messaging. Perhaps the time has come to open the debate on message limitation whereby political campaign messages, both political party and lobbyist-run support campaigns are limited to a 30% public funding cap on negative messaging. Forcing political parties into 70% advertising spend on positive messages, that are promises of polity and policy, and limiting attack adverts, may be the true reform needed to reengage the electorate with the elected. Losing future generations engagement with politics risks the sustainability of the current political system itself. Democracy can and always should allow for freedom of speech, but if this speech comes with a price that will be paid by future generations then it is no longer free and no longer speech that builds a more positive polity for all.

Generation Y: Engagement over Politics

There is much debate on what is causing cynicism and apathy towards the political process by young voters. Whilst prior research has found that levels of cynicism are increasing, the increasing rates of young voters failing to enrol or register to vote is the most telling statistic that young consumers are no longer engaging with democracy in most Western systems. However, across the entirety of the advertising data set, Involvement-Interest was the highest consistent emotional response. This is a generational cohort who want to be heard, want to be part of the process, and the negative advertising message strategy is not meeting their needs, nor addressing their desire for engagement. Engagement will require political marketers to stand for something, to offer a positive value promise, and that may be a bridge too far in the present attack-focused campaign environment.

CONCLUSION

The implications of this study are that whilst negative commercials generate far higher arousal and recall levels over positive ads, the value of this is questionable if it is leading consumers to feel negative emotions connected to a brand. Fast paced political messages also need to be aware that viewers only have a limited capacity for processing televised messages (Lang 2000), and presenting too much information, especially complex information or dense infor-

mation messages due to the high number of cuts, will mean that they will not process the information in the message regardless of how arousal or interesting the message might be.

The findings from this study indicate that it would be better for political brands to focus on slow paced positive messages that generate greater likability and positive emotions, to increase the chances of being elected and to develop more favourable attitudes towards both the brand and the advertisement.

Does the Effect Replicate in China?

Tom van Laer, Cass Business School, City University of London, UK

ABSTRACT

Moore (2012 JCR) focuses on how specific linguistic content in word of mouth (WOM) influences North American storytellers. This research attempts to replicate her research with Chinese storytellers' hedonic experiences. Influenced by Confucianism Chinese storytellers' evaluations are generally lowered by explaining language yet less negative than North American storytellers' evaluations.

INTRODUCTION

Word of mouth (WOM) is the most influential form of marketing communications (Nielsen 2013). While most research starts from the assumption that it is the story-receiver (not the storyteller) who experiences WOM, Moore (2012) challenges this assumption and expands research on WOM.

She shows that the act of storytelling has a particular effect on the storyteller. She demonstrates that explaining language in stories weakens storytellers' evaluations of and intentions to repeat/recommend hedonic experiences but strengthens their evaluations and intentions in the case of utilitarian experiences, regardless of experience valence. Explaining language addresses why experiences happened or why experiences were liked or disliked.

In the four years following Moore's publication, a substantial number of researchers have cited the original article. To date, the overall Thomson Reuters Web of Science and Google Scholar citations counts are 21 and 53, respectively. The article has been cited 3 times in the *Journal of Consumer Research* (JCR) and 3 times in the *Journal of Marketing Research*. It was further awarded the JCR Ferber Award of 2012 and it ranks among the ten most cited JCR articles of 2012 (Harzing 2007).

Other researchers have investigated how WOM of hedonic experiences influences storytellers. Scholars largely converge on the viewpoint that unpacking an enjoyable past hedonic experience into its constituent sub-activities amplifies consumers' retrospective affective evaluation (Cowley 2014, Van Boven and Epley 2003, Vilches-Montero 2015, Vilches-Montero and Spence 2015). Telling the story of an enjoyable past experience also enhances experience duration estimation (Vilches-Montero and Spence 2015) and the self (Chawdhary and Riley 2015). Value derived from talking about experiences (Kumar and Gilovich 2015) and retrospective dilution of the most extremely negative moment in a positive experience (Cowley 2014) explain these amplifications. The previously mentioned articles measure the effects of WOM on storytellers in a western context. In contrast, Yang et al. (2014) show that audience responses moderate Chinese storytellers' experiences.

Despite Yang et al. (2014), however, extant research on WOM influence on the storyteller remains predominantly western, in terms of its empirical findings, and except for Moore (2012, 2015) and Vilches-Montero and Spence (2015), no research investigates explaining language. Meanwhile, in consumer research as in any other field, replications are one of the building blocks of the structures of knowledge. Replications are important for knowledge accumulation, and for gaining greater understanding into new and important effects. As such, Moore (2012) marks a starting point from which to initiate a replication study into a possible WOM effect on Chinese storytellers as well as a meta-analysis across the Chinese and North American samples.

This research highlights the importance of specific WOM content and demonstrates its impact on storytellers from different cultures. More than two millennia ago, upheavals across the East and West sparked ambitious visions of what humans could achieve, spearheaded by two trailblazers: Confucius and Socrates, great thinkers from the ancient world whose ideas still shape consumer behavior (Lian 2002; Yang 2009). They lay the foundations of the modern eastern and western world. While Socrates' philosophy challenged superstitious belief (Plato 399BC/2010), Confucius' vision led to the promotion of 观物取象 ("inferring from metaphors") and 中庸 ("the Doctrine of the Mean") (Legge 1971). Thus, Socrates encouraged his fellow citizens to rationally examine every aspect of their lives, and Confucius believed that moral education could transform both individuals and society. While Moore (2012) explains how Socratic thought influences North American consumers' explaining language and evaluations, the current research focuses on consumers that are Chinese and tests the impact of Confucianism on explaining language and evaluations. Given the morally didactic versus rational bases of Confucian versus Socratic thought, culture should differentially influence overall evaluations of hedonic experiences.

The study needed to meet the replication criterion. Therefore, the study needed to be conceptually related to the plethora of existing research. That is, we focused on hedonic experiences. A replication was performed on Moore's most comprehensive study (3A) with a predefined deviation: Chinese participants instead of North American participants. This way, the consumer research field can learn more about the relevance and boundaries of the effect of WOM on storytellers. We address three hypotheses for which Moore found support in a North American sample:

Hypothesis 1: Individuals using more explaining language will evaluate positive hedonic experiences less positively and negative hedonic experiences less negatively than individuals using less (or no) explaining language.

Hypothesis 2: Individuals using more explaining language will be less likely to repeat and recommend positive hedonic experiences and more likely to repeat and recommend negative hedonic experiences than individuals using less (or no) explaining language.

Hypothesis 3: Individuals using relatively more explaining language will be less likely to retell stories about hedonic experiences than individuals using less (or no) explaining language.

To answer the question of the boundary condition, we also include a meta-analysis across Moore's original, comparably designed studies 2 and 3A and the replication, following Chark and Muthukrishnan (2013) and Rosenthal and Dimatteo's (2001) procedures.

METHOD

The experiment is a replication of Moore's study 3A: Two hundred and four Chinese, who averaged 24 years of age (20–30 years) and included 63.7% women, participated. All had graduated from tertiary education. Participants were instructed to recall either a positive or a negative dining experience. Participants in the writing conditions then read that Dianping, "the Chinese Yelp", was trialing a guided online review process, so they would be given a series of sentences with blanks to fill in about their experience. They were told that they could fill in the blanks using any words they wished and as many words as they wished as long as the final sentence was coherent. They were asked to write exactly what they would say in a real online review for a highly inclusive hosting site for reviews of dining experiences, such as Dianping. On the next page of the booklet, participants in the writing conditions saw the explain or the nonexplain story shell. The nonexplain shell had 11 sentences with 22 blanks; the explain shell had explanatory clauses added to eight of the nonexplain shell sentences: "The best part of the whole experience was _____, because _____." Control condition participants did not see a story shell; they simply recalled an experience without writing about it. Because the participants' language skills did not necessarily include English, we carried out International Test Commission translation to Mandarin and back-translation procedures on all materials and instruments. Overall, the study was a 2 (valence: positive or negative) × 3 (story shell: explain, nonexplain, or none) between-subjects design.

After writing about their dining experience, participants reported their evaluations of the experience on four 9-point scales, and their intentions to repeat and recommend, as well as their likelihood of retelling the experience on 7-point scales (1 = not at all likely, 7 = very likely). Evaluation scales as well as intention to repeat and recommend the experience scales were standardized and combined into two dependent variables for brevity (evaluation: $\alpha = .98$; intention: $\alpha = .93$). Analyzing them separately yields similar results. Likelihood of retelling was left as a single-item measure.

The meta-analysis featured Moore's Studies 2 and 3A and our replication. Together, the 3 studies featured 378 participants (204 Chinese and 174 North American). We determined that there was no heterogeneity due to measurement decisions in the studies ($F(2, 15) = 1.76, p > .21$).

RESULTS

To test hypothesis 1, a model using valence, story shell, and their interactions to predict final evaluations ($F(5, 198) = 99.89, p < .001$) showed a large main effect of valence ($F(1, 202) = 487.93, p < .001$, partial $\eta^2 = .71$), and a small valence by story shell interaction ($F(2, 201) = 4.54, p < .02$, partial $\eta^2 = .04$).

Follow-up analyses do not support Moore's hypothesis 1. Participants in the nonexplain condition who wrote about positive experiences had more positive evaluations ($M = 1.00$) than participants in the control condition ($M = 0.83; F(1, 72) = 4.39, p < .04$). However, the explain condition ($M = 0.96$) differed neither from the nonexplain ($F(1. 71) = 0.61, p > .40$) nor from the control condition ($F(1, 67) = 1.27, p > .26$). Further, participants in the explain condition who wrote about negative experiences had more negative evaluations ($M = -0.78$) than participants in the control ($M = -0.41; F(1, 63) = 22.13, p < .001$) condition but did not differ from the nonexplain condition ($M = -0.56; F(1, 60) = 1.44, p > .23$).

To test hypothesis 2, a model using valence, story shell, and their interactions to predict final intentions ($F(5, 198) = 111.11, p < .001$) showed a large main effect of valence ($F(1, 202) = 545.25,$

$p < .001$, partial $\eta^2 = .73$). However, the interaction effect was not significant $F(2, 201) = 1.20, p > .30$, rejecting Moore's hypothesis 2.

To test hypothesis 3, a model using valence, story shell, and their interactions to predict likelihood of retelling ($F(5, 198) = 4.41, p < .001$) showed only a medium size effect of valence ($F(1, 202) = 17.15, p < .001$, partial $\eta^2 = .08$). However, the interaction effect was not significant ($F(2, 201) = 0.86, p > .42$) rejecting Moore's hypothesis 3. See table 1.

Table 1: Standardized Mean Evaluations, Intentions, and Likelihood by Valence And Story Shell, or Culture

		Experiment			Meta-analysis
		Evaluations	Intentions	Likelihood to retell	Evaluations
Positive	Explain	0.96	0.41	0.02	0.88
	Nonexplain	1.00*	0.56	0.20	1.05
	Control	0.83*	0.20	-0.81	0.96
Negative	Explain	-0.78*	-1.24	-1.00	-0.80
	Nonexplain	-0.56	-1.08	-0.45	-0.83
	Control	-0.41*	-1.11	-0.41	-0.66
Positive	Chinese	0.93			
	North American	1.10			
Negative	Chinese	-0.58*			
	North American	-0.96*			

Means marked with an asterisk (*) are significantly different from each other within that category.

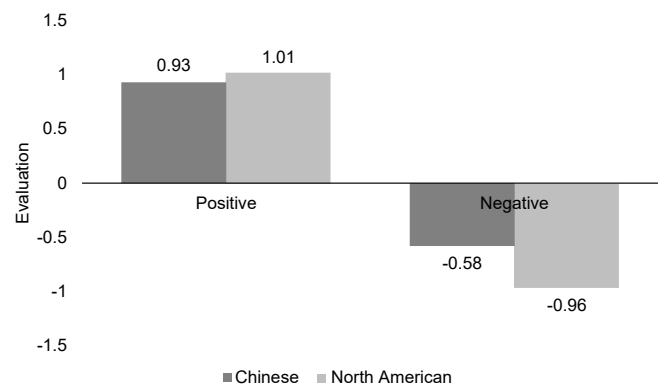
To conduct the meta-analysis, final evaluations found in Moore's Studies 2 and 3A and our replication were examined. A model using valence (the single consistently significant factor across the three studies), culture (Chinese or North American), and their interaction to predict final evaluations ($F(5, 12) = 90.27, p < .001$) revealed a large main effect of valence ($F(1, 16) = 409.33, p < .001$, partial $\eta^2 = .97$) and a large valence by culture interaction ($F(2, 15) = 4.01, p < .05$, partial $\eta^2 = .4$). Chinese and North American evaluations of positive experiences did not differ from one another ($F(1, 8) = .60, p > .40$). Chinese participants who wrote about negative experiences had less negative evaluations ($M = -0.58$) than North American participants ($M = -0.96; F(1, 8) = 10.02, p < .02$, partial $\eta^2 = .59$), as we detail in figure 1.


Figure 1: Standardized Mean Evaluations By Valence And Culture: Meta-Analysis

DISCUSSION

Moore (2012) demonstrates that explaining is a key process in altering North American consumers' evaluations of experiences; compared to those who told nonexplaining stories and to those who did not tell stories, only North Americans who told explaining stories had dampened evaluations of their hedonic experiences. Those who

told explaining stories were also less likely to retell their experience in the future. Further, her studies' story shell method constrained individuals' language use, weakening alternative explanations that these findings are due to differences in the detail or consistency of stories rather than differences in explaining language.

We used the same story shell method to examine the impact of explaining language on Chinese hedonic experiences. We demonstrate that the effects of explaining language on evaluations obtained for hedonic experiences (hypothesis 1) do not replicate for Chinese consumers, arguably due to their Confucian culture (Lian 2002) as we elaborate subsequently. In contrast to explaining for North Americans, *not* explaining why hedonic experiences were purchased or why they were liked increased evaluations of positive experiences for Chinese consumers. Whereas explaining why hedonic experiences were purchased or why they were disliked made evaluations of negative experiences less negative for North American consumers, explaining made evaluations of negative experiences *more* negative for Chinese consumers. Chinese storytellers are more situational in causal attribution of experiences (Morris and Peng 1994). Retrospective dilution of the most extremely negative moment in an experience seems more difficult to endorse.

Hypotheses 2 and 3, that hedonic experiences' individuals explain more influence their intentions to repeat/recommend and likelihood to retell, were not supported. Perhaps Chinese consumers are more willing to repeat/recommend experiences for esteem reasons (Hennig-Thurau et al. 2004) or they acknowledge less the importance of a consistent attitude-behavior relationship (Fishbein and Yzer 2003).

We used a story shell method where individuals write about their hedonic experiences by filling in the blanks of provided sentences. Evaluations may be hard to retrieve and consumers tend to recall the constituent activities of the experience in order to reconstruct them (Cowley 2014). Vilches-Montero (2015) shows that recalling these constituent activities in a packed versus unpacked fashion influences both the reconstruction process and its outcome. This may be a behavior where there is a fundamental cultural difference in play. Unpacking corresponds to the western cultural tendency to process information piece-by-piece. In contrast to unpacking experiences, Chinese cultural disposition dictates that evaluations of experiences are at least partial inferences from metaphors. To complete the story shell, our Chinese participants were asked to recall and write about an experience piece-by-piece; misaligned with Confucianism, this method may have dampened positive hedonic experiences and polarized negative hedonic experiences. Moreover, compared to the non-explain condition, the number of blanks in the explain condition was 36.4% greater. The difficulty of expressing their experience in this unpacked form may have further damped participants' evaluations in this condition. Though self-reported difficulty in writing did not predict evaluations ($F(15, 119) = 0.82$, $p > .64$), it is possible that social desirability influenced individuals self-reported difficulty in this study.

The meta-analysis provides strong support for a cultural explanation by comparing evaluations and demonstrating the distinctive effect of culture on evaluations. In this study, Chinese and North Americans evaluated positive experiences equally. Our meta-analysis also demonstrates an important cultural difference in WOM: Chinese participants reported less negative evaluations of negative experiences than North American participants.

Taking a morally didactic perspective of our findings indicates that North American consumers do not treat stories of negative hedonic experiences as resources for moral education. In keeping with the high value placed on didactic narrative within the Confucian

tradition however, Chinese consumers are likely to use storytelling to convey public moral standards. Confucianism thus culminates in the behavior formulated above. Evaluation is the expression of the Doctrine of the Mean: a cultural-level attitude that allows Chinese to make a choice that is acceptable. Morality determines this acceptability, that is, what the mean of most (other) humans find acceptable. Not surprisingly, Confucian-typical collectivism has been found to be positively related to response styles that use the scale midpoint and moderate values (Chen et al. 1995).

This work has implications for both consumers telling and receiving stories. Explaining language allows North American consumers who tell stories, to manage their reactions to experiences (Moore 2012). This work shows that the explaining language effect depends on the consumer's culture. While North American consumers can recover from negative hedonic experiences by explaining, Chinese consumers should know to leave explanations unsaid when telling stories. They can savor both positive and negative experiences by not explaining them. To manage this, Chinese consumers should beware of advertising or online review sites that provide vocabularies or story schemas that force them to express experiences in specific ways.

This work shows consumers who receive WOM, that the culture of the storyteller is essential. The impact of the story needs to be balanced against the impact of the culture on the storyteller: while receiving Chinese neutral stories should not influence North American consumers' own evaluations, North American storytellers would have evaluated Chinese neutrally evaluated experiences more negatively, and vice versa for Chinese consumers who receive North American stories. We suggest that story-receivers consider how culture influences the storyteller.

There are three avenues for further research in this area. First, future research could answer the call for more specific linguistic analyses to examine the impact of stories on Chinese consumers. While this paper examined the influence of written, Mandarin WOM on storytellers, Cantonese and other Asian languages could differentially influence storytellers in the transnational, imagined Asian world (Cayla and Eckhardt 2008). Second, scholars should identify other Confucian-related variables that influence Chinese storytellers, such as the power of social norms and the family (Legge 1971). Third, it is crucial to understand the influence of culture on storytellers in general. Consistent with Confucian and Socratic thought, the current research suggests that, on average, explaining why something negative occurred has a positive effect on North American consumers but a negative effect on Chinese consumers, since Chinese consumers likely are more aware of the universal and the mean than North American consumers. Although neither Confucian nor Socratic thought should greatly influence storytellers elsewhere, for instance in India, Buddhism should. That is, Gautama Buddha's thoughts and insights should influence Indian language use and evaluations: while a Chinese storyteller facing a negative experience might believe in the Doctrine of the Mean, an Indian storyteller facing a negative experience might believe in karma (Kopalle, Lehmann, and Farley 2010), with corresponding effects on evaluations and intentions.

Making of Celebrities: A Comparative Analysis of Taiwanese and American Fashion Bloggers

Hsin-Hsuan Meg Lee, ESCP Europe, UK

ABSTRACT

This study explores fashion bloggers' practices in establishing themselves as persona-fied brands and obtaining the celebrity status. Comparing between 20 U.S. and Taiwanese bloggers this research builds on social practice theory to examine how the fashionable amateurs perform micro-celebrity strategies under the influence of cultural institutional works.

INTRODUCTION

The development of social media has changed the landscape of branding and the dialogue about consumption. Some key consumers in the field, such as fashion bloggers, have attracted significant attention as they play an increasingly important role in shaping the fashion industry (Mora and Rocamora 2015). Prior research has studied how they obtain social capitals (McQuarrie, Miller, and Phillips 2013), negotiate with the fashion industry (Pedroni 2015), create and redefine markets (Dolbec and Fischer 2015; Scaraboto and Fischer 2013), and influence consumers through creating eWOM (Kulmala, Mesiranta, and Tuominen 2013). Though these studies highlight the significance of fashion bloggers, none of them investigate such an influence under different cultural and institutional context. As fashion is a cultural-specific social construct, it is critical to investigate the differences in practices among bloggers of various cultural backgrounds.

Fashion bloggers are important because of their micro-celebrity status and their influence on their followers. In the course of becoming celebrities, they often go through the practices of establishing themselves as persona-fied brands where they carefully articulate their personas with an artistic sense of fashion and taste. To exercise their practices, they have to negotiate with the institutional boundaries, which they helped establish, and are constrained by. Prior study suggests that personification of a brand involves associating human characteristics with brandable qualities within the person (Dion and Arnould, 2015). For bloggers to brand themselves through a persona consists of negotiating the presented self between themselves and the followers, as well as the fashion institutional works by and large. In this study, I propose to examine the practices of bloggers in negotiating their roles toward branded persons from the standpoint of practice theory and institutional works to understand how such practices are developed and formed in two different cultures. Specifically, the study analyzed 10 American and 10 Taiwanese bloggers as an indicative contrast between the East and the West. Among the long list of cultural values, the divergence of high-low context, individualism-collectivism and power distance may be most prominent to distinguish the practices of the two. The study seeks to understand the making of micro-celebrities in such different cultural contexts.

LITERATURE REVIEW

Institution and Practices Theory

The possibility of connecting with others who share similar interests is one of the most valuable outcomes of the development of social media. In the past decades, the market has been witnessing a growing number of individuals who present themselves online and have become "celebrities" that offer many of the features of brands. Persona-fied brands, i.e., branded persons through persona, have become particularly significant in the field of fashion industry. Part of this process is to carefully cultivate their self-presentation to deliver a desired impression on others (Vohs, Baumeister, and Ciarocco 2005). Prior study on digital self-presentation suggests that individuals tend to exercise favorable self in response to the audiences' preference of self-concept, personality styles and social roles (Jensen and Gilly 2003; Schlenker 2003).

The fashion industry, which has long been Western-centric, has embraced the bloggers in recent years (Pham 2013). It is going through some level of institutionalization of certain key features to include them (Findlay 2015). Bloggers help to establish and redefine boundaries of the institutional works at the market-level in the fashion industry even by their micro-level practices (Dolbec and Fischer 2015). However, these institutional works as such are different in the East and are still largely under development (Pham 2013). Institutional works that constitutes routine practices, norms, and rules that serve to guide and constrain the behaviors of individuals in the fashion industry are somewhat different across the countries. The transactional and social roles of fashion bloggers and their practices can be a reflection of the larger institutional works, but can also be their own practices that they are trying to establish in the institutions.

The differences in cultural values between the East and the West have been well documented in the consumer research literature. Heavily influenced by Legalism, Confucianism and Taoism, people from Eastern cultures, Taiwanese for example, mostly hold incremental beliefs that subscribe to self-cultivation, authorities and the harmony of groups. This is distinct from Western cultures, US for example, where emphasis is on individual uniqueness and people hold an entity belief that talents and values are static (Rattan et al., 2012). Paradigms, such as high and low context, individualism-collectivism and power distance have all been motivated to explain the difference in communication style, identity construction, relationship establishment, and the role of power in the society (Shavitt et al., 2006). It is unclear how individuals negotiate their practices under different institutions. The fashion industry sets an appropriate context for its steady development in online consumption (Salonen, Närvänen, and Saarijärvi 2014) and its developing institutional works in two different cultures.

To focus on the practices within the institution, the practice-theoretical view is adopted. Practice theory defines practices as routine ways of doing things, relating to objects and others, and describing and interpreting the world (Shove and Pantzar 2005). Consumer researchers have focused on many of these practices (Schau, Muniz and Arnould 2009). Recent research on institutional work has highlighted that certain types of practices that are common to individual actors contribute to building institutions, whether intentional or not (Lawrence and Suddaby 2009). Practices include establishing share understandings, procedures and engagements (Schau et al., 2009). In this paper, the framework of practice theory is applied to analyze how individual bloggers negotiate their ways to become branded persons.

Personified Brands and Micro-Celebrities

There are some existing practices in establishing online personas that have been previously studied. Exploring the characteristics of chef-persona, Dion and Arnould (2015) identified the two main practices in managing branded persons. They suggest that there are two facets embedded in persona-fied brands, alchemists and artists. Alchemists embodied the skills and know-how of the industry, whereas artists embraced the artistic sensibility. Brands can be man-

aged depending on the disconjunction or conjunction of the different facets. When the two facets are unified, a single person would be the full embodiment of the whole personas. One can argue that as brands develop and grow over time, there will be a need to disconnect the facets and allow different persons to work on the brands as a team. In other words, the capability of distinguishing between different facets could be critical to whether or not a blogger can evolve into a "real" brand. In the same vein, I propose that one of the key practices of fashion bloggers would be dealing with the two facets of persona, creation and execution.

Moreover, establishing intimacy is important in the context of social media, where celebrities can create a sense of closeness with the followers through various practices, including sharing carefully selected personal information (Marwick 2011). Prior research distinguishes bloggers' self-presentation based on authenticity and credibility. Based on the chosen self-image that is to be portraits online, bloggers carefully articulate how much they would want to reveal their true and/or exaggerated selves and how much commercial and branded exercises should be revealed (Kretz 2013). However, too much personal information whether it is real or fictitious may result in losing mystique as becoming celebrities is a "hierarchical and exclusive phenomenon" (Turner 2006). Prior literature on online personal branding suggests that individuals may try to strike a balance between the front stage, i.e., public personas, and the backstage, private personas (Marshall 2010). The strategic self-disclosure is part of the micro-celebrity practices, which also include thinking of followers as a fan base and thinking of oneself as a brand (Marwick 2013).

Just as having perona-fied brands, establishing micro-celebrity is also a performative practice that can be exercised on a continuum. Other than the values that have been discussed earlier, in the Western context where the concept of personal branding is institutionalized and micro-celebrities abound, fashion bloggers may exercise standard practices where they carefully cultivate their public private-self and manage the interactions with the followers with more care. The legitimacy of the actors' roles would have already been established as such. Legitimacy, in intuition theory literature, can be defined as 'a generalized perception or assumption that the actions of an entity are desirable, proper or appropriate within some socially constructed system of norms, values, beliefs, and definitions' (Suchman 1995, 574). Just as prior work has identified the plus-sized consumers as having less legitimacy than other categories of consumers in the fashion industry (Scaraboto and Fischer 2013), the legitimacy of the bloggers role may be harder to establish in certain institutions. Bloggers from the country where such a micro-celebrity institution is still in its infancy may be more inclined to be personal and true to their intimate self as the hierarchical structure has yet been established.

METHODOLOGY

To analyze and compare the key practices of successful fashion blogs in different cultures, an applied form of netnography was conducted (Kozinets et al. 2010). The method has been developed to study consumer behaviours online, focusing on the observation of textual discourses (Kozinets 2002). It has also been suggested to be a compatible approach used in conjunction with a practice theoretical framework (Rokka 2010). Focusing on the best practices in the field, 10 most popular fashion blogs from U.S., including Fashion Toast, Fashion Squad, Cupcakes and Cashmere, Sea of Shoes, Song of Style, Karla's Closet, Atlantic-Pacific, Sincerely Jules, VivaLuxury, and Wendy's Lookbook, and 10 from Taiwan, including Benshee, oops!!! i am An, Jessica, MAKE UP BEAUTY, Fashion Blog by Kimlafayette, Hannah's fashionlist, STELLA'S BLOG, MillyQ's Blog, I ♥ 77, and Little Miss SHOPAHOLIC are included

in the sample. The popularity was evaluated based on the number of page views, the number of replies on blog posts, the number of clicks of links to other websites, and the amount of followers on any related social media site, such as Facebook, Twitter, and Instagram. The blogs are primarily female fashion blogs that discuss clothes, cosmetics, and relevant fashion industry topics and were launched between 2007 and 2011. All bloggers appear to have obtained economic and social capital through their practices, such as sponsored items and fashion shows' invitations (McQuarrie et al. 2013), which is an indication of their legitimized roles in the fashion industry.

The verbal and visual texts visible in these blogs are analyzed, including both the blog posts and readers' comments. I focus on analyzing the practices of persona-fied bloggers, personal brands and the process of negotiating their public and private self. The pictures, the writing style, the interactions with the followers, as well as the followers' comments over time are also examined. Following a theoretical sampling process to maximize the opportunity to develop concepts and identity relationships between concepts (Corbin and Strauss 2014), the analysis built on continual comparisons between the data collected from different blogs.

ANALYSIS AND INTERPRETATION

It is an interactive process to redefine oneself from an amateur blogger and engage customers to a fashionable persona with celebrity characteristics who is well connected in the fashion industry. The results suggest that fashion blogging in two countries share similar norms and values to a certain extent but the practices to develop their personas and legitimize their role as recognized fashion bloggers vary between the countries.

Engaged Customers versus Branded Persona

Though all bloggers illustrate some forms of self-awareness in cultivating their "public private self", bloggers from the two cultures display a distinct set of practices. U.S. bloggers in general are more conscious in communicating their aesthetics. With professionally shot pictures, mimicking what can be found in fashion magazines, these bloggers carefully cultivate the public persona with an emphasis on fashion sense: *"If there's one piece of jewelry you should invest in this fall, it's the statement earring. I'm wearing a pair of oversized hoops from Céline above, perfect for adding an edge to a simple outfit!"* (*F.S. 06/10/2015*) This post, titled "the statement earrings," featuring two pictures, one with headshot and the other is a full body shot, and are credited to a professional photographer. U.S. bloggers appear to be aware that their styles are part of the persona and thus part of the personal brands. In order to establish themselves as a legitimate celebrity one day, they need to start distinguish between the artists' and the alchemists' roles. They see themselves as the brands that attract the fans.

In contrast, Taiwanese bloggers emphasize far more on the private self in their cultivated personas. On a similar topic about earrings, a blogger posted 10 pictures, which she took from her home studio and with both the products themselves, and the self-portrait pictures from various different angles. She also included a lengthy description with personal stories starting from her breakfast: *"Have any of you tried macha with lemon juices? They taste really nice! I've told you that I've been crazy about lemon juices lately. I drink it everyday until this morning I thought it's just too much and dug out my macha powder…"* (*b. 21/06/2015*). Taiwanese bloggers never really restricted their fashion blog posts to styling only. These bloggers separate themselves from the "real" commercial brands and see themselves merely as vehicles or endorser for them. They are engaged customers who have a good sense of fashion and happen to

enjoy sharing. Unlike U.S. bloggers who see the potential of separating the art from the artwork, Taiwanese bloggers are the artists that piece everything together.

The examples can be seen as a mere exercise of difference in communication style. Taiwanese bloggers, being in a high-context society, realize the need to provide excessive external cues to help the readers understand the contents, whereas U.S. bloggers, being in a low-context society, tend to present straightforward and simple messages. However, they may also signify the influence of different belief systems. Taiwanese culture subscribe to the incremental belief that roles of bloggers may be to guide and help the readers to change, learn and become a better self. The authority of bloggers is established through providing detailed account on how to become like them by including non-fashion related information. Conversely, the American bloggers are more of brands whereby like-minded people gather and share similar interests. Readers are not following the bloggers to self-cultivate but to seek inspiration to construct their identity.

Publicize the Private versus Privatize the Public

The differences in defining personal brands can also be signified by the displays of private and public personas. U.S. bloggers tend not to write anything personal. If there is personal information or private matters, they are often shared only after a professional persona has been established. The private information is there to add some personal touch to carefully cultivate the human aspects of the brands: *"My mom rented a beach house for the holidays so we spent Christmas right near the ocean with all my cousins, aunts, and uncles. Took a few photos so I thought I'd share them with you." (W. 29/12/2014)* Taiwanese bloggers, on the other hand, do not make such a distinction. The blogs often started from a site that shares personal information and only has slowly grown into the status where they hold social capital in fashion and can be seen as opinion leaders. Their personas are the image of girls next door that they proactively reject the celebrity status and insist on being merely commoners.

This becomes even more obvious when comparing the strategic self-disclosure and interactions with the followers by the bloggers from the two countries. U.S. bloggers generally do not engage in conversations with the followers on their blog posts. Most of the comments on the blogs are either spams or affectionate comments from the followers, which bloggers rarely reply. If there is a need to address the audience, the forms of dialogues and interactions often appear to be more public and in the forms of broadcasting, similar to that of celebrities: *"Many of you have asked and many have noticed that I haven't mentioned [code for boyfriend] in a long time." (W. 27/02/2015)* Conversely, Taiwanese bloggers interact frequently with the followers. Most of the observed bloggers reply every single comment on their blogs with either private or public messages and answer the questions in detail. The readers often feel so comfortable with the bloggers and may interact with them as friends. Once a blogger shared with the readers that she is going for a trip to Japan, many made similar comments: *"Would you be able to buy [a branded product that has been previously mentioned by the blogger] for me? I can transfer you the money." (Q. 05/05/2015)* This highlights the distinction between two cultures in terms of how the power can be established. There seem to be a paradoxical "leadership" exhibited by Taiwanese bloggers as they try to maintain both distance and closeness by combining self-centeredness with other-centeredness. Although all bloggers' posts are narcissistic by nature, and the ones from Taiwanese bloggers are perhaps even more so as they tend to include an excessive amount of selfies in their posts, Taiwanese

bloggers strive to be inclusive with their readers and deeply embed themselves in the network.

Bloggers Attain Institutional Roles

These practices then contribute to the development of institutions (or lack thereof) of fashion communities. U.S. bloggers treat their followers as fans and organize their communities as brand communities. The communities are places for fans to share each other's passion in fashion and affections in the bloggers themselves and to interact with one another. This type of brand community often does not require the presence of the bloggers themselves, i.e., the brand, because the brands in this context represent a symbolic value. The readers often comment on each other and help answer each other's questions. In terms of the bloggers' roles in the fashion industry, it is apparent that U.S. bloggers have been considered as real celebrities who have legitimate followings.

On the other hand, Taiwanese bloggers are part of the fashion communities; they are the leaders but are also the moderators. They are the star participants and often treated as the most knowledgeable and senior members of the communities by their readers. The communities are not formed around the personas but around the love for fashion, where bloggers are merely the most well regarded members. Most people when they show affections, they would comment on the appearance or the personalities of the bloggers rather than their fashion sense. The roles of bloggers in the fashion industry in Taiwan are closer to that of endorsers or spokespersons where they proactively explain and promote the items with detailed descriptions. These bloggers are opinion leaders by sharing their personal experiences on using the items.

CONCLUSION

The aim of this study was to explore the core mechanisms of how bloggers attain their roles through their micro-celebrities activities and how the practices differ between two cultural institutions. The result shows that practices in response to distinct cultural institution are important factors to consider in understanding the formation of persona-fied brands. Fashion bloggers and blogs have been extensively studied in the past where their significance in the articulation of the fashion industry and the culture has been proven (Mora and Rocamora 2015). However, most of the studies have been western-centric (Pham 2011); our study highlights that Eastern values, i.e., Taiwanese in our example, can detect a different process of practices formulation in how fashionable and stylish personas are supported and created.

It appears that the usual assumption of distinction between the 'frontpage' (i.e., the public persona) and 'backstage (i.e., the private persona) does not always apply in persona-fied brands. It is true that one can never truly understand the authentic 'real' self as the promoted 'public private self' is always staged and well articulated (Marshall 2010). However, when the external institutions have yet been established, the practices of such a distinction may prove to be challenging. In the case of our study, fashion bloggers in the Western fashion industry have been recognized as real forces in shaping and guiding fashion (McQuarrie et al. 2013). In the context where practices of micro-celebrities have been legitimized, the bloggers can present their personas with branded persons in mind and only carefully reveal the private self for improving authenticity (Marwick 2011).

In contrast, these practices of micro-celebrities are still under development in Taiwan where only those who have well-established expertise in societal functions can become celebrities. Celebrities are those with 'real' skills and knowledge in certain fields. Senses of

Table 1: Results Summary Table

Practices		Country	Data Instances
Actors	Branded Personas	U.S.	*"If there's one piece of jewelry you should invest in this fall, it's the statement earring. I'm wearing a pair of oversized hoops from Céline above, perfect for adding an edge to a simple outfit!"*
	Engaged Customers	Taiwan	*"Have any of you tried macha with lemon juices? They taste really nice! I've told you that I've been crazy about lemon juices lately. I drink it everyday until this morning I thought it's just too much and dug out my macha powder…"*
Presented Self	Privatize the public	U.S.	*"Many of you have asked and many have noticed that I haven't mentioned [code for boyfriend] in a long time."*
	Publicize the private	Taiwan	*Would you be able to buy [a branded product that has been previously mentioned by the blogger] for me? I can transfer you the money."*
Institutional Roles	Sponsored influencers	U.S.	*"Rocking all shades of blue because Spring is just around the corner and LA is having those gorgeous blue sky days! I love [brand name]'s new collection because it evokes everything I'm currently craving: ocean, freshness, crisp white shirts and denim everything- yes, everything, even pumps!...Thank you [brand name] for sponsoring this post. Styling, writing, and photography is all my own."*
	Endorsing opinion leaders	Taiwan	*"Let's talk about my recent favorite [brand name]! They have such a wide spectrum of styles that suits individual taste. Let's have a look at their website together. I really like the pictures they took….This article is a collaboration with [brand name]."*

fashion and style are regarded as good taste but not a real profession of its own. Under these circumstances that institutions of fashion is still a work in progress, the practices of persona-fied brands based on good taste is more challenging as the bloggers will have to contribute to shaping the larger institutional works while attempting to claim their own power.

Our final key finding is that the communities around fashion bloggers in the two cultural institutions are bounded by the practices that they have created. The shift between public and private is continuously (re-)defined through interactions between bloggers, their readers and the overall institutions. This interactive process is inherent in all practices of persona-fied exercises. The results are limited by the specific blogs and context chosen. While fashion bloggers provide a rich and relevant narrative in which to study social practices and cultural institutions, this research should be extended to other context as well as longitudinal studies to explore how the practices can continuously shape the institutions and how the institutions would change the practices in return.

From "Moving Consumption" to "Spacing Consumption:"
In Search of Consumption Geographies

Andrea Lucarelli, Stockholm Business School, Sweden
Massimo Giovanardi, School of Management, University of Leicester, UK

ABSTRACT

Based on an ethnographic study of a multi-sited festival this analysis highlights the spatial aspect of mobile consumption. By operationalizing the new mobilities paradigm via a non-representational approach this paper elaborates the concept of spacing consumption as the process whereby practices of consumption emerge as embodied performative and political.

INTRODUCTION

Over the last decade, human sciences have been trying to capture the supposedly increased mobility of society as a result of the flows and movements of people, objects, things, and ideas (Sheller and Urry 2004, 2006). Consumer research studies have been receptive toward this view of the world by producing several conceptual and empirical investigations that emphasize "mobile consumption issues in their worldwide and historical context" (Brembeck, Cochoy, and Moisander 2014, 1).

Consistent with the approach that Brembeck, Cochoy and Moisander (2014) refer to as "moving consumption," consumer research scholars have analyzed the "embodied sensibilities" of consumers dealing with "mobile-things" (Hansson 2014) and the importance of time and temporality in unpacking the mobile aspects of consumption (Figueredo and Uncles 2014; Dholakia, Reyes, and Bonoff 2014). This present paper aims to produce a further step in the investigation of the mobile nature of consumption phenomena by offering the theoretical concept of "spacing consumption." This concept captures the mobility of consumption activities in their relationship with their local context by better appreciating the inherent spatial dimension of consumption mobilities. In this effort, the paper resonates with recent work that emphasizes the role of space and place in consumption (Chatzidakis, Maclaran, and Bradshaw 2012; Chronis 2008; Chronis, Arnould, and Hampton 2012; Debenedetti, Oppewal, and Arsel 2014).

To fulfill its aim, this paper identifies non-representational modes of inquiry as an appropriate way to operationalize the new mobilities paradigm in the context of consumer research. In line with recent attempts within the marketing literature to appreciate aspects of consumption activities that are more than representational (Canniford and Bajde 2016; Hill, Canniford, and Mol 2014;), mobilities are seen here as the liaison between consumers and the space produced by them.

CONCEPTUAL FRAMEWORK

The theoretical framework for this paper explores the borders between mobilities and non-representational perspectives. An increasing number of studies in consumer culture theory have endorsed different types of relational ontologies (Canniford ans Bajde 2016). The new mobilities paradigm (Sheller and Urry 2004, 2006) represents an approach that is underpinned by a relational ontology as it promotes an understanding of society and the lived experiences of people (and consumers) not as fixed and given but as constantly played out from the relationships between their movements and trajectories. Furthermore, the new mobilities paradigm highlights the significance of materiality, bodily experiences, and emotions in determining how people are connected to their environment and how they make sense of it.

The ideas of mobility and on-the-move consumers have been "trickling down" into consumer research in different fashions. Some studies have endorsed this view by relaying on Baumann's (2000) perspective of liquidity and immateriality as a way to analyze "mobile" travelers negotiating identities via food consumption (Bardhi, Ostberg, and Bengtsson 2010), or some studies see it as a way to understand possessions with regard to global nomads (Bardhi, Eckhardt, and Arnould 2012). Other studies, instead, have embraced the spirit of the new mobilities paradigm theoretically and methodologically. For example, Hansson (2014) illustrates consumers' experiences of bringing items home from the store, highlighting the value of their "embodied sensibilities" during their trajectories in urban space. Figueredo and Uncles (2014), through their inquiry into temporal management and structuration of consumption, offer a conceptualization of the temporal dimension of consumption mobilities. Similarly, the temporality of consumption experience is illustrated through the lens of mobility in Dholakia, Reyes and Bonoff's (2014) analysis of the mobile media permeating the contemporary consumptionscape.

The present study extends this debate and appreciates the spatial character of consumption mobilities by identifying three different "modes" through which mobile consumption practices are articulated. These modes stress the aspects of embodiment, performativity, and political dispositions of consumers. Here, performativity refers to the expressive enactment of consumption practices whereby consumers articulate a mise-en-scène of bodily movements as a means of engaging in a communicative relationship with other consumers and the environment. Political dispositions, instead, understood in terms of affects through the ideas proposed by Spinozian philosophy, refers to experiential bodily states, or rather the deeply rooted emotional forces that drive the actions of consumers' bodies and can eventually become a tool to express social differences.

Situated at the core of the new mobilities paradigm is the idea that contemporary society is "in play," engineered through the movements of people and things that travel across space. Spatiality is indeed implicit in the very concept of mobility. A stimulating angle that combines focuses on both mobility and spatiality can be found by drawing from non-representational theories (Cadman 2009; Lorimer 2005; Nash 2000; Thrift 2000), which have recently been introduced in marketing theory (Hill et al., 2014) to highlight the emotional consumption geographies stretching beyond the realm of sight and visuality (Henshaw et al. 2015). Non-representational theories can be used in this respect in order to envision a research methodology that encourages spatial research practices (Vannini 2015, 4).

METHOD

In order to capture the spatial character of the mobilities implicit in consumption activities, this study identifies consumption practices as its unit of analysis. Following Beyes and Steyaaert (2011, 47), this effort intends to complement the established attention to visual and verbal self-reported accounts of participants by gaining insights into the materiality and performativity of spatiality. In line with a non-representational approach to research (Vannini 2015), a "performative ethnography" (Cadman 2009, 6) has been carried out. This resonates with Hill and colleagues' (2014, 14) call for ethnographers "to expand on research sites, contexts and samples by seeking out

novel ways to describe and track the distributed world of consumption." Accordingly, the authors of this current study endorse such an approach by immersing themselves into an itinerant and multi-site festival called "Pink Night" (La Notte Rosa) held in 2011.

The Pink Night Festival occurs every first weekend of July in one of the most widely recognized mass-tourism areas in Italy, the Romagna Riviera. The event was conceived by the Department for Tourism of the Rimini Province in 2006 to re-launch tourism and sustain economic development. The festival has been conceived as a participatory celebration in which 110 kilometer coast of "the entire Riviera turns pink" (promotional brochure). The organizers point out that the festival was designed as a response to the traditional format of Light Night or nuit blanche events for which white is instead the main thematic color.

Because of such features, the Pink Night constitutes an appropriate site for analysis. In fact, according to a mobile understanding of space, the festival can be recognized as a way through which the Romagna Riviera is set up "in play" through different activities going through different localities and temporalities. Indeed, the event involves 12 municipalities along the coast with the attractions occurring either simultaneously or at different times along the whole coastal area. In particular, concerts, live performances, fireworks, and other minor happenings are designed by both local administrative bodies and private contributors (for example, shop owners and hoteliers) with the aim of generating economic turnover around a multi-site experience of thematic consumption. Participants are encouraged to dress themselves in pink clothes and display a variety of pink accessories. The theme of the Festival encourages retailers to propose on the shelves a wide range of pink items and service providers to offer experiences playing around the main color of the celebration. As a result, pink street furniture, special menus at restaurants, lighting games, fireworks, decorated shop windows create an engaging atmosphere.

Data collection started with a preliminary text analysis of official documents as well as selected interviews held with key organizers which allowed the authors to collect background information and become acquainted with the staging of the festival. Subsequently, an intensive investigation of the festival resulted in a four day, around the clock full immersion of the researchers in the event, during which time they closely interacted with the environment and consumers, paying specific attention to how consumers enacted during the Festival across space. Not only were the researchers engaged in observing the bodily movements of the participants, but they themselves were similarly involved in movements, shifting from one location to another in order to capture the spatial practices of consumption within shopping areas and public spaces. This resonates with the spirit of mobility in methodology (Hein, Evans, and Jones 2008) which advocates methods such as observing transfer points, walking while

talking, and using time-space accounts to record movement. Mobile researchers followed consumers along their trajectories throughout the event by using cars and bicycles, but most often they traveled by foot.

The observation produced a series of field notes that were digitally recorded on site and then manually transcribed into about 20 pages and several pictures and videos. Further pictures were collected after the event online, via social media websites. Both transcripts and research-driven visual materials became object of a "thematic analysis" (Bryman 2008, 554) that helped create an index of central themes and sub-themes emerging from the data. This was chosen as an appropriate analytical method due to its flexibility, given the presence of heterogeneous types of data including both verbal transcripts describing practices and images illustrating practices.

While the verbal accounts produced by consumers at the festival were often central to understand the meanings guiding their consumption practices, the authors put efforts into capturing spatial and bodily aspects, offering detailed accounts of the movements and gestures of the consumers involved in the festival. In this respect, the present methodology incorporates the "internal design proxemics" construct (van Marrewijk and Broos 2012, 87) as a way to study the "spatial arrangements" and "sociomaterial performances" in consumption practices. Yet, by further considering movements and gestures, the present study integrates the prevalent representational modes of knowledge based on verbal and visual accounts that characterize established research procedures within consumer research (Hietanen, Rokka, and Schouten 2013).

DISCUSSION

Three of the main themes emerging from the analysis of the consumption practices captured during the Festival (see table 1) provide an opportunity to unpack the spatial aspect of the mobilities inherent in consumption activities. While more traditional aspects of consumption usually characterizing festivals are also identified in the analysis (i.e. "audiencing", "coordinating and planning"), the first three themes illustrated in table 1 are discussed to elaborate the concept of "spacing consumption" This concept of is a way to capture the generative movements that constitute consumption activities and simultaneously produce space through consumption practices (see figure 1). Through this conceptualization, consumption is viewed as a particular manner of dwelling and being rooted in space, highlighting the reciprocity between consumers' activities and the space where consumption "happens." In particular, the concept of spacing consumption understands the mobility of consumption practices as characterized by the three aspects which of "Embodiement and Corporeality", "Performativity" and "Political and Affection"(see table 1 and figure 1). These three aspects of practices capture three complementary aspect of the spatiality inherent in the consumption mobilities observed.

Spatial practices as embodied

During the Pink Night Festival, consumers construct their bodies as "space" literally through practices of ingestion such as drinking alcohol during the pedalata alcolica (a pub-crawl performed by cyclists) and through the work they do on their bodies by adorning it with pink accessories, thus contributing to the staging of a collective pink landscape in the streets and on the beach. It is through the idea of embodiment that the concept of spacing consumption allows us to better acknowledge aspects of movement that are not only or not at all cognitive and verbalized (Thrift 1997), as evident in the on-the-move consumption of alcoholic beverages and music performed by cyclists following the "DJ Baba mobile music station."

The aspect of embodiment thus understands consumption practices as activities that involve situated "flesh and blood" subjects whose lives unfold through reciprocal interactions with their environment (Thrift 1997). This is in line with accounts of non-representational aspects of consumption which recognize that precognitive corporal knowledge may transcend cognitive elaboration (Hill et al., 2014, 10). Acknowledgments of the significance of embodied experience in consumer research are certainly not unprecedented; for example, Joy and Sherry (2003) note the embodied aesthetic experience of consumers within art museums. Similarly, the significance of the embodied practices of a moving consumer has been highlighted by Hansson (2014) in his study of familial experiences of bringing items back home from the store. The concept of spacing consumption takes this perspective further by implying that consumption is a practical way by which people become involved in their world, create knowledge, and directly interact with their physical environment. This is in line with the argument of Goodman, Goodman and Redclift (2010, 6) who claim that "it is the very consumption of spaces and places by our (non)mobile bodies that gives us somewhere to live and make our lives, act from and be acted upon."

Spatial practices as performative

The pink-colored "flow of consumers," moving from one attraction to the other along the Romagna Riviera, exemplifies the performative character of spatial mobile practices. The moving bodies of pink-attired residents and tourists converge to form a co-constructed performance that shapes a picturesque pink geography along the main streets of the sea-resorts. The aspect of performativity refers to the expressive practices through which consumers engage in showings and presentations among one another and within their environments. This performative aspect (Thrift 2003) is strongly linked to the aspect of embodiment, as one of the principal ways whereby the bodies of consumers participate in consumption practices. This is in line with accounts of non-representational aspects of consumption which may be understood as assembled flows of presentation practices in space (Dirksmeier and Helbrecht 2008).

The theatrical metaphor of performance has often been referred to in consumer research (Chronis 2008; van Marrewijk and Broos 2012) as the idea that consumers perform on a given stage and in front of an audience. However, the concept of spacing consumption suggests a slightly different application of the performance metaphor that draws from the notion of performativity (Thrift and Dewsbury 2000). Consumption practices are not just choreographies enacted by performers on given stages of consumption (retail spaces or in shopping malls), but they might also be activities that contribute to the shape of those environments (e.g. public squares and beaches) and are therefore actively constitutive of them. The carnivalesque parade created by the flows of crowds moving from one attraction to the other between different municipalities and districts illustrates the performative characteristic of consumption. This picturesque flow of bodies becomes in itself an attraction that is able to encourage other consumers to purchase pink items and take an active role in the transformation of the landscape into a diffused experience of carnival.

Spatial practices as political

The aversion against the festival and the presence of tourists expressed by residents traveling "against the flow" and leaving the coastal areas is a spatial manifestation of consumption's political aspect. This is also exemplified by the contradictions observed between the corporeal disposition of consumers and the verbal discourses conveyed by them during the interaction with the researchers of this study. One of the informants, for example, criticized the event

while simultaneously expressing her commitment to it by actively participating in the pink carnivalesque parade.

The political aspect thus refers to the feelings and emotions characterizing consumption practices which result in manifestations of bodily movements and facial expressions. In line with non-representational accounts of consumption, affects can be seen as engines that engender consumers' mobilities that in turn produce change and keep consumption practices in motion (Hill et al., 2014, 11). This may be a promising avenue for consumer culture, as shown by the critical discussion of the affective body and the affective body image developed by Featherstone (2010). The affective character of the consumption practices emerging from the analysis of the Pink Night Festival provides empirical evidence for one of the most thought-provoking tenets of the new mobilities paradigm, namely the "recentring of the corporeal body as an affective vehicle through which we sense place and movement, and construct emotional geographies" (Sheller and Urry 2006, 216).

However, the analysis of this current study emphasizes that these emotional geographies are seldom neutral and rarely implicit in a flat space. In line with Thrift's conceptualization of the spatial politics of affect, consumers' practices appear to be embedded within a field of forces in which issues of control and resistance can emerge and be expressed in the way consumers move or do not move. This hints at the role played by affects in shaping people's political dispositions as highlighted by non-representational theorists (Cadman 2009, 6). The "bottleneck" observed at the entrance of the exclusive event held at the Grand Hotel in Rimini is an expression of mobilities and immobilities inherent in the consumer practices, with consumers being clustered through boundaries that they might not able to cross.
Figure 1: The concept of spacing consumption

CONCLUSIONS

This paper extends the existing literature that examines the role of mobilities in consumer research (Brembeck et al. 2014). This study highlights the spatiality that characterizes consumption mobilities through an account of consumption practices in a multi-site and participatory Italian festival. Following recent attempts to bring relational ontologies into marketing (Hill et al. 2014; Hietanen et al.

2013) and building upon the growing consumer research literature that explores the nexus between consumption and space (Chatzidakis et al. 2012; Chronis, 2008; Chronis et al. 2012; Debenedetti et al. 2014), the present paper argues that the idea of "moving consumption" is inherently spatial and therefore could be further conceptualized as spacing consumption, given the profound relationships between mobilities of products, consumers, and the spaces in which their trajectories are being played out.

Highlighting the spatial aspect of mobile consumption practices implies that the mundane practices of consumers cannot be easily separated from the spaces in which they occur. Consistently, this approach gives due recognition to the reciprocity between the mobility of consumption and the space both resulting and determining those mobilities. Consumption practices can thus be understood as happening in the form of a process of spacing that includes the performance of consumers via a multitude of spatial practices, occurring within a relational space that is in turn also affected by those spatial practices.

Consumption, conceptualized as an activity through which groups use interconnected systems of commercially produced images, texts, and objects to make collective sense of their environments (Arnould and Thompson 2005), could thus be understood as "one of the key relationalities actively constructing and changing spaces and places which in turn recursively affect consumption practices" (Goodman et al. 2010, 13). Accordingly, the construction of space and its consumption are closely intertwined and occur through the embodied and spatial practices of consumers. In fact, it may be suggested through the lenses of non-representational theories that consumption practices are not inherently stable nor are they separated from space, but rather they constitute a way of performing or transforming in the flows of everyday life.

This paper suggests that consumer research could look more closely at the consumption of space as a process that is associated with the construction of space and is based on consumers' activities. In other words, this implies an empirical effort "to detected minutiae underpinning of various consumption contexts" (Hill et al. 2014, 14) – meaning the mobile spatial practices identified in the present study – and "to connect these minutiae to larger scale events" – meaning how multi-site and itinerant festivals contribute to create and change "themed spaces" (Firat, Pettigrew, and Belk 2011) that go beyond the confined forms of theme parks or shopping malls, so as to embrace a whole region and its municipalities.

Echoing the words of Mansvelt (2005), the concept of spacing consumption can be defined as the process through which the mobile practices of consumption emerge as geographies of embodiment, performance, and power. Such an understanding does not restrict consumption to particular consumption sites and spaces, to the end of a commodity chain, to a circuit of culture, nor to practices of self-identification [...]. Rather, various modes of knowledge about consumption can be seen as performative of these things, circulating and being invested with power in situated contexts (Mansvelt 2005, 164).

The main limitation of this study lies in the transitory nature of the empirical phenomenon investigated. Even if the Pink Night Festival well represents the genius loci of a territory, its historical entrepreneurial orientation, and its attitude to adopt synergic event-marketing strategies, the consumption practices studied specifically refer to these particular circumstances. Other multi-site and itinerant festivals should be investigated in different locations, and also different forms of mobile consumption should be taken into consideration other than the forms allowed by the ephemeral character of festivals. Questions about the relevance of aspects such as embodiment should also be addressed by future studies by recognizing the differ-

ent manifestations of materiality and corporeality that characterizes consumption practices that occur in online and virtual contexts.

A Semiotic Ethnographic Inquiry into the Existential Effects of Chronic Pain on Consumer Behavior

Laura Oswald, Marketing Semiotics, Inc., USA

ABSTRACT

Chronic pain poses unique challenges for consumer research. Methods such as direct questioning and phenomenology fall short because, in the first instance, pain is so subjective as to elude verbalization. In the second instance, the individual encounter of researcher and subject does not provide enough context to produce generalizable conclusions about the population or the condition as a whole. By means of theory development and case analysis, the present paper illustrates how semiotic ethnography led to deep insights about the existential effects of chronic pain on consumers by decoding the non-verbal discourses consumers project into images, rituals, and the organization of domestic space. By comparing and contrasting consumers at various stages of their pain journey, the study also led to generalizable insights about the chronology of pain's effects on consumer experiences over time. The study contributes new methods to the medical research paradigm and also suggests direction for further research into the nature and treatment of chronic pain.

SEMIOTIC ETHNOGRAPHY

Semiotics-based ethnography draws from the dual legacies of Saussure's structural linguistics and the structural tradition in French sociology leading from Durkheim (1997 [1893]), and Mauss (2000 [1925]) to Lévi-Strauss (1974 [1963]) and Bourdieu (1998 [1994]). By drawing attention to the role of social codes in the production of meaning, Saussure (2000 [1916]) found that meaning is a social construction, "produced by someone for someone," not a product of nature. Emphasizing parallels between structural linguistics and culture, Lévi-Strauss eschewed the idea of culture as a transcendent, natural order. He interpreted the field site as a text structured by a paradigmatic system of interconnected binary codes. Binary codes structure the shared, normative, and iterable aspects of culture and account for the dialectical nature of cultural categories such as gender (male/female), power (dominant/dominated), or morality (good/evil). Although Bourdieu criticized structuralism for its overemphasis on universal laws, he nonetheless acknowledged the influence of Lévi-Strauss when he compared the cultural system or *habitus* to a kind of "language" (op. cit. p. 8).

Semiotic ethnography grew out of the debates of American anthropologists such as Sahlins (2004 [1965]), Geertz (1973), and Herzfeld (1983a, b) with structural anthropology in the 1970s and 80s. Though they agreed that, "at least certain aspects of behavior are coded (Joseph 1983, 211)," they underscored the contingent nature of cultural codes in relation to the messy vicissitudes of daily life. It is the semiotic ethnographer's task to reflect upon the emergence and decline of cultural codes over time and expose tensions and contradictions between multiple code systems at play in the site, as between consumers' statements and their ritual behaviors, social interactions, and possessions. Thus the ethnographic disposition is not simply a text, but a kind of performance that stages the intersection of codes, context, and inter-subjectivity in the active production of cultural meaning (Winner 1983). It also puts into play a dialectical relationship between theory and practice, leading Herzfeld (1983a, p. 100) to define semiotic ethnography as the "the pragmatic embodiment of theory." Theory links observable events to their implications for culture as a whole, while the field practice itself exposes ambiguous and even contradictory aspects of the field site which challenge theory. For example, though code theory provides the basis for analyzing culture, humans rarely conform rigidly to these codes in day to day performance. In this sense, semiotic ethnography describes a practice and an epistemological terrain that grounds the Consumer Culture Theory paradigm in consumer research (Arnould and Thompson 2005).

RESEARCH DESIGN

Twenty-four two-hour ethnographic interviews and observations were conducted across three U.S. markets in the homes of men and women ranging in age from 25 to 65. Respondents were recruited randomly from local telephone directories. The screener specified respondents that had lived with chronic pain for one to ten years and were seeking alternative treatments to the over-the-counter products and prescription drugs they were currently using.

We employed a mixed methodology to account for the effects of chronic pain on the semiotic, psychological, and existential dimensions of consumer behavior. The protocol was laddered to move from demographic and lifestyle factors to personality and emotion. It included a projective task designed to elicit symbolic associations between respondents' pain experiences and the symbolism depicted in set of abstract paintings. Research included a semiotic analysis of the layout, traffic flow, and the disposition of goods and pharmaceuticals in the home.

CONSUMER LIFESTYLES AND VALUES

Historical advertising for pain relief meds, including pharmaceuticals and OTC drugs, reflect the general emphasis of the medical profession on the physical side of chronic pain. Pain is a radiating red spot on the back or joints, causing patients to grimace and limit their movements. In contrast, findings from the current ethnography shed light on the effects of chronic pain on consumers' spiritual lives, what Jung (1960 [1916]) defines as the ability to transcend the moods and minutiae of everyday life and expand their existential connection to the wider world. Regardless of the length of time that they had lived with chronic pain, all respondents had sought purpose and meaning in their lives through volunteering, expressing themselves through arts and crafts, building additions to their homes, and generally making big plans for the future. The onset of chronic pain disrupted their plans. Their unfinished projects were often visible in the home or yard, sad reminders of the havoc that pain had wreaked on their plans.

Furthermore, respondents seemed more concerned about the effects of prescription pain medication on their cognition and sense of self than about the physical limitations that pain imposed on their lifestyles. Many of them feared becoming addicted if they took prescription drugs because alcoholism either "ran in their families" or they were recovering from addictions themselves. They typically took excessive dosages of over-the-counter medications such as Ibuprofen instead, and were surprised to learn that exceeding the normal dosage of Ibuprofen had potentially lethal effects on their kidneys.

Respondents were very resourceful, developing stratagems to perform daily tasks in spite of their disability. They scooted about the house on stools installed with wheels, they kept two sets of cleaning products, one upstairs and one downstairs, they used "grabber" tools for fetching objects from high shelves, or moved personal items, from medications to foods, to a central location in the family room to avoid walking. They dreaded depending upon family and friends. As

respondents lived with pain over longer periods of time, many still held out hope that they would overcome the pain over time. Still others succumed to depression and listlessness and centered their days on the next dosage of medication.

THE SEMIOTICS OF PAIN

The image sort exercise prompted respondents to associate pain with the visual elements in a set of Abstract Expressionist paintings, including works by Appel, O'Keefe, Picasso, Mondrian, Kandinsky, Pollack, and Delaney, which focus on the emotional dimensions of visual form rather than specific characters and stories. Respondents picked the top five of the images that best represented pain, on the one hand, and pain relief on the other. Among the five, they consistently ranked at the top two images for pain, including Appel's *Angry Landscape* (1967) and Delaney's *Untitled* (1954) and two images for pain relief - Georgia O'Keefe's *Music Pink and Blue, II*, (1918) and Mark Rothko's *White Center (Yellow, Pink and Lavender on Rose)* (1950) [Figure 1]. Results from the picture sort exercise suggest that the existential effects of pain on consumers far outweigh its physical effects.

Figure 1: The Semiotics of Pain

Respondents associated the disorderly, rough forms in *Angry Landscape* with the chaotic, unpredictable, moving, and capricious nature of pain. Only secondarily did they speak of the physical sensation of heat communicated by the color red and the sharp, jabbing experience of pain on the body, as represented by the color yellow and the jagged lines. Respondents compared the black in the background to the effects of pain on the mind as deadening, depressing, and dark. They also identified the menacing, face-like forms top left and right of the image with inner demons that hound them day and night. Black outlines set the faces apart from the surrounding swirl of colors and outline eyes and teeth that threaten the viewer. Respondents identified the color blue with the self, which is being reduced and overrun by the colors they associate with negative experiences. As one respondent put it, "Blue is me being blocked by pain."

Respondents also most frequently associated pain with *Untitled* (1954) by the American artist Beaufort Delaney. Though splashes of red, yellow, and green are toned down by touches of blue and the

white background, the overall design is dominated by the chaotic, swirling movement of brush strokes on the canvas. In reaction to this picture, respondents again emphasized the effects of pain on the self rather than the body. Pain causes mental confusion, loss of control, and disorder. It covers up the "blue," i.e. the self, as the lines in this picture cover up the blue color, rendering it a shadow of its former being.

From one interview to the next, most respondents associated the same symbols with their various sensory and emotional experiences of pain. Over the course of 24 interviews, the repetition of these kinds of associations gave rise to a kind of "pain lexicon" that consumers used to verbalize their experiences of pain [Table 1]. They gradually replaced vague dictionary terms for pain, such as heat and intensity, with symbols from the pain lexicon, such as colors and forms. They would say, for example, that pain relief expands the color blue (the self) and lightens the color red (intensity).

Table 1: The Pain Lexicon

Signifier	Experience	Category
Red	Intensity	Senses
Yellow	Heat	Senses
Black	Brain-numbing Depression Stasis	Mental outlook Emotion, Mood state Life projects
Blue	The Self	Identity
Jagged lines	Stabbing Threat Mess	Senses Emotion, Mood state Consumer behavior
Squiggly lines	Chaos Disorder	Mental outlook Lifestyle Life projects

THE SEMIOTICS OF PAIN RELIEF

Respondents reported that pain treatments mitigate but do not eliminate pain. In O'Keefe's *Music Pink and Blue, II*, (1918) and Mark Rothko's *White Center (Yellow, Pink and Lavender on Rose)* (1950) [Figure 2], pastel colors represent the cooling and softening effects of pain relief. In the O'Keefe, "The blue gets bigger," suggesting that pain relief improves personal integrity and control. The mind-numbing effects of black and the warming effects of yellow are either absent or under control. The smooth, curvy lines soften pain's intensity. The pastels in the Rothko painting cool the heat and intensity of the pain. The division of the canvas into two symmetrical halves communicates the sense of order, control, and purpose respondents associate with pain relief. The black line dividing the canvas across the middle reminded respondents that the effects of chronic pain were ever present even though medication may provide relief. By the end of each interview, respondents stopped using words like "relief" or "self" and used symbols from the pain lexicon instead. "The red softens to pink," "The black goes away," "The lines smooth out."

The picture sort exercise gave rise to a shared consumer discourse about the effects of chronic pain on the body, mind, and lifestyles of consumers. Though none of the respondents ever met each other, and though they were recruited randomly from the phone book, there was a high degree of consensus about the meanings they associated with formal aspects of the images such as colors, lines, and shapes. These findings confirm that art is a useful tool for probing the emotional recesses of consumer experience, because a culture's art forms a kind of universal language of the heart for

the social body. The artwork gave rise to a shared lexicon for both verbalizing ephemeral consumer experiences and finding common ground among a disparate group of patients suffering from the same condition.

Consumers' responses to the artwork also provided a key to understanding the semiotics of their lived environments, reflected in the effects of chronic pain on their ability to clean house, manage their possessions, and keep track of their medications.

THE DYSFUNCTIONAL SIGNSCAPE

The lived environment provides a rich signscape for decoding consumers' values, lives, and lifestyles. It serves as a counterpoint to consumer speech and provides access to consumer experiences that transcend language. It is organized to some extent by cultural codes related to the organization of goods, furnishings and people in domestic space. Social norms such as "cleanliness is next to godliness" define cultural expectations about keeping house and organizing possessions in drawers, cabinets and closets. They structure domestic space along the lines of binaries such as |sacred/profane| and |public/private| domains. Though individuals deploy these codes according to their personal tastes and lifestyles, cultural norms account for the fairly consistent organization of space, possessions, and traffic flow within the home in a given market.

The homes of chronic pain sufferers reflect the gradual breakdown of these cultural norms as the pain persists, creating chaos in their inner and outer lives. The most obvious sign of this decline is hoarding. In the early stages of their disability, pain patients manage the chaos by hiding the mess, beginning with a single closet and expanding into a spare bedroom. Over time, discarded clothing, furnishings, newspapers, dirty dishes, and refuse gradually extend from these enclosures into every area of the home, interfering with basic household functions such as eating and sleeping. They clutter hallways and bedrooms and crowd the living room, leaving very little room to sit down or get into bed. Even the kitchen is piled high with dirty dishes, pans, and garbage. [Figure 2]

Figure 2: The Semiotics of Pain in the Lived Environment

In the homes of long-term pain sufferers, hoarded goods seemed to possess consumers rather than the other way around. They blocked entry to the front door and disrupted consumers' movements within the home. The research team had to remove the mess from chairs and sofas to clear space to sit down. Even bedrooms and beds were piled high with discarded clothing and papers, leaving a narrow space for sleeping. Furthermore, as their homes submitted to the chaos, respondents increasingly dissociated themselves from their surroundings. Respondents dodged piles of hoarded goods as they went about their affairs, as if numbed into a state of denial about the severity of their dysfunction.

Chronic pain sufferers also collapse the boundaries that traditionally set off the sacred space of the medicine cabinet from profane, public areas of the home. The medicine cabinet represents a social and psychological boundary between the use and abuse of pain medications. As chronic pain encroaches on consumers' lives, they gradually move their medications to the profane, public spaces of the home. They may begin by storing drugs behind kitchen cabinets, but eventually move them to kitchen counters and coffee tables, or hang them in special bags from family room chairs, embedding their medications in daily life. The spatial trajectory from medicine cabinet to public space symbolizes the consumers' growing dependency on pain medications. They double and triple the recommended dosage for over-the-counter pain remedies and become addicted to pharmaceutical drugs.

In other words, chronic pain permeates every area of consumers' lives and transforms conventional spaces of consumption into places of dysfunction. As the chaos increasingly overcomes their homes, the whole family works around the mess by means of dissociation. At one such home, we were interviewing a high school teacher, surrounded by heaps of old junk in the family room, when her teenage son returned home from school. He walked through the mess and clutter up to the equally messy upstairs area, apparently screening out the disaster of his home life. Thus the effects of chronic pain on the domestic environment affect the whole family and are symptomatic of the individual's gradual alienation from their surroundings and a breakdown of their social and psychological integrity.

CONCLUSION

The semiotic ethnography exposed a shared consumer discourse across the data set that led to generalizable hypotheses about the existential effects of pain on consumers' lives. By means of a mixed methodology, the semiotic ethnography exposed parallels between the physical, psychic, and cultural implications of chronic pain for consumers. The picture sort paired colors and forms with pain sensations and highlighted the psychic and emotional dimensions of chronic pain. These insights were reiterated in the semiotic analysis of the social and cultural codes that organize goods in consumers' lived environments.

By highlighting the iterability of this theme across multiple levels of the data, the semiotic ethnography exposed a paradigmatic system in which themes and experiences were reiterated at the levels of sensation, psyche, and lifestyle. The approach triangulates findings across various levels of the data, which lends a certain reliability and objectivity to the semiotic ethnography that eludes interpretive research generally. Rather than rely upon the researcher's ability to interpret the field setting, semiotics draws inferences from the data itself by decoding the consistent association of signs and meanings in the data and identifying paradigmatic relationships between multiple cultural categories, from emotion to spatial semiotics.

The semiotic focus of the research also bridged the gap between consumer insights, marketing strategy and advertising. Findings provided a platform for new product development and marketing for a new form of pain management by discovering an unmet need of chronic pain patients for order and control. Furthermore, by generating associations between consumer experiences and specific signs and symbols, the semiotic perspective produced a set of signs and symbols for potential use in marketing communications.

FUTURE RESEARCH

The current thinking on chronic pain treatment emphasizes the efficacy of various medications on pain's physical effects on consumers (American Chronic Pain Association 2015). However, findings from the current study suggest that the existential effects of pain on consumers' lives - their sense of purpose, order, and control - may actually outweigh its physical effects. If true, the findings suggest that a more efficacious treatment protocol would integrate

pharmaceutical remedies into a holistic process that also treats the psychological and lifestyle dimensions of the disease.

Furthermore, the study prompts further investigation into the cultural factors that allowed consumers to develop a shared lexicon for chronic pain in the colors, shapes, and lines of some abstract paintings. On the one hand, the emergence of the pain lexicon illustrates in microcosm the role of psychic displacement in the theory of symbol formation (Freud, 1955 [1909]), as consumers project their emotional experiences into concrete symbols. However, the present study illustrated how one's personal projections may indeed be informed by shared cultural codes, contributing to the high degree of consensus we observed in the responses from one interview to the next. Future research might compare and contrast responses in this study, which included long-standing American residents, with those of recent immigrants from non-western countries.

ABSTRACT

This research focuses on the socialization process of black women consumers in relation to their haircare practices, reflecting what they have learned about their race and the social stigma and how they deal with it. Such process is distinguished by displays of power and discourses within the consumer's social network.

INTRODUCTION

Consumers are made, not born. In the field of consumer socialization, the pioneering study of Ward (1974) focused on the development of children and teenagers as consumers, highlighting the lasting effects of their early learning throughout life. Ward's work inspired numerous studies, generally focusing on the effects of marketing on children and adolescents, as wells as ethical and regulation issues (Belk, Mayer, and Driscoll, 1984; Butter, Popovich, Stackhouse, and Garner, 1981; Donohue, Henke, and Donohue, 1980; John, 1999; Moschis, 1985). Later, such perspective was expanded to encompass the socialization of the consumer in adulthood (Barnhart and Peñaloza, 2013; Casotti and Campos, 2011; Ekstrom, 2006; Moschis, 2007, 2012; Schau, Gilly, and Wolfinbarger, 2009; Shah and Mittal, 1997; Smith and Moschis, 1985). However, consumer socialization related to race is a field yet to be theoretically explored (Ekstrom, 2006).

This research focuses on the socialization process of black Brazilian women in relation to the consumption of hair products and services and what hairstyle represents in social terms (Santos, 2012). In Brazil, blacks and *pardos* (mixed race) comprise 51% of the population (Ipea, 2013), and women in this group embrace a variety of hairstyles; indeed, some use their hair to reflect a political stance against prejudice and to engender racial respect (Globo.com, 2015).

Until its independence in 1822, Brazil was a Portuguese colony. Throughout the colonial period, slavery was practiced. Some female slaves worked as domestics and lived in the houses of the wealthy, under better conditions than those living in the *senzalas* (slaves' quarters). Domestic services included cooking, breast-feeding and child-care for white children, companionship for white womenfolk and housekeeping. This slave group was well acquainted with the tastes of the masters and often exploited this in order to maintain a higher status (Freyre, 2006). This aspect of Brazilian history makes it possible to comprehend the cultural myth of a deeply relational nature, with people prizing relationships and avoiding direct conflict (DaMatta, 1986, 1997).

Brazil abolished slavery in 1888. Freed slaves remained marginalized in society, usually working low-paying jobs. Even now, Black Brazilians face inequality in many aspects of social life. (D'Amario, 2011; IBGE, 2014). Even if qualified, blacks are unlikely to attain prominent positions in companies (Batista and Leite, 2011; Ipea, 2013), and this gap is reflected their wages. Using the income of a Brazilian white male as a benchmark (100%), white women earn the equivalent of 68.7% of the benchmark, black men, 52%, and black women, 38.5% (Ipea, 2013). However, debating racial differences is not part of formal education in Brazil (Gomes, 2003). Racism is veiled under the guise of social acceptance (DaMatta, 1986). In "a society in which there is no equality among people, veiled prejudice is a much more efficient way of discriminating against people according to skin color, as long as they know their place" (DaMatta, 1986, p. 46).

Goffman's concept of social stigma (1963) helps us understand the socialization process of black women in their consumption habits. A stigmatized person is one who has characteristics socially considered as bad, dangerous, or weak (Goffman, 1963). Link and Phelan (2001) criticize this individualizing perspective and indicate that the concept of stigma has to take into consideration some interconnected components that have influence on it. They "apply the term stigma when elements of labeling, stereotyping, separation, status loss, and discrimination co-occur in a power situation that allows the components of stigma to unfold" (Link and Phelan, 2001, p.367). To a degree, the process of socialization through consumption of these women must reflect the intensification or superimposition of the stigma they face (Lamont and Monár, 2001). Their stigma seems to be reflected in the cultural myth of beauty standards of Brazilians, who value Eurocentric aesthetics (Freyre, 2002).

We seek support in the analysis of power and discourses relations proposed by Foucault (Foucault, 2015; Machado, 2007) to elucidate the socialization process of black consumers. According to the philosopher, power and discourses are always related in a way that is neither fixed nor predetermined and, therefore, must be investigated and understood. Power manifests itself not (only) as a binary opposition between dominated and dominants or as a set of laws and punishments, but as a network of subtle, sophisticated and unstable relations. Power relations are inherent in economic processes, relations related to expertise, kinship relationships, sexual relationships and all social institutions, which are therefore instantiations of socialization.

Moreover, where there is power, there is resistances that follow different types of logic and are irregularly distributed within the power network. Studies in the area of consumer behavior stress the role of resistance and anti-consumption (Cherrier, 2009; Hogg, Banister, and Stephenson, 2009; Kozinets and Handelman, 2004; Suarez, Chauvel, and Casotti, 2012; Thompson, 2014; Sandikci and Ger, 2010). In this context the question that guides this study is: *How the relations of power and discourses influence the consumer socialization of black Brazilian women in a context that devalues their racial origin, especially vis-à-vis haircare practices?*

METHOD

As data collection method, in-depth interviews were used in this research (McCracken, 1988). Fifteen women, aged between 28 and 52, wearing different hairstyles were interviewed. The interviews were conducted in 2015 and each lasted about an hour, resulting in approximately 320 pages of transcription. Five interviews took place at the interviewee's home, which provided an opportunity to photograph their hair products. The remaining interviews took place in public spaces at the interviewee's convenience. The data was subsequently analyzed and organized in categories that would indicate the presence or absence of a certain aspect (Bardin, 2006). An additional development in the analysis involved interpretations, taking into account the context in which a given aspect is present and inferences that might arise from it (Bardin, 2006; De Geer, Borglund and Frostenson, 2004). The objective was to shed light on what lies beneath the analyzed data (Mozzato and Grzybovski, 2011).

FINDINGS

Hairstyles worn by black women reflect what they have learned about their race and the social stigma that black people endure in their socialization process within the sphere of consumption. Such process is distinguished by subtle and dynamic displays of power within the consumer's social network. These manifestations of power consist of myriad relations with learnings about society as a whole and, more precisely, with the consumer's learnings. Power can affect the development of new areas of learning and exert influence to make them fit a dominant standard, one that dictates what is "true" and often perceived as absolute. Simultaneously, in the context of a critical self-awareness of race, learnings about resistance emerge in the relation between a black woman and her consumption. Nevertheless, these critical learnings can also bring about change in the active power structure, inducing social change, albeit somewhat slowly. All of this is reflected in consumer behavior.

We developed a conceptual framework (Figure 1) that highlights: (a) power and displays of discourse in the socializing network; (b) the core tension that emerge for those consumers and that revolves around fitting into, or resistance to, the prevailing standard in society; and (c) new discourses and practices, driven by how those consumers deal with such issues.

Power and Discourses Displays Influencing Socializing Processes

In Brazilian culture, the prevailing aesthetic standard is that of the "white biotype." Curly afro hair is popularly known disparagingly as "bad hair." The esteem for Eurocentric aesthetics represents a power display that directly affects black women's connection to their hair, engendering discourse and considerations on how to deal with this situation. Straightening of hair, thereby "erasing" racial traits, becomes a "normal" practice for some. Claudia (age 57, relaxed curls) said, "I thought that straightening your hair was normal, because my hair had to look the same as a white girl's." Having lived abroad for many years, Ana Paula (age 38, straightened hair) experienced a contrast in relation to other cultures: "In Europe, I had the kind of hair everyone wanted to copy. Here [in Brazil], you're encouraged to straighten your hair; but abroad, people are encouraged not to straighten it and to keep their identity."

Since childhood, the socialization process surrounding hair and what it entails develops in families and at school. Magda (age 45, hair extensions) recognizes the role of the parents in the reproduction of social representations based on prevailing beauty standards: "At home, the expression [bad hair] cannot be used; it was even the subject of a quarrel with my mother. She told me that one of my daughters had bad hair. She told me it was because she was conditioned by society to do so." Ana Paula, although the daughter of a white straight-haired woman, had in her black father a figure driving her to straighten her hair: "My father, who suffered a lot of prejudice — I don't know if he wanted to protect us — always encouraged us to straighten our hair."

Mothers are particularly important in the socialization process of black women as regards teaching them how to deal with their hair. Magda reproduces aspects of what she had learned with her mother in the socialization process with her own daughters, and made sure they always combed their hair. Amanda (age 38, braided), although the mother of a boy, makes sure he develops an awareness of his roots and to prize natural hair.

However, if family can prevent a black girl from having negative associations related to race, school may be the first environment in which the stigmatized face of what it means to be black in Brazil is revealed. Curly hair is an element of stigma, especially if blacks share a space with a white majority. They learn there is something "wrong" with their hair, their race.

> I would get to school and the kids would tease me because no one has this kind of hair. Because I attended upper class schools, and I was the only black kid. (Ana Paula).

The job market, the media and the structure of products and services inculcate seemingly important socializing influences. A person's hairstyle can mean the difference between landing a job or not. For the interviewees, getting their hair straightened made them more acceptable and served, in a sense, as a mechanism for fitting in socially, thus "erasing" traits of a socially devalued race. "The natural style is the least acceptable. When you go for an interview donning natural hair, you're going to be eliminated just because of your hair," says Ana Paula. Iconic black beauties, famous globally, are still lacking in Brazil. The recent presence of black female actors in Brazilian

soap operas might have had an impact on the "new" aesthetic condition of identification of new possibilities of beauty. Products and services geared to such consumers appear limited compared to other consumer groups. Flávia (age 50, white dreadlocks), for example, claims she cannot find suitable products for her hair: "I can't find them, not even for my daughter's hair." Consumption environments tailored to black consumers were cited as spaces that bring black women together, while also keeping them in touch with subjects that are particular and relevant to them. Magda recalls her experience at two black beauty parlors that, although they now longer exist, were a point of references in black aesthetics and definitive in terms of the racial socialization process. An alternative solution is to go online and check out the specialized blogs that can help black women look after their hair and bring them closer to issues related to race.

Core Tension

Black women learn, from very early, the centrality of the stigma they will have to face throughout life. A core tension arises and is reflected in consumption related to hair, i.e., whether to fit in socially or resist against prevailing beauty standards and social prejudice. Regardless of the interviewees' attitudes, new tensions emerged.

Maria (age 42, straightened hair) explains why she straightened her hair: "everybody, my color or not, but has curly hair, would straighten their hair; so I didn't want to feel different from the group." Although straightening her hair may have favored Claudia in the job market, it limited her in other social situations: "I started working and I can remember the huge sacrifice at weekends. Everyone would say, 'Let's go to the beach'; and I'd reply, 'How can I go to the beach? I'll get my hair wet. It won't dry at night, and I'll have to curl it, use a dryer, use hair bobs.' It was very bad." Magda notes the cognitive mismatch induced by the prevailing standard: "When I was a child, I was always the black kid. But the beauty standard was white, so it was hard for me to identify with being black." All the interviewees mentioned having heard someone—black or white—asking a black woman with straightened hair, "why don't you just accept your hair?" They would reply that people who straighten their hair might suffer social rejection, given that in the minds of some doing so might be construed as "not accepting" oneself as a black person.

> She thinks I have to wear natural hair, an afro or curly hair. I'm keen to be seen as an executive, so I think it looks great to have my hair straightened. I don't know if that's the ideal but, from my point of view, from everything I've experience since my childhood until now, I feel good about myself. (Maria).

Amanda reveals in her narrative the socializing influence from her family and friends, who were members of the black movement and would patronize the same beauty parlor: "[Those professionals] are benchmarks in afro hair and were very close friends with Mom and Dad […] so customers such as Zezé Motta [actress] were the 'black in evidence'." Amanda wore natural hair during childhood and, later on, had it afro permed and braided: "Hair that's part of my development as a human being. The thing about hair, to black people, is that it amounts to a symbol of resistance, of identity." Magda shows the impact of resistance in her personality and gender identification by describing the change from a short haircut that is "androgynous" compared to other "more feminine" hair styles: "My shaved haircut [...] is my masculine side, which is very strong in the sense of 'I will fight;' so, now I have to work with the softer, more feminine side. And that's where my hair fits in." This interviewee's argument explains how she appears to embody the socially constructed paradigm by associating gender issues and meanings to her black hair. Vilma (age 44, natural hair) sees the rise of a "new"

black woman who comes "learning to appreciate her hair" and hopes for social change driven by this new attitude: "She can appreciate letting her hair grow out and, in so doing, takes care of it so she can be beautiful, wonderful."

New Discourses and Practices

To cope with the tensions, consumers pursue new discourses and practices that enables them to position themselves more favorably in social reality. Taking care of curly hair is described by the interviewees as a daunting task. The respondents are aware that white women have many more options in terms of products and that it is easier for them to take care of their hair, in stark contrast with the "reality" of black women, which is limited by the market. With such restricted consumption — caused by the dearth of suitable products and services for curly hair — consumers seek out expertise in the subject, both those who wish to straighten their hair and those who opt for natural hairstyles. Some become experts, that is, take ownership of specific expertise about their hair type. Amanda elucidates:

> Because we are not represented in the mainstream so to speak, on television, in commercials, in major cosmetics brands, we use other tools. So we have blogs; we create a network of shared experiences. You pass it on to another […] Much different from the relationship that whites have with their hair.

Other consumers, beyond assuming ownership of learnings about curly hair, may also perform activities traditionally performed commercially. As such, they are considered consumer-producers (Cova and Cova, 2012). Claudia explains that "usually, good products are not formulated for afro hair […] so you have to plaster your hair with a product that is not meant for it, and wind up with a crazy mix that might end up working if it doesn't make your hair fall out."

Our last case related to expertise concerns a consumer who literally became a market player. Indeed, to some extent, Vilma became a hairdresser due to her unsatisfactory experiences with her hair: "I suffered a lot with that, so I said, 'no; that's enough! I'll find a way to do my hair myself and I'll become an expert in black people's hair'".

Besides the pursuit of expertise, we observed another adopted strategy using a discourse of *symbolic shallowness* in relation to black hair, aiming to break the link it has with issues of power and resistance. For Ana Paula, hair is "not necessarily a race thing: it has become a fashion accessory. Sometimes you're into straightening it because you want to change the shape, the structure, just like you change your clothes." This strategy of symbolic shallowing is directly at odds with the position of consumers who perceive their hair as an element of black women's awareness-raising and politicization. As Marilda (age 47, hair extensions) explained:

> It concerns accepting yourself as a black woman, accepting your beauty, your natural hair, the way a [black woman] is. Some will speak of ancestry; some will speak of the beauty of Africa, seeking to distance themselves from this Eurocentric beauty. As such, this hair is a proxy for a political place; it represents a political stance.

FINAL COMMENTS

Socialization studies on consumers reveal how an individual enters society, in a context in which, according to Foucault (2015), diverse, subtle and sophisticated displays of power are in place. The subtlety that Foucault refers to is even more expressive in a society such as Brazil's, which has as a cornerstone a reverence for harmony in personal relations and an avoidance of open conflict, thus

Table 1: Black Female Consumers Socialization Universe

Power and Discourses Influences in Socialization Process	Core Tension: To fit or to resist?	New Discourses and Practices

• Stigma and eurocentric aesthetics standard circulating in Brazilian culture
• Contrasting in relation to mentioned foreign cultures
• Parents raising (or not) critical awareness about racial issues
• Exposure in school and other environments of white majority reinforcing stigma
• Job market ruling acceptance of hair styles
• Market offerings limiting consumption
• Market environments and blogs tailored to black consumers promoting learning experiences
	• To Fit:
	  ○ Felling of "belonging" in society and access to opportunities
	  ○ Social sanctions
	  ○ Cognitive dissonance about ethnic identity
	• To Resist:
	  ○ Ethnic pride
	  ○ Feeling of social change trigger
	  ○ Social marginalization, restriction of opportunities and loss of a socially-constructed "femininity"
		• Expertise:
		  ○ Pursuing of new practices and expertise in order to cope with social "reality"
		  ○ Performing activities traditionally performed commercially
		  ○ Becoming a real market player
		• Symbolic shallowness as a strategical discourse
		• Politicization: Raising black women's critical awareness with "new aesthetic preferences"
		• Solidarity with formation of social networks supporting consumption

engendering the appearance of tolerance towards diversity, while all the time a veiled discrimination prevails (DaMatta, 1986). The interviewees' narratives show power relations in the most varied of spheres: the prevailing aesthetic standard; hiring in the job market; low representativeness of blacks in the media; emotional and partnership relations criteria; and — as concerns our study — the dearth of availability of suitable products and services in the market. Hearing from the interviewees that their hairstyle might be the deciding factor for their hiring is one of the situations that illustrates how hair, and all the attendant consumption, acts as a mechanism of social fit.

These subtle power relations affect directly the socialization process of black consumers. Throughout life, consumers seem to have contact with deconstructive socializing forces, which influence them with messages of the type, "I will teach you to not accept yourself." Family appear to be relevant vehicle to raise critical awareness about racial issues, although not always does reality proceed in that direction. Family and relatives introduce young blacks to social representations, contributing to reinforcing or superimposing the stigma black people face, as well as aiding in accessing products and services.

If those consumers cannot find suitable products and services for their hair — if they do not see themselves portrayed the media — and if the market seems not to align with their nature and welfare — the pursuit of expertise in a network of racial solidarity is sparked within them. Such networks consist of shared practices and learnings about consumption, oftentimes, addressing gaps in the market. The alternative for such women is to socialize in a "private universe." This reality contrasts with that of their white counterparts.

Co-creation can be an important marketing tool, promoting a narrowing of the gap between companies and black consumers and the development of products and services tailored to their reality. Solidarity networks developed by those consumers offer relevant clues for reshaping distribution and communication strategies. Blogs and virtual communities appear as enabling environments for fostering learning and practices related to this "private universe." Additionally, appreciation of the tensions surrounding consumption is essential for crafting authentic advertising that is true to consumers' reality and provides symbolic repertoire to maximize their welfare.

We suggest that future research investigate different generations issues in order to understand intergenerational cross-influences and the evolution of the consumer universe related to black hair over time. Our findings suggest that a specific study could be conducted

as to the different levels of expertise adopted by black consumers, focusing on their practices, competences and restrictions. Moreover, we would like to emphasize the contextual potential studied in our findings in order to explicate implications of consumption as a revealing element of the complex sociocultural mores embedded in relations of power, discourses and resistances.

Bringing Together Japanese Organic Food Consumers and Producers After Fukushima

Sumire Stanislawski, Tokyo International University, Japan

ABSTRACT

This paper qualitatively analyzed how an organic food delivery company acted to protect producer livelihoods while simultaneously ensuring feelings of safety for consumers after Fukushima. It was found that transparency and provision of choices were used to help create perceptions of safety that went beyond government claims of safety.

FOOD SAFETY CONCERNS AFTER FUKUSHIMA

Fukushima and its surrounding regions are major contributors to Japan's agriculture and fishing industries. Due to its geography, farmland is scarce in Japan, with only 12.1% of total land suitable for cultivation (Statistics of Agriculture, Forestry and Fisheries 2014). Japan has been struggling with a low food self-sufficiency ratio (39% as of 2013 on a calorie supply basis), the rising age of commercial farmers (61.6% aged 65 and over as of 2010), and a lack of young fishers (24.9% aged 44 and under as of 2014) (Statistics Bureau 2015). Despite the aftereffects of the Great East Japan Earthquake, tsunami, and nuclear accident disaster on March 11, 2011 (hereinafter referred to as "3.11"), Japan cannot easily afford to abandon a significant portion of its fertile land or its diminishing number of farmers and fishers (see figure 1).
Figure 1: Prefectures Subject to Radiation Monitoring by Regulations (From Consumer Affairs Agency (2013), *Food and Radiation Q&A in English*, 8th Edition, p. 20)

Therefore, instead of banning food from all potentially contaminated areas, the government instead chose to limit consumers' internal radiation exposure by implementing relatively strict provisional limits for radioactive materials in food. This was amended to an even stricter limit a year later (see table 1 for international comparisons of regulatory limits). This has been largely successful in keeping contaminated foods out of the marketplace (see Consumer Affairs Agency 2013 for regulation details and Merz et al. 2015 for food monitoring outcomes).

Consumer reactions to this new reality have been complex. On the one hand, there is an ethical consumption movement to help support reconstruction through actively buying products from affected areas called *ouen* (literally "aid") consumption (Stanislawski et al. 2015). On the other hand, there is fear of potential adverse health risks, resulting in avoidance and so-called "harmful rumor damage." Defined by Sekiya (2011) as "economic damage caused by media coverage of social issues that results in people perceiving 'safe' things as dangerous, and which leads to avoidance of consumption, tourism, and transactions" (p. 12), this term has been used to highlight damage to livelihoods caused by avoidance of products deemed "safe" by regulatory standards. Consumer unwillingness to purchase produce from Eastern Japan, regardless of scientific data backing claims of safety of all products in the marketplace, show that expert claims of safety do not always translate into feelings of safety for consumers.

Similar trends are seen in consumer discomfort with genetically modified (GM) foods, despite expert claims of safety and positive social impacts (Wansink and Kim 2001). Like radiation exposure, the long-term impact of genetic modification is a complex issue with differences of opinion even among experts, which makes it difficult for the average consumer to fully understand. The organic food movement has largely come out against GM foods and has often led campaigns against them. For example, Dreezens et al. (2005) found that consumer attitudes toward genetically modified foods and organically grown foods are negatively related. As such, it is logical to think that organic food consumers would be especially sensitive to radiation concerns and would strongly avoid products from potentially contaminated areas. Yet, research into Japanese ethical consumers, which included organic food consumers, has found that awareness of "harmful rumor damage," trust in marketplace regulations, and feelings of obligation to help support reconstruction have acted to counter such concerns to some extent and have led to support of *ouen* consumption (Stanislawski, et al. 2015).

A factor to consider is Japan's organic food sector's historic focus on building mutual support in a relational, rather than a transactional, approach (Parker 2005). The focus is "not only towards the organic standard of the food but to the quality of the relations between the consumer and producer" (ibid., 8). Within this context of long-term mutually supportive relationships, the thought of abandoning producers in their time of need would lead to hesitancy and guilt. And yet, many consumers who purchase organic food do so precisely because of their reluctance to eat "unsafe" food. Such conflicting feelings have created a conundrum for Japanese ethical consumers to navigate.

Various actors have stepped forward to help resolve this situation by acting as intermediaries between consumers and producers to increase feelings of safety in the marketplace beyond mere adherence to government regulations. A notable example of this is Daichi wo Mamoru Kai Co., Ltd., literally "Association to Preserve the Earth," (hereinafter, Daichi). Founded in 1975, Daichi's organic food delivery business is one of the pioneers of the organic food movement in Japan. Daichi's mission is to: 1. Protect and grow Japan's primary sector, 2. Protect people's lives and health, and 3. Create a sustainable society. However, the aftermath of Fukushima has made it difficult to simultaneously achieve missions 1 and 2. Some may even consider it a paradox for Daichi to sell food that feels "unsafe" to consumers, even if it is to protect organic farming in Japan. This

TABLE 1: Limits on Radioactive Cesium in Food (Unit: Becquerel/kg)

Product	Daichi (limits as of Apr 2012)	Japan (limits as of Apr 2012)	Japan (provisional limits)	Republic of Korea	US	EU
Drinking Water	6	10	200	370	1200	1000
Milk	10	50	200 (including dairy products)	370	1200	1000
General Foodstuffs	6–50 (depending on item)	100 (including dairy products)	500	370	1200	1250
Food Items for Babies	6	50	200 (baby formula)	370	1200	400

Adapted from Prime Minister of Japan and His Cabinet (2012), *Post 3/11: Food Safety in Japan*, p. 2, with EU and Daichi values added by the author. Daichi's lowest limit of 6 bq/kg is based on the detection limit of their equipment (Daichi 2012). See Kimura (2013) for a comparison of the limits set by the Japanese government versus alternative food outlets including Daichi.

paper explores how Daichi has navigated the dilemma of its conflicting desires to protect producer livelihoods and to provide feelings of safety for consumers.

By studying this unique case, this paper helps to broaden the understanding of how marketplace actors can help shape perceptions of safety and guide consumer purchase decisions under situations of complex uncertainties and trade-offs where there are no easy answers. This has implications not only for GM foods, but also for food safety and consumption in general.

METHOD

As there is not much research into how ethical consumers are navigating the post-3.11 realities in Japan, a qualitative study was chosen for its ability to help understand complex social phenomena at the exploratory phases. This paper analyzes Daichi's communications on the impact of 3.11 to its consumer members and the general public by examining information made available through their corporate website including notifications, press releases, and blogs. Over 400 pages of data were analyzed, covering a period from March 2011 to December 2015. Supplemental information was also collected from books published by Daichi's founder (Fujita and Komatsu 1992; Fujita 1995, 2005). Such naturally occurring data, which exists independent of researcher intervention, is useful when recounting of the research phenomenon is not likely to be sufficiently detailed, accurate, or complete (Lewis 2003, 57). Inductive thematic analysis was used to identify patterns across the dataset (Braun and Clarke 2006).

FINDINGS

Framing support as larger issue of sustainability. Along with many other groups, Daichi has been working to help revitalize Japanese agriculture, with a particular emphasis on organic methods of cultivation. They have consistently communicated that producers are equal to consumers and are not merely there to serve consumeristic needs. Consumer members are asked to accept misshapen or imperfect produce (that is rejected by supermarkets), dirt and occasional bugs, and substitute products (when weather conditions prevent expected harvests). When there are natural disasters, both producer and consumer members are solicited to help those impacted (through financial donations and purchase of blemished products). Daichi also hosts seminars, farm visits, and other events to bring producer and consumer members together to build face-to-face relationships. They teach consumers that access to safe organic food requires commitment from all parties, and that there needs to be a mutually beneficial

relationship for organic farming to be sustainable in the long-term. This is placed in the context of food self-sufficiency as an issue of national security—an understandable concern for a nation that suffered from food shortages during and after WWII. Thus, it is no surprise that Daichi refused to abandon affected producers in the immediate aftermath of 3.11 and spoke out against harmful rumor damage.

[Daichi will work to] protect food safety by providing appropriate information to consumers and distributing safe food. At the same time, ... prevent additional hardships for producers in disaster-hit areas from harmful rumor damage. (March 23, 2011)

Daichi emphasized that producers in disaster-hit areas were the biggest victims and that they should not be punished for something that was beyond their control—especially when scientific evidence indicated that their food was within safe limits for consumption. In addition, consumers' responsibility to support these farmers was framed as a larger sustainability issue by expressing that abandoning these farmers would endanger food security for future generations.

If [harmful rumor damage] persists, producers may quit farming ... [with] disappearing farmers and fields. This means a loss of food for future children. (April 4, 2011)

Daichi will fulfill our two missions of providing safe food to members and protecting Japan's primary sector (protecting the production base of food so that our children and grandchildren will never go hungry in the future). (April 6, 2011)

This places a portion of responsibility for the future of food security on consumers' willingness to support affected producers. This is likely a solid argument to use on organic food consumers, who tend to be aware of such sustainability issues. However, there was a backlash from consumers to the use of the term "harmful rumor damage," as there are indeed real concerns about food safety in the post-3.11 world. This is especially true for those with children, since they are considerably more sensitive to radiation than adults.

We fully understand not wanting to let children eat [potentially contaminated food]... [Our intended meaning was] "damage occurring to producers when denied distribution and sales due to unsupported rumors," and was not targeted at consumer behavior of "wanting to refrain [from buying] things that have any measure of contamination"... we regret that our expression may have caused distress. (April 27, 2011)

Although Daichi continued to advocate support for producers from affected areas, they became more sensitive to consumer perceptions of safety. After this, the term "harmful rumor damage" was largely replaced with "reluctance to buy" to indicate consumer avoidance of products from affected areas. This is a more neutral term that does not tie avoidance directly to farmers' suffering; nor does it judge consumers for acting based on their own feelings of safety.

Enabling informed choices through transparency

Daichi worked to reassure consumers that continuing support for producers would not mean extra health risks for them by stating that foods from evacuated areas and those above government limits were not being distributed, even while openly admitting that this may not seem like enough for some consumers.

> *It's an agonizing choice, but we are forced to start by taking responsibility to at least not distribute food above the government's provisional limits. Currently, we cannot develop our own distribution standards, but it does not mean that we think this is acceptable in the long-term … we must establish an independent measuring system … in order to provide food you feel safe eating. (April 27, 2011)*

While acknowledging consumers' lack of trust toward government limits, Daichi stated that they did not want to prematurely launch their own limits without confirming it was reliable (accurate measurement system), doable (achievable for producers), and usable (timely disclosure). To this end, Daichi became one of the first private companies to purchase a germanium semiconductor detector in September 2011, then trained their employees in its correct use, and have continued to publish results online.

Daichi also tried to shape larger public discourse by establishing the "Roundtable for Discussion on Food and Radiation" with other major players in the natural food delivery industry (see Kimura 2013 for details). In February 2012, this roundtable jointly issued a public comment strongly criticizing the government's lack of transparency, its delay in releasing updated limits, and its methodology for setting these limits. Also, each group set forth their own testing procedures and limits in response to consumer distrust of government practices and its assurances of safety.

Notwithstanding their commitment to producers, Daichi's limits were set much lower than the government's when announced in February 2012 (see table 1). Daichi also actively cooperated with their producer members to monitor and decontaminate fields in affected regions ahead of government initiatives. Daichi lent radiation-measuring instruments to enable local producers to monitor levels of contamination, test the effectiveness of various decontamination efforts, and release gathered data.

> *Daichi is pursuing decontamination initiatives in cooperation with producing regions … to restore consumers' feelings of safety … there is no time to wait for government action … Daichi has the unique ability to do this because of our strong network with producers that emphasizes "face-to-face relationships" and our traceability system that accurately tracks the cultivation history of each field. […] If Japanese consumers do not feel safe choosing domestic food, Japan's primary sector will decline. (August 26, 2011)*

Daichi also helped to publicize the results of such initiatives. For example, they reported on a Fukushima rice farmer group's decontamination efforts, including the use of radiation-absorbing or-

ganic materials and potassium silicate in their fields. In 2011, this group tested 341 unpolished rice specimens with only four specimens above the 10 bq/kg detection limit. These were all under 12.1 bq/kg (see table 1), and no contamination was detected after polishing. By reporting on such producer efforts, Daichi showed that these were the same trustworthy farmers who had always worked to provide safe food. By transparently reporting cultivation methods and results obtained, consumers were given the ability to make informed decisions. It also enabled producers across Japan to learn what practices were effective against radiation contamination.

> *Daichi will share [this] empirical data and widely disseminate information to other producers in order to pursue ways of production that protect consumers from radioactive contamination. (August 26, 2011)*

Providing ways to support and avoid. Due to the immediate need to prevent the collapse of producer member's livelihoods, Daichi first put priority on their needs. Within a month of the disaster, Daichi had put together multiple ways for consumers and producers from other regions to support them: sending messages of support; giving cash donations; buying surplus products (with shorter expiry dates due to disrupted distribution) and other products with a portion of sales going toward donations; and buying the "Let's Do It Fukushima and North Kanto Producers Set" (weekly delivered vegetables set). Daichi spoke about the suffering of farmers in affected regions and asked consumers to support reconstruction in whatever ways they could.

> *Those who can do so, please support by eating produce from Fukushima and [nearby regions]. If this is difficult, please cooperate with the [donations collected by Daichi] or buy … products from other affected areas to support producing regions. There isn't only one way … let's all work together… to support Japan's primary sector." (April 4, 2011)*

Yet, Daichi also recognized that scientific appeals of safety cannot fully reassure consumers, and that many wished to protect their loved ones by entirely avoiding anything that felt unsafe. Since May 2011, Daichi has featured items with no radioactive material detected (focusing on foods frequently consumed by children) in a separate section of their weekly catalog for ease of ordering. Three months after the above-mentioned set to support producers, Daichi also launched a set for consumers to conveniently avoid produce from affected areas.

> *[Daichi] will launch the "Safe Vegetable Set for Children," a set of vegetables from Western Japan and Hokkaido … in order to meet the demands of families with small children worried about effects of radiation." (July 8, 2011)*

Though priority was given to producers, Daichi did respond to consumer desires in a relatively timely manner. Yet, Daichi has struggled to maintain a balance between supporting producers and responding to consumer demands to avoid produce from affected regions. Daichi has been open about the difficulty of simultaneously fulfilling these needs.

> *Since immediately after the nuclear accident, Daichi has worked to support producers … However, in real terms of vegetable shipments, we were unable to obtain sufficient results. We struggled with the frustration of wanting to support, but being unable to do so. On the other hand, we are painfully aware*

of consumers' desperate need to "protect my child from radiation," especially for mothers with small children. This has been a year in which Daichi has struggled with these [conflicting] issues. (February 29, 2012)

Despite Daichi's struggles to meet their somewhat paradoxical goals, many consumers have embraced Daichi's strict limits, transparency, and provision of choices that go beyond what is provided in the general marketplace. The number of Daichi's consumer members increased from 115,994 in 2010 to 241,000 in 2015, reflecting consumer desire for feelings of safety that go beyond governmental regulations based on expert claims.

DISCUSSION

This paper analyzed how an organic food delivery company grappled with its conflicting desires to protect producer livelihoods and to provide feelings of safety for consumers after 3.11. At first, Daichi seemed to be operating on an understanding that they could help reinforce the ideals of mutual support embedded in the Japanese organic farming sector by emphasizing consumer's ethical obligations to help support producers to protect the future of organic farming in Japan. In their communication to consumers, Daichi emphasized that most food from affected areas was "safe" based on government limits, and focused on farmers' suffering and the potential long-term damage to Japanese agriculture. However, this overlooked the emotional aspect of risk perception, wherein scientific information or expert claims do not necessarily lead to trust (Engdahl and Lidskog 2014). Since consumers did not feel that food from affected regions was safe, they pushed back against the use of the term "harmful rumor damage" and its implication that consumers were obliged to support producers or be perpetrators of damage. Similar to GM foods, it was found that consumers who have reservations regarding safety are unlikely to be swayed by expert (especially government) claims of safety or an appeal to larger social benefits (Costa-Font et al. 2008).

Daichi responded by switching the focus of their communications to how they were working to be a trustworthy partner for consumers to navigate the complex realities of the post-3.11 world. To this end, they joined forces with other major industry players and established a roundtable to publicly critique the government and announce their voluntary adherence to more stringent testing procedures and stricter limits. As Kimura (2013) states, "this kind of networking with other similar-minded organizations, as well as engagement with media and the government, is necessary for standard-setting groups to function meaningfully…" (p. 25).

Also, Daichi acted to build trust in their handling of radiation contamination by backing these limits up with accurate measurement systems, timely disclosure, and openly discussing their difficulties and struggles. Such transparency in the food supply chain is an effective means of building trust toward food safety (Beulens et al. 2005). Furthermore, Daichi reported on producer-led decontamination initiatives in order to rebuild trust for producers. This acted to renew the traditional ideals of the Japanese organic food movement that "include the social dimension alongside environmental and health objectives and promoted enhanced relations between consumers and producers as a way of building necessary trust and accountability" (Parker 2005, 16) where "to trust the producer was to trust the food" (ibid., 8).

Daichi's strong desire to help affected producers led them to create multiple ways for consumers to support producers. Yet, they also provided ways for consumers to entirely avoid food from affected areas. Though seemingly in conflict, this allowed Daichi to pursue their goals of protecting Japan's primary sector and protecting people's lives and health, which had become somewhat paradoxical in the aftermath of Fukushima. Through these various means, Daichi has worked to restore the severely damaged trust in food safety in order to rebuild a foundation for mutually supportive relationships between organic food consumers and producers. Daichi's work to restore consumer feelings of safety in choosing domestic produce shows a way forward for Japan's agricultural industry to overcome the lasting damage of 3.11.

Due to its exploratory nature, this study is limited. It only considered how one organic food delivery company responded to producer and consumer needs after 3.11. Future studies can analyze other actors in the organic food marketplace, including other intermediaries, producers, and consumers. For example, interviews can be conducted with Japanese organic food consumers and producers to see how 3.11 impacted their understanding of risk, trust, and mutual support. Such studies can also test whether the findings of this paper can be generalized.

"I Know what I Like": Parallel Tastes in Fine Art Consumption

Tajana Stankovic, University of Strathclyde, UK
Andrea Tonner, University of Strathclyde, UK
Alan Wilson, University of Strathclyde, UK

ABSTRACT

This paper explores taste through practices in online and offline fine art consumption. Through online communities art expertise has become democratised beyond established institutions but online art communities represent distinct and parallel practices tastes and cultural capital. Online expertise does not grant cultural capital offline nor impact established taste regimes.

INTRODUCTION

In pursuits such as fashion, wine, and art it has been argued that the fashionista, oenophile, and aficionado are those who fully appreciate their respective experiences (Clarkson et al, 2013). Such experiences have historically been regarded as high threshold activities with expertise available to few, guarded by gatekeepers and difficult for the lay individual to achieve (Joy and Sherry, 2003a). However the ever-growing spectrum of online mediated platforms where enthusiasts in many fields share their passions, is changing established institutional structures and forging a new understanding of consumption meanings and hierarchies of access. This paper explores how taste is developed and negotiated in online mediated consumption groups in the context of fine art. Drawing upon a qualitative case study within the UK art market, it discusses the practices that lie at the heart of taste in this context and how online consumption differs from traditional offline practices. It argues that, in art, expertise is no longer the preserve of the critic or art seller with vested interests in desirable taste, rather it becomes democratised as novices engaging in online art communities come to represent a distinct form of distributed cultural authority. Thus, it contributes to recent calls for a more complete understanding of the democratizing role of the Internet in shaping the practice of taste and taste-making (Arsel and Bean, 2013; Dolbec and Fischer, 2015) as well as the deinstitutionalisation of taste (McQuarrie et al.,2015) in online-mediated communities.

Art as field for Cultural Capital Display

The high arts have been commonly seen as symbols of cultural capital. High levels of difficulty are associated with an adequate enjoyment and appreciation of these goods and significant knowledge of their aesthetic codes and canons considered necessary to consume them (Üstüner and Holt, 2010). Power to define these generally acceptable standards of taste lies in the hand of few individuals who have acquired a certain amount of knowledge either through education or social experience (Hoyer and Stokburger-Sauer, 2012; Drummond, 2006).

Art as a field of consumption has therefore been conceived among the paramount grounds that see actors claiming a position within the social hierarchy by pursuing status idiosyncratic to the field (Bourdieu, 1984). Following Bourdieu, taste is an essential component of cultural capital and thus good taste is "prescribed by professional experts in a particular cultural field" (Holbrook, 2005; 75). Judgements of taste are thus found to be inherently powerful signs in defining identity as well as compelling markers of group affiliation (Bourdieu, 1984). The arts are thus characterized by a distinctive cultural capital specific to the field where taste has been commonly conceptualized as an instrument that navigates individuals in evaluating, categorizing and drawing connections between objects and consumption (Hoyer and Stokburger-Sauer, 2012; Coskuner-Balli and Thompson, 2013).

In comparison to this structuralist perspective where taste serves as cultural boundary maker, postmodernism considers the consumer as cultural omnivore, an actor with intrinsic agency (Firat and Venkatesh, 1995). Arguing for a fading of hierarchies in advanced societies, objects become freed from tightly defined consumer practices and a spectrum of styles emerges from a newly conferred semiotic malleability (Baudrillard, 1996). So while cultural capital remains a powerful concept it is demonstrated not through the acquisition of consumption objects but rather through increased focus on the manners of consumption (Holt, 1998). Accordingly, more recent studies have served to form a definition of the forms of field-dependent capital that consumers acquire by participating in distinctive consumption communities (Arsel and Bean,2013; Arsel and Thompson 2011; Schau, Muniz, and Arnould, 2009).

Taste as Idiosyncrasy of Practice

Cultural capital, an important asset for status display, is enacted in consumption through the portrayal of tastes and consumption practices (Allen, 2002; Üstüner and Holt 2007, 2010; Holt, 1988). Studies have explored the manner in which different levels and forms of cultural capital shape tastes, preferences and consumption patterns (eg. Allen 2002; Arsel and Bean 2013; Holt 1998). As such, recent studies point to the conceptualization of taste as practice (Holt, 1998), performance (Hennion, 2007) and regime (Tonkinwise, 2011; Arsel and Bean, 2013). Holt's (1998) interpretation of taste focuses on the meaning consumers attach to their product choices and Hennions (2007) definition is centered around the way in which taste materializes through acts of consumption, yet both agree that taste cannot be reduced to mere product choice. Taste regimes emerge as discursively entrenched systems (Arsel and Bean, 2013) which navigate and instruct aesthetic practices, offering a comprehensive understanding of taste by looking both to the symbolic meanings assigned to consumption objects as well as the performative 'doing' of taste. This shifts the focus from the object of consumption to the underlying practices involved. Practice theory has therefore become a common means of theorizing acts of consumption and developing our understanding of both enthusiast groups and the objects of their desire (Warde, 2014).

With the increase in a 'social media savvy society', not only has the Internet changed the modalities of production, sale and distribution of art, it has also changed the modalities of consumption as "no longer does an individual have to abide by the dictum of a cultural elite – critics and historians" (Joy and Sherry, 2003a; 157). An individual's ability to discern between the beautiful and dexterous versus the laboured and unpleasant has been thus described as taste in a specific field of consumption (McQuarrie et al., 2015). The advent of new forms of community such as those found within social media have brought with them a range of new ways of demonstrating taste and influencing the individual. Their democratising power is challenging the traditional institutional dictums of aesthetic judgement making way for new taste makers and taste making. It is increasingly argued that individuals develop their cultural capital in a specific field by exercising taste through investment in these online communities (Arsel and Bean, 2013). Such communities have been

defined as groups formed around a shared passion or interest which mediate the learning and negotiation process through participation among members of the collective in order to achieve a mutual understanding of common practices (Goulding et al., 2013). Hence, a community of practice is described as a "group of people who share a concern or a passion for something they do and learn how to do it better as they interact regularly" (Wenger 1998; 10). Practice Theory is being used to explore contemporary taste because it addresses the collective commitment of participants in a community, emphasizes the way in which objects are meant to be used, the way they are valued and the shared engagement in defining a collective purpose of existence (Warde, 2014).

Nevertheless, despite the online-mediated opportunity to exercise the doing of taste (Arsel and Bean, 2013) detached from institutional structures and axioms in the field of art, Di Maggio's (1987:445) argument that "populations of artworks can be partitioned into groups, or genres, on the basis of the persons who choose them" continues to be relevant through this definition of objectified taste. Indeed Aresel and Bean (2013:899) argue that in these democratized spaces emerges "a discursively constructed normative system that orchestrates practice in an aesthetically oriented culture of consumption" developing what they defined as a taste regime.

METHOD

The data comes from a qualitative case-study of the UK art market (Yin, 2014).

We approach art experiences through the lens of constructed subjective meanings encompassing consumption and embodiment processes of aesthetic appreciation (Joy and Sherry, 2003b). Therefore we sought to gather data encompassing "ideas, emotions and understanding of all who take part in an activity in such a way that a common or shared outlook emerges" (Biesta, 2010; 716), we did this through a series of semi-structured interviews with a range of stakeholder groups in the art world, with the aim of articulating the viewpoint of the actors' experience regarding a socially constructed reality and the situational dependency of the studied phenomena (Maxwell 1996; Denzin and Lincoln 2008). We spoke with 12 art consumers participating in online art communities. We also gathered the perspectives of intermediaries with traditional institutional roles. This set of respondents was constituted by 12 galleries, 2 intermediary companies, 5 artists and a large art-fair director. These informants helped in corroborating, challenging and providing alternative perspectives on the accounts of the key informants and thus aided in achieving a triangulation of viewpoints to sustain a deeper understanding of the phenomena (Schouten, 1991). In total, 25 hours of interviews were transcribed.

Data was analysed adopting the content analysis method, which consists of the identification of themes that have emerged from the collected data (Spiggle 1994). After we determined recurrent themes, new emergent themes have been identified with the aim of broadening and developing the understanding of taste as negotiated within online appreciation communities (McCracken, 1988; Moisander and Valtonen, 2006).

FINDINGS

Findings begin by examining traditional access barriers grounded in cultural capital levels, and proceed to discuss the forms of emergent practices and taste structures in the newly formed online art spaces drawing comparisons with conventional offline tastes.

Cultural Capital as Requisite for Access

Our data shows that consumers find the art market an unfamiliar consumption territory but one which they have often longed to be part of. As C5 discusses:

I have a problem, being a nurse you have to be aware of everything you put on social media. I was once put aside by my manager and asked what I was doing and I think that the girls in my office don't understand why I'm so into art. So I say to them, why you go to the gym? It is the same thing but I don't think they understand (C5)

This reflects the discussions in the literature that art has been often epitomised as consumption heavily marked by cultural capital class based distinction. It is assumed that a formal education (Drummond, 2006) and thus a high level of embodied cultural capital (Holt, 1988) is necessary in order to be granted access to the traditional art practice system. This creates conflict in consumers' who find themselves at odds with these expectations as C3 discusses:

Buying art is always experienced with joy but also a bit of guilt. I do come from a low background family, I am not really educated in a traditional way or manner (C3).

Perpetuating this distinction, gallery owners, also usually collectors and consumers with traditional education in the field of art, commonly classify themselves as part of an exclusive community and recognise that this creates a cultural threshold which is difficult to traverse.

'People are frightened to go into galleries…there is this aura of intimidation' (G1); 'the art world created this mystic world around them so people are afraid to step into it' (G3) and 'they see it with suspicion and doubt' (G4).

The perception that art is an exclusive domain meant for privileged individuals who are accustomed to this type of leisure activity due to their habitus is reflected in the experiences of consumers when they engage with the traditional structures of the market as C3 discusses:

Galleries make me feel uncomfortable. I once walked into a gallery, and I could immediately see the evaluation of me, almost bombastic language came out from the lady, floury language…I felt myself playing into the role and I came out feeling really dirty. It wasn't a nice experience for me at all. (C3)

For many consumers their experiences in the traditional art domains make them reject such places as relevant art access point and seek out alternatives less bound by the taste dictates of the market.

Knowledge as Quintessence of Good Taste

Art is considered a knowledge product with the assumption that "the purchase of art is based on the knowledge of experts" (Joy and Sherry, 2003a; 176). The importance of knowledge about the product category has emerged as a focal point of discussion among traditional galleries, experienced buyers and online consumers. Stakeholders of the art world firmly state the difference between 'good taste' and 'bad taste' using the pool of knowledge or field specific capital. Gallery Owner 6 discusses:

The more experienced is the art buyer he has a better idea about what is good quality, whereas a less experienced person is just

interested in an image for the house and they will go for the safer option…I would say they look for different things. (G6)

Given that the interpretation of good taste is considered an outcome of education and knowledge, the gallery institutions consider that they serve an informational role (McQuarrie et al., 2015). They provide customers with mentoring and advice in order to help them progress from novices to connoisseurs:

> *We are trying to teach them…we are trying to make them recognize the differences and appreciate the quality of a piece of art. They need to understand what is behind it.(G7)*

As such, dealers and galleries feel both ability and obligation to shape and develop taste (Joy and Sherry, 2003a) in the traditional sense. The transfer of knowledge is thus tied into a series of practices which result in a bonding link between institution and customer: *we sort of build relationships with our clients quite strongly because we go and install the work, we advise them…they are loyal to us* (G8)

Conversely, knowledge in online-mediated communities is separated from institutionalized actors in the field. Arsel and Bean (2013) thus argue that consumers develop field-specific capital through participation in these consumption spaces. However, from the accounts of novice consumers it emerges that knowledge is not a dominant component of their experience. They emphasize the affective over the symbolic and do not try to emulate the scholarly practices of the cultural elite.

> *All I know is what I like and why I like it... It is not an academic exercise…Galleries frame what is considered good art (C1).* I am not a dry academic though, I learn what I am interested in. (C3)

Novice consumption preferences and product choices are guided by autotelic pleasure (Holt, 1998; Thompson, 2013) rather than symbolic meaning (Belk, 1988). Online art community participants do not exhibit strategies aimed to resist the hegemonic forces of established market institutions rather they engage in conversations about art based upon their strong enthusiasm and fascination with the field (Dolbec and Fisher, 2015). Accordingly, they show differences in understanding and interpretation of the meaning assigned to objects of art. They define taste purely based on hedonic criteria shaped by community consensus. Shared taste overrules scholarly discussions of artistic worth.

Extending the findings of Arsel and Bean (2013) and Dolbec and Fisher (2015) our findings suggest that a new parallel taste regime is being established in online art appreciation.

> *Quality in art difficult to judge? It's nonsense and I will tell you why...this is when snobbery comes in and elitism. Somebody is relying on somebody else telling them the worth of something. To be true to yourself, you should be able to judge that worth yourself...(C1)*

A regime of aesthetic standards liberated from market institutions, where value is understood through individual judgement rather than set guidelines of taste practice, offers every participant the opportunity to express judgement on what is taste and negotiate acceptance of this within this community.

> *You don't have to be knowledgeable about art. Either you like it or you don't like it. The technique of what they do and how they do it, I don't have knowledge about that. It looks simple but people tell me it is not simple. (C6)*

Scaraboto and Fischer (2013) suggest that parallel taste structures emerge as novice consumers amend institutional practices. Contrary to Arsel and Bean's (2013) account, art taste regimes do not converge through discursive systems, participant interaction and experience exchange because the online art sphere is deprived of the traditional market taste-makers and the knowledge pool is not enriched by these voices. Rather the participants believe that market actors such as gallery owners are undermining the art world due to their disregard of novice tastes: B*ecause I think it is elitist and they are just serving a specific clientele.(C7)*

A parallel can be drawn also with Schouten and McAlexander's (1995) community of riders who depreciate both richer subgroup and lower milieu consumers. Our online communities label the traditional circle of art buyers pretentious snobs.

Online Space as Negotiator of Taste

Our data suggests that consumers who develop their passion for art using online platforms, do not encounter the traditional codes of consumption (Üstüner and Holt, 2010). Along these lines, the modality of product evaluation and criteria for judgement differ between the group of novice internet consumers and the more experienced buyers. Novice taste becomes tightly linked to personal identity and social affiliation (Richins, 1994; Rindfleisch et al., 2009). Accordingly, participation in one online collective implies the rejection of views and practices associated with the traditional offline art world (Wenger, 1998). As C1 explains:

> *I find it all a bit pretentious...the art can have a great story behind but the reality is how it leaves you feeling. I don't even understand what these people are saying..."I don't like this piece of art, I've been told a short story about it and now I love it...". So would not that person be better reading a book if they like stories. For me it has to leave a feeling and a story is not going to change that. (C1)*

Novice buyers highlight the importance that aesthetic criteria bear over the interpreted meaning and discourse underpinning the product thus emphasising the role of beauty over technique. The engagement of consumers in online art spheres enables them to be assimilated in novice art consumption practices however the cultural capital acquired through these interactions stays specific to the field of online mediated art consumption without a clear evolution of the underpinning practices.

> *There is so much online people can find that at the end they build a market for it that feeds itself. But I don't know if this market ever becomes educated…I think that all the social media does that… There is so much art out there online and a lot of people do not understand quality even though they are very confident about their knowledge (C4).*

Vargo and Lusch (2011) suggest that value is defined and dependent upon both symbols and practices which can be considered as institutions that guide the process of evaluation. Traditional cultural class consumers, by engaging with institutions like galleries and attending events such as vernissages and exhibition openings, have the opportunity to interact with other participants in the field thus securing a sharing of understandings and experiences which will enable them to interiorize such practices (Saatcioglu and Ozanne, 2013). Complex discussions involved with the meanings of the objects being appreciated and the cultural pedigree of the artist (Üstüner and Holt, 2010) become dominant: *I think the narrative of a painting,*

the journey of a painting is very important…it is not just a picture on the wall (Art Fair).

Interaction is a necessary component for successful constitution of a shared identity (Goulding et al., 2013). Shared understanding is achieved through the sharing of experiences, contexts, institutions and language (Akaka, 2014) highlighting the specificity of doing taste (Arsel and Bean, 2013) in the online and offline art worlds. The what (object), the how (doings) are mutually acknowledged with collectively defined understanding, however the why (meaning) (Akaka, 2014) sets the point of departure between expert and novice Internet consumers' art consumption.

CONCLUSIONS

This paper extends understanding of the ways in which taste emerges from practice. It bridges the divide between taste as embodied and taste which is dependent upon individuals' agency (Arsel and Bean, 2013) distinguishing between institutionally governed practices and those founded on the principles of free access and rights of expression championed by the internet (McQuarrie et al., 2015). Online, taste emerges from idiosyncratic practices, consumer preferences and understandings that are characterised by a distinctive normative system applicable only to the online consumption context. The online system has evolved as a consumption alternative to the power laden, cultural capital rich offline art market which retains high access barriers (Holt, 1998). Online art consumption emerges as a hedonic rather than knowledge driven domain (Hoyer and Stokburger-Sauer, 2012) with distinctive practices, taste structures (Sandicki and Ger, 2010) and cultural capital (Scaraboto and Fischer, 2013). So while platforms of online participation may have widened art's accessibility, rather than evening out tastes and practices, they result in the formation of parallel taste structures (Sandicki and Ger, 2010). This may be attributable to the flexibility and ephemeral nature of relationships among participants within the online art world, which resemble publics rather than communities. Arvidsson and Calliandro (2015; 399) suggest that "public sharing of perspectives and experiences that derive from a plurality of identities and practices, […] are not elaborated into explicitly recognized common values that can provide a source of identification" explaining the multiplicity of online practices evident in this study. This represents a suitable avenue for future research about the making of taste in a broader range of online spaces.

Consuming "To Have No Self": Kawaii Consumption in Japanese Women's Identity Work

Satoko Suzuki, Kyoto University, Japan
Saori Kanno, Komazawa University, Japan
Kosuke Mizukoshi, Tokyo Metropolitan University, Japan
Yoshinori Fujikawa, Hitotsubashi University, Japan

ABSTRACT

This paper explores consumption and identity using data collected in Japan. We find that consumptions are sometimes used to "eliminate" a sense of self contrary to past researches proposing "extended self." In the society where self-expression has less significance possessions don't necessarily define individuals or aid in maintaining their identity.

INTRODUCTION

Bagozzi (2013) claims that "consumption begins and ends with the self" (255). This statement represents a premise that underlines much of the existing research on consumption and identity, particularly those conducted in the U.S. In this perspective, consumers are viewed as those attempting to achieve their identities and to self-actualize through consumption. However, in some cultures, a state of having "no self" is accepted (Doi 1971). In such cultures, consumption may be used not to self-actualize but rather to achieve a state of having no self. Using the data gathered from Japanese female consumers on *kawaii* (cute) consumptions, we explore how consumption plays a role in identity formation in a culture where self-actualization is less significant.

Although cultural differences in the conceptions of self have been much researched in anthropology and psychology (e.g., Benedict 1946; Heine et al. 1999; Spencer-Rodgers et al. 2009; Markus and Kitayama 1991; Rosenberger 1992), very little research has been done to examine cultural differences in consumers' identity project (exceptions are Kimura and Sakashita 2013; Suzuki and Akutsu 2012). Given the growing interest in redefining existing consumer theories that are primarily based on data gathered in the U.S. (e.g., Arnould 1989; Joy 2001), this study on consumption and identity in a non-Western culture is appropriate.

This article is organized as follows. In the first section, we briefly review the existing literature on consumption and identity; we then discuss the Japanese concept of self. This enables us to understand cultural differences in the pursuit of self-actualization and to explore the ways in which consumption is related to the Japanese consumers' identity formation. In the second section, we describe the methodology used in this study. In the third section, we analyze the data and argue that in Japanese culture, consumptions are sometimes used to create "having no self" (*jibun ga nai*) situations. In the fourth section, we provide suggestions for future research.

CONCEPTUAL FRAMEWORK

Consumption and Identity[1]

Past research on consumption and identity has focused on how people use consumption to define themselves and maintain their sense of identity (e.g., Belk 1988; McCracken 1986; see Arnould and Thompson 2005 for a review). For example, Belk (1988) examines how consumers use possessions to extend, expand, and strengthen their sense of self. He concludes that "we are what we have and that this may be the most basic and powerful fact of consumer behavior" (160).

Belk's concept on self and possessions, the "extended self," has been very influential and has generated many discussions. Soon after its publication, Cohen (1989) criticizes that the concept is imprecise and not fully articulated. For example, Cohen asks whether the extended self is differentiated from the inner "core self." Belk (1989) replies that "it is not possible or desirable to draw an absolute distinction between things that comprise the inner self and things that comprise the extended self" (129). He continues that "rather than seeking absolute conceptualizations of extended versus core self, a more satisfactory perspective is to regard extendedness as relative" (130). He explains that we could measure the degree to which possessions are perceived to be a part of an individual's self. Although Cohen and Belk disagree on the necessity of preciseness toward the extended self concept, they agree that people have a self.

Here, consumption is seen as helping define people's sense of who they are. In short, consumer identity researchers presume that people are active identity seekers and that they use consumption to express their self. Although recent works acknowledge that developing and maintaining a consistent sense of self is difficult today (Ahuvia 2005; Bahl and Milne 2010), consumers continue to be regarded as striving to actualize their selves. Ahuvia (2005), for example, shows how consumers use loved objects and activities to construct a coherent identity narrative in the face of social forces pushing toward identity fragmentation.

In contrast, this research argues that not all consumers are active identity seekers and that consumption is not always used to achieve self-actualization. In some cultures, people choose to have no self in some occasions. In such cases, consumption can be used to "eliminate" the sense of self. This role of consumption has thus far been overlooked by consumer identity researchers. In the next section, to illuminate cultural differences in the sense of self between East and West, the Japanese conceptions of self will be discussed.

"To Have a Self" versus "To Have No Self"

The expression "to have no self" (*jibun ga nai*) can be found in the Japanese language. Doi (1971) argues that this expression is peculiar to the Japanese, with no equivalent expression in the languages of the West. Furthermore, there is a difference in the use of the first person pronoun between the West and Japan. "In the West, there is a linguistic emphasis on the use of the first person, and the child is awakened to an awareness of the self from a very early age, so that expressions equivalent to *jibun ga nai* have never come into everyday use – the use of expressions similar to it, being confined to clearly abnormal cases, such as schizophrenia" (134). In contrary, in Japan, the first person pronoun is often omitted. In the West, "to have a self" is a norm; however, it is not so in Japan.

According to Doi (1971), "to have no self" symbolizes the type of relationship that one has with others. An individual "has no self" when submersed in a group. For example, when one has no self, he or she agrees with the group even when his or her interests or values do not coincide with those of the group. In other words, "to have no self" is a state in which an individual does not maintain a self in a group. In *zen* philosophy, "no-self" (*muga*) is defined as a loss of oneself in the totality (Johnston 1970; Mathers, Millers and Ando 2009) and is accepted as a positive state.

---

1   In this paper, following Belk (1988), the terms "self," "sense of self," and "identity" are used as synonyms for how a person subjectively perceives who he or she is.

The idea of integrating group into a sense of self is not new in consumer identity research. Relying on social-identity theory (Tajfel 1978), consumer researchers have assessed how consumptions related to social categories, roles, or groups to which an individual belongs allows individuals to unify their everyday actions and make up a global sense of self (e.g., Kleine, Kleine and Kernan 1993). However, past research has assumed that social identities contribute to the achievement of an individual's sense of self. For example, Belk (1988) acknowledges that individuals have multiple levels of self such as individual, family, community, and group; however, all of these levels are considered to be a part of the individual's self. This study, in contrast, considers cases where the individual's self is non-existent as a result of submersing in the group.

Kawaii Consumption in Japan

Kawaii consumption was selected as the specified domain of experience for this study. *Kawaii* has been a major driver of consumer culture in Japan since 1970s, particularly among young women (Kinsella 1995; Granot, Alejandro, and Russell 2014). *Kawaii* has become a cultural phenomenon that can be seen almost everywhere from fashion to daily necessaries (e.g., cartoon toiletries). Japanese companies, and even banks and government have been using animated characters in their marketing communications to attract consumers.

Whereas the term is literally translated as "cute," Kinsella (1995) explains that "*kawaii* essentially means childlike; it celebrates sweet, adorable, innocent, pure, simple, genuine, gentle, vulnerable, weak, and inexperienced social behavior and physical appearances" (220). She continues that *kawaii* style is associated with acting childish in an effort to partake in some of childhood's simplicity, happiness, and emotional warmth. *Kawaii* appears to be transitory, imperfect, or immature; however, it includes emotional intimacy that eliminates psychological distance by creating an illusion of closeness. The esthetic to praise "childlike" or "imperfect" things has always been accepted positively by Japanese culture, as indicated by a description related to *kawaii* in the *Pillow Book* (*Makura no Sōshi*) which was written by *Sei Shōnagon*, a lady-in-waiting in the 11th century.

Examining the socio-cultural meaning of the concept of cute, Granot et al. (2014) explains that *kawaii* is "embedded in the culture and manifests itself in social and gender roles, particularly those of young Japanese women" (73). It is important to point out that affection for cute things for women means more than reflecting their preference; it is a reflection of a deep longing for the time when they were girlish and young (Granot, Greene and Brashear 2010), or in other words, when they were free and peaceful with no fetters or distress. Hence, we assumed that the *kawaii* consumption would be a good context to study consumption and identity project, particularly among Japanese women.

METHOD

This study employed a hermeneutic approach, a commonly used approach in consumer identity research (e.g., Arnold and Fischer 1994; Thompson 1997; Thompson, Pollio, and Locander 1994). In-depth interviews with 24 Japanese female informants were conducted. Our sample was composed of various age groups and included high-school students, undergraduate students, working single females, and married females having children (see table 1). The informants were recruited using a research agency. They were given 10,000 yen (about $100) for their participation. The interviews lasted three hours and were audiotaped. The data collection process took place between June 15 and 18, 2006. All the interviews were conducted in the local language (Japanese).

To obtain a first-person description of consumers' experience, the interview aimed to have a conversation with the informants.

Respondents were assured of anonymity (names used here are all pseudonyms). The questions and probes were aimed at obtaining descriptions of experiences and were not intended to confirm theoretical hypotheses. Such attempts were important to capture the true feelings of informants because Japanese people have a tendency not to reveal their true inner feelings (Doi 1971).

We analyzed the text composed from the interviews, moving from a discussion of the part to the whole (Joy 2001; Thompson, Locander, and Pollio 1989). We discussed each theme extensively before reaching a consensus, attempting to be open to the possibilities afforded by the text (Thompson and Tambyah 1999).

FINDINGS

Through the findings section, this article shows that Japanese female consumers sometimes use *kawaii* consumptions to create "having no self" situations. The first section briefly provides the background by introducing the versatility of *kawaii* concept and explains how this contributes to creating a sense of "having no self," particularly by hiding the core self through sympathizing with others' *kawaii*. The article proceeds by detailing two themes related with *kawaii* consumptions and "having no self" situations: eliminating the self to gain acceptance in society and the dependency embedded in *kawaii*.

Versatility of the Kawaii Concept

Many of our participants use the expression *kawaii* because the word does not have any special meaning to them. For example, Mai, a 17-year-old high-school student, describes *kawaii* as an easy to use word to compliment others. When Mai uses the word *kawaii*, she does not need to provide a meaning herself. Instead, the recipient of communication will provide the meaning. In fact, Mai comments that she does not necessarily like the things or activities that she describes as *kawaii*. Thus, when she says "that's *kawaii*" to praise others' possessions, it does not mean that she agrees with their preferences. Here, it is important to note that the recipients believe that Mai also likes things or activities that she refers as "that's *kawaii*." In other words, Mai's true feelings, as well as her core self, remain hidden from others.

Similar to Mai, many Japanese females use *kawaii* consumption to sympathize with others' *kawaii*. Consider the reflections of Lisa, a 28-year-old working single female. She comments: "When others feel 'it's *kawaii*,' I feel 'indeed, it's *kawaii*' just so that we can talk about the same story." When asked to talk about *kawaii* objects, Lisa mentioned the lion magnet that she displays at her office. Lisa explains that she received it from her colleague as a gift. Lisa agrees that the magnet is *kawaii*; however, she does not have a special feeling toward it. In other words, she neither likes or dislikes it. If others feel that the lion magnet is *kawaii*, Lisa is happy to display it at her office even though she does not really like it.

Eliminating the Self to be Accepted by Society

Many Japanese females associate *kawaii* with a girl's image. The examples given as *kawaii* consumption in the Table 1 illustrate this. Many of *kawaii* things are colored pink, a color that symbolizes a girl. *Kawaii* things also represent girlishness. In Japan, *kawaii* is a word that often describes the society's ideal girl. Therefore, Aiko, a 32-year-old working mother, comments: "Every girl wants to be *kawaii*." Japanese females also believe that males expect girls to be *kawaii*. Hana, a 27-year-old working single female says, "Girlish ones benefit more. From the male perspective, girlish ones are more *kawaii*."

Table 1: Informant Profiles

Pseudonym	Age	Example of kawaii consumption	Occupation	Family
Aiko	32	pink-colored goods	Part-time job at building maintenance company	Married, child(ren)
Aki	19	manicures	Undergraduate student	Not married
Anna	20	pink furnitures	Undergraduate student	Not married
Aya	16	*Seventeen* (teen magazine)	High-school student	Not married
Chie	18	Minnie Mouse keyholder	High-school student	Not married
Emi	18	skirt	Undergraduate student	Not married
Erika	18	comic book by Miku Sakamoto	Undergraduate student	Not married
Hana	27	Hello Kitty goods	Real estate company employee	Not married
Iku	27	photo-taking of her daughter	Full-time housewife	Married, child(ren)
Jun	29	Japanese-taste hair ornament	Administrative staff at highway public corporation	Not married
Kana	31	peach	Administrative staff at tableware sales company	Not married
Kei	19	heart-shaped cushion	Undergraduate student	Not married
Kumi	32	kitten illustrated memo pad	Credit card company employee	Not married
Lisa	28	lion-motif magnet	Administrative staff at construction company	Not married
Mai	17	fashion	High-school student	Not married
Meg	28	hairstyle	Full-time housewife	Married, child(ren)
Misa	16	Alice-in-Wonderland motif hair ornament	High-school student	Not married
Nami	15	bear	High-school student	Not married
Rika	26	photo-taking of her children	Full-time housewife	Married, child(ren)
Rio	22	pink, heart-shaped bracelet watch	Undergraduate student	Not married
Sae	17	Anna Sui fragrance	High-school student	Not married
Saya	35	flower-motif hair ornament	Full-time housewife	Married, child(ren)
Yuko	34	photo-taking of her daughter	Part-time job at apparel mail-order company	Married, child(ren)
Yuri	32	accessory	Administrative staff at apparel company	Not married

For Rio, a 22-year-old undergraduate student, *kawaii* is closely associated with her ideal female image. Rio considers *kawaii* as a compliment and says that she becomes happy when others think of her as *kawaii*. Thus, she desires a pink, heart-shaped bracelet watch and a pink bracelet, hoping that others will see her as *kawaii* when she is wearing them.

When Rio adopts *kawaii*, she is submersing herself in the Japanese society and its values. Rio is attracted to *kawaii* simply because the society highly evaluates it. In fact, she does not have her own opinion about *kawaii*. Nor does she pursue her own uniqueness.

I don't like doing something that is very unique. I feel *kawaii* when I am wearing things that others consider as *kawaii*. I feel good when others think of them as *kawaii*. Thus, when others feel *kawaii* toward the things that I feel as *kawaii*, I am assured that I was not wrong.

Dependency Embedded in Kawaii

When asked about *kawaii* consumption, many Japanese mothers mention consumption for their children. For example, Yuko, a 34-year-old mother of a 3-year-old daughter, narrated about her daughter's photo being taken dressed up like a princess. She explains that she feels happy when her daughter is *kawaii*. Yuko felt happy seeing her daughter dressed up.

Yuko emphasizes that she gave birth to her daughter, suggesting that she feels a sense of oneness with her daughter. Her *kawaii* consumption for her daughter suggests that Yuko is consuming things and experiences that she cannot consume herself. Yuko distinguishes adult and children's worlds, and feels that adults cannot consume *kawaii*. She mentions that "When I see [my daughter] dressed up, I feel *kawaii* […]. I feel *kawaii* for those things that I cannot do."

Here, we see that Yuko is dependent on her daughter and has no self. Doi (1971) argues that the sense of "having no self" is closely connected with the concept of *amae* (dependency). An individual who is at the mercy of *amae* has no self or ego. Doi (1971) defines *amae* as "the attempt to deny the fact of separation" (p. 75) and explains that the psychological prototype of *amae* is the emotion felt by the baby towards its mother; *amae* "works to foster a sense of oneness between mother and child" (p. 75). Here, we see *amae* can also be felt by the mother towards her child and that *kawaii* consumption plays a role in reinforcing oneness between the two. Yuko recognizes that *kawaii* belongs to children and not to adults. However, she is consuming *kawaii*-related objects and activities not only for her daughter but also for herself, as she is experiencing *kawaii* consumption through her daughter.

DISCUSSION

Revisiting the Centrality of Identity Issues in Consumption

Post Belk (1988), the assertions that identity issues are central to consumption and that possessions are a part of the self have been supported by consumer identity researchers (e.g., Ahuvia 2005). However, this research illuminates the possible boundary condition to these assertions – in some cultures, consumption may not necessarily reflect the individual's self. During the three-hour-long in-depth interviews with the 24 Japanese informants, the narratives about their *kawaii* consumption to submerse themselves in a group or society appeared many times. In such cases, the informants possessed *kawaii* objects and engaged in *kawaii* behaviors not because they thought of such objects and behaviors as *kawaii* but because others thought of them as *kawaii*. The informants possessed *kawaii* objects not for expressing their selves but rather to be accepted by the group or society. *Kawaii* objects or behaviors serve not as a means of expressing their selves, but as a socialization tool of blending themselves to achieve the "to have no self" (*jibun ga nai*) state in the community. In Japan, consumptions sometimes do not reflect the self or help to express a sense of self.

Cultural Differences in Self, Individual Motivations, and Social Strategies

In Western cultures, expressing one's individuality and uniqueness has an important function in society (Markus and Kitayama 1991). In such cultures, self-expression through extending the self through consumption is a part of individuals' strategies to be successful in the society (Belk 1988; Takemura 2014). However, in East-Asian cultures, individuality and uniqueness are less valued (Markus and Kitayama 1991), and social relationships are generally determined by environmental and social constraints (Yuki and Schug 2012). In such cultures, self-expression has a relatively weak effect in social lives (Takemura and Suzuki in press). Our findings suggest that consumptions to "eliminate" self or create a sense of "having no self" could function as a useful strategy to be accepted in such societies.

Our interviews with the Japanese females showed that *kawaii* consumption is often used as an individual's social strategies. Lisa's possessing a lion magnet that she herself does not necessarily think as *kawaii*; Aiko, Hana and Rio's wearing *kawaii* clothes and accessories to present socially desired girly images; and Yuko's dressing up her three-year-old daughter like a princess fulfill social needs such as sympathizing with others, seeking socially praised ideals, and fostering a sense of oneness with others, respectively. Through *kawaii* consumption, Japanese consumers are striving to "have no self" as a way to be successful in their own culture. Figure 1 explains the cultural differences between East Asia (Japan) and the West in terms of consumption, self, and society.

"Having No Self" and Collective Identity

"Having no self" at a glance seems to be similar to collective identity. However, as mentioned before, we argue that the two concepts are different. In our study, the Japanese females consuming kawaii goods or services did not discuss how family, community, or group play as part of their own selves. Instead, they explained how buying kawaii goods and using them helped them eliminate their selves and submerse into the group. Here, a "no self" is created.

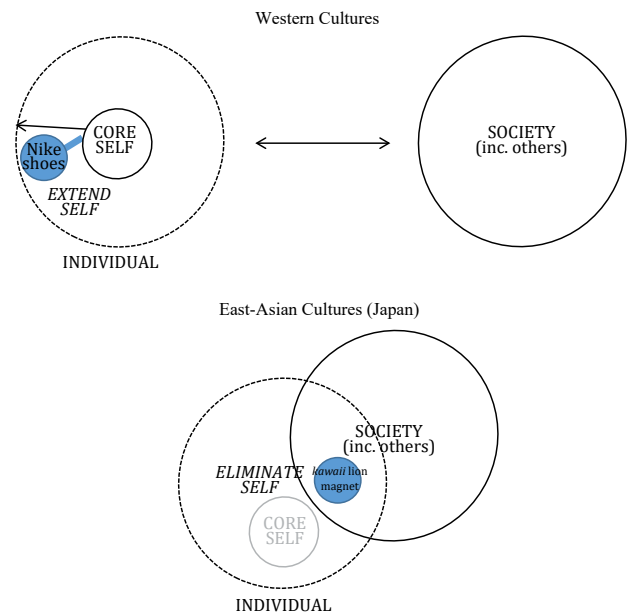
Shau and Gilly (2003) have engaged in a similar yet different discussion in which they introduce the concept of affiliative identity. Using the examples of how consumers use brands and hyperlinks to


Figure 1: Cultural Differences in Consumption, Self, and Society

create cyber self-representations, Shau and Gilly explain the difference between individual and affiliative identities. Individual identity demonstrate "me," whereas affiliative identity establishes "we." However, in affiliative identity, people are not sacrificing the idea of an integrated self. In other words, "me" is a part of "we" and thus, "we" is a collection of many "me"s. In contrast, in "no self" situations, "me" does not exist as part of group identity.

CONCLUSIONS

In general, the objective of the consumer identity project is to actualize a sense of self and answer the "Who am I" question. In this perspective, consumption could be used by individuals to define their identity. However, this research has illuminated cases where consumers are not attempting to actualize their selves. In such cases, individuals may use consumption to submerse in a group and thus to "eliminate" the individual's self.

This research only assessed female participants, which is its major limitation. We need to further explore consumption and explore the "to have no self" state in male participants, most likely in a different consumption context (i.e., not *kawaii* consumption).

This study also raises the question of the generalizability of our research findings to people in other East-Asian cultures, such as China, Korea, and Taiwan. Since Doi's (1971) findings of "having no self" are based on Japanese people, we need to further investigate whether "having no self" state, as well as the role of consumption to create such a state, exists in other East-Asian countries.

Furthermore, since the data for this article were collected in 2006, follow-up data collection in the present context may be necessary to supplement data.

Nonetheless, this article extends the past research on consumption and identity by challenging the universal assertions of the centrality of identity in consumption (e.g., Bagozzi 2013; Belk 1988). It also showed the role of consumption to "eliminate" a sense of self, which has thus far been overlooked by the consumer identity researchers.

When Credibility Truly Matters Online:
Investigating the Role of Source Credibility for the Impact of Customer Reviews

Wolfgang Weitzl, University of Vienna, Austria
Elisabeth Wolfsteiner, University of Vienna, Austria
Sabine Einwiller, University of Vienna, Austria
Udo Wagner, University of Vienna, Austria

ABSTRACT

This research shows differential effects of source credibility in an online customer review (OCR)-context. Drawing on the heuristic systematic model's notion regarding the co-occurrence of systematic and heuristic processing we show that source credibility exerts a persuasive effect when OCRs are positive (non-diagnostic) but not when they are negative (diagnostic).

INTRODUCTION

The internet provides consumers extensive opportunities to share their positive and negative experiences, opinions and sentiments towards products or brands in the form of online comments. Within recent years, online customer reviews (OCRs), i.e., peer-generated product evaluations posted on company or third-party websites (Mudambi and Schuff 2010), have become increasingly popular among consumers who regularly consult OCRs in all stages of the purchasing process (Filieri 2015). The practical importance of OCRs within the marketing communication mix is well recognized among scholars. A rich body of academic studies supports the notion that OCRs can exert a strong influence on consumer decision-making (Filieri and McLeay 2013; Senecal and Nantel 2004; Smith, Menon, and Sivakumar 2005) and product purchases in different categories (e.g., electronics, hotel rooms) (Cui, Lui, and Guo 2012; Zhu and Zhang 2010).

The direction and strength of the persuasive effect of OCRs are dependent on the valence of the message, i.e. whether it is negative or positive, and on the credibility of its source. Research suggests that the credibility of the message source is particularly important online (e.g., Dou et al. 2012) as a predictor of OCRs' persuasiveness (Cheung et al. 2009). Source credibility of OCRs refers to the extent to which the reviewer is perceived as a knowledgeable source for product information and can be trusted to give an objective opinion on the product (Goldsmith, Lafferty, and Newell 2013). It is widely assumed that in the online context, credibility perceptions act as a key moderator of OCR influence, in that highly credible positive (negative) information is more influential than low-credibility positive (negative) information (e.g., Pan and Chiou 2011). In this research we show that this understanding may be too simplistic. Drawing on an extension of the heuristic systematic model (Chaiken 1980) regarding the co-occurrence of systematic and heuristic processing (Chaiken, Liberman, and Eagly 1989; Chaiken and Maheswaran 1994), we shed light on the differential effects of source credibility in an OCR context. Specifically we show for two different types of products (search and experience goods) that source credibility exerts a persuasive effect only when OCRs are positive, but not when they are of negative valence.

BACKGROUND

According to the dual-process models the 'heuristic-systematic model' (HSM, Chaiken 1980) and the 'elaboration likelihood model' (ELM, Petty and Cacioppo 1986), individuals apply two different modes of information processing to form their judgments. When motivation and ability to process a given piece of information are sufficiently high, people engage in systematic processing (HSM) or

follow a central route (ELM) which means that they use considerable mental effort to scrutinize the content of a message. However, when motivation or cognitive capacity are low, individuals adopt heuristics and simple decision rules (e.g., friends or experts can be trusted) to make their judgments. One of the key assertions of the HSM is that when individuals switch from heuristic to systematic information processing because they are motivated and capable of doing so, this does not rule out the possibility that heuristic processing may still be adopted (Bohner, Chaiken, and Hunyadi 1994). Instead, the model posits that the two modes can occur concurrently. Chaiken et al. (1989) argue that the influence of a heuristic cue is, however, often attenuated when individuals process a message systematically because they draw their judgmental confidence from the message content. Yet, when individuals are motivated to process systematically, either they may be unable to do so or the message content does not provide unequivocal information that enables them to come to a conclusion, so that the persuasive impact of heuristic cues is enhanced. In their seminal study on the co-occurrence of heuristic and systematic processing, Chaiken and Maheswaran (1994) show that source credibility has a persuasive effect under systematic processing when the information provided is ambiguous. When the information is clear, on the other hand, source credibility does not exert an effect when individuals are motivated and able to engage in systematic processing.

In the current research context, we argue that the valence of an OCR determines whether it is perceived as clear or ambiguous. Findings on the negativity bias, i.e. that people value negative information more than positive information (e.g. Baumeister et al. 2001; Rozin and Royzman 2001), suggest that negative information is, in general, less ambiguous than positive or neutral information (Herr, Kardes, and Kim 1991). This is because negative information is more diagnostic of the character of an entity (person, product or firm) (Skowronski and Carlston 1987). Positive information, on the other hand, is open to multiple interpretations (Hoch and Deighton 1989), because even the worst product can have at least some positive attributes (Herr et al. 1991). On the internet, the ambiguity of positive OCRs is aggravated by the anonymous environment that facilitates unethical marketing communication in the form of faked reviews (Mayzlin, Dover and Chevalier 2012) or the removal of unfavorable comments by the marketer or platform owner. Doh and Hwang (2009) contend that it is especially in higher-involvement situations that consumers become suspicious about positive eWOM messages. Furthermore, negative compared to positive peer information is sparse in the online context (Bronner and Hoog 2010), which makes negative OCRs also more notable, attention-grabbing and salient (Willemsen et al. 2011) than positive OCRs.

OCRs are usually read by consumers to learn more about a certain product or service which they are considering purchasing. Thus, it can be assumed that the users of OCRs are at least moderately motivated to process the message and form an accurate judgment of the respective product or service. When the OCR is of negative valence, i.e. unambiguous and diagnostic, message content is scrutinized and used for judgment formation. Information about the message source may be noticed. Its effect is, however, attenuated because sufficient

confidence in the judgment can be drawn just from the message content (Chaiken et al. 1989). When the OCR is positive, on the other hand, message content alone is not sufficient to form a judgment because it is rather non-diagnostic and open to multiple interpretations. Thus, consumers will apply the source-credibility heuristic in addition to the content provided in the OCR (see Chaiken and Maheswaran 1994). High levels of perceived source credibility are likely to trigger the simple decision rule "knowledgeable persons' product recommendations can be trusted" that influences an individual's message judgment by influencing his/her thoughts, which ultimately determines message acceptance (Chaiken and Maheswaran 1994).

From the above discussion, we hypothesize an interaction between OCR valence and source credibility on product attitude and purchase intention:

Hypothesis 1:   *a) When OCR valence is negative, consumers' product attitudes and purchase intentions are influenced by message content and not by source credibility. However, b) when OCR valence is positive, consumers' product attitudes and purchase intentions are influenced by message content as well as source credibility.*

When consumers process positive OCRs, they take the information on the credibility of the source into account for their judgment formation. When source credibility is high, the arguments given in the OCRs should be perceived to be of higher quality compared to when credibility is low (e.g., Chu and Kamal 2008). Thus, we expect the effect of source credibility on product attitudes and purchase intentions to be mediated by perceived argument quality. We define OCR argument quality as the individuals' subjective evaluation of the arguments conveyed in the message as strong and cogent on the one hand vs. weak and specious on the other (Petty and Cacioppo 1981). Thus, our second hypothesis reads:

Hypothesis 2:   *The effect of source credibility on product attitudes and purchase intentions in the case of positive OCR valence is mediated by perceived argument quality.*

We expect this effects to be stable across different types of products. Consequently, in order to ensure the external validity of our argument, the hypotheses were tested across two replicative studies which focus either on search goods (study 1) or on experience goods (study 2).

STUDY 1

Study 1 compares the effects of positive (vs. negative) information in OCRs on product attitude and purchase intention in review situations that provide information from high- (vs. low-) credibility sources. Fictitious reviews for a fictitious digital camera were used to manipulate OCR valence and source credibility in an online experiment. eWOM experiments frequently use digital cameras as representatives of products that are of relevance to the target audience and thus allow the construction of a realistic experimental setting. Digital cameras are sound examples of search goods (e.g., Pan and Chiou 2011).

Method

Design, participants, and procedure

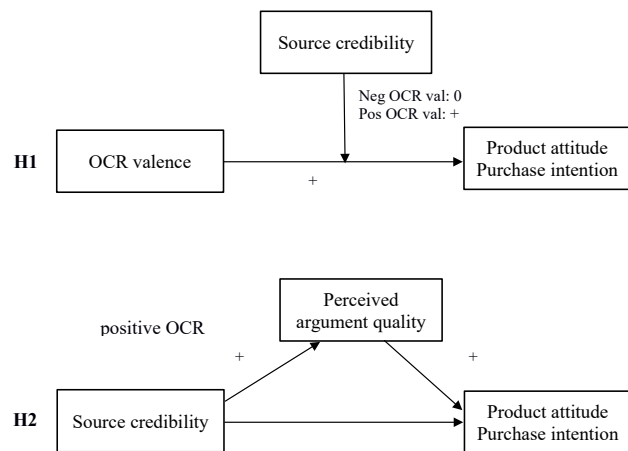
A 2 (OCR valence: positive vs. negative) × 2 (source credibility: high vs. low) between-subjects full factorial design was applied


Figure 1: Summary of Research Framework

to test the proposed hypotheses. The participants were 195 (68 % female, M_{age} = 25 years) students from several German-speaking universities, randomly assigned to one of the experimental conditions. By participating in the experiment, students got the chance to win an Apple iPod Nano.

Participants were told to imagine that they visited a webpage with a product description and several OCRs in the course of their pre-purchase information search for a digital camera. In the high source-credibility condition, participants received the information that knowledgeable and trustworthy peers had provided product reviews. In the low source-credibility condition, the reviews were supposedly written by dubious and anonymous reviewers. Next, participants were exposed to the product description (including a picture of the digital camera) and the reviews. To ensure external validity, the stimulus material looked like a screenshot from a real webpage. The reviews were placed below the product description. In the positive valence condition, five different reviewers commented the product with five different positive reviews (i.e., description of product advantages, recommendation to buy the product). In the negative valence condition, the product received five different negative reviews (i.e., description of product disadvantages, warning against buying the product) from five different reviewers. Afterwards, participants answered questions that measured the variables of interest.

Measures. Seven-point rating scales (1="strongly disagree" to 7="strongly agree") measured the variables. Three items collected information for argument quality (Luo et al. 2013; α = .92), three items assessed product attitude (Kim and Gupta 2012; α = .96) and four items measured purchase intention (Pavlou and Gefen 2004; α = .95).

Results

Preliminary analyses

The manipulation of OCR valence (three items from Park and Lee 2008, 1="negative" to 7="positive", α = .99) was successful. Participants evaluated the positive OCRs significantly more positively than the negative OCRs (M_{pos}^{val} = 6.45 vs. M_{neg}^{val} = 1.23; t(193) = 42.08, p < .01). Our manipulation of source credibility (five items from Weitzl 2014, 1="low credibility" to 7="high credibility", α = .92) also showed the predicted effect. Source credibility was significantly higher in the high- than in the low-credibility scenario (M_{high} = 4.58 vs. M_{low} = 3.47; t(193) = 6.83, p < .01). Furthermore, OCR valence did not influence source credibility (M_{pos}^{cred} = 3.96 vs. M_{neg}^{cred} = 4.13; t(193) = .95, p = .345).

Table 1: Summary of Key Findings

Study 1 Search good		Study 2 Experience good	
N = 195; 68 % female, mean age: 25 years		N = 221; 72 % female, mean age: 23 years	
Cronbach's alpha			
Perceived argument quality	α = .92	Perceived argument quality	α = .88
Product attitude	α = .96	Product attitude	α = .98
Purchase intention	α = .95	Purchase intention	α = .96
Manipulation check			
Valence	α = .99	Valence	α = .98
1.23 vs 6.45	p < .01	1.73 vs 6.17	p < .01
Credibility	α = .92	Credibility	α = .94
3.47 vs 4.58	p < .01	3.93 vs 5.00	p < .01
Product attitude H1a & H1b (Moderation analysis)			
Valence	p < .01	Valence	p < .01
Credibility	p > .05	Credibility	p > .05

** p < .01, * p < .05

A MANOVA with OCR valence and source credibility as independent variables and product attitude and purchase intention as dependent variables yielded a significant main effect of OCR valence (V = .31, F(2, 190) = 42.22, p < .01), a non-significant main effect of source credibility (V = .02, F(2, 190) = 1.85, p = .16) and a significant interaction between OCR valence and source credibility (V = .06, F(2, 190) = 6.14, p < .01). Follow up ANOVAs and planned comparisons then tested the moderation postulated in H1 for product attitude and purchase intention independently. Additionally, a mediation analysis tested H2.

Main analyses product attitude

A two-way ANOVA of product attitude revealed a significant main effect of OCR valence (F(1, 191) = 84.34, p < .01) and a non-significant main effect of source credibility (F(1, 191) = 2.84, p = .093). More importantly, results showed the predicted significant interaction between OCR valence and source credibility (F(1, 191) = 6.72, p < .05). Planned comparisons showed no significant dif-

ference for sources of high vs. low credibility when valence was negative ($M_{neg,high}$ = 2.63 vs. $M_{neg,low}$ = 2.79; t(191) = -.61, p = .542), supporting H1a. In the positive-valence condition, high source credibility led to significantly better product attitude than low source credibility ($M_{pos,high}$ = 4.71 vs. $M_{pos,low}$ = 3.95; t(191) = 3.19, p < .05). This finding supports H1b.

H2 postulates that perceived argument quality mediates the effect of source credibility on product attitude when OCR valence is positive. Mediation analysis (Hayes 2013; Model 4, bootstrap sample n = 5000) was applied to test this hypothesis. Results revealed a significant indirect effect of source credibility on product attitude through perceived argument quality (β = .46, p < .01, 95% CI = [.18, .78]). Specifically, results showed that source credibility positively influenced perceived argument quality (β = .85, p < .01), which in turn predicted product attitude (β = .53, p < .01). The direct effect of source credibility on product attitude was not significant (β = .30, p = .131). Thus, as predicted in H2, perceived argument quality mediates the effect of source credibility on product attitude in the case of

positive OCR valence. In contrast, for negative OCR valence, results revealed no significant mediation.

Main analyses purchase intention

A two-way ANOVA of purchase intention revealed a significant main effect of OCR valence (F(1, 191) = 45.33, p < .01), a non-significant main effect of source credibility (F(1, 191) = 3.34, p = .069) and, as predicted, a significant interaction between OCR valence and source credibility (F(1, 191) = 12.25, p < .05). Planned comparisons showed no significant difference for high- and low-credibility sources when valence was negative ($M_{neg,high}$ = 1.95 vs. $M_{neg,low}$ = 2.27; t(191) = -1.13, p = .261), supporting H1a. With positive valence, high source credibility led to significantly higher purchase intention than low source credibility ($M_{pos,high}$ = 3.90 vs. $M_{pos,low}$ = 2.89; t(191) = 3.97, p < .01). This result is in favor of H1b.

For H2, the mediation analysis revealed a significant indirect effect of source credibility on purchase intention through perceived argument quality (β = .51, p < .01, 95% CI = [.22, .88]). Specifically, results showed that source credibility positively influenced perceived argument quality (β = .85, p < .01). Perceived argument quality then predicted purchase intention (β = .60, p < .01). The direct effect of source credibility on purchase intention was also significant (β = .50, p < .05). Thus, perceived argument quality partially mediates the effect of source credibility on purchase intention in the case of positive OCR valence. In contrast, for negative OCR valence, results revealed no significant mediation.

STUDY 2

The purpose of study 2 was to replicate the observed effects of OCR valence and source credibility for another product type: experience goods. The booking of a hotel room was used as the scenario for the pre-purchase information search for an experience good. All other aspects of the design and the manipulations were identical to those of study 1.

Method

Design, participants, and procedure

The experimental design was identical to study 1. Participants were 221 (72 % female, M_{age} = 23 years) students from several German-speaking universities, randomly assigned to one of the experimental conditions. By participating in the experiment, students got the chance to win an Apple iPod Nano.

Participants were told to imagine that they visited a webpage with a description of a hotel and several OCRs in the course of their pre-purchase information search for booking a hotel room. Manipulation of source credibility was identical to study 1; the reviews used in the positive and negative OCR condition were adapted for the context of study 2.

Measures

We assessed all variables with the same measures used in Study 1 (argument quality: α = .88, product attitude: α = .98, purchase intention: α = .96).

Results

Preliminary analyses

Using the same measures, we assessed the manipulation of OCR valence (α = .98) and source credibility (α = .94). Both manipulations were successful. Participants evaluated the positive OCRs significantly more positively than the negative OCRs (M_{pos}^{val} = 6.17 vs. M_{neg}^{val} = 1.73; t(219) = 25.48, p < .01). Additionally, source credibility was significantly higher in the high than in the low source-credibility scenario (M_{high} = 5.00 vs. M_{low} = 3.93; t(219) = 6.32, p < .01). Furthermore, OCR valence did not influence source credibility (M_{pos}^{cred} = 4.48 vs. M_{neg}^{cred} = 4.45; t(219) = -.15, p = .878).

A MANOVA with OCR valence and source credibility as independent variables and product attitude and purchase intention as dependent variables yielded a significant main effect of OCR valence (V = .48, F(2, 216) = 101.25, p < .01), a non-significant main effect of source credibility (V = .01, F(2, 216) = 1.22, p = .30) and a significant interaction between OCR valence and source credibility (V = .06, F(2, 216) = 7.16, p < .01). Follow up ANOVAs and planned comparisons then tested the moderation postulated in H1 for product attitude and purchase intention independently. Additionally, a mediation analysis tested H2.

Main analyses product attitude

A two-way ANOVA with product attitude as the dependent variable revealed a significant main effect of OCR valence (F(1, 217) = 203.00, p < .01) and a non-significant main effect of source credibility (F(1, 217) = .052, p = .819). More importantly, results showed the predicted significant interaction between OCR valence and source credibility (F(1, 217) = 14.31, p < .01). Planned comparisons revealed a significant difference for high- and low-credibility sources when valence was negative ($M_{neg,high}$ = 2.44 vs. $M_{neg,low}$ = 3.08; t(217) = -2.51, p < .05). This result is contrary to H1a. In the case of positive OCR valence, high source credibility led to significantly better product attitude than low source credibility ($M_{pos,high}$ = 5.69 vs. $M_{pos,low}$ = 4.97; t(217) = 2.84, p < .01). This result is in favor of H1b.

For H2, the mediation analysis revealed a significant indirect effect of source credibility on product attitude through perceived argument quality (β = .40, p < .01, 95% CI = [.12, .79]). Specifically, results showed that source credibility positively influenced perceived argument quality (β = .76, p < .01). Perceived argument quality then predicted product attitude (β = .53, p < .01). The direct effect of source credibility on product attitude was not significant (β = .32, p = .079). Thus, in the case of positive OCR valence, perceived argument quality mediates the effect of source credibility on product attitude, which supports H2. For negative OCR valence, results revealed no significant mediation.

Main analyses purchase intention. A two-way ANOVA of purchase intention revealed a significant main effect of OCR valence (F(1, 217) = 132.82, p < .01), a non-significant main effect of source credibility (F(1, 217) = 1.32, p = .252) and, as predicted, a significant interaction between OCR valence and source credibility (F(1, 217) = 9.81, p < .05). Planned comparisons showed no significant difference for high- and low-credibility sources when valence was negative ($M_{neg,high}$ = 2.26 vs. $M_{neg,low}$ = 2.64; t(217) = -1.40, p = .163), supporting H1a. With positive valence, high source credibility led to significantly higher purchase intention than low source credibility ($M_{pos,high}$ = 5.09 vs. $M_{pos,low}$ = 4.27; t(217) = 3.03, p < .01). This result is in favor of H1b.

For H2, the mediation analysis revealed a significant indirect effect of source credibility on purchase intention through perceived argument quality (β = .42, p < .01, 95% CI = [.13, .85]). Specifically, results showed that source credibility positively influenced perceived argument quality (β = .76, p < .01). Perceived argument quality then predicted purchase intention (β = .56, p < .01). The direct effect of source credibility on purchase intention was not significant (β = .41, p = .087). Supporting H2, in the case of positive OCR valence, perceived argument quality mediates the effect of source credibility on purchase intention. In contrast, for negative OCR valence, results revealed no significant mediation.

DISCUSSION

The results of this research shed light on the differential effects of source credibility in an online context, clarifying previous inconclusive findings. Specifically we clarify under which conditions the credibility of the author of an OCR matters. With its notion of the co-occurrence of systematic and heuristic processing, the HSM (Chaiken 1980; Chaiken et al. 1989) provides a highly applicable theoretical basis to explain the effect of source credibility in the case of positive but not negative OCRs. This is because positive OCRs are rather non-diagnostic, especially in the online context, where positive reviews are vast and often perceived as biased. The source credibility effect is mediated by the evaluation of argument quality, indicating that the heuristic information was used systematically. This strengthens the HSM's notion of co-occurring processing modes and extends previous findings on the systematic processing of heuristic information (Darke et al. 1998).

The research has some limitations. The effect of source credibility was only tested in a situation where consumers are rather motivated to process the information. In a situation where low motivation or ability and thus heuristic processing predominate, source credibility should always have an influencing effect because message content is not or cannot be processed. To measure systematic processing more thoroughly, applying a thought listing procedure would help to gain better insights into the processes underlying the effects of OCR valence and source credibility on product attitudes and purchase intentions. Furthermore, future research should validate the findings using non-student samples and additional product settings. This would enable us to provide an in-depth analysis of potential product category differences.

The Style is the Brand: The Poetic Choreography of Idea Behaviour

Roel Wijland, University of Otago, New Zealand
Stephen Brown, University of Ulster, Ireland

ABSTRACT

This article introduces style as the behavioural determinant to represent order, clarity and the enchainement of ideas as it inscribes itself into a brand. It proposes to conceptualise the relationship between consumer behaviour and idea behaviour, and advances style differentiation as the fundamental poetic function of the brand, in an increasingly fragmented, fluid and chaotic perceptual universe. Brand style offers a refreshing critical perspective on distinctive lyrical expression, as a vehicle for managerial consolidation, and how its core choreography may be poetically communicated.

STYLE AND THE PARADOX OF THE LAST REMAINING CONSTANT

'Le style est l'homme même.'
(Buffon 1894)

The more splintered marketing's meaning particles and atomic artefacts in the consumer's physical, digital, and literally mobile universe become, the more urgent the quest for a theoretical and managerial anchors for the conveyance of brand meaning is. The explosion of possible meaning and communication channels offers an abundance of disjointed richness in which few of the traditional brand models that promise a soothing coherence or constancy survive. Postmodernity has unsecured and unmoored and endless deferral of meaning, managers have embraced the inevitability of relinquishing control over their brand's destiny, and the upmost achievement is to perform the parting ritual with some elegance (Kelly 1994). In response to these shifts in the provenance and influence of idea generation, both consumer behaviour and marketing have suspended the belief in the power of brand-initiated ideas in return for the exclusive and wholesale embrace of the co-creative, participatory, customer-initiated, consumer-led, crowd-sourced ways of world-making. The consumer-brand relationship has become a tennis match in which conceptual models and praxis decrees new rules in which only one player seems to have the initiative, and the brand's newly acquired role is to endlessly practice the return of the consumer's serve, every minute of the day. On the face of it, 2016 very much seems the wrong year to revisit this disequilibrium and make a case for the primacy of an invigorating idea behaviour in the face of consumer's 200 mile per hour bombardment. Brand meaning is less and less managerially determined and the disposal of the influence of idea centric arguments has been accepted as a matter of fact (Iglesias and Bonet 2012; Iglesias, Ind, and Alfaro 2013).

This article makes a humble proposal to revisit *style* as a source for inspiration to support the idea side of the court, in the context, full acceptance and celebration of the fluid interactions pertaining to brand meaning. The style edict proclaims that the content itself is predisposed and ultimately defined by the manner in which it is expressed. We identify style in elements, motives and form relationships, but not least in an all-over quality which we may call expression (Ackerman 1962, 1978). It has been argued that style is easily understood and perceived, and difficult to parse and study. Or to revisit the earlier tennis metaphor: Novak Djokovic's style includes how he hits a tennis ball, plus a range of other expressive qualities that makes his winning performances distinctively characteristic. The performance of style is at once subjectively witnessed with ease as a directly grasped quality and near unanalysable (Toolan 1996). In everyday life and as a social process, distinguishing styles is empirically unproblematic (Rosenblum 1978). As an aesthetic academic challenge, a phenomenon that in its essence defies to be broken down in elements and features and derives its relevance from a holistic expressive complexity has proven to be precariously enigmatic. Its resistance to deconstruction in combination with its elusive perceptual directness makes the seemingly simple notion of style an under-investigated area in consumer and idea behaviour.

Style in its broadest sense has long been seen as one of the most *constant* of physiological products (Gourmont 1907). Style has been defined as a strand in a culture or civilization and a coherent, self-consistent way of expressing certain behavior or performing certain kinds of acts (Kroeber 1963). Style provides an internal order in its expressiveness (Schapiro 1994). Style correlates habits of meaning within the credible limits of expressive variability. This basic and foundational reliability as a reference to a way of being, combined with the natural propensity to serve marketing's eternal call for differentiation, make explorations into aspects of style a contemporary attraction. Style definitions live in different guises in many disciplines, but its meaning is captured in a shared simplicity and directness in the common understanding as: an idiosyncratic way of doing something. This idiolect, as the particular variety of codes used, provides an aesthetic propeller shaft towards an inner unity. Style literally sets and defines the tone and provides a driving force back to the core of a being, entity or dynamic cultural artefact. Style concerns itself with precision and conciseness of expression, fluency in its characteristic rhythm and flow, and in a distinctive tone of voice. There are beneficial *paradoxical* aspects to the referential anchoring qualities of the style concept, which make it more attractive for the contemporary concerns in fragmented meaning making universe. Style is a more valuable concept in the currency of studies of markets, marketing and behaviour as the understanding of the dynamic quality of its constancy is unfolded.

First, the constancy of style is relative. As a centripetal force is still gradually variable, in the same way one voice can mellow, become more ironic or philosophical over time. It is subject to an evolving sameness from a recognizable core. While resistant by virtue of its reliance on its past utterances, buffing and corrosion add to the owned differential patina of its voice. Second, style survives in its distinctive deviation from a norm; this can be achieved by situational deviation and individual deviation (Osgood 1960b). Its inclination to remain true to its expressive roots is contingent to the changing situational backdrops against which it resonates. The congruent quality of a recognizable style over time may support of the functioning of perceptual fluency (Fransen, Fennis, and Pruyn 2010). Third, the form *is* the substance, or the content. Style and substance are often so inextricably intertwined, it is does not make sense to distinguish the what and the how (Jacquette 2000). Style theorists would propose that 'a different way of saying is in fact saying a different thing' (Hough 1969). As such, critical stylisticians struggle with the common what-how separations of definitions of content and style. Fourth, style is defined both in any particular moment and in the attributable expression across moments. Style is exemplified in instances, but by nature relational. Stylistic moments must cohere sufficiently to integrate into a series of related patterns (Kroeber 1963). Fifth, while style's fluidity and all-over cloudiness is difficult to capture in discrete ele-

ments, aspects such as the timbre of a tone of voice, the rhythm of flowing utterances require an exactness of expression to maintain its holistic quality. In style as much as in poetry, expression depends on 'le mot juste', and precision gives it power.

STYLE AS POETIC BRAND CHOREOGRAPHY

'No verse is free for a man who wants to do a good job.'
(Eliot 1917)

Style has been proposed as an essentially poetic quality of expression. Style is *the point* of poetry (Widdowson 1992, 1996). Style is a poetic code, with terms that may be expounded or avoided (Jakobsen 1960). The justification for style as a poetic concept is not least supported by its scope: the variety of expression and syntax possible in poetry is far wider than in prose. While content may be narrated, style is embodied in its lyrical quality. What sets poetry apart from prose is what sets style apart from content. Poetic language is extraordinarily precise (Chatman 1960). Style study requires the same thoroughness as the under logical paradigms, and has to find the lyrical balance between a vagueness of sensing and feeling and the precision of expression. Style offers a pervasive, rigorous unity (Holly 1997). The conception of style as an idiolect, requires the same approach as poetics: a sequence of non-banal utterances (Householder 1960), instantly attributable, and high density scapes presented with a decisive brevity. Poetics and stylistics share an analytical elusiveness. We perceive a style or a poem without being able to fully analyze their properties into elements or specify the necessary and sufficient conditions for it (Goodman 1975) .

The turbulent introduction and acceptance of poetics in consumer behaviour (Sherry and Schouten 2002; Wijland 2011) is reminiscent of the struggle to discern a role for style in consumer research. The expressive and the cognitive don't make great dinner conversations nor bedfellows, and the observation *'style enters, where facts stops and feelings start'* (Goodman 1975) indicates the mimetic relationship style and poetry have with the dominant logic of research culture.

Much more interesting than the how-what distinction in the style debate is the notion that style in the idea making process *precedes* the conceptual idea as a guiding principle for the genesis of behaviour. In the evolving praxis of creative briefings of agencies, the word style is rarely literally mentioned, but tone of voice has never left the initial strategic parameter of a given behavioural change challenge. The planner's briefings that contain this defining tone of voice description are less a systematic observation of expressive difference, as an intuitive anchor expressed with a lyrical and poetic brevity. The poetics of style offer a pathway to a fluid brand choreography. Poetic brandscapes are nonlinear universes of idea behaviour, not unlike modern dance. The current acceptance that in the last instance prescriptive models prove not to be able to cope with the generative nature of brand meaning, entails we may abide in long-motion sequences within the stylistic spaces the brand affords itself, like a free-versed ballet. A brandscape is a style generating machine, and perpetually in motion, while in constant conversation with its own origins and conventions.

CONSUMER BEHAVIOUR AND IDEA BEHAVIOUR

There is no purer form of advertising
than writing a poem
that's what the monk told me
if I were a conceptual artist
I would make high-budget trailers
of john updike movies, but no actual movie.
(Riviere 2012)

Scott's (1994) call for methods in consumer behaviour that study style, without reducing an utterance to its components has remained largely unanswered. Why has style not been fully unfolded as a conceptual approach in idea behaviour or marketing communication? It closest opening gambits for integration in mainstream discussions eventuated during the adjacent upswing of rhetorics in consumer behaviour, and the development of theoretical models for lifestyles. The commonalities of life style in consumer behaviour and brand styles in idea behaviour includes that both embody observable *patterns* that develop and emerge from the dynamics of living in a society (Lazer 1963; Plummer 1974).

Style fits the schemata of consumer behavior in that it may be primarily designated as a depiction *after the fact* (Ackerman 1978), based on the consumer's perception of traits common to a brand. In contrast, style fits the protagonistic approaches in the conscious development of the idea behavior in the fact that it can be an intentional strategy of influence and persuasion, prior to market interaction. What remains in this argument is that style is not superficially decorative or ornamentally subservient to content, but the brands buttress and articulation of its essence as inalienable lyrical expression.

In the predominantly textual study of rhetoric in consumer behavior (McQuarrie and Mick 2003; McQuarrie and Philips 2008; Mick 1986), style features in the margins. It may be that at a paradigmatic level a phenomenological concept such as style, defies the application of a semiotic arsenal is inclined to notice the symbolic qualities of content. The common methodological approach in rhetoric, whether textual or visual, has been content analysis. In most cases this concerns itself with the 'what' of content, and a counting of elements. This approach was not least enabled by a highly organised media landscape, in which the limited shape of expression and ingrained schemata (a print advertisement or a TV commercial) allowed structured comparisons and a counting of elements or units, in an academic research environment dominated by positivist expectations. The relative mental distance from aesthetic considerations in the wider behavioural research community easily disposes of style as a redundant decoration. In this environment and in the habit of content analysis excellent researchers have limited the style concept to 'an arrangement of elements' (McQuarrie and Phillips 2008) as a matter of course, based on the formal attributes of an archaic media landscape that no longer exists. The loss of both traditional media and the formal aspects of a particular vehicle consistency disable the known research mechanics as going concerns. The opinion that any differentiation and establishment of a rhetorical system has to start in the tight focus on a magazine ad or banner ad (McQuarrie 2008) precludes the contemporary development of style constructs. Well before these relatively recent investigations, it has been confirmed that the nature of style resists fragmentation into units and an intonation of an utterance that cannot be isolated easily or even pointed to with precision (Scott 1994). Scott calls for methods that study style, without reducing it to its components. In visual rhetoric the sender's intent frames a message with an interested party's attempt to influ-

ence an audience (Scott 1994). The quality of the crafting of content by its producer takes center stage in this living argument under a new firmament that is less served by signal processing, and more based on an exploration of fluid state-space models. How a situated idea behaves in embodied and experiential contexts transcends traditional mediation.

While in the body of work of rhetoric, style has been affirmed to carry a great deal of information (Mick 1986; Phillips and McQuarrie 2002; Stern 1992), the challenging observation of idiosyncratic expression, rhythm, fluency and tone of voice of utterances didn't fit a well-developed and sophisticated programme of schemes, tropes and rhetorical figures (McQuarrie and Mick 1992). Its study requires a programmatic shift from content analysis to style analysis, and as such inevitably includes the bravery of accepting that the flavours of the how are a potentially more unifying force than the functional what components. Interpretive frameworks in consumer behaviour, including ones that find their justification in rhetoric, have usually gravitated to content rather than form. The approach in which rhetoric doesn't rise above a traditional chasm of style versus content, and the acute separation of the two is seen as a defining characteristic of rhetoric (McQuarrie and Philips 2008) doesn't do much to enhance the potential of style to rise above the status of decorative embellishment in consumer behaviour and marketing. The salient differences between content and style analysis beyond the what and how chasm are that content analysis is concerned mainly with making inferences *from* message indicators to either source or receiver states and characteristics, style analysis is more concerned with predicting (or interpreting) *to* message indicators or events from knowledge of source variables (Osgood 1960a).

In contrast with the study and culture of the creation of brand and idea behavior, aesthetic considerations in general struggle to find the main stages of academic consumer behavior and marketing literature. In disciplines other than marketing and consumer behaviour, the burgeoning area of stylistics has enabled a richer evolution of the style concept. The claim of stylistics include that it offers a systematic study of expression, it can within limits increase knowledge, that such knowledge can be consolidated, and can be communicated to others. The critical stylisticians who make creative brand ideas and define how they behave in the market look for expressions that are perceptually and expressively salient. Idea behaviour is the approach to the differential understanding of the performance of existing and newly developed market interventions and assumes the creation of performative ideations are a consequence of a brand's history, and living interactive motivations. Idea behaviour is by nature experiential and embodied and its space for expressive variability is both influenced by a brand's heritage and the urgency of its environmental currency. Ideas in a brand context are stylised concepts for worldmaking.

THE BEHAVIOURAL QUALITIES
OF BRAND STYLE

'What style shall I choose to clear up the immense chaos of diverse, contrary, often vile, and sometimes sublime sentiments which ceaselessly agitate my soul?'
(Rousseau 1955)

The cursory treatment of brand style in both academic and managerial circles may be linked to its elusive character (Person and Snelders 2010). Yet, the dynamic aesthetics of a differentiated style offer managers one of the last serial motives to normative idea behaviour for their brands. It offers a behavioural grounding to chal-

lenges as yet unexplored, with an in-built radar to keep a distance from competing expressions and experiences. The contemporary attraction of the style concept as a stable pattern for behavioural change may be argued on the basis of four organic angles that offer new opportunities for the inner quality of idea behaviour.

Style is a relational concept

Style represents order, clarity and not least the opportunity of an *enchainement* of ideas (Buffon 1894), as a true perception of the relation between objects. In the same way that service dominant logo proposes brand value-in-use (Merz, He, and Vargo 2009), style offers a structure for expressive patterns-in-use (Widdowson 1996). Style both defines form and a relational pattern, and the internal relationships among the individual parts (Ackerman 1962). It is an expressive linking pattern in the dynamic connection of discrete moments, and a relation between the (brand) expression and the world.

Style is an experiential concept

It offers a media-independent and embodied perspective to the potential harmony of the lived and performed patterns of idea behaviour. Style is the characteristic 'signature feature' (Jacquette 2000) of the functioning of a brand. *Style is a contextual concept.* In current mobile segmentation strategies, the intent of behavioural ideation aims less for a resonance with the profile of an individual or group, than relevance in the situations in which we communicate. Style influences the ordonnance of ideas and the arrangement or disposition of parts. *Style is a gravitational concept.* Style has been embraced as an autonomous set of understandings in a social setting (Rosenblum 1978). Style gravitates to its own tone, and may at once resist and promote formational development. Styles may dynamically change over time, within their own pace and rhythm. A change in idea behaviour is in itself set by the parameters of style the expressive artefacts a brand carries within itself. The fluid aesthetic patterning occurs within an internalised behavioural heritage as a confluent conversation with its own history. *Style is a poetic concept.* What makes new explorations in style such a promising trajectory for idea behaviour in part sustained by an internal aesthetic rectitude. Both style and poetics survive by means of an associative under-coding. The adjacency of the aesthetic concepts of poetics and style, may is exemplified in their common dependency on the necessary openness to potential meaning association (Eco 1989; Wijland 2009).

The brand concept has already been prefixed to a plethora of marketing themes and notions: from brand identity to brand design, from brand image to brand personality and brand culture to brandscape. This article proposes a re-invigorated interest in the potential of brand style in mobile, and digital, experiential and embodied contexts. Based on the earlier style definition, brand style is the idiosyncratic way in which a brand *does* something. Novak Djokovic's style is best expressed in his behaviour. The legitimization of this initial call for a fresh engagement with style as an act may be recaptured as follows. Brand style is a timeless media- and vehicle-independent concept and viable in future contexts. It is a performative concept that is actionable and discernable in any environment. Brand style is a behavioural concept. It shows a longitudinal mentality in aesthetic dimensions, how old and new ideas act, and what they are able to credibly claim and communicate. Brand style offers a rare normative reference in a fluid landscape, both within itself an in relation to other brand styles. Finally: brand style offers the poetic openness for engaging market dances. It is uniquely positioned to accommodate the full complexity of a brand's presence (Wijland and Fell 2009).

CONCLUSION

Style is the answer to everything.
A fresh way to approach a dull or a
dangerous thing.
To do a dull thing with style
is preferable to doing a dangerous thing
without it.
./.
Not many have style.
Not many can keep style.
I have seen dogs with more style than men.
Although not many dogs have style.
Cats have it with abundance
./.
Style is the difference,
a way of doing,
a way of being done.

6 herons standing quietly in a pool of water
or you walking out of the bathroom naked
without seeing
me.

(Bukowski 1972)

The behavioural study of the interactive style of market dialogues may be intimated from a consumer and idea perspective of the creative continuum. This article challenges the widely accepted shift in the balance of the brand's authorial intent to exclusively consumer-led views and may reclaim the creative space within the subtleties of the internal and relation powers of brand style. This is not to turn back the clock towards a preordained, nostalgic or lost supremacy for makers, but rather an argument for a poetic choreography in which a brand's idea makers can confidently set the tone, rhythm and expression for interaction. In synchronization with the urgent call for a honing of the rhetorical skills of brand managers in the face of a consumer-centric meaning making landscape (Iglesias and Bonet 2012) this article proposes a re-evaluation of style as a future-oriented driver for idea behaviour.

Brand style is not primarily conceived to be reactive; it is the implicit protagonist in the business of the continuous genesis in idea behaviour. Whether in text or visual, in embodied performance or silent experience, style creatively leaves its finger- and foot-prints all over the behaviour of brand ideas.

The Effect of the Extraordinary: Reliance on Feeling over Reason in Decision Making

Xuhong Zhuang, Kobe University, Japan

ABSTRACT

In this research another factor that may influence consumers' relative use of feeling-based or reason-based decision making is advanced. Across two online experiments we found that participants who in the extraordinary situation (uncommon and infrequency) were rely more on feelings than in the ordinary situation (common and frequency).

INTRODUCTION

In this study we investigate the impact of temporal focus (ordinary vs. extraordinary) on decision-making events. Past research has suggested that consumer judgments and decisions can be categorized into two modes: reason-based and feeling-based. In the reason-based mode, people carefully consider the target attribute's information in an overall evaluative judgment (Bettman, Luce, and Payne 1998). In the feeling-based mode, people use subjective, affective reactions toward the target or momentary feelings (Pham 1998; Schwarz and Clore 2007). To delineate the characteristics of the two decision-making modes, past studies have explored the conditions under which consumers rely on feelings over reason in making judgments and decisions. Researchers have found that consumers are more likely to rely on their feelings when making a decision given the following conditions: (a) when their processing resources are limited (Shiv and Fedorikhin 1999), (b) when they have an experiential consumption goal (Pham 1998), (c) when the outcome of the decision is set in the near future (Chang and Pham 2013), and (d) when they have an independent self-construal (Hong and Chang 2015).

In this research, another factor that may influence consumers' relative use of feeling-based or reason-based decision making is advanced: affective feelings are relied on more in an extraordinary situation than in an ordinary situation.

EXTRAORDINARY AND AFFECTIVE REACTIONS

In this paper, ordinary experiences are defined as those that are common, frequent, and within the realm of everyday life. In contrast, extraordinary experiences are uncommon, infrequent, and go beyond the realm of everyday life (Sussman and Alter 2012).A number of studies have shown that affect tend to be experienced more intensely when people are in an extraordinary situation. Arnould and Price (1993) revealed that extraordinary consumption experiences have been reported as positive activities with a positive intensity. In neuroscience, the stimuli "infrequency" and "newness" are referred to as "novelty." Novelty can be defined in several ways, and different types of stimuli have been referred to as novel in the literature (Schomaker, Roos, and Meeter 2014): (1) stimulus novelty (Courchesne, Hillyaed, and Galambos 1975), referring to stimuli that have never been experienced before; (2) contextual novelty, referring to stimuli that might be familiar but differ substantially from others experienced in the same context; (3) deviance novelty, referring to stimuli that are rare and physically stand out from the others in the experimental context; and (4) expectedness novelty, referring to stimuli that cannot be predicted based on the immediately preceding ones. New, novel stimuli often receive priority in processing: they elicit an orienting response (Sokolov 1963) and automatically attract attention (Escera, Alho, Schroger, and Winkler 2000). "Novelty seeking" refers to the tendency of humans and animals to explore unfamiliar stimuli and environments (Reed, Mitchell, and Nokes 1996). Costa, Tran, Turchi, and Averbeck (2014) reported that novel stimuli excite dopamine neurons and activate brain regions that receive dopaminergic input, so the notion that dopamine modulates novelty seeking is supported. In addition, dopamine had been shown to drive exploratory behavior in novel environments. Finally, recent neuroscience studies suggest that the neural populations involved in the processing of stimulus pleasantness are more strongly activated when stimuli are novel, which could result in different or stronger emotional responses (van Peer, Grandjean, and Scherer 2014).

EXTRAORDINARY STITUATIONS AND DECISION MAKING

In past research, ordinary versus extraordinary situations have been found to affect the differential accessibility and intensity of affective responses. We propose that, apart from the differential accessibility of affective responses in decision making in extraordinary or ordinary situations, the affective system also produces a differential reliance on these responses. Past research has reported many characterizations of extraordinary experiences, including an escape from modern society; or unfettered straying from the rules, rationality, and stress of everyday life (Tumbat and Belk 2011). Sussman and Alter (2012) investigated how consumers account for exceptional expenses, and how this process may differ from accounting for ordinary expenses. The authors focused on biases at the planning phase, when people consider making exceptional purchases. They suggested that consumers would underestimate exceptional expenses; in contrast, consumers accurately forecasted ordinary expenses. Further, past research also suggested that a feeling-based manner is relatively qualitative, while a reason-based manner is relatively quantitative (Hsee and Rottenstreich 2004). Thus, a feeling-based manner produces notable sensitivity to weather, a stimulus defined by presence or absence (i.e., a change from 0 to some scope), but little sensitivity to subsequent increments of scope. In contrast, a reason-based manner produces relatively constant sensitivity over the entire range. One interpretation of these findings may be that people in ordinary situations are more likely to rely on reason and are consequently more capable of accurate predictions. In contrast, people in extraordinary situations are more likely to rely on feelings and are consequently more impulsive in their consumption.

Building on such past research, the current study proposes that being involved in ordinary or extraordinary experiences has implications for how consumers rely on feelings over reason in making judgments and decisions. In ordinary situations, people tend to analyze and think about the target problem, thus relying on reason in making judgments. In contrast, in extraordinary situations, people tend to stray from rules and reason under the influence of intense and affective reactions, so they may rely on feelings in making judgments.

STUDY DESIGN

The hypothesis was tested using two online experiments. In experiment 1, participants were asked to choose between an affectively superior option and a functionally superior option in either an ordinary condition or an extraordinary condition. The results showed that consumers' preference for the affectively superior option was greater in an extraordinary situation than in an ordinary one. In experiment 2, a different testing method was used that examined the impact of incidental mood on participants' judgment of a target option. The results showed that incidental moods had a stronger mood-congruent influence on behavioral intentions toward the target in the extraordinary situation than in the ordinary one.

Participants

In this research, all participants came from Japan and were recruited randomly through the online labor market Yahoo Crowd Sourcing. Several control questions were asked after the main manipulates to check if they were attentive in follow instructions. Participants who did not pass the control questions were excluded from the sample.

Pretests for the decision-task stimuli

Two restaurants were used as task stimuli for the choice, with each described based of six attributes. Three of the attributes were designed as functional dimensions: the volume of the dinner course, access to public transportation, and free seconds of vegetables. The remaining three attributes were designed to be affective dimensions: the view from the restaurant, the amount of sunlight, and the soothing ambiance of the restaurant. To ensure the validity of the stimuli among the participants, two pretests were conducted.

The first pretest aimed to verify if the six attributes pertained to the affective and functional dimensions. We asked 98 participants to rate the restaurants' 6 attributes on a seven-point scale (1 = "appeals to my thoughts," 7 = "evokes my feelings") (Hong and Chang 2015). After averaging three functional dimension items and three affective dimension items, we ran a one-way repeated-measure ANOVA on these scores. The results showed that the affective dimensions evoked more feelings ($M = 5.60$) than the functional ones ($M = 4.33$; $F(1, 97) = 65.74$, $p < .001$). From this result, we used these six attributes to design affective and functional dimensions for the restaurant stimuli.

The second pretest was conducted to further confirm people's tendency to use either a feeling-based or reason-based decision strategy when faced with an affectively superior option or a functionally superior option, respectively. 150 participants were asked to choose between two options using different decision strategies. For the feeling-based condition, the participants were asked to use a feeling-based decision strategy. They were instructed to make decisions based on "emotions and feelings toward each of the options." For the reason-based condition, participants were asked to follow a reason-based decision strategy. They were instructed to make their decisions based on "logical reasoning of the pros and cons of each option" (Pham et al. 2001; Hong and Chang 2015). As predicted, the participants asked to rely on their feelings were more likely to choose the affectively superior option over the functionally superior one than those asked to rely on reasons (75.7% vs. 19.7%, $\chi 2(1) = 47.06$, $p < .001$). These findings suggest that the relative preference between two restaurants can be seen as indicative of the differential reliance on a feeling- versus reason-based decision strategy.

EXPERIMENT 1

The first experiment tested the basic hypothesis that in making a decision, consumers are more likely to rely on their integral feelings toward their options when they are focus on extraordinary rather than ordinary situation. To test this hypothesis, after the participants were manipulated to place temporal focus on either extraordinary or ordinary situation, they were asked to choose between two restaurants: one that was affectively superior and another that was functionally superior. It was predicted that participants choosing between the two restaurants in an extraordinary situation would exhibit a greater relative preference for the affectively superior restaurant than participants choosing in an ordinary situation.

Method

Design: A total of 131 participants (62.6% women, average age = 33.82) were randomly assigned to one of the two experimental conditions (temporal focus: ordinary vs. extraordinary).

Procedure: In this experiment, participants were manipulated to imagine an ordinary or extraordinary situation. For the ordinary group, participants were asked to envision R City as a beautiful port town. They imagined that they regularly visited the city several times a week. They were told that this week they were going to visit R City again with their friends. The extraordinary group was also asked to imagine R City as a beautiful port town; however, they were told that they never had the opportunity to visit it, and at long last they were finally going to R City with their friends.

Then, participants were given a choice: They were told to imagine that they were going to choose a restaurant when they visit R City this week with their friends. Pictures and descriptions of the two restaurants were presented to them (see Table 1). The two restaurants had the same prices. The first dependent measure was participants' choice between the two restaurants. The second dependent measure was participants' relative preference for the two restaurants, which was assessed on a seven-point scale (1 = "strongly prefer restaurant A," 7 = "strongly prefer restaurant B"). In addition, to check their insight in the process underlying decision making, they were asked to indicate how they made their decision on a seven-point scale (1 = "I made my decision based on the logical balance of pros and cons," 7 = "I made my decision based on how I would feel about having dinner at the restaurant") (Chang and Pham 2013).

Table 1

Restaurant A	
Inside of restaurant	Part of the dinner course
Volume of the dinner course: 11 dishes A short walk to the nearest train station Free seconds of vegetables No windows	
Restaurant B	
Inside of restaurant	Part of the dinner course
Volume of the dinner course: 7 dishes Four bus stops from the nearest train station No free seconds of vegetables Oversized window with breathtaking view	

As a check of the manipulation of focus to ordinary or extraordinary, participants were asked to rate three nine-point items anchored at "ordinary experience/extraordinary experience," "common experience/uncommon experience," and "frequent experience/infrequent experience" ($\alpha = .93$). To assess potential confounding factors, participants were asked to rate their mood on three nine-point items ("bad/good," "unpleasant/pleasant," "sad/happy"; $\alpha = .86$).

Results

Preliminary analysis

As predicted, participants reported a greater focus on the extraordinary in the extraordinary condition ($M = 7.21$) than in the ordinary condition ($M = 2.40$; $F(1, 130) = 357.58$, $p < .001$). The ordinary or extraordinary focus manipulation did not influence participants' moods ($F < 1$).

Choice and relative preference

As predicted, participants were more likely to choose the affectively superior restaurant in the extraordinary condition than in the ordinary condition (57.5% vs. 22.4%, $\chi2(1) = 16.37$, $p < .001$). Participants also exhibited a stronger relative preference for the affectively superior restaurant in the extraordinary condition ($M = 4.40$) than in the ordinary condition ($M = 3.02$; $F(1, 130) = 18.34$, $p < .001$). Further, participants displayed higher reliance on feeling in the extraordinary condition ($M = 4.71$) than in the ordinary condition ($M = 3.28$; $F(1, 130) = 12.07$, $p < .01$). These results are consistent with the hypothesis that people are more likely to rely on affective inputs when they focus on the extraordinary than when they focus on the ordinary, even though all information on the target is held constant. The results are summarized in Table 2.

Table 1

Experiment 1: Pretest 1		
Verify that the six attributes pertain to affective and functional dimensions as intended		
	Affective dimensions	Functional dimensions
"Appeals to my thoughts" vs. "evokes my feelings"	5.60	4.33
Experiment 1: Pretest 2		
Verify use of feeling-based and reason-based decision strategies for affectively superior option and functionally superior option		
	Feeling-based strategy	Reason-based strategy
Choice of affectively superior option (%)	75.7%	19.7%
Experiment 1		
Effect of ordinary and extraordinary context on preference between affectively and functionally superior options		
	Ordinary	Extraordinary
Choice of affectively superior restaurant (%)	22.4	57.5
Relative preference for affectively superior restaurant	3.02	4.40
Relative reliance on feeling over logical assessment	3.28	4.71
Experiment 2		
Effect of temporal focus (ordinary vs. extraordinary) and incidental mood on intention		
	Positive mood	Negative mood
Ordinary focus	4.22	4.34
Extraordinary focus	5.20	4.40

EXPERIMENT 2

A limitation of experiment 1 is that we manipulated the participants' integral feeling toward targets by varying the cognitive versus affective information across pictures. Some may wonder: was their decision making due to the cognitive versus affective aspect, or to the verbal versus pictorial aspect? In experiment 2, we used a more direct manipulation of affect, one that was able to hold information about the target constant.

Past research has shown that incidental feelings from preexisting mood states are often misattributed to the target object (Schwarz and Clore 2007). If a temporal focus on the extraordinary indeed promotes a greater reliance on feelings over reason, then incidental feelings arising from preexisting moods should exert a stronger mood-congruent influence on judgments by consumers focusing on the extraordinary rather than the ordinary. In this experiment, participants' incidental moods were manipulated and the effect of mood on their judgements of the target option were observed. It was predicted that participants' incidental moods would produce a stronger mood-congruent influence in the extraordinary condition than in the ordinary condition.

Method

Design

A total of 253 participants (70% women, average age = 35.38) were randomly assigned to 1 of 4 conditions in a between-subjects experimental design: 2 (extraordinary vs. ordinary) × 2 (positive mood vs. negative mood).

Procedure

Participants were told that they would take part in two unrelated studies. The "first" study manipulated participants' feelings by varying their mood state. Under the pretense of studying people's ability to comprehend short video clips, participants were asked to watch and rate two video clips. The first clip was designed to elicit neutral affective states that were constant across conditions, and its purpose was to reinforce the cover story and make the mood manipulation (for the second clip) less blatant. The second clip was designed to elicit either a positive or negative affective state. For the positive condition, a five-minute edited scene from a comedy series was used. For the negative condition, a five-minute edited scene from a TV program about a child stricken by cancer was used. After viewing each clip, participants answered a series of comprehension-related questions designed to reinforce the cover story and a control question. Among the various distractor items, participants were asked to rate their mood on three items on a seven-point scale; the purpose here was to check the effectiveness of the incidental mood manipulation ("bad/good," "unpleasant/pleasant," "sad/happy"; $\alpha = .90$).

In the "second" study, participants were manipulated into two conditions (the same used in experiment 1): ordinary condition vs. extraordinary condition. Then, participants were asked to complete a decision task. They were shown descriptions of a restaurant (which was the same as restaurant B in experiment 1). As the main dependent measure, participants were asked to rate their intention to go to the restaurant on a seven-point scale (1 = "definitely will not go," 7= "definitely will go"). Finally, in order to check the manipulation of temporal focus, participants were asked to rate three items on a nine-point scale anchored on "ordinary experience/extraordinary experience," "common experience/uncommon experience," and "frequent experience/infrequent experience" ($\alpha = .85$).

Results

Manipulation check

Participants reported a greater focus on the extraordinary in the extraordinary condition ($M = 7.05$) than in the ordinary condition ($M = 3.84$; $F(1, 252) = 225.72$, $p < .001$). The analysis revealed a significant main effect on mood: participants' moods were more positive after exposure to the positive-mood version of the stimuli ($M = 4.93$) than after exposure to the negative-mood version ($M = 3.05$; $F(1, 252) = 216.36$, $p < .001$).

Behavioral intention

If a temporal focus on the extraordinary indeed encourages a greater relative reliance on feelings over reason in judgments and decisions, then incidental moods should produce a greater influence on behavioral intentions in the extraordinary condition than in the ordinary condition. Participants' intentions to go to the restaurant were subjected to a 2 (focus on ordinary vs. extraordinary) × 2 (mood) ANOVA. Consistent with the prediction, the interaction between temporal focus (ordinary vs. extraordinary) and mood was significant ($F(1, 252) = 4.38$, $p < .04$). As shown in Table 2, participants' mood states exerted a stronger mood-congruent influence on intentions in the extraordinary condition (Mpos = 5.20 vs. Mneg = 4.40; $F(1, 252) = 6.59$, $p < .02$) than in the ordinary condition (Mpos = 4.22 vs. Mneg = 4.34; $F < 1$). The main effect of temporal focus (extraordinary vs. ordinary) was significant ($p < .02$), but the main effect of mood was not significant ($p > .12$).

DISCUSSION

This study advanced a novel hypothesis about a previously unrecognized facet of the affective system, which is a greater reliance on affective feelings when making decisions in extraordinary situations compared to decisions made in ordinary situations. Confirming this hypothesis, it was found in experiment 1 that when participants were given the choice between an affectively superior option and a functionally superior option they exhibited a stronger relative preference for the affectively superior option when in extraordinary situation. Experiment 2 produced additional direct evidence that people in extraordinary situations rely more on feelings. In this experiment, incidental moods were found to have a stronger influence on intentions for participants in the extraordinary condition than in the ordinary condition. This study makes several important contributions to the literature. First, in past research, several factors of people's reliance on feelings have been suggested. For example, the representativeness of the feelings in relation to the target (Strack 1992), the relevance of the feelings to the judgment (Pham 1998), and so on. We extended these previous findings by investigating another important factor: ordinary and extraordinary situations. We also made a contribution to the literature on extraordinary research. Past research has focused on consumers' planning fallacies related to extraordinary purchases when setting budgets or making predictions (e.g., Ulkumen, Thomas, and Morwitz 2008; Stilley, Inman, and Walkefield 2010). Further, people are more likely to make biased predictions when forecasting extraordinary purchases rather than ordinary ones (Sussman and Alter 2012). Thus, different reason-based processing manners are associated with ordinary and extraordinary situations. Extending this line of thought, we focused on how ordinary versus extraordinary situations affect both reason- and feeling-based manners of processing in judgments and decisions.

One limitation of this study is that, while we manipulated participants' integral affect (experiment 1) or incidental mood (experiment 2) to test the main hypothesis, we did not use specific emotions such as anger, disgust, or fear. Therefore, a possible avenue for future research would be to extend the discussion to specific emotions. Another limitation is that we tested our hypothesis in only one context (choice of restaurant); future research could test it in other contexts. Further, in the current research, given that the context (ordinary or extraordinary) is an important factor of people's reliance on feelings, an important question is how it operates in combination with other factors. Future research could test the efforts at interaction between ordinary or extraordinary situations and other factors.

Analyzing Antecedent Factors of Cognitive Dissonance using E-Commerce Data

Keiko Yamaguchi, GiXo Ltd., Japan
Makoto Abe, University of Tokyo, Japan

ABSTRACT

This paper provides managerial guidance on the factors that might prompt cognitive dissonance using actual e-commerce panel data. This is achieved by translating cognitive and emotional antecedent factors found in previous research into observables through online data and constructing a hierarchical model to control individual heterogeneity and situational differences.

INTRODUCTION

Under fierce competition, e-commerce firms need to aim at increasing the average customer spending through cross-selling and up-selling. To increase the revenue per customer, many EC sites encourage their customers to purchase more products and/or more expensive goods through the use of a recommendation system. However, such purchases are often accompanied by cognitive dissonance in the mind of customers (Holloway, 1967). When this happens, consumers try to resolve the dissonance mainly by two means (Festinger, 1957). One way is to search for information that justifies their purchase decision (Rosenfeld et al., 1986), and the other is to return the purchased product. If the cognitive dissonance is not resolved, it can lead to the customer's dissatisfaction toward the product and the store (Montgomery and Barnes, 1993), generating negative word-of-mouth, or even stop shopping at the store altogether (Hunt, 1991). Therefore, finding a customer's action that might prompt cognitive dissonance is crucial to help companies to address cross-selling and up-selling effectively.

Current research into cognitive dissonance offer little guidance to identify a consumer's action forewarning its occurrence. Most studies are conducted through surveys or experiments in laboratories, providing limited applicability to the field setting of EC. When cross-selling and up-selling, EC sites need to know what kinds of shopping behavior and types of product might lead to the consumer's action forewarning the occurrence of cognitive dissonance, so that sellers can take preventive measures in advance.

In light of these gaps and concerns, we aimed to find the "precursor", the consumer's action that might prompt cognitive dissonance, and provide managerial guidance on capturing the presages and taking preventive actions in a novel way. Unlike most consumer behavior studies, we utilized field data, specifically actual access log and purchase data collected by an EC site, in the following manner. First, by observing a post purchase online behavior, we classified customer purchases into two categories: one with the precursor and one without. Second, we translated latent antecedent factors of cognitive dissonance that have been validated in previous studies, such as the customer's cognition and feelings, into observable shopping behaviors, product attributes, and customer characteristics. We then constructed statistical models to relate these factors to the precursor of cognitive dissonance.

This study contributes to the theoretical and practical knowledge of cognitive dissonance in two ways. First, we confirmed the antecedent factors of cognitive dissonance in a field setting. Previous research has relied mainly on survey studies because many of these factors are unobservable. Furthermore, their theory testing was conducted at the aggregate level by controlling individual differences in a laboratory setting. Such an approach permits the inclusion of few moderating variables that might affect the occurrence of cognitive dissonance. In contrast, we used panel data to analyze each customer at multiple points in time, accounting for not only situational differences but also individual differences in the occurrence of cognitive dissonance. We incorporated an idea proposed by Festinger (1957), that the occurrence and frequency of cognitive dissonance differ among customers and purchase occasions, into our model to confirm their validity. As far as we know, this is the first empirical study to address this heterogeneity issue. Second, we obtained insight into observable antecedent factors from access log data, which allows EC sites to take preventive actions so that customers do not experience cognitive dissonance.

CONCEPTUAL BACKGROUND

Among numerous empirical studies of cognitive dissonance, our research is related to investigation of its antecedent factors. The factors studied in previous research include choice difficulty (e.g., Menasco and Hawkins, 1978); emotional factors, such as anxiety about the act of the purchase itself (e.g., Hunt, 1970; Keng and Liao, 2013); confidence of the rightness of a purchase decision (e.g., Bell, 1967; Keng and Liao, 2013); and cognitive factors, such as needs for product knowledge (e.g., Sweeny et al., 2000). Some research has proposed methods to measure the strength of these antecedent factors in stimulating cognitive dissonance (e.g., Montgomery and Barnes, 1993; Sweeney et al., 2000).

MODEL SPECIFICATION

We constructed a statistical model that relates the precursor of cognitive dissonance to observable antecedent factors. The dependent variable in our model was a binary indicator of whether a post-purchase action presaging the occurrence of cognitive dissonance is observed or not. The post-purchase action will be explained in detail in the next section. The independent variables were the customer's shopping behaviors before purchase, attributes of the purchased products, and customer characteristics.

First, we applied a standard binary probit model to establish the relationship. Let y_{isp} denote the post-purchase action at p-th purchase in session s by customer i. With a latent variable z_{isp},

$$y_{isp} = I(z_{isp} > 0)$$

where $I(c)$ is an indicator function that returns 1 if condition c is satisfied and 0 otherwise. Given customer'shopping behaviors and product attributes x_{isp}, z_{isp} is

$$z_{isp} = x'_{isp}\beta + v_{isp}, \quad v_{isp} \sim N(0, 1)$$

where x_{isp} is a $(K + 1) \times 1$ vector composed of a constant term and K independent variables and β is a $(K + 1) \times 1$ parameter vector.

Next, to accommodate that the impact of customer's shopping behaviors and product attributes on the precursor of cognitive dissonance differs among customers, we relaxes the parameters to be customer-specific as β_i.

Finally, we tried to identify the factors that cause this customer difference with respect to his/her site usage characteristics. Customer-specific β_i is specified by a vector of moderating variables describing his/her site usage, d_i, as

$$\beta_i = Qd_i + n_i, \quad n_i \sim MNV(0, V_\beta)$$

where d_i is a $(M + 1) \times 1$ vector composed of a constant and M variables, and Q is a $(K + 1) \times (M + 1)$ parameter matrix (Rossi et al., 2005).

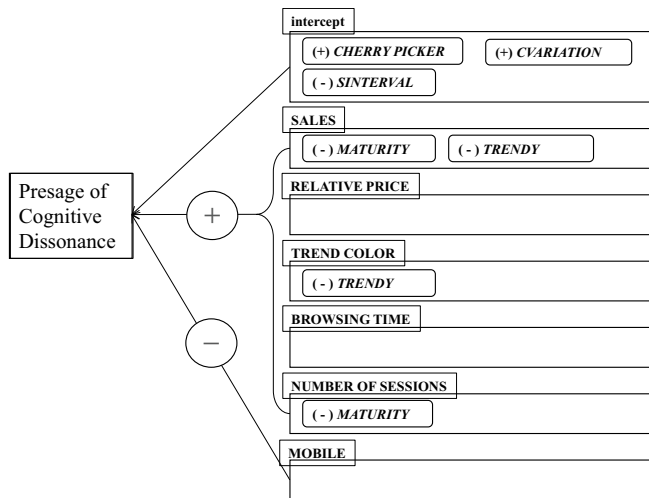
The first model, which assumes that all parameters are the same across customers, is referred to as the "base model." The second model, in which customer-specific parameters are estimated, is referred to as the "individual model." The third model, in which customer's site usage characteristics are hierarchically incorporated into their own parameters, is referred to as the "hierarchical model." The parameters in these three models were estimated using a Markov Chain Monte Carlo method. The model fits were then compared both in estimation and validation periods.


Figure 1: Estimation Result of the hierarchical model
* Moderating variables (in italics) are included only if significant at 90% or above credible level

EMPIRICAL STUDY

Data

We applied our models to actual business transaction data from an anonymous fashion EC portal site in Japan. The data included customer's access log data and purchase history from September 2011 to April 2013 (JASMAC, 2013). This fashion EC portal site contains over 500 stores on its platform and each store sells one or multiple brands. This category stimulates emotional buying, which is often accompanied by cognitive dissonance (e.g., Clover, 1950; Bellenger et al., 1978; Park et al., 2012). In addition, with numerous variations in color, material, design, style, and brand over a wide price range, choice difficulty may prompt the occurrence of cognitive dissonance (e.g., Menasco and Hawkins, 1978). It appeared that the data from this fashion EC site was ideal for our empirical analysis.

From the database, we selected active customers who had purchased more than 10 times at this EC site during this period and had been a site member for less than 10 years. We further limited the customers to those who had made both types of purchases, with and without the post-purchase action presaging cognitive dissonance, so that customer-specific parameters could be identified. This resulted in 255 customers. The first 90% of the sessions in the data were used for parameter estimation, and the last 10% were used for model validation.

Dependent Variable: Precursor of Cognitive Dissonance

Sweeney et al. (2000, p.374) stated "The concept of dissonance ... best fits the period that immediately follows the purchase decision but precedes use or experience with the result of the purchase decision." They conducted a survey of customers who were in a "gamma" phase (Oliver, 1997), that is, in the intervening period between a product purchase and its usage. Likewise, other prior studies that aimed to develop measurements of cognitive dissonance analyzed surveys that were conducted in the gamma phase or immediately following the purchase (e.g., Bell, 1967; Hunt, 1970; Menasco and Hawkins, 1978; Korgaonkar and Moschis, 1982).

Hence, in this study, we distinguished between purchases with the precursor of cognitive dissonance and normal purchases by observing an online behavior in the gamma phase. The EC portal site we analyzed starts a delivery process on the day of order, and customers cannot cancel their orders once the delivery process begins. Based on this business practice, we defined the gamma period for this online data as the duration from an order till the end of the session. When customers feel cognitive dissonance, they tend to explore information that justifies their decision-making after purchase (e.g., Rosenfeld et al., 1986; Hennig-Thurau and Walsh, 2003). In online shopping, this behavior corresponds to revisiting the product page after placing an order, for example, to view pictures of the product and/or read the product descriptions again. Hence, if a customer came back to the ordered product's webpage after purchase within the same session, we regarded this post-purchase action as the precursor of cognitive dissonance. The proportion of purchases with and without the post-purchase action was similar for the estimation and validation data, thereby providing validity to this criterion as the precursor to some extent.

Independent Variables

The independent variables consisted of shopping behaviors, product attributes, and customer characteristics, and were classified into two types. The first type varied from purchase to purchase, and directly affected the occurrence of cognitive dissonance. The second type was stationary (i.e., it did not vary by purchase occasion) and represented customer characteristics of online browsing and shopping behaviors at the EC site. In our study, the direct influence of the first type of independent variable on the precursor of cognitive dissonance was moderated by the second type of variables through hierarchical modeling.

Direct Variables

Previous studies found that the higher the purchase price, the more likely and serious the cognitive dissonance becomes (e.g., Kaish, 1967; Oshikawa, 1970; Sweeney et al., 2000). Perception of a purchase price is affected by the internal and external reference prices formed through product search and comparison (Kalyanaram and Winer, 1995). Hence, we constructed a variable that was a ratio of the price of a purchased product to the average price of the category to which the purchased product belonged, and we named it "RELATIVE PRICE." The average price of the category was calculated with regular prices in the product catalog provided by the EC portal site. Another price-related variable included was a dichotomous indicator of whether the purchased product was on sale or not, called "SALES." Several researchers have pointed out that sales promotions stimulate customers to purchase by providing an excuse to rationalize their decision (Beatty and Ferrell, 1998; Hoch and Loewenstein, 1991). This excuse might fade away once the order is placed, and the customer is unable to substantiate the purchase decision afterward. Consequently, we hypothesized that sales prompts the presage of cognitive dissonance.

The more difficult the purchase decision is, the more likely it is that cognitive dissonance occurs after the decision (Holloway, 1967; Montgomery and Barnes, 1993). Multitudes of alternatives spawn the anxiety of whether one made the right decision and fear of regret, thereby causing cognitive dissonance (Bell, 1967; Menasco and

Hawkins, 1978). As a proxy for the difficulty in choice, we used the "NUMBER OF BRANDS" for the category in the EC store where a customer made his/her purchase.

Consumer's higher self-confidence about the purchase decision makes the occurrence of cognitive dissonance less likely (Bell, 1967; Montgomery and Barnes, 1993). We posited that the longer the elapsed time of a customer's product search and comparison in the shopping process, the lower the customer's self-confidence becomes, and thus the occurrence of cognitive dissonance is more likely. Here, we included two independent variables. One was "BROWSING TIME" that represented how long a customer browsed a product during the session in which the purchase occurred. Another was the "NUMBER OF SESSIONS," which was a logarithm of the number of sessions in which a customer had viewed the same product before the purchase session. We expected that both browsing time and number of sessions would be positively related to the precursor of cognitive dissonance.

Park et al. (2012) showed that sensory attributes, such as the color, textile, and design of apparel products, trigger emotional buying, which tends to cause cognitive dissonance afterward. We focused on product color as a sensory attribute (Rowley 2001) in our study, and created a binary variable, "TREND COLOR," representing whether the color of the purchased product is a trend color of the year or not. In order to define trend color, we referred to the "Color of the Year" presented by Pantone LLC and set it to 1 if the color of the purchased product corresponded to the color of the year and 0 otherwise. We expected trend color to prompt the precursor.

Ozok and Wei (2010) found that, people prefer using PC over mobile devices in online shopping, because PC's larger physical interfaces make information retrieval and entry easier. Hence, mobile devices are used more for accomplishing specific purchase tasks, whereas PC is used more for casual browsing, which could lead to emotional purchases with cognitive dissonance. Furthermore, the fact that mobile devices are relatively unsuitable for longtime browsing means their users are less likely to exhibit returned visits after purchase. We constructed "MOBILE" variable, using 1 if accessing via a mobile device and 0 if accessing via PC. We expected mobile to exhibit a negative sign.

Columns 2 to 4 of the table summarize our hypotheses and interpretations about the expected signs of the parameters for the seven independent variables.

Moderating Variables

We now describe the independent variables that indirectly affect the presage of cognitive dissonance. These moderating variables depict customer's site usage characteristics and do not vary from purchase to purchase. The variable "MATURITY" was used to represent the number of days since a customer registered as a member

Table 1

	Sign	Hypotheses	Reference	Base model estimate	Individual model mean	Individual model std. dev.	Maturity	Hierarchical Model Cherry Picker	Hierarchical Model Trendy	Hierarchical Model Covariation	Hierarchical Model Sinterval
intercept				-0.834**	-0.999	0.771	0.0658	0.1311*	0.068	0.1809**	-0.218**
SALES	+	If a purchased product is on sale, an excuse to rationalize the purchase tends to prompt the precursor of cognitive dissonance.	Kaish (1967), Oshikawa (1970), Montgomery and Barnes (1993), Sweeney et al. (2000)	0.090**	0.011	0.763	-0.253**	-0.0954	-0.157*	0.1081	-0.041
RELATIVE PRICE	+	If a relative price of a purchased product is expensive, its higher stake tends to prompt the precursor of cognitive dissonance.	Hoch and Loewenstein (1991), Beatty and Ferrell (1998)	0.104**	0.190	0.489	-0.002	-0.016	-0.044	0.0075	-0.006

* Significant in 90% credible interval

of the EC portal site as of the last day in the data. The variable "SINTERVAL" was used to represent the average store-visit interval for the EC site. The variable "CVARIATION" was a ratio of the number of colors that a customer purchased divided by the total number of purchased products. If the colors of the purchased products were all different, CVARIATION equaled 1.

Next, two variables were related to customer's online shopping behaviors. Arnold and Reynolds (2003) studied hedonic browsing, which is a type of browsing that seeks entertainment, pleasure, and recreational values. They tried to link six motivations to hedonic browsing. We adapted two of the six motivations, which were value shopping and idea shopping, from the access log data. Value shopping is a shopping behavior for the purpose of bargain-hunting. In this EC site, most brands usually conduct a sales promotion in January and July every year. We regarded the two-month periods centering on January and July as sale periods and calculated "CHERRY PICKER" to indicate the fraction of visits during the sales over the entire period. We regarded CHERRY PICKER as a proxy for value shopping tendency.

Idea shopping, on the other hand, is a shopping behavior based on consumer's desire to be familiar with the latest fashion. In this EC site, new products are launched in early March, June, September, and December. We considered the one-month periods centering on these four time points as new product launch periods. We calculated "TRENDY," which indicated the fraction of visits during a new product launch over the entire period. Hence, we regarded TRENDY as a proxy for a customer's idea shopping tendency.

RESULTS

Column 5 of the table shows the estimated parameters in the base model. All estimates had the same signs as hypothesized. The precursor of cognitive dissonance was prompted if the product was on sale, was the trend color, and was expensive. Furthermore, if the browsing time of a product was long (i.e., high browsing time) or a customer browsed the same product many times before purchase (i.e., number of sessions is large), these shopping behaviors tended to cause the presage. The estimate for mobile was negative as expected. The estimate for number of brands was positive, potentially suggesting a positive relationship between choice difficulty and the presage of cognitive dissonance. However, because it was not significant in the 95% credible interval, we excluded number of brands from the subsequent models.

Bottom two rows of the table show the goodness of fit for the three models in this study. First, all indices of the goodness of fit for the individual model were superior to the ones for the base model in both estimation and validation periods. This result indicates that the impact of independent variables on the precursor of cognitive dissonance widely differs among customers, suggesting the importance of accounting for customer heterogeneity. Next, the goodness of fit for the individual and hierarchical models was close to each other in both the estimation and validation periods, which implies that variations in parameters β_i across users are explained well by the site usage characteristics included in the hierarchical model.

We next interpreted the estimates of the individual and hierarchical models in detail. Column 6 shows the basic statistics of the distributions of parameters β_i for each user in the individual model. The signs of the means of β_i were the same as the signs in the base model. The standard deviations differed by variable, suggesting a difference in the extent of the heterogeneity. In particular, the impact of sales, trend color, and mobile on the precursor of cognitive dissonance varied widely by customer. The distributions of relative price, browsing time, and number of sessions had relatively small

variations (i.e., standard deviations), implying moderate homogeneity among customers.

The hierarchical model explains the heterogeneity of the parameters by customer's site usage characteristics. Column 8 reports the estimate of matrix Q, mitigating effect of the moderating variables on the direct impact of product attributes and customer's shopping behaviors.

First, we looked into the relationship between the intercept (i.e., base tendency to prompt the precursor of cognitive dissonance) and the site usage characteristics. Customers who visited this EC site during a sale (CHERRY PICKER), who were likely to choose various colors (high CVARIATION), and who frequently visited this EC site (small SINTERVAL) were likely to presage the cognitive dissonance. In other words, sales promotions and sensory attributes, such as color, were likely to prompt the precursor of cognitive dissonance. The presage was not likely to arise for infrequent visitors because they tended to have specific purposes in mind to buy something and less emotional buying may occur.

Next, we examined the moderating variables (MATURITY and TRENDY), both of which were significant at over a 90% credible level on some variables. Customers may not presage cognitive dissonance if they are more experienced with the EC site (Olson and Dove, 1979; Tse et al., 1990). If customers are relative novices, their insufficient knowledge and uncertain expectations about the store might lead to less self-confidence about the purchase, which subsequently can prompt the precursor after the purchase. Column 7 shows that the MATURITY variable had a negative moderating impact on all direct factors, implying that the more mature customers become, the less the impact of their shopping behaviors and product attributes become. The sole exception was TREND COLOR, but the result was not significant. In particular, the moderating effects of MATURITY on sale purchases (SALES) and multiple viewing of the product prior to purchase (NUMBER OF SESSIONS) were significant at the 90% credible level.

A similar interpretation applies to the TRENDY variable. Customers who visited this EC site frequently during a new product launch period were knowledgeable and experienced so that the direct effects could be moderated. Column 7 shows that TRENDY also had a negative moderating impact on all of the direct factors that cause a customer to presage the occurrence of cognitive dissonance. Specifically, the moderating effects of TRENDY on sale purchases (SALES) and trend color purchases (TREND COLOR) were significant at the 90% credible level.

CONCLUSIONS

This paper aimed to identify the precursor of cognitive dissonance, confirm its relationship with antecedent factors found in the previous studies, and provide managerial guidance on the observable factors that prompt it. Previous studies indicated that the occurrence of cognitive dissonance differed among customers and purchase occasions. However, they have not yet proven it. In order to substantiate the validity, we utilized longitudinal data of customer's purchases at multiple points in time to address customer heterogeneity in the individual model, and incorporated moderating variables in the hierarchical model. In addition to this novelty, we offered some managerial implications that were actionable by EC sites by translating the cognitive and emotional factors used in previous studies into shopping behaviors, product attributes, and customer characteristics, all of which are observable through online data.

The results confirmed many of the findings of previous studies. The precursor of cognitive dissonance is more likely to be prompted (1) if purchase decisions are more difficult to make, (2) for prod-

ucts with higher price, (3) for products that are on sale, and (4) for emotional purchases that are associated with sensory attributes. The impact of the last two factors, as well as the use of mobile devices, on the presage of cognitive dissonance varies widely by customer. This heterogeneity is partly explained by how much experience customers have with the EC site. In particular, the effect of shopping behaviors and product attributes that prompt the precursor of cognitive dissonance can be moderated for experienced customers.

There is a limitation in this research. Customers, under cognitive dissonance, might seek information outside of the EC site to justify their decisions. Thus, one potential extension is to consider customers' behavior on other websites as well as in the offline environment, for example, by combining survey data.

Competitive Papers—Extended Abstracts

Effects of Meritocratic Beliefs on Consumer Expectations for Unearned Preferential Rewards

Jungyun Kang, Sungkyunkwan University, Korea
Sunghee Jun, Seoul National University, Korea
Kiwan Park, Seoul National University, Korea
Hakkyun Kim, Sungkyunkwan University, Korea

EXTENDED ABSTRACT

These days, companies frequently employ unearned preferential rewards through a variety of ways such as lottery scratch-offs or roulette games to induce customer interest and to attract their attention. The target of earned preferential rewards is determined by customers' efforts or loyalty. On the contrary, in the case of unearned preferential rewards, how the target is determined is uncertain or has not been justified (Jiang, Hoegg, and Dahl 2013). Prior research on preferential rewards has focused mainly on earned preferential rewards; as a result, there exists little research on unearned preferential rewards, despite its common usage. Thus, we concentrate on the effect of unearned preferential rewards and propose that customers' reactions to unearned preferential rewards depend on their meritocratic beliefs.

Meritocracy, which is the prevalent principle in Western culture, is a belief that the hierarchical social status is determined by an individual's merits (Foster, Sloto, and Ruby 2006; Major et al. 2007; McCoy and Major 2007). Individuals who endorse this belief justify inequality in society because they view members of higher status groups as more talented or hardworking than those of lower status groups. Drawing on prior research, we suggest that people who endorse meritocratic beliefs expect to win in unearned preferential reward contexts when they spend more (vs. less) money. In other words, we predict that meritocratic people consider the amount of money they spend as their merit, and that they think they deserve unearned preferential rewards.

Study 1 was designed to test whether meritocratic people were more likely to expect a higher probability of winning an unearned preferential reward when they spent more (vs. less) money. Participants were asked to imagine that they received a lottery scratch-off ticket after purchasing $120 or $1.20. They were also told that the average purchase amount per customer was $20. After reading the scenario, they rated their probability of winning the lottery scratch-off ticket on a seven-point scale (1 = very low; 7 = very high). Finally, we measured participants' meritocratic beliefs (e.g., *I feel that people get what they are entitled to have*; Lipkus 1991). Results showed that the interaction between meritocratic beliefs and the purchase amount was significant. Participants with high meritocratic beliefs were more likely to expect a higher (lower) probability of winning the lottery when they were asked to imagine that they had purchased $120 ($1.20). In contrast, in the case of participants with low meritocratic beliefs, the effect of the purchase amount on the expected probabilities disappeared.

In Study 2, we manipulated participants' meritocratic beliefs by using a scrambled sentence task (McCoy and Major 2006). Thus, Study 2 employed a 2 (Prime: Meritocracy vs. Control) × 2 (Purchase Amount: $120 vs. $1.20) between-subjects design. We asked participants to imagine a situation in which they received a lottery scratch-off ticket, the same as that in Study 1. The results replicated those of Study 1. When participants in the meritocracy condition imagined that they had purchased $120, they expected a higher chance of winning the lottery than when they had purchased only

$1.20. In contrast, in the control condition, the purchase amount did not influence participants' desired probabilities.

The purpose of Study 3 was to investigate whether meritocratic consumers, who paid a high amount, formed negative attitudes toward a shop when they failed to get unearned preferential rewards. We performed a 2 (Meritocracy Manipulation: Meritocracy vs. Control) × 2 (Purchase Amount: $2,500 vs. $25) ANOVA on intentions to revisit the shop. In the losing ticket context, we found that meritocratic people were unwilling to revisit a store when they spent a high amount, whereas revisit intentions of non-meritocratic people were not affected by the amount they spent.

Finally, Study 4 was conducted at a nail care shop to improve our research's validity. Consumers were invited to fill out a consumer survey, including the amount they paid, the expected probability of winning the lucky event, and their meritocratic beliefs. As expected, the results replicate our previous studies and show that meritocratic people perceive themselves as deserving unearned preferential rewards when they spend high amounts in an actual service purchase context.

Taken together, these results demonstrate that people with meritocratic beliefs tend to apply the merit principle, even when preferential rewards are not based on clear criteria. Our findings contribute to understanding how customers react to unearned preferential rewards.

Customer Empathetic Responses toward Brands Being Treated Unfairly

Thomas Allard, Nanyang Technological University, Singapore
Lea Dunn, University of Washington, USA
Katherine White, University of British Columbia, Canada

EXTENDED ABSTRACT

The consensus within word-of-mouth (WOM) literature is that negative reviews lead to lower brand ratings and positive reviews lead to higher brand ratings (e.g., Chevalier and Mayzlin 2006; Fornell and Westbrook 1984). Recent research, however, has begun to cast doubt on this general assumption and showed that nuances *within* the reviews themselves moderate the effect of review valence on consumer reactions (Chen and Lurie 2013; Hamilton et al. 2014). The current research extends this literature and postulates that inferences about the perceived unfairness of WOM communication can have ironic positive implications for consumer evaluations of the reviewed brand. Specifically, we show that negative-unfair reviews can lead to more positive consumer responses than even positive WOM because of consumers heightened feelings of empathy toward the brand.

While the rich literature on fairness in consumer behavior has focused on the consumers' own experience of fairness during a service encounter, the current research examines the impact on consumer choices of perceived fairness for a third party. We define perceived fairness as the perception that the review was honest and impartial, free from self-interest or prejudice (Brockner et al. 2003) and hypothesize that perceptions of unfairness activate empathetic concerns for the brand under review.

Empathy is a vicarious response to the assumed emotions of another (Eisenberg 1991; Eisenberg and Miller 1987) which often arises as a response to the suffering of others (e.g., Jackson, Meltzoff, and Decety 2005). Pertinent to the research at hand, empathy activates moral concern for other people (Batson et al. 2007), often under conditions where the target has been perceived to have been wronged in some way (i.e., some standard of fairness or justice has been violated; Hoffman 2001). This concern for others being wronged was shown to motivate the restoration of fairness, either by compensating the victim or by punishing the wrong-doer (e.g., Batson et al. 2007; Carlsmith, Darley, and Robinson 2002; Darley and Pittman 2003). Given that brands can be viewed as people (Aaker 1997; Fournier 1998).We build on work showing that empathy will lead to positive and helpful responses to other *people* who have been wronged in some way, to propose that the same might be true of *brands*.

The current research suggests that when negative WOM about a brand is perceived to be unfair, this enhances empathetic concerns for the brand and results in positive consumer responses, such as higher willingness to pay, likelihood to recommend, and willingness to patronize. We demonstrate this basic effect and explore empathy as its underlying mechanism through the mediation of state empathy (S1) and moderation by trait empathy (S2). In addition, we demonstrate how managerial intervention can increase the likelihood of such empathetic responses (S3).

Study 1 demonstrates the effect of perceived fairness in WOM on positive consumer response and provides mediational evidence that feelings empathy underlie this effect. Participants were asked to read a review for a local restaurant that mentioned the same type of enjoyment over a "tasty full meal breakfast" with coffee for a total of $12. In the negative review conditions, the reviewer also mentioned being "robbed" by how much was charged for the coffee. In the negative-fair condition, the reviewer complained that the coffee within the $12 combo was $4.50. In the negative-unfair condition,

the reviewer complained that the coffee was $0.50. Thus, in the negative-unfair condition, the manipulation revolved around complaining about a good deal. Participants were asked to rate their level of empathy toward the brand, patronage intentions, and perceptions of review fairness. We found that negative-unfair WOM ($M = 4.80$) leads to higher patronage intentions than both the negative-fair ($M = 3.24$) and, more importantly, the positive WOM ($M = 4.04$) conditions (Overall: ($F(2, 179) = 25.98$, $p < .001$). Empathy towards the brand mediates the results.

Study 2 explores the mechanism of empathy by measuring trait empathy and showing that only participants who are predisposed to feel empathy (moderate to high on trait empathy; 31th percentile or higher), the difference in patronage intentions was significant between a negative-fair and negative-unfair review (Interaction: B = -1.33, SE = .46, $t(117) = 2.47$, $p = .01$).

Finally, in Study 3, we demonstrate how brands can enhance empathetic relationships with the consumers by taking steps to make the brand more relatable and person-like. Building off of work on how brands can be perceived as humanlike, we found that for those who were exposed a personlike brand response (vs. generic), willingness to purchase was higher ($F(1,234) = 8.93$, $p < .01$). Once again, empathy towards the brand mediates the results.

Overall, the results provide converging evidence that when consumers perceive negative WOM about a brand as unfair this leads to positive brand responses (e.g., higher WTP). This effect is due to enhanced empathy for the brand (S1 and S3), moderated by trait empathy (S2), and can be magnified through managerial interventions (S3).

This paper contributes to growing literature examining consumer inferences regarding online WOM (e.g., Moore 2015) by showing that when negative WOM is seen as unfair, this can ironically enhance brand evaluations. Thus, the current research offers two primary theoretical contributions. First, our results build on and extend past research showing that cues within WOM can influence consumer judgments about the brand by bringing to light the role of (un)fairness.

Second, while research has reported numerous instances of consumers being concerned about brands feeling empathy for them (e.g., Parasuraman, Zeithaml, and Berry 1988), we suggest that such relationship may be bi-directional wherein consumers can also experience empathy for brands. The current research suggests an empathy-driven mechanism whereby negative WOM triggers positive brand responses, even in light of negative information about the brand. Thus, we contribute to extant knowledge on empathetic reactions in consumption (e.g., Aaker and Williams 1998; Argo, Zhu, and Dahl 2008). In doing so, we highlight that companies can enhance empathetic relationships with consumers and inoculate themselves against negative WOM.

The consensus within word-of-mouth (WOM) literature is that negative reviews lead to lower brand ratings, and positive reviews lead to higher brand ratings (e.g., Chevalier and Mayzlin 2006; Fornell and Westbrook 1984). The current research highlights conditions under which this commonly observed effect does not emerge and even reverses. Building on research showing that cues within consumer reviews can influence consumers' attributions about the responsibility for the service failure (Chen and Lurie 2013; Hamil-

ton, Vohs, and McGill 2014), we suggest that negative reviews perceived as unfair can trigger feelings of empathy for the brand being wronged which, ironically, result in higher liking and patronage intentions. Importantly, we show that these higher liking and patronage intentions exceed those that result from a positive review. We argue that empathy for the brand acts as the mechanism of this effect.

This research makes several contributions to the existing literature. First, we provide initial evidence that consumer perception of unfairness in WOM can subsequently trigger positive evaluations and behavioral intentions toward the brand. Second, we provide support for an empathy mechanism by showing how these effects are magnified under conditions where the consumer can empathize with the brand. Third, we extend previous literature on consumer-brand relationships (Aaker 1997; Aggarwal 2004; Fournier 1998) by demonstrating that our effects occur because consumers can experience empathy for brands.

THEORETICAL DEVELOPMENT

Due to the inherent trust that consumers place in WOM, reviews have been shown to impact dramatically responses to companies and brands, including increased willingness to pay (Houser and Wooders 2006) and product sales (Chevalier and Mayzlin 2006; Liu 2006). The consensus is that positive reviews lead to higher product sales by enhancing positive attitudes and expectations regarding the brand, while negative reviews lower brand evaluations and intentions (e.g., Chevalier and Mayzlin 2006; Godes and Mayzlin 2004; Liu 2006; Sonnier, McAlister, and Rutz 2011; Zhu and Zhang 2010).

Research has begun to cast doubt on the general assumption that positive and negative reviews always lead respectively to positive and negative outcomes for the brand. Cues in the reviews can change outcomes. For example, Chen and Lurie (2013) found cues within the review—temporal contiguity markers (i.e., cues suggesting that the review was published soon after the service encounter)—increase the persuasiveness of reviews because they lead people to attribute the positive review to the product experience, not the reviewer's personal motives. Moreover, Hamilton et al. (2014) found that using dispreferred markers aimed at softening the negative information featured in reviews (e.g., "I'll be honest,") leads to reviewers being seen as more credible and resulted in higher willingness to pay for the product being reviewed.

All in all, extant research demonstrates that inferences about the reviews can moderate the effect of review valence on consumer reactions. We suggest that one of those factors influencing judgments is perceived fairness. While previous work on fairness in consumer behavior has typically focused on how the consumer's own experience is directly impacted by the service treatment (Brockner et al. 2003), our operationalization is that perceived fairness comes not from the consumer's own service experience, but from the cues that cast doubt on the veracity and self-interested nature of the WOM communication. We postulate that unfair negative reviews signal that the brand is being wronged. Thus, we expect inferences about the unfair nature of negative reviews to lead consumers to experience empathy for the brand, enhancing brand evaluation.

The Role of Empathetic Responding

Empathy is a vicarious response to the assumed emotions of another (Eisenberg 1991; Eisenberg and Miller 1987) which often arises as a response to the suffering of others (e.g., Jackson, Meltzoff, and Decety 2005). Empathetic processing involves viewing another person's situation from their perspective and understanding how a person will react emotionally and cognitively to that situation as if it were affecting them directly (Granzin and Olsen 1991). Empathy has

been shown to be an individual trait difference (Davis 1980) as well as arising from contextual cues.

Within the realms of positive psychology and marketing, empathy has been shown to activate moral concern for other people (Batson et al. 2007), often under conditions where the target has been perceived to have been wronged in some way (i.e., some a standard of fairness or justice has been violated; Hoffman 2001). This sensitivity to moral outcomes for others has been shown to be a powerful source of motivation to restore fairness, either by compensating the victim or by punishing the wrong-doer (e.g., Batson et al. 2007; Carlsmith, Darley, and Robinson 2002; Darley and Pittman 2003).

We build on work showing that empathy will lead to positive and helpful responses to other *people* who have been wronged in some way, to propose that the same might be true of *brands*. Indeed, brands can be seen as having person-like qualities (Aaker 1997; Fournier 1998). While previous work has shown numerous instances of how brands show empathy for consumers (e.g., Keller 1993; Parasuraman et al. 1988), we propose that customers might also feel empathy for brands. We propose the perception that a negative review is unfair will activate empathetic concern toward the brand, which will then trigger consumer responses aimed at compensating that brand (e.g., willingness to pay, likelihood to recommend, patronage intentions). More formally, we predict:

Hypothesis 1:   *Negative WOM (e.g., reviews) perceived as unfair will lead to positive ratings and behaviors toward the brand.*

Also, we anticipate that feelings of empathy toward the brand will mediate these positive consumer responses to unfair WOM.

Hypothesis 2:   *Feelings of empathy will mediate the relationship between perceptions of unfairness in negative WOM and positive consumer responses toward the brand.*

Finally, given that our conceptual framework, we further predict heightened positive responses to unfair negative WOM under conditions that enhance or allow for the ability to empathize with the brand. For instance, under a predisposition for empathy and following managerial interventions aimed at making the brand more personable.

Hypothesis 3:   *Factors that increase empathic responding will moderate the effect of WOM unfairness on consumer responses. In particular, increases in the ability to empathize with the brand will lead to more positive reactions in the face of an underserved negative WOM.*

We test the aforementioned hypotheses in three experimental studies. In Study 1, we show the basic effect that unfair negative WOM lead to positive consumer response as well as the mediational role of empathy. Study 2 provides moderation evidence of empathy. Finally, Study 3 shows how managerial actions can facilitate positive response.

STUDY 1

Study 1 provides an initial test of our framework suggesting that unfair negative WOM can lead to even more positive consumer responses than positive WOM. We employed a one-factor, 3-level (WOM type: positive v. negative – fair v. negative – unfair) between-subjects design. Perceived fairness was manipulated through an on-

line review of a local restaurant. We keep all elements of the review the same but vary coffee price across conditions to highlight perceptions of a good or bad deal for the coffee (e.g., price partitioning; Bertini and Wathieu 2008). Specifically, the negative review contained a complaint about a seemingly bad deal (fair condition) or a good deal (unfair condition).

Method

Participants and Design

One hundred eighty-two participants recruited through Amazon Mechanical Turk took part in this experiment in exchange for money (44% female, M_{age} = 32.7). The dependent variable of interest was patronage intentions toward the restaurant covered in the review.

Procedure

Participants experienced one of three conditions where they were asked to imagine reading an online review for a local brunch restaurant. Service delivery was kept constant across conditions by having each review describe enjoyment over a "tasty full meal breakfast" with coffee for a total of $12 and by showing the same brunch picture. However, in both negative conditions, the review also contained a negative comment about the price of coffee within the $12 combo. In the negative-fair review, the meal and the coffee were priced at $7.50 and $4.50 respectively. In the negative-unfair review, both items were priced at $11.50 and $0.50 respectively. For mediation purposes, participants rated the extent to which they experienced feelings of empathy toward the restaurant (sympathy, empathy, compassion; 9-point scale, α =.97). Participants rated the extent to which, if they were looking for a brunch in a near future, they would consider the restaurant described in the review using two bi-polar 7-point scales: "unlikely-likely," "improbable-probable" (α = .98). To validate our fairness manipulation, participants also rated the extent to which they perceived the review to be fair (fair, deserved, justified, reasonable; 7-point scale α = .97).

Manipulation Check

Results from an ANOVA revealed a significant main effect of review type on perceived fairness (F (2, 179) = 60.67, p < .001) validated our fairness manipulation.

Results

For empathy toward the brand, results revealed a significant effect of review type (F(2, 179) = 25.98, p < .001). Empathy toward the brand was higher in the negative-unfair (M = 5.68, SD = 2.37) compared to the positive (M = 3.27, SD = 2.05; t(179) = 6.28, p < .001) and the negative-fair conditions (M = 3.16, SD = 1.97; t(179) = 6.30, p < .001). There was also no difference in the extent to which participants experienced empathy toward the brand in the negative-fair compared to the positive WOM condition (t < 1).

For patronage intention, results revealed a significant effect of review type on patronage intentions (F(2, 179) = 10.76, p < .001). Importantly, patronage intentions were higher in the negative-unfair (M = 4.80, SD = 1.69) compared to the positive (M = 4.04, SD = 1.97; t(179) = 2.33, p < .05) and the negative-fair conditions (M = 3.24, SD = 1.67; t(179) = 4.63, p < .001). As expected, patronage intentions were higher in the positive compared to the negative-fair condition (t (179) = 2.48, p =.01).

Next, we tested whether reported feelings of empathy toward the brand could explain patronage intentions using a dummy coding for a multi-categorical mediation analysis (Hayes and Preacher 2013). Results revealed that heightened feelings of empathy toward the brand in the negative-unfair WOM conditions could explain the

difference in patronage intentions between the negative-unfair and the negative-fair condition (B = 1.02, SE = .22, CI$_{95}$ [.65, 1.54]) and between the negative-unfair and the positive condition (B = .97, SE = .21, CI$_{95}$ [.62, 1.43]). In comparison, empathy for toward brand does not account for the difference in patronage intentions between the positive and negative-fair WOM conditions (B = .04, SE = .15, CI$_{95}$ [-.25, .32]).

Discussion

Study 1 provides initial evidence for both the basic effect and mediational role of empathy. Interestingly, Study 1 suggests that such empathetic responses can be even more positive than those following exposure to positive WOM. Study 2 provides additional support for our explanation relying on empathy by showing how individual differences in trait empathy moderate this relationship.

STUDY 2

In study 2, we measure trait empathy and test whether it moderates the positive consumer responses following exposure to unfair negative WOM. We predict that individuals who have a higher predisposition to empathize with others will be more sensitive to the unfairness of the negative review. This is because those high in trait empathy are more sensitive to the negative circumstances of others (Davis 1996; Loggia, Mogil, and Bushnell 2008).

Method

Participants and Design

One twenty-two participants recruited through an undergraduate subject pool took part in this experiment in exchange for course credit (69% female, M_{age} = 19.9). The experiment was a 2 (WOM type: negative-fair vs. negative-unfair) X continuous (trait empathy) between-participants design. The dependent variable of interest was patronage intentions toward the restaurant covered in the review.

Procedure

Participants experienced one of two conditions where they read an online review for a local restaurant. In both negative review conditions, the customer complained about having to wait for the replacement of a bowl of soup that was served too cold. In the negative-fair condition, the customer had to wait "30 long minutes" for replacement. In the negative-unfair condition, the customer had to wait "5 long minutes" for replacement. Participants rated the fairness of the WOM (α = .97) and their patronage intentions to the restaurant in a near future (α = .98) using the same measures as in the previous study. To test for moderation, we measured participants trait empathy using the 7-item Empathetic Concerns scale (α = .78) from Davis (1980; e.g., When I see someone being taken advantage of, I feel kind of protective toward them).

Manipulation Check

Participants perceived the negative-unfair (M = 2.93, SD = 1.43) as less fair compared to the negative-fair review (M = 4.53, SD = 1.34; t(119) = 6.39, p < .001) supporting our WOM fairness manipulation.

Results

Results revealed a significant two-way interaction between WOM type and trait empathy in predicting patronage intentions (B = -1.33, SE = .46, t(117) = 2.47, p = .01, CI$_{95}$ [.24, 1.85]). This interaction was qualified by a main effect of WOM type (B = 3.45, SE = 1.71, t(117) = 2.02, p < .05, CI$_{95}$ [.07, 6.84]) and of trait empathy (B = .98, SE = .37, t (117) = 2.66, p = .01, CI$_{95}$ [.25, 1.71]). Next, we used to the Johnson-Neyman technique to examine where along the

continuum of trait empathy participants started to express empathetic responses toward the brand. Results revealed that for participants who scored at 3.51 or above on the empathy scale (31th percentile), the difference between the negative-fair and negative-unfair review on patronage intentions was significant.

Discussion

Results from Study 2 provide additional support for our key prediction that negative reviews can trigger positive consumer responses when they are perceived as unfair. Importantly, our results suggest that such effect starts to operate even among those low in trait empathy but is magnified among those high on trait empathy.

STUDY 3

Study 3 was designed to show how the type of managerial response to negative WOM can increase empathetic concerns for the brand. Since people are more likely to engage with a person rather than an amorphous logo (Epley, Waytz, and Cacioppo 2007) and brands can be perceived as holding humanlike traits and have intentions (Aaker 1997; Kervyn, Fiske, and Malone 2012), we suggest that brands can evoke greater empathy by responding with a personable (v.generic) type of communication (i.e., by speaking as a firm employee instead of as the brand itself), leading to higher consumer willingness to pay for the brand's product.

Method

Participants and Design

Seventy-seven participants recruited through Amazon Mechanical Turk participated in this experiment in exchange for money (43% female, M_{age} = 33.1). The experiment was a 2 (response type: generic vs. personable) X perceived fairness of the negative review (continuous) between-participants design. The dependent variable of interest was willingness to pay for the brand's product.

Procedure

All participants were first asked to read a negative online review about a failed order from a brand selling reusable water bottles. The negative review was purposefully crafted to appear weakly supported by having the customer voice dissatisfaction with the brand's inability to meet an exceptionally high level of service quality. The review was presented with the brand's response prompting a follow-up with the customer. In the generic (personable) response condition, the response came from the brand's corporate account (an employee) and directed the consumer to a customer service (employee direct) phone number for further inquiries.

Participants answered measures of perceived fairness of the negative review on two seven-point bipolar items "unreasonable-reasonable" and "not deserved at all-very deserved" (α = .88) and state empathy toward the brand using the same measures as in previous studies (α = .97). Participants were then shown a featured product from the brand (a 24 oz. stainless steel water bottle) and asked to report their willingness to pay for that product—using a slider scale ranging from $0.00 to $20.00. Response type did not significantly influence perception of deservingness of the negative review (r = .14, p > .20). Finally, as a manipulation check, participants also rated the extent to which they perceived the brand to have positive anthropomorphic qualities between the personable (M = 6.56, SD = 1.89) and generic response (M = 5.58, SD = 1.70; t (75) = 2.40, p < .05) conditions, using four 9-point items: "personable," "approachable," "amicable," and "friendly;" 1: not at all, 9: very much (α = .95).

Results

The results revealed a significant interaction between perceived fairness of the negative review and response type on willingness to pay (B = -1.40, SE = .53, t(73) = 2.61, p = .01). For participants who rated the negative review at 1.99 or below on the perceived deservingness scale (14th percentile), willingness to pay for the product was significantly higher in the personable response type compared to the generic response type. In contrast and although not foreshadowed in our predictions, for participants who scored at 5.82 on the perceived fairness scale (87th percentile), willingness to pay for the product was significantly higher in the generic response compared to personable response type.

Conditional Indirect Effect

We further tested for mediation by feelings of empathy toward the brand conditional on how perceived fairness of the negative review. We observed a significant indirect effect between response type and willingness to pay through empathy when participants perceived the negative review as unfair (-1 SD: B = 1.12, SE = 0.70, CI_{95} [0.11, 2.92]) but not when perceived as fair (+1 SD: B = -0.03, SE = 0.28, CI_{95} [-0.85, 0.32]). In other words, consumers who perceived the negative review as unfair were subsequently willing to pay more for the brand's product when the brand's response was personable compare to a generic-type response due to heightened feelings of empathy toward the brand.

Discussion

Study 3 provides further evidence to support our empathy-driven account for the relationship between unfair negative reviews and positive consumer responses. In particular, when the brand seemed more relatable and person-like, this led to greater empathy toward the brand and more positive responses in response to unfair (vs. fair) negative reviews.

GENERAL DISCUSSION

Taken together, the results across three studies provide converging evidence that consumers perceiving negative WOMC as unfair can subsequently display positive responses toward the firm due to empathetic feelings toward the brand. Across three studies, we show that perceptions of unfairness result in positive brand outcomes. We show that this is due to enhanced empathy for the brand (S1), moderated by trait empathy (S2), and can be achieved through managerial interventions (S3)

This paper contributes to growing literature examining consumer inferences regarding online WOM (e.g., Chen and Lurie 2013; Moore 2015). While previous work has, for the most part, focused on identifying the conditions under which negative WOM leads to negative reactions, we show that consumers' perceptions of fairness of negative reviews can enhance brand evaluations. Thus, the current research offers two primary theoretical contributions. First, our results build on and extend past research showing that cues within WOM can subsequently influence consumer judgments about the brand (e.g., Chen and Lurie 2013; Hamilton et al. 2014; McGraw, Warren, and Kan 2015) by bringing to light the role of (un)fairness.

Second, while research has reported numerous instances of consumers being concerned about brands feeling empathy for them (e.g., Parasuraman et al. 1988), we suggest that such relationship may be bi-directional wherein consumers can also experience empathy for brands. Specifically, the current research suggests an empathy-driven mechanism whereby negative WOM triggers positive brand responses, even in light of negative information about the brand. Thus, we contribute to extant knowledge on empathetic reactions in consumption (e.g., Aaker and Williams 1998; Argo et al. 2008; Escalas and Stern 2003). In doing so, we highlight that companies

can enhance empathetic relationships with consumers and inoculate themselves against negative WOM.

When 2 + 1 is Less Than 3: Comparative Pricing Strategies for Premium Upgrades

Thomas Allard, Nanyang Technological University, Singapore
David J. Hardisty, University of British Columbia, Canada
Dale Griffin, University of British Columbia, Canada

EXTENDED ABSTRACT

Using both field and laboratory studies we show that consumers selecting between vertically differentiated products (i.e., between a standard and a premium—objectively better, but more expensive—version) are more likely to select premium options when premium prices are quoted as the cost of upgrade rather than the total price of the premium option. Specifically, we show that Comparative Pricing (CP) strategies make premium options appear less expensive than objectively identical All-Inclusive Pricing (AIP) due to the smaller numbers used in the price difference representation.

From fuel surcharges to required printer ink cartridges, managers have long used various approaches separating the total cost of products into various mandatory components, to reduce price sensitivity and increase demand, by making the total purchase price less transparent, increasing reliance on the base price (Morwitz, Greenleaf, and Johnson 1998). The current research builds on and extends the research on price partitioning to the context of voluntary upgrades, by introducing the notion of CP. By highlighting the price difference between vertically differentiated products, CP will lead consumers to anchor their value judgments on the highlighted trade-off between a particular feature improvement and the price of that improvement. As such, because the difference in price will always be a smaller numeral than the total price of the premium option, we expect CP to increase the proportion of consumers selecting a premium option by making such an option appear relatively less expensive. In other words, we expect consumers facing price information using CP to undergo a process akin to saying "it's not $120, it's only $20 more [than $100]," lead to more upselling under such conditions.

In Study 1 we partnered with a local food bank, using a between-participants design (CP vs. all-inclusive pricing). We set-up a booth advertising for a food bank donation at the heart of a busy Student Union building. A research assistant spoke the following instructions to passing students (N=81): "Did you know that a bag of nutritious food for a person in need costs about $10 to fill completely? Thinking about students' budgets, we have two levels of suggested donation. The Basic food pack is $4 or, if you want to donate more, the Helper food pack is [$6/$2 more]." Depending on the price framing condition, this more generous option was offered for either "$6" in the all-inclusive-pricing (AIP) condition or for "$2 more" in the CP condition. A significantly higher proportion of people selected the premium donation tier (i.e., Helper food pack) in the CP condition (P=69%) compared to the AIP condition (P=39%; $\chi2$=5.78, p<.05).

Study 2 provides evidence that CP makes the premium option seem cheaper than AIC, and proposes a moderator to reverse the effect. If quoting the sales price using CP leads to increased choice of the premium option because consumers perceive the premium option as cheaper, we should observe the opposite effect when the participant acts as a seller and receives an offer using a CP frame because the offer price in the CP frame will appear cheaper and thus undesirable to the seller. This experiment uses a 2 (framing: CP vs. AIP) X 2 (transaction domain: buyer vs. seller) between-participants design.

Participants (N=221) read a scenario about a buyer-seller interaction for a used bicycle sold through classified ads. Participants took either the role of the buyer or the seller. In the buyer [seller] scenario, they had shown interest in purchasing one of two second-hand bicycles a seller had put up for sale [a buyer had shown interest in purchasing one of two second-hand bicycles they had put up for sale]. One bicycle, the premium product, was superior because of better gear options (21-speed vs. 3-speed model) and better parts (brand-name parts vs. generic parts). In the AIP condition, the seller [buyer] was offering to sell [purchase] either the regular bicycle for $150 or the premium bicycle for $210. In the CP condition, the price of the premium bicycle was framed as "for $60 more". Participants selected which of the two bicycles they would purchase [sell] and rated the expensiveness of the premium option (1-7 item).

In the buyer condition, participants in the CP condition were more likely to purchase the premium bicycle (P=70%) than those in the AIP condition (P=50%). In the seller condition, we observed a significant reversal where participants in the CP condition were less likely to sell the premium bicycle (P=26%) than those in the AIP condition (P=46%; interaction (B=1.69, SE=.57, Z=2.91, p<.01). Consistent with our prediction, perceived expensiveness mediated the effect.

In Study 3, we examine how heuristic processing (measured by response time) magnifies the upselling effect following CP (as opposed to heuristic processing for Price Partitioning). Participants (N=219) were instructed to imagine themselves shopping for a plane ticket from New York to Los Angeles and shown two different flight options. One of the two flights was cheaper at $169.00 but took longer to reach the destination because of a connection through San Francisco. The other flight was direct. Participants could select this premium flight for either "$219.00" (AIP condition) or "$50.00 more" (CP condition).

Those who made quicker, and presumably more heuristic, decisions (5.8 seconds: 1SD below the mean), were more likely to choose the premium option in the CP (P=60%) than in the AIP condition (P=31%). In contrast, those who made slower, and presumably more systematic decisions (35.5 seconds: 1SD above the mean), showed no significant difference between the CP (P=62%) and AIP conditions (P=63%); interaction B=-.88, SE=.43, Z=2.06, p<.05.

Study 3 supports our account that comparative pricing increases preference for premium options because participants focus their value assessment on the price difference, not the total price. Consistent with this theorizing, the CP framing leads faster, hence more heuristic decision-makers to select more premium choices than the AIP framing. However, this difference between CP and AIP framing disappeared for participants who spend a longer time on their choice, because those in the AIP condition are more likely to extract the price difference, replicating the effect of the CP manipulation.

Guilt trips: Transportation and the Persuasiveness of Guilt Appeals

Paolo Antonetti, Queen Mary University of London, UK
Paul Baines, Cranfield University, UK

EXTENDED ABSTRACT

In three longitudinal experiments, we test a model proposing narrative transportation as a determinant of guilt appeal effectiveness. Eliciting guilt favors immersion in the communication and this process facilitates compliance. We examine guilt appeals' longitudinal effectiveness (in a recycling promotion context) and show that 1) the persuasiveness of guilt appeals is mediated by narrative transportation, and 2) their effect is stronger when the message is delivered through video rather than text.

Three days after exposure to a guilt appeal, participants were recontacted. In study 1 and study 2, participants were allocated to one of two conditions (high guilt versus low guilt). Study 3 has a 2 (guilt: high versus low) X 2 (medium: video versus text) design and tests the role of media on the longitudinal effects of transportation. A chain of causal links that connects guilt elicited at time one, as a consequence of seeing the campaign, with the individual likelihood to anticipate guilt at time two is proposed. It is further hypothesized that the ability to anticipate guilt at time two will drive compliance. A thorough assessment of guilt messages require the examination of these indirect paths and their effects on persuasion (Antonetti & Baines, 2015; Antonetti, Baines, & Walker, 2015). Narrative transportation in the campaign (Green & Brock, 2000; Phillips & McQuarrie, 2010) is a key mediator linking reactions at time one with the potential outcomes at time two.

In study 1 and 2 participants are asked their intentions to recycle (Knussen and Yuke, 2008). In study 3 we measure self-reported recycling behavior "over the last few days" (Webb, Mohr, and Harris, 2008). We also ask whether participants would be willing to share their personal email address in order to receive "more information on the campaign and other steps you might take to promote recycling in your local community." The dichotomous answer (Yes/No) is treated as a further dependent variable.

At time one the guilt appeal influences 1) guilt felt by participants and 2) narrative transportation. However, the manipulation does not influence directly the other variables. A mediation analysis using PROCESS (Hayes, 2013; Model, 6) allows testing for the indirect effects predicted. We calculate 95% confidence intervals using bias-corrected and accelerated bootstraps and 10,000 resamples (Hayes, 2013). Results are consistent with our expectations. The indirect effect is in line with our theorizing. For study 3, we estimate the model using also the dichotomous dependent variable measuring decisions to share the email. Results show a positive indirect effect through narrative transportation (effect: .06, CI from .02 to .13). The model offers a Nagelkerke R^2 of 11%.

The role of the medium used to communicate the message moderates the impact of narrative transportation on self-reported behavior. At time one, the medium used to deliver the message does not interact with the guilt appeal condition (PROCESS, Model 1) neither in the prediction of experienced feelings of guilt (effect: .003, p = .97, CI from -.17 to .17) nor on the level of narrative transportation (effect: -.05, p = .36, CI from -.16 to .06). To assess whether the medium used has an effect consistent with our model, we test for a possible interaction on the dependent variable at time two (PROCESS, Model 14). The model yields a positive interaction between medium and narrative transportation (effect: .15, p < .05, CI from .03 to .26). While the impact of narrative transportation is very weak when the message is delivered through text (effect: .05, CI from .001 to .08), it

is significantly stronger when the communication is through a video (effect: .12, CI from .07 to .18).

Data from study 3 is used to conduct a path analysis using a PLS-SEM approach (Hair, Ringle, and Sarstedt, 2011; Henseler et al., 2014). Results of model estimation using SmartPLS 3.0 and 5000 re-samples for bootstraps are in line with our predictions. Guilt experienced as an outcome of watching the ad leads to narrative transportation (β = .23, t = 3.96, p < .001, f^2 = .23) and transportation influences the anticipation of guilt at time two (β = .45, t = 8.88, p < .001, f^2 = .26). Anticipated guilt contributes to explaining recycling behavior (β = .31, t = 5.21, p < .001, f^2 = .09). We find that guilt experienced after watching the video at time one has a small negative direct effect on self-reported recycling at time two (β = -.26, t = 4.82, p < .001, f^2 = .03). Finally, the effect of transportation on behavior is not statistically significant (β = .10, t = 1.54, p = .11). The indirect effect of guilt experienced after watching the appeal on the behavior measured at time two is positive (β = .11, t = 3.51, p < .001, R^2 for the model 16%) supporting our theoretical expectations.

A multi-group analysis indicates the paths between anticipated guilt and behavior (p = .04) and between narrative transportation and anticipated guilt (p = .06) are different between the two media (the latter marginally). The group seeing the video shows stronger paths between transportation and anticipated guilt (β_{video} = .54 vs. β_{text} = .39) and between anticipated guilt and behavior (β_{video} = .42 vs. β_{text} = .21).

While some are skeptical about guilt appeals (Graton et al., 2016; O'Keefe, 2002) others advocate their use (Agrawal and Duhachek, 2010; Han et al., 2014). The model presented offers an alternative account. Our study indicates guilt appeals have weak effects and can backfire. However, they have a positive indirect effect and facilitate individual tendency to immerse in the message and anticipate feelings of guilt; a powerful source of self-regulation (O'Keefe, 2002). This raises two implications. Firstly, to understand the effectiveness of guilt appeals under different conditions it is necessary to explicitly hypothesize the different paths that might cause persuasion (or resistance) under different circumstances (Hayes, 2009). Secondly, marketers should use guilt cautiously and more research is needed before the explicit use of guilt in marketing messages is implemented.

Dimorphous Expressions Inform Consumers of Users' Motivational Orientations

Oriana R. Aragón, Clemson University, USA

EXTENDED ABSTRACT

Product messaging that provides information about the emotional experience associated with a product is particularly important when the emotional experience is part and parcel to the product's value (Holbrook & Hirschman, 1982). Therefore, emotional expressions displayed by users in advertising campaigns or reviews might be particularly relevant in communicating the emotional experience associated with products, and subsequently, the value of said products to prospective buyers.

Normatively, expressions of emotion are monomorphous, that is, one expression broadly represents one category of emotion (e.g., smiles represent happiness, Eckman & Friesen, 1971). Sometimes however, expressions are dimorphous (Aragón, 2016; Aragón & Bargh, 2016; Aragón & Clark, 2016; Aragón, Clark, Dyer, & Bargh, 2015), that is, two alternating or scrambled expressions represent and communicate one category of emotion (e.g., "tears of joy," both smiles and tears represent happiness). For examples of dimorphous expressions, some people smile when sad (Frederickson & Levenson, 1998), smile when embarrassed (Ambadar, Cohn, & Reed, 2009), display aggression when tender (Aragón, et al., 2015), cry when happy (Fernández-Dols & Ruiz-Belda, 1995), and aggress when triumphant or adventurous (Aragón & Bargh, 2016).

In dimorphous expressions, the incongruent emotional expressions (e.g., aggressive shouts or tears when happy) represent *and* communicate both the expressers' emotional experiences and motivational orientations. Research by Aragón and Bargh (2016) found that happiness expressed through both smiles and aggression (fist pumping, yelling, showing of teeth, loud vocalizations) represented and communicated appetitive orientations, i.e., "feelings of wanting to go," "to move," and "to accelerate." In contrast happiness expressed with both smiles and sad displays (tears, crumpled body posture), represented and communicated consummatory orientations, i.e., "feelings of wanting to pause," "to stop," and "to rest."

Multiple conceptually overlapping theories converged on these activation-type dimensions to the experience of emotion (e.g., Bradley & Lang, 1994; Feldman Barrett, 1998; Frijda, Kuipers, & Terschure, 1989; Russell, 2003). Cultural and individual differences factor into the expression of, and value given to, emotions based upon these dimensions (Mogilner, Kamvar, & Aaker, 2010; Tsai, Knutson, & Fung, 2006). Moreover, these activation-type dimensions are effective predictors of consumer preferences and consumption (Alba & Williams, 2013; Nenkov & Scott, 2014).

Participants were provided with dimorphous or monomorphous expressions in online reviews for a vacation resort. Hypotheses were as follows:

Hypothesis 1: *Shouts versus tears of joy would transmit differential messages about reviewers' emotional-motivational experiences and subsequent preferences for vacations, over and above what a smile communicates.*

Hypothesis 2: *The fit between emotional expressions (shouts versus tears of joy), inferences of motivational orientations (appetitive versus consummatory) and inherent product qualities (action or relaxation packages) will align for participants' own desires and this alignment will increase subjective product values.*

In Study 1 (N = 200, MTurk) participants read a review of a luxury resort vacation in which the emotion was expressed as: "so happy I smiled", "so happy I yelled, yes!" and "so happy I cried." When happiness was expressed through yelling "yes!" participants inferred the reviewer was in an appetitive state and preferred an action package. In contrast, when participants read happiness expressed through crying, participants inferred the reviewer was in a consummatory state and preferred a relaxation package.

Study 2 (*N* = 284, MTurk) replicated Study 1 with additional questions into participants' own desires for similar emotional experiences and subsequent value placed on products. This investigation also probed present versus future focus. Here highlighted are findings from present-focus, meaning participants' desires and judgments in the moment. Cry condition participants inferred consummatory states for the reviewer, subsequently wanted that same consummatory experience in the relaxation package over the action package, and placed a higher value on the relaxation package than the action package. In contrast participants in the yell-yes condition inferred appetitive states for the reviewer, subsequently wanted that same appetitive experience in the action package over the relaxation package, and placed a higher value on the action package than the relaxation package.

When happiness was presented with yelling "yes!" participants inferred that the reviewer was in an appetitive state and preferred an action package. In contrast when happiness was presented with tears of joy, participants inferred that the reviewer was in a consummatory state and would prefer a relaxation package. Participants not only took the expressions provided by the reviewer to infer the reviewer's emotional-motivational state and preferences, but also participants aligned their own desires for appetitive and consummatory experiences with action and relaxation vacation packages respectively. Products that aligned with these emotional-motivational states were subsequently given higher values.

Attainment Goals and Maintenance Goals:
The Appeal of Approach Versus Avoidance Framed Strategies

Gizem Atav, James Madison University, USA
Kalpesh K. Desai, University of Missouri-Kansas City, USA

EXTENDED ABSTRACT

Self-regulation research suggests that different strategies become more appealing at different stages of goal pursuit (e.g. Huang and Zhang, 2013). Despite important findings on how strategy selection can improve motivation however, our understanding of this phenomenon thus far is primarily concerned with goal *attainment*. Yet, goal attainers and maintainers approach their self-regulation goals differently, leading to important behavioral outcomes (Jiraporn and Desai 2010). Given the high rates of relapse during maintenance, our research explores how motivation can be improved through appropriate strategy selection during maintenance as well as attainment stages of a savings goal. Additionally, while past research has examined the influence of different goal pursuit strategies, our research investigates the role of framing the same strategies as either approach (e.g. cook your meals at home) or avoidance (e.g. avoid eating out). In doing so, the primary questions that we explore are: Could a reason for relapse in maintenance be that after attaining a goal, the adopted strategies lose their appeal? Can reframing these strategies boost motivation and improve self-regulation? To answer these questions, we focus on the role of different emotions, and particularly pride, in creating a divergence among the appeal of approach and avoidance strategic frames for goal attainers and maintainers. We argue that maintainers, because they experience more pride, will refuse to be restricted through avoidance strategies and find approach-framed strategies more appealing.

Across 5 experiments we manipulate goal type through a scenario telling respondents that their savings were either at (maintenance condition) or below (attainment condition) the recommended level. Strategy framing was manipulated through a recommended list of either approach (e.g. cook your own meals more frequently) or avoidance (e.g. do not eat out frequently) framed strategies.

In Study 1 (n=65 MTurk participants), subjects read a scenario prompting them to think about maintaining their savings at 10% of monthly income, followed by the strategy framing manipulation. Results showed that respondents found approach-framed strategies more appealing than avoidance-framed strategies $(F(1, 61) = 6.58, p<.05)$, were more likely to adopt them $(F(1, 61) = 6.57, p<.05)$, and were willing to use them for a longer time $(F(1, 61) = 3.88, p=.05)$.

Study 2 (n=87 MTurk participants) explored results from Study 1 at higher savings goals (20% of monthly income) and provided a preliminary analysis of the level of pride among goal maintainers. Following the maintenance scenario, respondents reported their likelihood to adopt the suggested strategies and completed the four-item pride scale ($\alpha= .96$). Maintainers were more likely to adopt approach than avoidance-framed strategies $(F(1, 85) = 3.45, p=.06)$ and their level of pride was significantly higher than the midpoint $(t = 7.58, p< .001)$.

Study 3 (*n*=85 students), compared the appeal of approach and avoidance-framed strategies among goal maintainers and attainers. Results showed a significant interaction between goal type and strategy framing on the appeal of the strategies $(F(1, 81) = 4.99, p<.05)$ and respondents' likelihood to use them for a long time $(F(1, 81) = 8.77, p<.01)$. Maintainers found approach framed strategies more appealing and were more likely to use them for a long time than avoidance framed strategies (all *p*s < .01).

Study 4 (*n*=113 MTurk participants) was conducted to test if the insignificant results in Study 3 were due to the student sample. Similar to Study 3, we found a significant interaction between goal type and strategy framing on likelihood to adopt the suggested strategies $(F(1, 109) = 7.28, p<.01)$ and the length of time they would be willing to use them $(F(1, 109) = 6.99, p<.01)$. Maintainers were more likely to adopt approach than avoidance $(p=.08)$ while attainers were more likely to adopt avoidance than approach framed strategies $(p<.05)$. Similarly, maintainers were willing to use approach framed strategies for a longer time than avoidance framed strategies $(p=.05)$ whereas attainers were willing to use avoidance framed strategies for a longer time than approach framed strategies $(p=.08)$.

Study 5 (*n*= 117 MTurk participants) explored whether pride was underlying the effects found in Study 4. Results revealed that maintainers experienced higher pride than attainers $(p<.001)$. We also found a significant interaction between goal type and strategy framing on likelihood to adopt the suggested strategies $(p<.05)$. Attainers were more likely to adopt avoidance than approach $(p<.01)$ framed strategies. While maintainers were directionally more likely to adopt approach than avoidance framed strategies, this effect was not significant. We found support for our hypothesized moderated mediation such that the effect of goal type on one's likelihood to adopt a strategy through pride depends on the framing of the strategy (Hayes, 2013; model 14). Conditional indirect effects showed that for approach strategies, the indirect effect of goal type on likelihood to adopt the strategy is significant (conditional indirect effect = .55. 95% CI = .23 to .96).

Results from five studies show that goal maintainers and attainers differ in their inclinations towards approach and avoidance framed strategies. Results from the moderated mediation analyses suggest that differences in level of pride may explain why attainers and maintainers differ in their inclinations towards approach framed strategies. Our findings contribute to research in self-regulation by investigating how level of pride and strategic inclinations may be different in the attainment and maintenance stages of goal pursuit. They also offer a practical solution on how motivation may be retained during the maintenance stage of goal pursuit.

On Self-Construal and Lie Acceptability:
Culture and Consumer Responses Toward Deceptive Advertising

So Hyun Bae, Hong Kong Baptist University, Hong Kong
Xiaoyan Liu, Southwestern University of Finance and Economics, China
Sharon Ng, Nanyang Technological University, Singapore

EXTENDED ABSTRACT

In March 2016, Volkswagen was sued by the US Federal Trade Commission (FTC) for deceptive advertising. The FTC alleged that Volkswagen deceived consumers by manipulating the emissions test results and falsely claimed that its cars were low-emission and environmentally friendly. Since the scandal first came to light in 2015, sales of Volkswagen automobile have sharply decreased in United States (7%), United Kingdom (14%), and France (3%). Interestingly, however, the fraud does not seem to have affected Volkswagen's sales in many Asian countries. In fact, despite the company's disgrace in other parts of the world, its sales increased in China by 3.6% and chalked up considerable gains in South Korea. Such an ironic turn of events raises an important question: why consumers in some countries reacted very differently to Volkswagen's deceptive advertising from those in other countries?

Consumers expose to deceptive advertising, or "advertising intended to mislead consumers by falsely making claims, by failure to make full disclosure, or by both (AMA)," almost every day. However, research to understand consumers' reactions toward it is still limited (e.g., Gaeth and Heath 1987; Tipton, Bharadwaj and Robertson 2009). The current research aims to examine how culture, self-construal in particular, influences consumers' acceptance of and responses toward deceptive advertising. Specifically, we propose that consumers with independent (vs. interdepend) self-construal are less likely to accept and respond more negatively to deceptive advertising. Prior research on culture and lie in interpersonal relationship has provided relevant evidence for our theorization. For instance, Aune and Waters (1994) showed that people high in individualism are less likely to accept lies. Similarly, van Hemert et al. (2002) revealed a significant negative correlation between individualism and attitude toward lie across 23 countries. In addition, Mazar and Aggarwal (2011) found that individualistic culture showed more negative attitude immoral behavior than collectivistic culture.

One possible explanation for the cross-cultural difference in lie acceptability is variation in people's attribution tendencies. Prior research has demonstrated that people in independent culture are more likely to attribute human behavior to their dispositions, such as personality, character and capability; whereas people in interdependent culture are more likely to believe that human behavior is regulated by the interaction of dispositional and situational factors (Choi et al. 1999). In other words, compared to interdependents, independents will view deceptive advertising as less acceptable because they tend to believe the falsifying or omitting information in advertisement is triggered solely by the advertisers' personal traits. In contrast, interdependents tend to believe such behavior is influenced not only by advertiser's dispositions, but more importantly the external factors (e.g., social norms). To sum up, we propose:

Hypothesis 1:   Compared to interdependents, independents are less likely to accept deceptive advertising.

Hypothesis 2:   Internal attribution mediates the impact of self-construal on deceptive advertising acceptability.

Four studies have been conducted to test our theorization. Study 1 aims to test the impact of self-construal on lie acceptability in general. 79 US participants and 80 Indian participants recruited from Mturk attended this study. Participants were invited to answer the lie acceptability scale (Oliveira and Levine 2008) embedded in a personality survey. As expected, results showed that US participants were lower in lie acceptability than Indian ones (M_{Indian} = 4.40, M_{US} = 3.59; $F(1, 157)$ = 24.75; $p < .01$). Regression analysis further revealed a negative impact of nationality (dummy coded; 0 = Indian, 1 = US) on lie acceptability (β = -.81, t = -4.98, $p < .01$).

The objective of study 2a is to test H1. A total of 237 Chinese participants were recruited for this study. Participants were either told that one of their friends informed buyers the faulty screen (honest ad condition) or did not mention it (deceptive ad condition) when selling his used notebook online. After reporting their attitude toward and their acceptance of the deceptive ad, participants completed the Singelis' (1994) self-construal scale. Regression analysis revealed a significant interaction between self-construal and ad type (β = .78, t = 2.59, $p = .01$), with independents reported more negative attitude to the deceptive ad ($M_{independents}$ = 5.70, $M_{interdependents}$ = 4.74; $p < .01$), while no difference was found in the honest ad condition ($M_{independents}$ = 2.67, $M_{interdependents}$ = 2.71; $p > .1$). Furthermore, independents reported lower level of deceptive ad acceptability ($M_{independents}$ = 2.52, $M_{interdependents}$ = 3.31; $p < .01$) in the deceptive ad condition but not in the honest ad condition ($M_{independents}$ = 4.13, $M_{interdependents}$ = 3.96; $p > .1$). Study 2b (N = 146) replicated the findings of study 2a by manipulating individual level self-construal based on Brewer and Gardner's (1996) work.

Study 3 aims to provide evidence for H2. A total of 244 participants from a Singaporean university completed this study. Participants first completed the same self-construal priming task used in study 2b. Then, participants read a deceptive ad about a food company that over-reported ingredients of its products. Participants' attitude toward and acceptance of such deceptive advertising were measured. Next, the extent to which participants internally attributed the deceptive advertising to the company's traits was measured. As expected, independents perceived the deceptive ad as more negative ($M_{independents}$ = 4.12, $M_{interdependents}$ = 3.76; $p = .01$) and less acceptable ($M_{independents}$ = 2.80, $M_{interdependents}$ = 3.15; $p = .06$), and were more likely to attribute the deception to the firm ($M_{independents}$ = 5.63, $M_{interdependents}$ = 5.40; $p = .03$). Bootstrapping analysis showed the "self-construal → internal attribution → deceptive ad acceptability" mediation was significant (Mediated effect = .10, SE = .05, 95% CI = .01 ~ .22). Thus, H2 was supported.

To sum up, the current research provides converging evidence that independents (vs. interdependents) were less likely to accept deceptive advertising, which was mediated by their tendency to make internal attribution. This research contributes to the currently limited research on lie acceptability and deceptive advertising. Further, it expands existing cross-cultural research by showing that culture not only impacts individual engagement in deception but also their attitude toward deception and deceptive marketing practices. In addition, as more product frauds have been disclosed nowadays, findings of our current research will also provide valuable insights for marketers

By the Grace of Brands: The Role of Brand Leadership in the Process of Restoring Control

Joshua T. Beck, University of Oregon, USA
Alexander Bleier, Boston College, USA
Ryan Rahinel, University of Cincinnati, USA

EXTENDED ABSTRACT

The world can sometimes appear chaotic. When it does, individuals try gaining control via two primary pathways. The first, *personal agency*, involves self-reliant goal pursuit, whereas the second, *external agency*, involves relying on powerful others to gain a sense of control (Landau, Kay, and Whitson 2015). This latter path explains why lack of control increases endorsement of dominant gods and governments that seem able to influence personal outcomes (Kay et al. 2008; Kay et al. 2010; Laurin, Kay, and Moscovitch 2008). In the present investigation, we explore whether and how brands can provide external agency to consumers who feel control is lost.

Past research has demonstrated that lack of control increases desire for particular product attributes. This research has focused on the personal agency route to control restoration and found that lack of control increases pursuit of products that serve as useful tools rather than easy solutions (Cutright and Samper 2014; Shepherd et al. 2011). We compliment this research by considering how brand attributes may facilitate control restoration via external agency.

Ostensibly, brands may appear to lack the qualities of known external agents. After all, brands' abilities to influence outcomes in a free economy are considerably limited, and consumers should not attribute specific brands with similar powers to that of a ruling government or controlling god. Or should they? Strikingly, our research finds just that: leading brands are more greatly endorsed by consumers under conditions of low personal control. Evidence from four controlled experiments indicates that despite the inability of brands to directly structure the world or influence personal outcomes, low-control consumers imbue leading brands with a heightened ability to provide order. This motivated belief subsequently leads to more positive evaluations and greater purchase intentions for leading brands when personal control is low. A field study supports these findings. Across counties of the United States, higher crime rates, as proxies for consumers' lowered control (Geis and Ross 1998), predict increased purchase intentions, word of mouth, and use for brands higher in leadership. Notably, this effect is specific to brand leadership and not conceptually similar constructs such as familiarity.

Evidence from five studies supports our theorizing. Study 1 revealed that temporary reductions in personal control significantly increased likelihood of choosing a gift card redeemable for a brand leader (vs. non-leader). Study 2 provided a conceptual replication: low (vs. high control or a baseline condition) increased attitude toward a fictitious brand framed as a leader (vs. non-leader). Studies 3 and 4 provided insight into the underlying mechanism. The effect of low control on brand leader endorsement was mediated by motivated beliefs that brand leaders provision order (study 3). Furthermore, reducing the perceived influence of a brand leader attenuated this mediation (study 4), indicating that order-provisioning beliefs are predicated on the plausibility that brand leaders might wield influence in the world. Finally, study 5 highlighted the real-world implications of our theorizing using a national sample of U.S. consumers. Rather than manipulate personal control, in this study we examined crime as an environmental factor that correlates with lower feelings of personal control (Geis and Ross 1998). We merged data on crime rates of counties across the U.S. with consumers' ratings of actual brands and employed a multilevel random effects model to examine whether consumers in areas with higher crime were more likely to endorse brand leaders. As expected, we found a significant crime × leadership interaction that, when decomposed, revealed a significant positive effect of crime level on purchase intentions, brand usage, and word-of-mouth intentions when brand leadership was high (vs. low). An estimation of average purchase intentions for brands across counties illustrated the considerable differences in the extent to which consumers in areas with differing crime rates seek out brand leaders. These findings provide important insights for managers to better allocate their marketing efforts across promising target markets.

Overall, our research contributes to a better understanding of brands and personal control in two important ways. First, we show that a certain type of brands—leaders—can act as external agents of indirect control who are imbued with an ability to provide control to consumers who lack it. Second, we reveal important consequences of industry leadership. Research has documented how and why benefits accrue to brands with industry influence (e.g., Palmatier et al. 2006; Shapiro and Varian 1999). We take a consumer-centric perspective and pinpoint specific circumstances (i.e., low control) under which individuals confer benefits to brand leaders and find them increasingly desirable. We therefore provide fresh insight into ways brand leadership can self-perpetuate.

Marketing, Get Ready to Rumble: Why Consumers Appreciate Brand Rivalries

Johannes Berendt, German Sport University, Germany
Sebastian Uhrich, German Sport University, Germany

EXTENDED ABSTRACT

Previous research has focused on the dark sides of brand rivalry. It has been labeled as destructive competition (Vogler 1994) with negative consequences such as consumer schadenfreude, outgroup derogation and hostility (Ewing, Wagstaff, and Powell 2013; Hickman and Ward 2007; Phillips-Melancon and Dalakas 2014). Therefore, most brands stay away from public conflict—a missed opportunity, because ingroups need strong outgroups to define themselves against (Fournier and Lee 2009). Sociologists have long maintained that conflict comes along with certain benefits (Simmel 1996), and people develop a positive self-concept by showing who they are and what they consume as well as by showing who they are not and what they do not consume (Bhattacharya and Elsbach 2002; Muniz and Hamer 2001). Yet the extant literature emphasizes the identity-damaging aspects of rivalry. We develop and empirically assess a model that uncovers the positive effects of brand rivalry on consumers' self-concept.

The concept of rivalry has only recently captured researchers' attention. Kilduff, Elfenbein, and Staw (2010) conceptualize rivalry as a special competitive relationship that is subjective and exists primarily in people's minds. Rooted in social identity theory, scholars agree that rivalry includes a certain element of threat. Tyler and Cobbs (2015, 230) define a rival as a "highly salient outgroup that poses an acute threat to the identity of the ingroup." Noting that not all outgroups are equal, White and Dahl (2007) confirm that dissociative reference groups can pose an identity threat to consumers. However, an identity threat is not restricted to negative consequences. We provide theoretical and empirical evidence that brand rivalries boost consumers' identities, as expressed by increases in perceived group distinctiveness, group cohesion and public collective self-esteem. We propose three mediating variables. While identification with the favorite brand and disidentification from the rival brand are derived from the intergroup relations literature, we introduce a mediating variable that is specific to rivalry: the perceived reciprocity of brand rivalry.

To test our model, we conducted three studies in three different consumption settings (team sports [N = 748], smartphones [N = 253], cars [N = 230]). The independent variable assessed the perceived intensity of a rivalry between two brands. It was measured with the single-item "How intense do you think is the rivalry between your favorite [soccer team / smartphone brand / car brand] and its [archrival]" on a 10-point scale (1 = not very intense, 10 = very intense). All other constructs used multi-item 7-point rating scales (1 = do not agree, 7 = strongly agree). Statistical testing ensured convergent and discriminant validity, and common method variance was not deemed a problem.

Across the three studies, the model displayed a very good fit to the data, explaining a significant proportion of the variation in the scores for perceived group distinctiveness, perceived group cohesion, and public collective self-esteem. In all studies, perceptions of brand rivalry intensity exerted a positive and significant total effect on perceived group distinctiveness (study 1: $b = .29$, $p < .001$; study 2: $b = .52$, $p < .001$; study 3: $b = .20$, $p < .01$) and public collective self-esteem ($b = .11$, $p < .05$; $b = .34$, $p < .001$; $b = .14$, $p < .05$). Perceptions of brand rivalry intensity also exerted a positive and significant total effect on perceived ingroup cohesion in studies 1 ($b = .23$, $p < .001$) and 2 ($b = .45$, $p < .001$) but not in study 3 ($b = .10$, $p = .17$).

The results further showed that perceptions of brand rivalry intensity exerted a significant total indirect effect on consumers' self-concept. Via the three mediators, perceptions of brand rivalry intensity exerted a positive and significant total indirect effect on perceived group distinctiveness ($b = .26$, $p < .001$; $b = .43$, $p < .001$; $b = .15$, $p < .05$) and perceived group cohesion ($b = .22$, $p < .001$; $b = .38$, $p < .001$; $b = .13$, $p < .01$) in all three studies. Perceptions of brand rivalry intensity exerted a positive and significant indirect effect on public collective self-esteem in studies 1 ($b = .20$, $p < .001$) and 2 ($b = .28$, $p < .001$) but not in study 3 ($b = .05$, $p = .15$). Across the three studies, seven of the nine indirect relationships were mediated by brand identification and perceived reciprocity of brand rivalry, whereas rival brand disidentification mediated just one out of nine possible relationships. None of the direct effects of perceptions of brand rivalry intensity on the self-concept variables were significant, suggesting indirect-only mediation.

Contrary to previous research, the findings indicate that a brand rivalry is not restricted to negative outcomes. It assists consumers in building a positive self-concept and enhances their identities by increasing their perceived distinctiveness, perceived ingroup cohesion, and public collective self-esteem. Hence, this research contributes to a more balanced view of brand rivalries and provides empirical evidence for the notion that public conflict with competitors can have advantages.

It would be interesting to debate whether the benefits of rivalry, in line with the old saying that competition is good for everyone in the marketplace, could even prompt cooperation between competitors to create a perception that a rivalry is reciprocal, because this mediator is the key underlying mechanism that explains why rivalry enhances the self-concept. In a follow-up experimental study, we manipulated the perceived reciprocity of rivalry and detected a significant main effect on perceived group distinctiveness ($\eta^2 = .02$, $p < .05$) and group cohesion ($\eta^2 = .03$, $p < .01$). Rivalry is not a one-way street but seems to require back-and-forth exchanges between consumers.

Additional research is needed to explore the dual outcomes of rivalry, weighing the positive effects against the negative effects to get to the bottom of a construct that is ubiquitous yet has received little attention in either marketing or social psychology. Future research could also explore the effects on important downstream benefits (e.g., willingness to pay or brand preferences).

Theorising Gender, Theorising Fat: The Material-Semiotics of the Obesogenic Environment For Professional Women Weight-Cyclers

Shona Bettany, Liverpool John Moores University, UK
Ben Kerrane, Lancaster University, UK

EXTENDED ABSTRACT

Enduringly, Western cultures in late modernity have inextricably linked fat and the female body (Rail 2012). In her seminal feminist work, "fat is a feminist issue", Orbach (1978) posits that the cultural climate of pervasive gender inequality makes women fat. Drawing on Freudian theory, Orbach theorised that female obesity can be explained by an unconscious desire to resist gender inequality and sexism in contemporary society. She posits that fat, for women within a culture of sexism, carries benefits *vis a vis* the desexualisation of the body and the commensurate ability to become invisible as a sexual being, allowing women to become more visible to men as equals, colleagues and friends. However, despite this intervention, 35 years later, the prevailing cultural, medical and policy view today remains, located as it is within dominant neo-liberal discourses of choice and responsibility, that being fat is largely due to individual lifestyle and consumption failures. That is, fat remains an individual matter, rather than a cultural or environmental one.

Countering this, recently studies using the concept of the "*obesogenic environment*" (Townshend and Lake, 2009) have emerged, which present a more distributed, material-semiotic explanation of the emergence of fat bodies. The term "obesogenic environment", has emerged within urban studies and occupation health, and refers to "*an environment that promotes gaining weight and one that is not conducive to weight loss*" within the workplace or community (Swinburn, et al., 1999). In other words, the obesogenic environment refers to a physical environment that helps, or contributes to, obesity (Powell et al 200). Obesity, from this perspective, is not viewed as an individual responsibility, or due to failed individual consumption choices, but is viewed as a normal physiological response to an individual's interaction with their environment.

In the light of this, this paper seeks to revisit the relationship between fat, gender, consumption and the material environment, challenging this focus on individual responsibility by longitudinally studying the life histories of 2 professional women. Both women are categorised by extreme yo-yo dieting (or weight cycling) involving several life course weight loss/gain cycles of 50+ lb. Yo-Yo dieting or "weight cycling" (Friedman et al 1998) is seen as part of a pathological continuum of purge/binge cycles, with bulimia at the extreme end, characterised by a very short lived purge/binge cycle, with purging taking place on the very day of binging (Goncalves 2014). Yo-yo dieting, at the other end of the continuum, extends the time cycle with less extreme binging and purging (i.e. not involving vomiting, but dieting), and can encompass several years within one cycle. The specificity of yo-yo dieting allows an understanding of what might be seen, using an individualist framework, as sustained success at weight control and sustained failure at weight management, cycling within one individual over time, and as such, we suggest, can offer an interesting account of both states (i.e. quasi-sustained thinness and fatness), and also, of the associated transitions. This allows exploration of what happens to change states so dramatically and quasi-sustainably, and the commensurate lessons that can be learned by academics interested in consumption, marketing and health.

Professional women were selected due to the literature outlined above, firstly that fat is certainly gendered female, and impacts upon women in very specific ways, and secondly, that professional women work within a context where to be fat runs counter to a successful identity project, the role of female executive. Within the well documented, general cultural backdrop of dominant idealised norms of female thinness and self-control (Bordo 1993, Sawicki 1991) it seems that women in professional roles feel the pressure to conform even more keenly, and are especially subject to cultural norms re desirable thinness (Rodgers 2012). Research has shown weight gain affects women's chances for professional success (Haskins and Ransford 1999, Rothblum 2005), slimness is associated with professional women being in control, being effective, being a high achiever and having the necessary "executive presence" (Goudreau 2012). Growing numbers of high-achieving professional women have been reported to suffer from eating disorders in order to counter pressures to perform authentic professional role identities (Barnett 1986) and an enduring link between subscribing to the superwoman ideal and eating disorders has been made (Messinger et al 2007). Older women, a category into which high achieving, director level executive women are likely to fall, are increasingly becoming subject to intense pressure to conform to beauty norms, and look young for their age through surgery and weight control (Bordo 2003). Exacerbating this, as De Brun *et al* (2013) argue, professional women's participation in the workforce and higher levels of disposable income, with increased commuting times and often long working hours, creates lifestyles with related impacts on food choices and physical activities. In particular, increased demand for energy dense convenient foods and reduced physical activity are evident (McCarthy & Collins, 2008). Women, in general, have been noted to be more susceptible to comfort eating activities (Woodruffe 1997), and in often stressful professional roles, the consumption of comfort food has been found to be used as a coping mechanism (Tanofsky-Kraff et al., 2008) leading to positive calmness effects and encouraging further overeating of energy-dense foods, which are associated with weight gain (Adam & Epel, 2007). This behavioural response, which induces physiological changes, has been observed more often among high stress females (Tomiyama et al, 2011).

This paper then, seeks to develop a theoretical framework, based on a material-semiotic approach, to fat and femininity within the construction and maintenance of a professional female identity, that counters individualistic accounts of obesity and offers understanding of the consumption practices around the emergence of the body as obese within the obesogenic environment, which has the potential to inform both academic understandings of these processes, and also social and health-related marketing and consumption practitioners.

More Than Just the Money:
Psychological and Behavioral Consequences of Participating in Crowdfunding

Sally Bitterl, Vienna University of Economics and Business, AUT
Martin Schreier, Vienna University of Economics and Business, AUT

EXTENDED ABSTRACT

Pebble Time is a successful example of "reward-based crowdfunding". In 2012, the venture received a total of more than $10 million in funding from thousands of individuals on the crowdfunding platform Kickstarter in return for the promise of delivering the watch once it became available in marketable quality. Since then, the venture has grown into a sizable company with 130 employees. More generally, Kickstarter reports to have helped raise more than $2 billion for almost 100,000 projects crowdfunded by more than ten million individuals since its launch in 2009 (Kickstarter 2016). Across platforms, the worldwide volume of crowdfunding in 2015 is estimated at more than $34 billion (http://reports.crowdsourcing.org/). Crowdfunding has thus emerged as a potentially effective complement to standard financial intermediaries which seems to have broad appeal for money seekers and providers alike.

Only recently, the phenomenon's practical significance has also stimulated growing interest among researchers across disciplines. Mollick and Kuppuswamy (2014), for example, studied the longer-term implications of crowdfunding and discovered that more than 90 percent of the successfully funded projects on Kickstarter survived the first year after funding, with a third of them generating sizable revenues of more than $100,000 per year. At the same time, Agrawal, Catalini, and Goldfarb (2011) find that almost two thirds of the money-seeking ventures do not succeed in raising funds. Research has consequently started to look into antecedent factors of successful crowdfunding, including the dynamics and success factors of the crowdfunding process (Agrawal, et al. 2011; Burtch, Ghose, and Wattal 2015; Mollick 2014; Kuppuswamy and Bayus 2015) and the motivations of individual consumers to engage in crowdfunding in the first place (Boudreau et al. 2015; Gerber, Hui, and Kuo 2012; Ordanini et al. 2011).

In this research, we take a different approach and aim to contribute to the emerging crowdfunding literature by offering a first empirical exploration of the potential consequences of crowdfunding participation from a consumer behavior perspective. Specifically, we ask whether participating in a crowdfunding project, as opposed to merely buying the same underlying product in a classic market exchange setting, may bring about some unique psychological consequences among participating consumers.

A longitudinal field-type experiment investigated whether participating in a real crowdfunding project (i.e., an ice cream cabinet at the Library Café) increases the extent to which consumers can personally connect to and identify with the focal venture and if so, whether this may also affect a series of managerially important downstream variables captured up to several months after the initial interaction. Hence, we utilized a one-factor design (participation in crowdfunding vs. couponing). At time 1 participants in the treatment condition (n = 142) could use the €3 they had earned earlier to help crowdfund the ice cream cabinet. As a reward, participants would get a voucher worth three scoops of ice cream from the Library Café. In contrast, participants in the control condition (n = 150) were allowed to take part in a pre-sale coupon initiative of the Library Café. Specifically, participants could use their €3 to purchase a coupon which would give them three scoops of ice cream at a special price; as in the treatment condition, participants were informed that the regular price for three scoops of ice cream was €3.40. All participants learned that

they could pick up their reward/coupon in the lab at time 2 (i.e., approximately two weeks later), and as an outside option, they were offered the same alternative (Post-its) as in the treatment condition. All participants indicated their choices and personally dropped their €3 into one of two boxes ("Crowdfunding/Coupon – Ice Cream at the Library Café" or "Post-its"). Thus, apart from the focal treatment the two conditions were identical. The money collected was then actually used to acquire the ice cream cabinet. Between two and three weeks later (time 2) those who opted in at time 1 in both conditions received an ice cream loyalty card, which contained their voucher stickers and some additional stickers to buy more ice cream if they wanted to (at the regular price). Unbeknownst to the participants, each sticker had a unique respondent identification number which allowed us to track their behavioral responses. The time 2 session concluded with a short questionnaire intended to capture the participants' degree of identification with the venture. Time 3 refers to a period of 14 weeks in which we collect participants' stickers as a measure for consumed ice cream scoops. Two weeks after the end of the time 3 observation period, and approximately eighteen weeks after time 1, we conducted an online survey (time 4) in order to assess some potential longer-term effects of the original crowdfunding participation on customers' engagement.

This research reveals three important findings: First, it is found that participating in a real crowdfunding project, as opposed to merely buying the underlying product in a classic market exchange setting, increases the extent to which consumers can personally connect to and identify with the underlying venture. Second, we find that in aggregate significantly more scoops of ice cream were actually consumed in the crowdfunding versus coupon condition. Third, it is found that crowdfunding participation, via elevated levels of self-venture connections, is positively related to managerially important downstream variables such as increased subsequent consumption of the venture's products and more positive word-of-mouth behavior. The findings thus suggest that crowdfunding might indeed trigger more pronounced engagement activities among participating consumers; after the initial "treatment," they might simply wish to stay closer to "their" project and, in doing so, exhibit greater demand for the direct and indirect fruits of the venture.

When Perceiving Low Control Fosters Great Expectations:
The Case of Financial Decision Making

Sean Blair, Georgetown University, USA

EXTENDED ABSTRACT

Mark Twain purportedly once quipped, "Everyone talks about the weather, but no one does anything about it." Underlying this pithy observation is the idea that we often lack control over the events in our lives. Indeed, everyday life is replete with experiences that threaten personal control by undermining the belief that one can personally predict, affect, and steer events in the present and future (Kay et al. 2009). This raises the question as to whether and how personal control threats influence consumers' downstream judgments and decisions.

One prediction is that incidental personal control threats will worsen outcome expectancies. This stems from past research showing that people often overestimate their likelihood for positive outcomes because they assume future conditions and behaviors will be ideal (Tanner and Carlson 2009). This suggests that perceiving low control in one context may serve as a generalized reminder that the world is not ideal, which in turn would make salient the fact that factors outside one's control could preclude positive outcomes in other contexts as well. Thus, incidental threats personal control threats may lower the perceived likelihood for positive outcomes more generally.

In contrast, I argue that incidental threats to personal control are likely to increase the perceived likelihood for positive outcomes. I develop this hypothesis by adopting a motivational framework whereby personal control is construed not only as a situational appraisal but also as a fundamental motivation (Fiske 2014; Heider 1958; Kelly 1955). Building on the notion that control motivation reflects a more fundamental need for competence—that is, the need to use control *effectively* in shaping one's environment (Burger 1987)—I posit that threats to personal control heighten people's desire for competence, motivating them to believe they will be effective in producing desired outcomes in unrelated domains. I report three experiments that test this proposition in the context of financial decision making.

Experiment 1 examines whether an incidental personal control threat improves outcome expectancies and, if so, whether this is mediated by greater perceived competence. I manipulated personal control using a writing task where respondents elaborated on either a movie they had recently seen (baseline-control condition) or a fabricated quotation from a philosopher, which was pretested to threaten personal control (low-control condition). Next, respondents completed an ostensibly unrelated task where they constructed a stock portfolio. They reported how likely it was that their portfolios would outperform the average and their perceived competence in constructing the portfolio (Note: because the outcome expectancy DV is a relative measure whereas the perceived competence DV is absolute, one does not necessarily imply the other—thus, a respondent could perceive himself as incompetent in the task but still expect to perform as well or better than the average simply because he perceives others as equally incompetent). Results showed that respondents believed their portfolios were more likely to outperform when they were in the low (vs. baseline) control condition ($p=.04$, $d=.23$), and greater perceived competence mediated this effect (95% CI=.01–.21).

Experiment 2 provides additional evidence for my proposition that this effect is driven by a heightened desire for competence by showing that it is stronger for positive outcomes perceived as more diagnostic of competence. I first measured perceived diagnosticity by asking respondents the extent to which they perceived their outcomes in the stock market as reflecting their own competence. I then manipulated personal control by asking respondents to elaborate on something in their lives over which they had no control (low) or complete control (high). Finally, I presented respondents with a price chart for a stock they were considering and measured their perceived likelihood of profit. As predicted, the impact of personal control on outcome expectancies varied as a function of perceived diagnosticity ($\beta=.41$, $p=.001$). I explored this interaction using the Johnson-Neyman technique (Johnson and Neyman 1936; Spiller et al. 2013) to identify regions of significance for the simple effect of personal control at varying levels of perceived diagnosticity. Analysis revealed a positive effect of low (vs. high) personal control on outcome expectancies when perceived diagnosticity was relatively high (i.e., 70.42 or higher on 100-point scale) but a negative effect when perceived diagnosticity was relatively low (i.e., 33.38 or lower).

Experiment 3 provides causal evidence for the moderating role of perceived diagnosticity by manipulating rather than measuring it as in E2. I manipulated perceived diagnosticity by varying whether or not personal control was threatened in the same domain as the subsequent judgment. The rationale for this manipulation is that one cannot use control effectively (i.e., be competent) in a domain where one does not have control at all. As such, threatening control in the same domain should make respondents less likely to perceive positive outcomes as reflecting their own competence. To manipulate personal control, I varied perceived predictability, an important antecedent of personal control (Skinner 1996). Respondents first completed an ease-of-retrieval task (Schwarz et al. 1991) where they generated either 12 or 2 ways to predict an event, the rationale being that generating 12 (vs. 2) ways to predict an event is more difficult, thereby lowering perceived predictability. To manipulate threat-domain, I varied whether respondents were asked how to predict the weather (unrelated-domain) or stock price (related-domain). Finally, respondents completed the same financial judgment task as in E2. Analysis revealed the predicted interaction ($F(1, 144)=4.26$, $p=.04$), such that respondents in the low (vs. high) predictability condition believed their investment was more likely to be profitable when the threat was unrelated to investment outcomes ($p=.003$, $d=.66$), but not when it was related ($p=.90$, $d=.03$). This is consistent with the notion that threatened respondents were motivated to exaggerate their likelihood for a positive outcome, but only to the extent that they believed it would reflect positively on their competence.

These experiments suggest that the perception of low control can paradoxically make people more optimistic about their outcomes by motivating them to believe they will be effective in unrelated domains. Accordingly, this effect is more likely to occur for positive outcomes perceived as highly diagnostic of competence.

Delighted by Deviating Design:
The Relation between Construal Level and Surface Mimicry

Tess Bogaerts, Ghent University, Belgium
Christophe Labyt, Ghent University, Belgium
Mario Pandelaere, Virginia Tech, USA

EXTENDED ABSTRACT

Previous research demonstrated that people respond more favorably to new product designs that are good representations of their product category (Veryzer and Hutchinson 1998). However, evaluations of atypical products are not per definition negative, but depend on the degree of incongruity between the product and its associated category (Mandler 1982). In current paper, we advance the idea that consumers' processing mode or the degree of abstract versus concrete construal may as well affect ensuing product evaluations. Previous research on construal level theory has demonstrated extensively how mentally constructing objects or events at either abstract, higher-level construals or concrete, lower-level construals can affect several consumer behaviors (Dhar and Kim 2007). Yet, how construal level may affect consumers' attitude towards product designs received little or no research attention. Nevertheless, resolving the incongruity between a product and its general category may be easier when people think more abstractly than concretely.

To answer this question, we focused on products that incorporate visual features of unrelated objects, fauna, or flora into their visual design (Lidwell, Holden, and Butler 2010). This technique called "surface mimicry" transfers some constituting attributes of one category to an unrelated category, and hence introduces some incongruity. To resolve this incongruity, and to appreciate such atypical product designs, people need to recognize that some atypical product attributes refer to another product category. As such, they need to be able to make relevant abstractions to categorize these attributes into a broader, unrelated category. Therefore, we expect that this type of product design will evoke more abstract, higher-level processes.

In Study 1, 99 participants evaluated ten products of everyday use with either a typical design or an atypical design following the principle of surface mimicry. Next, we offered a categorization task adapted from Rosch (1975). This categorization task involves deciding upon the category membership of exemplars that were pretested as good, mediocre, or poor members of their category (9xFurniture, 9xVehicles, and 9xVegetables). Participants indicated how well each exemplar fits within its category (1="very poor", 10="very good"). The results showed a main effect of both type of exemplar $(F(1.61,157.77)=2260.50,p<.001)$ and product design $(F(1,98)=20.23,p<.001)$. More importantly, the interaction between product design and exemplars yielded significant $(F(1.61,157.77)=4.82,p=.015)$. Follow-up analysis demonstrated that evaluating atypical product designs did not alter participants' classification of good exemplars $(M\text{typical}*\text{good}=6.83$ vs. $M\text{typical}*\text{good}=6.76;$ $F(1,98)=2.36,p=0.13)$. However, participants who evaluated atypical designs did find that the mediocre $(M\text{typical}*\text{mediocre}=6.83$ vs. $M\text{typical}*\text{mediocre}=6.76;$ $F(1,98)=9.48, p<0.001)$ and poor exemplars $(M\text{typical}*\text{poor}=2.76$ vs. $M\text{typical}*\text{poor}=2.32;$ $F(1,98)=6.73,p<0.01)$ were better exemplars than participants who evaluated the typical product designs. This difference in degree of category membership was the largest for the poor exemplars. These results demonstrate that evaluating products with atypical designs compared to typical ones evoked a higher level, abstract form of cognitive processing.

In study 2, we aim to replicate these findings and investigate whether this cognitive process is moderated by the personal tendency to attach great value to the visual aspects of products (CVPA; Bloch et al., 2003). As in the previous study, we presented 78 participants with ten pictures of either typical product designs or atypical ones applying surface mimicry. Next, we administered the BIF-questionnaire (Vallacher and Wegner 1987) that asks how respondents mentally construct 24 different activities: concrete or abstract. Finally, we assessed the CVPA scale. In line with previous results, we found that participants who evaluated the atypical product designs more frequently chose the higher level description of the BIF-items $(M\text{typical}=13.13$ vs. $M\text{typical}=12.31; F(1,77)=4.60,p=.035)$, indicating a more abstract way of processing. In general, a higher score on the CVPA-scale was not related to a preference for the higher or lower level descriptions $(F(1,77)=0.01,p=.942)$. Interestingly, the interaction between the CVPA-scale and type of product design yielded significant $(F(1,77)=5.25,p=.025)$. Johnson-Neyman follow-up analysis of the interaction revealed that participants scoring at least 3.8 (out of 5) on the CVPA-scale construed the activities as more abstract after they evaluated products with atypical designs compared to typical designs. No significant differences arose for people scoring lower than 3.8 on CVPA-scale.

In the final study, we wonder whether people will not only engage in abstract thinking when seeing atypical designs, but will also be more likely to pay a premium price for products with such atypical designs when they are placed in an abstract mindset. Participants were assigned to either an abstract or a concrete mindset condition by answering *why* versus *how* they would engage in an activity (Freitas, Gollwitzer, and Trope 2004). Next participants indicated the amount (in EUR) they wanted to pay for five products that either had a typical or atypical design developed by the principle of surface mimicry. In line with our expectations, we found a significant interaction between mindset and product design $(F(1,118)=5.72, p=.02)$. When an abstract mindset is activated, people are willing to pay more for products with an atypical design $(M=7.54)$ compared to a typical design $(M=4.72; B=2.83,t(118)=3.63,p<.001)$. In contrast, when people think more concretely, they want to pay as much for atypical designs $(M=5.99)$ as for typical ones $(M=5.82; B=.17,t(118)=.22, p=.83)$. Another regression analysis with CVPA as additional variable yielded a significant three-way interaction between mindset, product design, and CVPA $(F(1,118)=4.38, p=.04)$. When people score low on the CVPA scale they do not differentiate between typical and atypical designs irrespective of their mindset $(B=.39,t(118)=.25,p=.80)$. When people score high on the CVPA scale, however, they would pay significantly more for atypical products when they are thinking more abstract $(B=5.00,t(118)=3.25, p=.001)$.

Taken together, we found that atypical product designs can instigate abstract processing (1), that bringing people in such a higher-level construal results in more favorable evaluations of products with atypical designs (2), and that this is especially true for people who show a higher than average concern for product design. As such, we contribute both to construal level theory and research on product design and prototypicality in particular. Future research could further investigate how marketers can promote atypical products by activating an abstract mindset. For now, we can conclude that abstract minds are delighted by designs that deviate from prototypicality.

Impact Bias or Underestimation?
Outcome Specifications Determine the Direction of Affective Forecasting Errors

Eva Buechel, University of South Carolina, USA
Carey Morewedge, Boston University, USA
Jiao Zhang, University of Oregon, USA

EXTENDED ABSTRACT

People rely on affective forecasts to anticipate the emotional impact of future events. Consequently, affective forecasts have an integral role in decisions, from everyday choices about what to eat for lunch to those with consequential personal, medical and legal implications (e.g., Blumenthal 2004; Ditto, Hawkins, and Pizarro 2005; Eastwick et al. 2008; Halpern and Arnold 2008; Maroquin, Nolen-Hoeksema, and Miranda 2013; Mellers and McGraw 2001; Miloyan and Suddendorf 2015; Riis et al. 2005; Woodzicka and LaFrance 2001). Affective forecasters are generally accurate when predicting whether an event will be pleasant or unpleasant, but often err in their predictions of *how* pleasant or unpleasant the event will be (Artz 1996; Mathieu and Gosling 2012; Rachman and Artz 1991). Early affective forecasting research demonstrated a widespread *impact bias*, a systematical tendency for forecasters to *overestimate* the hedonic impact of future events, ranging from HIV test results over tenure decisions, to their favorite sports team winning or losing a game (for reviews, see Gilbert and Wilson 2007; Wilson and Gilbert 2003, 2005, 2013). Recently, several countervailing cases have been documented in which forecasters systematically *underestimate* the hedonic impact of future events, such as the emotional pain induced by milder forms of sexism or sad fictional stories, and the pleasure gleaned from highly probable or distant future prizes (Andrade and VanBoven 2010; Bosson, Pinel, and Vandello 2010, Ebert and Meyvis 2014; Dunn et al. 2007; Gilbert et al. 2004a; Nordgren, Banas, and McDonald 2011). We propose a process account that can explain these seemingly incongruous findings and predict the direction of affective forecasting errors.

The hedonic impact of an event is influenced by general outcome specifications of the event such as its magnitude, duration, psychological distance, and probability of occurrence (Ebert and Meyvis 2014; Mellers et al. 1997). Some outcome specifications such as magnitude and duration are positively correlated with the hedonic impact of the event (e.g., presumably, winning more money feels better than winning less money, and a longer commute feels worse than a shorter commute). Other outcome specifications such as probability and psychological distance are negatively correlated with the hedonic impact of the event (e.g., presumably, winning $100 feels better if one had a 1% chance of winning than a 99% chance, and receiving $100 today is more exciting than receiving $100 a year from today; Brandstaetter, Kuehberger, and Schneider 2002; Ebert and Meyvis 2014; Mellers et al. 1997).

Critically, affective forecasters are typically more sensitive to the effects of outcome specifications on the hedonic impact of an event than are experiencers (Aknin, Norton, and Dunn 2009; Buechel et al. 2014; Dunn, Wilson, and Gilbert 2003; Ebert and Meyvis 2014; Gilbert et al. 2004b; Hsee and Zhang 2004). Because experiences are more affect-rich than the simulations upon which affective forecasts rely, experiences usurp more attentional resources necessary to attend to and be impacted by outcome specifications (Buechel et al. 2014; Ebert and Meyvis 2014; Morewedge et al. 2010). We suggest that consequently, the relationship between outcome specifications and hedonic impact is amplified in affective forecasts compared to experiences, resulting in both overestimation (i.e., impact bias) and underestimation (i.e., its inverse) of hedonic reactions.

The direction in which an outcome specification modulates the hedonic impact of an event allows us to predict which affective forecasting error is more likely to occur. In general, we predict that when outcome specifications are positively correlated with the hedonic impact of an event (e.g., magnitude or duration), forecasters should overestimate the extent to which high specification values will intensify its impact and low specification values will diminish its impact. Conversely, when outcome specifications are negatively correlated with the hedonic impact of an event (e.g., probability or psychological distance), forecasters should overestimate the extent to which low specification values will intensify and high specification values will diminish its impact.

To test our theory, we simultaneously manipulated both kinds of outcome specifications in two experiments. We expected that when both specifications were aligned in their modulation of hedonic impact—high magnitude and low probability or low duration and high psychological distance—they would have an additive effect, leading forecasters to systematically overestimate (i.e., impact bias) or underestimate (i.e., its reverse) the hedonic impact of experiences. When the specifications were misaligned, we predicted that their effects would be countervailing, leading to less extreme predictions and forecasting errors.

STUDY 1: PROBABILITY AND MAGNITUDE

We first tested our theory by manipulating the probability and magnitude of a positive experience. Because forecasters should be more sensitive to magnitude and probability specifications than experiencers (e.g., Buechel et al. 2014; Aknin et al. 2009), forecasters should overestimate the hedonic impact of winning a less probable larger prize (i.e., exhibit an impact bias) and underestimate the hedonic impact of winning a more probable smaller prize (i.e., exhibit its inverse).

Method

Participants and Design

Three hundred and ninety undergraduate students and pedestrians (149 females; M_{age} = 24.56 years, SD = 9.66) received course credit or $2 for participating. Each was randomly assigned to one condition in a 2 (role: forecaster, experiencer) x 2 (magnitude: small, large) x 2 (probability of winning: 10%, 90%) between-subjects design.

Procedure

Each participant was seated in a private cubicle with a survey and a prize. In the small magnitude condition, the prize was one .5oz packet of M&M's. In the large magnitude condition, it was a bag (~11oz) containing twenty-one .5oz packets of M&M's. All participants played a game of chance. Participants won the prize if they drew a ball marked with an "X" from an opaque bag containing 10 balls. Participants in the 10% (90%) probability of winning condition were told that 1 (9) of the 10 balls was marked with an "X." To minimize suspicion, 7 balls were actually marked with an "X" in all conditions.

Forecasters first predicted how happy they would be if they drew a ball with an "X" and won the prize on a 13-point scale (1 = *Very Unhappy*; 13 = *Very Happy*). They won the prize if they drew a ball with an "X" and did not win the prize if they drew an unmarked ball.

Experiencers first won the prize if they drew a ball with an "X" and did not win the prize if they drew an unmarked ball. They then reported how they felt on the same scale used by forecasters.

As manipulation checks, all participants then assessed their subjective likelihood of winning (1= *Extremely Low*; 13 = *Extremely High*) and the subjective size of the prize (1 = *Extremely Small*; 13 = *Extremely Large*). As an attention/comprehension check, participants indicated the stated probability of winning in an open-ended format.

Results and Discussion

Only the 329 participants who correctly indicated their probability of winning were included in subsequent analyses. Exclusions did not differ by condition ($\chi^2(1, N = 390) < 2.55, p > .13$). Fifty-seven experiencers who did not win the prize were excluded from the analyses, leaving a final sample of 272 participants. There were no other exclusions; differences in degrees of freedom reflect missing values for the reported variable.

Manipulation Checks

A 2 (role: forecaster, experiencer) x 2 (magnitude: small, large) x 2 (probability of winning: 10%, 90%) between-subjects ANOVA revealed that the subjective likelihood of winning was lower in the 10% conditions ($M = 4.22, SD = 2.27$) than in the 90% conditions ($M = 10.81, SD = 7.41; F(1, 253) = 77.30, p < .001, \eta^2 = .23$). All other effects: $Fs < 2.98, ps > .09$.

The same ANOVA revealed that the subjective magnitude of the large prize was greater ($M = 8.73, SD = 2.77$) than the small prize ($M = 5.09, SD = 2.47; F(1, 253) = 111.79, p < .001, \eta^2 = .31$). All other effects: $Fs < 3.11, ps > .08$.

Forecasted and Experienced Emotional Impact

Happiness ratings were submitted to a 2 (role: forecaster, experiencer) x 2 (magnitude: small, large) x 2 (probability of winning: 10%, 90%) between-subjects ANOVA. The analysis revealed a main effect of probability ($F(1, 262) = 6.92, p =.01, \eta^2 = .03$). More important, the analysis revealed the two predicted significant 2x2 interactions between role and outcome specifications: A role x probability interaction indicated that forecasters were more sensitive to probability specifications than were experiencers *(F(1, 262) = 7.87, p = .005, \eta^2 = .03)*. A role x magnitude interaction indicated that forecasters were more sensitive to magnitude specifications than were experiencers ($F(1, 262) = 4.02, p = .046, \eta^2 = .02$). All unreported effects: $Fs < 1.80, ps > .18$.

As predicted, additive differences in sensitivity to outcome specifications between forecasters and experiencers produced two qualitatively different forecasting errors when they were aligned in their modulation of the hedonic impact of the event: Simple effect tests revealed that in the large magnitude/10% chance of winning conditions, forecasters *overestimated* their happiness about winning the prize ($M = 10.53, SD = 1.65$) compared to experiencers ($M = 9.04, SD = 2.61; F(1, 262) = 9.18, p = .003, \eta^2 = .03$). Conversely, in the small-magnitude/90% chance of winning conditions, forecasters *underestimated* their happiness about winning the prize ($M = 8.38, SD = 1.63$) compared to experiencers ($M = 9.25, SD = 1.58; F(1, 262) = 4.03, p = .046, \eta^2 = .02$).

Forecasters were more accurate when the effects of outcome specifications were misaligned. Affective forecasts and experienc-

ers' reports did not differ for the small-magnitude/10% chance of winning conditions or the large-magnitude/90% chance of winning conditions, $Fs < 1$.

STUDY 2: DURATION AND PSYCHOLOGICAL DISTANCE

We next tested our theory by manipulating the duration and psychological distance of a negative experience. Because forecasters should be more sensitive to duration and psychological distance specifications than experiencers (Ebert and Meyvis 2014), forecasters should overestimate the hedonic impact of a longer and psychologically near event, and underestimate the hedonic impact of a shorter and psychologically distant event.

Method

Participants and Design

Four hundred and seventy-eight Mturk workers (234 females; $M_{age} = 34.00$ years, $SD = 11.46$) received 40¢ for participating. Each was randomly assigned to one condition in a 2 (role: forecaster, experiencer) x 2 (duration: short, long) x 2 (psychological distance: near, distant) between-subjects design.

Procedure

Participants first saw an image of a puppy trapped in a sewer, a preview of the video they would watch. The video duration was ten seconds in the short condition and three minutes in the long condition. To manipulate its psychological distance, participants were either told the event was filmed two days ago (near condition) or eight years ago (distant condition; Trope and Liberman 2010).

Forecasters predicted how sad, distressed, and absorbed they would be after watching the video on 9-point scales (1 = *Not at all*; 9 = *Very Much*; adapted from Ebert and Meyvis 2014). They then watched the video. Experiencers watched the video and then reported their current feelings on the same scales.

As manipulation checks, participants then assessed its subjective duration (1 = *Very Short*; 7 = *Very Long*), and the subjective temporal distance to the event (1 = *Very Close*; 7 = *Very Far*)[1]. Finally, we administered an attention check (Oppenheimer, Meyvis, and Davidenko 2009).

Results and Discussion

Only the 403 participants who had a novel IP address and passed the attention check were included in the subsequent analyses. Exclusions did not differ by conditions, $\chi^2(1, N = 478) < .48, p > .26$. There were no other exclusions; differences in degrees of freedom reflect missing values for the reported variable.

Manipulation Checks

A 2 (role: forecaster, experiencer) x 2 (duration: short, long) x 2 (psychological distance: near, distant) between-subjects ANOVA revealed that the subjective duration of the ten-second video was shorter ($M = 1.49, SD = 1.39$) than the three-minute video ($M = 4.29, SD = 2.04; F(1, 385) = 195.24, p < .001, \eta^2 = .33$). All other effects: $Fs < 1$.

The same ANOVA revealed that the event was psychologically closer when it presumably occurred two days ago ($M = 3.16, SD = 2.19$) than eight years ago ($M = 4.14, SD = 2.72; F(1, 384) = 15.00, p < .001, \eta^2 = .04$). All other effects: $Fs < 1.90, ps > .17$.

---

[1] There were no significant differences between conditions for an additional rating of whether the video was believable, all $Fs < 1.8, ps > .18$.

Forecasted and Experienced Emotional Impact

The three dependent measures assessing emotional impact were highly correlated ($\alpha = .75$) and aggregated into an index of negative affect (as in Ebert and Meyvis 2014). This index was submitted to a 2 (role: forecaster, experiencer) x 2 (duration: short, long) x 2 (psychological distance: near, distant) between-subjects ANOVA. The analysis revealed a main effect of role ($F(1, 395) = 4.45$, $p =.036$, $\eta^2 = .01$). More important, the analysis revealed the two predicted significant interactions between role and outcome specifications: A role x duration interaction indicated that forecasters were more sensitive to duration specifications than were experiencers ($F(1, 395) = 7.74$, $p = .006$, $\eta^2 = .02$). A role x distance interaction indicated that forecasters were more sensitive to temporal distance specifications than were experiencers ($F(1, 395) = 5.21$, $p = .023$, $\eta^2 = .01$). All unreported effects: $Fs < 2.76$, $ps > .09$.

As predicted, additive differences in sensitivity to outcome specifications between forecasters and experiencers produced two qualitatively different forecasting errors when they were aligned in their modulation of hedonic impact: Simple effect tests revealed that in the long/near video conditions, forecasters *overestimated* negative affect ($M = 6.89$, $SD = 1.68$) compared to experiencers ($M = 5.75$, $SD = 1.66$; $F(1, 395) = 10.23$, $p = .001$, $\eta^2 = .03$). In the short/distant video conditions, however, forecasters marginally *underestimated* negative affect ($M = 5.51$, $SD = 1.58$) compared to experiencers ($M = 6.13$, $SD = 1.58$; $F(1, 395) = 3.45$, $p = .064$ [$p = .032$, one-tailed], $\eta^2 = .01$).

Forecasters were more accurate when the effects of outcome specifications were misaligned. Forecasts and experiencer reports did not differ in the short/near video conditions ($F(1, 395) = 1.5$, $p > .20$) and forecasters only marginally overestimated negative affect in the long/distant video conditions ($F(1, 395) = 3.03$, $p = .08$, $\eta^2 = .004$).

GENERAL DISCUSSION

Because affective forecasters are more sensitive to specifications of outcomes than are experiencers, the direction of affective forecasting errors is contingent on the direction in which outcome specifications modulate the hedonic impact of events. When outcome specifications are positively correlated with hedonic impact (e.g., magnitude, duration), forecasters overestimate the extent to which high specification values will intensify and low specifications values will discount its impact. When they are negatively correlated with hedonic impact (e.g., probability, psychological distance), forecasters overestimate the extent to which low specification values will intensify and high specification values will discount its impact.

The results of our two experiments demonstrate these patterns across four kinds of outcome specifications—magnitude, probability, distance, and duration—in both positive and negative domains. Consistent with our theory, when two outcome specifications were aligned in their modulation of hedonic impact, their additive effect led to two predictable and qualitatively different forecasting errors: overestimation and underestimation of hedonic responses. Outcome specifications led to weaker, less consistent forecasting errors when their effects were in opposition. As our theorizing and our studies imply, however, we do not suggest that forecasting errors will be absent in all cases of opposing outcome specifications. If one outcome specification is more heavily weighted in prediction than in experience for integral or incidental reasons, it may eclipse opposing effects of other outcome specifications.

Overall then, reconciling previous demonstrations of both forecasting errors, our theory and evidence suggest that overestimation (i.e., impact bias) is more likely to occur for events that are large, unlikely, psychologically near and/or long in duration (e.g., Aknin et al. 2009; Dunn and Ashton-James 2008; Gilbert and Wilson 2007), whereas underestimation is more likely to occur for events that are small, likely, psychologically distant, and/or short in duration (e.g., Andrade and Van Boven 2010; Bosson et al. 2010, Ebert and Meyvis 2014; Gilbert et al. 2004a, 2004b).

Deciding in the present and planning for the future requires people to not only accurately assess which experiences will make them feel good or bad, but also assess how good and how bad those experiences will make them feel (e.g., Mellers and McGraw 2001). Our theory and findings reconcile the seemingly incongruous cases in which forecasters overestimate and underestimate the hedonic impact of future events. Moreover, our theory elucidates when, why, and in what directions forecasters will err in their predictions.

The Fixed Unit Effect: When Size Does Not Matter, But Number of Units Does

Myla Bui, Loyola Marymount University, USA
Brennan Davis, California Polytechnic University, USA
Collin Payne, New Mexico State University, USA
Maura L. Scott, Florida State University, USA

EXTENDED ABSTRACT

We introduce the "fixed unit effect" (FUE), such that in the presence of others, consumers choose and eat a fixed number of food units, regardless of the size of the unit, based on what they perceive to be a socially appropriate quantity for a given food (e.g., eating two slices of pizza is appropriate). Consumers have prior notions of what is appropriate and use internal standards, as opposed to being guided by what others are consuming. The result of this effect is that, while the unit quantity selected is fixed, the total caloric intake varies with unit size (i.e., smaller or larger units), and consumers will eat more calories from larger units.

We contend that the FUE occurs in social, rather than non-social, eating situations. However, the FUE does not merely occur based on matching the behavior of others. It is an internal standard meant to convey personally consistent yet socially acceptable behavior. The FUE is a heuristic that consumers use in social situations to consume a socially appropriate amount of food, particularly for vice foods where consumers may feel more social judgment toward their consumption behavior.

Eight studies demonstrate the FUE. Four of the eight studies involve demonstrating the FUE by asking participants to *consume actual food* including cinnamon rolls, donuts, snack crackers, and pizza. Experiment 1A and 1B demonstrate the basic FUE with pizza and cinnamon rolls. Experiments 2, 3, 4A and 4B uncover the social parameters of the FUE. Studies (Experiments 5A and 5B) demonstrate the moderating role of food type (vice vs. virtue). Taken together, these studies provide robust support for the FUE across multiple food types, and demonstrate the social and product factors that cause the FUE.

In experiment 1A, participants read a scenario about movie night at their apartment with friends and plenty of pizza, and then saw the full pizza, which was either sliced in 16ths or 8ths. Participants then indicated how many slices they would like to eat. Results support the fixed unit effect: there was no difference in the number of pizza units selected, but there was a significant difference in the number of calories selected.

Experiment 1B was a field experiment at a farmer's market. In this case, participants were offered free cinnamon rolls that were either small or large units, depending on the booth. As in experiment 1A, there was no difference in the number of cinnamon rolls participants ate, but there was a significant difference in the number of calories consumed.

The next studies demonstrate the parameters of the FUE: that this is a social phenomenon, although it is social it is not driven by mimicry of others' behavior. Experiment 2 employed a 2(consumption: public, private) x 2(small, large) between subjects design. Participants were invited to a pizza taste testing study (with either all small slices or all large slice), where they ate either alone or at a table with 3-4 people. Results showed that when consumers ate with others, the FUE emerged (i.e., no difference in the number of slices selected, but significant difference in number of calories consumed). When consumers ate alone, they ate a significantly greater number of the smaller slices, but showed no difference in caloric intake. This provides preliminary evidence of the social nature of the FUE.

Experiment 3 replicates the FUE using a different food: actual eating of cheese filled Ritz crackers during a social networking event. It also tests whether consumers eating these foods mimic the behaviors of others or follow an internal standard; in this case, consumption is public, but we removed the ability for participants to see how much others put on their plates. In other words, participants will know they are going into a social context where they will be eating with others, but they must select their food in isolation without seeing what anyone else has selected. We found that the FUE still arises in this context, even though participants are not able to mimic the amount taken by others.

Experiments 4A/4B delve further into the question of social behavior by examining the question of how participants expect others to consume. Both studies employ a 2(donut size: small, large) between subjects design. Experiment 4A replicates the FUE using actual eating of another food: donuts (i.e., participants eating in full view of other people showed no difference in the number of units selected, but a significant difference in the calories consumed). After eating, we asked participants how much they thought others would eat in the same situation; participants thought participants would eat significantly more units of the smaller donuts than the larger ones. In Experiment 4B, using an online format, we showed participants one of the two types of donuts and asked two questions: how much they thought other people would eat, and what would be the appropriate amount for other people to eat. Consistent with experiment 4A, participants expected others to select significantly more donuts from in the small donut condition, however, when asked about what is appropriate, consistent with the FUE, participants showed no difference in the number of donuts they thought would be appropriate for other people to select.

Experiments 5A/5B both employed a 2(food unit size: small, large) x 2(vice, virtue) between subjects design. Consistent with our theorizing about the FUE being a heuristic to help consumers manage social judgments about their consumption, and the idea that consumption of vice foods carries more judgment than consumption of virtuous foods, we find across two studies that the FUE holds for vice foods, and is attenuated for virtue foods.

Taken together, our research findings establish that in social settings, food unit size does not impact the number of units taken, as consumers rely more on internally guided fixed-units to consume; however, it does impact total calories consumed. This suggests that smaller food units can help attenuate consumption of vice foods, while larger units facilitate such eating behavior.

The Many-Faced Consumer:
Practices And Consequences of Social Media Government

Laurent Busca, Université Toulouse Capitole, France
Laurent Bertrandias, Université Toulouse Paul Sabatier, France

EXTENDED ABSTRACT

A recent body of literature started to investigate marketing as a technology of government (Beckett 2012). Several studies looked at what is called the "marketing governmentality" (Cova and Cova 2009) and expose the way marketing discourse create representations, while others investigate the consequences of these representations on consumer subjectivity (Zwick and Dholakia 2004). According to Foucauldian theory (Foucault 1975), these representations are part of the government activity. Beyond consumer subjectivity, we still know little about how marketing practice organizes consumption systems of power (Thompson 2004). Moreover, research about this performative capacity of marketing government is scarce when it comes to online communities, while their management is a core business activity. Communities are often understood as fostering consumer empowerment (Labrecque et al. 2013), while Social Media Management (SMMt) aims at governing online consumers (Zwick and Denegri-Knott 2009). The scope of this activity is wide and includes different marketing activities; as a result, it concerns marketing in a broader sense. We therefore investigate empirically the SMMt practice to answer two questions: how do marketing practices create and reinforce representations of consumers? What are the consequences of these practices?

We conducted a three years long netnography on a community of Social Media Managers (SMMs): The ForumMyCM, with more than 8000 SMMs, 7-8 posts per day and 20-25 comments per day. We conducted 10 interviews with SMMs ($M_{duration}$ = 50 min) and collected two types of additional sources: professional literature (13 blogs and 3 books among the most cited by the community and 12 reports about SMMt) and 11 software providers' blogs and institutional websites (they provide all the analytical tools used daily by SMMs and therefore their metrics participate in creating representations). These providers are Hootsuite, Sentiment, Lithium, Over-Graph, trackur, Agorapulse, Viralheat, Cision, Mention, nukesuite and SΛ.

We use a framework based of the concept of governmentality (Foucault 2004). We focus on four elements: the ontology (what the entities are), the deontology (what the entities must become), the ascetics (which practices are enacted) and the teleology (what the aim of the practices is). This framework is adapted from foucauldian theory of ethics (Foucault 1984).

We find that the SMMt practice is composed of three fundamental practices: framing, defining categories and their nature; channeling, moving entities from one category to another; optimizing, acting on one category to influence some of its relevant properties. These practices are interrelated: framing defines which relationships exist between categories for the channeling part and the relevant properties for the optimizing part; channeling practices can help optimizing the target category, and optimizing a category can create channeling effects. The framing operation in our case defines three categories: conversation, made of words, community, a collection of individuals acting as a whole, and influencers, specific individuals. Conversation, while its size is unknown, is considered eternally active: whatever the brand does, conversation exists. Community is of finite size and mortal: SMMs have to act on it so it remains active. While composed of individuals, it is always treated and measured at an aggregated level. Influencers are individuals who were extracted from the aggregated mass because of a remarkable behavior, and are treated individually. This system of practices has two main consequences.

First, SMMs are subject to loyalty tensions. They work for the brand but are also attached to the community. When humanizing their interaction, SMMs take over the brand's actions, and may pursue their own objectives instead of the brand's ones. As such, the role of SMM is subject to interpretation: should the SMM be embedded in the organization or in the community? Second, some practices can also result in the creation of new categories of population; we call that the derivation effect. For example, optimizing the size of the community, considering the size as a valuable metric led to the apparition of companies selling fake fans. Fake fans represent a category of their own, distinct from the community. SMMs consider them prejudicial, but their practices contribute in creating them: consumers' agency can counteract SMMs' strategies even though this agency fits into the social media governmentality. Derivation effect originates in the difference between the SMM's mission and the dispositive's teleology. The derived categories are part of the dispositive but SMMs still consider them "bad behaviors". The derivation effect illustrates a type of misbehavior which cannot be conceived as resistance in Foucault's terms (Foucault 1975), as resistance represents behaviors going against the current organization of power relationships.

We contribute to marketing governmentality studies by outlining the fundamental role of representations in SMMt. The circle of practices (framing, channeling, optimizing) has two functions: on one hand, it stabilizes representations and allows marketing actions; on the other hand, the derivation effect allows the evolution of the system of representations. As a result, similarly to organizational path dependence, the circle of practices orientates market evolution while avoiding a deterministic lock-in (Garud, Kumaraswamy, and Karnøe 2010). The derivation effect may be a fundamental mechanism in market evolution, and future research should investigate it more closely.

We extend the study of the figures of the consumer (Cova and Cova 2009). While previous research outlined the discursive aspects of the representational activity, we point at its material aspects: the architecture of software carries representational features (Orlikowski 1992) and therefore influences marketing governmentality. Service providers are therefore important actors in market structuration, as the tools they provide participate in fixing consumer representations. Future research should build on previous market devices studies (Callon, Millo, and Muniesa 2007; Zwick and Cayla 2011) to deepen our understanding of the role of business service providers in consumer markets evolution and to add material features to the discursive aspects of marketplace power structures (Thompson 2004).

Consumers Rely More on Online Review Scores
When They First Form an Independent Opinion

Adrian R. Camilleri, RMIT University, Australia

EXTENDED ABSTRACT

There is evidence indicating that consumers increasingly rely on review score information to help them make purchase decisions (Punj, 2013), and that this reliance impacts upon choice behaviour (e.g., Cheung et al., 2009) and sales (e.g., Chevalier & Mayzlin, 2006). However, existing research has overlooked the important research question considered in this paper: does it matter when a consumer is exposed to review scores? More specifically, do purchase intentions vary depending on whether consumers read review scores before versus after forming their own opinion of a product? On the one hand, the same information is available. On the other hand, a wealth of evidence suggests that preferences can vary as a function of order.

A primacy effect occurs when a person forms a judgment more consistent with the *first* presented argument whereas a recency effect occurs when a person forms a judgment more consistent with the *last* presented argument. The literature associated with order effects in persuasion is quite mixed with some studies finding primacy effects and some finding recency effects (Haugtvedt & Wegener, 1994; Hogarth & Einhorn, 1992). In contrast, the literature associated with order effects in the advice-taking literature tends to find primacy effects (Koehler & Beauregard, 2006; Sniezek & Buckley, 1995; Yaniv & Choshen-Hillel, 2012).

Given the variety of differences between typical persuasion tasks, typical advice-taking tasks, and use of review score information to inform product evaluations, we thought it was important to collect new data. We also noted a number of different theories that made different predictions, including Bayes' Rule, support theory, consistency theory, accessibility-based anchoring, adjustment-based anchoring, and Gricean conversational norms

In our first experiment, half the participants were allocated to a Pre-Post group and half to a Post-only group. Participants in the Pre-Post group were exposed to a product description before stating an initial intention to buy the product. Participants were then exposed to a review score distribution before making a second evaluation. In contrast, those in the Post-only group were exposed to both the product description and the review score distribution simultaneously before making a single product evaluation. We found that consumers tended to put more weight on review score information in a Pre-Post condition compared to a Post-Only condition. This effect was robust to average review score: a positive average review score (i.e., 4.6/5) was more likely to increase intention to purchase and a negative average review score (i.e., 3.4/5) was more likely to decrease intention to purchase for those in the Pre-Post group. This effect was also robust to product type in that it held for both an experience good and a search good.

In order to test between competing theories, we carried out a second experiment. Half the participants were presented with the product description and then, on the next page, the review score information whereas the others were presented with this same information in reverse order. In addition, half the participants were asked for two evaluations - one after the first piece of information and another after the second piece of information - whereas the others were only asked for single evaluation after both pieces of information. We found that consumers tended to put more weight on the information that was presented second (i.e., a recency effect).

The main observation we made across our experiments is that the weight accorded to review score information when consumers are making a product evaluation critically depends on *when* that information is encountered. We found that consumers tended to weight review score information more when that information was received after the consumer had formed an initial product evaluation based on the product description. The effect appears to be robust to: whether the average review score is above versus below initial expectations; whether the product is a search or experience good; and whether the initial evaluation was explicitly stated or implicitly formed by the separation of information.

Our explanation for the observed results is an adjustment-based anchoring process (Epley, 2004; Tversky & Kahneman, 1974). According to this account, consumers generate an initial evaluation based on the product description that they assume is close to the true value of the product but are ready to adjust away if given new information. The model provided by Hogarth and Einhorn (1992) describes how this adjustment process occurs. People use new pieces of information to update the existing estimate according to an averaging process as they try to estimate the true value. This averaging process can take place either after each new piece of information (a step-by-step processing strategy) or only after all pieces of information have been presented (an end-of-sequence processing strategy). Following Hogarth and Einhorn, we argue that, where possible, people try to match cognitive strategy with response mode. Therefore, when consumers first form their own evaluation from a product description and then learn about product reviews, a step-by-step processing strategy is adopted. In contrast, when consumers' form an evaluation based on both the product description and reviews presented together, then an end-of-sequence processing strategy is adopted. Importantly, the model predicts recency when adopting a step-by-step strategy and primacy when adopting an end-of-sequence strategy. These predictions are borne out by all of the reported experiments.

For managers, the presence of order effects affords possibilities of potentially effective strategies regarding the placement of review score information to favor certain products depending on those product's reviews. First, our data inform on whether review score information should appear in search results, and near the top of product pages. Second, our data inform on whether review score information should appear in printed ad magazines

For consumers, the presence of order effects is likely to lead to lower-quality decision due to bias, lack of consistency, and less efficient decision processes. One basic strategy to give more weight to review scores, which we argue is closer to the optimal approach, is for consumers to adopt a step-by-step processing strategy by first considering the product description, forming an evaluation, and then consciously adjusting that evaluation based on the review scores.

The Moral, The Team, and The Ends:
A Three-Motive Model of Moral Judgment for Politics and Other Team Contexts

Troy Campbell, University of Oregon, USA
Heather Mann, Duke University, USA
Dan Ariely, Duke University, USA

EXTENDED ABSTRACT

What motives underlie moral judgments in team contexts? For judgments in contexts of competing team such as brands, political parities, and universities what motives drive moral judgments? How do moral judgments vary across different aspects of actions and actors? How do moral judgments vary by whether one is on the "team" of the actor whose behavior is in moral question?

Despite the explosion of research in moral judgment (Bhattacharjee, Berman, & Reed, 2013; Graham, Haidt, & Nosek, 2009), these questions remain incompletely understood. Furthermore, these questions have been largely examined in isolation. This project celebrates the advancements of research on particular moral motives, but also recognizes the need for an integrative advancing model and empirically testing that model.

In this paper, we present a basic three-motive model of moral judgment relevant to contexts where team and group based outcomes are involved. Through the illustrative and pertinent context of politics, we show how this model can help us make predictions of people's moral judgment propensities. Integrating the three motives together provides a clear but nuanced view of moral judgment in team based contexts. It illustrates why sometimes one might fail to find strong evidence for a certain moral motive, because other motives might be more active. It provides a view of moral judgment as a series of motives pushing against and constraining with one another. Human moral judgment may be complex, but with this integrative model, we hope to make it more predictable.

The model includes three motives and subsequent predictions.

Moral Motive Prediction: People will generally hold that the same moral standards should be used without bias to judge various politicians, regardless of the individualistic characteristics of any politicians, such as the politician's party.

Team Motive Prediction: Partisans will condemn an immoral action more when done by a politician from the opposing political party rather than by their own political party.

Ends Motive Prediction

There will be a greater own team member favoring bias, between moral judgments of actors from one's team versus another team, when the actor takes actions that is beneficial for the actor's team than only for the actor's self.

Integrating the three motives provides a clear but nuanced view of moral judgment in team based contexts. Using the pertinent content of politics, we conducted four studies.

Study 1 tests and finds that people overwhelmingly have a conscious moral motive to apply the same moral standards across actors, regardless of the actor's team. We find that the overwhelming majority people explicitly report that they hold similar standards for the politicians regardless of party. Though there are some differences observed in explicitly stated standards, the differences are small, especially compared to the differences observed in the later studies.

In line with a team motive, Study 2 finds that with individual instances of specific immoral violations, people engaged in strong biased judgments of an actor in a manner that favors a team member. However, the moral motive seems to produce a "boundary" on this motivated bias such that the team-favoring bias exists but is not unlimitedly strong. These findings were observed during the 2012 United States presidential election. In a between subjects design, partisans indicated that it was more wrong for the candidate from the other party (i.e., Barack Obama or Mitt Romney) to engage in "ethically gray" actions such providing favors to campaign donors, not fully disclosing information to the public, and scheduling votes when politicians are away.

Study 3 showed the strength of motive to be biased, affects the amount of bias. Using a hypothetical versus real action paradigm, Study 3 tested how the strength of bias can be exaggerated when motivational needs are higher and provides insights into how people can generally seem or feel relatively unbiased—because they exhibit a stronger bias only when most needed (i.e., with the action is a real versus a hypothetical moral violation). This study was performed at the local level by asking partisans at the North Carolina State Fair opinions about local politicians.

Finally Study 4 examines the considerations of ends, finding a specific ends motive in addition to a general team motive. This motive builds from the fact that team members can engage immoral actions that can be team-benefiting (e.g., getting oneself elected such that a member from the other party does not get elected) or only actor-benefitting (e.g. cheating on a spouse, personal tax evasion). Here, the ends-motive makes predictions that the other motives do not. It specifically predicts that actions which directly yield team-benefitting ends (e.g., politicians getting elected) will be receive more team member favoring leniency bias than actions that do not directly yield the ends (e.g., transgressions in the politician's personal life). Results supported these predictions.

Today, popular discourse over immorality in many intergroup contexts tends to place the blame on a selected few. For example, in politics and brand settings, we overwhelmingly point fingers at the politicians and CEOs. However, this research suggests that by compromising our moral standards, ordinary citizens are partly responsible for the current corrupt state of affairs in politics, organizations, and businesses. Collectively, we may allow and forgive unethical behaviors in those that most directly represent and serve our teams. Ultimately, we fail to discerningly police actors with the consistent morality required of ethically functioning democracies and market economies. When it comes to addressing the sorry state of morals in politics, brands, businesses, sports, and even sometimes schools, it may be time to stop pointing fingers at the top, and instead look into the mirror.

The Visual Acuity of Less:
Why People Underestimate Increases but not Decreases in Quantity

Pierre Chandon, INSEAD, France
Nailya Ordabayeva, Boston College, USA

EXTENDED ABSTRACT

We examine whether people perceive the magnitude of physical size increases similarly to how they perceive size decreases. Research in psychophysics and consumer behavior has shown that visual estimates of increases in object size are strongly inelastic, meaning that people strongly underestimate the actual magnitude of the size increase (Chandon and Wansink 2007; Krishna 2007; Stevens 1971). Other studies have indicated that estimates of quantity decreases may be more elastic and thus more accurate (Ordabayeva and Chandon 2013), but no research has directly compared the two types of estimations. Yet, such estimations are common in today' marketplace, where package sizes increase and decrease frequently (Felten 2012; Nestle 2003), and where consumers rely on their visual package impressions to judge product size in the absence, and in the presence, of size information (Lennard et al. 2001).

While existing theories may have some bearing on this issue, little research has studied it directly. The psychophysics literature assumes that estimations of size increases and decreases follow the same process and hence are both inelastic. The anchoring and adjustment literature predicts the same degree of anchoring when the anchor is above or below the true value. Prospect theory predicts an asymmetry in the valuation of size gains and losses, but it assumes that size decreases are construed as psychological losses and size increases are construed as gains, and that the magnitude of the size increase and decrease corresponds to the magnitude of the perceived gain and loss.

Importantly, existing theories have overlooked the fact that the estimation of size decreases in physical quantities is distinct from the estimation of size increases in that physical quantities can never be negative. Thus, the natural lower bound (zero) is salient when estimating size decreases, but the natural upper bound is absent when estimating size increases. This makes estimating size decreases an interpolation task, bounded by the large reference size as well as zero, and estimating size increases an extrapolation task, only bounded by the small reference size.

We build on prior research which showed that interpolation tasks are easier than extrapolation tasks, for object perception and learning of functional relationships between variables (Kellman 2003; McDaniel and Busemeyer 2005). We expect that estimations of decreasing quantities will be less inelastic, and thus more accurate, than estimations of increasing quantities. We expect that the asymmetry between estimations of size increases and decreases will be reduced: (a) when estimations of both size increases and decreases require extrapolation (i.e., when the lower zero bound is removed from estimations of decreasing sizes); and (b) when an upper bound is salient in estimations of size increases.

In Study 1, Mechanical Turk participants saw portions S, M, and L of peanuts containing 52, 182, and 367 peanuts displayed vertically. Given the size of a reference jellybeans portion, they estimated the sizes of peanuts portions. In the supersizing condition, the reference (52 jellybeans) was identical to portion S of peanuts. In the downsizing condition, the reference (367 jellybeans) was identical to portion L of peanuts. Participants also indicated whether portion S at $.25 or L at $1.50 provided better value for money (L was better at .23 cents per nut). The results revealed that size estimations were more accurate and people thought that portion L provided better value for money when sizes decreased vs. increased from the reference (portion L appeared to be 9.7 times bigger than S vs. 6.3 times when portions decreased vs. increased, and 92% vs. 81% of participants thought that portion L was better value when portions decreased vs. increased).

In Study 2, experts (chefs at Paul Bocuse Culinary Institute) saw four portions (S, M, L, XL) of mashed potatoes, soup, and salad displayed horizontally in professional containers. In the control condition, participants estimated the final sizes of portions given the size of the reference. For supersizing, given the size of portion S, participants estimated portions M, L, and XL. For downsizing, given the size of portion XL, participants estimated portions L, M, and S. In the factor of change condition, participants estimated how many times larger one portion was than another. For supersizing, they estimated how many times larger portions M, L and XL were than S. For downsizing, they estimated how many times larger portion XL was than L, M, and S. The factor of change estimation forced the estimates to range between 1 and infinity, which required extrapolation. The results revealed that size estimations were more accurate for downsizing than supersizing when estimating final sizes of portions (L appeared to be 14.10 vs. 10.54 times bigger than S for downsizing vs. supersizing), but not when estimating factors of change between portions (L appeared to be 11.64 vs. 11.71 bigger than S for downsizing vs. supersizing).

Study 3 replicated these results with novices (Mechanical Turk participants) and two factor of change conditions which had people estimate either the larger factor (how many times larger one portion was than another) or the smaller factor (how many times smaller one portion was than another).

In Study 4, participants estimated increasing or decreasing amounts of iced tea and jellybeans displayed in identical glasses. The same size (M) served as a reference across conditions (people estimated L, XL for supersizing; S, XS for downsizing) to rule out reference size effects. We varied the palatability of the iced tea (by adding sugar or salt) and jellybeans (by using regular or disgusting flavors) to rule out prospect theory as an alternative explanation. Participants estimated final sizes, or poured the required quantities of product into or out of the glass, which was naturally bounded by the edges (bottom and top) of the glass and required interpolation. As predicted, the asymmetry emerged when estimating portions, but not when pouring portions – independent of palatability (which ruled out prospect theory).

Study 5 further confirmed the role of estimation bounds and extended their effects beyond food products by showing that the asymmetry is eliminated when an explicit numeric upper bound limits estimations of the size of a file download.

The Thought Counts: Effect of Surprise on the Consumption Experience of Gifts

Charlene Y. Chen, Nanyang Technological University, Singapore
Claire I. Tsai, University of Toronto, Canada

EXTENDED ABSTRACT

Although surprise-and-delight marketing campaigns have received tremendous media attention and positive customer feedback in recent years, such strategies are under-utilized (LoyaltyOne 2015). Marketing research on surprise gifts has also been scarce. Based on findings that sensory consumption experience often assimilates to pre-consumption expectations (Plassmann et al. 2008; Wilson et al. 1989), we propose that surprise prolongs recipients' enjoyment of gifts over time by triggering a cognitive belief that surprise gifts are special and thoughtful (Belk 1996).

In all experiments, we either surprised participants with a gift right before they received it or informed them in advance, a procedure adapted from Valenzuela, Mellers, and Strebel (2010). The novelty of our paradigm was that all participants rated the gift multiple times, allowing us to demonstrate that surprise prolonged consumption enjoyment over time. Experiment 1 tested how surprise interacted with time to influence consumption enjoyment of a gift by employing a 2(surprise)8(time/trials) mixed design with surprise being the between-subjects variable and time/trials as the within-subject variable. A 2(surprise)8(time-trials) mixed repeated-measures ANOVA on enjoyment ratings yielded a significant two-way interaction ($F(2.35, 117.72) = 2.94$, $p <.05$). Consistent with the principle of hedonic adaptation, enjoyment declined over time in both conditions (average $\beta_{surprise} = -.42$, $\beta_{announced} = -.63$; one-sample t-test against 0: $t_{surprise}(23) = -4.88$, $t_{announced}(27) = -7.76$, both p's $<.001$). However, it declined at a slower rate in the surprise condition than the announced condition (independent-samples t-test: $t(50) = 1.73$, $p =.09$).

We employed the same procedure in subsequent experiments. In Experiment 2, we extended the finding to a marketing context by telling participants the gift giver was a company and tested whether beliefs of specialness mediated our effect. We used a 2(gift: announced vs. surprise) × 6(trial) mixed design with gift as the between-subjects variable and trial as the within-subjects variable. The gift in this experiment was a computer desktop wallpaper. A 2(gift) 6(trials) repeated-measures ANOVA yielded a significant two-way interaction ($F(2.35, 731.76) = 3.31$, $p <.05$). Enjoyment declined at a slower rate in the surprise condition than the announced condition (average $\beta_{surprise} = -.22$, $\beta_{announced} = -.32$; one-sample t-test against 0: $t_{surprise}(160) = -7.85$, $t_{announced}(152) = -9.43$, both p's $<.001$; independent-samples t-test: $t(312) = 2.24$, $p =.026$). Additionally, beliefs about the specialness of the gift and tendency to savor the gift sequentially mediated our effect (indirect effect = .29, CI = [.11, .54]).

Experiment 3 ruled out attention and mood-amplification as alternative explanations by testing the effect of surprise on negative experiences. If surprise caused people to pay more attention (Wilson et al. 1989) and increased the intensity of affective reaction (Mellers 2000), then enjoyment should be lower for an unpleasant gift in the surprise (vs. announced) condition. If the notion about surprise gifts was driving our effect, then surprise should prolong enjoyment regardless of valence of the gift. We employed a 2 (gift: announced vs. surprise) 2(valence: pleasant vs. unpleasant) × 6(trial) mixed design with gift and valence as the between-subjects variables and trial as the within-subject variable. Participants received an image of a painting as a gift. They received either the pleasant, original version, or the unpleasant, decolorized version. A 2(surprise)2(valence)6(time/trials)mixed repeated-measures ANOVA yielded a significant two-way interaction between time/trials and surprise condition ($F(2.43, 520.86) = 2.91$, $p <.05$). Participants reported greater enjoyment of the surprise gift over time regardless of valence (pleasant and unpleasant gifts: average $\beta_{surprise} = -.22$, $\beta_{announced} = -.33$; one-sample t-test against 0: $t_{surprise}(116) = -6.59$, $t_{announced}(100) = -9.30$, both p's $<.001$; independent-samples t-test: $t(216) = 2.12$, $p =.035$).

In Experiment 4, we further tested our proposed mechanism by manipulating directly the association between surprise gifts and specialness. Participants in the special condition affirmed the notion that surprise gifts are special and thoughtful. Participants in the not-special condition came up with arguments to counter this common belief. We also examined downstream consequences by asking participants to predict their usage of the gift and enjoyment in the future.

The experiment employed a 2(beliefs about surprise gifts: special vs. not special) × 2(gift: announced vs. surprise) × 6(trial) mixed design with beliefs and gift as the between-subjects variable and trial as the within-subject variable. The gift items were the wallpapers from Experiment 2. A 2(gift) × 6(trials) repeated-measures ANOVA revealed a significant two-way interaction in the special condition ($F(1.84, 224.58) = 3.35$, $p <.05$) but not in the not-special condition ($p =.65$). Within the special condition, enjoyment levels across trials declined at a slower rate in the surprise condition than the announced condition (average $\beta_{surprise} = -.20$, $\beta_{announced} = -.35$; one-sample t-test against 0: $t_{surprise}(58) = -4.01$, $t_{announced}(57) = -6.30$, both p's $<.001$; independent-samples t-test: $t(115) = 2.08$, $p =.04$). We submitted likelihood of using the wallpaper and predicted enjoyment from viewing the wallpaper to two-way ANOVAs. There were significant two-way interactions between beliefs and gift on likelihood of usage ($F(1, 237) = 5.63$, $p <.05$) and predicted enjoyment ($F(1, 237) = 3.89$, $p =.05$). Specifically, in the special condition, participants reported being more likely to use the surprise gift than the announced gift ($M_{surprise} = 5.19$ vs. $M_{announced} = 2.86$; $F(1, 237) = 13.80$, $p <.001$) and predicted greater enjoyment from the surprise gift ($M_{surprise} = 6.48$ vs. $M_{announced} = 4.31$; $F(1, 237) = 15.65$, $p <.001$). Predicted usage and enjoyment did not differ by gift in the not-special condition (both p's $>.21$).

Our research demonstrates that surprise prolongs consumption enjoyment of gifts over time and provides insights into the psychological process driving the effect. Consistent results across various product categories, real-time measures, and downstream variables attest to the robustness of our findings. Data ruled out attention and mood-amplification as alternative explanations. This work complements the literature of gifting and surprise by identifying expectations of surprise gifts as special and showing that surprise can enhance consumption enjoyment even for negative stimuli. It also has important managerial implications for enhancing and managing customer experiences.

The Found Time

Jaeyeon Chung, Columbia Business School, USA
Leonard Lee, National University of Singapore, Singapore
Donald Lehmann, Columbia Business School, USA
Claire Tsai, University of Toronto, Canada

EXTENDED ABSTRACT

Time is one of the most, if not the most, limiting factors of an individual's life. People struggle to make the best use of the limited resource to attend to various activities in life (e.g., work, family time, house chores, etc.)

With constrained daily schedules, a gain of unexpected time – due to cancelled meetings, shorter than expected queues in stores, early plane arrivals – all help loosen the constraint of busy schedules. Yet, while such gains of extra time are fairly common in our lives, there has not been systematic research on how people utilize this "found time."

To understand how people treat and use their found time, we compare a windfall gain of time with an analogous resource - windfall money (Camerer 2003). While windfall money shares many aspects with found time, there are also major differences between the two resources. For example, unlike gains of money, time is less fungible and more perishable, holistic and transitive (Okada and Hoch 2004). Further, thinking about money leads people to focus on value maximization while thinking about time leads people to focus on emotional meaning and well-being (Liu and Aaker 2008).

Drawing from research on time versus money (Lee et al. 2015; Liu and Aaker 2008; Okada and Hoch 2004), we propose that consumers are more likely to use windfall gains of time (vs. money) for experience-driven hedonic (vs. utilitarian) purposes. As time is a resource that closely relates with psychological well-being (Liu and Aaker 2008), consumers prefer to use it to enhance their well-being by balancing their lives rather than devoting it to work-related achievement. That is, the mental representation of the norm (Kahneman and Miller 1986) on how time should be spent is different from how people think about spending money; while spending time on hedonic activities (e.g., family time, relaxation) is often desired and perceived as appropriate, spending money for hedonic purchases (e.g., purchase jewelry, dessert) is often viewed as non-virtuous. In fact, our pretest results suggest that consumers regard spending time on hedonic activities as being important in life, and that they are dissatisfied with the amount of time they are currently spending on these activities; by contrast, people are much less likely to consider spending money on hedonic purchases as being important in life, and are generally satisfied with their current level of monetary expenditure.

In eight experiments, we demonstrate that consumers are inclined to spend found time for hedonic (vs. utilitarian) purposes. Experiments 1-3 demonstrate this basic effect. Experiments 4-5 examine the definition of found time while replicating the findings from previous experiments. Experiment 6 provides evidence for a potential explanation of these findings: people tend to spend their found time on hedonic activities so as to regulate their work-life imbalance.

EXPERIMENT 1: MAGAZINE CHOICE STUDY

The primary purpose of Experiment 1 was to test the basic hypothesis that consumers are more willing to spend a windfall gain of time (vs. money) on hedonic (vs. utilitarian) activities.

Method

Participants (N = 123) imagined receiving an unexpected gain of either one hour or $10 at their workplace. They imagined spending their gain to read (*time* condition) or purchase (*money* condition) either a hedonic magazine (i.e., TV Guide) or a utilitarian magazine (i.e., Kiplinger's personal finance magazine).

Results and Discussion

Consistent with our hypothesis, Chi-square results revealed that participants in the *time* condition were more willing to spend their gain on the hedonic magazine than those in the *money* condition (Time = 60.5% vs. Money = 41.7%, $p = .039$). The findings from Experiment 1 provide initial evidence that people are more willing to spend their windfall gain of time (vs. money) on hedonic activities. However, one might attribute this effect to potential idiosyncratic differences between the two magazines and the possibility that the hedonic option requires less effort than reading. We tested these alternative accounts in the next experiment.

EXPERIMENT 2. FILM CHOICE

Method

Participants (N = 104) were randomly assigned to one of four conditions in a 2 (resource: time vs. money) × 2 (effort: none vs. additional) between-subjects design. Depending on the condition, participants either imagined hearing from their boss that they could leave an hour early from work (*Time* condition) or that they had won a $10 lottery (*Money* condition). In addition, they were either told that they could use their gain to watch a short film at a streaming website (*no effort* condition) or that they could watch a film at a local theater 20 miles away (*additional effort* condition). The dependent variable was their inclination to watch one of two films: a short film (1) for education, or (2) for fun (11-point Likert scale).

Results and Discussion

Again, participants in the *time* (vs. *money*) condition were more willing to watch a fun film, irrespective of whether additional effort was required to engage in the activity ($M_{time} = 10.34$ vs. $M_{money} = 8.86$, $p = .052$) or not ($M_{time} = 9.84$ vs. $M_{money} = 8.17$, $p = .039$). Experiment 2 replicated the findings in Experiment 1while controlling for the activity and varying activity goals. Because the above results suggest a ceiling effect, we employ a different DV in the next experiment.

EXPERIMENT 3A. A LARGER ACTIVITY CONSIDERATION SET

There were two main goals for Experiment 3. First, we employed a larger activity consideration set to systematically understand resource allocation. Second, we examined whether our findings are limited to situations where the windfall gain is small (vs. large).

Method

Lab participants (N = 41) were assigned to one of the two conditions in a mixed design: (resource: time vs. money; between-subjects) × (amount: small, large; within-subject). Participants either imagined leaving work an hour early (*time* condition), or winning a lottery of $12 (*money* condition). Next, they indicated how they would spend the gain by distributing the gain across eight categories that were composed of four hedonic and four utilitarian activities. Then, they imagined gaining five hours ($60) instead of one hour

($12) and indicated how they would spend the larger gain by repeating the same distribution task.

Results and Discussion

Consistent with the prior findings, participants preferred to spend their windfall gain on hedonic activities both when the gain was small (M_{time} = 65.67% vs. M_{money} = 42.06%, p = .045) and when it was large (M_{time} = 63.67% vs. M_{money} = 37.94%, $p < .001$). These results replicated the pattern of results in Experiment 1 and 2 while employing a bigger activity consideration set. Importantly, the pattern emerged for both small and large gains.

EXPERIMENT 3B. REPLICATING THE FINDINGS WITH M-TURK REPLICATION

The goal of Experiment 3B was to replicate the findings from Experiment 3A by (1) using a non-student sample to further enhance the generalizability of our findings while (2) reducing the size of the consideration set to six different activity categories (we removed the "exercising for fun" and "self-improvement" categories as these two goals often overlap with each other).

Method

The experimental design was essentially the same as in Experiment 3A except that we changed the time/money ratio to $10/1 hour ($50/5 hour) to match the M-Turk pay rate (N = 61).

Results and Discussion

Again, participants preferred to spend their windfall gain on hedonic goals in the *time* (vs. *money*) condition, both when the gain was small (M_{time} = 74.48% vs. M_{money} = 52.07%, p = .022) and when it was large (M_{time} = 69.53% vs. M_{money} = 56.21%, p = .085).

Experiment 3C. M-Turk Replication (6 categories) – 1 hour vs. 3 days

Experiment 3C was designed to (1) examine whether our findings hold with an even greater amount of gain, and to (2) strengthen the study design by counterbalancing the order of the windfall gain amount (small vs. large).

Method

Participants (N = 113) engaged in the same activity-distribution tasks in Experiment 3B with the same mixed design, except that the amount of gain was $10/1hour (small gain) and $720/72 hours (large gain). The order in which participants read the small and large gain scenarios was counterbalanced.

Results and Discussion

Participants were more willing to spend their windfall time (vs. money) on hedonic activities both when the gain was small (60 min vs. $10; M_{time} = 68.44% vs. M_{money} = 52.45%, p = .047) and when it was large (72 hours vs. $720; M_{time} = 66.76% vs. M_{money} = 47.14%, $p < .001$). The order of the tasks did not affect the pattern of results (p = .764).

Together, Experiments 1 – 3 confirmed that people are more willing to spend their windfall time than their windfall money on hedonic activities. One may argue, however, that these findings can be attributed to any type of time gain, rather than the *windfall* gain of time. In the next two experiments, we address this issue by examining the definitional properties of "windfall" gain in our focal phenomenon. In particular, Experiment 4 compares the "not-earned (vs. earned)" aspect, and Experiment 5 compares the "unexpected (vs. expected)" aspect of the windfall gain.

EXPERIMENT 4. GAIN: NOT EARNED VS. EARNED

Methods

Participants (N = 151) were randomly assigned to one of four conditions in a 2 (resource: time vs. money) × 2 (source: windfall vs. earned) between-subjects design. Participants either imagined learning that they could take four hours off due to a delay in supplier schedule (*windfall-time* condition) or their employer's recognition of their own efforts (*earned-time* condition) at their workplace. Alternatively, participants imagined receiving a $40 cash reward, either because the reward resulted from a change in commodity prices that improved firm profits (*windfall-money* condition) or in recognition of their efforts (*earned-money* condition). After reading one of the four scenarios, all participants allocated the 240 minutes/$40 across six activity categories.

Results and Discussion

Consistent with prior findings, people were more willing to spend their windfall time versus money ($M_{windfall-time}$ = 62.83% vs. $M_{windfall-money}$ = 49.56%, p = .049) on hedonic activities. People were more willing to spend their time on hedonic activities when it was earned (vs. windfall) ($M_{earned-time}$ = 87.89%; $p < .001$). In comparison, participants were directionally but insignificantly more willing to spend their money on hedonic purchases when it was earned (vs. windfall) ($M_{earned-money}$ = 55.74%, p = .357). These results suggest that time (vs. money) that is earned gives people a stronger justification to spend the gain on hedonic activities.

EXPERIMENT 5. GAIN: UNEXPECTED VS. EXPECTED

Experiment 5 examines another definitional property of "found time": the unexpected (vs. expected) gain of time. We predicted that people are inclined to use their time (vs. money) for hedonic purposes only when the gain is unexpected (vs. expected). Second, we further examined the generalizability of the findings by demonstrating that our hypothesis holds even when the gain arises from a non-work source.

Procedure

Participants (N = 183) were assigned to one of four conditions in a 2 (resource: time vs. money) × 2 (expectation: unexpected vs. expected) in a between-subjects design All participants first imagined that they were members of YMCA. Participants in the *time* conditions first read that YMCA was closing that day and that they had one hour to engage in other activities. Half of these participants were told that they just learned about the closure (*time- unexpected* condition) while the other half were told that they had been aware of the closure for a week (*time-expected* condition). Participants in the *money* conditions imagined winning a $10 cash prize awarded to local YMCA members; they were told either that they just learned about the prize (*money-unexpected* condition) or that they had been aware of the prize since a week ago (*money-expected* condition). After reading one of the four scenarios, all participants responded to the distribution task across six categories.

Results and Discussion

Consistent with prior results, participants were more willing to spend their unexpected gain of time (vs. money) on hedonic activities ($M_{unexpected-time}$ = 68.64% vs. $M_{unexpected-money}$ = 47.12%; p = .005). However, people's inclination to spend the gain of time on hedonic activities attenuated when it was expected (vs. unexpected) ($M_{expected-}$

$_{time}$ = 53.33%; p = .043). There was no significant difference between the two *money* conditions ($M_{expected-money}$ = 55.83%, p = .295).

The results of Experiment 5 demonstrate that it is not simply a gain of time that leads people to spend on hedonic purposes, but rather an *unexpected* gain of time that leads people to indulge. Overall, results from Experiments 4 and 5 tapped into the definitional properties of found time. In Experiment 6, we seek evidence for a potential explanation of the pattern of results.

EXPERIMENT 6. EXPLAINING THE FOCAL PHENOMENON

We predicted that people prefer to spend their windfall time for fun because they generally under-spend their time on hedonic activities in life. If this were true, we would find an amplified effect among individuals who experience greater discrepancy between how much time they *want* to spend on hedonic activities and how much time they are *currently* spending on these activities. Further, these individuals, namely, those who experience "work-life imbalance," would experience less guilt when deciding to spend their found time on hedonic activities.

Procedure. Participants (N = 109) either imagined being given an unexpected four-hour time off from work (*time* condition) or unexpectedly winning a $40 lottery (*Money* condition) before completing a similar activity-distribution task across six activity categories as in the earlier experiments. Next, we asked participants how much guilt (3 items) they would experience when spending the gained four hour/$40 on recreational (vs. work-related) activities. Lastly, we asked participants to report how they typically spend their time and money in each of three categories ("work/necessities" vs. "fun/recreational" vs. "others") by distributing either 24 hours (*time* condition) or 100 points (*money* condition). They repeated the same procedure to indicate how they *ideally* would like to spend their time and money across the three categories.

Results and Discussion

Consistent with the prior findings, participants in the windfall *time* (vs. *money*) condition were more willing to spend their gain on hedonic activities (M_{time} = 73.42% vs. M_{money} = 51.98%, p < .001).

Discrepancy in resource expenditure as a moderator. We examined whether the discrepancy between ideal and actual expenditure of the focal resource predicted participants' spending decision. First, we calculated two discrepancy scores: (1) a time-discrepancy score = (ideal – actual amount of time spent on hedonic activities), and (2) a money-discrepancy score = (ideal – actual amount of money spent on hedonic purchases). Within the *time* condition, people who spent insufficient time on hedonic activities (e.g., greater time-discrepancy score) were more willing to spend their found time on hedonic activities (p = .005). Within the *money* condition, people who spent insufficient amount of money on hedonic purchases did not particularly want to spend their windfall money on hedonic purchases (p = .431;).

Guilt as a mediator. A mediation analysis (Hayes 2012) revealed that people with greater time-discrepancy score experienced less guilt (α = .83) in spending the found time on hedonic activities; the unexpected time gain allowed them to allocate more of their time to these activities (CI = .11, 1.66).

GENERAL DISCUSSION

Eight experiments revealed that consumers consistently prefer to spend their found time on hedonic activities (1) when they have both small and large activity consideration sets; (2) even when spending the gain requires "additional effort"; and (3) regardless of whether the gain is small or large. Further, the results suggest that people's tendency to spend the time on hedonic activities (4) is more pronounced when the time is earned (vs. not earned), but (5) declines when the gain is expected (vs. unexpected). Furthermore, these effects are attributed to work-life imbalance, such that greater work-life imbalance leads to less guilt and a greater preference for spending found time on hedonic activities.

This research introduces the notion of "found time," a resource that we encounter in our every day lives, but which has not been thoroughly investigated in prior research. In addition, we compare found time and windfall money to provide a better understanding of how expenditure decisions differ between these two resources. Furthermore, we find empirical evidence to suggest that people hold different norms regarding how time should be spent as supposed to how money should be spent; they attempt to use their found time to achieve a greater work-life balance.

The Role of Implicit Theories in Evaluations of 'Plus-Size' Advertising

Melissa Cinelli, University of Mississippi, USA
Lifeng Yang, University of Mississippi, USA

EXTENDED ABSTRACT

The use of larger-sized models in advertising has become more popular in the wake of a substantial body of research documenting the negative effects of exposure to slim models on women's self-esteem (Richins 1991; Wan, Chattopadhyay, and Leboe 2013) and body-satisfaction (Grabe, Ward, and Hyde 2008; Groesz, Levine, and Murnen 2002). Recent research has examined the effectiveness of larger-sized models in beauty and fashion advertisements, largely concluding not only that fashion models do not need to comport to current thin standards to be effective (Martin, Veer, and Pervan 2007; D'Allesandro and Chitty 2011; Papies and Nicolaije 2012; Jansen and Paas 2014) but also that using average- or larger-sized models may be more socially responsible (Alessandro and Chitty 2011). Underlying much of this existing literature is the importance of perceived similarity and self-referencing in driving consumers' positive responses to larger-sized models. Yu et al. (2011), drawing on research connecting perceived similarity to perceived model attractiveness (Horton 2003), found that perceived similarity to the model mediated female participants' attitudes toward an advertised apparel brand. In the context of targeting plus-sized consumers, then, these findings suggest that larger-sized models should be especially appealing to plus-sized consumers, to the extent that the consumer is able to see herself in the model.

When evaluating their perceived similarity to the model, consumers may consider not only their objective body size, but also their subjective beliefs about the extent to which their body size may change in the future. Originally studied in the context of beliefs about intelligence, implicit theories about the malleability of one's attributes have recently been extended to beliefs about body size (Burnette 2010). Entity theorists perceive their body size as relatively fixed and unchanging, while incremental theorists believe their body size to be temporary and malleable. Drawing on the conceptualization of implicit theories, we argue that individuals sharing an objectively similar body size with a model may differ in their subjective mental representation of how similar or dissimilar they are to the model in the advertisement. Specifically, we hypothesize that entity theorists will perceive more similarity with models who are objectively similar in size, while incremental theorists, in line with their overarching self-improvement goals (Nussbaum and Dweck 2008), will perceive greater similarity between themselves and objectively thinner models, as these models represent a desired, and possible, future body size. We further hypothesize that these differences in similarity participations will lead to differences in attitudes towards the advertised product.

A pretest identified a model that was perceived to be overweight, but not very overweight, or obese. In Study 1, participants completed self-report height and weight measures and a body-specific implicit self-theory scale embedded within several unrelated measures. Participants were then presented with a print advertisement featuring this model in a shift dress and were asked to indicate how much they liked the choice of model for the advertisement, as well as their attitude toward the featured dress. Although all respondents reported liking the brand's choice of model, product evaluations were affected by the respondents' size and implicit self-theory. Among respondents who believed their body size could be changed (incremental theorists), obese respondents liked the product marginally more than did overweight respondents. However, among respondents who believed their body size to be fixed (entity theorists), obese respondents liked the product significantly less than did overweight respondents. Study 2 introduced perceived similarity as a mediator of these effects, examined the body-relevance of the advertised product as a potential boundary condition by using a single ad to advertise either a dress (body-relevant) or shampoo (body-irrelevant), and added purchase intentions as a behavioral dependent variable. Replicating the results of Study 1, Study 2 found that product attitudes and purchase intentions varied as a function of both the respondents' body size and implicit self-theory. This relationship, in turn, was mediated by perceived similarity to the model. Among entity theorists, who believe that their body size is relatively fixed, perceived similarity to the model appears to largely depend on the objective similarity between the model and the consumer. However, incremental theorists, who believe their body size to be relatively malleable, appear to imagine themselves as thinner than they actually are, leading them to perceive similarity with the model when she has an objectively smaller body size. Additionally, the hypothesized effects were observed only when the advertised product was body-relevant. When the model's body size was not relevant to the product being advertised (e.g., shampoo), the evaluation of perceived similarity to the model was no longer dependent on objective body size and implicit self-theory, and, as a result, these factors did not affect product evaluations.

Our work contributes to the literature on model body size by suggesting that what is considered an obtainable body size will vary among female consumers according to their current size and their beliefs about the malleability of that body size. Future work should examine whether perceived similarity, generally, and the effects of objective body size and implicit self-theory, specifically, similarly affect men's responses to products advertised by male models of varying body sizes. As with female models, male models have traditionally conformed to a single body type. U.S. retailer Target has recently created a stir by using its first plus-sized male model to advertise products in the Big & Tall section of their website (Olya 2015). Additionally, a central question in the model body-size literature asks when consumers of all body types will be receptive to the use of plus-sized models. Future work should examine whether normal- and overweight consumers have equally positive responses to the use of larger-sized models in advertisements for non-body-relevant products.

Behavioral Interventions to Reducing the Negative Consequences of Deferrals on Subsequent Blood Donation

Michel Clement, University of Hamburg, Germany
Martha Wegner, University of Hamburg, Germany
Nina Mazar, University of Toronto, Canada
Ann-Christin Langmaack, University of Hamburg, Germany

EXTENDED ABSTRACT

The American Red Cross (2014) argues that the number one reason donors give blood is because they "want to help others". However, not everybody willing to donate blood is allowed to. The blood donation process requires individuals to register and to provide information about their health history and the places visited in a certain period. Only if all health conditions are fulfilled, a willing blood donor may give blood. However, too often not all conditions are fulfilled and individuals are either deferred forever (e.g., due to incurable disease) or *deferred for a temporary period* such as two months (e.g., due to low hemoglobin levels; one of the main reasons).

The number of temporary deferrals is substantial. Data provided by the German Red Cross (GRC) blood donation service shows that on average 11.1% of individuals showing up on any given day to donate blood are temporarily deferred. The likelihood of being deferred is especially high at a very early stage of a blood donor-life cycle, as inexperienced blood donors often do not know all health requirements. Medical research indicates that temporal deferrals reduce individuals' likelihood to return at a later opportunity to donate blood, and do so significantly for first-time donors (Custer et al., 2007; Halperin, Baetens, and Newman, 1998). In one study, for example, only 21% of first-time donors returned within three years after being temporarily deferred for low haemoglobin levels compared to a 64% return rate among repeat donors (Hillgrove et al., 2011). Thus, the current research studies the life-saving question of how to better manage such temporary deferrals in order to increase individuals' likelihood to return for blood donation at the next blood drive. Blood donation services worldwide struggle to solve this problem.

The current best practice approach of the GRC and blood services in many other countries is to give to deferred individuals the same thank-you-gift (e.g., a thank you-button or coffee mug with the GRC logo) that they give to individuals that donated their blood. Yet, the deferred individuals' return rate is lower. Unlike individuals that donate their blood, deferred individuals have invested their time and effort to come to a blood drive and have expected to contribute to the greater good, potentially even feel a warm glow (Andreoni, 1990; Ferguson et al., 2012) without achieving these goals (Laran and Janiszewski, 2009); an experience that is likely to be frustrating and unfulfilling, and may even result in anger (Custer et al. 2007; Halperin, Baetens, and Newman 1998).

Blood donation services need to address these negative effects of deferrals in order to increase individuals' return rate. The current research tests in an online (study 1) and in a field experiment (study 2) the impact of four different strategies that examine the effectiveness of (1) appreciation, (2) reciprocity, (3) commitment, and (4) warm glow on the intention to return for blood donation and individuals' actual return rate.

In study 1, we confronted 1,641 participants with a scenario in which a friend wants to donate blood and is deferred by the doctor after 30 minutes wait time due to a low hemoglobin level-test result. We tested between participants potential new deferral strategies of the GRC. We examined the four types of strategies (appreciation, reciprocity, commitment, and warm glow) across 12 conditions. For example, appreciation was tested in form of the current best practice

of handing out a thank you-button (control) versus a verbal "Thank you" from the medical doctor. Reciprocity was tested among others in the form of providing the friend with medicine that will increase the iron level in the blood versus a leaflet containing information about iron deficiency. Commitment was tested in the form of handing out a new appointment card. Finally, for the warm glow strategy, we tested the effectiveness of various alternative good deeds offered to the friend, such as a monetary donation or painting a part of a picture for children in a cancer hospital.

Focusing on participants with blood donation experience (N = 1,002), regression results indicated that at least one instantiation of each of the four strategies was expected to significantly increase the likelihood of the deferred friend to return for blood donation (in comparison to one of the current best practice approaches of the GRC).

In study 2 we were able to test three strategies in the field. Based on the results from study 1 and practical limitations (the GRC does not plan to hand out donor cards to first-time visitors that got deferred), we decided on observing actual donation behavior of deferred individuals across the following two strategies in addition to control-appreciation (a coffee mug gift; one of the current best practice approaches of the GRC): commitment (new appointment card) and warm glow (offering to paint a small square within a big picture for a children's hospital). The GRC provided the data about returned and non-returned donors after a period of four months when another donation was theoretically possible. The final sample consisted of 85 deferred donors who received either an appointment card or could paint a picture, and 865 deferred donors who received a coffee mug. We ran logistic regressions to estimate the propensity scores for our subsequent matching procedures. Our findings consistently indicate that providing the donor with a new appointment or an opportunity to do an alternative good deed results in significantly higher rates of return (71% and 73%, respectively) after a deferral compared to the current practice of handing out a thank you gift (52% and 53%, respectively).

The current research addresses a major social problem in blood donations and tests strategies to re-motivate deferred individuals to return. Together, in two studies we find that recognizing the effort of the deferred individual by handing the individual a thank you gift leads to inferior results compared to simply setting a new appointment or offering to spend some more time to paint a picture for a children' hospital. Our results provided clear managerial guidelines that are now being executed by the GRC blood donation service.

Do I Get Stronger When I Stop to Eat My Spinach?
The Impact of Planned Breaks on Self-Regulation

Rita Coelho do Vale, UCP-Catolica Lisbon School of Business and Economics, Portugal

EXTENDED ABSTRACT

Past research has outlined the importance of planned deviations on goal- pursuit (Coelho do Vale, Pieters, and Zeelenberg 2016). However, no specific research has focused specifically in understanding the impact of planned breaks on consumers' self-regulatory ability. That is the aim of the present research.

Previous research has highlighted that although individuals acknowledge the importance of engaging in virtuous behavior, they often find it difficult do so (Ein-Gar 2015). The reason for this is typically related with people's inability to self-regulate themselves, with individuals being more likely to succumb to various flawed decision strategies when lacking self-regulatory resources (Baumeister, Sparks, Stillman, and Vohs, 2008). In the dieting domain, for example, it has been shown that although dieters can resist temptations in the short term, they tend to fail on subsequent tasks of resisting to temptations, because of the reduced resources that are available for self-regulation (Vohs and Heatherton 2000). In line with this, Wansink and Chandon (2014) highlighted the need to help consumers develop strategies to persist in their dieting quests. Moreover, it has also been shown that several factors can influence consumers' ability to be able or not to self-regulate behavior. For example, recent work from Job and colleagues (2015) suggests that individuals who believe that willpower is an abundant resource tend to exhibit better self-control after demanding tasks. Other work from Salerno and colleagues (2015) indicated that for consumers with self-regulatory goals the feeling of pride experienced after self-regulatory accomplishment can discourage their engagement in further self-regulatory tasks, licensing them to indulge. Also Walsh (2014) showed a boundary effect of self-control, but this time with findings suggesting that goal priming can attenuate the depletion effect on a subsequent self-control task.

Despite all these previous studies, more research needs to be conducted to offer consumers strategies they can implement to better exert self-regulation and attain their goals. For example, findings from Campbell and Warren (2015) stress the importance f goal monitoring, since consumers tend to exhibit a progress bias in goal-pursuit, with expectations of goal attainment moderating the progress bias.

The present research builds on the idea that when consumers exert effort in engaging in virtuous behavior, self-regulatory resources become depleted, decreasing the ability to proceed with further self-regulatory activities (Baumeister 2002; Muraven and Baumeister, 2000; Schmeichel and Baumeister 2004). Relaxation or deviation from virtuous activities may then be needed in order to allow the replenishment of self-regulatory resources and to allow individuals to proceed with self-regulatory activities. For example, Gailliot and colleagues (2007) findings revealed that the exertion of self-control in tasks of varied nature reduced blood glucose levels and that restoring the level of glucose to a sufficient level typically improves self-control (Gailliot and Baumeister, 2007). We propose then that deviations from virtuous or goal-consistent behaviors, because of the potential hedonic valence of these activities, may help consumers' regain self-regulatory resources, allowing them to persist in further self-regulatory tasks.

We claim however that it is crucial that these deviations are planned because unplanned deviations might easily be interpreted as failures and might lead to a "what-the-hell" effect (Cochran and Tesser, 1996) with self-regulatory behaviors being interrupted. There-fore, in a similar vein to Popeye, we propose that to plan in advance to stop once in a while to "eat my spinach" may be helpful, making consumers stronger to continue with their self-regulatory quests. Findings from two experimental studies support this idea revealing that breaks can be a powerful strategy to increase consumers' ability to proceed with further self-regulatory tasks.

In study 1, we tested our predictions using an objective behavioral measure of self-control to assess self-regulatory ability effects of planned goal deviations. We used the maximum amount of time that participants can squeeze a handgrip, building on prior depletion research (Muraven et al., 1998). In study 2, using a similar procedure to the previous study in which participants were asked to list their thoughts while avoiding to think on a white bear, we assessed consumers' reported self-regulatory resources. Both studies were computer-based (Authorware 6.0, Macromedia Inc. 2001).

Importantly, the fact that self-regulatory tasks were performed just for a few minutes in both experiments and that even so we found significant effects rules out the possibility that our findings could have been explained by simple fatigue. It is striking that mental thought control task exerted for a just brief period of time interferes with participants' ability to perform a physical task--the self-regulation measure. The consistency of findings across the experiments indicates that indeed the inclusion of self-regulatory breaks leads to less strain on self-regulatory resources than no-break processes, thus contributing to higher likelihood of proceeding with self-regulatory tasks. The two experiments underline the importance that self-regulatory misaligned activities are planned and incorporated *a priori* in the self-regulatory process.

This finding supports our prediction that prior knowledge of the possibility of engaging in self-regulatory breaks increases the ability to proceed with further self-regulatory tasks. Participants in the planned break group showed higher self-regulatory ability than participants that performed exactly the same task sequence but did not know in advance the possibility of engaging in the self-regulatory break during which they could engage in tasks of different nature.

Our results demonstrate that when consumers incorporate in their self-regulatory pursuits the possibility of engaging in planned-misaligned activities this enhances their self-regulatory ability, which may also enhance their likelihood of long-term goal attainment. This is new, and it points to the importance of flexibility in tasks that involve the continuous exertion of self-regulation. Unplanned misaligned activities (the "breaks") may feel as failures and thus set a "failure cascade" in motion, with a "what the hell" effect as result, such that self-regulatory tasks are completely abandoned. Our results suggest that quite the contrary happens when breaks are planned, strengthening self-regulation and showing that indeed it may be a good strategy to stop and eat spinaches along the self-regulatory quest.

Consumer Endorsements:
When and How Do Consumers Remember Their Own Misleading Recommendations?

Elizabeth Cowley, University of Sydney, Australia
Christina I Anthony, University of Sydney, Australia

EXTENDED ABSTRACT

Consumers are often encouraged to recommend brands (i.e. "like us" on Facebook). On some occasions, particularly when incentivized, consumers may endorse brands that they don't really like very much. An interesting question is when and how do consumers remember their own misleading recommendations? Remembering previous endorsements, and the veracity of the endorsements, is important as the remembered endorsements may affect future decisions and word-of-mouth. The research reported here contributes to the growing interest in consumers lying to other consumers and to marketing/service professionals (Anthony and Cowley, 2012; Argo and Shiv, 2010; Argo, White, and Dahl, 2006; Sengupta, Dahl, and Gorn 2002) and the ensuing consequences. We discuss deception, arousal, and autobiographical memory research to support our hypothesis that heightened arousal, caused by the act of lying, improves memory for the misleading information communicated.

DECEPTION AND AROUSAL

Most people consider themselves to be moral (Mazar, Amir, and Ariely, 2008) and are motivated to behave in a manner consistent with their moral identity (Stets and Carter, 2011). However, the pursuit of social or personal goals often requires the communication of deceptive information (Mazar and Ariely 2006; Mazar and Hawkins, 2015). Given that communicating deceptive information in the form of telling a lie is believed to be immoral (Spranca, Minsk, and Baron, 1991), a conflict emerges for the liar (Mazar and Ariely, 2006). Moral conflict has been shown to increase the activation of the autonomic nervous system, or arousal, in the liar (Karim et al. 2010).

It is important to note, that not all lies are alike with respect to the conflict created and the resulting arousal felt by the liar. Previous research has made a distinction between lies of commission where details, known to be false, are communicated as true and lies of omission where details are purposefully concealed with the intent to mislead (Bok, 1978). Importantly, people consider lies of commission to be more immoral (Spranca, Minsk, and Baron, 1991) and as such, commission lies are associated with a greater discrepancy between moral self and the act of lying. Given the increased conflict between what the liar believes to be a moral action and how the liar is behaving (Mazar, Amir, and Ariely, 2008), arousal should be greater for commission lies compared to omission lies.

AROUSAL AND MEMORY

Autobiographical memory research has shown that emotionally-arousing events are better remembered than non-emotional events (Conway et al. 1994). One explanation for improved memory of emotional event information is that arousal narrows attention and favors processing of the emotion-eliciting information, which results in better memory for details central to the emotional aspects of an event compared to details peripheral to the emotional component of an event (Burke, Heuer, and Reisberg 1992; Easterbrook 1959). Based on this reasoning, we hypothesize that when lies involve heightened arousal due to a moral conflict, memory for the lie should be more accurate because the lie is central to the communication.

Another theoretical explanation for improved memory of emotional events is priority binding (Hadley and MacKay, 2006). According to priority binding, emotional arousal during encoding encourages stronger binding of the information central to the emotional event to the episodic context (peripheral, non-lie information) because it facilitates retrieval. Therefore in contrast to an attention-narrowing account, a priority-binding explanation would predict that arousal felt when lying should enhance memory for both central and peripheral information. We include tests and measures to reveal whether attention narrowing or priority binding better explains the data.

PRESENT RESEARCH

In four studies we provide evidence that consumers who offer misleading endorsements (to gain financially or because they are under social pressure) have significantly more accurate memory for the content of their false recommendation when the consequences of their lie are greater. In each study participants record a false recommendation for a marketer (study 1) or a friend (studies 2-4). We manipulate (or measure) the consequences of the lie and measure memory for the recorded message one day later. In studies 1 and 2, lies of commission (pre-tested to be more consequential than omission lies in terms of moral conflict, n = 51) result in more accurate memory for the content of the lie than lies of omission. In studies 3 and 4, we manipulate the consequences directly via a stakes manipulation adapted from DePaulo, Lanier, and Davis (1983) and find the same result. Results from all studies show that liars in high consequence conditions remember the content of their false recommendation more accurately and that the effect is mediated by heightened arousal. We also show that that memory for peripheral details is less accurate for liars in high consequence conditions. In other words, we find a trade-off between memory for central and peripheral details which supports the attention narrowing explanation. The results essentially eliminate the priority binding explanation. We also eliminate the alternative explanation that any type of arousal improves deception memory.

CONCLUSION

The results reported here offer insight into when and why consumers remember – or forget – the misleading endorsements they provide. Given that arousal heightens and attention narrows at the point of communicating the misleading endorsement, particularly for liars by commission, it is possible that from a moral balancing perspective (Nisan, 1991), the consumer may attempt to 'compensate' or 'correct' for their inflated memory for the deceptive endorsement, by communicating less positive recommendations or word-of-mouth about the brand in the future. It is also possible that liars by omission actually become more positive about the brand and behave more like an advocate. Our findings provide the first step towards understanding how deceptive endorsements affect consumer behavior by focusing on consumers' memory biases for the misleading information they have communicated. In addition to examining the consequences for WOM communication, future research will determine how memory for false endorsements affects consumers' satisfaction for the brand/service provider, repeat patronage and loyalty.

Fields of Transcultural Practices:
The Role of Religion in Multicultural Marketplaces

Angela Gracia B. Cruz, Monash University, Australia
Yuri Seo, University of Auckland, New Zealand
Margo Buchanan-Oliver, University of Auckland, New Zealand

EXTENDED ABSTRACT

While previous studies of the intersections between religion and consumer behavior have largely conceptualized religion as a source of marketplace differences (Delener 1994; Engelland 2014; Hirschman 1983; Minton et al. 2015; Wilkes et al. 1986), based on a view of religion as stable belief systems within homogenous, ordered, and bounded consumer cultures, what is less developed is an account of the role of religious practices in light of increasing cultural complexity. In particular, there is further scope to consider the role of religion in relation to the dynamics and complexities of multicultural marketplaces (Demangeot et al. 2015; Jamal 2003; Kipnis et al. 2014). Specifically, what role does religion play in shaping multicultural marketplaces?

To redress this theoretical gap, this paper draws on the concept of transculturality (Welsch 1999), shifting our attention beyond religion as a stable belief system toward religion as a field of transcultural practices. The concept of transculturality can be understood both as a distinct theoretical perspective of cultures and as a unique approach for exploring cultural dynamics (Flüchter and Schöttli 2014). Transculturality contests the traditional Herderian perspective of cultures, where cultures are conceived as self-contained and homogenous entities delimited from external influences (Herder 1966). Instead, transculturality posits that cultures are inherently dynamic, hybridized, and deeply entangled. Whereas other approaches would be either concerned with comparing and contrasting one culture to another (i.e., a cross-cultural approach) or exploring ways in which the 'clashes' between separate cultures can be mitigated (i.e., an intercultural approach), a transcultural approach involves understanding the beliefs and practices that transcend borders (Brink 1994) and fostering cultural interconnections at a more abstract level than the content and meaning of individual cultures.

Our conceptualization of religion as a field of transcultural practices is empirically grounded in a hermeneutic analysis (Thompson 1997) of depth interviews with 24 Southeast Asian immigrant consumers living in Auckland, New Zealand. To enrich and deepen the consumer narratives, visual and reflexive methods were deployed. First, each participant was asked to select objects and photographs which represent their experiences of migration (Zaltman and Coulter 1995) and use drawings to represent their social networks and social identities (Bagnoli 2009). Second, each participant was interviewed twice in line with open narrative reflexivity (Thompson et al. 1998). In their second interview, participants were presented with the researchers' emerging interpretations and provided an opportunity to correct, qualify, or further deepen their initial responses.

Our analysis identified two interrelated sets of transcultural practices through which religion shapes multicultural marketplaces. The first set of practices facilitates entry into multicultural marketplaces, by easing the process of border crossing and enabling social capital development. While transnational migration is a challenging process requiring adaptation and socialization on multiple fronts (Peñaloza 1994), religious fields offer a modicum of stability through the stresses of transition. In doing so, religious fields ease the process of border crossing for consumers entering into a new marketplace. An additional mechanism through which religions can facilitate an entry into multicultural marketplaces is by enabling the development of social capital, which has been shown to be a crucial ingredient in fueling integration into a new society (Luedicke 2011; Üstüner and Holt 2007).

The second set of practices facilitates mutual entanglement within multicultural marketplaces, by fostering intercultural competency development, sharing of cultural consumption rituals, and enabling the flows of material resources. First, through the development of skills and experience in communicating with people from other cultural backgrounds, religious practices enable participants to observe, learn, and practice intercultural competency (Demangeot et al. 2013). Second, mutual entanglement is further facilitated through the sharing of cultural consumption rituals across cultural boundaries. Finally, religious practices facilitate transcultural entanglement through the diffusion of material resources, reflecting the local- and global-scale "travel of material things in everyday life" (Brembeck et al. 2015, 1).

This paper helps to advance the growing literature on religion and marketing in two ways. First, beyond the dominant treatment of religion as a 'micro-culture' (Cleveland et al. 2013; Hirschman et al. 2011; Lindridge 2005; Minton et al. 2015; Steenkamp 2001), a transcultural approach moves religion beyond a view of each religious tradition as a bounded system. Instead, religion emerges as an open and dynamic system which is deeply contextualized and whose function morphs to meet the character of the cultural context in which it is embedded. Second, in addition to the present focus on how religion produces differences in marketplace behaviors (Delener 1994; Engelland 2014; Hirschman 1983; Minton et al. 2015; Wilkes et al. 1986), this paper also sheds light on the transcultural properties of religion which are held in common across diverse religious traditions. Rather than becoming a dividing force in contemporary multicultural marketplaces, religious fields are also revealed to be hybridized and hybridizing fields of transcultural flows. Overall, in the context of multicultural marketplaces, religion emerges as a key site for the performance of practices which fuel transcultural dynamics.

Boundary Crossing and the Diffusion of Cultural Innovations

Pierre-Yann Dolbec, Concordia University, Canada

EXTENDED ABSTRACT

This research examines the development of a musical scene in Croydon, UK in the late 90ies and early 2000s (the FWD>> scene), which later developed into the dubstep music genre (in the early-to-mid 2000s), and was integrated into the popular music category of Electronic Dance Music (EDM) (in the early 2010s). I concentrate on the transference, translation, and transformation of the knowledge associated with this innovative new sound between a local scene, a trans-local niche, and a mainstream market.

The emergence of electronic music in the popular music market offers an ideal field site to inquire about the role of consumers in the creation of objects that foster the preservation of cultural innovations and their transformation to fit existing mainstream market conventions.

Electronic music, an umbrella category that regroups a number of different genres, started in the late 70s and early 80s in the U.S. Since then, more than 300 genre names have been alluded to in this category (McLeod 2001). Some of these genres were started in local clubs, such as the Warehouse for house music (Reynolds 2012), the Blue Note for drum 'n' bass (Burns 2013), and the Happy Days club nights for UK garage (Titmus 2014), before moving to the niche of electronic music, and then to the popular music market. A number of these genres are still being enjoyed by consumers and produced by musicians. Some of the more popular genres are now the anchoring elements of the US$6B market constructed around EDM.

I answer the two following research questions: first, what actions do niche consumers and prosumers perform to foster the creation of a boundary infrastructure and second, how does a boundary infrastructure facilitates the crossing of the boundaries between each market level. Previous research has seldom examined the market processes underlying the accumulation of cultural innovations and ensuring their continuation over time, instead concentrating on the intentional efforts of market actors in enacting changes (see Dolbec and Fischer 2015). Moreover, the diffusion of cultural innovations is often perceived as the result of the active work of market actors (Crane 1999; Lena and Peterson 2008), which relegates to the background the role of the knowledge-based infrastructure necessary for the discussion of such innovations across a number of social worlds

This research project aims at contributing to the extent literature by showcasing the role of consumers and to producers in the construction of a boundary infrastructure and fleshing out dynamics happening at the boundaries between three different market levels: local, niche, and mainstream. Such an approach provides a new conceptual lens to the study of the diffusion of innovation and the evolution of market systems (e.g., Giesler 2008; 2012; Martin and Schouten 2014).

My findings emerge from the analysis of an extensive qualitative data set comprised on 14 long and 32 short interviews as well as a 14 months netnography, and archival data from newspaper articles (369), secondary interviews (101), and conference panels (32). I iterated back-and-forth between the data collection and the analysis and triangulated my findings between sources and time periods. My findings were devised both from a theoretically-grounded approach and an emergent one. This approach follows existing recommendations in the literature (Belk, Fischer and Kozinets 2013; Langley 1999; Spiggle 1994).

I adapt Carlile's (2002, 2004) framework on boundary crossing to explain how actors construct and use a boundary infrastructure, effectively creating a memory for a market, to bridge all three market levels. I explain how the interactions between consumers and producers lead to the creation of a boundary infrastructure, a "stable regime of boundary objects" (Bowker and Star 2000: 313) that facilitates the bridging of the boundary separating two "worlds" (such as in this case a local market and a transnational niche market). First, knowledge crosses an information-based syntactic boundary through knowledge transfer through the use, for example, of taxonomies, storage, and retrieval technologies. For example, as dubstep was emerging as a local innovation from the city of Croydon, a consumer created an important library of pirate radio shows that became a go-to destination for consumers interested in learning about dubstep. I show how actors' efforts to archive and catalog the productions and evolution of the FWD>> sound facilitated the knowledge crossing from Croydon to the greater niche of electronic music. Second, knowledge crosses a meaning-based semantic boundary through knowledge translation through the use, for example, of cross-functional teams (or in this case niche consumption communities) and boundary spanners. A key point here is the generation of a shared understanding for consumers and producers located on each side of the boundary. I show how the creation of niche consumption communities was an important step in the creation of shared understanding. Third, knowledge crosses a politically based pragmatic boundary through knowledge transformation through the use, for example, of objects and models that demonstrate possible form, fit, and function (Carlile 2004). Boundary objects such as prototypes and exemplars contribute to the crossing of the pragmatic boundary. I identify the creation of a compilation by London superclub Fabric as a key moment in the transformation of dubstep which moved the center of the community away from Croydon and allowed for an influx of producers interested in developing the new sound highlighted on this compilation. It had as a consequence the reinterpretation of the power dynamics and the transformation of the sound into what is now known as dubstep.

This paper repositions the work of the online conversations and initiatives of consumers by highlighting their crucial role in creating a boundary infrastructure that participates in the diffusion of innovation. This represents a departure of the role of consumers' online work, which previously has been conceptualized as being individualistic and centered on the self (e.g., Belk 2013), or centered on the creation of innovations (e.g., Kozinets, Hemetsberger and Schau 2008). This work is of interest for a variety of scholars studying market system dynamics, the diffusion of innovations, digital marketing and the work of consumers.

Consumer Co-Creations: Understanding Disappointment with Co-Created Products

Leigh Anne Novak Donovan, Illinois State University, USA
Richard J. Lutz, University of Florida, USA

EXTENDED ABSTRACT

Close brand relationships and consumer co-creation opportunities are usually positive for consumers and companies. However, not all co-creation experiences are successful and positive. We explore the 'dark' side of consumer co-creation and the negative reactions, such as embarrassment and failure attribution, felt by consumers and how they can impact self-esteem.

Consumer participation in the co-creation of products is at an all-time high and has yielded a wide range of positive outcomes attributed to product customization (e.g. Franke, Schreier, and Kaiser 2010; Moreau and Herd 2010; Mochon, Norton, and Ariely 2012). While the positive effects of successful co-creation have been explored, attempts at co-creation and designing products are not infallible. We investigate how consumers react to disappointing co-created products by exploring consumer reactions following disappointing (or satisfying) co-created items as moderated by prior brand relationship and whether this can be attenuated.

The branding literature has established that consumers often form self-brand connections and that these brands are then incorporated into one's self-concept (e.g. Escalas and Bettman 2003). Researchers have begun investigating how consumers with strong self-brand connections react to failures (Donovan et al. 2012; Cheng, White, and Chaplin 2011). Donovan et al. (2012) found consumers are more likely to forgive a brand when they have a strong self-brand connection prior to the failure. Cheng et al. (2011) explored how self-brand connections influence consumer reactions to negative information about brands they are close to, demonstrating that consumers do not want to accept this information because this would hurt the self as well as the product. Through two studies we examine how consumers react to co-created failures based upon prior self-brand connection.

Weiner, Russell, and Lerman (1978) proposed two types of emotional reactions following a critical incident. First, people experience general, undifferentiated responses of positivity versus negativity. Second, a more complex emotional reaction is experienced not only to the event, but also to the self-relevant implications of a positive or negative event. Thus, one is not just responding to the valence of the event, but to what that event is thought to imply about the self (Brown and Dutton 1995). Individuals' responses to these emotions are more likely to be experienced along with internal attributions rather than external attributions (Weiner, Russell, and Lerman 1979). Thus, we predicted that those with close self-brand connections feel more self-relevant emotions when a co-created product disappoints (Study 1) and that the relationship between self-relevant emotions and self-brand connection are mediated by attributions (Study 2). As previous research has shown, when a consumer has a close relationship with a brand and this brand is portrayed negatively, the consumer's self-esteem can be damaged (Cheng et al. 2011). We predict that consumers with a close self-brand connection will show decreased self-esteem when they make internal attributions following the failure.

Study 1 was designed to test the emotional reactions to a co-created product design (successful/unsuccessful) and the prior relationship with the brand (close/distant). We operationalized this by having participants respond to a scenario that involved either a successful or an unsuccessful customized design of Nike shoes (N=90). A significant interaction of outcome and self-brand connection was observed on negative emotional reactions: shame ($\beta = .25$, SE = .11; t (86) = 2.31, p = .02) and embarrassment ($\beta = .24$, SE = .13; t (86) = 1.93, p = .05). Spotlight analysis of the continuous measures confirmed that those with prior close self-brand connections were more ashamed (Mclose = 3.80 and Mdistant = 2.90) and more embarrassed (Mclose = 4.24 and Mdistant = 3.32) by their customized failure in the unsuccessful scenario ($p < .05$) for both emotions. Study 1 demonstrates that close self-brand connections increase the negative emotions such as embarrassment and shame following a failed customization.

Study 2 examined the relationship between emotions and attributions in response to a failed co-created product. We wanted to understand how internal and external attributions would influence reactions to a failure based upon prior brand relationship and explore the impact of an inoculation condition. We focused on the negative aspect of an online customization consumption experience, and participants were randomly assigned to the normal or inoculation condition. In the inoculation condition, participants were informed that items may appear differently on their screen, due to color differences, brightness, etc. We measured self-brand connections, using the Inclusion of the Other in the Self (IOS) measure (Reimann and Aron 2011), attributions of locus and control, emotional responses of shame, embarrassment, self-consciousness, and state self-esteem.

We found that attributions of control mediated the relationship between IOS and shame with a 95% confidence interval excluding zero (-.15 to -.001) and the interaction of IOS x locus of control demonstrated how attributions and brand relationship interact on feelings of shame ($\beta = -.17$, SE = .08; t (48) = -2.1, p = .04). If the failure was attributed to the self and there was a close brand-self connection, shame was highest (MClose = 4.60 versus Mdistant = 2.62). However, when the failure was attributed to the brand, no significant effect was observed for shame (MClose = 2.09 versus MDistant = 2.35). Thus, attributions were influencing negative self-referencing emotions. However, when the inoculation was introduced, this effect completely disappeared (p = .70) and the mediation was also insignificant (95% confidence interval was -.03, .24) Next, we examined whether attributions and self-brand connections affected state self-esteem. We found a significant interaction of attribution x self-brand connection on state self-esteem ($\beta = .07$, SE = .04; t (48) = 2.02, p < .05). Again, when the inoculation was introduced the interaction was not significant (p = .48).

Next, two sequential mediations using PROCESS Model 6 (Hayes 2012) were performed to examine whether close relationships, internal attributions and emotions affected felt state self-esteem. We found significant mediation from IOS→attributions→emotions→self-esteem, with a 95% confidence interval excluding zero (.001 to .056) (all other paths insignificant). Next, using multiple self-critical emotions estimated the mediation IOS→attributions→Shame→Self-consciousness→State self-esteem. We found a significant three mediator sequential mediation with a significant 95% confidence interval (.0005, .0358) and all other paths insignificant. Thus, the mediation analyses provided clear evidence of how disappointing co-created products can affect state self-esteem. Neither sequential mediation was significant when the inoculation was introduced.

Overall, our results provide novel and significant insights into a growing form of consumer-brand interactions. We documented new findings relating to self-brand connections, brand co-creations and

how attributions can influence self-esteem. Additionally, a managerial actionable inoculation was introduced that successfully attenuated the effects of attributions and self-brand connections. When the inoculation was introduced, all interactions and mediations disappeared, as expected. Those with close self-brand connections no longer attributed the failure to the self and, thus, did not experience a dip in self-esteem. They were able to attribute the failure to a technology failure instead.

Reducing Uncertainty by Increasing It:
How Inducing Uncertainty in Uncertainty Appraisals of Reviewer Trustworthiness Attenuates Bias Correction and Product Devaluation

Christilene du Plessis, Erasmus University, The Netherlands
Andrew T. Stephen, Oxford University, UK
Yakov Bart, Northeastern University, USA
Dilney Goncalves, IE Business School, Spain

EXTENDED ABSTRACT

We investigate how consumers process product reviews written by other consumers (i.e., "user-generated content" or UGC reviews). Though some consumer behavior research investigates the impact of review content on readers (e.g., Villanueva, Yoo, and Hanssens, 2008) the research does not examine how information that accompanies reviews influence processing.

Reviews are often accompanied by additional auxiliary-information such as information about the reviewer (e.g., if the reviewer is a novice or expert) or review generation process (e.g., if the reviewer was paid to write the review). In this research, we investigate when and why uncertainty induced by auxiliary-information will and will *not* carry over to adversely impact consumers' evaluations of reviewed products. This is important because UGC reviews can be useful to consumers when evaluating products. However, concerns regarding reviewer trustworthiness often undermine the utility of UGC reviews. Thus, this research investigates the processing of UGC reviews under uncertainty, and when and why its adverse effect on judgments is mitigated.

Despite extensive research on source credibility in the context of persuasive communications (e.g., Sternthal, Dholakia, and Leavitt, 1978; Kang and Herr 2006) and WOM (e.g., Herr, Kardes, and Kim,1991), little is known about the role of uncertainty in consumers' processing of UGC reviews. Though it is obvious that uncertainty regarding source trustworthiness should result in information discounting, it is unclear when and why this will *not* occur. This is important because source-related uncertainty undermines review usefulness. We theorize that metacognitive processing of source-related uncertainty can determine when it will adversely impact judgments. Such processing entails thinking about or elaborating on uncertainty (i.e., doubting one's doubts). We propose that merely thinking about uncertainty, can mitigate its adverse effect on product evaluation. This occurs without having to establish or defend reviewer credibility or trustworthiness. Instead, we show that "mere thought" can lead to uncertainty about source-related uncertainty, which undermines its impact on judgments. Of course, elaborating on source-related uncertainty could also solidify doubts, thus enhancing its adverse effects on judgments. As such, it is shown that the mere thought effect depends on whether source-related uncertainty is integral (enhance) or incidental (attenuate) to judgment formation.

In **study 1**, we use field data collected from Amazon.com and exploit a natural experiment across a diverse set of products. For each product we collected both uncertainty-inducing reviews (where it is disclosed that reviewers were incentivized) and reviews that do not induce uncertainty (without any uncertainty-inducing auxiliary-information). For uncertainty inducing reviews, reviews of products that are associated with high elaboration (because consumers are highly involved in the purchasing decision) were perceived as more helpful than reviews of products that are associated with low elaboration ($b=1.35$, $t=2.69$, $p< .02$). There was no difference in the perceived helpfulness, due to elaboration, for reviews that do not induce uncertainty ($b=.01$, $t=.02$, $p=.98$).

In **study 2** we consider when elaborating on source-related uncertainty will *not* adversely affect judgments. We predicted that participants told that incentivizing reviews is common practice would be *more* inclined to doubt their uncertainty in the trustworthiness of the reviewer when they spend time elaborating on their uncertainty. This occurs because it is unclear whether the reviewer was incentivized because he/she expected payment or because the company wanted to bias the review. In contrast we predicted that participants who are told that incentivizing reviews is uncommon practice would be *less* inclined to doubt the validity of their uncertainty, regardless of how much time they spend elaborating on it.

We tested whether the effect of incentive disclosure (paid=1, not paid=-1) on product evaluation through uncertainty appraisals was moderated by payment norm (payment-uncommon=-1, pooled payment-common=1) and evaluation time. As predicted, in the payment-common condition there was a significant negative indirect effect of disclosure on product evaluation through uncertainty when evaluation time was lower (-1 SD; indirect effect=-.31, 95% C.I.=[-.44, -.17]), but not when evaluation time was higher (+1 SD; indirect effect=.02, 95% C.I.=[-.10, .19]). In the payment-uncommon condition the negative indirect effect of incentive disclosure on product evaluation through uncertainty was significant when evaluation time was lower (-1 SD; indirect effect=-.21, 95% C.I.=[-.40, -.02]] and when it was higher (+1 SD; indirect effect=-.30, 95% C.I.=[-.57, -.08]).

In **study 3** we consider when elaborating on source-related uncertainty will adversely affect judgments. We show that uncertainty only influences judgments when elaboration renders it integral (i.e., when uncertainty is deemed to be credible and useful in judgment formation). Building on study 1, this effect is explored using auxiliary-information about whether or not a reviewer was paid. Consistent with our hypothesis that uncertainty should not be credible in order for it to become incidental when elaborated upon, some participants were told the payment source is a nonprofit organization that does not stand to benefit from a favorable review. We expected to *not* find an uncertainty-mediated effect of this incentive disclosure on product evaluations when the review is positive and when the uncertainty is thought through (high elaboration), because the uncertainty will not be credible. This was also predicted for participants who were not told that the reviewer was paid to write the review. Conversely, some participants were told the payment source was the product developer or seller. Since these sources stand to benefit from a positive review, elaboration on source-related uncertainty was expected to render uncertainty integral to judgment formation. The silent and paid by nonprofit conditions were pooled in the analysis (-1) as were the developer and seller conditions (1). We find a significant negative indirect effect of disclosure, through uncertainty, on product evaluations when elaboration was high (95% C.I.= [-.14, -.03]), but not when elaboration was low (95% C.I.= [-.10, .01]). In other words, when elaborating on uncertainty renders it integral in judgment formation merely thinking about source-related uncertainty makes it important.

This research contributes to the UGC reviews and WOM literatures by examining how consumers process UGC reviews under

uncertainty and, when and why source-related uncertainty distorts the influence of reviews on consumer product evaluations.

Reminders of the Sun Influence Men's Attitude towards Luxury Products

Mohammed El Hazzouri, Mount Royal University, Canada
Kelley Main, University of Manitoba, Canada
Donya Shabgard, University of Manitoba, Canada

EXTENDED ABSTRACT

Consumers purchase luxury products for various reasons including expressing personal values (Richins, 1994) and mimicking successful others (Mandel, Petrova, & Cialdinia, 2006). An evolutionary perspective suggests different motives; females seek mates who have resources that help provide for their offspring (Buss &Schmitt, 1993). Thus, males use luxury products to signal their resources and attract females (Schmitt & Buss, 1996). When motivated with mating goals, males prefer luxury products (Griskevicius et al., 2007; Saad, 2007). In this research, we investigate how a nature related variable associated with human mating can influence men's preference for luxury products.

The different seasons and human conception are correlated (Roenneberg & Aschoff, 1990a). Conception peaks during the summer months (Lam & Miron, 1994). Photoperiod- length of daylight-has been found to be the strongest predictor of seasonality of conception (Roenneberg & Aschoff, 1990b). Given that daylight influences human mating, then it is plausible that reminders of the sun may trigger this motivation and increase males' preference for luxury products. We investigate how reminders of the sun affect male consumers' preference for luxury products.

EXPLORATORY STUDY

We conducted an exploratory search on Google Trends related to variation of searches for the term luxury throughout the year. We conducted a search for the weekly popularity of the term "luxury" worldwide and for a few specific countries for a period of seven years 2008-2014. Results showed that searches for the term luxury peak in the weeks following June 21st (the longest day of the year in the Northern Hemisphere). For northern hemisphere countries, searches peaked following June 21st while for southern hemisphere countries, searches peaked following December 21st.

STUDY 1

This study was a 2 (sun reminders: no vs. yes) x 2 (gender: male vs. female) designed to examine how reminders of the sun affect preference for high-end brands. Undergraduate students (N=210, 52.4% female; M_{Age}=20.12) at a northern city participated in this study. Sun reminders were manipulated by asking participants to arrange scrambled words that contained (did not contain) words related to the sun into complete sentences. Participants reported their positive mood (PANAS scale; Watson, Clark, & Tellegen 1988), and preference for high-end brand names (rating the importance of having high-end brands) for publicly (e.g. glasses) and privately (e.g. towel) used products (1=not important at all; 7=very important).

Results of planned comparisons showed that men reported significantly higher preferences of high-end brand names for publicly used products when reminded of the sun than when not (M_{No}=4.25 vs. M_{Yes}=4.80; F(1,206)=4.07 , p<.05). Reminders of the sun had no effect on men's preference of high-end brand names for privately used products or women's preference of either product category.

Mediation analysis using Process Model 7 (Hayes, 2013), indicated the interaction of sunlight reminder and gender did not predict positive mood (ß=.40; t(206)=1.26, p>.1). However, positive mood predicted preference of high-end brand names of publicly (ß=.27; t(207)=3.40, p<.01) and privately used products (ß=.23; t(207)=3.01, p<.01). For men, results revealed a significant conditional indirect ef-

fects of sun reminders on preferences for high-end brand names of publicly (ß=.11; 95% CI =0.0070 to 0.3019) and privately used products (ß=.10; 95% CI =0.0099 to 0.2798). For women, the indirect effect was insignificant for publicly (ß=.00; 95% CI =-0.1270 to 0.1277) and privately used products (ß=.00; 95% CI =-0.0997 to 0.1366).

STUDY 2

In this study we further examined whether sexual motivation contributes to men's preference for luxury products when reminded of the sun. We also examined whether the geographical location of participants (northern vs. southern states) influences the expected effects. The effect of sunlight seasonality on humans should be more prominent for those living far away from the equator (Northern USA) than those living near the equator (Southern USA) since seasonal variation of lengths of daylight is larger in areas further away from the equator. This study was a 2(Sun reminder: no vs. yes) x 2(Location: north vs. south). Participants viewed an advertisement for Hugo Boss with a background that either featured a sunny sky (Sun reminder: yes) or a dark sky (Sun reminder: No). Male participants from Mturk completed this experiment online (N=125, M_{Age}=33.84). The final sample included 121 participants as few participants were excluded for not reporting their state of residence or for reporting extreme values on the dependent variables (z>2.5). Participants indicated their attitude towards the brand (4 items on a 7-point bipolar scale- good: bad, etc. (α=.91)). Later, participants viewed five sexualized images of heterosexual couples and rated them (7-point bipolar scale – unattractive: attractive, etc. (α=.89)).

Results of planned comparisons showed that residents of northern states reported significantly higher attitude towards the brand (M_{No}=4.78 vs. M_{Yes}=5.39; F(1,115)=4.63, p<.05) and sexual motivation (M_{No}=5.82 vs. M_{Yes}=6.37; F(1,115)=4.85, p<.05) when reminded of the sun than when not. Residents of southern states did not show such a difference for attitude or sexual motivation (p>.1). Mediation analysis (Process Model 7, Hayes 2013) indicated that the interaction of sun reminder and location significantly predicted sexual motivation (β=-.82, t(115)=-2.46, P=.01). Sexual motivation significantly predicted attitude towards the brand (β=.48, t(116)=5.05, P<.001). Finally, results revealed a significant conditional indirect effects of sun reminder on attitude towards the brand for residents of northern states (ß=.26; 95% CI =0.0615 to 0.5674). There was no significant conditional indirect effect of sun condition on attitude towards the brand for residents of southern states (ß=-.13; 95% CI =-0.3798 to 0.0674).

CONCLUSION

Our studies provide evidence that sun reminders positively affect males (but not females) attitude towards publicly used luxury products. This effect is mediated by sexual motivation. Men who live further away from the equator (northern US. States) are more affected by the effect of sun reminders.

This research contributes to the evolutionary psychology literature as it establishes that sun reminders trigger sexual motivation. Second, findings of this research add to our understanding on how the environment affects consumer behavior. Since our findings indicate that reminders of sunlight can activate sexual motivation, we suggest that such reminders may successfully replace sexual images in advertising that are usually used to increase sales of luxury products.

Comparison Focus:
The Asymmetric Impact of Context Effects on Advantaged versus Disadvantaged Options

Ioannis Evangelidis, Bocconi University, Italy
Jonathan Levav, Stanford University, USA
Itamar Simonson, Stanford University, USA

EXTENDED ABSTRACT

When considering the introduction of a new product, a product manager needs to assess the effect of the new product on sales of the existing product line. For instance, what would be the effect of adding an expensive hard drive that offers more capacity than cheaper competitors on the shares of the existing hard drives in the market? A product manager who consults academic research in search of an answer to this question is unlikely to find a consistent guideline. First, the normative principle of "independence of irrelevant alternatives" (IIA) asserts that adding new options should have no effect on the relative preference for the original options (Ray 1973). Second, the "similarity hypothesis" (Tversky 1972) asserts that a new option can influence relative preference for the original options in the set by drawing share from the more similar option. Third, in contrast to the similarity hypothesis and the IIA principle, consumer research on "context effects" demonstrates that a new option can influence relative preference by increasing the choice share of the more similar option. For instance, an alternative is chosen more often when an inferior decoy is added next to it (Huber et al. 1982). Similarly, an option is chosen more frequently when it becomes an intermediate option by the addition of a new extreme option to the set (Simonson 1989; Simonson and Tversky 1992).

In this paper we advance a new hypothesis, comparison focus, which attempts to explain when each of these three predictions will be observed. Comparison focus invokes the relative advantage of one option over another in the baseline set to predict how changes in choice set configuration influence choice shares. Comparison focus predicts that a given change in choice set configuration is more likely to benefit a target option that is disadvantaged (i.e., has a low choice share) compared to a target option that is advantaged (i.e., has a high choice share) in the baseline set. Comparison focus predicts both replications and reversals of established context effects. Our research is prompted, in part, by the recent debate that has called into the question the very existence of context. Here we take the position that even though context effects are a real phenomenon, they are not necessarily observed in every situation in which a new option is added to a set. Thus, the key question—which also serves as the focus of this paper—is when context effects are more likely to be observed or, by extension, when normative hypotheses are more likely to be satisfied or violated.

We find support for comparison focus in fifteen studies and in a series of meta-analyses using both real and fictitious products with a wide range of attributes. In our first six studies (Studies 1a-1f), we test comparison focus in the case of extremeness aversion. These studies show that the addition of a new extreme option increases the share of the more similar intermediate option when that option is disadvantaged rather than advantaged in the baseline set. In our next five studies (Studies 2a-2e), we test comparison focus in the case of the attraction effect. We find that the addition of an asymmetrically dominated option increases the share of the target when that option is disadvantaged rather than advantaged in the baseline set. In our final four studies we directly (Studies 3a-3b) and indirectly (Studies 4a-4b) test and find supporting evidence for our proposition that changes in choice set configuration drive decision-making by drawing attention away from the focal comparison (between the target and the competitor), therefore reducing the chances of that comparison taking place. Thus, disadvantaged alternatives tend to benefit relative to their advantaged counterparts because the new choice set configuration dilutes the weight of the original advantage on choice.

We should note that, although a majority of our stimuli are adapted from prior research that reports evidence of context effects, we observe both replications and reversals of prior findings depending on the relative advantage of the target in the baseline set. Our findings suggest that context effects are not necessarily predicated on stylized product representations with numerical attributes. Our research also challenges the common assumption that context effects occur where consumers have relatively high preference uncertainty, and shows that context-dependent preferences can be observed even under low preference uncertainty. In this regard, comparison focus offers a new perspective on context effects: rather than operating as heuristic solutions when making trade-offs under high uncertainty, context effects arise as a result of the comparisons consumers make between alternatives in a set, even when preference uncertainty is low.

Hedonic Editing Revisited

Ellen Evers, University of California Berkeley, USA
Alex Imas, Carnegie Mellon University, USA
George Loewenstein, Carnegie Mellon University, USA

EXTENDED ABSTRACT

In daily life, we generally experience of a lot of negative and positive events and outcomes. How do we evaluate situations consisting of multiple experiences? One could expect that the way we experience a set of experiences is merely the sum of these experiences; the pleasure of winning $30.- plus the pleasure of winning $20.- is equal to the pleasure of winning $50.-, and the pain of losing $5.- ten times in a row is equal to the pain of losing $50.- at once. But research suggests that the way we evaluate series of experiences is not always just the sum of the evaluation of the individual experiences (Fredrickson & Kahneman, 1993).

Based on prospect theory, we would assume that people try to mentally combine negative experiences. After all, due to prospect-theory consisting of a convex loss-function, the sum of the experience of two painful outcomes is bigger than the experience of the combination of the two outcomes. On the other hand, we should like to separate positive experiences, since it is more pleasurable to have two smaller good things than it is to have one larger good thing happening. This intuition has been expressed by Thaler (1985) as part of this work on mental accounting calling this process of selectively integrating and segregating outcomes *"hedonic editing"*. Even though these predictions (integration of losses and segregation of gains) appear fairly straightforward, research on the integration of experiences and outcomes has failed to find any conclusive evidence that people indeed group negative events differently from positive ones. For example Thaler & Johnson (1990, Experiment 2) presented participants with two negative outcomes and asked them whether a person experiencing both negative events at the same time, or a person experiencing the events a week apart would be more upset. Contrary to expectations, no systematic effect was found that participants expected those experiencing the events on the same day would be less upset. Linville & Fisher (1991) also tested whether people were more likely to integrate losses as compared to gains, but did so using a slightly different method. Similar to Thaler & Johnson (1990) they also presented people with two events, but they asked participants to indicate whether, if the first event happened today, they would prefer the second event to take place today as well, or rather one week later. Overall, they found that participants wanted to both gains, as well as losses to happen one week apart. Thus, their results did *not* support the idea that people are more likely to integrate losses as compared to gains. Taken together, it appears that people do *not* group positive events and outcomes differently from negative ones. This lack of support for hedonic editing has even lead Thaler (1999) to proclaim a "failure of the hedonic editing hypothesis."

Then what determines when and how people aggregate outcomes? As mentioned by Kahneman and Tversky (1984) it seems likely that two events that are encoded in the same mental account are aggregated before evaluation while those that are not part of the same account are evaluated separately. If that is the case, we would *only* expect hedonic editing effects to emerge whenever there is reasonable flexibility in the degree to which two outcomes can be part of the same mental account or not. If two bad outcomes cannot plausibly be part of the same mental account, they cannot be integrated even if it would make those events feel less bad. For example, even though it may feel less bad to first aggregate a painful visit to the dentist with one's favorite vase breaking before evaluating those events, it seems impossible to come up with a mental account that could encapsulate both. Just like some outcomes cannot share the same mental category, other outcomes may be extremely difficult to segregate because they obviously belong to the same category. For example, it may feel more pleasurable to win four times $50.- in the lottery rather than $200.- at once, but one has to be quite skilled at self-deception to convince oneself that a single lottery-win of $200.- is actually four separate instances of a $50.- gain. The ability to hedonically edit ones outcomes thus appears to be constrained by the degree to which the relationship between outcomes is ambiguous enough for these outcomes to plausibly share a mental account or not. If the outcomes are clearly part of one category, segregation is unreasonable and both gains and losses will be integrated. If the outcomes are clearly members of different mental accounts, integration is implausible and both losses and gains will be evaluated as segregated outcomes. However, when there is flexibility in the degree to which the outcomes belong to the same mental category, we would expect to find evidence for hedonic editing. In these cases, people will be more likely to integrated losses and segregate gains.

In five experiments we test whether the degree of category/membership is an important moderator of hedonic editing effects. More specifically, in Experiment 1 we investigate and find that people are more likely to integrate losses when these losses occur in the same domain rather than in different domains. Then, in Experiment 2 we replicate and extend Experiment 1 both by testing similar, dissimilar and moderately similar outcomes, as well as including both losses and gains. For losses we find that increased similarity leads to an increase in preference for them occurring the same day, while for gains this pattern does not emerge. In Experiment 3 we do not manipulate the (dis)similarity of the outcomes, but instead manipulate the width of the category. When the category is perceived to be broader, participants were more likely to integrate the negative outcomes. Finally, in Experiment 4a and 4b we test the underlying process and find that these differences in preference for outcomes occurring on the same vs. different days can be explained by the degree to which participants place these outcomes in the same category.

Moving Forward, Falling Back:
How Perceptions of Motion Mask the Dangers of Unhealthy Consumption

Tatiana M. Fajardo, Florida State University, USA
Jiao Zhang, University of Oregon, USA
Michael Tsiros, University of Miami, USA

EXTENDED ABSTRACT

Logos (whether visual or verbal) can be designed to suggest motion (Luca, Krishna, and Elder 2014). In general, motion generates a sense of aesthetic excitement and interest (Freyd 1993). In line with this, logos comprised of dynamic images typically increase consumer engagement. They may also lead to more favorable brand evaluations if there is a perception of fit between the associations of motion and brand characteristics. Specifically, Luca, Krishna, and Elder (2014) demonstrate that dynamic logos lead to more favorable brand attitudes than static logos when paired with modern (as opposed to traditional) brands, and this effect is driven by a perception of fit between motion and modernization.

Beyond this, little is known about the downstream consequences of utilizing dynamic logos. In this research, we examine the effect of logo dynamism in the context of self-control dilemmas. We propose that the perception of motion in a logo triggers thoughts of the future. Consumers generally exhibit an optimism bias, such that they associate the future with an increase in their well-being. We hypothesize that this perceived increase in their future well-being will lead consumers to indulge more in the present. This suggests that dynamic logos will increase the consumption of vices. We tested this hypothesis across four studies.

We first examined whether perceptions of logo motion could influence actual consumption. In Study 1A, we demonstrated that participants' likelihood of selecting an unhealthy snack (e.g., chocolate chip cookies) over a healthier alternative (e.g., raisins) was significantly increased when the snacks were associated with a dynamic logo (i.e., a swinging pendulum vs. a still pendulum). In Study 1B, we demonstrated that participants would consume more of an unhealthy snack (e.g., chocolate) when it was paired with a dynamic logo rather than a static logo (i.e., a leaping horse vs. a still horse). Logo type, however, had no influence on how much of a healthy snack (e.g., granola) participants would consume. Having demonstrated that dynamic logos increase vice consumption, in the next studies we examined the mechanism underlining this effect.

According to our conceptualization, dynamic logos create the perception of motion. The perception of motion leads to an expected increase in future well-being. Consumers use this expected increase in future well-being to justify potentially harmful consumption in the present, leading to an increase in vice consumption. Whether motion leads to an expected increase in future well-being should depend on the direction in which the motion is perceived to be traveling (Chae and Hoegg 2013; Topolinski and Sparenberg 2012). In Study 2, we employed two types of dynamic logos, one with motion towards the right (i.e., a horse leaping towards the right) and one with motion towards the left (i.e., a horse leaping towards the left). The expectation being that a dynamic logo with motion towards the left would not influence vice consumption because it would not lead to an expected increase in future well-being that could be used to justify vice consumption in the present.

The results of Study 2 supported this theorization. When the dynamic logo featured the perception of forward motion (i.e., motion towards the right) purchase likelihood for a vice product significantly increased. However, when the logo featured the perception of backward motion (i.e., motion towards the left) purchase intent for the vice product (marginally) decreased. Logo type and direction of perceived motion had no effect on purchase intent when consumers considered a relatively virtuous product. Importantly, these results rule out several alternative explanations which would attribute our effect to an increase in arousal or a perception of fit between vice products and motion.

In Study 3, we extended these results by directly manipulating participants' time orientation. Under control conditions, we saw a replication of earlier results. A dynamic logo significantly increased purchase intent when a product was presented as a relative vice; logo type did not influence purchase intent when a product was presented as a relative virtue. When participants were primed to think about their future, there was only a significant main effect of product type. Regardless of whether the ad featured a dynamic logo or a static logo, purchase likelihood increased when the product was presented as a vice. Any effect of logo type and/or product type was eliminated when participants were primed to think about their past.

Our theorization suggests that if consumers did not perceive the future optimistically or were unwilling to use an expected increase in future well-being to justify unhealthy consumption in the present, dynamic logos would not benefit vice products. We tested this idea in Study 4. In Study 4, we measured participants' concern of future consequences (CFC). CFC is a personality trait defined as the extent to which an individual considers the future outcomes of their current behavior and the extent to which they are influenced by these imagined outcomes. Consumers high in CFC are less likely to use an expected increase in future well-being to justify unhealthy consumption in the present (Adams and Nettle 2009; Kovac and Rise 2007). Among participants low in CFC (below the mean CFC index rating), there was a significant product type by logo motion interaction, the pattern of which replicated earlier results. Furthermore, as we expected, the positive effect of a dynamic logo on vice consumption was mediated by perceptions of how justifiable consumption of the product would be. Among participants high in CFC (above the mean CFC index rating), the product type by logo motion interaction was not significant. Purchase intent among these participants was not influenced by logo type, regardless of whether the product was presented as a vice or a virtue.

A substantial body of literature has focused on these strategies consumers use to control their short-term consumption impulses in order to secure long-term interests. In other words, this literature has focused on how consumers consciously or unconsciously limit their choice of vices. In this research, we examine how an external marketing cue, the brand's logo, may threaten consumers' ability to control their consumption of vices.

In Good Shape: The Influence of Container Curvature on Consumers' Perceptions and Consumption

Alexandra Festila, MAPP Centre, Department of Management, Aarhus University, Denmark
Polymeros Chrysochou, MAPP Centre, Department of Management, Aarhus University, Denmark

EXTENDED ABSTRACT

Whether we do our grocery shopping at a supermarket, eat at our favourite restaurant or have a drink in a bar, our foods and drinks most often come in a container. This means that the contact we have with food is almost always mediated by a package. Packages themselves come in all shapes and sizes, even for products belonging to the same product category. Take, for example, the different shapes found in the soda and juice categories - from the hour-glass shape of Coca Cola bottle to the rounded shape of Tropicana. Or, for example, the differently shaped glasses used in various specialties of beers. But does package shape influence our perceptions about a product and our consumption behaviour?

Research has tackled this issue from many angles. The shape of packages and containers has been shown to influence the inferences consumers make about the content of food such as taste and calorie estimation (Becker et al. 2011; Koo and Suk 2016), or to even influence choice and consumption (Raghubir and Krishna 1999; Yang and Raghubir 2005). For example, Raghubir and Krishna (1999) showed that rectangular packages that are more elongated are perceived to be larger than same-size packages that are less elongated. Such a distorted perception further influences how much consumers eat (Raghubir and Krishna 1999; Wansink and Van Ittersum 2003). On the other hand, Koo and Suk (2016) provided evidence that, at the same time, consumers perceive a food product in elongated packages to be less caloric than an identical food in a wider packages of equal capacity. The above-mentioned research accounts for rectangular shapes. In the case of more organic and irregular shapes Folkes and Matta (2004) unveiled a different mechanism, such that package shapes that attract more attention are perceived to be larger than same size packages that attract less attention. Our undertaking in the present research is to build upon and extend this literature by investigating whether the actual curvature of the container can influence consumers' inferences and consumption behaviour.

In particular, in Study 1 we propose and demonstrate that the curvature of the container is likely to act as a cue for evaluating a food item's healthfulness, due to the different conceptual associations activated by the shape. Previous research has shown that consumers are prone to use certain implicit cues to make inferences about a product's healthfulness and caloric content. For example, the colours used on the package (Schuldt 2013), the typeface depicting the brand (Karnal et al. 2016) and even the shape of the package (Koo and Suk 2016) carry certain symbolic meanings that are used by consumers to make inferences about a food item's healthfulness. Although they are explicitly unrelated to health, these cues activate certain associations that will spill over to judgements about a food item's healthfulness and caloric content. Similarly, our premise is that the curvature of the container triggers associations with the human body (Epley, Waytz, and Cacioppo 2007) and that consumers use these associations to make inferences about caloric content and food product healthfulness. When a food product is presented in a concave container (where the mid-point is more narrow than the upper and bottom parts), it will be perceived to be lower in calories and more healthy than when the same food product is presented in a convex container (where the mid-point is wider than the upper and bottom parts). Our account for this is that a concave container resembles a healthy body, whereas a convex container resembles an unhealthy

body. In Study 1 (between-subjects) respondents (N=226) were exposed to a bottle of juice that was manipulated to be either concave or convex and asked to estimate the caloric content (on a scale from 0 to 300 calories) and report perceived healthfulness of the product (on a 9-point scale). Respondents who saw the juice in the convex container estimated the juice to have more calories (M=198.19) than those that saw the juice in the concave container (M=170.43), t(224)=3.46, p=.001, d=0.46. Additionally, the juice presented in the convex package was perceived to be significantly less healthy (M=6.61) than the juice presented in the concave package (M=7.13), t(224)=2.58, p=.010, d=0.35.

In Study 2 we also find that container shape can moderate how consumers' eating control discourse influences their anticipated consumption guilt. Using the same stimuli and design as in Study 1, this time respondents (N=339) were asked to report how guilty they would feel if they consumed the juice. Additionally, we also assessed consumers' eating control with a three-item 7-point scale (M=3.49; α = .72) (Chrysochou et al. 2010). Following a regression analysis, the marginally significant interaction between eating control and container shape (β = -.32, t(335) = -1.96, p=.051) suggests that individuals high in eating control feel more anticipated consumption guilt than individuals low in eating control when the food product is presented in a convex package, but not when the product is presented in a concave package. This is in line with previous findings which show that restrained consumers are more susceptible to nutrition information and derive more guilt when eating foods they believe to be unhealthy or high in calories (Wansink and Chandon 2006).

In Study 3 we show that consumers also eat more when the food is displayed in a convex container compared to when the food is displayed in a concave container. Participants (N=61) were instructed to serve themselves with M&Ms that were presented in either a convex or concave glass (between-subjects). Our results suggest that participants that served M&Ms from the convex glass had a significantly higher caloric intake (M=42.91) than participants that served M&Ms from the concave glass (M=26.36), t(59)=3.29, p=.002, d=0.85. This means that participants that served M&Ms from the convex glass had on average 63% more caloric intake than those that served the M&Ms from the concave glass. This is contrary to one's first intuition that people will try to eat less from a food they consider to be high in calories or unhealthy. Our explanation for this effect is that there is another mechanism that takes over in a consumption situation, where the package becomes a visual measurement tool to monitor consumption (Wansink 2004). In this sense, it is more difficult for consumers to monitor the food displaced from a convex container because the level remaining in the container appears to decreases at a slower pace (due to a wider middle). The opposite would hold true for a concave container.

Overall, our findings indicate that the curvature of a package can influence what consumers infer about that product (the number of calories and perception of healthfulness), how they feel about consuming that product (anticipated consumption guilt) and ultimately their consumption behaviour (how much they eat), extending previous research carried out in this area (Wansink 2004). This could inform both food-marketing practitioners and public policy that aims to assist consumers in making optimal food-related decisions. For example, if the aim is to enhance perceptions of healthfulness mar-

keters might want to use a concave shaped package. On the other hand, consumers might also be benefited from being served from a concave container, as this will enable them to downsize their consumption.

However, our research is not free of limitations. We still need to acquire a more-in-depth understanding of the mechanism behind these effects and the generalizability of our current results should be accounted for through further replication studies. Additionally, certain contextual or individual factors might moderate these relations. For example, in the first two studies the food stimuli used was relatively virtue (orange juice) while in the third study the food stimuli was relatively vice (M&Ms). This has also been shown to impact consumers' perceptions and consumption behaviour (Chernev and Gal 2010).

To Me or Not to Me:
Personal Body as Contested Ownership

Elena Fumagalli, HEC Paris, France
Luca M. Visconti, ESCP Europe, France
Kristine de Valck, HEC Paris, France

EXTENDED ABSTRACT

This paper advances extant knowledge in the field of consumer studies dealing with alternative forms of ownership (access-based consumption, Bardhi and Eckhardt 2012; hybrid economies, Scaraboto 2015; liquid ownership, Bardhi, Eckhardt, and Arnould 2012; and sharing, Belk 2010). In particular, we are interested in examining contested ownership, a subject position that has so far received scant attention in consumer studies. Contested ownership is defined as the market condition consumers experience whenever their entitlement to a given possession is jeopardized and they are faced with some form of economic, emotional, psychological, and/or social cost. Contested ownership extends the stream of research that has investigated the processes by which individual possessions are translated into shared possessions (Giesler 2008), and vice versa (Bradford and Sherry 2015; Epp and Price 2010; Visconti et al. 2010).

We explore contested ownership in the context of contemporary body modification practices (Bjerrisgaard, Kjeldgaard, and Bengtsson 2013; Featherstone 1999; Patterson and Schroeder 2010). We give particular attention to non-mainstream forms of body modification (e.g., branding, scarification, sub-dermal implants) and body performance (e.g., body suspension), where contested ownership is particularly prominent. Nonetheless, we also include practices such as tattooing and piercing, not only for their widespread diffusion—in the US 21% of the population has at least one tattoo, with 20,000 tattoo studios and an annual revenue of the tattoo industry of about $2.3 billion (TAM 2015)—, but also because of the evidence that even a single tattoo or piercing can unleash vivid tensions around body ownership. The modified person uses his/her own body—an individual possession *par excellence*—to pursue some personal benefit, including artistic desires, augmented physical functionalities, beautification, identity expression, physical pleasure, psychological well-being, and social affiliation. Yet, several body-modified people report having been blamed, discriminated against or offended, both within their inner circle of family members and friends as well as in wider professional and social circles. We document a variety of affective, cultural, economic, legal, and social tensions characterizing the daily life of body-modified people. Our empirical study explores: (1) the lived experience of people whose legitimate entitlement to their body is contested; (2) the resources they mobilize in order to resist disentitlement; and, (3) the forces at play favoring disentitlement.

We adopt a longitudinal approach, with data being collected over eight years (2009-2016). Consistent with the market-oriented ethnographic tradition (Arnould and Wallendorf 1994), we combined ethnographic interviews with observations in modifiers' studios and during specific events (e.g., body suspension conventions), and observations of online forums (Kozinets 2002). We conducted 16 in-depth interviews (McCracken 1988) with 14 different informants (lasting from 90 minutes to several hours). 93 additional short interviews (lasting from 30 to 90 minutes), all semi-structured and obtained from different informants, complement our interview dataset. Internet observation was also multi-sited, yet focused on the Body Modification Enzine (BME.com), which has become the global gathering platform of the body modification community. In order to check for the cultural embeddedness of body modification meanings, practices, and ownership contestation, we collected data from more than 20 different countries. Overall, our dataset includes 1,218 pages of interview transcriptions, 32 pages of field notes, and 6,989 pages of netnographic data, all in Times New Roman 12, double-spaced. Besides our primary data, we also gathered a large amount of secondary data (articles, books, films), which served to explore the history of body modification as well as to triangulate our interpretations with those of other researchers. Secondary sources totaled approximately 1,215 pages of text and 330 minutes of video. We analyzed primary and secondary sources individually and then through open and axial coding (Spiggle 1994). QRS Nvivo assisted data analysis. Codes, categories, and themes resulted from an iterative process.

Our findings are centered on (inter)personal tensions arising from body modification and resulting in states of contested body ownership. By means of a semiotic square, we first document four types of subjective positions that body-modified people may experience with reference to their body: (1) the practical body, (2) the utopian body, (3) the experiential body, and, (4) the mundane body. The semiotic square provides a rich and varied representation of the motivations leading people to modify their bodies. Such motivations can be organized along two main criteria: (1) the nature of motivations (expressive versus hedonic); and, (2) the main recipient of the modifications (others/outer-directed versus oneself/inner-directed). Regardless of the nature and recipient of motivations, our data shows that most body-modified people do not undertake modifications for subversive or provocative reasons. Still, many are faced with an environment that reacts to their modifications with mixed feelings ranging from tolerance to incomprehension, from fear to disgust, and from rejection to discrimination. Our data reveals that critical reactions to body modifications are not only emotional and cultural, but are also meant to limit body-modified people's freedom to alter their own body. Consequently, they disclose tensions about whom ultimately owns the body: the body-modified person, his relatives or society at large.

Notably, contested ownership is not limited to tensions arising between the body-modified person and people outside this subculture. First, our research has unveiled tensions arising at the personal level. Typically, modifications with which a body-modified person does no longer identify may create severe states of psychological tensions. Second, contested ownership can also emerge within the body modification subculture, both with other body-modified people, as well as with one's modifier (e.g., when a modifier rejects practicing a modification requested for motives considered futile or unworthy, or when the modification is deemed too risky or illegal). Our analysis furthermore reveals how contested body ownership is affected by facilitating and hindering factors on the individual, micro-social and institutional level. While local factors (e.g., cultural, legal, social) may account for variation in the findings, body modification appears as a largely transcultural market phenomenon (Berry et al. 2002), engendering states of ownership contestation at a global sphere.

"Will We Hate Google One Day?"
A Convention Theory Perspective on Public Brand Evaluations

Sabrina Gabl, University of Innsbruck, Austria
Verena E. Stoeckl, University of Innsbruck, Austria
Andrea Hemetsberger, University of Innsbruck, Austria

EXTENDED ABSTRACT

With ubiquitous access to online social media and the democratization of consumer voice, everything and everyone potentially becomes subject to public evaluation. For many years now, researchers have observed how consumers engage publicly in rating, commenting, and contesting brands online, and how these evaluations cumulate to a more networked, better informed, and potentially more powerful public opinion (Arvidsson 2008; Benner, Reinicke, and Witte 2004). A rich body of research has studied brand evaluations and their commercial relevance for brands in the context of brand communities (Schau, Muñiz, and Arnould 2009), innovative consumer communities (Kozinets, Hemetsberger, and Schau 2008), and brand publics (Arvidsson and Caliandro 2016). Fournier and Avery (2011, 200) link critical consumer evaluations in social media with the assessment of brand value, when stating that—in an age of criticism—the accumulations of consumers' "authoritative judgment and critique" determine the interpretations of brand messages and the value brands afford. Arvidsson (2010) identifies an increasing tendency of consumers in an information society to objectify the ethical value of brands in general sentiments rather than in formal ethical standards.

Although these observations suggest that public brand evaluations build on a plurality of opinions about a global brand's value, consumer researchers thus far neither account for the multiplicities of values engaged in public brand evaluations in global audiences, nor do consumer researchers account for the strategies that apply in public brand evaluations. To address these gaps, this netnographic study sets out to investigate public brand evaluations directed at the Google brand, one of the most debated brands in public for its continual reinterpretation and violation of existing social arrangements (Giesler 2015).

Drawing on convention theory's notion of *test* (e.g., Boltanski and Thévenot 2006 [1991]; Dansou and Langley 2012), this study identifies, analyzes, and interprets public brand evaluation directed at the Google brand over an eleven year time frame (2004-2014) on one of the largest, global online tech platforms—Slashdot.org. For data selection, we followed the netnographic criteria on traffic and data richness defined by Kozinets (2010) and ended up with seven threads (with, typically, between 400 to 600 and 1,000 comments) per year. Convention theory provides a conceptualization that aids the uncovering of evaluative principles at work in public critique and justification. It argues that in moments of test, in which current understandings are under critique, actors do not only argue from their individual perspectives, but also underline and justify their arguments by showing their relevance to a limited set of higher-order principles or *orders of worth* (e.g., Boltanski and Thévenot 2006 [1991]; Thévenot, Moody, and Lafaye 2000) and "engage discursively, and even strategically, with [these multiple orders] to justify their position and achieve legitimacy" (Ramirez 2013, 848).

Findings reveal a plurality of orders of worth mobilized in discussions and illustrate how tests of the Google brand predominantly raise civic, market, and industrial orders of worth. We find two major evaluative strategies that coordinate public brand evaluation: *negotiating a leeway of acceptable brand conduct* and *allocating responsibilities*. Contributors to Slashdot continually *negotiate the leeway of acceptable brand conduct* by comparing Google's conduct with what they regard to be worthy or to be *common goods*—best for the general public (Moody and Thévenot 2000). Overall, tests are either directly based on orders of worth or they refer to other entities and perform benchmarking procedures. For example, actors repeatedly mobilized the civic world when they argued that Google's actions were compliant with the law—a common good according to the civic order of worth. Benchmarking procedures often involved comparisons to industry players (e.g., Microsoft) or similar cases. For example, actors relativized Google's business practices by mobilizing market orders of worth and comparing them to business practices of competitors. Actors situated brand actions either within or outside the negotiated leeway, continually reset the boundaries of acceptable brand conduct, and allowed acceptable actions to balance unacceptable ones.

Allocating responsibilities is an evaluative strategy through which actors want to make sure that the right party is scrutinized. The allocation of responsibilities can either be based on an established leeway or can involve the recognition that the brand under scrutiny is moving in a grey area, as there are no precedents or clear leeways of acceptable conduct to draw on. In discussions of privacy issues (situated mostly within the domestic or the civic order of worth), for example, justifications of the Google brand aimed to shift responsibilities to the government or even the individual. Actors argued that the government should not ask for user data and that individuals are responsible for their online footprints. Shifting responsibilities to other entities is most important for a brand when it allegedly operates outside of its leeway of acceptable brand conduct.

The contribution of this study is threefold: Firstly, we discuss public brand evaluations as a form of ethical engagement in a globalized economy. We suggest that when the lack of global governance systems makes it difficult to assign collective moral duties on brands and to monitor compliance with collectively defined rules (Giesler and Veresiu 2014; Holt 2002), public brand evaluations provide a dynamic and potentially powerful tool for auditing a global brand's conduct and for charging or deflating a brand with "ethical capital" (Arvidsson and Peitersen 2013, 92). Secondly, we introduce a convention theory perspective on public brand evaluations. Convention theory offers a huge potential by emphasizing "systemic and structuring influences" (Askegaard and Linnet 2011, 381) and allowing researchers to "escape from the alternative between formal universalism and unlimited pluralism" (Boltanski and Thévenot 1999, 365). Thirdly, we offer a nuanced interpretation of how public brand evaluations can direct brand conduct in global arenas—similar to a brand monitoring tool (cf. Giesler 2012; Thompson, Rindfleisch, and Arsel 2006)—and influence public understandings of brands against a macro-context. By observing brand critique and justification in test situations, brand managers can learn about the evaluative criteria applied and entities involved in benchmarking processes.

Softness in the Ear: How Musical Sophistication Influences the Interaction Between Music and Expected Haptic Softness

Maximilian Gaerth, University of Mannheim, Germany
Haiming Hang, University of Bath, UK

EXTENDED ABSTRACT

Auditory atmospherics such as background music in the shopping environment are one of the most investigated elements of the store atmosphere. However, also in the online context, the frequently demanded strategic implementation of sensory stimulating marketing strategies (Krishna 2010, 2012) represents a promising approach to respond to the challenge of selling products for which sensory information is diagnostic. Consequently, retailers and other service providers are constantly interested in utilizing new findings in order to create a distinctive brand experience (Hultén, Broweus, and van Dijk 2009). Although existing research has widely investigated crossmodal interactions involving the auditory modality, it still leaves many important questions unanswered; for instance, can musical sophistication influence the interaction between music and haptics? Prior work rarely looked specifically at the underlying mechanisms of individual differences in multisensory perceptions. In view of the fact that the capability to decode musical meaning is assumed to be a function of musical background (Knöferle et al. 2015), how would musically sophisticated consumers respond to soft (vs. hard) music when shopping for textiles compared to consumers with low levels of musical sophistication?

In this research, we contribute to furthering such understanding by providing three experiments demonstrating how musical sophistication affects audio-tactile interactions. In particular, we show how higher musical sophistication enhances consumers' expectations about the haptic softness of products after listening to soft (vs. hard) music. Musical sophistication is defined here as "psychometric construct that can refer to musical skills, expertise, achievements, and related behaviours" (Müllensiefen et al. 2014, p. 2).

Extant research has established that perceptual information in different sensory modalities can be recoded into abstract formats whose semantic dimensions partly overlap (Martino and Marks 1999; Melara and Marks 1990). In addition, marketing research on the crossmodal effect between music and haptics indicated that music is, in fact, translated into semantic associations related to musical as well as haptic softness (Imschloß 2014). Integrating the findings from these research streams, there are three main ways as to how musical sophistication can affect audio-tactile interactions: (1) impact on strength of semantic associations related to musical softness, (2) impact on strength of semantic associations related to haptic softness, or (3) both. We predict that musically sophisticated consumers are better at decoding soft (vs. hard) music into semantic associations related to musical softness. In comparison to consumers with low levels of musical sophistication, these associations may be recoded and lead to stronger semantic associations related to haptic softness, which result in an increased expected haptic softness (EHS). Based on previous findings on the influence of tactile information on evaluations (Grohmann, Spangenberg, and Sprott 2007), especially for products for which haptic information is diagnostic, we also expect increased levels of EHS to affect product evaluations. Thus, musical sophistication may also have an indirect positive impact on product evaluations.

Three studies tested our predictions: Study 1 employed a 3 (music: soft vs. hard vs. no) × 4 (product category: scarf vs. tablet vs. chair vs. book) mixed factorial design with music as between-subjects factor. Participants evaluated the EHS of four unbranded pictured products after listening to two pretested song excerpts that were either perceived as soft or hard; whereas, participants in the control condition listened to no music. We further tested the moderating effect of musical sophistication on audio-tactile interactions. The results showed that after listening to the soft (vs. hard) song version, participants only expected products for which softness is diagnostic to be softer, in our case a scarf. Moreover, musical sophistication significantly moderated this effect of soft (vs. hard) music on consumers' EHS.

Study 2 was designed to examine the underlying mechanism of the positive influence of musical sophistication on audio-tactile interactions. Similar to Study 1, after participants were presented with a picture of the scarf from Study 1 and listened to either soft or hard music, we asked them to evaluate the strength of their associations related to musical as well as haptic softness (Imschloß 2014). A moderated serial multiple mediation (Hayes 2015) with strength of associations related to musical softness (M_1) and strength of associations related to haptic softness (M_2) as mediators, and musical sophistication as the moderator, revealed that musical sophistication significantly moderated the indirect effect of soft (vs. hard) music on EHS through M_1 and M_2 in serial (95% CI: .008, .193). This suggests that musically sophisticated people are better at recoding auditory cues (e.g., soft music) into semantic associations related to haptic dimensions. However, results of Study 2 also generally revealed that music is not translated into semantic associations related to haptic softness without being previously decoded into semantic associations related to musical softness.

As our theory assumes that musical cues of haptic softness can influence product evaluations since they may serve as quality indicator for products for which haptic information is diagnostic (Grohmann et al. 2007), in Study 3, we tested a moderated mediation model. Results supported previous findings that EHS fully mediates the effect of soft (vs. hard) music on product evaluations (intention to purchase, attitude towards the product, willingness to pay) (Imschloß 2014). Consistent with our prediction, this mediation was stronger among participants with higher levels of musical sophistication.

The current research is the first that provides insights about the conditions for crossmodal interactions involving the auditory and haptic modalities. In particular, products for which haptic softness is diagnostic are most likely to be subject to audio-tactile interactions. In addition, we contribute to sensory marketing literature by considering the potential impact of individual differences on the ability to match auditory and haptic dimensions with respect to the interactive nature of music and personality (Rentfrow and Gosling 2003).

Advance Gratitude Expressions as a Prosocial Appeal

Leandro Galli, University of Warwick and London Business School, UK
Katherine White, University of British Columbia, Canada
Piotr Winkielman, University of Warwick, UK and UCSD, USA
Hongwei He, University of Strathclyde

EXTENDED ABSTRACT

Each day, millions of people worldwide rely on the kindness of others for their basic well-being, and charities are experiencing growing difficulty attracting sufficient support. The current debate thus revolves around how best to appeal to potential donors for help (YouGov, 2012). We introduce the novel concept of an advance gratitude expression as a prosocial appeal and we demonstrate how a simple: *"Thank you in advance for your support"* embedded in marketing materials can increase prosocial behaviour, by awakening the donor's "sleepy moral self" (studies 1 and 3). We further elucidate upon the mechanism by demonstrating that perceived connectedness to the recipient of the cause moderates the effect, by showing that under conditions of low connectedness, advanced expressions of gratitude can backfire (study 2).

Gratitude is expressed when altruistic benefits are received. By expressing gratitude one recognises that the benefactor has acted with fairness and justice, in considering and responding to the welfare needs of others, and so gratitude goes hand in hand with an increased moral awareness (Emmons and McCullough, 2004). Past research has examined the consequences of expressing gratitude after some prosocial act had already been conducted (Raggio & Folse, 2011, Grant & Gino, 2010). What remains unexplored is whether (and if so, why), "*an advance expression of gratitude*", a term we coin to denote instances in which gratitude is conveyed to prospective benefactors prior to them providing or agreeing to provide assistance, can persuade these to act benevolently. While donating may be generally regarded as a moral act, this is not always the case, people can refuse others help when it is not apparent that is it the right thing to do (Lee et al., 2014). We propose that advance expressions of gratitude can signal something about the request itself, by rendering potential benefactors more aware of its moral significance. This proposition is based on the growing evidence showing that ethical judgements can be malleable when individuals face subtle cues that non-consciously activate the moral self. (Leavitt et al., 2015 Reynolds, Leavitt & Decelles, 2010). Because of the moral nature of gratitude (Haidt, 2003) we posit that an advance gratitude expression will trigger one's moral identity. In turn, this will increase moral awareness, defined as a person's determination that a situation contains moral content (Reynolds, 2006), and translate into greater prosocial behaviour. More formally:

Hypothesis 1:   *Advance gratitude expressions result in increased prosocial behaviour.*

Hypothesis 2:   *The effect of advance gratitude expressions on prosocial behaviour is mediated by moral awareness.*

Gratitude is also an other-focused emotion (Tangney et al., 2007) and prior research has found that people are more receptive to other-focused emotional appeals when connectedness to others is high (Aaker & Williams, 1998). Connectedness to others can be conceptualised through the lens of self-construal theory. Self-construal (independent vs. interdependent) represents an individual's general predisposition to identify with others. Interdependents view themselves as fundamentally connected to others, whereas, independents are concerned with keeping their distance and not being influenced (Singelis, 1994). We postulate that when connectedness to others is high (i.e. interdependent) individuals will be more receptive and responsive to advance gratitude expressions resulting in increased prosocial behaviour (H3a). However, when connectedness is low (i.e. independents), we expect an advance expression of gratitude to backfire (H3b) because independent self-construal individuals wish to keep their distance, and would therefore likely view the expression as manipulative.

Study 1 (N=50) was a main effect field study, with a real behavioural outcome. Passers-by were invited to partake in a marketing research study conducted on behalf of The British Columbia Society for the Prevention of Cruelty to Animals. Participants were randomly assigned to evaluate either an "advance gratitude expression" or a control poster advertisement. The advance gratitude poster condition additionally included the following: *"Thank you in advance for your support."* In the advance gratitude condition average donations were higher (F (1, 49) = 8.323, p=0.006, M=\$2.83 vs. M= \$2.08). Moral awareness was also measured with two items (α= 0.764)[1]. Increased moral awareness fully mediated the relationship between advance gratitude on donation amount, 95% CI, (b=0.2739, $C_{95:}$ 0.0368, 0.6946). We measured "norms of reciprocity"[2] as a competing mechanism, but no mediation was found (b=0.0312, $C_{95:}$ -0.0331, 0.2910). Therefore, Study 1 supports H1 and H2.

Study 2 sought to exclude competing explanations, by examining a theoretically relevant moderator- the ethical or moral nature of the request. It is plausible that an advance gratitude expression arouses emphatic concern or as already noted, taps into implicit norms of reciprocity. If these alternative explanations hold, then advance gratitude should increase compliance also under morally dubious circumstances (albeit perhaps to a lesser extent).Yet, if the moral awareness explanation is valid, one would predict a backfiring effect when the request made is morally dubious. We manipulated the ethical credibility of the charity making the request by assigning high vs. low scores on three ethically relevant criteria. N=408 (recruited online), partook in the 2 (advance gratitude: yes vs no) x 2 (ethical credibility of the charity: high vs low) between subjects randomised factorial design. The advance gratitude condition charity advert additionally included: *"Thank you in advance for supporting a puppy in training"*. The ethical credibility x advance gratitude interaction on donation intention was significant (F (1,407) = 7.3, p=0.007), such that, when the request for support came from the "unethical" charity, expressing advance gratitude reduced donation intentions $M_{Nogratitude=}$4.4 vs. $M_{Gratitude=}$3.8 F (1,407) =3.5, p=0.06. Whereas, the opposite applied when the expression came from a charity with morally sound credentials, $M_{Nogratitude=}$4.6 vs. $M_{Gratitude=}$5.1 F (1,407) =3.7, p=0.05, providing further support that moral awareness is the underlying mechanism (H2).

Study 3 tested the effect of connectedness to others by manipulating participants' self-construal. 206 M-Turkers, partook in the 2 (self-construal: independent vs. interdependent) x 2 (advance grati-

---

[1]   "Contributing to the BC SPCA cause has moral implications", "Contributing to the BC SPCA is the "right" thing to do".
[2]   "Others expect me to donate"

tude expression: yes vs. no), between subjects factorial design study. Self-construal was manipulated via a short story exercise (Garner et al, 1999). Participants were subsequently exposed to an advertisement of a food bank charity requesting donations on behalf of the Roberts family (pictured). The advance gratitude condition also included *"Thank you in advance for your support from the Roberts Family"*. An interaction of self-construal*advance gratitude on volunteering intention reached significance $F_{(1,202)} = 11.04$, p=0.001. For interdependently primed individuals receiving the advance gratitude expression increased volunteering intention, $F_{(1,202)} = 7.5$ p=0.007 ($M_{nogratitude}$=3.9 vs$M_{gratitude}$=5.1). Whereas, in the independent condition, advance gratitude backfired $F_{(1,202)} = 3.9$ p=0.051

($M_{nogratitude}$=5.6 vs. $M_{gratitude}$=4.7). Thus H3a and H3b are both supported.

Our results suggest that a simple expression of advance gratitude can help charities gain important scarce resources, without additional costs. Yet, advance gratitude expressions are not a blunt tool and attention must be paid to ensuring the target audience perceives a connection with the cause, or the effect can be counterproductive. From a theoretical perspective, we introduce the novel concept of advance gratitude expressions and show that these can give rise to a process of moralisation, thus making contributions to both the gratitude and morality literatures.

Do Consumers Learn New Currencies as They Learn New Languages?
The Impact of Price Syntax and Synonyms on Learners' Proficiency

Charlotte Gaston-Breton, ESCP Europe Madrid Campus, Spain
David Luna, Zicklin School of Business Baruch College CUNY, USA

EXTENDED ABSTRACT

Consumers are frequently placed in a situation where they are exposed to prices in a foreign currency (FC) but relatively little research has investigated how consumers learn another currency. Previous studies in the context of the Euro changeover focused on long-term adjustment strategies (Marques and Dehaene 2004) or on individual rules of thumb (Raghubir, Morwitz and Santana 2012). Our research extends previous findings and helps us develop new theory on how currencies are learned. To understand that process, we compare learning a new currency to learning a new language.

Consistent with our language-learning analogy (Kroll and De Groot 2005, Luna and Peracchio 2001), we consider three factors that influence foreign price processing and learning: *lexical* (i.e., regarding the prices themselves), *syntax* (i.e., the way foreign currency and home currency are combined together in an exchange rate table), and *synonym* (i.e., consumers' exposure to reference prices in the foreign currency). Three experiments investigate the interaction between those three factors and their impact on learners' proficiency (accuracy in estimating, recalling and ranking prices in foreign currency).

Study 1 tests the interaction effect between price lexical (difficulty of the exchange rate) and price syntax (mode of presentation of the exchange rate) on learners' proficiency (accuracy in price estimation, recall and ranking). In particular, we designed a 2 (difficulty of exchange rate: easy (1FC = 2\$), difficult (1FC = 0.8\$) x 2 (mode of presentation of exchange rate: home-centric (1\$ = xFC), foreign-centric (1 FC= x\$)) between-subjects experiment.

Studies 2 and 3 test whether price lexical (difficulty of the exchange rate) and price synonyms (foreign reference prices) interfere in foreign price learners' proficiency (accuracy in price estimation, recall and ranking). In Studies 2 and 3, the context of presentation of the prices is manipulated through the presence or absence of prices of competing retailers (External Reference Prices, or ERPs) for the same products (study 2) and for different products (study 3). Study 2 was a 2 (difficulty of exchange rate: easy (1FC = 2\$), difficult (1FC=3.2\$) x 2 (context of presentation: ERPs present or absent)) between-subjects experiment. Study 3 was a 2 (difficulty of exchange rate: easy (1FC= 2\$), difficult (1FC= 0.8\$) x 2 (context of presentation: ERPs for the same products vs. for different products within the same category)) between-subjects experiment.

Stimuli, sample and measures were similar in the three experiments. An average of one hundred undergraduate students at a large New York University participated in the studies. Respondents were asked to imagine a shopping situation in a foreign country. They were exposed randomly to 14 common grocery goods they needed to buy varying in terms of expensiveness (products with lower or bigger tickets in study 1) or in terms of purchase frequency (infrequently or frequently purchased products in studies 2 and 3). The prices of the products were presented in the foreign currency with the currency conversion rate to US\$ they were assigned to. Then, they answered self-reported measures of the extent to which they had used direct-access and/or conversion strategies to process foreign currency prices. Subsequently, respondents had to estimate the price of the total basket, recall the exact price of each product and rank the products according to their expensiveness.

Accuracy in estimating shopping basket, recalling exact price and relative price rank were measured as the Absolute Price Devia-

tion from the correct total basket, the correct individual prices and the correct ranking of the prices of the products, or APDs (Estelami and Lehmann 2001). If the APD's indicators are high, the accuracy in estimating and recalling FC prices are low and vice-versa.

On overall, our findings underline that the conversion strategy (exact or approximate) has a primacy over the direct-access strategy (intuition-based or anchor-based). However, this strategy does not lead systematically to a superiority in foreign price learning. Regarding APD in estimating total basket, there are no direct effects but significant cross-over interactions between the difficulty of the exchange rate and i) the mode of presentation of the exchange rate ($F(1, 96)= 7.4$; $p= .008$); ii) the exposure to ERPs ($F(1, 73)= 4.05$; $p = .048$); iii) the exposure to similar or different ERPs ($F(1,81)= 2.9$, $p=.09$). Regarding APD in recalling prices, there is a significant interaction of the difficulty of the exchange rate and its mode of presentation on exact price recall ($F(1, 96)= 3.3$; $p= .07$) and correct ranking of the prices of the products ($F(1, 86)= 5.04$; $p= .027$). The interaction between difficulty of the exchange rate and presence of ERPs is not significant with respect to accurately recalling the prices in FC of the 14 items but with respect to accurately ranking them ($F(1, 73)= 4.05$; $p= .048$).

When the easiness of an exchange rate or the task to perform lead consumers to process prices in their home currency, the syntax of the exchange rate (the way it is presented) must be home currency centric (and vice versa) and the price synonyms (exposure to ERPs) should be consistent with the strategy used and task to perform. Our findings underline that foreign price processing is not influenced only by the difficulty of the exchange rate (lexical factor). The mode of presentation of the exchange rate (syntactic factor) and the exposure to previous price information (synonym factor) also influence foreign price learning. Although a conversion does not directly allow respondents to perform better on price memory tasks, the manner in which the exchange rate and reference prices are presented will influence learning strategy process and performance.

How the Norm of Reciprocity Influences Sharing in Direct and Generalized Exchanges

Alina Geiger, University of Bayreuth, Germany
Class Christian Germelmann, University of Bayreuth, Germany

EXTENDED ABSTRACT

Even though sharing is universal and by no means a new concept, it was neglected in consumer research until Belk's seminal work in 2010. Research on sharing has been growing rapidly since then. One stream of this research follows an ethnographic approach and offers valuable insights into particular phenomena within the sharing economy (Gollnhofer, Hellwig, and Morhart 2016; Scaraboto 2015). Others expand knowledge with survey data (Habibi, Kim, and Laroche 2016; Hellwig et al. 2015). Despite the growing interest in this phenomenon, there is surprisingly little experimental research (Lamberton and Rose 2012) on the mechanisms behind the sharing of physical objects. Therefore, the aim of our research is to shed more light on the underlying processes, by looking at the interplay between sharing and reciprocity norms.

Prior research has found that reciprocity is involved in peer-to-peer sharing (Albinsson and Perera 2012; Corciolani and Dalli 2014; Habibi et al. 2016; Hellwig et al. 2015), but that it lacks clear reciprocity rules (Gollnhofer et al. 2016). Therefore, we want to investigate how an explicitly stated reciprocity norm influences sharing, compared to the absence of such an explicit norm. In addition, we consider exchange structure, since reciprocity differs in direct exchanges compared to generalized exchanges (Ekeh 1974). In direct exchange, an individual B will reciprocate directly to individual A in exchange for that what A has given to B (Willer, Flynn, and Zak 2012). In generalized exchange (Ekeh 1974) with "collective reciprocity" (Corciolani and Dalli 2014, 769), recipients are not obliged to reciprocate directly to their giver, but only indirectly through someone else.

Social exchange theory states that individuals provide each other with resources, because they expect to receive something in return (Blau 1964; Homans 1958). In social exchanges, the norm of reciprocity can function as a "starting mechanism" and as a "stabilizing mechanism" (Gouldner 1960, 176), because receiving implies an obligation to reciprocate (Blau 1964). Furthermore, according to Cialdini and Goldstein (2004), norms can induce norm-congruent behavior only when they are salient. Consequently, we expect an explicitly stated norm to affect the appeal of sharing platforms. We also propose that in the absence of an explicit norm, the expectation of balance of reciprocity affects sharing intentions.

The objective of our first study was to examine the appeal of different platform designs prior to the decision to join the platform. Therefore, we asked our participants to evaluate the front page of a new sharing website for booksharing. We used a 3 x 2 between-subject design, crossing reciprocity principle (explicit norm vs. two control conditions: gratitude or absence of an explicit norm) and exchange structure (direct vs. generalized), and randomly assigned 232 participants to one of the conditions.

As expected, without a clearly stated norm, potential giving did not influence the intention to participate directly, but was mediated by an expected balance of reciprocity. In the case of an explicit norm, intentions to participate were higher, but not significant in the direct exchange condition, and lower but not significant in the generalized condition. However, moderation analysis revealed a significant interaction between explicit norm and exchange structure. In the case of an explicit norm, intentions to participate were significantly lower in generalized exchange, compared to balanced exchange. Activating gratitude, and mentioning no norm at all, did not yield significant effects.

The norm of reciprocity implies both rights and duties (Gouldner 1960). In this vein, receiving does imply an obligation to reciprocate, but giving also justifies receiving. Furthermore, while giving is important for reaching a critical mass (Botsman and Rogers 2010), peer-to-peer sharing depends on both the giving and taking of resources (Schade, Nitschke, and Sattler 2005). Without anyone taking, there is no circulation of resources. For this reason, we do not focus solely on giving, but giving *and* taking as an indicator of sharing intensity in our second study. Building on our results from study 1, we expect an explicit norm to decrease sharing intensity in generalized exchange. In this context, one might give more cautiously, because generalized exchange requires more trust (Ekeh 1974) that one will indeed receive appropriate reciprocation (Takahashi 2000). Additionally, taking might be more reserved, because the explicit norm underlines the obligation to reciprocate and it is not specified to whom one should give in the future, in order to comply sufficiently with the explicit norm.

In study 2, we randomly assigned 162 participants to a 2 (explicit norm vs. no norm mentioned) x 2 (direct vs. generalized exchange) between-subject design. This time, additionally to the front page, they saw how it would look when logging in on the website as a registered member. All participants saw an unbalanced status quo where prior giving exceeded prior receiving.

The results confirm Gouldner's (1960) assertion that prior giving justifies subsequent taking. As expected, significantly more participants chose to look at other's books first, after they had seen the stimulus material. Their decision was independent of the experimental condition. Furthermore, sharing intensity was lower in generalized exchange in cases of an explicit norm. Moderation analysis revealed a significant negative effect in the generalized condition; while there was no effect in the direct exchange condition.

Our findings extend Gouldner's (1960) view on the norm of reciprocity as an initiator and stabilization of social exchange, since we could also show that explicit norms can restrain sharing within generalized exchange in our context (i.e., sharing of physical objects without strong connection between members). However, in order to fully understand the influence of explicit norms in direct and generalized exchange, future research should take into account trust (Ekeh 1974), identification and levels of benefit (Willer et al. 2012).

In conclusion, our findings contribute to the ongoing discussion on the role of reciprocity in sharing (Arnould and Rose 2016; Belk 2010, 2016). Furthermore, we provide additional evidence that generalized exchange is not *per se* more effective than direct exchange, in contrast to what is argued by Lévi-Strauss (1949/1969) and Ekeh (1974). This evidence has implications for sharing platforms regarding platform design and communication.

Congruence and Incongruence in Advertising-Medium Combinations:
More Than Just Two Sides of the Same Coin

Claas Christian Germelmann, University of Bayreuth, Germany

Peter Darke, Schulich School of Business, York University, Canada
Sebastian Macht, University of Bayreuth, Germany

EXTENDED ABSTRACT

Congruence/incongruence has been a key influencing factor in the marketing and advertising literature. We focus on perceived congruence/incongruence between an advertised product category and thematic media content of the vehicle in which it appears (e.g., type of magazine). Existing advertising research suggests that increased congruence generally has positive effects on consumer evaluations, although incongruence can also lead to positive evaluations under specific circumstances. Congruent (as opposed to incongruent) combinations have been described as easier to understand and to memorize (Dahlén 2005, 90; Maille and Fleck 2011, 71). Positive effects of incongruence are often explained by more extensive processing by consumers when they face moderately schema-incongruent information (Mandler 1982) because they want to resolve the incongruence (Dahlén et al. 2008).

The majority of existing studies rely on forced exposure and on explicit ratings of ad-media congruence. Conscious attention to congruence may be less evident when consumers are incidentally exposed to advertised products (e.g., while flipping through a magazine), or when congruence is assessed via less obvious open-ended measures. Under such circumstance, any evaluative effects of congruence are more likely to operate on evaluations through automatic processing.

Conversely, we expected incongruent combinations to garner more attention than congruent combinations under incidental exposure. We base this prediction on Maheswaran and Chaiken (1991) who found that incongruent elements of an advertisement increased the level of elaboration applied to the ad. Study 1 experimentally examines the degree to which consumers consciously focus on congruence or incongruence between an ad and the thematic media content under conditions of forced versus incidental exposure. Our predictions were that consumers would be aware of the congruence between advertising and media primarily under forced exposure conditions, while they would be more aware of incongruence between the ad and medium under the more naturalistic conditions of incidental exposure.

Our theorizing further suggests that congruence and incongruence may evoke different forms of information processing that respectively have positive *and* negative effects on consumer evaluations, albeit by very different means. This possibility is addressed in Study 2, where we include a control condition in order to split the effects of congruence and incongruence, and isolate the effects of each on consumer evaluations and the underlying information processing involved.

EXPERIMENTAL STUDY 1

We manipulated congruence versus incongruence of the ad/medium combination, as well as the method of exposure (incidental vs. forced). Sixty non-marketing male students were exposed to an ad (EPSON ad, Printer) that was either congruent (COMPUTER BILD) or incongruent (AUTO BILD) with the magazine in which the ad appeared. Participants were exposed to the ad either in a forced exposure condition (magazine cover and target ad visible together), or in an incidental exposure condition (magazine cover, followed by a series of individual ads including the target and filler ads displayed for 3 sec/page).

A logistic regression showed a significant congruence/incongruence X incidental/forced exposure interaction on spontaneous mentions of congruence/incongruence (p=.003). Consumers rarely mentioned thematic congruence spontaneously under incidental exposure (6.67%), but were significantly more likely to mention congruence when exposure was forced (73.33%, p<.001). The interaction between exposure and incongruence further implied that when consumers were incidentally exposed to the ad they were more likely to spontaneously focus on thematic incongruence than congruence (46.67% vs. 6.67%, p=.01), whereas this difference was not significant under forced exposure (46.67 vs. 73.33%, p=.13).

Thus, positive effects of congruence observed under incidental naturalistic exposure conditions are likely to be the result of a relatively automatic process, whereas any negative evaluations of ad-magazine incongruence seemed more likely to involve conscious, deliberative information processing, possibly focused on the intended purpose or meaning of the incongruity. These predictions are examined in Study 2 by including an additional control condition that allowed us to tease apart the different forms of information processing that were likely to apply to the effects of congruence and incongruence.

EXPERIMENTAL STUDY 2

107 non-marketing students were randomly assigned to one of the three experimental groups (congruent, incongruent, or control). We used the same magazines as in study 1, but now combined with the fictitious brand name NANOX in order to avoid biases caused by preexisting brand attitudes. In the new control condition, participants only saw the NANOX ad. The incidental exposure procedure from study 1 was used, as this was the more realistic condition.

Since both the traditional fluency and persuasion knowledge explanations for the effect of ad-medium (in)congruence could work at the same time, both paths were first modeled and tested simultaneously using SEM (congruent=1, control=0, incongruent=-1; GFI .903; RMSEA .061). Supporting the fluency explanation, congruence had positive effects via the consistency—fluency—Aad—Aproduct—PI path. In addition, the novel pk predictions for incongruent ad-medium combinations were also supported. In this case, incongruence led to negative effects via the consistency—pk—Aproduct—PI path. When isolated in separate models that compared either ad-medium congruence or incongruence to controls, only the negative incongruence effects via perceived manipulative intent (pk) remained significant. Thus, results from the second study were consistent with the traditional view that increased congruence generally has positive effects on consumer evaluations, but importantly this was due to a combination of positive fluency effects associated with congruence, and negative pk effects associated with incongruence. Furthermore, when the effects of congruence and incongruence were better isolated, the negative effects of incongruence on consumers' evaluations via the pk mechanism proved to be more robust than the traditional congruence—fluency model.

GENERAL DISCUSSION

We find that consumers seem to focus on congruence only when forced exposure is applied. Under incidental exposure, we find almost no attention on congruence. However, consumers are relatively aware of incongruence even under incidental exposure. Study 2 suggests that incongruence can evoke a negative process of its own, which operates through persuasion knowledge. It can be argued that past results that show positive congruence effects involving fluency by comparing congruent vs. incongruent conditions under forced exposure may have: 1) inflated attention to congruence per se, and 2) inadvertently confounded two very different congruence and incongruence processes.

"The Review is Sponsored by": The Effect of Sponsorship Disclosure on Blog Loyalty

Maximilian H. E. E. Gerrath, Leeds University Business School, UK
Bryan Usrey, Leeds University Business School, UK

EXTENDED ABSTRACT

Consumers often consult online reviews before making a purchase decision. These reviews have become a dominant source for product-related information (Senecal and Nantel, 2004). Thus, many firms have begun to partner with online review sources, such as blogs, as a new form of marketing communication (Dellarocas, 2003).

Past literature suggests that firm sponsorship could be detrimental to blog loyalty. This is due to the notion that blogs act as an independent source of information. Therefore, when sponsoring an online review, blogs risk backlash that could damage trust and credibility (Kozinets, et al., 2010), and may lead to reduced blog loyalty. However, it is posited that hiding firm sponsorship could further damage loyalty towards the blog. Thus, it is advised that blogs disclose firm sponsorship to their readers. This is supported by past literature, which has shown the positive impact of disclosure in a variety of contexts.

Review balance is introduced as a moderator, whereby a product evaluation can either be one or two sided. A two-sided review could increase the credibility of the author, as the presentation of negative information may be seen as working against the self-interest of the sponsoring firm. A one-sided review, however, may be viewed as advertising (Schlosser, 2011), and thus, decrease blog loyalty. Next, based on attribution theory, it is posited that readers have the ability to either attribute the sponsored online review to an internal or external motive. External motives are likely to be ascribed to an outside actor (i.e. the firm), whereby internal motives may be attributed to the author's internal interests. Thus, it is expected that an intrinsic disclosure statement will enhance the positive effect of disclosure on blog loyalty, regardless of review balance. However, a one-sided review is likely to be attributed to the firm (author) when it is one (two) sided.

In four experiments, we examine the negative effect of firm sponsorship of an online review on blog loyalty. Furthermore, review balance is tested as a method by which the negative impact of sponsorship may be reduced. Next, we examined whether involuntary disclosure can further enhance the negative effect of firm sponsorship. Finally, we test whether an internal (vs. external) motivated disclosure statement can enhance (reduce) the effect of disclosure on blog loyalty. All four studies had participants examine an online review for a product.

In Study 1, 600 YouTube video blogs were examined to uncover the effect of sponsorship on blog attitude, measured by the percentage of dislikes per total likes on the video. A significant result was found ($p < .01$), whereby the dislike ratio for a sponsored post ($M = 8.87\%$) was high than a non-sponsored post ($M = 3.30\%$).

Therefore, Study 2 was designed to test whether this result held in an experimental setting with a written online review on blog loyalty. In the sponsored condition, respondents were informed that the review was sponsored by a brand, while no information was provided in the non-sponsored condition. As predicted, it was shown that the sponsored condition significantly ($p < .01$) reduced blog loyalty. In addition, a two-way interaction for sponsorship and review balance was found ($p < .05$), whereby blog loyalty suffered from sponsorship, particularly if it was one-sided review. However, this was negated with a two-sided review.

In Study 3, the role of disclosure voluntariness was examined as well as the moderating condition of review balance. In the disclosure condition, respondents were informed that a firm had sponsored the online review. In the involuntary disclosure condition, respondents were informed from a third party that the review had been sponsored. As hypothesized, voluntary disclosure had a significantly ($p < .01$) positive effect on blog loyalty. Furthermore, an interaction was found ($p < .05$), whereby both sides were attributed to have influenced the review in the involuntary disclosure condition, while the firm (author) was attributed in the one (two) sided condition.

Finally, in Study 4, a 2 (internal vs. external disclosure statement) x (one vs. two-sided review) experiment was examined on blog loyalty and attribution was examined. Results demonstrated that internal disclosure had a significantly positive effect on blog loyalty ($p < .01$) and attribution ($p < .01$), which indicated that respondents attribute the review to the author. An interaction found whereby a one-sided review was only seen as negative on blog loyalty when an external disclosure statement was given ($p < .05$). However, this was reduced when a two-sided review was presented. A similar interaction was found on attribution ($p < .05$). When external and one-sided, the review was attributed to the firm, compared to two-sided, when was attributed to the author. For both one and two sided, when internally motivated, there was a positive effect on blog loyalty and the review bias was attributed to the author.

Taken together, these studies contribute to existing online review literature by discovering that firm sponsorship has a negative effect on blog loyalty. In addition, this negative effect is enhanced when the sponsorship was involuntarily disclosed. When a disclosure was provided, a two-sided review was able to reduce the negative effect of firm sponsorship on blog loyalty. Furthermore, an internal disclosure statement was able to enhance blog loyalty, regardless of review balance. Thus, the findings provide practical insights for bloggers and firms when seeking sponsorship agreements.

When Money Doesn't Talk:
Corporations Receive Less Credit for Monetary Donations

Rachel Gershon, Washington University, USA
Cynthia Cryder, Washington University, USA

EXTENDED ABSTRACT

Recent literature about charitable giving and corporate social responsibility finds that donating is complex, both in terms of doing good and gaining credit (Newman and Cain 2014). Previous scholarly work has debated the best way for donors to receive charitable credit for giving. While monetary donations are arguably the most useful for nonprofits to receive, we predict that corporate donations of goods appear to be more authentic. Authentic motives are important for receiving charitable credit and might be key for corporate giving in particular due to firms' association with profit and susceptibility to suspicion regarding prosocial behavior (Vlachos et al. 2009). Although charities typically prefer monetary donations, this research documents that corporations that donate money are judged less favorably than corporations that donate tangible goods. This "money doesn't talk" effect hinges on consumers' assessments of authentic prosocial motivation: corporate monetary donations are perceived as strategic and less authentically motivated than equivalent donations of goods.

We test our hypotheses across 5 studies. Study 1 documents the basic effect that corporations receive less charitable credit for donating money than for donating equivalent goods. Experimental stimuli described a fictional company, Spades Hardware store, as donating either 1) "$50" 2) "$50 worth of canned food" 3) or "a box of canned food" to their local food bank. The second and third conditions were both included to test whether merely mentioning money was sufficient to induce a "money doesn't talk" effect for corporate donations. Participants then rated the company on seven qualities: generous, altruistic, helpful, charitable, kind, beneficial, and "the extent to which they make the world a better place". These qualities loaded onto a single factor, which we call "charitable credit". Consistent with the "money doesn't talk" hypothesis, we observe a significant decrease in the amount of charitable credit that a company receives when donating money versus goods. We observe that this difference in charitable credit due to donation type persists whether or not the monetary value of a goods donation is specified.

Study 2 tested the hypothesis that authenticity mediates this preference for goods donations. We asked participants to rate Spades Hardware on how authentically motivated their donation was. We also tested two plausible alternative mediators: effort and sacrifice. While we believed that authentic motivation was mediating this effect, it was important to rule out the possibility that people were rewarding companies because they perceived goods-donations to be more effortful than, say, writing a check. As predicted, donations of goods garnered more charitable credit than donations of money and this effect was mediated by the perceived authenticity of these donations. Neither effort nor sacrifice mediated this effect.

Study 3 explored a potential moderator of this effect. We propose that low perceptions of authentic prosocial motivation may apply to corporations in particular. Corporations generally are viewed as low in warmth, and thus less likely to be viewed as having authentically good intentions (Fiske et al. 2002). Corporate donors therefore may be particularly vulnerable to the market-exchange signals that are communicated when donating money. By contrast, individuals are viewed as fundamentally social and warm (Aaker, Garbinsky, and Vohs 2012), and thus more likely to be perceived as having genuine interest in helping others regardless of donation type.

We therefore predict that individual donors will be less susceptible to image concerns when donating money, and will not be subject to the "money doesn't talk" effect. Participants in study 2 were assigned to read a brief vignette describing either Spades Hardware or a family (the Jones) that donated $50 (a box of canned food) to a food bank. As hypothesized, firms received less charitable credit for giving money than for giving goods, whereas the opposite pattern was found for individuals. In other words, participants rated the company more favorably when they donated goods, but rated the family more favorably when they donated money.

Study 4 continued to investigate donor warmth as a moderator of this effect. In order to test this moderating factor we manipulated company warmth. For the high-warmth conditions, Spades Hardware is described as "a friendly, community-based hardware chain which focuses on serving the community and customer satisfaction." For the low-warmth conditions, Spades Hardware is described as "a small corporate hardware chain which focuses on profit and business success." Participants were then told that the company donated either $1,000 or canned food worth $1000 to their local food bank. Consistent with our predictions, we found a significant interaction between donation type and brand image. When the company was described as having a low-warmth image, people rated the company more favorably for donations of goods (vs. money), consistent with the "money doesn't talk" effect. When the company was described as high in warmth there was no difference in charitable credit rating based on donation type. Purchase intentions followed the same pattern as charitable credit scores.

In Study 5, we tested warm brand image as a moderator using two real world companies: Pepsi and Bolthouse Farms. A pre-test confirmed that Pepsi is perceived as having a low-warmth image while Bolthouse Farms is viewed as high-warmth. Consistent with our previous moderator study, Pepsi, the low-warmth brand, showed the "money doesn't talk" effect, with people rating the company as significantly more charitable when they make a donation of goods. Bolthouse Farms, however, showed no difference in charitable credit score based on donation type. Once again, purchase intentions followed the same pattern as charitable credit scores. This further demonstrates that warm brand image attenuates the preference for corporate donations of goods.

Despite the fact that monetary donations are the most frequent donation type and the donation type that charities prefer, these studies find that companies who donate money receive less credit for their charitable behavior – and benefit less in terms of purchase intent – than companies who donate equivalent tangible goods. Therefore, companies aiming to maximize charitable credit may benefit from spending their philanthropic funds on thoughtful donations of goods, because at least in some cases, when it comes to corporate giving, money doesn't talk.

When Goal-Derived Assortments Lead to Goal-Inconsistent Choices

Kristof Geskens, Vlerick Business School, Belgium
Andrea Bonezzi, New York University, USA
Alexander Chernev, Northwestern University, USA
Karen Gorissen, Ghent University, Belgium
Bert Weijters, Ghent University, Belgium

EXTENDED ABSTRACT

In this research we suggest that goal-derived assortment organizations reduce the likelihood that consumers choose the option that offers maximum goal attainment. To illustrate, we predict that consumers who are looking for an eco-friendly car are less likely to choose the most eco-friendly car when the assortment is organized by goals (e.g., 'green', 'adventure', 'sports' categories) compared to other ways of assortment organization. We argue this occurs because goal-derived organizations are likely to make the items grouped together appear equivalent in terms of their instrumentality for goal achievement, a phenomenon we term *goal-based similarity*. As a result, goal-relevant attributes become less diagnostic for making a choice and consumers turn to other goal irrelevant, and possibly even goal competing, benefits to make their final choice. The data from four empirical studies support our predictions.

In study 1, respondents (N = 117) were randomly assigned to one of two conditions: randomly organized versus goal-derived assortments (with the same items). The assortments consisted of six items, described on five attributes: three common attributes, one focal-goal attribute and one competing goal attribute. In the choice sets there was one option offering maximum goal attainment: the goal-maximizing item. Respondents were given a specific consumption goal before making their choice. Results showed that the relative choice share of the goal-maximizing item was significantly lower in the goal-derived compared to the randomly organized assortment. Furthermore, choice shares of the second item in the goal-derived subset was significantly higher in the goal-derived versus the randomly organized assortment, showing that a goal-derived organization can shift preferences away from the goal-maximizing item.

In study 2, respondents (N = 165) were randomly assigned to the conditions of a 2 (task: choose vs. reject) x 2 (assortment organization: random vs. goal-derived) between-subjects design. In the choice task, respondents were asked to select their most preferred option, in the rejection task they had to reject unwanted items until their most preferred option remained. Next, participants were told that their chosen item was not available anymore and they had to select their second most preferred item. After each choice we asked to indicate to which extent the chosen item was instrumental for attaining the prompted goal. This allowed us to compute a goal-based similarity measure by subtracting the perceived instrumentality of respondents' second choice from that of their first choice. Results showed that goal-derived organizations decrease the likelihood that individuals choose the item that is most instrumental to fulfill their active goal and that respondents perceive their first and second choice as being more equally instrumental for goal fulfillment in a goal-derived versus randomly organized assortment, but only when the choice task encouraged respondents to view grouped items as similar.

In study 3, respondents (N = 121) were randomly assigned to one of two experimental conditions, a goal-derived versus a brand-organized assortment. The same items were grouped together, only the label of each group differed between conditions. Respondents were given a specific consumption goal before making their choice. Results showed that the choice share of the goal-maximizing item was significantly lower in the goal-derived organization compared to the organization by brand. Similarly, the choice share of the runner-up option was significantly higher in the goal-derived organization versus the assortment by brand, meaning that goal-derived organizations drive choice shares away from the goal-maximizing item towards the runner-up item.

In study 4, participants (N = 144) were randomly assigned to the conditions of a 2 (assortment organization: random vs. goal-derived) x 2 (choice dimension: goal-relevant vs. goal-irrelevant) between-subjects factorial design. After being primed with a "green consumption" goal, respondents were asked to imagine they were renting a car and were given an assortment, organized either randomly or by goals. Before making their choice, we informed respondents that the car rental company suggested one specific car as the default choice: the car that scored second highest on the goal-relevant dimension (eco-friendliness), and second lowest on the goal-irrelevant dimension (power). Respondents were then offered the opportunity to 'trade-up' to a better option: either superior on the goal-relevant dimension or on the goal-irrelevant dimension. We measured respondents' likelihood of switching and their willingness to pay for the trade-up option on top of the rental price for the default option. Results revealed that in a goal-derived assortment, respondents were more likely to trade-up and pay more for superiority on the goal-irrelevant dimension than on the goal-relevant dimension. The opposite holds for the randomly organized assortment.

With four empirical studies we document the impact of goal-derived assortment organizations on consumer choice across a variety of product categories and consumption goals. In particular, we demonstrate that compared to randomly organized assortments (experiments 1, 2 and 4) or assortments organized by brand (experiment 3), consumers choosing from goal-derived organizations are less likely to choose the goal-maximizing item. In addition to demonstrating that the choice of a particular option is contingent on the type of assortment organization, we show that a similarity effect drives these results. In particular, we show that grouping items by the underlying consumption goal they serve increases their goal-based similarity or in other words, their instrumentality for fulfilling that goal (experiment 2). When the choice task was designed such that similarity effects were less likely to occur (rejection task), perceived goal-based similarities were reduced and the effect of goal-derived organizations on choice was mitigated. We further theorized that the increase in goal-based similarity in goal-derived organizations makes goal-related attributes less diagnostic for choice. Since the items in a goal-derived subset are no longer perceived as being different on the goal-relevant dimensions, other, goal-irrelevant dimensions are used as a choice criterion. As a result, consumers shift their preference to those items that score higher on goal-irrelevant attributes, even if they have to give up performance on goal-relevant attributes (experiment 4).

Shared Happiness and Relational Identities among French Grandmothers and Grandchildren

Delphine Godefroit-Winkel, OPI, Morocco
Marie Schill, Université Reims Champagne-Ardenne, France

EXTENDED ABSTRACT

There has been a growing interest in happiness among scholars and intergovernmental organizations over the last decade. We generally agree that being happy is about feeling good (e.g. Costley et al. 2007). Most of the research on happiness belongs to the psychological and economic realms (Gilbert 2015). In consumer research, happiness has been extensively studied in its relations to materialism (Belk 1985; Richins 1994) and, more recently, in its impact on consumer choice (Mogilner, Aaker and Kamvar 2012). But a gap remains in our knowledge on consumer happiness and its relations to consumers' life projects. While consumer happiness is largely conceived as private matters (e.g. Lee and Chakravarti 2006), insight from recent studies indicates that people may be happy when they feel connected to others (Costley et al. 2007) and to their family (Nelson et al. 2013), in particular.

In this research, we aim to extend our knowledge on consumer happiness. In particular, we seek to understand the dynamics between happiness and consumers' identity projects. We raise the following questions. First, how does happiness manifest in consumption experiences? Second, how does happiness relate to consumers' identity projects? Third, what are the underlying interpersonal dynamics?

In the pursuit of understanding identity building, we located our research among French grandmothers and grandchildren. Family appears indeed as a remarkable context to study the wide range of consumer identities (Epp and Price 2008). Family members build diverse individual, relational and collective identities. Relational identity is conceived as the qualities and attributes of a sub-group that make it particular. It can be enacted, among others, from intergenerational transfers or everyday interactions (Epp and Price 2008). Data collection consisted of interviews with 23 French grandmothers and grandchildren dyads. Informants were selected according to established principles of variety and contrast.

Our analysis of grandmothers and grandchildren discourses advocates three stages that characterize happiness and relational identity. First, we observed that happiness may permeate the genesis of a grandmother identity at a grandchild birth. Happiness is manifest in our elderly informants' discourses when telling about their grandchildren's birth. They often experience an unequaled experience of their first meeting with a newborn grandchild. Moreover, grandmothers may find in particular spaces (e.g. the newborn care department) a set of resources that facilitate the genesis of a specific grandmother identity that is directed to the newborn. In short, each grandmother identity appears as a unique identity that is crafted after the birth of a particular grandchild and that is pervaded with particular emotions.

Second, we suggest that happiness may pervade the building of a relational identity between a grandmother and a particular grandchild. During the first years of a grandchild, many grandmothers expressed an intense happiness that is enacted through the presence of the grandchild. While the grandchild grows up, he-she may also express forms of happiness while sharing consumption activities with his-her grandmother (e.g. shopping, playing games, or watching cartoons together). Research has shown that sharing the same traits, temperaments, common tastes or common values characterize relational identities (Epp and Price 2008). We suggest that sharing the same happiness is also a core element that facilitates the building of a unique relational identity.

Third, our findings show happiness and relational identity may fade when the grandchild enters adolescence. Many informants report sharp changes when the grandchild turns into adolescence, as visits become scarce, and friends are taking more importance in the teenager's life. In such case, grandmothers fear the fade of their relational identity. Though nostalgia and anxiety pervade their discourses, grandmothers still express a sense of shy happiness. They often keep tangible souvenirs (e.g. grandchildren drawings, presents), as reminiscence of their fading relational identity with their grandchildren. These treasures from the past have the potential to revive a sense of happiness. Authors advocate that the marketplace structure impacts on consumer emotions (Beruchashvili and Moisio 2014). Here, we find that grandmothers use consumption to balance their emotions.

While most research has depicted consumer happiness as an intrapersonal emotion (e.g. Costley et al. 2007), we suggest that happiness may (1) be situated at the (sub)group level and (2) be shared among the (sub)group members. Further, we show how happiness may evolve among a grandmother-grandchild sub-group. Happiness may first manifest at the grandmother level, than it may be shared between the grandmother and the grandchild, and finally, happiness may fade and leave room for individual nostalgia. In short, our findings suggest that happiness may harmonize a set of consumer identity projects and consumption activities.

The Impact of 'Known Value Item' (KVI) Prices on Product Price Perceptions and Expectations

Frank Goedertier, Vlerick Business School, Belgium
Bert Weijters, Ghent University, Belgium
Karen Gorissen, Ghent University, Belgium

EXTENDED ABSTRACT

We propose and test an integrative framework of Known Value Item (KVI) price effects on (1) perceptions of assortment expensiveness, as well as (2) expected prices for products that are to be introduced in the assortment, and (3) perceived expensiveness of specific target products with a known price. Central to our framework is the proposition that KVI prices affect other price perceptions through two routes. First, KVI prices serve as a signal of assortment expensiveness, and assortment expensiveness is used to predict the future prices of upcoming products through assimilation. Since KVI price as such is not informative for predicting prices of newly to-be-introduced products, we expect that assortment expensiveness fully mediates this effect. Second, we posit a similar assimilation process for target products that are already part of the assortment (and for which prices are known): KVI price acts as an indicator of assortment expensiveness, which in turn acts as a cue for target product expensiveness (i.e., assimilation). But at the same time, the price of the target product is evaluated relative to the KVI price, with higher KVI prices making the target product price appear relatively less expensive (i.e., contrast). The effect of KVI price on assortment expensiveness is moderated by KVI user status (with a stronger effect for users vs. non-users). Assortment size is hypothesized to attenuate the impact of KVI price on assortment and target product expensiveness, but to strengthen the effect of assortment expensiveness on target product expensiveness. The model is put to the test in four empirical studies (that also include intentional outcome variables). Study 1 and 2 focus on upcoming, but as yet unpriced products; Study 3 and 4 focus on priced products already available in the assortment.

In Study 1, respondents (N = 82) were randomly assigned to one of two experimental versions of a bar price list (Low KVI price, with lager on tap at €1.50 vs. high KVI price, €2.50), and rated assortment expensiveness, the expected price of a new product the bar would introduce (a mojito cocktail), and their intention to visit the bar. Results showed a significant positive effect of the KVI price manipulation on perceived assortment expensiveness and of assortment expensiveness on expected target product price and visiting intention. Assortment expensiveness fully mediated the experimental effect on the outcomes.

In Study 2, respondents (N = 582) were shown a fictitious bar price list with three experimental conditions: Lager on tap 25cl priced €1.80, 25cl priced €2.40, or 33cl priced €2.40. Respondents rated assortment expensiveness, price expectation for a non-existing product (a mojito cocktail), and intention to visit this bar. Finally, respondents selected the beverage they most commonly order when visiting a bar. We tested whether KVI user status (user vs. non-user) moderates the impact of KVI unit price and volume. The findings support the direct effect of KVI unit price on perceived assortment expensiveness, and the indirect effect on expected target product expensiveness also observed in Study 1 (with full mediation). KVI users show a stronger effect of KVI price but are also more likely to (correctly) discount the effect of package size increases on price. Nevertheless, for both KVI users and non-users, a change in package size (leading to a decrease or increase of the absolute price of the KVI) can trigger similar effects as lowering or increasing the actual price of the KVI.

In Study 3, respondents (N = 447) saw a fictitious online Neuhaus chocolates store, including two priced products: the Neuhaus Ballotin as the KVI, and the Neuhaus Collection Mild box as the target product. KVI price was manipulated by varying package size at a constant unit price: a 250g box priced at €15 vs. a 1kg box priced at €60. Participants rated target product expensiveness, assortment expensiveness, and target product purchase intention. As hypothesized, presenting consumers with the larger KVI (with a correspondingly higher price) led to an increase in perceived assortment expensiveness, which in turn positively influenced perceived target product expensiveness and led to a decrease in target product purchase intentions. Simultaneously, however, the larger KVI also negatively influenced the perceived target price expensiveness (when controlling for the effect of assortment expensiveness).

Study 4 (N = 476) uses the same KVI and target product as Study 3, but additionally manipulates assortment size (extended vs. limited assortment). Results show that in the limited assortment, KVI price increases lead to a stronger contrast effect while the net assimilation effect stays approximately the same.

To sum up, in four studies we provide evidence that KVI prices affect price expectations of (unpriced) upcoming target products via one route (assimilation), and price perceptions of target products already offered in the assortment via two routes (assimilation and contrast) that act in opposite directions – i.e. competitive mediation. On the one hand, KVI prices affect the perception of assortment expensiveness, which in turn spills over to price expectations of non-existing target products that are announced to be added to the assortment and perceptions of existing target products already offered in the assortment - this is an assimilation effect. But on the other hand, only for existing target products, KVI prices also serve as a benchmark against which the price of an existing target product will be evaluated. Thus, lower KVI prices can strengthen the perception that the new item is expensive - this is a contrast effect.

Whereas previous research has typically addressed this as an either/or question, we add to the literature by showing that both processes occur simultaneously. Which process has the dominant effect depends among others on the size of the assortment that is shown (more extended assortments primarily weaken the direct contrast effect). Finally, the contrast and assimilation effects can be obtained not only by actually changing the price of a reference product, but also by changing the package size. KVI users turn out to be less prone to this size/price bias (i.e., they more accurately distinguish between higher unit price and larger package size).

Aesthetic Contrast Motivates Prosocial Behavior

Amir Grinstein, Northeastern University, USA & VU Amsterdam, The Netherlands

Ann Kronrod, Michigan State University, USA & Northeastern University, USA

EXTENDED ABSTRACT

Society is facing and increasingly addressing environmental and social problems such as pollution, malnutrition, and poverty. However, research and practice reveal that motivating people to behave in a socially responsible manner can be challenging and prosocial marketing campaigns are often ineffective (Duclos and Barasch 2014; Evans 2006; Kristofferson, White, and Peloza 2014). This highlights the need to examine motivations of prosocial behavior and communication approaches that are effective in encouraging such behavior. The focus of the current research is on visual images, which are typical in prosocial marketing communication. Specifically, we focus on the aesthetic nature of the visuals and its influence on prosocial behavior.

In a consumption context, aesthetic appeal (the degree to which an object is pleasing to the eye) has a favorable influence on consumer evaluations of ads, products, and brands (Bloch, Brunel, and Arnold 2003; Hoegg, Alba, and Dahl 2010). It is therefore unsurprising that marketers often incorporate aesthetic elements into commercial marketing communications. But what is the role of aesthetics in non-commercial contexts, such as communication designed to encourage prosocial behavior? The main goal of prosocial marketing is not to enhance evaluations or engender product desire but to persuade people to help others. An important notion is that pleasure is not the inevitable or only outcome of aesthetic experience; notably, a long tradition of aesthetics theory highlights empathy as a central component of aesthetic experience (Dissanayake 1992). Empathy is a central mechanism that drives helping behavior (Bagozzi and Moore 1994), so visuals that evoke empathy may be effective in prosocial communication. In light of this, is it beneficial to use aesthetic appeals as a means of elevating empathy and encouraging prosocial behavior?

There is mixed evidence for the persuasiveness of aesthetics in prosocial contexts (Eagly et al. 1991; Fisher and Ma 2014). On the one hand, people often afford attractive individuals more attention and better treatment, which in our view suggests that aesthetics can motivate prosocial behavior via a physical attractiveness stereotype, in line with the beauty-is-good effect (Langlois et al. 2000; Middlewood and Gasper 2014). On the other hand, Fisher and Ma (2014) find that favorable characteristics associated with aesthetic appeal (e.g., attractive children in need) may sometimes *reduce* empathy because the positive attributions make aesthetic individuals and objects appear less needy. Further, depiction of poverty, which is not aesthetically pleasing, may enhance empathy (Nickols and Nielsen 2011), and disfigured faces can evoke both disgust and empathy (Stone and Potton 2014). Thus, aesthetically displeasing appeals may also prompt helping behavior.

What, then, is the optimal use of aesthetics to motivate prosocial behavior? Prior literature indicates that both pleasing and displeasing visuals can evoke empathy and motivate helping behavior, and we therefore suggest that the optimal visual draws on both these elements, in what we term *aesthetic contrast*. Aesthetic contrast refers to a visual in which the aesthetically pleasing is juxtaposed with the aesthetically displeasing. In the following sections, we will argue that a particularly favorable response in terms of empathy and resulting mobilization for prosocial action arises from a visual with an aesthetically pleasing individual among a displeasing group. We further
argue that empathy is driven by two antecedents: (1) identification with the target of the prosocial cause (encouraged by the pleasing individual object) and (2) a sense of the need of that target (encouraged by the displeasing group of objects).

Specifically, we put forth the following set of hypotheses:

Hypothesis 1: *A visual image featuring an aesthetically pleasing individual among an aesthetically displeasing group has a more favorable influence on prosocial behavior than does a visual featuring an aesthetically displeasing individual among an aesthetically pleasing group, an aesthetically pleasing individual among an aesthetically pleasing group, or an aesthetically displeasing individual among an aesthetically displeasing group.*

Hypothesis 2: *The favorable influence of the visual on prosocial behavior is mediated by empathy toward the target of the prosocial cause.*

Hypothesis 3: *The influence of the visual on empathy is mediated by identification with and perceived need of the target of the prosocial cause.*

We test our hypotheses through 5 experiments (in the field, lab, and online) that focus on different prosocial contexts. Study 1a is a field experiment designed to investigate the influence of a visual with aesthetic contrast on donation behavior in a retail setting. Study 1b provides further evidence that the effect relies on aesthetic contrast; color contrast or an attractive object alone do not produce the same effect. Study 2 demonstrates the mediating role of empathy. Study 3 provides evidence for the full underlying process, including the antecedents of empathy: identification and perceived need. It also rules out an alternative explanation, namely, that our findings are not driven by aesthetic contrast but by perceived functionality. Finally, study 4 tests a boundary condition by investigating the moderating role of category similarity.

Overall, this research offers multiple key contributions. First, it is one of very few investigations focused on aesthetics in a prosocial marketing context. We shed light on prior findings regarding the impact of aesthetic appeal in prosocial marketing communication and to some extent also resolve apparent conflicts between these findings. Second, we introduce and demonstrate the role of aesthetic contrast in promoting prosocial behavior. Third, we implicate empathy as the mechanism underlying the influence of aesthetic contrast on prosocial behavior, while also demonstrating the roles of identification and perceived need in encouraging empathy. Fourth, whereas previous research has focused on human attractiveness as the source of aesthetic pleasure, we demonstrate our hypothesized effects with both human and non-human aesthetic appeals. Finally, the reported findings are not only relevant from psychological and consumer research points of view, but they are also of practical importance, considering the challenges involved in motivating prosocial behavior.

The Effect of Smileys as Motivational Incentives on Children's Food Choices: A Field Experiment in European Primary Schools

EXTENDED ABSTRACT

This study investigates the efficacy of a simple, motivational incentive—a smiley stamp—in promoting vegetable and salad consumption among primary school children.

Incentives are given to induce a behavioral change in the short term and potentially form habits in the long term (e.g., Becker and Murphy 1988). Whereas their short term effect is as predicted by behavior modification theories—an increased probability of the behavior on which it is contingent—an incentive may actually generate one of three possible outcomes (List and Samek 2014). The incentive may initially modify behavior, which then bounces back to baseline after incentive removal (standard economic theory); the incentive effect may remain even after the incentive is removed (habit formation theory), the observed behavior may fall below baseline after incentive removal because of a crowding-out of intrinsic motivation (self-determination theory; Deci, Koestner, and Ryan 1999). Whether an incentive is successful depends on how much an individual enjoys the activity, values the incentive, or cares about his/her image vis-à-vis self or others (Benabou and Tirole 2006). Incentives must also be awarded for a concrete, easily understandable task that is simple to measure (Angrist, Bettinger, and Kremer 2006).

We conducted a field experiment in 10 primary schools in five European countries using one control and one treatment school per country. The six-week experiment was split into three two-week periods before, during, and after the experimental treatment. Treatment was a smiley stamp for choosing a portion of vegetables or salad. Data was measured on individual level. In the control group, there was no treatment and no stamp card; we measured choice, consumption and waste on aggregate level.

Pretreatment, we measured no differences in vegetable and salad choice and consumption or in waste between the treatment and control schools. However, during the treatment period, in all five countries, we observed a significant increase in both choice and consumption, but also in waste. Postintervention, the differences between the treatment and control schools decreased but nevertheless remained significant. Country differences were observed. No significant age or gender differences were found.

This study thus demonstrates that low-cost motivational incentives such as a smiley stamp can be used across different countries to motivate school children to increase their vegetable and salad consumption and make healthier eating choices. It also underscores the high relevance of context for behavioral change.

Children on Sale: The Interactive Roles of Fundraising Promotion and Prosocial Identity on Charitable Intent

EunJoo Han, Auckland University of Technology, New Zealand
Claire Heeryung Kim, Indiana University, USA

EXTENDED ABSTRACT

In the United States, individuals donated over $220 billion in 2006 (Giving USA 2007). As an effort to increase charitable giving, prosocial acts have been extrinsically incentivized by offering monetary or physical incentives such as tax breaks and thank-you gifts, or by making a targeted prosocial act less costly (e.g., offering a discounted rate for joining a child sponsorship program as a sponsor). Such practices introduced by both a government and charitable organizations have spurred considerable research on the roles of extrinsic incentives in charitable giving, and researchers reported converging evidence for the detrimental effects of extrinsic incentives on prosocial behavior (e.g., Ariely, Bracha, and Meier 2009; Uri Gneezy and Aldo Rustichini 2000). For example, offering thank-you gifts decreased donations across a wide variety of charities and gift types (Newman and Shen 2012). Monetary incentives were found to decrease blood donation (Mellström and Johannesson 2008). Ariely et al. (2009) also suggested that offering monetary incentives decreases individuals' motivation to help. This finding was found to be more pronounced in a public (vs. private) setting.

Although prior work has made a substantial contribution to the literature, we found three important gaps in the extant. First, researchers have been mostly focused on the effects of offering monetary incentives such as thank-you gifts. Second, researchers have not tested the psychological mechanism that dampens people's charitable intent in a controlled lab setting (Ariely et al. 2009). The third important gap is on the limited understanding of potential moderators in the relationship between extrinsic incentives and charitable intent.

The present research aims to reduce the gaps in three important ways. First, we investigate a different type of external incentives: A fundraising promotion that makes a targeted prosocial act less costly. To this end, we focus on the context in which a charity offers a discounted rate for a targeted prosocial behavior. Specifically, since 2014, Save the Children runs a fundraising promotion targeting existing donors in its child sponsorship program. The promotion offers a discounted rate for being a sponsor of another child. All donors are required to donate $27 a month if they desire to join the child sponsorship program; but for those who join the program during the promotion period, a discounted rate of $17 a month is applied. This practice is relatively new, but seems to be quickly adopted by other organizations since it may cost less in soliciting donations than offering monetary incentives. Thus, the present research discusses a practically relevant issue in charitable giving. This setting of research also enhances a theoretical contribution since offering an incentive that makes a targeted prosocial act less costly is not identical to offering monetary or physical incentives. In the former context, donors do not receive any reward such as a thank-you gift, but they simply give less amount of resources compared to other donors who join the prosocial act or program during a non-promotional period. To the best of our knowledge, the present research is the first that investigates the role of a non-reward-based, extrinsic incentive in charitable giving. In line with prior work, we propose that a fundraising promotion that offers a discounted rate for a targeted prosocial act will decrease charitable intent.

Second, we unravel the underlying mechanism that drives charitable intent, with a focus on trust toward a charity. Trust toward a charity is an important antecedent of donation behavior (Bur-

nett 1992; Melendez 2001; Sargeant 1999). For example, Melendez (2001) found that donors only contribute to organizations that they trust and are confident about. Evidence also shows that trust affects people's willingness to become a donor and the amount of money they give (Burnett 1992; Sargeant 1999). Although trust is an important antecedent of donation behavior, prior work has overlooked its role in the relationship between extrinsic incentives and prosocial behaviors. In our research, we posit that a fundraising promotion that offers an extrinsic incentive (i.e., a discounted rate for a targeted prosocial act) will decrease trust toward a charity by giving unethical impressions such that the charity has not properly utilized the funds appropriately, thereby decreasing donation behavior.

Third, we suggest an important moderator that could influence the relationship between a fundraising promotion (i.e., offering a discounted rate for a targeted prosocial act) and charitable intent: One's prosocial identity. In particular, we posit that the detrimental effects of the extrinsic incentive will be more pronounced in the donation context because it will hamper trust toward a charity among individuals who consistently engage in costly prosocial behaviors (i.e., those high on prosocial identity). Donation behaviors are considered highly involved, producing a socially recognizable prosocial self (Michelletti 2003). Therefore, individuals high on prosocial identity will be reluctant to donate if a charity offers a discounted rate for a targeted prosocial act since helping involves high responsibility and self-actualization for them. However, the extrinsic incentive will not influence charitable intent for those who are low on prosocial identity. Prior work has shown that individuals who are not engaged in costly prosocial behaviors will subsequently behave in consistent with the self-perception (Gneezy et al. 2012). Taken together, these findings suggest that offering an extrinsic incentive that makes prosocial acts less costly will cause reactance to individuals who are high on prosocial identity.

In the remainder of this paper, three studies will be reported. Study 1 provides initial evidence for the hypotheses. Study 2 demonstrates the mediating role of trust toward a charity. Study 3 provides a confirming evidence for the mediating role of trust by directly manipulating the level of trust toward a charity. If the proposed effect is indeed mediated by trust toward a charity, offering a discounted rate for a targeted prosocial act should diminish the negative effect of the promotion on charitable intent when a charity puts effort for transparency (e.g., disclosing how donation funds are spent and an actual impact that the donation funds have on the cause or beneficiary group) (Bennett and Gabriel 2000; Hyndman 1990; Palmer and Randall 2000).

STUDY 1

Study 1 aimed to provide initial evidence for the hypotheses. We predicted that among individuals high on prosocial identity, offering a discounted rate on the suggested, or required, donation amount would lead to a decreased willingness to help. By contrast, such a promotion in a donation drive was not expected to influence individuals' charitable intent among those who are low on their prosocial identity.

The study adopted a context similar to Save the Children's child sponsorship program. Save the Children runs a fundraising promotion that offers a discounted rate for new child sponsors. All donors

are required to donate $27 a month if they desire to join the program; but for those who join the program during the promotion period, a discounted rate of $17 a month is applied. By adopting a recent business practice of charitable giving in a controlled lab setting, we aimed to enhance ecological validity of the study as well as its internal validity.

Method and Procedure

Ninety people recruited from Amazon Mechanical Turk participated in the study in return for monetary rewards. This study was a single factor (Fundraising promotion: Promotion vs. Control) between-subjects design. In the beginning of the survey, we measured participants' prosocial identity by observing how much they were willing to donate in response to an actual opportunity to give to a local charity. Gneezy et al. (2012) suggest that costly prosocial behaviors serve as a signal of prosocial identity and that people behave in consistent with their self-perception. Thus, those who are high (vs. low) on prosocial identity would help others more in general, and therefore, be more likely to give to a good cause when there is an opportunity to help. To measure participants' prosocial identity, we first instructed them that more than 50% of participants would get a $10 bonus reward and that the system would randomly select the winners. Participants were then asked if they would donate their bonus reward to a local charity if they were selected as a winner, and if so, how much they would donate. We informed that the amount of money they submitted in this question would be automatically deducted from the $10 bonus reward and would be donated to a charity.

Next, participants were engaged in a set of five spatial intelligence questions for 3 minutes as a filler task. We included the filler task to make sure that participants' decision on donating their bonus reward does not influence their charitable intent in the main task.

Subsequently, participants viewed an advertisement of an international charity's child sponsorship program. In all conditions, the ad described the potential beneficiary as a 4 year old girl, named Modedalene, from Haiti. From the advertisement, participants learned that child sponsorship is the most effective way to powerfully transform the futures of vulnerable children growing up in poverty and that Modedalene is waiting for someone to become her sponsor. The last sentence in the ad contained the promotion manipulation. In the promotion-control (i.e., no promotion) condition, the sentence read "Please sponsor Modelalene for $5 a month." In the promotion condition, it read "The minimum donation for the child sponsorship program is $10 a month; however, if you respond to this mail today, you will be able to sponsor her at a discounted rate – just $5 a month."

After the promotion manipulation, participants were asked to report how willing they were to donate $5 a month to help Modedalene based on a 7-point scale. For the manipulation check, we also asked to what extent participants believed that the advertisement utilized marketing techniques based on a 7-point scale.

Results and Discussion

We first observed whether the fundraising promotion manipulation worked as intended. As expected, those who were exposed to a discounted donation rate reported that the given ad utilized marketing techniques more ($M = 5.86$, SD = 1.60) than those who were not exposed to the promotional message ($M = 4.02$, SD = 2.12; $t(87) = 4.47, p < .001$).

Next, we examined the interactive effect of prosocial identity and fundraising promotion on individuals' charitable intent. To this end, we regressed a dependent variable—participant's charitable intent—on fundraising promotion, prosocial identity (measured), and an interaction term. The analysis revealed a main effect of prosocial

identity ($\beta = .26$, $SE = .08$, $t(85) = 3.24, p < .01$) and of fundraising promotion ($\beta = -.83$, $SE = .39$, $t(85) = 2.13, p < .05$). More importantly, there was a significant interaction between prosocial identity and fundraising promotion on participants' charitable intent ($\beta = -.47$, $SE = .15$, $t(85) = 2.97, p < .01$). To explicate the observed interaction, simple slope analysis was conducted. Following Aiken and West (1991), we plotted regression lines at one standard deviation above and below the mean for prosocial identity. When we examined people who were high on the prosocial identity, we found that offering a discounted rate for the prosocial act decreased people's willingness to help ($\beta = -4.51$, $SE = 1.30$, $t = 3.47, p < .01$). Observing people who were low on the prosocial identity, we found that offering a discounted rate for the prosocial act did not influence individuals' willingness to help ($\beta = .17$, $SE = .52$, $t = .32, p = .74$).

This study provided the initial evidence for our hypotheses. In the next study we more closely look at the mediating role of individuals' perceived trust toward a charity in the proposed relationship.

STUDY 2

In study 2, we explored the mechanism underlying the proposed relationship between an extrinsic incentive and prosocial identity on charitable intent. We predicted that for those who are high in prosocial identity, offering an extrinsic incentive that makes a targeted prosocial behavior less costly would decrease trust toward a charity, thereby reducing one's willingness to give to a good cause. We predict that those who are low in prosocial identity will not be affected in terms of their perceived trust to the charity, and thus, their willingness to help.

Method and Procedure

One hundred and twenty-four people recruited from Amazon Mechanical Turk participated in the study in return for monetary rewards. This study was a single factor (Fundraising promotion: Promotion vs. Control) between-subjects design. We followed the identical procedure to Study 1. But after having participants indicate their willingness to help the beneficiary in the ad (a dependent variable), we assessed participants' trust toward the charity in the ad by having them respond to 7 questions ($\alpha = .98$). Sample items were (1) I trust this charity to spend donated funds to improve Modedalene's life and (2) I trust this charity to always act in the best interest of the cause. In addition, to rule out motivational accounts suggested by prior work (e.g., Ariely et al. 2009; Uri et al. 2000), we assessed participants' intrinsic motivation using 4 items ($\alpha = .94$). Sample items were (1) This charity's fundraising approach dampens an inner drive to help Modedalene and (2) I would feel pleasure by expending an effort to help Modedalene. All responses were submitted based on a 7-point scale.

Results and Discussion

An ANOVA demonstrated that participants in the fundraising promotion condition were more likely to think that the advertisement utilized a marketing technique ($M_{price} = 5.71$, $SD_{price} = 1.23$, $M_{control} = 5.02$, $SD_{control} = 1.23$; $F(1, 122) = 8.88, p < .01$), confirming that our manipulation worked as intended. Next, we conducted a mediation analysis to find the mediating role of trust toward a charity in the proposed relationship. Following Preacher, Rucker, and Hayes (2007), we tested the moderated mediation hypothesis using the bootstrapping analysis in the SPSS moderated mediation macro (MODMED; model 2. Specifically, we entered fundraising promotion as an independent variable, trust toward a charity as a mediator, prosocial identity as a moderator and one's willingness to donate as a dependent variable. As predicted, the analysis (based on 5,000

bootstrap samples) confirmed that trust toward the charity in the ad mediated the proposed relationship for participants who were high in prosocial identity ($\beta = -.53$; $p < .05$), but not for those who were low in prosocial identity ($\beta = -.14$; $p = .43$). To test whether change in intrinsic motivation mediated the relationship between a fundraising promotion and prosocial identity on charitable intent, we conducted the same analysis with intrinsic motivation as a mediator. Supporting our hypothesis, intrinsic motivation did not mediate the proposed relationship for both participants who were high in prosocial identity ($\beta = -.27$; $p = .35$) and for those who were low in prosocial identity ($\beta = .26$; $p = .35$).

Study 2 successfully replicated the findings in Study 1. Also, Study 2 provided the evidence for the mediating role of trust toward a charity in the proposed relationship. In the next study, we aimed to provide confirming evidence for the mediating role of trust by directly manipulating it.

STUDY 3

The goal of Study 3 was twofold. First, we aimed to corroborate the argument for the mediating role of trust toward a charity. To this end, we manipulated the level of trust toward a charity by providing how the donation fund would be spent for a year.

Second, for robustness, the study examines the proposed relationship in a different context: Donation to a local food bank. If there is a global consensus formed with respect to helping children in poverty, those who are high on prosocial identity might have been more affected by social influences than those who are low on prosocial identity. So, in Study 3 we aimed to replicate previous findings in the context of charitable giving to a local food bank. Also, the study adopted a situation where a donor is expected to make a one-time contribution instead of monthly basis, long-term contributions.

Method and Procedure

One hundred sixty-three undergraduate students at a large US university participated in this study in return for partial extra course credit. The study was a 2 (Fundraising promotion: Promotion vs. Control) X 2 (Trust: Maintained high vs. Control) between-subjects design. As in Studies 1 and 2, we measured participants' prosocial identity by having participants indicate how much money they would donate if they were selected as a winner of a $10 bonus reward. Then participants were engaged in the filler task identical to Studies 1 and 2 for three minutes.

Subsequently, participants viewed an advertisement soliciting a donation to a local food bank. In the promotion-control conditions, the advertisement informed participants that their $5 donation would help the food bank stretch its food buying power and better address various local needs. In the promotion condition, participants learned that the food bank generally expects a $10 contribution from each donor to improve its capability to buy food and to fulfill various local needs and that it temporarily runs promotion for fundraising by offering a discounted rate — a $5 one time donation—for donors who make a contribution in response to the ad. In the high trust conditions, participants learned that 97% of their donation directly goes to help the homeless in the local area and the ad displayed the itemized budget for the money spent in 2015. In the trust-control condition, participants were not informed about how the donation money was spent for the previous year.

After the trust and promotion manipulations, participants were asked to indicate their willingness to donate to the food bank on a 7-point scale.

Results and Discussion

We regressed a dependent variable— participants' charitable intent— on fundraising promotion, prosocial identity, trust toward a charity, and interaction terms. We found a main effect of prosocial identity ($\beta = .10$, $SE = .02$, $t(155) = 4.13$, $p < .001$) and a marginally significant main effect of trust ($\beta = .20$, $SE = 11$, $t(155) = 1.81$, $p = .07$). More importantly, the analysis revealed a significant three way interaction between prosocial identity, fundraising promotion, and trust on participants' charitable intent ($\beta = .05$, $SE = .02$, $t(155) = 2.11$, $p < .05$). To explicate the observed interaction, simple slope analysis was conducted based on regression lines at one standard deviation above and below the mean for prosocial identity (Aiken and West 1991). In the trust-control condition, we replicated previous findings. Observing people high on the prosocial identity, we found that offering a discount rate for the potential prosocial act decreased people's willingness to donate ($\beta = -.91$, $SE = .33$, $t = 2.76$, $p < .01$). Observing people who were low on prosocial identity, offering a promotional rate did not influence individuals' charitable intent ($\beta = -.15$, $SE = .14$, $t = 1.14$, $p = .26$). In the high trust condition, the negative effect of fundraising promotion for charitable intent diminished. Examining those who were high on prosocial identity, offering a discount rate for the one-time contribution did not decrease participants' willingness to donate ($\beta = .30$, $SE = .40$, $t = .74$, $p = .46$). Similarly, individuals who were low on prosocial identity were not influenced by fundraising promotion either ($\beta = .06$, $SE = .16$, $t = .35$, $p = .73$).

This study provided confirming evidence for the mediating role of the perceived trust toward a charity. We successfully replicated findings of Studies 1 and 2 when trust was not manipulated to be high. However, the negative effect of an extrinsic incentive, or a fundraising promotion, on charitable intent diminished when the advertisement contained an effort to raise the trust toward a charity: Those who were high on prosocial identity did not show a decreased willingness to help even when they were exposed to a promotional fundraising message as long as they were informed about how the donation fund would be spent by the charity. This finding is consistent with prior work discussing how important it is for charities to foster trust is (Burnett 1992; Melendez 2001; Sargeant 1999). This finding also corroborates our argument that individuals' trust toward a charity mediates the proposed relationship between prosocial identity and fundraising promotion on charitable intent.

Our research contributes to the literature on the effect of extrinsic incentives in charitable giving by looking into the roles of non-reward-based, extrinsic incentives on prosocial behavior. The current findings also enhance practical relevance by pointing out what is wrong with the current practice of Save the Children in its fundraisi

Exploring the Antecedents and Consumer Behavioral Consequences of "Feeling of Missing Out (FOMO)"

Ceren Hayran, Koc University, Turkey
Lalin Anik, University of Virginia, USA
Zeynep Gürhan-Canlı, Koc University, Turkey

EXTENDED ABSTRACT

Today, we are more aware of the numerous alternative activities happening around us than ever before. Notifications about events, conversations, and gatherings taking place swamp our newsfeeds, yet, we often lack the resources to participate in all. Consequently, we are likely to experience an aversive feeling of missing out on the known but unattended experiences.

Despite the extensive press on FOMO (e.g., JWT 2012), scarce empirical work exists on this ubiquitous phenomenon (Przybylski et al., 2013). Entered the Oxford English Dictionary in 2013, FOMO stands for "fear of missing out". Due to its conceptual distinction from fear, we conceptualize FOMO as "feeling of missing out". In our work, we examine the immediate feeling of missing out triggered by social cues at a particular moment, indicating a present time orientation about one's current situation. We elaborate on FOMO in a nomological web of constructs, explore its antecedents (i.e., when and how it occurs), and link FOMO to consumer behavior. Based on a series of online, laboratory and field studies, we define FOMO as "the negative affective state that individuals encounter as a result of becoming aware of the fleeting favorable and self-relevant experiences that are taking place in the environment, from which they are absent." Importantly, we depict several real-life contexts where FOMO is experienced.

Study 1 explored three possible antecedents of FOMO in a 2 (self-relevance: low, high) X 2 (perceived favorability: low, high) X 2 (popularity: low, high) between-subjects design. Participants (n=340) read about dining at a newly opened restaurant and were asked to imagine checking social media notifications and coming across information about alternative activities. We manipulated self-relevance by indicating that the participant could (vs. not) easily picture herself attending alternative activities; perceived favorability of alternatives by telling that the participant found alternatives more (vs. less) favorable than the dining experience. Participants wrote about the imagined alternatives, and were presented with other respondents' ratings of these alternatives as highly (vs. not) favorable. Then, participants' revisit intentions to the restaurant (1=not at all/7=very much) was measured. Adapted from Przybylski et al. (2013), situational FOMO was measured with three statements: "It bothers me that I am in the know about but out of touch with the activities and experiences that are going on around", "I am worried that I can't take part in the activities that are going on in my surroundings", "On this Friday evening, to what extent do you feel like you are missing out on alternative activities and experiences taking place in your environment?" (1=not at all/7=very much), averaged into a single FOMO index (α=.93). Set of personality variables and affective measures were used as covariates throughout the studies to rule out alternative explanations. Surprisingly, popularity of alternatives didn't have an effect on FOMO or on revisit intentions (p's>.05). There was a significant interaction between the effects of self-relevance and perceived favorability of alternatives on FOMO. When favorability was high, high (vs. low) self-relevance group experienced higher FOMO (5.03 vs. 3.15; $F(1, 332)$=76.14, p<.01); when favorability was low, low (vs. high) self-relevance group experienced lower FOMO (2.01 vs. 3.17; $F(1, 332)$=27.71, p<.01). A three-way ANOVA also revealed a significant interaction between

the effects of self-relevance and perceived favorability of alternatives on revisit intention. When favorability was high, high (vs. low) self-relevance group had lower revisit intentions (3.97 vs. 4.74; $F(1, 332)$=13.74, p<.01); when favorability was low, there was no effect of self-relevance on revisit intentions (p>.05). Macro's mediated moderation model with 5,000 bootstrapped samples revealed that FOMO mediated the effect of favorability X self-relevance interaction on revisit intention (b=-.19, 95% CI [-.406, -.042]).

Study 2 replicated study 1 findings by adopting a more realistic manipulation of popularity of alternatives; Facebook "Like" button images ("0" vs. "over 100" Likes). Results supported that both perceiving alternatives as favourable and self-relevant, but not necessarily as popular, were preconditions of FOMO.

Study 3 explored FOMO among undergraduate students who were taking courses at summer school. Students (n=83) were assigned to FOMO vs. control groups. FOMO group read about students' summer vacation preferences, which were found to be highly favorable and self-relevant in a pretest. Control group read neutral information. Manipulation check confirmed that FOMO group experienced stronger feelings of missing out. Controlling for other affects, students in the FOMO group indicated lower willingness to attend summer school the following year (4.05 vs. 5.17, p<.05), and were less willing to recommend it to their friends (5.22 vs. 5.83, p=.07).

Study 4 examined FOMO in a real office environment. 74 individuals from 6 companies completed our survey during overtime work after 17.00 pm. FOMO group read information about six (pretested) events that were concurrently taking place in town; control group was provided with neutral information. Manipulation was successful. FOMO group indicated a lower momentary job satisfaction (3.65 vs 4.32, p<.05) and lower willingness to stay for overtime work again the following week (3.54 vs. 4.49, p<.05).

Lastly, study 5 investigated FOMO during an enjoyable experience. Participants at a museum event (n=67), with a high baseline enjoyment level (M=6.37, 7-point scale) were assigned to FOMO vs. control groups. FOMO group read information about six (pretested) events concurrently taking place in town; control group read neutral information. Participants' variety-seeking tendency and their guess about how many events could be going on in the area that evening were measured as covariates. Manipulation check was confirmed, but there were no differences in other negative feelings (relative deprivation, constraint or regret; p's>.05). In addition to revisit intentions, participants' willingness to accept a monetary amount (measured on a $0-40 sliding scale) to quit their current activity to attend an alternative activity was measured. FOMO group's revisit intentions were lower (5.48 vs. 6.12, p<.05), and they were willing to accept a lower dollar amount to leave the museum event ($22 vs. $28.29, p<.05) suggesting that FOMO might lead to lower valuation of one's current experience.

Our research contributes to the limited existing work on the emerging FOMO construct by exploring its antecedents and consequences for consumer behavior. We demonstrate that FOMO is driven by the awareness of favorable and self-relevant experiences taking place in one's surroundings. While the popularity of unattended experiences (e.g., Facebook likes) is frequently featured as

an important antecedent of FOMO in the media, our findings reveal that it doesn't influence the extent of FOMO unless the missed out experiences are found personally relevant and favorable. From a managerial perspective, FOMO decreases intentions to repeat a current experience (i.e., redo/revisit intentions) and may decrease the valuation of and recommendation intentions for the current experience. Importantly, we show that FOMO may even be experienced during enjoyable experiences (e.g., fun social event), in the absence of negative feelings like regret.

Blink and You'll Miss It: The Consequences of Ephemeral Messaging

Daniel He, Columbia University, USA
Ran Kivetz, Columbia University, USA

EXTENDED ABSTRACT

Media scholars and web commentators call it the *internet paradox* (Kraut et al. 1998; Marche 2012; Weinberg 2014): while social media has expanded the size of consumers' social network, consumers feel less intimately connected with the friends they communicate with online. Despite gaining more access into the lives of others, people feel less interpersonal closeness -- often failing to find the level of intimacy, presence, and immersion experienced in face-to-face interactions (McPherson, Smith-Lovin, and Brashears 2006; Turckle 2011). The internet paradox is one reason why both social media platforms (*e.g.*, Facebook; Zuckerberg 2014) and communications researchers (Baym 2010; McKenna and Bargh 1998; O'Sullivan, Hunt, and Lipper 2004) have pursued methods for creating more immersive virtual settings, with the goal of reproducing the richness of face-to-face interactions felt in the real world.

Typically, social media firms have attempted to make the virtual more real by employing technological innovations that enable transmitting *more and richer* content (Baym 2010; Daft and Lengel 1984; Short, Williams, and Christie 1976). For example, in the case of Facebook, the relatively impoverished means of sharing personal content through status updates has been and continues to be augmented over time. The process started with the addition of photo sharing capabilities, and then with video sharing capabilities, and in the near future with virtual reality capabilities (Rubin 2014). By implementing the ability to transmit visual and auditory information, Facebook has created a user experience that is more immersive than its original solely text-based interface.

Beyond these technological improvements, we propose that immersion and realism in a virtual setting can also be experienced by incorporating ephemerality, which is the quality of transience and disappearance, into the exchange of digital content. The extant literature suggests that ephemerality may create a more immersive experience, in which consumers are more in the ("present) moment. First, research on memory and photo taking indicates that an ephemeral experience, such as viewing artworks in a museum through one's own eyes, results in better memory of the artworks than taking photographs of the art (Henkel 2013). This research suggests that engaging with reality ephemerally rather than through a camera's lens enables individuals to be more immersed in the experience.

Second, unlike permanent messages, which can be saved and read at another time, ephemeral messages vanish after they are viewed, which grounds the interaction to the present. Focusing on a target that is in the present can create an immersive experience, as evidenced by the literature on mindfulness (Brown and Ryan 2003; Hanh 1976; Kabat-Zinn 1990). For example, mindfulness research shows that focusing on breathing -- which is an action that occurs from moment to moment -- anchors attention in the present and creates an immersive experience in which thoughts, feelings, and sensations pass from one second to the next (Bishop et al. 2004). By making digital content fleeting, ephemeral messaging anchors interactions in the present, which creates a more immersive experience when communicating on social media.

Third, the literature on *flow* demonstrates that when attention is directed towards an activity in the present that is reasonably challenging, people enter a state of flow, which entails an immersive experience of flowing from one moment to the next (Csikszentmihalyi 1977; Fortin and Dholakia 2005; Nakamura and Csikszentmihalyi 2014). In this state, consumers are completely absorbed in the task at hand, and their attention must be sustained on the activity occurring in the moment in order to stay in flow. By drawing attention to messages that are transitory, ephemeral messaging encourages consumers to attend to the correspondence and become immersed in the interaction.

Together, the aforementioned research suggests that communicating ephemerally increases immersion, which produces four interrelated consequences of being ("present") in the moment. In Study 1, we demonstrate the basic phenomenon by showing that when the same photo messages are transmitted ephemerally rather than permanently, receivers of the message are more immersed in the experience and develop more interest in joining the activity portrayed by the message. Study 2 shows that when messages convey a mix of both positive experiences (*e.g.,* images from the Super Bowl) and negative information (*e.g.,* reminder that the consumer's favorite team lost), ephemeral, as opposed to permanent messaging, increases consumers' preference to participate in the event; this result supports our conceptualization that ephemerality allows consumers to be more immersed in an experience. Study 3 manipulates the level of immersion and indicates that when immersion in a unifying, coherent experience is made more difficult by transmitting photo messages from multiple, distinct locations (as opposed to from a single location), ephemeral messaging can more effectively restore the level of immersion compared to permanent messaging. Study 4 investigates interactions between pairs of participants who communicated through a chatting app with either ephemeral or permanent messaging; the results indicate that ephemeral messaging led to more interpersonal closeness and immersion than permanent messaging in interactions that would lead to anxiety arising from rumination. In a social interaction that induced less anxiety, ephemeral messaging did not result in more interpersonal closeness than permanent messaging. Study 5 shows that when presented with a sunk cost dilemma for a plan that consumers had just arranged, those who made their plans using an ephemeral messenger rather than a permanent messenger were more resistant to the sunk cost bias. Finally, Study 6 demonstrates that by being in the moment, consumers become more creative when they solve anagram puzzles ephemerally than permanently.

A Goal Dependent Model of Certainty and Information Seeking

Sharlene He, Northwestern University, USA
Derek Rucker, Northwestern University, USA

EXTENDED ABSTRACT

Information seeking and processing represents a central domain of inquiry within consumer behavior. A core tenant of many theories and models is that consumers' desire for information is driven by a need to reduce uncertainty (e.g., Chaiken, Liberman and Eagly 1989; Driscoll and Lanzetta 1965; Maheswaran and Chaiken 1991; Weary and Jacobson 1997). Consumers can often be relatively certain or uncertain about brands they encounter. Based on the principle of uncertainty reduction, consumers should be more likely to search for information about more uncertain brands.

The present research proposes that the uncertainty reduction principle is far less invariant than captured in current models. In particular, we explore the idea that the opposite can often be true: consumers may engage in *less* information search about options accompanied by uncertainty. Specifically, we introduce and test a goal-dependent model that proposes individuals interpret uncertainty in the context of their overarching goals. Although uncertainty increases information processing when a knowledge goal is focal, uncertainty decreases information processing when an efficiency goal is focal.

In prior paradigms demonstrating the classic effect (i.e., uncertainty increasing information seeking and processing), the active goal pertained to *knowledge acquisition* (Lanzetta and Driscoll 1968; Weary and Jacobson 1997). Under a knowledge goal, greater uncertainty signals larger deficiency in knowledge, thus acquiring information about an uncertain (vs. certain) brand enables more progress towards the knowledge goal. This is consistent with existing explanations of the classic effect. However, consumers might often have *efficiency* goals, such as making a purchase decision under time constraint (Duncan and Olshavsky 1982; Punj and Staelin 1983). In this situation, information is a means to an end and consumers need to allocate their time and energy to reach a decision. We propose that, under an efficiency goal, greater certainty signals a higher likelihood of goal attainment. Consequently, seeking information about a relatively certain (vs. uncertain) brand enables more progress towards the goal.

We test our goal-dependent account in five experiments with different manipulations of uncertainty. Manipulation checks assessing uncertainty were included in each experiment and showed that the manipulations had the intended effect. Although we replicate the classic effect when a knowledge goal is present, we consistently show a reversal when an efficiency goal is present, such that consumers engage in greater information seeking for more certain as opposed to more uncertain options.

Experiment 1

Participants (N = 119) were assigned to conditions in a mixed 2 (brand: low- vs. high-uncertainty) x 2 (goal focus: knowledge vs. efficiency) design with brand as the within-participant factor. We presented participants with two fictitious brands that were rated equivalently by consumers; they were told a friend had tried and recommended one (low-uncertainty). Goal focus was manipulated by informing participants that they want to increase knowledge (*knowledge*) or are shopping under time constraint (*efficiency*). The dependent measures were rated likelihood of seeking information for each brand and choice of which brand's website link to click on.

A significant uncertainty x goal interaction for information seeking emerged, $p < .001$. Under a knowledge goal, participants were more likely to seek information about the high-uncertainty ($M = 5.80$, SD = 1.21) than the low-uncertainty brand ($M = 5.32$, SD = 1.46), $p = .075$. In contrast, under an efficiency goal, participants were more likely to seek information about the low-uncertainty ($M = 5.12$, SD = 1.72) than the high-uncertainty brand ($M = 4.47$, SD = 1.55), $p = .015$. Furthermore, participants in the efficiency condition chose the link for the low-uncertainty brand (82.8%) more often than those in the knowledge condition (59.3%), $p = .006$.

Experiment 2

Participants (N = 201) were assigned to conditions in a 2 (uncertainty: high vs. low) x 2 (goal focus: knowledge vs. efficiency) between-participants design. Participants were provided with a goal and read some information about a brand. Those in the low uncertainty condition then listed three things they knew about the brand, while those in the high uncertainty condition listed three things they didn't know. Dependent measures were amount of additional information desired and amount of time they wanted to spend learning about the brand ($r = 0.56$).

A significant uncertainty x goal focus interaction on information seeking was present, $p = .017$. In the knowledge focus condition, those in the high-uncertainty condition ($M = 5.10$, SD = 1.00) wanted more information than those in the low-uncertainty condition ($M = 4.65$, SD = 1.27), $p = .086$. In the efficiency focus condition, a reversal occurred: less uncertain individuals ($M = 4.71$, SD = 1.28) wanted more information than those feeling more uncertain ($M = 4.28$, SD = 1.23), $p = .092$.

Experiment 3

Experiment 3 (N = 154) used a similar design and procedure as Experiment 1 to examine information acquisition behavior. Participants were presented with two real brands, pretested to differ in uncertainty but be equivalent in attitude. They were presented with a knowledge or efficiency goal and allowed to read three pieces of information in total before selecting a brand.

To measure information seeking, the percentage of information selected about the uncertain brand and the percentage of time spent reading about the uncertain brand were combined ($r = 0.85$). A one-way ANOVA with goal focus as the factor revealed that participants in the efficiency condition engaged in less information seeking for the uncertain brand ($M = 66.44\%$, SD = 16.05%) compared to participants in the knowledge condition ($M = 72.62\%$, SD = 19.96%), $p < .05$.

Experiment 4

Experiment 4 examined the mechanism for why an efficiency goal produces more information seeking when people are relatively certain versus uncertain. Participants (N = 140) were all given an efficiency goal and assigned to a high- or low-uncertainty condition using the manipulation from Experiment 2. Participants completed measures assessing desire for information, uncertainty, and expectations of goal attainment.

People sought more information when relatively certain versus uncertain, replicating the efficiency goal findings of previous experiments, $p < .001$. Serial mediation analysis examined the hypothesis that uncertainty reduces expectations of goal attainment under an efficiency goal. The indirect effect was significant, $\beta = 0.27$, $z = 3.49$, $p < .001$, supporting our model.

A fifth experiment replicated the efficiency goal findings in a paradigm with multiple real brands. The present research makes an important theoretical contribution by demonstrating a reversal of the classic effect as well as by introducing a theoretical model specifying when and why each effect occurs.

Consuming *Bondieuserie*: Raising the Profile of Religious Kitsch Consumption

Leighanne Higgins, Lancaster University, UK
Kathy Hamilton, University of Strathclyde, UK

EXTENDED ABSTRACT

Consumer research discussions of pilgrimage have centred on three predominant conversations; new-age pilgrimage (O'Guinn and Belk, 1989), secular/brand pilgrimage (Kozinets, 2001; Borghini et al., 2009), and religious/spiritual pilgrimage (Scott and Maclaren, 2013, Kedzior, 2013; Turley, 2013; Moufahim, 2013; Higgins and Hamilton; 2014: 2016). However, emphasis has been placed upon the intangible experience, with few investigating the symbolic value of the physical goods associated with the pilgrimage. Furthermore, currently consumer research has neglected the popularly consumed kitsch object. Within religious settings, kitsch has been discussed briefly and negatively, with researchers to date believing such items to be "offensive" (Belk et al, 1989; Turley, 2013), in bad taste (Maclaren et al. 2012) and an "inappropriate mixing of the Sacred and the Profane" (Belk et al, 1989, 25). Yet if so, why do religious marketplaces offer such goods, and why do their consumers – most often religious followers - consume these goods? Drawing on the emergent findings of a three-ethnographic study at the Catholic pilgrimage site of Lourdes, this paper aims to raise the profile of religious kitsch objects, offering insight into the symbolic and functional value consumers gain from such "material manifestations of religion" (McDannell, 1995, 4).

RELIGIOUS CONSUMPTION, KITSCH AND *BONDIEUSERIE*

Consumer research discussions of religious consumption have focussed upon the consumption of religious clothing and objects as a means of communicating sense of self or religiosity (Zwick and Chelariu, 2006; Wong, 2007; Jafari and Goulding, 2008; Sandikci and Ger, 2010; Rinallo et al., 2013). With Rinallo et al. (2013) finding consumption of the fashion rosary bead (traditionally used by Catholics to keep track of structured prayer) to be "both sacred and secular at the same time" (2013, 36), enabling religious consumers simultaneously to be in fashion and faith. Further research uncovered the consumption of religious objects to enable communication with Deity (Higgins and Hamilton, 2012) or with loved ones (Moufahim, 2013). Indeed Moufahim (2013, 2) asserts that material consumption is "necessary for a pilgrimage experience to be successful". However, consumer research overlooks the role and significance of the religious kitsch good.

Within Christianity, the French word "*Bondieuserie*" (McDannell, 1995, 165), refers to both "religious knickknacks" and the "notion of the conformingly banal". However English has no translation for *Bondieuserie*, subsequently alliterative, derogative terms such as "Catholic/ Christian kitsch", "Holy hardware" and "Jesus Junk" (McDannell, 1995, 222) have become popular. Turley (2013, 169) describes Catholic Kitsch as "anachronistic, clichéd, derivative, mass–produced, populist and in poor taste", resonating with Belk et al.'s (1989, 25) belief that religious kitsch decontextualizes, is "offensive" and an "inappropriate mixing of the Sacred and the Profane". This study critiques this derogative viewpoint, uncovering the religious kitsch object to encase symbolic and functional value.

CONTEXT & METHODOLOGY

Lourdes, a beacon of hope and renewal for sick and healthy pilgrims, hosts over six million consumers annually, making it, after Paris, the second biggest tourist destination in France. Lourdes is an example of a "place-directed market created by the crowds drawn to a sacred place" (Scott and Maclaren, 2013, 196). For outside the Sanctuary gates of Lourdes, exists a consumption-scape of 220 souvenir shops, equaling one shop for every 30,000 pilgrims, offering all types of products from the religious prayer card and rosary bead, to the kitsch sparkly religious statues and the popularly consumed luminous religious goods.

In keeping with standard ethnographic practice, multiple methods of data collection were employed. Fieldwork data resulted in over 200 pages of double spaced field-notes, approximately 3000 visuals (photographs and videos), and many informal and serendipitous interviews with pilgrims on site at Lourdes, which were audio-recorded when possible. Depth interviews were conducted with twenty-three respondents lasting from thirty minutes to four hours in length enabling the understanding of personal life histories. All interviews were transcribed verbatim, tallying over 1000 double spaced pages of transcription. Data was analyzed thematically with the religious kitsch good emerging as important to pilgrimage consumption.

"BIG BEADS FOR BIG PRAYERS": THE FUNCTIONAL AND SYMBOLIC NATURE OF KITSCH OBJECTS

"…I was gifted a set of Rosary beads that you could hang at the top of the door and they could reach the ground and the beads were the size of my fists, and Melanie [friend] said to me I think maybe last year, I don't know what was happening in her family, but she said "we need big prayers". So I packaged them off and said to her "here's big beads"…And they had a family rosary [prayer session] downstairs with Melanie's mother and father – well her dad is mostly in bed all of the time – and they were laughing because he kept losing his rosary beads so she brought them in and said "well you won't lose this one" and her little grandkids now they all use these big ones…" (Phillip, 63).

Patrick outlines the trajectory of what he initially viewed as a "tawdry" set of rosary beads, as becoming gifted, re-gifted and finally moving from symbolic to being functionally used within a family prayer setting. The functional value of the rosary beads departures from Belk et al's (1989, 9) belief that to maintain sacredness within an object, the Sacred object must remain "beyond mundane utility". However, this study uncovers sacred and religious goods can be both functional and symbolic. For although the above beads were initially viewed as "tacky" and "laughter provoking" (McDannell, 1995), at their core they remain known as a prayer tool aiding a Catholic to say the rosary. Consequently, with time and through sacralisation via gift giving (Belk et al., 1989), the big beads regain both sacred and functional value.

To end, we raise the profile of religious kitsch goods and draw on the notion of *Bondieuserie* to demonstrate that religious goods, which have been negatively perceived in previous research, can in fact be symbolically and functionally valued. Thus, we believe and agree with McDannell (1995) that the material dimension may be one way that religion can be better understood and the meanings of religious life better "deciphered" (McDannell, 1995, 2).

When Exploding Deals Create Competitive Customers:
Understanding the Psychological Consequences of Scarcity Marketing Tactics

Jillian Hmurovic, University of Pittsburgh, USA
Kelly Goldsmith, Northwestern University, USA
Cait Lamberton, University of Pittsburgh, USA

EXTENDED ABSTRACT

Scarcity marketing tactics are a time-honored mainstay in promotional advertising. It is common for television, online, and in-store advertisements to emphasize the limited nature of promotional offers, often referencing either the limited quantity (e.g., "while supplies last!") or limited time (e.g., "one day only!") associated with a promotional offer (Cialdini 2009). The pervasive use of both tactics is not surprising, given that the practical value of such promotions has been supported by academic findings, which reveal that perceptions of scarcity often positively correlate with perceptions of desirability, value, and purchase intentions (e.g., Brock 1968; Inman, Peter, and Raghubir 1997; Sevilla and Redden 2014).

However, in the current research, we highlight an important caveat to these prior findings. In a series of studies, we evidence that time-based scarcity promotions can produce the ironic effects of motivating consumers to (1) devalue the promoted product and (2) look for better deals elsewhere. This shift in consumer behavior occurs because consumers exposed to time-based scarcity marketing promotions are more likely to be aware that they are being manipulated by the retailer. This activation of persuasion knowledge subsequently engenders a sense of competition with the retailer, which produces these negative results.

By testing this, we provide a novel and important demonstration of the negative consequences of time-based scarcity marketing. Further, we highlight an important and heretofore unrecognized distinction between the psychological consequences instantiated by time-based scarcity marketing tactics versus quantity-based scarcity marketing tactics. Whereas quantity-based scarcity marketing tactics have been shown to increase competition among consumers (Aggarwal, Jun, and Huh 2011), we provide evidence that time-based scarcity marketing promotions can have the negative effect of increasing a sense of competition with the retailer, which has negative consequences for how retailers' products are valued.

Recent research in this domain has demonstrated that consumers exposed to reminders of resource scarcity adopt a competitive orientation (Roux, Goldsmith, and Bonezzi 2015). We suggest that scarcity marketing tactics may provoke a competitive orientation in certain contexts. Indeed, Aggarwal et al. (2011) found that print advertisements highlighting limited quantity increased perceptions of competition with other consumers, thereby increasing participants' purchase intentions.

However, whereas quantity-based scarcity marketing tactics engender competition among consumers, we suggest that time-based marketing tactics will engender a competitive orientation toward the retailer. We draw from the literature on persuasion knowledge (e.g., Friestad and Wright 1994) to argue that consumers perceive time-based scarcity marketing tactics as evidence that the retailer is trying to manipulate them (e.g., Campbell and Kirmani 2000). Consequently, consumers will become suspicious of the retailer (Campbell and Kirmani 2000), and will be more inclined to regard the retailer as an adversary (trying to maximize his own financial gain). For this reason, consumers will be motivated to (1) devalue the promoted product and (2) engage in search elsewhere for the same product when they are exposed to time-based scarcity marketing tactics, as

compared to other conditions. To date, we have conducted three studies to investigate this idea.

In Study 1, MTurk participants (n = 383) imagined shopping online for a tablet for their significant other, viewing a fictional retailer's website advertising the discount. Participants saw a timer counting down until the deal expires (time-scarcity condition), a timer counting down until the retailer's two-year anniversary (time-control condition), or no timer (control condition). Participants in the time-scarcity condition reported significantly lower WTP for the promoted product than both control conditions, despite recognizing that significantly less time remained to purchase the product. There was no difference, however, for product quality perceptions or website quality perceptions. Thus, contrary to prior literature, these results indicate that time-based scarcity marketing can cause consumers to devalue the promoted product.

Study 2 replicates this effect in a laboratory setting and examines whether consumers exposed to time-scarcity promotions engage in greater product search behavior as a result of a competitive orientation towards the retailer. Participants (n = 131) first read the same study 1 scenario (conditions: time-scarcity; time-control; control) and then had the opportunity to search competitors' websites for a better deal, subsequently rating their felt competition with the retailer. Those in the time-scarcity condition reported a significantly greater desire to "beat" the retailer. Additionally, the time-scarcity condition spent marginally more time than those in the control conditions searching competitors' websites for a better deal. Importantly, the effect of time scarcity promotions had a positive, indirect effect on search time through participants' competitive orientation towards the retailer. Thus, consistent with our theorizing, consumers exposed to time scarcity promotions experienced greater competition with the retailer, subsequently motivating them to search for the promoted product elsewhere.

In study 3, we directly demonstrate the mediating role of persuasion knowledge activation. Using a 2 (Scarcity: time-scarcity, control) x 2 (Recipient: self, other) between-subjects design, we exposed MTurk participants (n = 371) to an online shopping scenario similar to previous studies. In addition to manipulating product recipient, we randomized the countdown start time (time-scarcity condition). Participants estimated the time they'd be willing to spend searching for a better deal and then rated their competitive orientation (towards retailer and other consumers), persuasion knowledge, affect, and psychological reactance. Those exposed to the time-scarcity promotion indicated more persuasion knowledge and greater felt competition with the retailer, but did not differ from the control condition in consumer competition, affect, or psychological reactance. Critically, time-scarcity promotion exposure had a positive, indirect effect on search time, through the effect of persuasion knowledge on experienced competition with the retailer. Thus, in line with our predictions, we find that time-scarcity promotions activate consumers' persuasion knowledge, which increases consumers' competitive orientation toward the retailer and, consequently, increases consumers' willingness to search for a better deal.

In sum, the current research evidences that time-based scarcity promotions can produce the ironic effects of motivating consumers to (1) devalue the promoted product and (2) look for better deals elsewhere. As such, this investigation not only offers practical impli-

cations, but theoretical advancements both for the literature on scarcity promotions and for understanding the psychological processes instantiated by exposure to scarcity marketing promotions.

More than Words:
a Psycholinguistic Perspective on the Properties of Effective Brand Slogans

Brady Hodges, Texas A&M University, USA
Caleb Warren, Texas A&M University, USA
Zachary Estes, Bocconi University, Italy

EXTENDED ABSTRACT

Slogans help define a brand's identity and strengthen its positioning. Firms across the world spend millions of dollars each year creating and communicating slogans, such as "The Ultimate Driving Machine," "What's in your Wallet?," and "Like a Good Neighbor..." (Edwards 2011). Surprisingly, despite the ubiquity of slogans in today's marketplace, there is little consensus on what makes for a "good" slogan. (Bradley and Meeds 2002; Dass, Kohli, Kumar, and Thomas 2014; Kohli, Leuthesser, and Suri 2007; Kohli, Thomas, and Suri 2013; Lagerwerf 2002).

We attempt to improve understanding of what makes slogans effective by drawing on the rich literature in cognitive psychology and psycholinguistics. Specifically, we draw on evidence that the lexical, semantic, and emotional properties of individual words influence both memory and perceptions (Cortese, Khanna, and Hacker 2010; Kensinger and Corkin 2003). Whereas previous studies have focused largely on exploring the effectiveness of slogans at the composite level, we investigate what constitutes an effective slogan by examining the linguistic characteristics of each of the discrete words in the slogan. This approach has the unique potential to advance the literature by unearthing key insights into the distinctive word properties of the most effective slogans, offer practical advice into optimal word-choice strategies, and deliver some actionable tools for a manager's slogan design toolbox.

Effective slogans should increase brand awareness and strengthen brand attitude (Keller 1993). Because memory for marketing communications influences brand awareness, we investigate how the linguistic properties of a slogan's words influence slogan recognition. Additionally, because the extent to which consumers like a marketing communication directly and indirectly influences brand attitudes (MacKenzie, Lutz, and Belch 1986; Mitchell and Olson 1991), we further investigate how consumers' liking of slogans is influenced by the linguistic properties of a slogan's words. These constitute our dependent variables in the analysis (i.e., slogan recognition and slogan liking) for which we postulate and test seven hypotheses concerning the influence of eight distinct psycholinguistic variables.

Citing dual process theory (Evans 2003), we hypothesize that the psycholinguistic properties of slogans that serve to increase processing fluency will increase liking, but simultaneously reduce recognition, and vice versa. This would have significant managerial implications for slogan design. More specifically, slogans employing words that require more effortful system 2 processing should be more easily recognized, but at the expense of reduced liking. The reverse should be true for slogans dense in words that facilitate a more fluent system 1 processing. The underlying nature of this dual-process account serves as the key theoretical basis for each of the following hypotheses.

Hypothesis 1$_{a,b}$: $_{(a)}$Slogans with a greater number of words will be recognized more, $_{(b)}$but liked less.

Hypothesis 2$_{a,b}$: $_{(a)}$Slogans dense in high-frequency words will be recognized less, $_{(b)}$but liked more.

Hypothesis 3$_{a,b}$: $_{(a)}$Slogans dense in orthographically dissimilar words will be recognized less, $_{(b)}$but liked more.

Hypothesis 4$_{a,b}$: $_{(a)}$Slogans dense in concrete words will be recognized more, $_{(b)}$but liked less.

Hypothesis 5$_{a,b}$: $_{(a)}$Slogans dense in words acquired at a young age will be recognized less, $_{(b)}$but liked more.

Hypothesis 6$_{a,b}$: $_{(a)}$Slogans with the brand name included will be recognized more, $_{(b)}$but liked less.

Hypothesis 7$_{a,b}$: $_{(a)}$Slogans dense in positively valenced and arousing words will be recognized more, $_{(b)}$and liked more.

EMPIRICAL ANALYSIS

We test our hypotheses on a sample of 845 real slogans for brands spanning multiple industries, product classes, and geographic locations. We measured the psycholinguistic properties of each of the 845 brand slogans by breaking each slogan into its individual words, and then used established psycholinguistic databases (e.g., the English Lexicon Project; Balota et al. 2007) to obtain values for each of the eight psycholinguistic variables. We then computed slogan-level averages by taking the average score across all of the words in each slogan for each independent variable (e.g., slogan concreteness = the average concreteness across all the words in the slogan).

We assessed slogan recognition and liking by surveying 594 undergraduate students at a large U.S. university. Participants indicated the extent to which they liked 50 randomly selected slogans and then were presented with a surprise recognition test for the 50 slogans they evaluated with 50 distractor slogans included (see Cortese et al. 2010 for a similar example). Consistent with the hypotheses, brand slogans using words that facilitate faster, less effortful processing were more liked but were less likely to be correctly remembered. Conversely, slogans with psycholinguistic properties that stimulate a more effortful, conscious processing were associated with higher levels of recognition but less favorable liking ratings. Specifically, the results indicate that, on average, slogans employing more common, less orthographically-confusable, and less concrete words are more liked. Keeping the brand name out of the slogan likewise increases slogan appeal. On the other hand, longer slogans that are comprised of less common and more concrete words exhibit higher levels of recognition. Including the brand name in the slogan is also associated with enhanced memorability.

LAB EXPERIMENT

Next we conducted a confirmatory laboratory experiment (N = 252) to test the results of the empirical analysis and improve the liking or recognition of real brand slogans by altering the psycholinguistic properties. More specifically, to improve slogan liking, synonyms that were more common, less orthographically similar, and

less concrete were sought to replace a slogan's existing core words. For example, Club Med's slogan "the antidote for civilization" was revised to "the cure for mankind." Similarly, to improve recognition, synonyms that were less common, more orthographically confusable, and more concrete were pursued. For example, Toyota's slogan "get the feeling" was changed to "snag the sensation." Slogan liking and recognition were assessed on a sample of 252 undergraduate students at a large U.S. university. Results corroborated the findings of the previous empirical analysis. For each of the unique slogan sets the revised slogans outperformed the original slogans in the expected manner.

Visualizing Emergent Identity of Assemblages in the Consumer Internet of Things: A Topological Data Analysis Approach

Donna Hoffman, George Washington University, USA
Tom Novak, George Washington University, USA

EXTENDED ABSTRACT

The Internet of Things (IoT) represents a new phase of the Internet where consumers can not only interact with smart devices, but devices can interact with each other. Consumers can interact with smart devices like wearables, thermostats, lights and more, devices can interact with other devices, and devices can even interact with content on the Internet. We propose that interactions in the IoT create assemblages of consumers, digital information, and physical devices. IoT assemblages have emergent capacities (things they can do or have done to them) that are not present in the consumers, digital information or physical devices by themselves. Such capacities come from the ongoing interactions among the various components of the assemblage, rather than from the components themselves (e.g. DeLanda 2006, Hoffman and Novak 2015). For example, a smart networked toaster can learn from other toasters that it is being used less than average, it can flip its lever angrily to get our attention and encourage us to use it more, and it can complain about us on Twitter when we don't use it enough and ask someone to come and take it to a better home (Rebaudengo, Aprile and Hekkert 2012). The toaster's identity emerges from its capacities exercised in these interactions.

Using assemblage theory to anchor our conceptualizing and motivate our methodological approach, our objective in this paper is to understand the identity of a particular IoT assemblage and examine how its identity has evolved over time. The identity of an assemblage - "what it is" - is defined as the properties, capacities and tendencies that emerge through processes that initiate and sustain the ongoing interactions between the parts of the assemblage (DeLanda 2011). The identity of an assemblage is important because consumer experience emerges from a person's interactions with an assemblage, and consumer experience is influenced by the identity of that assemblage (Hoffman and Novak 2015).

One example of an IoT assemblage is the online service IFTTT. com, launched in 2011. IFTTT is a Web and app-based platform that allows consumers to connect nearly 300 different channels through user-created If-This-Then-That rules called "recipes." IFTTT channels include physical connected home and car devices, wearables, social media, mobile apps, news sources, photo and video sites, and more. IFTTT users collectively run 20 million recipes each day for making various things happen (Lunden 2015). For example, one recipe might change one's smart bulbs pastel blue when it is raining, and another recipe might turn on mood music to play along with the lights as it rains. IFTTT does not stipulate how consumers create recipes for interaction, and thus the way that people choose to use IFTTT determines IFTTT's very identity. Each IFTTT recipe is a consumer-created interaction among components, with IFTTT an assemblage that has emerged from these interactions over time.

The paper is organized as followed. First we briefly consider aspects of assemblage theory relevant for understanding IoT assemblages. Then we describe empirical data we collected from IFTTT. com describing 120,253 consumer-created IFTTT recipes, and introduce Topological Data Analysis (TDA) (e.g. Carlsson 2009, 2014; Lum et al. 2013), a methodology ideally suited to analyze the emergent capacities and identities of assemblages. We conclude with a brief discussion of the contribution.

ASSEMBLAGE THEORY AND TDA

In recent years, assemblage theory has been applied to a range of consumer behavior and marketing problems, including dissipation of a brand's audience (Parmentier and Fischer 2015), consumption experiences (Canniford and Shankar 2013), outsourced family caregiving (Epp and Velageleti 2014), long-distance family practices (Epp, Schau and Price 2014), heterogeneous consumption communities (Thomas, Price and Schau 2013), consumption-driven market emergence (Martin and Shouten 2014), and Doppelganger brand images (Geisler 2012). In our use of assemblage theory, we focus on several key ideas from the interpretation and reformulation of assemblage theory (Deleuze and Guattari 1987) by DeLanda (2002, 2006, 2011) and the subsequent interpretation of DeLanda's framework within the IoT context by Hoffman and Novak (2015).

The concept of interaction is crucial to understanding assemblages, with the interaction event serving as the fundamental unit of analysis. However, an assemblage is not merely a collection of heterogeneous interacting components, but a connected whole with emergent capacities that is more than the sum of its parts. As described by DeLanda (2002, 2006, 2011), entities (i.e. assemblages and their components) are characterized by capacities, which specify what an entity can do and what can be done to it. An interaction event involves paired capacities of entities, where the capacity of one component to affect is paired with the capacity of another component to be affected. An IFTTT recipe is thus an interaction of components (corresponding to the two channels involved in the recipe), where the capacity of one channel to affect (the "trigger channel") is paired with the capacity of another channel to be affected (the "action channel"). Through on-going interaction of these and many other components, new capacities of the larger assemblage can emerge.

In considering how the capacities of an assemblage emerge, DeLanda (2002, 2006, 2011) introduces the concept of the underlying *possibility space* as a mathematical topological structure that defines the potential emergent capacities of an assemblage. Within the possibility space, any given assemblage is a *singular realization* of the many potential assemblages that can emerge, and is thus one of a population of assemblages. We view an individual IFTTT recipe as a singular realization that has actually been created and used by a consumer. In addition, the possibility space contains *optimal locations* that are topological invariants that define "extreme forms" (DeLanda 2006 p30) and serve as attractors that influence long term trajectories of an assemblage through the possibility space, shaping the form of assemblages as they emerge. These optimal locations structure the possibility space and influence the population of the singular realizations (i.e. actual assemblages) that emerge. From a consumer behavior perspective, we can view these optimal locations as underlying needs or consumer segments that drive the formation of individual IFTTT recipes. This is an important point since we are concerned not just with the IFTTT recipies that a single consumer creates, but with the larger population of all IFTTT recipes that have emerged.

DeLanda's concept of the possibility space is particularly helpful, in that it allows us to translate the concepts of assemblage theory into mathematical form, meaning that it is possible to analyze actual interaction data to produce visualizations of the identity of an assemblage. Recent computational advances have led to the development of a hypothesis-free approach based on topology that allows for the quantitative analysis of functions of very high-dimensional data and

the visualization of the data structure in low-dimensional topological spaces (e.g. Carlsson 2009, 2014; Lum et al. 2013). The approach, termed topological data analysis (TDA), is an especially compelling approach to inferring the identity of an assemblage as revealed by the interactions among its components.

DATA

Our data were collected in June 2014 by scraping all Web pages on IFTTT.com that contained publicly viewable user-generated IFTTT recipies created over a three year period from mid-2011 to mid-2014. Altogether, we obtained 120,253 IFTTT recipes that were created by 60,230 unique IFTTT users. For each recipe, five key variables characterizing the recipe were obtained: 1) trigger channel, e.g. "iPhone IOS Location," 2) specific trigger expression for the trigger channel, e.g. "You enter an area," 3) action channel, e.g., "Philips Hue Lights," 4) action expression for the action channel, e.g., "You enter an area," and 5) title the IFTTT user gave to the recipe that they created, e.g. "Turn on my lights when I get close to my home."

The data matrix was very sparse due to the very large number of levels of categorical variables - 86 unique trigger channels, 354 unique trigger expressions, 69 unique actions channels, and 124 unique action expressions. To be able to determine the degree to which two IFTTT recipes are similar to each other, we created binary variables for each word in the trigger expression, action expression, and title using WordStat 7. An exclusion dictionary was used to eliminate stop words (e.g. a, an, the, etc.) and lemmatization was applied to collapse different inflectional forms of a word into its base, dictionary form (i.e. the lemma). This resulted in a total of 1101 binary variables: 86 binary variables from the actual trigger channels, 280 binary variables from words in the trigger expressions, 69 binary variables from the actual action channels, 103 binary variables from words in the action expressions, and 563 binary variables from the text of the recipe titles.

The resulting matrix of 120,253 recipes and 1101 variables coded the IFTTT recipes at a very fine level of granularity, producing 132 million data points. Such complex "big data" representing consumer behavior present challenges for conventional data reduction and visualization approaches. Principal components analysis (PCA) of the data revealed 401 eigenvalues greater than one accounting for 73% percent of the variance, while a scree plot showed an elbow at five components which accounted for only 3% of the variance. A plot of the first two principal components was uninformative, accounting for only 1.5% of the variance, and with each component characterized by only a few of the over 1101 variables. Multiple correspondence analysis (MCA) performed on the Burt matrix created from the 1101 binary variables again extracted 401 dimensions, and took six hours to compute using Stata on a modern desktop computer. The first two dimensions of the MCA accounted for 8.17% of the variation in the data, but the plot was no easier to interpret than the PCA with only a few variables characterizing each dimension. Additionally, K-Means and hierarchical clustering solutions were not clearly interpretable due to the large number of variables. Thus, conventional dimensional reduction and visualization approaches have considerable difficulty revealing clear patterns in the complex dataset of IFTTT recipes created over a three year period.

METHOD

TDA (Carlsson 2009; Lum, et.al. 2013) uses computational topology techniques on complex high-dimensional data to produce a three-dimensional topology of simplicial complexes (discrete, combinatorial objects) in which groups of data are represented as nodes that contain rows that are similar to each other in the high-dimensional variable space and the edges connect nodes that share rows. The simplicial

complexes capture the topological and geometric structure at a specified resolution and the resulting topological network can be examined to discern patterns in the data. Compared to techniques like PCA and MCA where interpretation may vary depending upon one's choice of rotation and coordinate scaling, TDA also possesses the property of coordinate freeness, so the shape of the data can be represented independent of a coordinate system. TDA networks are also invariant under deformation. Additionally, TDA provides a compressed representation in that if we are willing to sacrifice a little detail, we can obtain a simpler structure that still has the same interpretation (note that the same is not true in going from a three- to two-dimensional PCA solution). While a detailed description of TDA is beyond the scope of this paper and is well-explained elsewhere (e.g. Carlsson 2009; Singh Memoli and Carlsson 2007), we outline the basic approach taken by TDA software such as Ayasdi (Ayasdi.com) and Python Mapper (Singh, Memoli and Carlsson 2007), as follows.

Any rectangular data matrix can by analyzed by TDA, such as our data where the rows are 120,253 IFTTT recipes and the columns are 1101 binary variables. A metric is selected to represent the distance or similarity among the rows, and one or more more real-valued functions, or lenses, are applied to the column variables to calculate the image of the data. For example, we might use a Euclidean or City Block distance metric (many other metrics are possible), and as lenses use coordinates from the first two dimensions of a multidimensional scaling solution (many other functions are possible). Given the image of the data (i.e. the function mapping), we cover the image. To do so, we first place the rows into overlapping groups according to the values of each function, creating a set of overlapping groups for each function. A resolution parameter for each function controls the number of groups, and a gain parameter controls the degree of overlap of groups. We then create overlapping bins as the Cartesian product of the groups created for each function. So, if we created 20 groups for two functions, we would have 400 bins. Row within bins have similar values across both functions, and because of overlap, rows can fall into multiple bins. Once the rows have been placed in overlapping bins according to the function values, rows that fall within each bin are independently clustered on the original data, typically with single-linkage clustering, using a measure of similarity based on the chosen metric. Each within-bin cluster becomes a node of the network, representing a set of rows that are similar with respect to the metric. Edges connect nodes that have rows in common. The resulting network of nodes can be readily visualized in low dimensional space. Different choices of metrics and lenses can reveal different aspects of the data, and a robust solution will provide similar interpretations across different values of resolution and gain parameters.

RESULTS

We used Ayasdi 3.0 software to perform a TDA of the IFTTT recipe data described earlier. Since all 1101 variables are binary, we used the City Block metric to calculate the distance between two recipes as the count of the number of binary variables on which two recipes differ. The lenses we used to put the recipes in overlapping bins were the coordinates of each row from a two-dimensional MDS solution. The resulting TDA network shown in figure 1 contains over 98% of the IFTTT recipes, with 2790 interconnected nodes containing 118,226 IFTTT recipies. The network is shown as a heatmap, with nodes containing 500 or more recipes colored in red. Nodes containing few recipes are colored in blue. (A small set of discrete networks set of 1305 nodes containing the remaining 1.7% of IFTTT recipes were outliers and not included in figure 1).

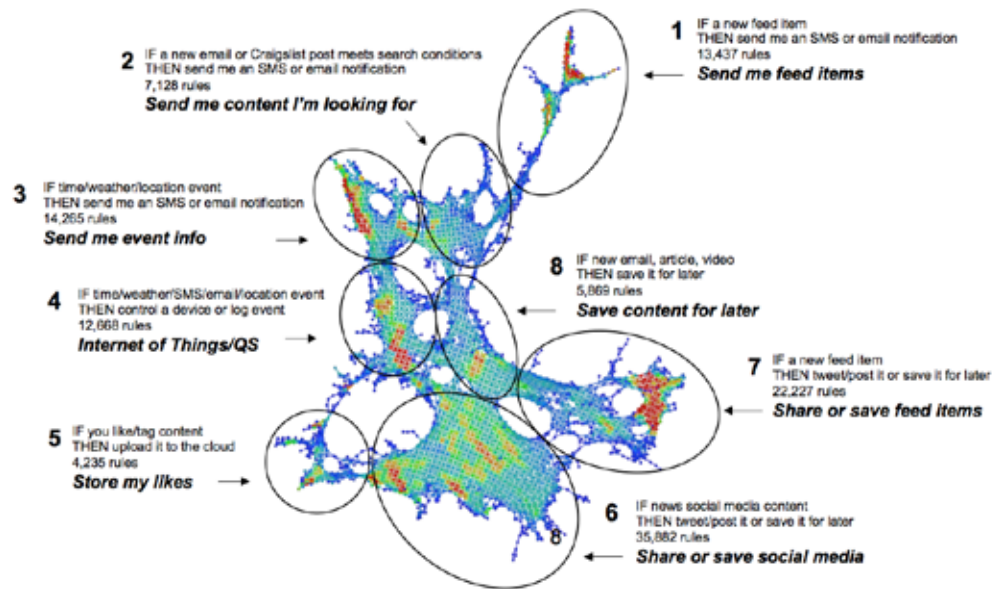
We can view IFTTT at two levels. At the highest level of IFTTT as a whole, the shape of the network in figure 1 reveals the structure


Figure 1

and identity of the entire assemblage of all IFTTT recipes. However, we find it more useful to think of IFTTT at the lower level of an individual IFTTT recipe, in which case we can view figure 1 as representing the possibility space from which the thousands of individual IFTTT recipe assemblages emerged as singular realizations. Certain distinct and high-density areas in the network correspond to optimal locations in the possibility space, representing underlying consumer needs that influence the creation of certain types of recipes. The eight groups of nodes are circled in figure 1 corresponding to "flares" or other distinct groups of nodes in the network with high density. We can interpret these eight groups of nodes based on which of the 1101 binary variables most differentiate those groups from the remainder of the data, based upon statistical significance of hypergeometric p-values. The resulting interpretations and number of recipes in each group are summarized in figure 1.

We interpret several groups to illustrate how the method reveals emergent capacities of the assemblage. We can see that group 1 at the top corresponds to IFTTT recipes where users are sent an SMS or email if there is a new RSS feed item. In contrast, group 7 at the bottom right corresponds to IFTTT recipes where users share or save RSS feed items. The red color indicates there are large numbers of recipes in both groups, and the different locations in the network indicate that RSS feeds are being used in IFTTT recipes in two very distinct ways. Group 4 at the left center of the network contains IFTTT recipes involving IoT and quantified self (QS) interactions, while Group 5 at the lower left of the network contains IFTTT recipes which people developed to archive content that they liked to the cloud. Additional groups are identified in figure 1. We note that while it might look as if TDA is uncovering clusters, conventional cluster analysis fares just as poorly as the PCA and MDS approaches, as we discussed above. Further, the TDA does far more than simply uncover clusters in the data because clusters are only one aspect of the topological structure.

We were also interested in how IFTTT recipes may have evolved over the three year time period, and how recipes that included a social media channel differ from those that did not. The TDA was repeated, adding two additional lenses, or functions. Since these additional lenses simply used known values of explanatory variables, they are referred to as "data lenses." The first data lens was a two-level categorical variable specifying whether a recipe did or did not include a social media channel, and the second data lens

was a three-level categorical variable specifying whether the recipe was created in the first, second, or third year. These lenses were used to partition the data into six groups, within which the earlier TDA was replicated, with results shown in figure 2. The top of figure 2 shows networks for IFTTT recipes that do not contain social media channels, for each of the three years; the bottom shows networks for IFTTT recipes containing social media channels.

First, circled in orange, are groups of nodes that correspond to recipes in which either nonsocial (top) or social (bottom) information is collected and saved. While this collecting and saving function is present for both nonsocial and social recipes, it is more developed for nonsocial recipes which have a complex pattern of flares representing multiple sub-types of recipes for collecting and saving. Second, circled in blue, are recipes which notify the user (through SMS, email or smartphone notification) of nonsocial or social information. These recipes have a clear flare structure indicating they are distinct from other types of recipes. Third, circled in green are recipes that deal with automation. There are both nonsocial (smart home) as well as social (scheduling tweets) types of automation. This section of the network does not have a clear structure, indicating that clearly distinct ways of automating have not yet emerged. Fourth, in purple we see a group of IFTTT recipes that are used to broadcast and share information. Since social media is used for broadcasting and sharing, this group only appears in the social media networks.

Looking over the three years, this sequence of networks shows that for both nonsocial and social IFTTT recipes, the basic structure emerged in year 1 in a fragmented form, becoming more organized and interconnected in years 2 and 3. Over its first three years, IFTTT introduced large numbers of new trigger and action channels, new triggers and actions within channels, and new ways of combining triggers and actions. This is reflected in the increasing interconnectivity of IFTTT recipes over time. But despite the influx of new channels, this sequence shows that the same basic motivations for using IFTTT persist over the first three years.

DISCUSSION

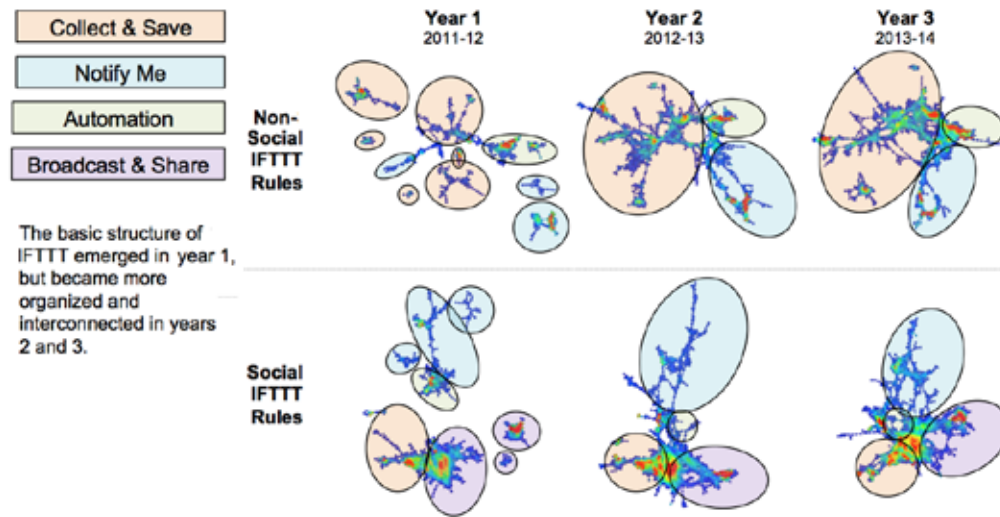
The topological networks we produced from the IFTTT interaction events provide insight into the nature of the singular realizations that may structure the possibility space. This, this approach specifies not just the "what is" IFTTT experience for any given user, but also the


Figure 2

emergent themes underlying the "what could be" IFTTT experience for all consumers. TDA lets us visualizes the identity that emerges from the Internet of Things, using interaction events as the unit of analysis.

From an assemblage theory perspective, IFTTT is an assemblage that emerges from the capacities of trigger and action components that are exercised through sets of interaction events over time. The topologies we have constructed represents the possibility space underlying the IFTTT recipes. The possibility space contains points of attraction – for example "collect and save content" – that influence the creation of many different variation of recipes that accomplish this objective. Last, beyond this descriptive role, TDA supports productive hypothesis generation and can play an important role in subsequent predictive modeling by clearly indicating ways that predictive models do not fit the data.

TDA helps visualize the "possibility space" in the consumer IoT and provides fundamental insight into the nature of interaction by emphasizing the identity that emerges from interaction. The contribution of this methodological approach is three-fold. First, it supports qualitative research seeking in-depth insights as to how experience in the consumer IoT evolves over time. Second, the shapes

The Heat Up / Cool Down-Model of Boycotting

Wassili Lasarov, Christian Albrechts University of Kiel, Germany
Stefan Hoffmann, Christian Albrechts University of Kiel, Germany
Ulrich Orth, Christian Albrechts University of Kiel, Germany
Karoline Held, Christian Albrechts University of Kiel, Germany

EXTENDED ABSTRACT

In the last decades, consumers have joined boycotts with increasing frequency to exert economic pressure on corporations they deemed to act irresponsibly. Over the last years, the marketing literature has provided valuable insights into consumers' boycott motivation (e.g., Klein, Smith, and John 2004; Sen, Gurhan-Canli, and Morwitz 2001), mainly drawing from theories of social psychology and economic models (e.g., theories of fairness and reciprocity). Scholars have identified promoters that drive consumers to join boycotts, such as self-enhancement, as well as inhibitors that prevent consumers from boycotting, such as a lack of substitutes, inconvenience, disbelieve in boycott efficacy (Hoffmann 2011; Sen, Gurhan-Canli, and Morwitz 2001). Notwithstanding, to date only few studies analyzed the temporal dimension and the longitudinal dynamics of boycott participation. None of these studies examined possible changes in motivational determinants or perceived egregiousness leading to changes in boycott participation over time.

To fill this gap, the present paper reports three mixed-methods studies that jointly explore the intrapersonal processes thought to be responsible for a decrease in boycott participation. We suggest that in a "heat up"-phase, the agenda setting of the media firstly raises broad awareness of the boycott trigger which increases egregiousness. However, during a "cool down"-phase many consumer fall back to their consumption habits and stop boycotting due to high subjective costs. Yet, it is necessary to distinguish different consumer segments that follow different dynamics of egregiousness and boycotting behavior. The paper makes at least three contributions to the literature on unethical firm behavior and consumer boycotts.

First, this paper tackles the triggers, promoters and inhibitors of boycott participation in the heat up-phase. We content analyzed internet postings related to the documentary on the commentary site of an online newspaper. The article in the news-website was published on February 13th 2013 and describes the documentary which was released on the same day. A total of 612 readers published postings related to the article in the commentary-section. Our results suggest that participation costs play a pivotal role when it comes to a decision for or against a boycott. In some cases consumers' decision to boycott the company was justified by the low costs which are associated with alternatives. On the other side, the majority of expressed inhibitors were expected participation costs as well, such as the distance to the next electronic retailer and the narrow assortment of alternative retailers.

Second, the paper explores the reactions and dynamics of media and society after the egregiousness act. According to the agenda setting theory (McCombs et al. 1977), the media influences the direct proportion to the emphasis placed on news, e.g. about the egregious behavior of a company. Therefore, when the proportion of this case in the media changes through other news, consumers shift their perception on other topics. Initial and often massive reporting about an irresponsible corporate act raises egregiousness fast and intensively. However, consumers' frustration cool down during the course of time as media coverage decreases. Hence, we expect that the perceived egregiousness corrodes over time. Therefore, we investigated the dynamic effects of the media coverage over time through comparing the media coverage of an irresponsible corporate act to the brand index over time as indicators for the dynamics of perceived egregiousness. We used google news to find and analyze 134 news articles which were related to the triggering TV documentary, starting with the publishing date, February 13th, till June 1st by means of a content analysis. We applied a frequency analysis to examine the valence of the articles (positive/neutral or negative). Our results provide evidence that the media coverage of this topic decreases and thus drives a shift of consumers' perception towards other news. Perceived egregiousness is considered as the main driver for boycott intention corrodes over time.

Third, we identified groups of consumers who differ in their perceived egregiousness and boycott behavior over time. While we expect that a decrease in perceived egregiousness will foster a lower boycott participation, we posit that this decrease may not apply uniformly to all consumers. Despite media coverage and the irresponsible act of the company, some consumers may not change their consumption pattern over time. We name this type of consumer the ignoramus. We further consider two types of consumers who both quit boycotting over time but vary in their underlying levels of egregiousness. First, forgetters display changing level of egregiousness and also alter their boycott participation over time, while forsakers remain on a stable level of high egregiousness, but change their boycott participation. In the following, we discuss how inhibitors (esp. subjective costs of boycotting) affect these three groups of consumers differently. Five months after the triggering TV documentary was broadcasted, we conducted a study in which we asked 305 participants to indicate their current egregiousness and participation and to retrospectively evaluate both constructs five months before. Our results suggest that the impacts of promoters and of inhibitors vary across different boycotter groups. Ignoramus are more likely to rely on the reputation of the boycotted company. Forgetters emphasize their boycott-related subjective costs and hence differ from Forsakers. They wish to join the boycott but recognize that subjective costs (e.g., greater mental effort for seeking new alternatives) are higher than personal rewards (e.g., boosting or maintaining self-esteem by responding to social pressure). Thus, they revert to purchase products of the initially boycotted company even though they still have a high level of perceived egregiousness.

The Language Backfire Effect: When Language Switch Threatens Consumer's Identity and Affects Satisfaction Toward the Service

Jonas Holmqvist, Kedge Business School, France
Yves Van Vaerenbergh, KU Leuven, Belgium
Micael Dahlén, Stockholm School of Economics, Sweden
Renaud Lunardo, Kedge Business School, France

EXTENDED ABSTRACT

The vast majority of both the service and sociolinguistic literatures argues that serving customers in their first language yields positive effects (Holmqvist and Grönroos 2012; Van Vaerenbergh and Holmqvist 2013). This is echoed by research in the field of sociolinguistics, which shows that employees tend to switch to the language in which a customer feels more comfortable (Callahan 2006), and that people hold more favorable attitudes towards persons who show efforts to speak their first language, or a language in which they feel more comfortable (Genesee and Bourhis 1982). However, relying on self-determination literature and the need for consumers to feel in autonomy and competent (Deci and Ryan 2000), we propose that the positive effect of the use of first language does not hold in service settings where international consumers might prefer to speak the local language.

In study 1A, 89 adults from Sweden and Finland (57.3% female, M_{Age}=28.9) participated in a two-group scenario-based experiment. Participants read a scenario where they had to imagine themselves visiting Paris, and going to a café. The waiter addresses the consumer in French, and the Scandinavian consumer responds in French, the local language. The waiter either responds in French (condition 1) or in English (condition 2). A short conversation follows and exactly the same phrases are said in both scenarios. After reading the scenario, participants evaluated filler items, and their satisfaction on a scale from Maxham and Netemeyer (2002). A check was made that respondents reported at least some knowledge of French, as a basic knowledge of both languages was required for the study. Results reveal that consumers who are served in French, the local language, exhibit higher satisfaction (M=6.14) than consumers who are served by a waiter who switches language and serves customers in English (M=4.21; F(1,87)=40.60, p < .001).

Study 1B aims to replicate findings from Study 1 using another context. Respondents (n=120 French adults, M=31.68, 45.8% female) were randomly assigned to one of two conditions. Before participating in the experiment, a check was made that the respondents had at least a basic knowledge of English, as a basic knowledge of this language was required for the study. Participants were then asked to imagine they are tourists visiting London. After some sightseeing, they visit a restaurant where the waiter addresses them in English, the local language, and the consumers respond in the same language. In scenario 1 the waiter continues in English and a short and rather basic conversation takes place in English. In second 2, the waiter switches language after the respondent's first phrase in English, and the waiter then continues the conversation in French. Exactly the same things are said in both scenarios, the language in which it is said is the only difference. After reading the scenario, respondents reported their satisfaction (α=.81). Results replicate those from Study and reveal that participants who are served in their second language feel more satisfied (M=5.60) than participants who are served in their first language (M=5.19, F(1, 118)=6.24, p < .05). These results, however, stem from a social context where consumers are alone, leading to the question whether the effect of language switch on satisfaction would be replicated in a different social context.

Study 2 employs the same method as in Study 1B but uses the social context of being accompanied by a partner. Respondents (n=118 French adults, M=31.00, 50.8% female) were exposed to the same scenario as in Study 1B, except for the respondents now reading that they are in London with their partner for a romantic weekend. The respondents then reported their satisfaction (α=.73) as well as their perceived identity threat (Aquino and Douglas 2003; α=.90). In contrast to the results in the previous studies, results reveals that in this specific context where consumers are not alone, respondents feel more satisfied when served in their first language (M_{First}=5.51, M_{Second}=5.14, F(1, 116)=3.98, p < .05). Results also reveal mediating effect of identity threat (confidence interval: -.46; -.11). Specifically, in the social context when consumers are not alone, a language switch leads to higher identity threat (β=.92, p < .01), which subsequently leads to a decrease in satisfaction (β=-.28, p < .001). These results indicate that when consumers are not alone and served in their second language, feeling that their identity is threatened leads to lower satisfaction with the service.

Overall, these results indicate that there are situations in which consumers prefer to use their second language and may react negatively to a language switch. This effect, here identified as a language backfire effect, occurs when the consumer is alone, and does not hold when the consumer is in the company of others. In this specific case, consumers prefer being served in their first language and may perceive the language switch as a threat to their identity, leading to lower satisfaction.

Health Messages: The Roles of Emotions and Type of Healthcare Advocacies

Donna Hoffman, George Washington University, USA
Tom Novak, George Washington University, USA

EXTENDED ABSTRACT

Emotions can influence how individuals process health information such as anti-drinking messages (Agrawal and Duhachek 2010) and self-focused or family-focused health appeals (Agrawal, Menon, and Aaker 2007). Healthcare messages can promote health behaviors to detect disease, such as doing breast self-examinations to detect breast cancer (Meyerowitz and Chaiken 1987). Alternatively, healthcare messages can encourage behaviors to prevent disease, such as using sunscreen to prevent skin cancer (Detweiler et al. 1999). Despite this abundance of literature on how emotions can influence the persuasiveness of health messages, there is a lack of studies that investigate how incidental emotions enhance or hinder the effectiveness of prevention or detection advocacies. This research is designed to close this gap.

Research has shown that individuals perceive detection behaviors as more risky than prevention behaviors because detection behaviors involve the risk of finding out whether they are ill. In contrast, prevention behaviors can maintain one's current health state and have little, if any, shortcomings (Rothman et al. 1999). Risk perceptions associated with prevention and detection behaviors influence the persuasiveness of framed appeals. Studies have clearly established the links between emotions and health risk perceptions (Keller, Lipkus, and Rimer 2003). However, individuals experience different emotions, so incidental emotions may lead individuals to differently evaluate prevention and detection advocacies, which differ in risk level. Emotional certainty is related to risk-seeking propensity and optimism; therefore, it can influence how consumers evaluate prevention and detection advocacies.

Some emotions are associated with certainty, while others are associated with uncertainty (Smith and Ellsworth 1985). Emotion shapes how individuals process information through appraisals related to certainty. Previous research has also examined the effects of emotional certainty on consumer judgment and decision making. Sad individuals prefer high-risk, high-reward choices while anxious individuals prefer low-risk, low-reward choices, because sadness is associated with high certainty appraisal tendencies while anxiety is associated with high uncertainty appraisal tendencies (Raghunathan and Pham 1999). Both positive and negative emotional states can influence judgment and information processing. Positive affect helps process health-threatening messages for individuals vulnerable to health risks but not for those with low vulnerability, while negative affect has no impact on health message processing regardless of vulnerability (Das and Fennis 2008).

Despite a lot of recent work on emotions, we have little understanding of how emotional certainty interacts with emotional valence to jointly influence persuasiveness of health messages. Whether the effects differ by the nature of health advocacy is unknown. We expect that for certainty emotions, negative emotions lead to greater persuasiveness of detection advocacies than positive emotions. Conversely, for feelings of uncertainty, positive emotions compared with negative emotions aid the effectiveness of detection advocacies. However, certainty and valence do not exert an influence on the effectiveness of prevention advocacies.

Two studies using different health contexts tested these expectations. In study 1, we selected four emotions differing on the dimensions of pleasant/unpleasant and certain/uncertain (Smith and Ellsworth 1985). Participants were asked to think of a life event that they had experienced that made them feel *proud* (positive emotion associated with certainty), *angry* (negative emotion associated with certainty), *surprised* (positive emotion associated with uncertainty), or *anxious* (negative emotion associated with uncertainty). Next, participants read information about either (1) a mouth rinse that could help prevent plaque accumulation or (2) a disclosing rinse that could help detect areas of plaque accumulation (Rothman et al. 1999).

Participants rated their intention of using the advocated oral rinse. The results indicated that after viewing a detection advocacy, participants who felt angry were more persuaded by the advocacy than those who felt proud. In contrast, for a detection advocacy, participants who felt surprised were more persuaded by the advocacy than those who felt anxious. After participants viewed a prevention advocacy, they were equally persuaded regardless of whether they experienced positive or negative emotion or whether they experienced emotions associated with high certainty or high uncertainty.

To test the robustness of the findings of Study 1, in Study 2 we use a different product and different emotions to manipulate emotional valence and emotional certainty. Participants were asked to think of a life event that they had experienced that made them feel *happy* (positive emotion associated with certainty), *hopeful* (positive emotion associated with uncertainty), *disgusted* (negative emotion associated with certainty), or *anxious* (negative emotion associated with uncertainty). Participants read information about either a skin lotion that helps prevent skin cancer or a skin lotion that helps detect skin cancer for the detection advocacy. All participants read the same basic information about skin cancer. Participants were asked to answer true/false questions based on the pamphlet they read about facts on skin cancer (Menon, Block, and Ramanathan 2002).The results revealed that after viewing a detection advocacy, participants who felt disgusted had higher quiz scores than those who felt happy. In contrast, after viewing a detection advocacy, participants who felt hopeful scored higher than those who felt anxious. For the prevention advocacy, participants were equally persuaded regardless of whether they experienced a positive emotion or negative emotion or whether the emotion was associated with high certainty or high uncertainty.

Taken together, this investigation identifies a relationship between emotion and the effectiveness of prevention and detection advocacy. To our knowledge, our research is the first to demonstrate the role of specific emotions in persuasiveness of prevention and detection advocacy. We extend the literature on emotions by focusing on the role of emotional certainty. Our research has implications for direct-to-consumer advertising and public policy.

Consumer Brand Knowledge: A Multiple Memory Systems Model

Ming Hsu, University of California Berkeley, USA
Yuping Chen, National Taiwan University, Taiwan

EXTENDED ABSTRACT

Consumer research studies focusing on memory processes have traditionally conceptualized consumer memory in terms of a single unitary process (Alba, Hutchinson, and Lynch, Jr. 1991). Based on connectionist models of associative memory, consumer knowledge is typically thought of as a network of nodes and connecting links, where nodes represent stored information or concepts and links represent the strength of association between nodes.

These models, derived from cognitive psychology, have proven extremely useful for consumer researchers by providing a powerful way to explain a variety of experimental and observational data. Associative memory, for example, has been used to explain and relate a diverse set of marketing phenomena, including how consumers use brand names and product attributes as retrieval cues for information about product performance, why brands can extend to some categories but not others, and conditions under which brand alliances can benefit or hurt firms (van Osselaer and Janiszewski 2001) each feature-benefit association will develop independently. During adaptive learning, features will compete to predict benefits and, thus, feature-benefit associations will develop interdependently. We find adaptive learning of feature-benefit associations when consumers are motivated to learn to predict a benefit (e.g., because it is perceived to have hedonic relevance).

Despite the influential and parsimonious nature of a single process account of memory, it has been appreciated for some time in cognitive psychology that, far from a unitary entity, human memory is comprised of multiple systems with distinct neural substrates that have evolved to serve different cognitive functions. That is, memory is not a monolithic faculty but rather a collection of relatively independent systems, which are characterized by different patterns of learning, unlearning, and biases.

Episodic memory, for example, is fast forming and organized around context, but is relatively easy to bias and distort, where as semantic memory is organized around concept, and is more resilient to distortions. In contrast to both episodic and semantic systems, Pavlovian habit systems, likely underpinned by reinforcement mechanisms, are largely implicit, and slow in acquisition as well as extinction. Finally, these systems are known to interact, alternatively compensation and competing under different conditions. For example, habit memory is known to be triggered by context rather than goals, which in turn depends on the integrity of episodic systems.

Although prominent in psychology and cognitive neuroscience, the idea of multiple memory systems is rarely explicitly incorporated into conceptualization of consumer memory. Consequently, existing work invoking the idea of different forms of memory (typically between implicit and explicit processes, or goals and habits) have largely evolved independently without reference to each other. In this study, we describe a new approach to understanding dimensions of consumer memory by drawing on recent advances in cognitive neuroscience of learning and memory. Because memory processes relate to internal mental representations that are not directly observable, one must simultaneously consider both the memory representation and the processes that act upon it to draw inferences about memory structure from behavioral data (Alba et al. 1991). For this reason, neuroscientific methods that are capable of probing these representations at the neural level have been instrumental in testing and refining psychological theories of memory (Schacter 1999).

Specifically, we tested the hypothesis that consumer memory for brands is comprised of distinct forms of memory traces that relies on different memory systems. A total of 18 participants underwent functional magnetic resonance imaging (fMRI) while being shown a set of 45 of logos of well-known brands in a passive viewing task. Next, we sought to relate brain activity to three distinct dimensions of brand knowledge. Participants were asked to complete (i) the brand personality scale (Aaker 1997)identify the \"Big Five\" dimensions, and explore the meaning of each dimension, no parallel research has been conducted in consumer behavior on brand personality. Consequently, an understanding of the symbolic use of brands has been limited in the consumer behavior literature. In this research, the author develops a theoretical framework of the brand personality con- struct by determining the number and nature of dimensions of brand personality (Sincerity, Excitement, Competence, Sophistication, and Ruggedness to capture brand knowledge of a set of traits that consumers project onto brands, (ii) the brand experience scale (Brakus, Schmitt, and Zarantonello 2009) to capture the experiences, feelings, and sensations that result from interactions with brands, and (iii) brand preference scale to capture consumer value for the brands.

To address how these components of brand knowledge are stored in the brain, we applied newly developed machine learning tools to functional neuroimaging data that allows us to ask whether a brain regions contains the different forms of memory as captured by our scales. This is different from traditional approaches that focus on how brain activity in a single region differs across two or more conditions, our approach, referred to as model-based decoding, focuses on whether brain activity across multiple regions or networks contains information about a particular cognitive construct (Poldrack 2011).

First, we found that information about brand personality was contained in areas of the medial and lateral prefrontal cortex (permutation test p<0.01). This is consistent with known roles of these regions in semantic memory retrieval and the notion that the brand personality construct largely consists of semantic associations that consumers associate with brands (e.g., whether a brand is down to earth). In contrast, we found that brand experience was contained in the insular cortex as well as the hippocampal formation (permutation p<0.01). This is striking given the known role of the insula in affective processing and the hippocampal formation in episodic retrieval and vivid recall of past experiences, and is consistent with the notion that, unlike brand personality, brand experience captures episodic and affective experiences consumers have with the brand. Finally, we found that brand preference is represented in the striatal regions (permutation p<0.01), which is consistent with substantial neuroeconomic literature implicating this habit system in value representation.

Taken together, our results provide strong support for the notion that distinct types of memory traces are activated simultaneously and in parallel during brand evaluation, and that they relate to notions of semantic, episodic, and habit memory systems that are among the most well studied divisions in human memory. More broadly, a multiple memory systems view can change how managers design brand strategy efforts aimed to increase recognition and recall rates by targeting each system and maximizing complementarities between these systems.

The Impact of Power on Reliance on Feelings versus Reasons in Decision Making

Yunhui Huang, Hong Kong University of Science and Technology, China
Jiewen Hong, Hong Kong University of Science and Technology, China
Hannah H. Chang, Singapore Management University, Singapore

EXTENDED ABSTRACT

Power refers to the asymmetric control over other individuals or over valued resources in social relations (Magee and Galinsky 2008). Recent research suggests that power can translate directly into a psychological state that influences individuals' attitudes and behaviors. For example, possessing power liberates people to express their true attitudes and pursue their personal goals (e.g., Anderson and Berdahl 2002; Galinsky, Gruenfeld, and Magee 2003) and decreases attention paid to others (Goodwin et al. 2000; Lammers et al. 2013). Relatively less research, however, has investigated the impact of power on consumer decision making. In this research, we propose that consumers who feel powerful (vs. powerless) would exhibit a greater relative reliance on feelings versus reasons in decision making.

We suggest that this occurs because when consumers feel powerful, they are more likely to feel confident in their decision making, increasing the tendency to rely more on affective feelings in their decisions. In contrast, when consumers feel powerless, they are more likely to feel doubtful in their decision making, increasing the tendency to rely more on cognitive reasoning in their decisions. First, consistent with the notion that power increases a sense of confidence, research has demonstrated that high-power individuals are more likely to exhibit overconfidence in decision making (Fast et al. 2011), express (vs. inhibit) their attitudes (Anderson and Berdahl 2002), and take actions rather than stay put (Galinsky, Greunfeld, and Magee 2003) compared to low-power individuals. Experiencing power also leads to confidence-related states such as optimism (Anderson and Galinsky 2006), risk taking (Anderson and Galinsky 2006), and illusionary control (Fast et al. 2009). Second, on the other hand, extant research has provided preliminary evidence that an elevated sense of confidence associated with high (vs. low) power states might influence consumers' relative reliance on feelings and phenomenal experiences. For example, people are more likely to rely on their cognitive feelings (e.g., the ease-of-retrieval heuristic) under conditions of high (vs. low) personal certainty (Greifeneder et al. 2010; Müller et al. 2010) and rely on their emotional reactions if they have high (vs. low) chronic self-esteem (Harber 2005). To the extent that cognitive feelings and emotional reactions are more likely to enter consumer decisions under conditions of high certainty (Greifeneder et al. 2010) and self-esteem (Harber 2005) and that certainty and self-esteem are closely related with confidence (Fischhoff, Slovic, and Lichtenstein 1977; Pelham 1991), high-power consumers who tend to experience higher confidence should be more likely to rely on affective feelings than reasons in making decisions compared to low-power consumers.

We tested our hypothesis in five experiments. To provide initial evidence for our hypothesis, experiment 1A first manipulated power using episodic recall (see Galinsky, Gruenfeld and Magee 2003). Participants indicated their relative preference between an affectively superior and a cognitively superior laptop. Results showed that participants in the high-power condition exhibited a stronger preference for the affectively superior laptop ($M = 4.53$) than those in the low-power condition ($M = 3.56$; $F(1, 64) = 4.17$, $p < .05$).

Experiment 1B replicated the result of experiment 1A using a word fragment completion task to manipulate power (see Magee et al. 2007). Furthermore, experiment 1B directly measured participants' relative reliance on feelings versus reasons in making their choices. Mediation analysis confirmed that the observed effect of power on the choice between an affectively superior and a cognitively superior laptop was driven by participants' differential reliance on feelings versus reasons in decision making.

Experiment 2 tested the hypothesized effect by manipulating participants' incidental feelings and power states orthogonally. Based on prior research (e.g., Schwarz and Clore 1983), we hypothesized that incidental moods should exert a greater influence on product evaluation for high-power participants than low-power participants. Results revealed a significant interaction between mood and power ($F(1, 277) = 4.11$, $p < .05$): high-power participants indicated higher willingness-to-pay (WTP) for the product in the positive-mood condition ($M = \$57.31$ SD) than in the negative-mood condition ($M = \$41.46$; $t(277) = 2.95$, $p < .05$). In contrast, low-power participants indicated comparable WTP regardless of their mood states ($M_{positive} = \$52.22$, $M_{negative} = \$50.19$; $t(277) = .20$, $p = .84$).

Experiment 3 examined the hypothesized effect by observing whether a fit between a consumer's power state and the decision strategy induced by this particular power state leads to increased valuation of the chosen option (see Higgins 2005). Participants whose power states were varied were instructed to rely on feelings or reasons in making their decisions. The analysis yielded a significant interaction effect ($F(1, 137) = 4.50$, $p < .05$) such that high-power participants (vs. low-power participants) indicated higher WTP when they made their decisions following a feeling-based (reason-based) strategy.

Experiment 4 tested an implication of the hypothesized effect. Hsee and Rottenstreich (2004) suggest that valuations based on affect is less sensitive to the "scope" of the evaluative stimulus than those based on cognition. If high- (vs. low-) power states promote a greater relative reliance on feelings, high-power consumers should be more likely to exhibit scope insensitivity compared to low-power consumers. Participants whose power states were varied were shown a one-day travel package containing one or four tourist spots, and asked for their WTP for the package. Results showed a significant interaction between power and scope ($F(1, 139) = 5.30$, $p < .05$). For low-power participants, their WTP was higher for the four-spot package than for the one-spot package ($M_{4\text{-spot}} = \$160.61$ vs. $M_{1\text{-spot}} = \$87.62$; $F(1, 139) = 4.26$, $p < .05$). However, for high-power participants, their WTP exhibited the scope-insensitivity bias ($M_{4\text{-spot}} = \$122.24$ vs. $M_{1\text{-spot}} = \$106.80$; $F(1, 139) < 1$, $p = .36$).

Our research contributes to the literature on power by following an emerging stream of research that examine how power might influence decision-making processes. In another study (not reported due to space limit), we directly varied confidence and power orthogonally to examine our conceptual rationale that the hypothesized effect is due to confidence. Our research offers practical suggestions for designing advertisements. Campaigns with largely emotional (functional) appeals might be more effective for a high-power (low-power) audience.

Crush on You: Romantic Crush
Increases Consumers' Preferences for Strong Sensory Stimuli

Xun (Irene) Huang, Nanyang Technological University, Singapore
Ping Dong, University of Toronto, Canada
Meng Zhang, Chinese University of Hong Kong, China

EXTENDED ABSTRACT

Romantic crush is formed by desiring for another person whom one finds powerfully attracted to and wants to spend a lot of time with. It is a universal experience which is often expressed in movies, songs, romance novels, and even social media apps (e.g., Crush Notifier on Facebook). However, given the prevalence of this experience, relatively little attention has been given in understanding the effect of this experience on consumer preference.

Romantic crush has some distinct features from other desirable experiences. First, during a crush, people are romantically attracted to a specific another. This longing can be very profound. To this extent, romantic crush is the same as romantic love. However, in a crush, the desired intimacy and sensory contact with the target person is absent (Furman and Collins 2009; Oettingen and Mayer 2002). Due to the lack of enough sensory stimulation from their desired person, people in a crush may fantasy about having sensory contact with this person (seeing, hearing, smelling, touching, or kissing this person; Furman and Collins 2009). Second, not only does a romantic crush differ from a typical romantic love, it also differs from other affections, like those between family members or close friends. The latter kinds tend to be mutual. Third, a romantic crush is also different from the desire for other non-human end states (e.g., a dream job). The latter is more abstract and does not involve the desire for sensory intimacy.

In our view, the experience of romantic crush is a positive, passionate, romantic feeling for another person. This experience is unilateral and characterized by the lack of intimacy and sensory stimulation from the desired other. This experience, once activated, can be powerful, even if it may be short-lived or never acted on.

Drawing on the growing body of literature on compensatory consumption (e.g., Lee and Shrum 2013; Lisjak et al. 2015; Rucker and Galinsky 2013), we propose that when the experience of romantic crush is salient, the unsatisfied desire for intimacy and sensory stimulation (from the desired another) may lead people to have a general preference for products and services that can elicit strong (vs. weak) sensory stimulations (e.g., a louder store music, a strongly scented hotel room).

We conducted a pretest and six experiments to test these propositions. The results of pretest showed the predicted similarities and differences between romantic crush and other related experiences (e.g., stable romantic relationship, mother's love, and desiring for a dream job).

Study 1 was conducted on participants who self-reported as being single. We compared participants' choices for products and services between those who were having a romantic crush and those who were not. Participants were presented with multiple pairs of options and were asked to make a choice. In each pair, one option elicited a strong sensory stimulation whereas the other elicited a weak stimulation (e.g., strong vs. weak-flavored coffee; an iPad cover of smooth vs. rugged texture). Results showed that participants who had a romantic crush were more likely to choose the options eliciting stronger sensation than those who did not.

Study 2 replicated the effect of Study 1 by manipulating the salient experience of romantic crush. Participants were asked to write a detailed story about a personal experience (romantic crush, desired job and shopping trip). To avoid any potential interference across the sensory domains, we employed five sub-studies to examine the effect of romantic crush on each of the five senses respectively. Again, we found that after participants imagined and described a personal experience of romantic crush, they would prefer products or services that can elicit stronger (vs. weaker) sensory stimulation.

Study 3 tested the mediating role of the unsatisfied desire for intimacy and sensory contact with the desired person. This study had two conditions: romantic crush versus stable romantic relationship. The results showed that participants who imagined romantic crush (vs. stable relationship) vividly expressed a greater preference for a higher level of sensory stimulation when watching a 4D movie. This effect was mediated by the desire for intimacy and sensory contact with the imagined social target.

In Studies 4 to 6, we employed a more natural and easy-to-implement manipulation of romantic crush: the exposure to posters depicting crush-related images and statements. In Study 4, we compared the crush-themed posters condition with a no-poster baseline. The results showed that participants in the crush condition preferred a tight (vs. loose) hug from "Mickey Mouse", a dark (vs. light) colored T-shirt, a high (vs. low) volume store music, a strongly (vs. lightly) scented candle, and a strong (vs. weak) flavored coffee. Moreover, after viewing crush-related posters, participants had a general preference for stronger sensory stimulation, as compared to their counterparts in the baseline.

Studies 5 and 6 then used real behavior as DVs, and included the experience of *mother's love* as the control. Specifically, in Study 5, participants were asked to self-pick tea leaves to make their own cup of tea; the actual amount of loose leaf tea was measured as the DV. As expected, participants in a romantic crush condition took greater amount of tea leaves (i.e., preferring a stronger taste). Study 6 measured participants' real choice between two types of gift cards. As predicted, those in the romantic crush condition were more likely to choose the 4D movie (rather than the bookstore) gift card, indicating a preference for stronger sensory stimulation.

Taken together, we have identified a novel antecedent of consumers' preference for stronger (vs. weaker) sensory stimulation, namely, the salient experience of romantic crush. This research contributes to the literature of subjective experiences, sensory marketing, and compensatory consumption. (926 words)

From Nothingness into Being:
Creation and Resilience of a Decentralized Brand

Mariam Humayun, York University, Canada
Russell Belk, York University, Canada

EXTENDED ABSTRACT

Money has long been considered the source of all evils in society, linked variously to envy, greed, and the corrosion of human relations (Miller 1987, Belk and Wallendorf 1990). Simmel (1978) said money alienates beings by making relations more abstract, and argued that cynicism lies at the root of alienation by reducing every human relation to a monetary value -- an idea for which neo-liberalism is often critiqued. Mauss (1954) too might well agree that it was money that made it possible to replace the social obligations and underlying debt that gifts created. Graeber (2014) points out in his treatise on debt how coinage changed the nature of social relations, where individuals became able to trust in the promise of a payment. But what if money became a mystical source of faith and fodder for ideological beliefs uniting a diverse community? What if it went from *nothingness* into *being*[1]?

The cryptocurrency Bitcoin destabilizes many of the assumptions about the nature of money. In this study, we focus on Bitcoin as an instance of a *decentralized brand*. These are brands without any central authority, that operate as a network of different people or groups working with different ideals who, by design or default, collaborate in creating them. These brands are usually not created with profit as the main goal although it may exist. Pitt et al. (2006) and Hemetsberger and Reinhardt (2009) for instance describe how the Linux brand is supported and shaped by the open source community and monetized by IBM. This is more than "prosumption" (Ritzer and Jurgenson 2010) where both consumers and producers co-create in producing and adding to brand value (e.g., Facebook, Twitter, YouTube, eBay). Decentralized brands share a distributed user base with different motivations and goals; they act without any central authority. Anonymous, Wikileaks, and Tor are examples of other decentralized brands. Our question here is: what factors help decentralized brands weather multiple setbacks and emerge as resilient?

Bitcoin is essentially a digital 'currency' or a computer file (bit) that represents digital cash. It was created by a person or persons going by the name of Satoshi Nakamoto who remain(s) anonymous. Bitcoin came into being on the heels of the financial crisis of 2008 (Maurer, Nelms, and Swartz 2013, Bjerg 2016) and Satoshi is a messiah-like figure who gave the world Bitcoin and then selflessly disappeared into anonymity (Goodman 2014, McMillan 2014). With appropriate religious flourish, the first block of Bitcoins created eventually came to be known as "the Genesis Block" (Schneider 2015). Over the course of its short lifespan, Bitcoin has been subject to numerous crises, including the online illegal market Silk Road, the collapse of the Bitcoin exchange Mt. Gox, governance issues in its open source community, and being banned in several countries.

We draw on the ecological resilience framework as a metaphor to study Bitcoin as a decentralized brand (Gunderson 2000, Holling 1973). There are a number of key concepts from the resilience framework that are useful in understanding the progression of Bitcoin over the years. First, "change is neither continuous and gradual, nor consistently chaotic" (Redman 2005, 72, Holling 1973, Holling and Gunderson 2002), rather change relies on a slow accumulation of natural capital over time. And progress is "punctuated by sudden releases of and reorganizations of those legacies" (Redman 2005, 72). The resilience framework also provides the concept of an adaptive cycle comprised of four stages: exploitation, conservation, release (creative destruction), and renewal (reorganization). These adaptive cycles evolve through stabilizing forces and destabilizing forces that occur. Destabilizing forces are "important in maintaining diversity, flexibility, and opportunity"; while stabilizing forces help in maintaining "productivity, fixed capital and social memory" (Redman 2005, 72). Another feature of the resilience framework is the concept of "panarchy" which was coined to represent how ecosystems are governed (Allen et al. 2014, Garmestani and Allen 2006, Holling, Gunderson, and Ludwig 2002). This is important in understanding how decentralized networks, particularly those that depend on the internet, are governed.

The resilience of an ecosystem is tested each time there is a crisis, which means that historical analysis is often necessary in making sense of crisis impacts. Thus in studying Bitcoin ecosystem resilience, we focus on a few key events in recent history that have called into question Bitcoin's survival and helped transform it. These events include the closure of Silk Road, the collapse of Mt. Gox, the block-size debate, and the multiple Satoshi exposés. This is not a comprehensive list of crises that the currency has experienced; rather they represent incidents that fundamentally challenged Bitcoin's future and questioned its existence on an international scale. We use the price of Bitcoin and its evolving media coverage as proxies of its resilience. Through participant observation at Bitcoin events, in-depth interviews, archival data (newspapers), and a netnography, we analyze how consumers and different publics' narratives around Bitcoin changed over the course of these events and in their aftermath.

Our findings indicate that consumers invest Bitcoin with strong religious overtones, making it a technological 'religion of atheists' so to speak. Bitcoin has developed a network of advocates who appreciate being referred to as Bitcoin evangelists, proselytizers, backers, boosters, or fans (Muñiz and Schau 2005, Belk and Tumbat 2005, Kozinets 2001). The block-size debate, which threatened to split the Bitcoin community in two, highlights proprietary governance issues in a seemingly altruistic open source community with conflicts between the more capitalist-oriented and more libertarian ideology. Destabilizing forces such as the closure of Silk Road and Mt. Gox highlight how Bitcoin's memory and myth-making machine operates. With decentralized brands, the nature of information that gets shared is of crucial importance, and social media plays an important role as a stabilizing force.

This paper provides a conceptualization of decentralized brands and how they develop resilience. Our analysis adds a socio-cultural and historical facet to ecological resilience framework. There are also implications for understanding how consumers are changing the dynamics of cementing social media as a modern day myth-making engine.

Blaming McDonald's: Anthropomorphized Temptation, Failed Self-Control, and Support for Paternalistic Intervention

Julia D. Hur, Northwestern University, USA
Wilhelm Hoffman, University of Cologne, Germany
Minjung Koo, Sungkyunkwan University, South Korea

EXTENDED ABSTRACT

Temptation is a challenge for most people. Dieters get enticed by sugary cookies, students get tempted by TV shows when studying for exams, and smokers get seduced by the smell of a cigarette when trying to quit smoking. When facing self-control failures, one starts searching for a target to blame, and assesses whether the self or something else in the environment should be accountable for the failure (Heatherton and Nichols 1994). For example, do children fail to lose weight because they do not exercise enough, or because their school cafeteria is filled with junk foods?

Where people attribute responsibility for self-control failures has important implications for what strategies they use to prevent such failures in the future (Polivy and Herman 2002). If one holds the food industry responsible for causing obesity, for example, one will be more likely to support regulations on the industry's practices to reduce obesity. Those regulations often take the form of paternalistic interventions—policies and campaigns that change (Thaler and Sunstein 2008) or restrict the environment (Jonson, Lindorff, and McGuire 2012) to assist individual self-control—such as putting health warnings on tobacco products and restricting fast foods in schools. Despite potential benefits, one of the biggest hurdles for the implementation of paternalistic interventions is the public's lack of support, because interventions are often perceived to infringe upon personal autonomy and freedom (Felsen, Castelo, and Reiner 2013). It is thus of interest to examine factors that influence the endorsement of interventions.

The current research examines anthropomorphism—ascription of humanlike traits to a non-human agent—as one such factor that shifts the way people attribute responsibility for self-control failures, and thereby affects the extent to which people support paternalistic interventions to prevent such failures in the future. We propose that anthropomorphizing a tempting object (e.g., putting faces on food products) will increase delegation of responsibility to the object itself (e.g., fast food) and its manufacturer (e.g., fast-food companies). Anthropomorphizing a temptation creates the perception of another agent imbued with capability and intentionality and this agentic "presence" can lead people to delegate more responsibility to it for the outcomes of self-control. When people believe that a tempting object is responsible for causing self-control failure, they will also be more likely to hold the manufacturer that produces it accountable (Puzakova, Kwak, and Rocereto 2013). It follows that people will also be more likely to believe that regulating the object and its manufacturer is an effective strategy to prevent self-control failure in the future (e.g., fast-food ban in schools). That is, anthropomorphizing a tempting object will increase one's support for paternalistic interventions that impose regulations on it to prevent future failure.

Study 1 tested whether anthropomorphizing a tempting object would increase the delegation of responsibility for individuals' self-control failures to the object's manufacturer. We recruited only dieters, and presented them with potential weight gain as self-control failure. We used a high-calorie cookie as a tempting object, and as a manipulation of anthropomorphism, we applied a human-like (vs. round) shape to the cookie, provided it with a human name ("Jamie" vs. no human name), and described it in the first person (I vs. It). Participants then imagined a scenario whereby they gained weight after adding the cookie to their regular diet, and indicated the extent to which they attribute responsibility for the weight gain to the object's manufacturer (delegation of responsibility) and to themselves (self-accountability). As predicted, anthropomorphism increased delegation of responsibility to the tempting object's manufacturer but decreased self-accountability.

Study 2 extended the effect of anthropomorphism from the individual to societal levels (childhood obesity). Participants were presented with a poster for a health campaign in which the tempting object (i.e., fast food) was either anthropomorphized or not, and reported to what extent they held the object responsible for childhood obesity. As a manipulation of anthropomorphism, the poster contained pictures of fast foods that had human-face features (eyes and eyebrows vs. no such features) and the following tagline describing the fast foods in the first person [vs. objective]: "Do you blame *us* [these]?" As predicted, anthropomorphism increased the delegation of responsibility for causing childhood obesity to fast foods.

When people hold a tempting object responsible for self-control failure, they will be more likely to believe that regulating it is an effective strategy to prevent self-control failure in the future. Accordingly, Study 3 examined whether anthropomorphizing the tempting object increases one's support for paternalistic interventions that impose regulations on the object. We used the same materials and anthropomorphism manipulation as in Study 2, and measured the extent to which fast foods and their manufacturers should be regulated in a paternalistic manner with three items (e.g., "How strongly do you feel that fast food sales to children should be regulated by the government?"). As predicted, anthropomorphism increased participants' support of regulating fast foods and their manufacturers.

Lastly, Study 4 was designed to provide a more rigorous test on one's support for paternalistic regulations of a tempting object. Participants view the same poster on childhood obesity from Studies 2 and 3. They then read about two non-profit organizations that promoted either paternalistic regulation of the object ("Safe Lunch"; emphasizing the need for regulating the sales of fast foods in school cafeterias) or personal effort in self-control ("Youth Run"; emphasizing the role of exercise and the need for developing running programs for children), and chose one to which they were willing to donate their money and time. Participants also evaluated the perceived effectiveness of each organization's approach. As predicted, anthropomorphism increased perceived effectiveness of Safe Lunch's approach, which in turn increased the likelihood of supporting Safe Lunch over Youth Run.

In sum, the findings provide novel insights into the attribution of responsibility for self-control failures through the lens of anthropomorphism. When facing self-control failure, anthropomorphizing a tempting object increases one's delegation of responsibility for self-control failure to the object itself and its manufacturer. Subsequently, anthropomorphism increases the perceived effectiveness of paternalistic intervention as a strategy to prevent future failure, which further motivates people to support it.

Let's Look the Gift Horse in the Mouth:
A Closer Examination of How Consumers Respond to Free Offers

Björn A. Hüttel, University of Passau, Germany
Christian J. Wagner, University of Passau, Germany
Jan H. Schumann, University of Passau, Germany
Martin Mende, Florida State University, USA
Maura L. Scott, Florida State University, USA

EXTENDED ABSTRACT

Consumers' demand for free (i.e., zero-priced) offerings is an increasingly important issue, particularly online where free services grow continuously due to low costs and ongoing technological advances (Bryce, Dyer, and Hatch 2011). Indeed, free online offers are estimated to account for a market of $260-300 BN (Anderson 2009), and – notably – the world's most valuable company, Alphabet, offers free online consumer services through Google (Guardian 2016). Although consumers may not experience any monetary charge for free online services (Gupta and Mela 2008), the providers' business models typically rely on advertisements, on collecting and selling consumer data (e.g., e-mail addresses), and on 'Freemium offers' (i.e., consumers can purchase a Premium version of the offering for a fee). This insight triggers at least two questions: How do consumers perceive the corresponding benefits and non-monetary costs of free offerings? What underlying emotional processes drive consumers' responses to such offerings?

Prior research offers valuable preliminary insights into the mechanisms that drive the success of free products. Most notably, Shampanier, Mazar, and Ariely (2007) discovered the "zero-price effect" (ZPE), which describes the irrationally high demand for free offers when consumers choose between a free and a cost option (e.g., free versus 1 cent). According to the ZPE, free offerings imply only benefits but no downsides (i.e. no costs), which leads to an overly positive affective response, which in turn drives consumers to opt for the free option (Finucane et al. 2000). Because the costs are presumed to be constant (zero), Shampanier et al. (2007) theorize that the free character of a product constitutes an additional benefit for consumers.

The present research further investigates the mechanisms related to the ZPE, but expands prior work by proposing that non-monetary costs (NMC) play a systematic and meaningful role in how consumers respond to free offerings (Schumann, von Wangenheim, and Groene 2014). In the marketplace, consumers experience NMC two-fold: they are exposed to advertisements (Anderson 2009), and they must disclose personal data (Anderl, März, and Schumann 2015), which are important sources of revenue for companies. However, if consumers perceive such NMC, does the assumption of an overly positive affective reaction to free offers, as established by Shampanier, Mazar, and Ariely (2007) still hold? Because research on the NMC of free offerings is scant, we investigate the following research questions:

1. How do consumer-perceived non-monetary costs influence the ZPE?
2. Is the ZPE linked to an increase in perceived benefits regarding a focal offer?

Because the majority of zero-price (free) offerings consumers encounter are, in fact, online services (i.e., e-services) (Anderson 2009), our analytic focus rests in this context. We propose that at least three aspects might sabotage the ZPE: First, consumers have a 'free mentality' regarding e-services; that is, they believe that online content is supposed to be free (Dou 2004). Second, relative to physical products, free e-services could present a lower utility because they are intangible and consumers only obtain access rights (but no physical rights). Third, although there is no monetary charge, free e-services typically come with non-monetary costs (e.g., interruption through advertisements), which could mitigate the ZPE. These insights question why consumers would show an overly positive affective response to zero-priced e-services.

As outlined above, extant explanations for the ZPE state that the cost-free nature of free offers elicits a positive affective reaction, which leads to consumers choosing the free product (Shampanier et al. 2007). We propose a more nuanced account for the ZPE, which goes beyond affect *as a mere decision making cue*. Rather, we theorize that affect related to free offers can systematically alter consumers' perceptions of corresponding benefits and risks (e.g., non-monetary costs resulting from data disclosure).

Consumers' risk perceptions are central to their evaluations, behaviors, and choices (Dowling and Staelin 1994). Risk and benefits are often positively correlated (Alhakami and Slovic 1994). However, research suggests that risks and benefits are frequently *negatively related in consumer's minds* (Slovic et al. 1991). The greater the perceived benefits, the lower the perceived risk, and vice versa. The distance between perceived benefits and risks is particularly high when affect is involved (Alhakami and Slovic 1994). Drawing on these findings, we suggest that the positive affective reaction to a free offer should lead not only to the attribution of higher benefits, as assumed by Shampanier et al. (2007), *but also to a lower judgment of the non-monetary costs (i.e. risks)*.

First, across five experiments, our results extend prior research on the zero-price effect (Shampanier et al. 2007) by providing the first empirical evidence for the assumption that consumers attribute additional benefits to free offers. Second, we add a new perspective to the ZPE by taking non-monetary costs into account. Results show that the positive affective reaction towards free offers (i) *increases* consumers' attribution of benefits and (ii) separately *decreases* consumers' judgment of non-monetary costs (here, exposure to advertising). Furthermore we show the serial mediation driving the ZPE. Specifically, our analyses reveal that the affect-induced higher benefits as well as the affect-induced lower judgment of non-monetary costs are indeed the reason for the irrational demand pattern of the zero-price effect. Thus, we contribute to research on non-monetary value contributions of consumers (Anderson 2009) and customer engagement (Van Doorn et al. 2010) by providing further evidence that consumers actually perceive their non-monetary costs as costs and by demonstrating the impact of the non-monetary costs on the choice behavior of consumers. Third, we reveal additional process variables which explain why consumers' judgments of NMC are biased (i.e. reduced) in light of free offerings. Results show reciprocity as the underlying psychological process of consumers' lower judgement of non-monetary costs. Furthermore, we exclude the alternative explanation that consumers' lower judgements of NMC are due to a naïve underestimation of the scope of NMC related to free offers. Fourth, these studies generalize the zero-price effect, which has previously been studied with chocolates, to a novel context: e-services. Consumers show an irrationally high demand when the monetary price is zero despite the 'free mentality' online and despite the presence of non-monetary costs.

Do Skewed Base-Rates Affect Advertising Effects on Brand Attitudes?
On the Role of Pseudocontingencies in Evaluative Conditioning

Mandy Hütter, University of Tübingen, Germany
Forian Kutzner, University of Heidelberg, Germany
Klaus Fiedler, University of Heidelberg, Germany

EXTENDED ABSTRACT

Evaluative conditioning (EC) serves as the prototypical paradigm to study advertising effects on product and brand attitudes (Sweldens, Van Osselaer, and Janiszewski 2010; Walther, Nagengast, and Trasselli 2005). In a typical EC procedure, an (often initially neutral) conditioned stimulus (CS; e.g., a product) repeatedly co-occurs in close spatio-temporal proximity with a valenced unconditioned stimulus (US; e.g., beautiful landscapes, smiling people, celebrity endorsers). As a result, evaluations of the CS change in the direction of the US—a phenomenon known as the EC effect.

The investigation of EC has been mainly concerned with the effects on a specific CS (e.g., a product) in encapsulated pairing episodes. The conditioning of stimulus features across pairing episodes has received little attention. Recent findings demonstrate, however, that the pairing with valenced stimuli does not only have the potential to change attitudes towards individual CSs, but also towards cues that are shared by many CSs (Hütter, Kutzner, and Fiedler 2014). One shared cue in the consumer context is the brand by which an array of products is put on the market.

In the paradigm adapted for the present research, participants make more positive experiences with products of one brand than with another brand. That is, there is a statistical contingency between brand and valence of experience. However, this contingency is not perfect. That is, consumers also make negative experiences with products of the positive brand and positive experiences with products of a negative brand. One can thus disentangle the evaluation of the brands from the evaluation of single products. That is, if many positive experiences with one brand increase the liking even in products that led to negative experiences (and vice versa), it can be assumed that the evaluation of the brand exerts a direct effect on the evaluation of the products that carry its brand. This is precisely what Hütter et al. (2014) have shown across several experiments.

In the present research, we examine the impact of an intriguing contingency illusion that is caused by the joint skew of two variables irrespective of actual contingencies. This illusion is called a pseudocontingency. A pseudocontingeny constitutes a logically unwarranted inference that relates a rare (frequent) cue value to the rare (frequent) criterion value (i.e., valence; Fiedler, Kutzner, and Vogel 2013). For instance, if consumers sample many products of one brand and generally make positive experiences when sampling products, they might infer that this brand is generally positive—irrespective of the actual contingency existing between brands and consumer experience. The present research tested whether the evaluation of rare versus frequent brands is affected by the valence of the rare versus frequent USs, using a typical EC paradigm.

In the present research, we used schematic butterflies as CSs that each had an individual wing pattern, but systematically varied on three cue dimensions (i.e., wing color, wing shape, and body size). For each participant, one of these cue dimensions was skewed, so that there were few stimuli realizing one pole of the cue dimension, but many stimuli of the opposite cue category. At the same time, the valence of the USs was skewed, so that there were either many positive stimuli and few negative stimuli, or vice versa. All actual contingencies were zero.

Study 1 ($N = 245$) is a meta-analysis across three experiments that implemented skewed base-rates for the CS cues and US valence. The experiments differed only concerning the arrangement of stimuli on the screen during the conditioning phase. Overall, we found evidence for pseudocontingencies in evaluative ratings of the individual CSs only when participants saw many negative USs. These findings were further restricted to evaluative ratings of the CSs used for learning, that is, they did not spread to isolated ratings of the cue values.

In Study 2 ($N = 240$), we manipulated the strength of the skew (1:2 vs. 1:3) and included a manipulation check that assessed participants' perceptions of skew of all variables (i.e., US valence and all cue dimensions). This study did not demonstrate evidence of pseudocontingencies in the evaluative ratings. The manipulation check helped us to disentangle the perception of skew and the illusory inference of a contingency. It turned out that participants extracted the skew in the US valence, but not in the skewed cue. Hence, participants did not perceive joint skew in the first place. Moreover, an index of perceived joint skew also did not predict the size of the pseudocontingency in the evaluative ratings. That is, perceiving the joint skew was not related to evaluations.

In summary, the present research shows that the evaluations are rarely influenced by this contingency illusion – in contrast to a number of research paradigms in which pseudocontingencies were demonstrated to override actual contingencies. The present research differs from these paradigms in one important aspect. That is, participants have to extract the relevant cue themselves, while in recent investigations of the role of pseudocontingencies, stimuli differed on the cue only and/or that cue was explicitly stated. While we think that our operationalization is more ecologically valid than the previous ones, it is possible that participants would draw pseudocontingency inferences if they noted the joint skew of the CS and US variables. Future research should thus use a simpler paradigm, for instance, where stimuli differ only on the skewed cue dimension to draw conclusions.

In summary, at this point the present research suggests that the evaluation of rare versus frequent brands is not influenced by the valence of the rare versus frequent USs. Hence, if consumers are confronted with many commercials of a given company and usually see many positive (e.g., attractive, funny) commercials, the brand does not profit from frequent presentations in this positive context. In the present research, EC depended primarily on a statistical contingency between CS and US. That is, the evaluation of a brand will change when the brand predicts positive or negative experiences more than others, and when positive or negative experiences with a product are related to a given brand.

The Pursuit of Happiness and Quest for Wealth:
Do Materialists Really Save Less and Borrow More, and if so Why?

Esther Jaspers, Tilburg University, The Netherlands
Rik Pieters, Tilburg University, The Netherlands

EXTENDED ABSTRACT

This research examines consumer saving and debt and how these are related to materialism, over time. The amounts of money that people save and borrow have important consequences at both the individual and the macro-economic level. Fifty-five percent of U.S. households can replace less than one month of their income through liquid savings (Pew Charitable Trusts 2015), and the average U.S. household spends 9% of their income on debt interests alone (El Issa 2015). A number of psychological factors contribute to consumer debt, such as consumers' tendency to make incorrect predictions about future spending, and the categorization of saving and debt in separate mental accounts (Hershfield et al. 2015). Financial literacy (Soll, Keeney, and Larrick 2013) and consumers' propensity to plan (Fernandes, Lynch Jr., and Netemeyer 2014; Lynch Jr. et al. 2010) have also been found to be related to financial behavior. Other frequently mentioned causes of debt are poor management of finances, unrealistically high standards of living, and individuals' desire to "keep up with the Joneses" (Barba and Pivetti 2009; Christen and Morgan 2005; Schor 1998). In fact, excessive consumer debt has been blamed on materialistic values that are considered inherent in Western society (Richins 2011), but empirical research in this domain is surprisingly rare. This research aims to contribute to closing this important knowledge gap.

We propose that the three motivations for materialism ("possession-defined success," "acquisition centrality," and "acquisition as the pursuit of happiness") might have different effects on saving and debt. In particular, those who pursue happiness through acquisition rather than through other means (acquisition as the pursuit of happiness) may save less and be more inclined to get into financial debt than those who believe that possessions are a measure of success (possession-defined success). If the former view money predominantly as a means to gratify their immediate acquisitive desires, they might be more likely to overspend and consequently, get into debt. We also examine a potential explanation for why materialism may be a cause of debt, namely that materialistic consumers are impatient. Consumers have a general preference to consume now rather than later (Angeletos et al. 2001; Frederick, Loewenstein, and O'Donoghue 2002; Laibson 1998; Loewenstein and Thaler 1989), and we test the idea that consumers high in materialism are more impatient than consumers low in materialism. If this is the case, materialistic people should also prefer liquid assets over illiquid assets as these enable immediate spending, and thus instant gratification of acquisitive desires.

Two studies tested our theory. Study 1 used data from four waves of the annual household survey run by the Dutch National bank (DHS household survey) among a representative sample of 2,155 consumers in the Netherlands. The survey provides complete and precise measures of both saving and debt and the longitudinal nature of the data allow us to identify possible bi-directional associations between materialism and saving and debt over time, and to establish Granger causality (Granger 1988). This extends prior research on materialism which had to rely on general attitudinal rather than behavioral measures of saving and debt, on cross-sectional rather than longitudinal data, and on student rather than general population samples (Norvilitis et al. 2006; Pirog and Roberts 2007; Watson 1998). Using a cross-lagged panel model it found that overall materialism did not influence later saving, but did predict later debt. Importantly, and in line with our predictions, acquisition as the pursuit of happiness was negatively related to saving and positively related to debt. However, in this study, possession-defined success was unrelated to both saving and debt, counter to our predictions. The results do show that the three materialism motivations have differential effects on saving and debt. Moreover, saving and debt influenced all three materialism motivations such that people with lower saving and more debt had higher levels of materialism in later years. This reveals, not only that materialism influences saving and debt over time, but also that materialism is a response to a consumer's financial situation.

Study 2 used a large scale experiment of 2,848 regular consumers to test predictions about the associations between materialism, impatience and liquidity preferences. Participants engaged in a delay discounting task (Thaler 1981; Van den Bergh, Dewitte, and Warlop 2008), and indicated preferences for liquid or illiquid saving and debt based on two scenarios. The results showed that people high in overall materialism were indeed systematically more impatient and were more likely to prefer liquid debt over illiquid debt. Again, these associations appeared to be driven by the motivation acquisition as the pursuit of happiness. That is, people who strongly believed that possessions and acquisition are essential for their satisfaction and well-being in life were more impatient and preferred liquidity for both saving and debt. Acquisition centrality and possession-defined success did not significantly influence impatience or liquidity preferences.

Together, the results contribute to financial decision making research by showing that materialism not only influences consumer saving and debt, but that saving and debt also influence materialism, which can result in a self-perpetuating cycle. A recent study by Tully, Hershfield, and Meyvis (2015) showed that consumers facing financial constraint engage in more materialistic and less experiential consumption. Our results extend these findings by showing that those who are more financially restrained become more materialistic over time, whereas those who are better off financially become less materialistic over time. Furthermore, previous research has already shown that materialists are more impulsive buyers (Dittmar and Bond 2010) but the finding that materialism, and particularly the motivation acquisition as the pursuit of happiness, is related to impatience and liquidity preferences is new and has broader potential in explaining why materialism may lead to reduced consumer saving and increased debts.

Shake Hard Play Hard:
The Impact of Risk on Consumer Behavior in the Aftermath of Disaster

Jayson S. Jia, University of Hong Kong, China
Jianmin Jia, Chinese University of Hong Kong, China
Christopher Hsee, University of Chicago, USA
Baba Shiv, Stanford University, USA

EXTENDED ABSTRACT

Danger is an inescapable part of human existence; understanding how consumers naturally respond to and behaviorally cope with risk is theoretically important not only for marketing but for fields ranging from psychology to finance to public health. We use geophysical and mobile phone data of 157,358 victims of the 2013 Ya'an earthquake (Ms 7.0) in China to diagnose the effects of the disaster and test the hypothesis that hedonic activities have an important role in promoting psychological recovery. Combining mobile phone app usage data, field surveys, and the naturally occurring instrument of an earthquake, we investigate how experiencing different levels of real disaster risk changes human behavior. Contrary to the intuition that solemnity dominates society's response to tragedy, we find that hedonic activity (i.e., having fun) has a special role in alleviating the negative psychological impact of disaster. Furthermore, we document and model the temporal patterns of post-disaster recovery to advance a dynamic understanding of behavioral processes that are often studied from a static perspective.

We investigate how experiencing real risk (different levels of earthquake intensity) changes post-disaster behavior captured by daily individual-level usage of mobile applications, telecommunications, and internet, and whether these behavioral responses ameliorate perceived risk, the negative psychological state inflicted by the disaster. In this research, the earthquake is conceptually a multi-leveled experiential treatment of risk (that is difficult to replicate in the lab). The population scale data about each individual's daily app usage patterns reflects changes in daily life patterns after the shock of the earthquake. For example, one might infer that informational app usage corresponds to greater information seeking (i.e., greater uncertainty or greater desire for information).

We find that rather than reduce the scope of human activity, higher earthquake intensity yielded graded increases in communications (e.g., social networking, messaging), functional (e.g., informational tools), and hedonic (e.g., music, videos, games) app usage. Formally, we used a fixed effects model to show that higher levels of experienced earthquake intensity caused graded increases in app usage in each category. However, only increased hedonic behavior reduced perceived risk during recovery.

We measured perceived risk a week after the earthquake in a large scale field survey conducted by phone (N = 2000) that was linked to the mobile data (we only surveyed earthquake victims who we had mobile data for). Prior literature has used perceived risk to capture the negative psychological feeling induced by risk, which in our research reflects the negative psychological impact of experiencing earthquake risk). An instrumental variable analysis using a two-stage Tobit model (with censored dependent variables to account for the heavily right-censored perceived risk measures), showed that only increased hedonic behavior reduced perceived risk after the earthquake. Increased communications behavior, which one might have thought brought greater emotional support, predicted an increase in perceived risk, possibly as a result of more exposure to risk-related information. Functional behaviors were not significant

predictors of change in perceived risk, possibly because functional behaviors (like checking one's finances) occurred independently of risk perception.

We also map the temporal patterns of post-disaster behavioral recovery, which are not linear, but typically follow exponential-decay functions, i.e., initial behavioral spikes quickly decline and then persist for a long time at a low level. Overall, the characteristics and relative efficacy of each facet of the population's behavioral response intuit their shifting roles over time, and suggest that hedonics are an effective population-scale coping strategy that is often missing in society's response to disaster.

This research makes several conceptual, applied, and methodological contributions. Conceptually, the paper focuses on risk, which is a classic topic in marketing and the behavioral sciences. From a theoretical standpoint, we investigate the potential of utilizing hedonic consumer behavior as a means of promoting psychological recovery from negative psychological states. Despite the existence of an established literature on the power of hedonics, fun is traditionally perceived to be divorced from risk and governments often enforce anti-hedonic policies, such as compulsory national mourning and bans on leisure activities such as fun television programming. However, our results suggest that pleasure should be allowed to mix with tragedy, and that hedonics (particularly hedonic consumer behavior) play an important role in promoting population-scale psychological recovery. This finding is not only of interest to marketers, governments, and NGO's alike.

In addition to our conceptual findings related to risk and experiential psychology, we make numerous methodological contributions to consumer behavior research. We use new mobile big-data methods to explore several empirical questions in consumer psychology that have only become possible after the mobile and big data revolutions (e.g., the relationship between real risk experiences and changes in consumer behavior over time; it would have been difficult to replicate the psychological effect of the earthquake in a lab setting, or to measure its impact over time.). Our use of a mobile data in a rare natural experiment setting also explores the meaning of 'big data' (e.g., individual-level population-scale app usage) from a consumer behavior perspective. Our methodology is applicable to many domains of consumer behavior and social psychology, which have traditionally been criticized for small sample sizes, biased selection, and other methodology flaws, and stands to benefit from new advances of the big-data revolution. Both academia and industry are both increasingly affected by 'big-data' insights; finding new ways in which behavioral sciences can contribute to this growing conversation is existentially important for our field. We believe many such opportunities exist: statistics-oriented data sciences are often theory-light in human behavior and do not rigorously explore the psychological meaning of many behaviors that are observable in big-data. For example, what can mobile meta-data such as app usage reflect about what a person is thinking or feeling? In exploring such questions, we hope to demonstrate the value of consumer behavior research and psychological theory in 'big data'.

Argumentum ad Novitatem: Mere Newness as a Choice Heuristic

Joseph Yun Jie, University of California Riverside, USA
Ye Li, University of California Riverside, USA

EXTENDED ABSTRACT

Marketing researchers have extensively documented the role of product features that serve as a signal of quality such as price (De Langhe et al. 2014), brand (Keller 1993), country of origin (Hong and Wyer Jr 1989), and warranty (Purohit and Srivastava 2001). However, the date a product was released or produced, a readily available extrinsic cue (Miyazaki, Grewal, and Goodstein 2005) for many consumer products, has been largely ignored. More broadly speaking, we know very little about how chronological newness— newness related to the time dimension, such as production date or release date—impacts consumer decisions. The present research contributes to the extant literature in marketing and psychology on novelty by proposing a new kind of novelty seeking for options that are chronologically newer.

By construction, people should ignore chronological newness if the two options are identical in every other way. However, in four studies, we show that, when choosing between newer and older options with identical quality information, people prefer the newer option across a range of domains (studies 1-3). The preference for newer options persists even for die rolls and coin tosses, where there cannot be any difference in quality and where there is no social relevance to newness (study 2).

We propose a newness as heuristic hypothesis to explain our finding: in tasks involving the complexity of assessing probabilities and predicting values (Tversky and Kahneman 1974), people will use newness a shortcut to resolve choice difficulty. We provided process evidence, for they spent less time choosing newer options than older options (study 3a and study 3b) and deliberation can mitigate people's newness bias (study 3b). Last but not least, we found that newness can lead to higher willingness to pay in joint evaluation but not in separate evaluation (study 4).

In study 1, 100 participants were told that we randomly pick a great George Carlin joke each day and could choose to read either today's joke or yesterday's joke. Since the jokes were randomly picked from the same pool of old jokes, the expected quality should not differ by day; yet, 78% of participants chose today's joke over yesterday's joke, significantly greater than chance (p < 0.001).

In Study 2, 204 participants read that "every morning, one staff member will roll a fair die and record its result." They were told that they could bet on the die result from that morning or the morning one week ago, with winners doubling their experimental pay. Participants can self-determine whether the bigger or smaller die win. Among the participants for which "the bigger (smaller) die wins," 75.5% (65%) chose to bet on today's die (p < .001 and p < .01).

In Study 3a, 329 students placed a bet on today's die vs. yesterday's die roll, with winners doubling their pay. We randomly assigned students into high cognitive load and low cognitive load group (Gilbert and Osborne 1989; Kessler and Meier 2014; Shiv and Fedorikhin 1999). We again found the newness effect but no group difference between high load (79%, p < 0.001) and low load group (79%, p < 0.001), suggesting that the effect is quite automatic and not affected by cognitive load. Participants' time spent on making the choice predicts their choice in the low load group (logistic regression, $\beta = -0.13$, $z = -2.89$, $p < 0.01$), but not in high load group ($\beta = -0.03$, NS). The result shows that deliberation (as measured by decision time) affects the people's choice when cognitive resource are abundant, but not when they are limited.

In study 3b, we have adapted study 1 by asking 265 students to pick a George Carlin joke to read. Again we have found that the majority of participants chose the newer option (80%, p < 0.001). We also recorded their need for cognition (NFC) as a measure of deliberation tendency (Epstein et al. 1996; Godek and Murray 2008). Logistic regression shows that both NFC ($\beta = -0.12$, $z = -2.17$, $p < 0.05$) and decision time ($\beta = -0.26$, $z = -4.14$, $p < 0.001$) have a negative effect on mere newness bias, confirming the heuristic hypothesis.

In Study 4, 265 students were randomly assigned into 2 groups (lottery winning chance: high vs. low), and each student's willingness to pay (WTP) for the raffle ticket were measured five times, differing in when the raffle was drawn (one year ago, one month ago, one week ago, yesterday, today, in random order). Participants' willingness to pay was submitted to a 2 (between-subject factor chance) × 5 (within-subject factor time) repeated measure ANOVA. Not surprisingly, higher chances to win leads to higher willingness to pay ($F(1, 263) = 8.06$, $p < 0.01$). There was also significant effect on WTP ($F(4, 1052) = 9.14$, $p < 0.001$), but no interaction effect between risk and time ($F(4, 1052) = 1.80$, NS). To further test the linearity hypothesis within subject, we did a contrast in repeated measure design by constructing a Lambda Score for every participant (Rosenthal and Rosnow 1991). Both high risk group ($t(132) = 2.38$, $p < 0.05$) and low risk ($t(131) = 3.31$, $p < 0.01$) showed a significant linear trend. Even though every raffle ticket was the same and had the same chance to be drawn, they were still willing to pay a premium for a newly drawn raffle ticket.

Even though people may prefer newer option (or older option) for a variety of reasons, our study tried to answer a basic question: does people have a predictable preference pattern toward chronological newness (or oldness) when choosing from identical options. No matter it is choosing a randomly selected joke of a dead comedian, or betting on a die roll or a coin, the majority of people picked the newer option. Rational inferences, such as newer things being more advanced, trendier, more fresh, more pure, less contaminated, or containing more information value are very hard to explain our findings. We proposed a heuristic account and found process evidence to support it.

What Comes Next? Family Carers' Experiences of Role and Identity Transition on Cessation of the Caring Role

Carol Kelleher, University College Cork, Ireland
Helen McGrath, University College Cork, Ireland

EXTENDED ABSTRACT

Life transitions are key stages of identity formation impacting family consumption (Hibbert, Piacentini and Hogg 2016). Yet, while family carers experience loss when those whom they care for transition from home to residential care and eventually pass on, to date, extant caregiving and family consumption research and practice has not viewed the post-caregiving stage (i.e. when the caring role has ceased) as part of the larger care giving life course (Orzeck and Silverman 2008). Such transitions approximate cumulative rites of passage (Van Gennep 1960, Turner 1969) comprising identity rebuilding and present practical and emotional challenges for family carers. The purpose of this paper is to explore how family carers experience role and identity transition as they progress from 'family member' to 'family carer', to 'post-carer', with the latter reflecting the cessation of the caring role as the individual being cared for moves to or dies in a care home or dies at home. In line with Barnhart and Penaloza (2013), we characterize family caring as a dynamic and situated, socially constructed group phenomenon, where the assisting functions of family, friends, and paid service providers create a family caring ensemble (FCE). Within FCEs, performances of family care giving are multifaceted (Barnhart, Huff and Cotte 2014), resulting in the integration of family carers' role-based and person-based identities to constitute relational identities (Simpson and Carroll 2008).

An idealist ontology and relational constructionist perspective frames this qualitative study (Blaikie 2010). Depth interviews were conducted with eight family carers, four females and four males, who had experienced loss in relation to their family caregiving role, and who were identified through a Family Carer representative association. Emergent themes relating to carers' experiences of role and identity transitions and losses were induced from participants' narratives (Spiggle 1994).

We induced three phases of role and identity transition precipitated by multiple losses across the care giving life course, which we term reconfiguring, distancing and reconstituting. The first phase, reconfiguring, revealed how family members disengaged from their previous family identities on assuming the family carer role, often loosing friends in the process. For some, the transition from family member to family carer was subtle and gradual, for others it was experienced as sudden and disruptive. During the second phase, distancing, family carers contemporaneously experienced feelings of connection and separateness as the dual roles and identities of family member-family carer become entwined. In particular, some family carers wrestled with the transition from caring at home to caring at a distance following the care recipient's move to a care home. In other cases, experiences of gain were also evident. In the final reconstituting phase, family carers had to adjust to the ultimate and final transition – death of the care recipient and refashioning new identities.

Our first contribution relates to illuminating family carers' experiences of role and identity transitions on cessation of the caring role. While the role and identity transition phases induced might suggest a linear transition from family member to family carer over time, they were in fact cumulative, multifaceted and overlapping. We highlight that family carers faced multiple losses long before the death of the care-recipient (Orzeck and Silverman 2008) and that they are often uncertain as to what is "normal" and "expected" in terms of dealing with such losses (Moss and Moss 2012). We also integrate insights from the loss and bereavement literature with rites of passage perspectives to reveal that family carers moved between experiencing multiple losses to co-creating and reconfiguring new identities as they adjusted to life after care. Our second contribution is that we empirically illustrate how family carers' experiences of role and identity transition frame relational identities. Family carers narratives of multiple losses co-evolved as both they and the family members that they care(d) for experience parallel role and identity transitions. This relational perspective extends the work of Ashforth et al. (2001) and Ashforth (2000), which conceptualizes role occupancy in relation to occupying a single as opposed to multiple roles. Our third contribution is the extension of consumer research perspectives of care and family consumption (e.g. Barnhart, Huff and Cotte 2014; Barnhart and Penaloza 2013; Dean, Kellie and Mould 2014). We illustrate that family carers represent a "shadow workforce" whose work and role performance goes far beyond provision of care in the home to extend to care inside health care facilities and in conjunction with community services (Bookman and Harrington 2007).

As with all studies, our study suffers from a number of limitations. All participants were members of a regional Family Carer Association so the role of family carer was central to their identities prior to participating in the study, which was reinforced by other family carers in the association. Future studies might therefore examine whether family carers who are more isolated have different experiences to those highlighted in this study. Future studies might also integrate and overlay the family care recipient and other family members' experiences of role and identity transition with those of family carers in order to develop a more relational perspective on family caring.

In conclusion, transitions from family member to family carer to post carer are experienced as major life transitions that require family carers to juggle multiple roles, which can often a source of chronic stress for the duration of the caregiving period and implies intensive identity re-building within and beyond family networks (Orzeck and Silverman 2008). While family carers experience multiple losses and bereavement throughout the care giving life course (Boerner and Schultz 2009), over time a sense of renewal and positive gain may emerge as post carers refashion identities within and beyond the family (Ong et al. 2014). In line with Ghesquiere et al. (2011), we believe that family caregiving responsibilities should be categorized as work that should be supported and shared with public, social and health services, and not just viewed as familial duty. In this way, family carers can be supported in facilitating crucial family, community and societal roles in relation to family care provision.

The Impact of Large Versus Small Menu Size on Calorie Estimation

Junghyun Kim, Virginia Tech, USA
Yong Kyu Lee, York College, CUNY, USA
Paul Herr, Virginia Tech, USA

EXTENDED ABSTRACT

Estimating daily caloric intake, colloquially known as 'counting calories,' is a common tool for consumers seeking to maintain a healthy diet. Prior research on calorie estimation suggests that people tend to use heuristics when estimating number of calories; such reliance on heuristics, however, may be misguided, as judgmental biases such as the averaging bias or the healthy halo effect can result in inaccurate estimates (Chandon and Wansink 2007; Chernev and Chandon 2010; Raghunathan, Naylor, and Hoyer 2006). Prior research has focused on the biasing impact of meal-specific or item-specific factors (e.g., a meal with healthy and unhealthy items). Before evaluating each item, however, consumers may form an overall impression about a menu offered at a restaurant, which implies that the number of options on a menu may influence consumers' perceptions of both items and the restaurant. In addition, previous studies on the impact of assortment size have focused on preferences between a large and a small assortment and its influence on brand perception and choice (Berger et al. 2007; Chernev 2012). Nevertheless, there has been less attention on how the number of options on a menu may affect consumers' calorie estimation.

The present research aims at filling this gap by investigating the effect of menu size on consumers' calorie estimations and its consequences for their food choices. We specifically focus on i) the impact of menu size, in terms of the number of available options, on calorie estimations and ii) the process that underlie this estimation bias. Across four studies, we manipulate menu size by presenting a sandwich menu with different numbers of options and then ask participants to estimate the caloric content of a target item. Note that we only varied the number of sandwiches on a menu, but balanced items based on perceived healthiness to prevent potential issues that may affect calorie estimations (e.g., differences in overall calories for the menu).

In Study 1A (N = 205), we hypothesize that participants provided with a menu with more items estimate a higher calorie content of a target item than those given a menu with fewer items. We also propose that this estimate is distorted irrespective of the perceived healthiness of a target. A 2 (menu size: large vs. small) × 2 (perceived healthiness of a target item: healthy vs. unhealthy) ANOVA revealed that participants estimated a higher caloric content of a target item in the large menu condition regardless of its perceived healthiness (M_{large} = 439.51 vs. M_{small} = 374.54 for a healthy target item; M_{large} = 495.87 vs. M_{small} = 435.58 for an unhealthy target item).

The objective of Study 1B (N = 149) is to replicate the effect of menu size on calorie estimations and, more importantly, to rule out an alternative explanation (i.e., the contrast effect). In this study, we predict that participants will provide higher calorie estimate for a target item in a larger menu, but they will not show significant differences between two small menu size conditions. As expected, the data support our hypothesis that participants presented with the large menu not only estimated higher calories for the target than those who saw the small size menu with two unhealthy sandwiches (M_{large} = 502.18 kcal vs. $M_{small(unhealthy-unhealthy)}$ = 432.06 kcal, $p < .05$) but also believed it has more calories than those who saw the small menu with healthy and unhealthy sandwiches (M_{large} = 502.18 kcal vs. $M_{small(healthy-unhealthy)}$ = 408.50 kcal, $p < .02$). More importantly, we found that participants in the two small conditions did not differ in their estimates for the target item ($p > .50$).

Study 2 (N = 95) examines the process underlying the menu size effect on calorie estimations. Building on prior literature on range theory (Parducci 1965), we specifically compare a range of calorie estimates for a menu (i.e., the highest and lowest calorie estimate) and determine whether this subjective range drives the menu size effect on calorie estimations. Once again, the larger menu led to higher calorie estimates for the target item ($F(1, 93)$ = 3.59, $p = .06$; M_{large} = 427.20 vs. M_{small} = 370.39); importantly, this effect was mediated by the estimated calorie range for the menu (CI: .001 to .095). Though these results support our hypothesis that menu size widens estimated calorie ranges, one could argue that it is still unclear why they provided a greater calorie estimate *within* the range they widely formed. We propose that participants will tend to use an average of calorie estimates for the menu as a proxy when estimating a target item's caloric content (Huttenlocher et al. 1991; Huttenlocher et al. 2000). We further suggest that both a subjective range of calorie estimates for the menu and the average calorie content sequentially mediate the impact of menu size on calorie estimation.

In Study 3 (N = 144), we directly test this hypothesis using two-step mediation analysis. The data support our hypothesis that the number of options on a menu significantly influences i) participants' calorie estimates for the target (M_{large} = 739.1 vs. M_{small} = 664.6; $F(1, 142)$ = 2.98, $p = .09$), ii) range of calorie estimates for the menu (M_{large} = 495.01 vs. M_{small} = 328.08; $F(1, 142)$ = 27.68, $p < .01$), and iii) an estimated average calorie for the menu (M_{large} = 621 vs. M_{small} = 543.4; $F(1, 142)$ = 4.53, $p < .05$). A sequential mediation analysis showed that there was a significant indirect effect of two mediators on calorie estimation (95% CI: .075 to .229). In this study, we also compared the actual calories of participants' sandwich choices in order to investigate how the calorie estimation bias affects consumers' food choice. We expected that actual calorie contents in the selected sandwiches would be smaller when chosen from the large menu because participants may believe the same sandwich in a large (vs. small) menu contains more calories and thus choose one with fewer calories to maintain a healthy diet. As expected, the actual calorie content of participants' food choice is significantly lower (vs. higher) in the large (vs. small) menu condition (M_{large} = 709.5 kcal vs. M_{small} = 783.3 kcal; $F(1, 117)$ = 3.93, $p = .05$).

Taken together, our findings suggest that the number of options on a menu systematically influences consumers' calorie estimations. Further, this paper proposes a new underlying mechanism of calorie estimation bias and its impact on consumer food choice.

How Heavy is Your Smartphone?
Imaginary Weight Perception of Smartphone Users and Its Impact on Product Evaluation

Sang-Hoon Kim, Seoul National University, Korea
Yuna Choe, Seoul National University, Korea
Youseok Lee, Seoul National University, Korea

EXTENDED ABSTRACT

Smartphone usage is widespread, and many cellphone models have pre-installed applications for the consumers' convenience. It is also the most common way to add features on the smartphone by downloading different types of mobile applications. As many consumer researchers have studied the role of sense on consumer behavior, we were curious to investigate that the number of application icons works as subconscious visual cues and that such sensory experience affects the perception and judgment of the users. We hypothesize that seeing a greater number of software icons on the electronic devices may bring about the perception related to weight. More specifically, we want to find out whether people perceive their devices heavier given more icons displayed on the screen.

The current research is built upon previous research on sensory marketing, which is defined as the marketing activity "that engages the consumers' senses and affects their perception, judgment, and behavior" (Krishna 2012, 332). In marketing literature, much research has been done to explain the role of visual attributes of products and advertisements on consumer behavior (e.g. Jiang et al. 2015; Krishna 2012; Krishna and Schwarz 2014; Meert, Pandelaere, and Patrick 2014; Xu and Labroo 2013). Consumers perceive the product heavier when product visuals are located at the bottom-right (in comparison to top-left) position (van Rompay, Fransen, and Borgelink 2013), or they perceive the product heaviness increases when the product image is located in the bottom (Deng and Kahn 2009). Visual imagery, as a consequence, functions as a cue for weight perception.

Based on prior research, we expect that exposure to a greater number of objects could change the user's weight perception of the product. Specifically, the number of application icons can function as a visual cue, thus as more icons are displayed on the smartphone screen, consumers will perceive the product heavier. While the actual weight does not change, consumers could think heavy devices are full of software, running to its capacity, or lacked in speed. Consequently, greater perceived heaviness would have negative impact on the product evaluation.

In the pretest, we tested the hypothesis that the number of apps presented on the smartphone screen would increase the user's perceived heaviness. Participants read a short scenario that the manufacturer W is going to launch the smartphone model Y and participants were requested to estimate the weight of model Y in gram or ounce based on the information on model Y and competing models ranged from 129g to 145g. The result revealed that the group who viewed 60 app icons reported significantly higher perceived weight than the group who viewed 30 app icons (M_{large} = 147.61g, M_{small} = 137.83g; p = .020).

Study 1 replicated this result and screened out the most plausible alternative explanation that the effect of the number of apps on smartphone weight perception might be caused by visual density. The stimuli were identical to those of pretest except that the size of application icon was smaller in low-density condition than that of in high-density condition. Results indicate that participants in the 60 apps (large) condition rated the smartphone heavier than participants in the 30 apps (small) condition (M_{large} = 141.53g, M_{small} = 136.921g; p = .038). However, participants in the high-density condition rated the model Y as heavy as participants in the low-density condition (M_{high} = 139.80g, M_{low} = 138.20g; p = .457). Also, the interaction effect of the two main factors was not significant ($F(1, 132)$ = 1.651, p = .201).

Study 2 examined whether a smartphone with more applications installed is perceived as less appealing compared to a smartphone with a smaller number of applications, and whether this effect is mediated by the perceived heaviness. Participants read a short scenario that s/he is now using the model Y produced by the manufacturer W. In addition to the weight estimation, participants reported their attitude toward the smartphone, perceived quality, and satisfaction level. First, the effect of the number of apps on perceived heaviness was reconfirmed. Additionally, the mean score of attitude toward the smartphone for the large condition was lower than the mean score for the small condition (M_{large} = 5.1587, M_{small} = 5.5025; p = .026). The same tendency was found in perceived quality and satisfaction level. In addition, a bootstrap analysis with 5,000 resamples revealed that the 95% confidence intervals for the significant indirect effect excluded zero (CI: -.2416 ~ -.0207, $p < .05$). We also found that the perceived heaviness partially mediated the effect of the number of apps on perceived quality and fully mediated the effect on satisfaction level.

Study 3 diagnosed whether a smartphone with a larger number of applications installed decreases purchase likelihood of new mobile application than the one with smaller number of applications, and whether this effect is mediated by the perceived heaviness. After exposed identical scenario and stimuli with Study 2, participants read detailed information about fictitious media player application XYZ. Participants were then requested to report their estimation on smartphone weight and purchase intention toward the new released app XYZ. First, the effect of the number of apps on perceived heaviness was reconfirmed. Furthermore, the mean score of purchase intention on app XYZ for the large condition was lower than the mean score for the small condition (M_{large} = 4.2184, M_{small} = 4.7661; p = .035). In addition, a bootstrap analysis with 5,000 resamples determined that the 95% confidence intervals for the significant indirect effect excluded zero (CI: -.3282 ~ -.0310, $p < .05$), supporting our hypotheses.

The findings in the current research extend the knowledge about the role of visual on consumer judgments. While prior research has mainly dealt with the role of bodily experience of weight on perception (e.g. Chandler, Reinhard, and Schwarz 2012; Jostmann, Lakens, and Schubert 2009), the present research is the first to examine that the visual experience using app icons can function as a cue to estimate weight and to explore its impact on the product evaluation. This research provides insights about how providing pre-installed applications on smartphone may backfire; consumers may think that bloatware makes their product sluggish. Marketers might want to be cautious to communicate about many installed features. In order to overcome the limitations of scenario-based experiment, field studies with actual stimuli using a real smartphone are suggested to confirm our findings in the future.

Residential Mobility and Uniqueness Seeking

Minkyung Koo, University of Illinois at Urbana Champaign, USA
Andy H. Ng, University of Illinois at Urbana Champaign, USA
Shigehiro Oishi, University of Virginia, USA

EXTENDED ABSTRACT

People have a general desire to distinguish themselves from others (Brewer 1991; Snyder and Fromkin, 1977). This desire for uniqueness is clearly manifested in consumption as material possessions that consumers acquire and display make them look and feel different, and signal their distinctiveness to other consumers (Belk, 1988; Lynn and Harris, 1997a; Tian, Bearden, and Hunter 2001). The goal of the present research is to introduce personal history of residential mobility, the frequency of geographic relocation, as a novel predictor of the preferences for unique consumption and examine its underlying mechanism and moderating conditions.

We posit that personal history of residential mobility enhances the motivation to strive for personal distinctiveness, expressed by a preference for possessing and displaying unique consumer products. This is because residentially mobile people tend to place more importance on their personal selves (e.g., personality, skills) than collective selves (e.g., group affiliation, membership) as the former are less susceptible to social environmental changes than the latter (Oishi, Lun, and Sherman 2007). Since the personal self is achieved by possessing unique personal attributes that differentiate oneself from others (Brewer and Gardner 1996), residentially mobile (vs. stable) people who place more emphasis on their personal (vs. collective) selves will have a greater need for unique consumption.

We further expect that the link between residential mobility and uniqueness seeking would be heightened only when one's personal self can be manifested through consumption but not when such manifestation is not likely. Specifically, we predict that the effect on uniqueness seeking would be observed for symbolic products with which one could express one's desired identity (Berger and Health 2007) rather than utilitarian products (Shavitt 1990). It is because people's preferences and identity can be inferred from the products they purchase (Belk, Bahn and Mayer 1982), and particularly consumption of products with symbolic versus functional benefits is likely to be diagnostic of consumer characteristics (Shavitt 1990).

In addition, we assume that not everyone with the experience of moving prefers unique products because residential mobility has both positive and negative affective consequences (e.g., excitement as well as anxiety or loneliness) (Oishi et al. 2012). If moving to another city or town brings about significant changes in the existing social network and affiliations and thus the need to regain a sense of belonging in the new community, the need for social conformity may increase while the desire to stand out may decrease. In other words, while residential mobility can enhance the need for uniqueness through a heightened sense of personal self, this effect could be mitigated by the need for conformity associated with moving and shifting social relationships.

Uniqueness seeking involves social normative characteristics as manifested in the choice of uncommon or counter-conformity products that are endorsed by a minority group (Kim and Markus 1999). We predict that if the need for conformity is heightened in the process of moving and settling in a new community, individuals will be motivated not to stand out through the choice of counter-conformity products but to fit in with others by choosing more common or conventional products. This would particularly be the case when individuals are more prone to avoid risks and less explorative in trying new options but not when they are not afraid to take risks and tend to seek novelty.

In Study 1, we tested our central hypothesis that one's personal history of residential mobility predicts a general uniqueness-seeking tendency. Participants were shown seven sets of different combinations of shapes and asked to indicate the one that they liked the most. One of the shapes in each set was different from the other six shapes and thus was more unique than the rest. Participants reported the number of times that they had moved during elementary school, during middle school, and during high school. The total number of moves across the three different time periods was summed and served as an index for personal history of residential mobility. As expected, we found that one's personal history of residential mobility predicts their preferences for unique shapes.

In Study 2, we examined one's self-concept as the underlying psychological mechanism of the effect of residential mobility on the desire for uniqueness by measuring people's emotional reactions and intention to purchase unique products in a hypothetical scenario involving consumer products and brands. We found that personal history of residential mobility predicts positive emotional reactions and greater willingness to purchase unique products over common products when the product domain is identity-symbolic but that this effect disappeared when the product domain is not symbolic of one's identity.

In Study 3, we directly investigated the underlying mechanism by showing that the relative centrality of one's self-concept (personal versus collective) (Triandis and Gelfand 1998) mediated the relationship between personal history of residential mobility and self-reported chronic need for uniqueness (Lynn and Harris 1997b).

In Study 4, instead of measuring one's personal history of residential mobility, we established the causal relationship between residential mobility and consumer uniqueness seeking by priming the mindset for moving versus staying. Participants who were primed with a mobility (vs. stability) mindset showed greater desire for unique products. More importantly, this effect was observed only among those who have a tendency to engage in exploratory buying behaviour (Baumgartner & Steenkamp, 1996), a chronic disposition to seek novelty, to be curious about, and take risks in trying new options.

Our findings offer a number of important theoretical as well as practical implications for understanding the impact of geographic relocation of consumers by revealing the novel effect of residential mobility on uniqueness seeking. These findings also have novel practical implications for market segmentation and managerial decisions suggesting that the demand for unique products such as limited editions or the effectiveness of the use of popularity cues in advertising messages could be estimated based on the residential mobility of target consumers.

The Asymmetric Nature and Motivation of Experiential and Material Purchases, and Their Impact on Happiness

Sofia Kousi, Athens University of Economics & Business, Greece
Flora Kokkinaki, Athens University of Economics & Business, Greece

EXTENDED ABSTRACT

Experiential purchases have been found to make people happier than material purchases. In fact, several studies point to what Nicolao, Irwin, and Goodman (2009) call the 'experience recommendation', referring to the greater capacity of experiential purchases to contribute to happiness compared to that of material purchases. Experiential purchases, like vacations, concerts and spa treatments, made with the goal of adding another experience in life, contribute more to happiness than material purchases (Van Boven and Gilovich 2003; Nicolao et al. 2009; Howell and Hill 2009; Carter and Gilovich 2012). However, it has been asserted that the direct comparison between these two types of purchases is problematic, due to their inherent differences (Schmitt, Brakus, and Zarantonello 2015). The aim of the present research is to further explore and empirically test this hypothesis, and analyze its impact on happiness. The intended research outcomes can have significant implications for both consumer spending and wellbeing, and marketing strategic decisions.

Analyzing the recalled purchase examples and purchase options cited in published research on the topic points to some underlying biases: experiences mentioned tend to be hedonic and special one-time events, while materials more utilitarian, ordinary and in the context of respondents' everyday life. Additionally, as mentioned by Carter and Gilovich (2012) experiences tend to be more expressive of one's identity than materials, and thus potentially by extension more involving, providing an additional source of bias. No research to date has explored the impact of these characteristics on the relative happiness between the two types of purchases. The current research tests the hypotheses that recalled experiential purchases are more hedonic (H1), extraordinary (H2), self-expressive (H3), and involving (H4) than material purchases, and that given the same levels of these characteristics happiness derived is the same between experiences and materials (H5).

These fundamental differences in the nature of the purchases, by extension, impact the motivation behind each purchase. "Consumers purchase goods and services and perform consumption behaviors for two basic reasons: 1) consummatory affective (hedonic) gratification, and 2) instrumental, utilitarian reasons (Batra and Ahtola, 1990, 159). The current research also tests the hypothesis that experiential purchases are motivated by happiness-seeking (hedonic gratification), while material purchases are motivated by need satisfaction (instrumental reasons) (H6). Moreover, since hedonic and eudaimonic wellbeing overlap conceptually (Kashdan, Biswas-Diener, and King 2008), the above hypothesis can be extended to include meaning-seeking, which is an ingredient of eudaimonic happiness (Huta and Ryan 2010). Hence, an additional hypothesis is that experiential purchases are motivated more strongly by meaning-seeking than material purchases (H7).

Study 1: A series of 18 in-depth interviews were conducted. Participants completed a card sorting exercise, exploring their understanding of the distinction between experiences and materials. They were asked to categorize index cards with a material or experiential purchase written on them, using their own criteria. Unaided, participants did not make the distinction when sorting the cards. However, when the interviewer divided the cards into materials and experiences, participants understood the distinction and highlighted two key areas of difference between them. The first one focused on the na-ture of the purchases: experiential purchases were described as more hedonic and extraordinary, while material purchases were described as utilitarian and ordinary. The second difference was the purchase motivation: while experiential purchases were motivated by pleasure and leisure considerations, material purchases were motivated primarily by practical needs.

Study 2: The results of the qualitative study were empirically tested through a 2 (purchase type: experience, object) x 2 (purchase time: past, future) between subjects experiment. Experiences were indeed found to be more hedonic and extraordinary, but also more self-expressing and involving than material possessions. Moreover, experiential purchases were more highly motivated by both happiness and meaning seeking than material purchases. Respondents seem to have a stronger, more conscious motivation behind their experiential purchases. At the same time, both types of purchases were equally motivated by a sense of need. All the above properties give experiences a natural advantage, as they correlate highly with happiness. At the same time, the properties that were more pronounced in material purchases, such as the ordinary, utilitarian nature and a need motivation, were not correlated with happiness.

When these asymmetries were corrected by splitting each property into high and low using median split, experiential and material purchases contributed equally to happiness: material and experiential purchases resulted in similar levels of happiness when they were equally highly hedonic, self-expressing, extraordinary, involving and equally strongly motivated by happiness and meaning. This points to the mediating role of these properties, and highlights the fact that both types of purchases have the capacity to contribute to wellbeing.

The results of the study indicate that experiential and material purchases should indeed not be directly compared, as they differ greatly both in their nature and the motivation behind them. However, studying experiential purchases is important, since their natural happiness advantage can be a useful guide to learning how to maximize the happiness derived from our purchases. Studying experiential purchases more closely can give us a deeper understanding of the specific elements of consumption that enhance wellbeing. These elements can then be adapted to material purchases in order to increase the wellbeing elicited by them. Understanding these differences can also contribute to marketing communication and product positioning, for instance, by highlighting the hedonic nature and motivation behind a material purchase in advertising. Research is needed to further explore the impact of the different motivators on happiness, which would help consumers make more educated choices that will maximize their wellbeing.

The Absolute More, The Merrier:
How Dispositional Greed Influences Individual Thinking Styles

Goedele Krekels, HEC Lausanne, Switzerland
Mario Pandelaere, Virginia Tech, USA, & Ghent University, Belgium

EXTENDED ABSTRACT

Classic economic theories state that economic choices are based on rational thinking and an absolute thinking style (Stigler, 1987). However, research in psychology showed that information processing responds to changes in stimuli in a relative style (Fetherstonhaugh et al., 1997). Limited attention has been given to information showing that neither relative nor absolute thinking is generalizable across the population. Several basic experiments (e.g. Tversky and Kahneman, 1981) indicating relative thinking actually found that 30%-60% of the population show an absolute thinking style. As studies have shown that thinking style affects a variety of consumer decisions, individual differences in numerical information processing is hugely important for academics and management practitioners.

We examine dispositional greed, a personality trait that entails an insatiable, self-centered desire for more resources (Krekels & Pandelaere, 2015), to investigate stable individual differences in thinking style. We believe that their insatiability might drive greedy people to focus on absolute changes. In a first study, 150 MTurkers (90 Males, M age = 37.5, SD = 12.4) indicated their willingness to travel 6 minutes to save 10$ on two items (a USB flash drive (15$) and a winter jacket (125$), separated by filler items) (based on Tversky & Kahneman, 1981) and answered the Dispositional Greed Scale (DGS, Krekels & Pandelaere, 2015). A binary logistic regression including the location of the USB question (to control for order effects) showed that the greedier people are, the less they changed their answer between the USB drive and the jacket, indicating absolute thinking.

In a second study based on Azar (2011), 117 students (50 Males, M age = 23.4, SD = 5.7) saw three products (a laptop, household shopping, a plane ticket) at either a randomized expensive or cheap price (659€ - 475€, 76€ - 47€, 157€ - 98€). Respondents indicated their WTP for a similar product (a smaller laptop, shopping for lesser quality items, a plane ticket with transfer) and answered the DGS. We calculated respondents' absolute and relative price difference. Two general linear mixed models indicate that non-greedy people think relatively ($F_{(321.33, 309.76)} = 5.53$, $p < .05$), as their relative WTP is independent of the original price. Greedy people on the other hand think absolutely ($F_{(268.73, 130.58)} = 5.86$, $p < .05$), as their absolute WTP is independent of the original price.

Second, we suggest that this effect is due to a difference in marginal utility. The literature on scope neglect states that the value of an increase in X depends on the affective value of X (Frederick & Fischhoff, 1998). We hypothesize that for non-greedy people the original amount dictates subjective value, where above a certain threshold the subjective value of an increase is limited due to diminishing marginal utility. For greedy people on the other hand, the original amount has less informative value and thus less effect on the subjective value of an increase, showing less diminishing sensitivity (Kahneman & Tversky, 1984). 124 Students (54 Males, M age = 20.6, SD = 1.1) won candy bars (1 versus 4), and were given 1 extra bar. They indicated their happiness with the extra bar and answered the DGS. A linear regression showed that the effect of the original amount disappeared for greedy people (+1 SD, $F_{(1.128)} = .082$, $p = .78$) but was present for non-greedy people (-1 SD, $F_{(1.128)} = 9.802$, $p < .01$). This confirms that dispositional greed reduces diminishing utility.

A fourth study tracked the actual value functions: an absolute thinking style is not only linked with a smaller diminishing utility (a stronger correlation between the scope of a stimulus and its subjective value) but also with a higher associated value (a larger slope of the scope of a stimulus on its subjective value) (Kahneman & Tversky, 1984). 119 MTurkers (58 Males, M age = 41.7, SD = 13.5) saw 4 products (a steak, restaurant meal, a tablet, a television subscription) at 5 different levels (weight, number of courses, internal memory, number of channels) for which the lowest levels was priced ($5.99, $35, 129$, 25$). Respondents indicated their WTP for the 4 subsequent levels and answered the DGS. We calculated for each respondent and product separately, the correlation between the quantitative amount given and respondents' WTP and the slope of the regression line. A Manova analysis showed that greed positively predicts the correlations (Wilks' Lambda=0.839, $F_{(6, 90)} = 2.882$, p<0.05) for the steak ($p < .05$), restaurant meal ($p < .05$) and marginally the tablet ($p = .072$) but not the television subscription ($p = .477$). A second Manova showed that greed also positively predicts the slopes of the regression (Wilks' Lambda=0.095, $F_{(150, 311)} = 1.264$, p<0.05) for all products (all $p < .05$). Thus, more greedy people depict smaller diminishing utility and higher associated values.

Finally, absolute thinking supposedly leads to more rational decision making (van Boom, 2011). Therefore in a final study we examine the unit effect: attribute differences appear larger on scales with a higher number of units. In this situation relative thinking should lead to better choices. 133 students (57 Males, M age = 23.1, SD = 5.4) saw 12 home cinemas, rated on a 10-point scale ranging from 4 to 9.5 in steps of 0.5, or on a 1000-point scale ranging from 400 to 950 in steps of 50. Each participant indicated for the 12 systems their WTP to upgrade to the perfect system (based on Pandelaere, Briers and Lembregts, 2011) and answered the DGS. A multilevel linear regression analysis indicated that the stronger effect of quality in the 1000-point condition is enhanced for greedy people ($F_{(1, 1250.146)} = 5.338$, $p < 05$), but greed does not moderate the effect in the 10-point condition ($F_{(1, 1250.426)} = 1.154$, $p = .28$). These results indicate that in situations where relative thinking leads to more optimal decision making, it is greedy people who are worse off.

Out of Proportion?
The Role of Leftovers in Eating-Related Affect and Behavior

Aradhna Krishna, University of Michigan, USA
Linda Hagen, University of Southern California, USA

EXTENDED ABSTRACT

Food leftovers are commonplace, and have become more so. Average portion and package sizes have increased over time (Nielsen and Popkin 2003; Smiciklas-Wright et al. 2003). While these increased portion sizes brought along increased consumption (for a review see Herman, Pliner, Polivy, and Vartanian 2015), the increase in consumption has not kept up with the increase in portion size: a recent meta-analysis found that when portion sizes are expanded by 100%, people eat only about 35% more (Zlatevska, Dubelaar, and Holden 2014). As such, on average, consumers today tend to have greater amounts of food leftover.

Much prior work has investigated how larger *portions* directly lead to greater consumption, such as through visual biases (Chandon and Ordabayeva 2009; Krider, Raghubir, and Krishna 2001) or inferences about portion appropriateness (Diliberti et al. 2004; Herman et al. 2015). However, no attention has been given to how the larger *leftovers* that stem from larger portions may impact consumer behavior. Clearly, eating more food is an important and intuitive cause of weight gain. But is it possible that having more food *leftover* could also contribute to obesity, by giving consumers the sense that they didn't consume all that much after all?

As mentioned before, when portion size increases, consumption increases to a much smaller degree, effectively leading to more leftovers. This paper is the first to examine whether given equal actual consumption merely having more food leftover changes consumers' perception of how much they ate and consequently impacts subsequent eating and exercising behavior—an important and timely question that has, to our knowledge, not yet been studied. By holding constant the amount of food eaten and only varying the amount of leftovers, we are able to isolate any effects of amount *leftover* from amount *consumed*—two variables that are typically confounded in food consumption studies.

In brief, we propose that, holding actual consumption constant, larger amounts of food leftovers may increase subsequent eating and decrease subsequent exercising by reducing perceived consumption and thus bolstering consumers' self-evaluative feelings. The rationale for this proposition is as follows. Theories of perception (for a review see Stewart, Brown, and Chater 2005) and judgment and decision making (Hsee 1996; Tversky and Kahneman 1991), in one way or another, suggest that people perform relative rather than absolute judgments. For equal absolute consumption, having more food leftover means that the relative proportion of food eaten from the whole portion is smaller, and thus we predict that larger leftovers lead people to perceive they consumed less. Given that many consumers have a goal to curb their consumption or at least not overeat (Bublitz, Peracchio, and Block 2010; Vohs and Heatherton 2000) and feel bad when they overindulge (Ramanathan and Williams 2007), we predict that perceiving lower consumption may bolster people's self-evaluation. Based on findings that feeling better about one's current status regarding a goal can decrease efforts towards that goal (Amodio, Devine, and Harmon-Jones 2007; Carver 2003), we predict that the bolstered self-evaluation reduces consumers' motivation to compensate for their prior eating later on, as manifested in eating more and exercising less afterwards. Four experiments provide evidence in support of these predictions.

In study 1, people were asked to eat six squares of chocolate from a chocolate bar, either from an eight-square bar (small leftovers) or an 18-square-bar (large leftovers). People who ate six squares but had large leftovers rated their absolute consumption as lower than did those who ate six squares but had small leftovers.

Study 2A replicated this finding and also examined its impact on compensatory behaviors, as manifested in increased subsequent consumption. Students were presented with a cookie and asked to eat a designated equally sized area, either from a small cookie (small leftovers) or a large cookie (large leftovers). Afterwards, they could participate in an optional additional tasting of mini cookies. People with large leftovers rated their absolute consumption as lower and also ate more cookies afterwards than people with small leftovers. Study 2B replicated study 2A with a different type of compensatory behavior: exercising. People with large leftovers rated their absolute consumption as lower and walked fewer steps during a subsequent stepper task than people with small leftovers.

Study 3 tested the whole process model. Participants saw an image of the remainder of a chocolate bar resting on its wrapper with six squares had been eaten from the whole, and either three, six, 14, or 22 squares left. They were asked to imagine vividly having eaten the chocolate bar down to what they left of it. The larger the amount leftover, the lower was people's perceived consumption the lower were their negative self-evaluative feelings (guilty/regretful/shameful), and the lower was their motivation to compensate (eat less/work out/work out longer). Indeed, perceived consumption and negative self-evaluative feelings serially mediated the effect of leftovers on motivation to compensate.

In sum, across real and imagined consumption, we find that, holding actual consumption constant, larger amounts of food leftovers lead people to feel they consumed less. Importantly, this reduces real consequential compensatory behaviors—larger leftovers lead people to eat more and exercise less because perceiving lower consumption bolsters self-evaluative feelings, which in turn undermines their motivation to compensate.

This research reveals that food leftovers—that is, unconsumed food—can exert meaningful influence on consumers' perceptions, affect, motivation, and important health-related behavior. Aside from making yet another case against growing portion sizes, these findings highlight that proudly foregoing half one's meal may actually backfire and subtly undermine subsequent healthy behaviors. Implications for how consumers may better deal with leftovers to prevent or reduce this effect should be investigated.

It's Not You, It's Me: Consequences of Charitable Support Allocation on Consumer Prosocial Identity and Subsequent Support Behaviors

Kirk Kristofferson, Arizona State University, USA
Katherine White, University of British Columbia, Canada
Darren W. Dahl, University of British Columbia, Canada
Cait Lamberton, University of Pittsburgh, USA

EXTENDED ABSTRACT

The debate regarding non-profit fiscal practices continues to grow. Difficult economic conditions have prompted charitable organizations to implement large-scale marketing programs and attract highly skilled leaders. Whether salient to consumers or not, the funds to support these initiatives come from consumer support. The current research examines what happens to consumers' own prosocial identity and to their subsequent charitable contributions when they realize that less of their initial donation than expected has gone to the recipients of a charitable cause. While some research suggests that consumers might protect their identities by giving themselves credit for intending to act prosocially (Kruger and Gilovich 2004), we make the novel proposition that learning that support allocation (i.e., the amount of donation going to the charitable cause) was lower than expected can lead consumers to see themselves as less prosocial which also leads to decreased future prosocial action.

We define prosocial identity as the perception of how prosocial one perceives him/herself to be. On the one hand, research suggests that low support allocation information may not affect prosocial identity or future support due to the motivation to protect the self from ego or identity threats. For example, research finds that consumers judge their actions based on the impact they *intended* to make rather than actual performance (Kruger and Gilovich 2004). Alternatively, research also suggests that consumers may *internalize* this prosocial identity threat and reduce subsequent support. For example, research has shown that situational factors may positively or negatively impact prosocial identity and subsequent behavior (Aquino et al. 2009; Bandura 1991).

We make the novel prediction that after providing meaningful support for a charitable organization, consumers will perceive *themselves* to be less prosocial upon learning that less of their support went to cause recipients. We propose this novel process occurs because low allocation information reduces the positive benefits received from believing one's support made an impact in the lives of others (Aknin et al. 2014). Moreover, we propose this decreased prosocial identity process will reduce subsequent support not only for the supported organization, but also future support behavior. Thus, managerial decisions made by one organization may have detrimental effects on the success of others.

Study 1 documented our proposed model. After imagining supporting a charity, participants (n = 101) read one of two versions of a press release that outlined how funds were allocated between cause recipients (High = 91%, Low = 31%) and costs. Participants exposed to the low (vs. high) allocation information showed a decreased prosocial identity ($p < .05$), as well as lower likelihood of future support ($p < .05$, significant mediation).

Study 2 showed support for our decreased prosocial identity prediction by introducing an expectations moderator designed to elicit external attributions (Design: 2 (Allocation: Low, High) x 2 (Expectations: Control, High). Participants (n = 266) followed the procedure of study 1 but received an expectations manipulation prior to the allocation information. Participants in the control (high) condition read that similar charities allocated between 30-50% (90-100%) of support to recipients. Results revealed the predicted interaction.

Low (vs. high) allocation participants showed a reduced prosocial identity in the control condition which reduced support for both the previously supported and unrelated charities; no differences emerged when expectations were high (significant conditional indirect effect).

Study 3 introduced a task to bolster prosocial identity and used a (Design: 2 (Allocation: Low, High) x 2 (Bolster: Present, Absent). Participants (n = 170) first completed an effortful charitable volunteer task for a real charity for 20 minutes. Participants next read the press release manipulation, then performed the bolster essay task in which they wrote about a time they performed a charitable act (Present) or what they ate for lunch yesterday (Absent). Finally, participants completed prosocial identity and subsequent support measures. The predicted interaction emerged. Participants in the bolter absent condition exhibited the identity consequence (Low < High), which predicted a reduced support when allocation, but no differences emerged among bolstered participants.

Study 4 provided direct evidence for reduced prosocial identity using a repeated-measures design. Further, we ruled out deception as an alternative explanation (Darke and Richie 2007). Prosocial identity data was collected in two phases: first (via pre-survey) and last (lab experiment) weeks of the semester, resulting in a 2 (Allocation: Low, High) x 2 (Prosocial Identity: Pre-, Post-Support) mixed design. Participants (n = 135) completed the real volunteer task from study 3, read one of the two press releases, then completed post-support identity measures. Participants also indicated feelings deception and betrayal. At the end of the session, participants received a support request from a different non-profit. A significant interaction emerged ($p < .05$). Participants exposed to the low allocation information showed a direct reduction in prosocial identity ($p < .05$), but no difference emerged when allocation was high. Reduced prosocial identity then predicted lower agreement to help the unrelated organization ($p < .05$). Support allocation had no effect on feelings of deception or betrayal.

Study 5 reconciled our framework with action and intention research by introducing a novel moderator: support success. We predicted that when participants failed to meet their intended support, they give themselves credit for their intentions. However, after successfully supporting, we expected our prosocial identity consequence. Participants (n = 124) completed a modified form of the cold pressor task in which they submerged their arms in freezing water for 10 minutes to earn $10 for a charity. A separate group watched videos of participants completing the task, resulting in a 2 (Allocation: Low, High) x 2 (Support Success: Success, Failure) + 1 (Observer) design. After the support task, participants completed prosocial identity items. As expected, participants succeeding in supporting the organization showed a lower prosocial identity after exposure to low (vs. high) allocation information ($p < .05$), but failing participants showed no differences ($p > .65$). Analysis of observer ratings showed that participants who failed (succeeded) gave themselves credit for intentions and rated their identities as higher (lower) than observers judged them to be, thus rectifying our novel process with previous work.

Positive Effects from Negative Virtual Experiences:
How Virtual Reality Can Be Used Effectively in Marketing

Kirk Kristofferson, Arizona State University, USA
Michelle Daniels, Arizona State University, USA
Andrea Morales, Arizona State University, USA

EXTENDED ABSTRACT

Virtual reality (VR) technology is coming, and consumers are projected to spend over $5 billion in 2016 (Grubb 2016). Producers such as Samsung and Google are pushing VR hardware to consumers for extremely low cost, and content designers can now create and distribute VR content to consumers by streaming directly to smartphones (Pierce 2015). Brands and marketers have also leaped in head first under the assumption that the technology's increased immersion or transportation will engage consumers and increase sales (Escales 2004a, 2004b, 2007). However, no research has examined how the VR transportation actually occurs, or how marketing might be able to use it most effectively. This research seeks to take the first step in understanding the impact of this emerging technology by investigating the psychological processes that lead consumers to experience increased transportation in VR environments, and the downstream marketing consequences that this can have.

We make the novel prediction that increased transportation in VR over traditional two-dimensional (2D) media is driven by heightened orienting responses associated with emotion experienced through the VR environment; more specifically, the point of reference change from observer to actor (Hung and Mukhopadhyay 2012). Moreover, we predict that increased transportation resulting from orienting reactions will increase consumer intentions to engage in and support the same experience in the real world compared to a parallel 2D experience. Importantly, we demonstrate that the positive downstream consequences of VR can be driven by both positive and negative emotional content. In all studies, we contrast a VR medium with a 360-degree 2D medium. Thus, both formats are novel, cutting-edge tactics currently being explored by marketers, yet never tested theoretically for effectiveness.

Study 1 demonstrates that VR can lead to higher orienting reactions than 2D using a fear response. Participants (n=101) watched an aerial tour of Icelandic landscapes in VR or 2D. Shortly into the experience, the helicopter flew over a cliff exposing a rushing river below. The experimenter instructed participants to look down and step forward, giving the perception of stepping into the river below. Orienting fear responses (e.g., hesitation) were coded and as predicted, participants in VR (vs. 2D) exhibited significantly higher fear responses ($p < .0001$).

Study 2 shows support for our full framework using a different emotional response (protective). Participants (n=124) watched a video in either VR or 2D created to elicit a protective orienting response. When the video started, a man walked towards the camera to start a conversation. He *nonchalantly* turned away, then turned back and punched the camera. The camera snapped backwards then returned to its original position to mimic an individual taking a punch to the head. Upon completion, participants completed measures to assess how transported they felt in the environment. As predicted, VR (vs. 2D) participants exhibited higher protective responses (e.g., flinch, duck, $p < .01$) and reported higher transportation ($p < .01$). Supporting our framework, the indirect effect was significant.

Study 3 demonstrates our conceptual process using orienting responses associated with a positive emotion and extends our investigation to the downstream marketing potential. Undergraduates (n=123) participated in this study for $5. Participants watched a video in VR or 2D about a real non-profit endangered species conservation organization. The video showed a baby rhino drinking her morning bottle and elicited a happiness response. In the video, participants perceived to be standing beside the rhino in her pen with the curator. Upon completion, participants completed transportation measures. At the end of the study, they were given the chance to donate their $5 payment to the organization. As predicted, VR participants exhibited a significantly higher positive emotional response ($p < .001$) and reported significantly higher transportation ($p < .001$). Replicating study 2, the indirect effect was significant. Next, we found that VR participants were significantly more likely to donate their payment ($p < .01$), and that this higher support was driven by perceived transportation in VR. To test whether our proposed process led to the higher donation behavior, we performed a serial mediation analysis to test the indirect effect of media type on organizational support through emotional response and transportation. The serial indirect effect was significant at the 90% level, suggesting that it is in fact the stronger emotional responses consumers experience in VR that leads to the increased transportation, which then leads to higher subsequent support behavior.

Study 4 provides further process evidence through moderation using a negative orienting response (fear) and an experiential product. Because our theorizing proposes that it is the orienting responses driving transportation and persuasion, anything that weakens the degree to which consumers experience emotional reactions in VR should mitigate the observed increased presence. In Study 4, we operationalize this by using participants' fear of heights as a moderating factor. Participants (n=102) watched a video we created to elicit a fear response. The video took place on the edge at the steep mountain peak of Camelback Mountain. Participants were instructed to look down and take step off the cliff; afterwards they completed transportation measures, indicated their fear of heights, and finally their desire to hike Camelback in the near future. Results revealed that VR elicited significantly higher orienting fear responses than 2D among participants with moderate to high fear of heights, but not among individuals with no fear of heights. The results on transportation were identical, showing support for our claim that orienting reactions are necessary to elicit transportation in VR. Finally, increased transportation predicted a higher desire to seek out the featured real-world experience.

We provide the first investigation of the impact VR can have in marketing. We demonstrate that it is the heightened orienting responses experienced in VR that lead to increased transportation in VR versus 2D media. We show this process results from both positive and negative emotional content, and that increased transportation does not occur when the orienting response is not realized. Finally, we demonstrate that the increased presence in VR leads to increased support for the promoting organization and a higher desire for the real life experience.

The Effects of Self-Identity Activation and Emotions on Donation Decisions

Canice M. C. Kwan, Lingnan (University) College, Sun Yat-Sen University, China
Robert S. Wyer, Chinese University of Hong Kong, China

EXTENDED ABSTRACT

Sensitizing people to their self-identity at the time they receive an appeal for help can influence their compliance with this request (Hung and Wyer 2014; Langer and Abelson 1972). There are contingencies in this effect. Hung and Wyer (2014), for example, found that calling individuals' attention to themselves increased their willingness to help in-group members but decreased their willingness to help out-group members. This effect could simply reflect the use of similarity as a heuristic for decisions when the criterion is salient. However, it could also affect the subset of self-relevant knowledge that is salient to them at the time a donation decision is made and is used to interpret the situation at hand. This interpretation, and the emotional reactions it elicits, could mediate helping decisions.

The present research investigated the effects of activating self-identity on the use of these criteria and the emotions they elicit. We showed that when individuals are conscious of their self-identity at the time they receive an appeal, their donation decisions can be mediated by both empathy-induced distress and feelings of anticipated guilt. However, the effects of these reactions differ, depending on both characteristics of the victims and the perspective from which the situation is viewed.

IDENTITY ACTIVATION AND THE IMPACT OF EMOTIONAL REACTIONS

At least two types of emotions can mediate the impact of a donation appeal. First, people who feel socially close to victims may empathize with them and their donation decisions might be based on the feelings of distress resulting from this empathy (e.g., Aron and Aron, 1986). Second, these decisions can be influenced by perceptions of responsibility (e.g., Lowenstein and Small 2007) and the anticipation of feeling guilty if individuals do not fulfill their responsibility (Carlson and Miller 1987).

However, the effects of both empathy and obligation perceptions on donation decisions can depend on both (a) characteristics of the victims and the situation confronting them and (b) the accessibility of the self-knowledge used to interpret these characteristics. People's empathy, for example, may depend on their perceived connectedness to the beneficiaries. This, in turn, could be influenced by their interpretation of the beneficiaries as valued in their society at large. To this extent, empathy is likely to depend on the accessibility of self-knowledge that is relevant to the assessment of this connectedness. The assessment of one's personal obligation may likewise depend on the nature of these persons. However, it also depends on whether concepts associated with this normative obligation are called to one's attention at the time a donation decision is made.

Relatedly, Kettle and Häubl (2011) found that merely signing one's name was sufficient to activate people's self–identity and to increase the accessibility of self-knowledge. However, which aspects of this knowledge are likely to be applied in making judgments also depend on features of the situation at hand. When aspects of self–identity have implications for their behavior in a situation, priming their identity is likely to call attention to these implications. If their identity is not activated, however, concepts associated with these roles may not be applied.

EXPERIMENTS AND RESULTS

In Experiment 1 (N = 110), (Chinese) participants received an appeal for donations to help victims of child-trafficking. In this case, the victims were either Chinese (in-group members) or African (out-group members). Results yielded a significant interaction of self-identity priming and victim ethnicity ($F(1, 106) = 4.95$, $p = .028$), suggesting that activating their self-identity increased participants' donations to Chinese victims (from HK\$111 to HK\$164) but decreased their donations to African victims (from HK\$135 to HK\$61). These findings were accompanied by a similar interaction on disposition to empathize ($F(1, 106) = 4.87$, $p = .029$). Thus, this study provided evidence that the effects of identity activation depend on contextual factors that exist in the situation at hand.

Experiment 2 (N = 109) examined the specific emotions that mediate donation decisions and the impact of self-identity activation on the elicitation of these emotions. In this case, the victims to be helped were endangered species that were culturally desirable, undesirable, or irrelevant to (Asian) participants (sharks vs. snakes vs. dolphins, respectively). Results indicated that priming self-identity increased participants' disposition to preserve sharks (from HK\$67 to. HK\$74; $F(1, 98) = 3.31$, $p = .072$), decreased their disposition to preserve snakes (from HK\$46 to HK\$26; $F(1, 98) = 3.25$, $p = .075$) and had little impact on their disposition to preserve dolphins ($F < 1$). Results of bootstrapping showed that empathic distress mediated the effect of self-identity priming on the donations to snakes (95% CI: -2.0778 to -.2874; based on 5000 samples) but not sharks (95% CI: -.0657 to 1.9921). In contrast, guilt mediated the effect on the donations to sharks (95%CI: -1.4441 to -.0213) but not snakes (95%CI: -.3189 to .4489).

In Experiment 3 (N = 73), we conducted a 2 (signature: signing own name vs. signing another's name) x 2 (perspective: situation vs. donor) experiment. After the handwriting task, participants received an appeal to help victims of child trafficking. Some described either how the victims' situation occurred (situation condition) whereas others described either how they should help (donor condition). Activating self-identity increased donations when participants took the perspective of a donor (from HK\$72 to HK\$133; $F(1, 69) = 14.19$, $p < .001$) but had no impact on donations when they focused on the situation confronting the victims (HK\$82 vs. HK\$73; $F < 1$). Results of bootstrapping indicated two significant mediation pathways: (a) self-identity priming → perceptions of obligations → guilt → donations (95%CI: .0014 to .5552) and (b) self-identity priming → disposition to empathize → empathic distress → donations (95%CI: .0927 to 1.0145).

In summary, unobtrusively activating people's self-identity can have a significant impact on their responses to a donation appeal. These effects are mediated by different emotional reactions that depend on both (a) whether the potential beneficiaries are personally relevant and (b) whether recipients consider themselves as a donor at the time they encounter the appeal or focus on the situation confronting the victims.

The Impact of Hierarchical Decisions on Choice Extremeness

Jing Lei, University of Melbourne, Australia
Ying Zhang, Peking University, China

EXTENDED ABSTRACT

When consumers make a choice from a large number of alternatives, instead of viewing all available options at once and arrive at a final choice in one step, they often engage in a hierarchical decision process (e.g., Hauser 1986; Tversky and Sattath 1979). In the present article, we explore how making hierarchical choices (vs. one-step ones) impacts the extremity of consumers' preference in situations where alternatives are grouped into subsets trading off on two key attributes (e.g., tastiness and healthiness of food items). Although there is ample evidence showing that consumers tend to be loss-averse and opt for the middle-options when choosing from alternatives trading off on two attributes (e.g., compromise effect, Simonson and Tversky 1992; Simonson 1989), what remains relatively unclear is whether the same effect holds when they follow a hierarchical decision process.

Our research suggests that the choice following a hieratical process would differ significantly from the original one in a one-step choice. We build our investigation on the theory of goal-based choice (e.g., Barsalou 1983; Dhar and Simonson 1999) and the theory of self-perception (e.g., Bem 1967; 1972) and propose that, as compared to a one-step decision, a hierarchical decision provides consumers with the opportunity to identify their preference such that they would behave in a way that is consistent with the initial choice, resulting in more extreme final choices. This hypothesis is derived on the notion that people form their attitudes and preferences partially by inferring from their own behaviors, especially when the attitudes/preferences are weak or ambiguous (Bem 1972; Schnall and Laird 2003). To the extent that in a typical trade-off context all attributes involved are important, consumers tend not to hold a strong, pre-existing, or fixed preference. This ambiguity in preference, in turn, leads to compromises that are acceptable on all dimensions when people need to trade off on multiple attributes in a one-step decision (e.g., Simonson 1989; Simonson and Tversky 1992). However, in a hierarchical decision context, the initial choice for a category in some ways forces consumers to declare a preference between the competing attributes and choose a subset dominating in one of the attributes. Phenomenally, we should expect that, compared with a one-step choice, individuals are more likely to go for the extreme options in a hierarchical choice context.

Study 1 (n=172) was conducted with undergraduate students using a 2 (decision process: one-step vs. two-step) x 1 between-subjects design. All participants were asked to choose a snack as the reward for a filler study. In the one-step condition, participants chose from 4 snack options (A to D: whole natural almonds, slated roasted almonds, multigrain chips, and classic chips). In the two-step condition, participants chose between almond and chips snacks first, and then chose within the selected subset. The results showed that there was a significant increase in the choice share of the extreme option A (38.71% to 61.70%, Z = -1.98, p<.05), and a decrease in the middle option B (61.29% to 38.30%) in the two-step (vs. one-step) condition. Similarly, there was an increase in the choice share of the extreme option D (46.88% to 85.48%, Z = -3.96, p< .01) and a decrease in the middle option C (53.13% to 14.52%) in the two-step (vs. one-step) condition.

In study 2 (n=201), we directly manipulated the trade-off between two attributes using a 2 (decision process: one-step vs. two-step) x 1 between-subjects design with Mturk workers. They were instructed to solve as many puzzles as they can within 2 minutes. They were also told that viewing color patterns with calming or alerting effects can help solve puzzles. In the one-step condition, participants were asked to choose from 6 color patterns (A to F) with the calmness and alertness ratings. In the two-step condition, participants first chose between "patterns that make your mind calmer" and "patterns that make your mind more alert", and then chose a pattern within the selected subset. The results replicated our findings about the extremeness effect in study 1.

In study 3 (n=238), we tried to eliminate the extremeness effect using a 3 (decision process: one-step vs. two-step free-choice vs. two-step random-choice) x 1 between-subjects design with Mturk workers. In the one-step condition, participants chose a snack from four options of almonds. In the two-step free-choice condition, participants first chose between "original almonds" and "almonds with coatings", and then chose within the selected subset. In the two-step random choice condition, participants first chose between the two types of almonds by flipping a coin and then chose a snack from it. The comparisons between the one-step and the two-step free choice condition replicated our earlier findings about the extremeness effect. The comparison between the one-step and the two-step random-choice condition showed that, the increase in the choice share of the extreme option A (natural raw almonds) in the two-step random-choice condition was not significant (45.24% vs. 36.84%, Z = 0.80, p > .20), neither was the decrease in the choice share of the middle option B (low salted roasted almonds) (54.76% vs. 63.16%, Z = 0.80, p > .20). Similarly, the changes in the choice shares of options D and C were not significant. These results showed that, while a two-step process can make people choose more extreme options, it is on the condition that the subset decision is not attributed to an external (random) factor.

First, our research shows that when consumers make a single choice, breaking this task into multiple steps of a hierarchical process (e.g., subset decision and final choice) can make them focus on a particular goal and choose extreme options to highlight the goal. Our research also indicates that consumers need to re-evaluate the benefits of a compromising versus a maximizing strategy in their decisions. It seems intuitively wise to choose the middle options when consumers make trade-off decisions between two important aspects/attributes. However, in the cases when we are better off having more extreme options, simply changing the decision procedure can help us circumvent the instinct of choosing a compromised option.

Paying More to Save Less:
The Effect of Self-selected Price Bundling on Willingness to Pay

Yi Li, IÉSEG School of Management, France
Tatiana Sokolova, University of Michigan, USA

EXTENDED ABSTRACT

Price bundling is a prevalent marketing practice, where consumers receive a discount if they purchase two or more products together (Stremersch and Tellis 2002). Prior research has not investigated a specific type of price bundling in which retailers only fix the total number of products included in the bundle, and consumers can decide which products to put in the bundle, which we term "self-selected price bundling". Compared to price bundling with fixed bundled goods, self-selected price bundling can reduce the risk that consumers will react negatively to a perceived constraint of their freedom of choice (Bertini and Dholakia 2009) and decrease the likelihood that consumers will update their internal reference prices for the discounted goods (Raghubir 2004). Despite these advantages, self-selected price bundling gives retailers little control over which products consumers are going to purchase and how much they are going to spend on the bundle. Therefore, the current study attempts to understand consumers' spending decisions under the self-selected price bundling promotion.

In order to investigate consumers' spending decisions, we compare two simplest forms of self-selected price bundling: (A) buy two items, get *a discount on both items*; and (B) buy two items, get a *discount on the cheaper item*. Between these two promotions, at any given price discount, the "discount on both items" (hereafter "DoBI") promotion generates greater absolute savings than the "discount on the cheaper item" (hereafter "DoCI") promotion. If consumers' spending decisions are driven by the absolute savings, they should spend more when offered DoBI promotion than DoCI promotion. Two experiments showed the opposite spending outcome.

Study 1A adopted a single-factor (DoBI vs. DoCI) between-subject design. Participants read that they were shopping at a large apparel store, which offered a promotion: "*If you buy two items, you get a 40% discount on both items [on the cheaper of the two items]*". They had decided to buy a jacket that cost $50 and to purchase a second item in order to take advantage of the promotion. They were asked how much they were willing to spend on the second item on a six-item marked scale where 1="less than $10" and 6="more than $60". One-way ANOVA revealed that participants were willing to spend significantly less on the second item in DoBI condition (M=3.3), than in DoCI condition (M=4.1, $F(1, 51)$=6.05, p=.02). Study 1B replicated study 1A using a different price of the first item ($80), a different discount magnitude (20%) and a different type of response scale (a sliding bar anchored on $0 on the left, and $100 on the right). One-way ANOVA revealed again that participants were willing to spend less in DoBI condition ($30 vs. $40, $F(1, 60)$=4.93, p=.03).

Building on the literature in relative thinking and mental accounting, we propose a relative savings account to explain the spending decisions under the self-selected bundling promotion. The purchase of the second item triggers savings, which makes the spending on the second item and the savings on the whole bundle salient. Instead of evaluating the absolute savings, individuals consider whether greater savings on the bundle can be obtained with smaller spending on the second item. This relative savings consideration thus predicts that in DoBI condition, consumers will opt for a low spending on the second item to obtain a steep increase in savings on the first item. In other words, the absolute savings on the first item attracts down the spending on the second item. Therefore, even though DoBI generates greater absolute savings, consumers spend less on the second item in DoBI condition than in DoCI promotion.

Following this theorizing, we expect that consumers' spending on the second item will increase if the absolute savings on the first item is removed from DoBI condition (study 2) and will decrease if some savings is added to DoCI condition (study 3). Study 2 employed a 2 (DoBI vs. DoCI)×2 (control vs. coupon) between-subject design. In the coupon condition, participants read that they would use a coupon to pay for the first item. However, paying with coupon invalidated any savings on the first item. A two-way ANOVA revealed a significant interaction ($F(1, 101)$=4.53, p=.04). The result in the control condition replicated the previous findings (M_{DoBI}=$18, M_{DoCI}=$35, $F(1, 101)$=26.21, p<.001). The difference in spending became marginal in the coupon condition (M_{DoBI}=$26, M_{DoCI}=$33, $F(1, 101)$=3.51, p=.06). As predicted, the spending on the second item increased in DoBI condition after using the coupon ($26 vs. $18, $F(1, 101)$=5.59, p=.02). In study 3, we used a 2 (DoBI vs. DoCI)×2 (cash rebate vs. control) between-subject design. In cash rebate condition, participants received a cash reward conditional on purchasing two items, in addition to the bundle discount, which adds a steep increase in savings to DoCI condition. A two-way ANOVA revealed a significant interaction ($F(1, 137)$=8.99, p=.003). The result in the control condition replicated the previous findings (M_{DoBI}=2.9, M_{DoCI}=5.9, $F(1, 137)$=28.59, p<.001). In the cash deduction condition, there was no difference in spending across promotion formats (M_{DoBI}=4.1, M_{DoCI}=3.7, $F(1, 137)$=.36, p=.55). As predicted, participants in the DoCI condition reduced spending when there was a cash rebate (4.1 vs. 5.9, $F(1, 137)$=8.7, p=.004). Thus, study 2 and 3 provide processing evidence in support of a relative savings account: consumers evaluate their spending on the second item relative to the savings on the bundle and try to maximize the exchange efficiency.

Study 4 tested whether individuals switch to consider absolute savings rather than gain-loss ratios in the joint evaluation mode, providing that previous research shows the reliance of absolute versus relative evaluation is sensitive to evaluation mode (Bartels 2006; Hsee and Leclerc 1998). Study 4 employed a one-factor (DoBI vs. DoCI) within-subject experiment. Participants read both promotions and predicted consumers' spending on the second item in each promotion respectively. A pair-wise t-test showed that participants predicted consumers spend more in the DoBI condition (M=$66.05) than in the DoCI condition (M=$44.86, $t(21)$=4.04, p=.001), which was opposite to the findings above. This finding suggests that store managers may adopt a seemingly superior promotion which actually motivates consumers to spend less.

Cognitively Optimized Measurement of Preferences

Ye Li, University of California Riverside, USA
Daniel Wall, Rutgers University, USA
Eric Johnson, Columbia University, USA
Olivier Toubia, Columbia University, USA

EXTENDED ABSTRACT

Researchers, managers, and policy-makers are increasingly interested in measuring individual differences to predict behavior in the field. From measuring time and risk preferences in economics to contingent valuation in environmental science and policy, and from consumer surveys to conjoint analysis in marketing, predicting people's behavior is a big deal.

Every time we ask a respondent a question, we do two things: (1) We obtain data about some parameter(s) of interest, such as their discount rate or the part worth of a product attribute, and (2) We expend some of the respondent's limited attentional resources. This paper focuses on the tradeoff between additional precision and the depletion of attentional resources.

The intersection of precision and depletion is of increasing interest because of two related applications: The first is preference elicitation. Marketing has expended considerable effort to study how to model choices in one environment in order to predict choices in another. A good example of this is the use of conjoint analysis in new product design. The problem of how many questions to ask to get the best model is central to designing elicitation procedures. A related version of this question arises when we use adaptive procedures thought to minimize respondent fatigue (e.g., Green et al 1991; Toubia et al 2003).

The second application is more general: To test theories, researchers in marketing and psychology have increasingly turned to asking respondents to make many decisions. Several different trends have led to an increased use of many elicitation questions: More complex models require more observations as the number of parameters increases, and new techniques, such as functional magnetic resonance imaging (fMRI), demand many decisions to overcome noise in the desired physiological signals.

Both of these developments raise a general concern about the changes that occur as we ask respondents more questions. By asking more questions, are we changing the underlying process by which respondents answer them? A specific concern about the effects of answering questions on attention is ego depletion (Baumeister, Bratslavsky, Muraven, and Tice 1998), an idea originating in the social psychological literature. Perhaps, as respondents use this scarce executive resource to answer more questions (Vohs et al. 2008; Wang et al. 2010), they will move toward simpler, heuristic processes that may differ from those used for decisions in the real world application (Pocheptsova et al. 2009). For example, Levav and colleagues (2010) found that asking more questions increases the acceptance of defaults by the decision-maker, particularly when those questions are cognitively difficult.

In this paper, we develop a framework for understanding the tradeoff between additional signal and noise. Our goal is to help identify *a priori* changes in the underlying decision processes that might occur with more questions answered and how those changes will affect the reliability and validity of the models that are estimated on the data. One more specific goal of this research to help researchers thing about the best number of questions to ask, a term we will call q^*, in various situations.

We first develop a conceptual model that will generate predictions and insights to test in a series of three experiments that measure time preferences. We focus on time preferences for several reasons: (1) they are among the strongest individual difference predictors in the social sciences (Chabris et al 2008; Reimers et al 2009); (2) they are usually measured using minimal external information, often as binary intertemporal choices between a smaller outcome that is available sooner (e.g., $50 in today) and a larger outcome that is available later (e.g., $60 in 1 month); (3) there is a rapidly growing literature of both descriptive and normative models; and finally (4) they have become increasingly important in marketing, particularly in areas as diverse as food choice and consumer finance. We conclude by discussing general implications for preference measurement.

CONCEPTUAL MODEL

To study how repeated questioning may affect the reliability and external validity of preference measurement, we first develop a stylized model. In particular, we are interested in exploring conditions under which reliability and/or external validity may in fact decrease after some number of questions. The conditions we explore relate to the level of response error, the efficiency of the questions, the amount of variations in heuristics across decision makers and across sessions, and the speed with which respondents adopt heuristics within a session.

Our model reflects two countervailing forces that vary as the number of questions increase. First, more questions provide more data, which reduces the standard error of parameter estimates—i.e., estimates converges to some value. Second, more questions may increase the intensity of heuristic use, which may introduce bias. In other words, as more questions are added, our estimates become more precise (i.e., they have less standard error and converge to some value), but also potentially more biased (i.e., the value to which they converge may be further from the truth).

In this setting, we argue that a respondent, as they become fatigued or disinterested, might be tempted to adopt a heuristic. For example, for intertemporal choices, they may see if the difference in money is proportionally smaller or larger than the difference in time and chose the later option only if the payment seems to justify the wait, a heuristic that has recently gained significant empirical support (Marzilli et al 2015; Scholten and Read 2010; Scholten, Read, and Sanborn 2014). While such data will provide a clear estimate of the parameter in this estimation setting, the parameter that we estimate may not apply to situations when that heuristic is not used. For example, perhaps decisions to delay are made in advance so the smaller sooner is not available now. This removes any overweighting of the immediate reward, or present bias, from the decision, a factor that is confounded in the estimation procedure we have described. Alternately, in the actual savings decision, the time frames might be described in years or in terms of a specific date, and a different heuristic might be used in these circumstances (LeBoeuf 2006; Read et al 2005). If this is true, the increased accuracy that might be offered by asking more questions might be diminished or even offset by the increased use of heuristic processes.

Formally, we assume that Y_i varies with true individual parameters, denoted by X_i, and allow for idiosyncratic variations, reflected by a normally-distributed error term, ε_i:

$$(1) \quad Y_i = X_i + \varepsilon_i, \text{ where } \varepsilon_i \sim N(0, \sigma_\varepsilon)$$

We consider a researcher who tries to predict Y_i based on an estimate of X_i, generated by asking respondents questions (e.g., in-

tertemporal choices), a process which is potentially repeated over multiple sessions. $\hat{X}_{iwq}$ is the estimate of X_i for decision maker i in session w after question q. $\hat{X}_{iwq}$ reflects the two countervailing forces mentioned above: additional questions lead to convergence, but the quantity to which the estimate converges may become increasingly further from the truth due to the use of heuristics. In particular, as decision-makers answer questions, decision-makers may switch to a cognitively less demanding heuristic. This heuristic may use a subset of the information or make attribute-based comparisons rather than calculate expected utilities, and therefore using the heuristic produces estimates that may differ from X_i. If heuristic use is systematic, the result may be a biased estimate of X_i.

We denote the *potential* bias introduced by the use of heuristics as β_{iw}. The *actual* bias is likely to increase as the questionnaire progresses, and to converge to the potential bias as the number of questions increases. Therefore, we weigh β_{iw} by a function $\sqrt{\alpha(q)}$ which is non-decreasing in the number of questions.

With these assumptions, the combined effect of the true underlying value X_i and the use of heuristics after q questions is: $X_i + \sqrt{\alpha(q)}\beta_{iw}$. One the other hand, asking more questions reduces the standard error of the estimate—i.e., there is convergence with more questions. Respondents likely report their preferences with error, leading to imperfect estimates. However, as respondents answer more questions, estimates converge to the underlying construct, $X_i + \beta_{iw}$. We model this convergence using an additional normally-distributed error term, . To reflect the idea that estimates converge within a session, we model the variance of η_{iwq} as decreasing in q, that is, we assume: $\eta_{iwq} \sim N(0, \sigma_\eta \sqrt{\gamma(q)})$, where $\gamma(q)$ is a non-increasing function of q.

In sum, we assume that our estimate of X_i for decision maker i in session w after question q, is given as follows:

$$(2) \quad \hat{X}_{iwq} = X_i + \sqrt{\alpha(q)}\beta_{iw} + \eta_{iwq}$$

Where is a non-decreasing function of q, $\eta_{iwq} \sim N(0, \sigma_\eta \sqrt{\gamma(q)})$, and $\gamma(q)$ is a non-increasing function of q. Again, the second and third right-hand terms in Equation (2) capture the two countervailing forces mentioned above: $\sqrt{\alpha(q)}\beta_{iw}$ leads to an increasing bias due to heuristic use as q increases, and leads to a reduction in standard error as q increase.

In interest of space, we skip the proofs and present the most interesting model predictions about reliability and external validity.

Hypothesis 1:   *The use of heuristics can give rise to an eventual decrease in reliability with more questions asked, leading to an inverted U-shaped pattern (i.e., a peak) in reliability*

Hypothesis 2:   *A decrease in reliability with more questions asked is more likely when heuristics vary more across sessions.*

Hypothesis 3:   *A decrease in reliability with more questions asked is more likely when questions are asked in a more efficient manner, i.e., when convergence within a session is faster and/or when the use of heuristics increases at a slower rate.*

Hypothesis 4:   *The use of heuristics can give rise to an eventual decrease in external validity, leading to an inverted-U shaped (i.e., a peak) pattern of external validity.*

Hypothesis 5:   *An inverted-U shaped external validity pattern is more likely when the use of heuristics is more pronounced. Moreover, the peak happens earlier when the use of heuristics is more pronounced.*

Hypothesis 6:   *An inverted-U shaped external validity pattern is more likely when questions are asked in a more efficient manner. Moreover, the peak happens earlier when questions are asked more efficiently.*

STUDY 1: CONCURRENT VALIDITY IN DEEP TIME

Study 1 reanalyzed data from DEEP Time and the time preference external validity task collected by Toubia and colleagues (2013). This task consisted of 20 binary choices between smaller, sooner and large, later cash rewards. To assess external validity for estimated DEEP parameters, participants first completed a different time preference measure similar to the one used in Benhabib, Bisin, and Schotter (BBS; 2010). Specifically, each participant completed eight intertemporal matching questions, specifying the amount of money that would make them indifferent between a smaller, sooner amount and a larger, later amount. Half of the questions required filling out the smaller, sooner amount and half the larger, later amount.

After participants completed the BBS task, they were given the DEEP Time task, as described above. To make choices incentive compatible, 1 in every 100 participants was randomly selected to have one of their chosen DEEP Time alternatives paid for real money at the chosen time. All payments were made electronically.

Results

Concurrent validity

In order to investigate the effect of asking additional adaptive questions, we used the hierarchical Bayes approach to estimate β and δ after each of the 20 DEEP questions. That is, we fit all participants' responses to only the first question, to the first two questions, etc., up to all 20 questions, resulting in 20 sets of β's and δ's for each participant.

To understand the effect of answering additional questions on external validity, we calculated the absolute deviation (in dollars) between participants' actual responses on the BBS task with the predicted responses generated by their QTD model parameters. We then computed the median absolute deviation across the eight BBS questions for each participant, and took the median of each participant's medians. We found similar trends when looking at the mean of each question's median absolute deviation. We repeated this process using the QTD parameters estimated after each of the 20 DEEP time questions.

In order to demonstrate a statistical plateau in validity, we examined Pearson correlations (across the eight external validity questions) between each participant's actual responses and their predicted responses based on QTD parameters after each successive DEEP time question. We then converted these correlations to z-scores using Fisher's r-to-z transformation for ease of comparison, with clear evidence of an increase after the sixth question and no significant change after seven questions. To statistically test the trend, we analyzed a multilevel model on the r-to-z transformed correlations, with participant intercepts and fixed effects for each question order (20 separate effects), thus controlling for the correlated errors within each participant.

STUDY 2: RELIABILITY AND PREDICTIVE VALIDITY FOR REAL-WORLD TASKS.

In Study 2, in addition to measuring concurrent validity as a function of number of questions asked, we examined *predictive validity* by see how well DEEP Time parameters predicted self-reports of field intertemporal choice behaviors across health, financial, and personal domains (e.g., flossing, smoking, savings, and credit card repayment). We also assessed *test-retest reliability* by comparing participants' responses on two sessions separated by 4 months.

Methods

We reanalyzed data obtained from Bartels & Li (2015), who recruited a large, broadly sampled set of 1308 participants (542 female, ranging in age from 18 to 86, with a mean age of 40.91) including 603 from Amazon Mechanical Turk and 705 from Pureprofile (a market research firm).

Data consisted of DEEP Time data as a part of a larger study on how time preferences relate to field intertemporal choices. In addition to DEEP Time, participants completed a static set of intertemporal choices designed using Item Response theory, which can be used for tests of concurrent validity. Finally, participants self-reported the degree to which they exhibited a variety of field behaviors related to intertemporal choice (e.g. going to the dentist, eating healthily, and saving for retirement). All measures were collected twice, with about 4 months delay between sessions and an 83% retention rate. No time preference, field behavior, or demographic variable predicted attrition from the study. For more details, see Bartels & Li (2015).

Similar to study 1, we used the hierarchical Bayesian method to estimate the DEEP Time estimates after each of 20 questions answered, separately for each session.

Results

Reliability

Test-retest reliability specifically requires that participants' parameters elicited at different times are highly correlated. An important prediction of our model is a plateau or peak in test-retest reliability. This is, in our model, due to the heuristic process dominating the complex process. Test-retest reliability for the QTD beta and delta parameters estimated by DEEP time after each question plateaued after about six questions.

Concurrent Validity

We compared the DEEP estimates after each question to an external intertemporal titrator. Our model of choices predicts that external validity plateaus, or in some cases peaks, due to fact that the heuristic processes is elicitation specific and may not be measuring the "truth."

Using the QTD parameters after each of the DEEP questions, we calculated the estimated indifference point for all of the 12 matching questions, which can be found in the appendix. Then for each question within each participant we calculated the Pearson's correlation between the predicted and actual indifference points, meaning that we had 20 correlations for each of the 1308 participants. Due to skewness we then transformed these correlations via Fisher's r-to-z transformation. Next we ran a multilevel model with fixed effects for each of the 20 DEEP questions and random effects for participant. Fixed effects showed that concurrent validity plateaued at eight questions.

Predictive validity for real-world behaviors

Further in Study 2 we had multiple real world measures of time discounting. We oriented all variables such that higher numbers indicated more patience. For instance, the more often you go to the dentist the higher your score. To determine if the items could

be combined into one measure, we looked at Cronbach's alpha. The raw alpha for all of the items combined was .57. Since alpha was sufficiently large, we z-scored all of the relevant items and combined them into one real world intertemporal behavior factor. Then we ran a multilevel model with fixed effects for each of the questions along with the beta parameters. Predictive validity peaked at six to eight questions for beta and five to six questions for delta.

Discussion

Study 2 expands on Study 1 by reproducing the concurrent validity plateau with a different time discounting instrument. Further Study 2 shows that test-retest reliability peaks at a similar point and that validity with real world intertemporal choices peaks at about 4 questions. We do not, however, see how information acquisition changes as more questions are asked. Study 3 analyzes process data to track the evolution of acquisition across contexts, how these contexts lead to varying choices, and how well parameters within and across contexts predict real world decisions.

STUDY 3: SHIFTING HEURISTICS

While studies 1 and 2 replicate a plateau in predictive validity, they do not indicate why that plateau exists. As the number of questions grows, respondents may, because of fatigue, adopt a simplified strategy that minimizes effort. One version of this fatigue argument might say that respondents respond randomly, at the extreme simply not looking at any information or a small but random subset of information.

If this were the case, we would expect predictive validity to decrease with the number of questions each additional question adds random error to the estimated. The second possibility is that decision-makers adopt a heuristic strategy that simplifies choices, but that is consistent with the preferences established in the first few choices. If this were the case, we would expect predictive validity to remain constant, since each choice simply reflects prior choices and carries very little additional information.

However, to the extent that such heuristics reflect the context used in the experiment, we may see parameters that reflect both true tastes and the context. This suggests a rather interesting hypothesis: That predictions will be better within a context than across contexts.

Methods

Participants

We recruited 533 participants from Amazon Mechanical Turk and used MouselabWeb (Willemsen and Johnson, 2010), a process tracing technique to study information acquisition.

We constructed a set of 16 choices and randomly added or subtracted a small percentage of each of the amounts to make the amounts harder to process. We then generated a random presentation order for the 16 choices. Participants saw two blocks of these sixteen choices in the same random presentation order in a 2 (first block: day vs. hour) x 2 (second block: day vs. hour). The original 16 items were created with days as the time unit. To convert these to hour items we multiplied the number of days times 24. For both days and hours, we labeled today items "now." This was done because we felt that 0 hours has a different connotation than 0 days.). The second block could be consistent with the first block (e.g. if the participant saw hour items in the first block they saw the same items again in the second block) or could be inconsistent (e.g., if the participant saw day items in the first block the saw hour items in the second block.)

We also measured the same self-reports of real-world intertemporal choices as in study 2.

Results

Choices

We ran a multilevel regression with choice as the dependent measure (smaller sooner = 0, larger later = 1) and random effects of participant. We included main effects of context (day vs hour), which block the choice was in (first or second), and whether or not the second block was consistent with the first block (consistent vs. inconsistent), as well as all possible interactions.

Participants made significantly more impatient choices in the hours condition as compared to the days condition. The effect of hour versus day was more pronounced in the first block of choices. This attenuation in the second block could be due to a persistent heuristic which is created in the first block and lasts until the second block.

One of the major advantages of Mouselab Web is that we acquire how participants search. We leverage this advantage to investigate if heuristics develop as more questions are asked. One metric which can be used to describe how people are searching is the Payne Index (PI). The PI is calculated for each choice by subtracting the number of attribute transitions from the number of alternative based transitions then dividing by the sum of attribute and alternative based transitions. A higher PI means that participants make more within option transitions (e.g. a transition between the larger later amount and the larger later time) than between option transitions (e.g. a transition between the larger later amount and the smaller sooner amount).

We also ran a model to see if there was a difference in PI between the first block and the second block. Since choices were shown in the exact same random order we subtracted the block 2 paPI from the block 1 PI to get a measure of how differently participants were acquiring data in the second half. We ran a multilevel model predicting for each choice the difference in PI with varying intercepts for each participant. We also included main effects of what was the first frame that the participant saw (days or hours), whether the second block had a consistent or inconsistent framing with the first block, and an index of the number of choices made, and all possible interactions. The results suggest that participants maintain their heuristic in the consistent condition, but alter it, especially early, when seeing items which have an inconsistent frame.

Buy One Get One to Share: Preference between Bonus Packs and Price Discounts For Experiential Versus Material Products

Sarah Lim, Cornell University, USA
Oona Cha, Chung-Ang University, South Korea
Incheol Choi, Seoul National University, South Korea

EXTENDED ABSTRACT

Previous research on sales promotions has documented that consumers respond differently to economically equivalent price discounts and bonus pack promotions (Diamond and Campbell 1989; Li, Sun, and Wang 2007). However, most research has focused on the perceived economic value of promotional offers, and it remains unclear whether these promotions can offer different non-monetary benefits. This paper examines whether these promotions can entail different social benefits, and how this can change consumers' preferences between price discounts and bonus packs.

From an economic perspective, consumers may derive greater transactional utility from price discounts than from bonus packs (Sinha and Smith 2000). A reduction in cost provides greater savings in terms of the total expenditure than bonus pack offers; this enables consumers to spend the saved money for other purposes. Bonus pack promotions (especially, Buy-One-Get-One), however, can generate a unique social utility that price discount promotions cannot. Namely, an extra product can offer opportunities to enjoy consumption experiences with others, or shared consumption.

We argue that bonus pack promotions would be more likely to suggest shared consumption when offered for experiential goods than for material goods. Caprariello and Reis (2013) highlighted that unlike material products, experiential products are often consumed in the company of other people. Due to this social nature, an extra item for experiential products would be more likely to invite shared consumption, which allows consumers to share their emotions with companions and to build social bonds (Raghunathan and Corfman 2006; Ramanathan and McGill, 2007). However, for material products, the second item in a bonus pack deal would likely be used for the buyer herself, resulting in a superfluous item. Building on this, we propose that consumers' preference will shift toward bonus pack promotions from price discounts in particular for experiential goods rather than material goods.

Study 1 examined whether people prefer bonus pack promotions (vs. price discounts) differently depending on the product type. Participants were shown material or experiential goods with a side-by-side description of a price discount (i.e., 50% off) and a bonus pack (i.e., BOGO). For each product, they were asked to choose between the two options. As expected, participants chose the bonus pack over the price discount more often for experiential products than for material ones (53.1% vs. 25.8%; B = .59, Wald $\chi 2$ = 7.94, p < .01).

Study 2 tested whether this effect is driven by the social benefits associated with bonus pack promotions. The procedure of Study 2 paralleled that of Study 1, except the fact that we manipulated the shared use of bonus packs for experiential goods. Bonus packs for experiential goods were described as to needing to be used on the buyers' next purchase (non-shared consumption) or for an accompanying friend (shared consumption). When bonus packs for experiential products were framed as being for shared consumption, participants were more likely to choose the bonus pack for experiential products (56.2%) than for material ones (14.5%; B = -2.02, Wald $\chi 2$ = 19.31, p < .001). However, this difference in promotion choice was eliminated when bonus packs for experiential products was framed as for non-shared use (14.5% vs. 19.1%; B = .33, Wald $\chi 2$ = .41, p > .5).

Studies 3 and 4 investigated whether the desire for social interaction moderates preference for promotion type. In Study 3, results revealed a significant interaction between extraversion and product type (B = .25, Wald $\chi 2$ = 4.73, p < .05). For experiential products, the more extraverted participants were, the more likely they were to choose the bonus pack over the price discount (B = .40, Wald $\chi 2$ = 4.74, p < .05); however, for material products, the level of extraversion did not predict the promotion choice (B = -.11, Wald $\chi 2$ = .62, p >.4).

Study 4 attempted to further verify the moderating effect of the desire for social interaction by manipulating social exclusion with the Cyberball game task. Consistent with our prediction, a significant social exclusion x product type interaction emerged (B = .28, Wald $\chi 2$ = 5.37, p < .05). For experiential products, participants who were socially excluded chose the bonus pack promotion more often than those who were not (54.9 % vs. 38.2%; B = .34, Wald $\chi 2$ = 3.86, p < .05). On the contrary, for material products, choice of the bonus pack option did not differ between the exclusion and inclusion conditions (19.6 % vs. 27.6%; B = -.22, Wald $\chi 2$= 1.71, p > .2).

In conclusion, this research demonstrates that preference for bonus packs (vs. price discounts) is greater for experiential products than for material ones, and this pattern is attributable to shared consumption of bonus pack promotions. Taken together, this paper highlights the importance of the social benefits associated with sales promotion.

Moderation by Extremes:
Biases in Reward Perceptions Drive Compromise Effects in Financial Bundles

Peggy Liu, University of Pittsburgh, USA
Cait Lamberton, University of Pittsburgh, USA
Kelly Haws, Vanderbilt University, USA

EXTENDED ABSTRACT

"Moderation in all things, especially moderation."
–Ralph Waldo Emerson

Consumers strongly prefer compromise options with medium attribute levels rather than extreme options that are strong on one attribute but not another (e.g., Simonson 1989; Simonson and Tversky 1992). In a typical demonstration, people trading off quality and price prefer a medium quality and medium price option over a high quality but high price option and a low quality but low price option (Simonson and Tversky 1992). Indeed, a recent meta-analysis of 142 experiments showed that this tendency appears is robust across many contexts, study designs, and participant types (Neumann, Böckenholt, and Sinha 2016).

However, middle options in bundles (the simultaneous choice of multiple items) can take more than one form. Herein, we focus on financial portfolios, in which people commonly trade-off attributes of risk and potential reward across multiple items (Kaufmann et al. 2013; Urminsky and Kivetz 2011) and in which encouraging attribute balance is important. Past research on the compromise effect might suggest that people prefer an option with medium risk and medium return (hereafter, "moderate RR") to extreme options with low risk and low return ("low RR") or high risk and high return ("high RR").

Of note, however, the vast majority of compromise effect research has focused exclusively on choice when the middle option consists of a single item. By contrast, we propose that when consumers build portfolios, there is another way to arrive at a middle "balanced" option: a bundle of the extremes—50% low RR and 50% high RR items. Such a "bundle-of-extremes" option objectively has the same average risk and expected reward as a "bundle-of-pure-moderation" consisting of 100% moderate RR items. If people are simply averse to extremes and instead value average risk and average returns, then both options should be similarly valued, as they both offer moderate risk and moderate returns in the aggregate. Thus, the compromise effect should emerge in the same magnitude regardless of whether the middle bundle option is purely moderate or composed of extremes.

However, we propose that the option to select a bundle-of-extremes may lead to a stronger compromise effect than the option to select a bundle-of-pure-moderation. We argue that this will occur because the bundled context changes the way that people evaluate potential reward. Note that a bundle-of-extremes includes both high RR items and low RR items. We propose that people will anchor on the high rewards offered by the high RR items in the bundle-of-extremes, making it particularly attractive as a compromise option, without appropriately accounting for the high risk such potential rewards entail. There are several reasons for this prediction. First, such a pattern may reflect a self-positivity bias (Taylor et al. 2003), wherein consumers believe that positive outcomes will accrue to them, but that their risks of damage are lower than are others'. Second, it is well-established that a general optimism bias exists across many domains (Sharot 2011), which could lead individuals to focus on the upside potential of the reward rather than the downside of the risk involved. Third, people often exhibit motivated reasoning that biases their evaluations (Kunda 1990). Indeed, recent research suggests that aggregate evaluations are influenced less by unfavorable information, such as risk, than by favorable information, such as reward (Peysakhovich and Karmarkar 2016). Such a bias makes the bundle-of-extremes not only justifiable, allowing individuals to avoid an extreme choice either in terms of aggregate risk or reward, but attractive, in that it is perceived to offer higher reward.

Five studies supported our predictions: people were more likely to choose the middle option over the extremes (i.e., show stronger compromise effects) when the middle option consisted of a bundle-of-extremes than when it consisted of a bundle-of-pure-moderation, both with hypothetical stock portfolio allocations (Studies 1, 2, 5) and lottery ticket allocations involving actual monetary outcomes (Studies 3-4). This preference for a bundle-of-extremes over a bundle-of-pure-moderation was robust: it emerged both when only one middle option was available to each participant (Studies 1-4) and when both middle options were available (Study 5); when qualitative information was provided about the different options (Studies 1-3, 5) and when quantitative information was provided, explicitly equating the expected value of the options (Study 4). The results also emerged regardless of various participant characteristics (e.g., financial literacy, income, education).

Moreover, from a process perspective, variety seeking or naïve diversification did not explain this effect (Study 1). Rather, analysis of risk and potential reward perceptions showed that the two middle options were perceived as similarly risky but the bundle-of-extremes was viewed as more potentially rewarding; indeed, perceptions of the potential reward provided by the middle option mediate the effect of the different middle option offerings on choice (Studies 2-3). Given this perceptual bias, we also show that preference for a bundle-of-extremes over a bundle-of-pure-moderation is eliminated either when the bundle-of-pure-moderation middle option's expected value is increased (Study 4) or when people view a side-by-side simulation of potential options over time (Study 5), which allowed consumers to see that the higher risk entailed in a bundle-of-extremes offsets the higher potential rewards that it might offer, leading to the same objective outcome as the bundle-of-pure-moderation.

From a theoretical perspective, this research identifies a new moderator leading to amplification of the compromise effect. Importantly, our work also suggests that people may perceive risk and reward differentially as a function of a portfolio's variance. Accordingly, we introduce a new type of context effect—one in which the variance among aspects of a portfolio alters perceptions of the portfolio's explicitly-stated values. This research also has practical implications. Given that balance is often encouraged in investments, our research sheds light on which type of balance (a bundle-of-extremes or a bundle-of-pure-moderation) is more attractive to people and why. Additionally, our research suggests a practical way to shift people from one type of balance to the other: observing the potential outcomes of a bundle-of-extremes shifts preference to a bundle-of-pure-moderation—seeing the consequences of high variance makes it less attractive than it is in prospect alone.

The Unit Bias:
Evidence for a Categorization Bias in Estimating Quantities

Kailuo Liu, University of Toronto, Canada
Bernd Schmitt, Columbia Business School, USA

EXTENDED ABSTRACT

Consumers all the time estimate quantities as part of their decision making, purchase and consumption activities. For example, when they decide to go on a shopping trip to a supermarket, they may estimate how long it will take to drive to a store; how many candies there may be in a bag on the shelf; how long the tape on a tape-roll may be; and how heavy the shopping bag with the items that they purchased may be. Past research has shown several specific biases in estimating quantities, such as distance (Kang, Herr, and Page 2003), duration (Irmak, Walker, and Bearden 2010), volume (Raghubir and Krishna 1999), product count (Madzharov and Block 2010), area (Krider, Raghubir, and Krishna 2001), and calories (Chandon and Wansink 2007). This paper contributes to this literature by identifying a new and general bias when consumers estimate quantities similar to the examples given above.

We refer to this general estimation bias as the "unit bias." We posit that the unit bias results from the very nature of human categorization. That is, two or more categories do not only suggest or prime differences between the members of these categories (as a lot of prior research has shown); rather, categorization also includes subtle quantitative information, resulting in a heuristic that the components of two units or categories are perceived as having greater combined numeric value than one unit, even though, in reality, both may have the same value.

In seven experiments with five quantities, we show that when two units are contrasted with one, consumers provide longer time estimates, farther distance estimates, higher quantity estimates, longer length estimates, and higher weight estimates. Participants in all studies were recruited from Amazon's Mechanical Turk and randomly assigned to different experimental conditions as parts of between-subjects designs. Study 1 shows that people perceive a longer time walking between two kiosks, compared to walking between two windows within one kiosk, although the distance is the same. Study 2 asks participants to estimate their traveling distance on a train in 12 hours. People believe that they travel a longer distance from 18:00 to 6:00 (that is, over two days) than from 6:00 to 18:00 (that is, during the same day). Study 3 tests the unit bias with estimation tasks of product quantity. Given same weight, participants indicate that two smaller candy bags (weight = 11 oz + 6 oz) have more pieces of candy than one larger bag (weight = 17 oz). They also believe that the individual candy in the smaller bags weighs lighter than the larger bag. Study 4 expands the unit bias to length estimates. In a task to estimate the length of tape rolls, participants believe that the total length of two 4-ounce tape rolls to be longer than an 8-ounce roll. To illustrate the effect in weight estimation, Study 5a asks people to estimate the weight of two full 10L grocery bags (vs. one 20L bag). People believe two smaller bags weigh heavier than one larger bag. Study 5b uses the same between-group design with multiple units: one 30L bag, two 15L bags, three 10L bags, four 7.5L bags, five 6L bags, and six 5L bags. There is a significant linear trend between the estimated weight and unit number. Significant difference is found on the contrasts between one and two bags, and between three and four bags, but not other contrasts.

The final study explores the psychological mechanisms behind the unit bias by examining directly "pure" numbers as such, devoid of any object-related judgment. Specifically, we created random numbers and showed these numbers either categorized or not. That is, one group of participants saw the numbers in different colors, and the other group saw the numbers in black. After seeing all the numbers, both groups were asked how many numbers had been shown to them. Results indicated that the group with the colored numbers perceived to have seen more numbers than the group with all black numbers, supporting our claim that the mere act of categorization includes numeric information.

To summarize, our studies show that when consumers estimate critical numeric values as part of their decision-making process, two units result in a greater combined numeric value than one unit. Moreover, as Study 5b indicated, multiple units may lead to an even higher perceived value. Most importantly, we provide evidence that a categorical heuristics is the key mechanism behind the unit bias. The major contribution of our research is thus the identification of a general estimation bias in multiple domains and demonstration on how this bias operates. Whereas prior research focused on domain-specific effects and biases, including those that may be subsumed under the unit bias (Chandon and Wansink 2007; Irmak et al. 2010), the bias that we identified here manifests itself across a wide range of estimation judgments in which unit information is salient or be constructed ad hoc as salient (Barselou, 1983). This research thus contributes to consumer categorization theory by providing evidence for a new type of categorization effect, resulting from the activation of quantitative information inherent in categorization. Consumers seem to use this subtle information as a judgmental anchor to make numeric estimation judgments (Tversky and Kahneman, 1974).

Less Willing to Pay but More Willing to Buy:
Preference Reversals for Freebie and Non-Freebie Bundles

Zoe Y. Lu, University of Wisconsin - Madison, USA
Christopher K. Hsee, University of Chicago, USA

EXTENDED ABSTRACT

Normatively, both willingness-to-pay (WTP) and willingness-to-buy (WTB) reflect individuals' underlying preferences, and should yield the same preference order (Shafir 1993). For example, if individuals are willing to pay more for A than for B, that means they value A over B. Then, if the prices of A and B are the same, they should also be more willing to buy A than to buy B.

However, in the current research, we propose that holding items in a bundle constant, individuals' preferences for a freebie bundle (in which one or more items are designated as free) and for a non-freebie bundle (in which no items are designated as free) can reverse between WTP and WTB. Specifically, relative to individuals who encounter the non-freebie bundle, individuals who encounter the freebie bundle will indicate a lower WTP for the bundle, but a higher WTB for the bundle at a given price.

The reason, we propose, is that individuals base their WTP and WTB decisions on their inferences of the value of the bundle. When asked about WTP, individuals are not told about the price of their bundle, and will use their general knowledge about other products in the same category to infer the value of their bundle. Consequently, holding items in a bundle constant, individuals who encounter the freebie bundle will perceive the value of their bundle to be at least the same as individuals who encounter the non-freebie bundle; since part of their bundle is marked free, they will indicate a lower WTP price for their bundle. By contrast, when asked about their WTB, individuals are told about the price of their bundle, and will use the given price to infer the value of their bundle. Consequently, holding items in a bundle constant, individuals who encounter the freebie bundle will perceive the value of their bundle to be higher than individuals who encounter the non-freebie bundle (Simonson, Carmon and O'curry 1994; Thaler 1985), and therefore indicate a higher WTB at the given price.

Moreover, we propose that consumers will show not only a preference reversal between WTP and WTB, but also within each elicitation method. Specifically, if WTB is elicited directly, individuals encountering the freebie bundle will indicate a higher WTB at the given price than individuals encountering the non-freebie bundle; if WTB is elicited after WTP, individuals encountering the freebie bundle will indicate a lower WTB at a given price than individuals encountering the non-freebie bundle. Likewise, if WTP is elicited directly, individuals encountering the freebie bundle will indicate a lower WTP than individuals encountering the non-freebie edition; if WTP is elicited after WTB, individuals encountering the freebie bundle will indicate a higher WTP than individuals encountering the non-freebie bundle.

Five experiments, covering diverse contexts, tested our propositions.

In Study 1, participants (N=200) were randomly assigned to one of four conditions that constituted a 2 (bundle type: non-freebie versus freebie) x 2 (elicitation method: WTP versus WTB) factorial design. The stimulus was a twin-pack body wash. In the freebie condition, one of the two bottles was marked as "Free"; in the non-freebie condition, neither was marked as free. In the WTP condition, participants indicated how much they were willing to pay for the twin-pack of body wash; in the WTB condition, participants were told the price of the twin-pack was $12 and asked to rate how willing they were to buy it on a 7-point scale. The results demonstrated the predicted preference reversal: Participants were willing to pay more for the non-freebie bundle than for the freebie bundle ($t(100) = 5.25$, $p < .01$), yet they were more willing to buy the freebie bundle than the non-freebie bundle ($t(96) = 2.27$, $p < .05$).

Study 2 (N=220) replicated the preference reversal between WTP and WTB in a different context (purchasing a gift-set consisting of two coffee mugs). The study also probed for the underlying reason, and found that in the WTP condition, perceived value of the freebie bundle and the non-freebie bundle were statistically the same ($t(109) = 1.24$, $n.s.$), but in the WTB condition, perceived value of the bundle was significantly higher in the freebie condition than in the non-freebie condition ($t(105) = 3.25$, $p < .01$). These results corroborated our proposition that the WTP-WTB preference reversal stems from consumers' differential perception of the value of the product between the freebie and the non-freebie bundles.

Study 3 (N=201) adopted a 2 (bundle type: non-freebie versus freebie) x 2 (elicitation method: WTP+WTB versus WTB) factorial design. In the WTP+WTB condition, participants first responded to the question "What's the highest price you are willing to pay to get the two pens?" and then they responded to the question "The price for the two pens today is $1.20. Are you willing to pay this price to get the two pens?". The results showed that, in the WTP+WTB condition, 43% of the participants bought the non-freebie bundle, whereas 18% of the participants bought the freebie bundle ($\chi 2(1) = 7.24$, $p < .01$); in the WTB condition, 10% of the participants bought the non-freebie bundle, whereas 25% of the participants bought the freebie bundle ($\chi 2(1) = 4.14$, $p < .05$). A logistic regression on WTB shows a significant interaction between the bundle type and the elicitation procedure ($B = 2.35$, $SE = .74$; $p < .01$).

Study 4 and Study 5 replicated the above findings in mixed (rather than homogeneous) bundles. Furthermore, Study 5 showed that prompting consumers to consider their WTB before they indicated their WTP reversed their WTP for the freebie and the non-freebie bundles.

These results reconcile the seemingly contradicting findings in the existing literature on freebie evaluations -- that the presence of a freebie may either promote or devalue the bundle (e.g., Ascarza, Lambrecht and Vilcassim 2012; Kamins, Folkes and Fedorikhin 2009; Nunes and Park 2003), corroborate prior research postulating that preferences are constructed (e.g., Bettman, Luce and Payne 1998; Coupey, Irwin and Payne 1998; Lichtenstein and Slovic 2006), and highlight the role of inference in preference construction.

Gender Identity-related Reactions to Sex-typed and Unisex labeled Products

Susanne Ludwig, University of Mannheim, Germany
Stefan Hattula, University of Stuttgart, Germany
Florian Kraus, University of Mannheim, Germany

EXTENDED ABSTRACT

For decades, managers have recognized the importance of gender labeling, which describes a managerial approach that categorizes products on the basis of visible design features such as gendered symbols, names, or phrases according to the gender of the target group (Alreck 1994). Thereby, two approaches of labeling products with respect to gender have been used in daily practice. The first is to target the audience of one specific sex—so called sex-typed labeling (Milner and Fodness 1996). The second approach is integrative labeling, which addresses both sexes in one label—so-called unisex labeling (Markham and Cangelosi 1999).

Conventional wisdom suggests that targeting a specific audience should be more effective than addressing both genders in one label. While a link has been established in previous research between sex-typed labeling and important consumer outcomes, such as product evaluation or purchase intention (Ulrich 2013), no such relationship has been demonstrated for unisex labeling. This widespread belief in targeting a sex-specific audience with sex-typed labeling seems to prevail among practitioners, as indicated by results of a pilot study we conducted with 101 marketing managers. Indeed, 73.3% of the managers were convinced that sex-typed labeling is more effective than unisex labeling.

In two studies (N_{Study1} = 91; N_{Study2} = 149), we question the wisdom of the popular belief that sex-typed labeling is universally superior and thereby contribute in several ways. First, consumer researchers have recently argued that we are in a post-gender period in which the stark lines that have historically divided men's and women's consumption are blurring (Avery 2012). In responding to this suggestion, we introduce gender labeling as another area of marketing in which consumers' gender identity can explain behavior better than biological sex. The match of gender labeled products with an individual's biological sex was the basic argumentation in previous research highlighting the effectiveness of sex-typed labeling (e.g., Ulrich 2013), although it is now well understood that many roles, attributes, and attitudinal differences attributed to biological sex are, in fact, manifestations of gender identity (e.g., Costa, Terracciano, and McCrae 2001). Our results indicate that the explanatory power of biological sex for consumers' response to gender labeled products is negligible when additionally considering the more complex construct of gender identity. In this respect, we provide further evidence that a one-dimensional view on product gender (either masculine or feminine, or simply biological sex) is no longer adequate in studying product gender perceptions (Fugate and Phillips 2010), but a multidimensional understanding of gender might better explain the perception of gender cues such as product gender labels. Our results show that unisex labels evoke high perceptions of masculinity and femininity and therefore can be defined as androgynous.

Second, based on self-congruity theory, previous research has long argued for a superiority of sex-typed labeled products to fit the existing self-concepts of schematic consumers (possessing either masculine or feminine gender traits) and thus to stimulate their purchase behavior (Feiereisen, Broderick, and Douglas 2009). We acknowledge that gender congruity is an important mechanism to explain preferences for products, but further introduce the perceived functionality of a product as another highly relevant mechanism. We argue and empirically show that schematics engage in a dual process-

ing, evaluating gender expressive and functional aspects of the product and find that their need for gender self-congruity, which is satisfied by sex-typed labeled products, is counterbalanced by higher levels of perceived functionality prevalent in unisex labeled products. Unisex labeled products are associated with a larger repertoire of attributes and behavioral options. Just like people, these products are not limited to gender-appropriate usage, regardless of the nature of situations, but can better adapt to situational characteristics and are more flexible to their environments. Consequently, schematic consumers are indifferent between sex-typed and unisex labeled products.

Finally, we are first to study aschematic consumers' preferences for gender labeled products. In times of metrosexuality, this large consumer segment has emerged, possessing both a high level of masculine and a high level of feminine gender identity traits—the so-called androgynous consumer. For instance, recent research has consistently found that more than 30% of total participants fit this segment (Martin and Gnoth 2009). We assume and empirically show that gender congruity is less relevant for purchase decision and thus perceived functionality being the only decisive mechanism, which is why higher preference for unisex labeled products should exist. This assumption builds on gender schema theory (Bem 1981), which suggests that gender identity is a criterion that differentiates people with regard to processing gender linked information. Schematics are said to become even more traditional when gender-related roles are made salient, whereas nontraditional aschematics are expected to be less sensitive to gender cues, because they do not hold a strong gender-related internal cognitive structure (Schmitt, Leclerc, and Dubé-Rioux 1988). Instead, only utilitarian aspects, and more specifically perceived functionality, remain of importance for purchase decisions of aschematic consumers. Those individuals have a particular interest of a larger repertoire of behavioral options because they can better adapt to situations, respond more flexibly to their environments, and eventually experience better psychological health (van Tilburg et al. 2015). Consequently, our results show that the behavior of gender aschematic consumers differs significantly from that of gender schematics and gender labeling describes another area of marketing where targeting might backfire (Bhattacharjee, Berger, and Menon 2014).

We acknowledge several limitations that open avenues for future research. First, while our study employs a realistic online shopping scenario, research has shown that gender identity might be expressed differently when shopping online than when shopping offline (Dittmar, Long, and Meek 2004). The latter would imply a social situation and possibly cause social pressure. Second, in both studies, gender identity was measured before the evaluation of the target product, which might have activated the gender schema. Replication studies should consider measuring the variables separately. Finally, the sex-typed labels in our study were shown only to consumers of the respective biological sex. Although this is the most common labeling practice in daily management, it prevents from analyzing cross-gender labeling perceptions.

He's Just Not That Into Anyone: The Impact of Sex Fantasy on Attraction

Jingjing Ma, Peking University, China
David Gal, University of Illinois at Chicago, USA

EXTENDED ABSTRACT

A sex fantasy can be a fleeting thought of some sexual activity or an elaborate story about a sexual encounter; it can involve a blizzard of images or a quite realistic scene; it can involve memories of the past or anticipations of the future; it can occur during sexual activity or apart from it (Wilson 1978). We live in a world enriched with countless triggers of sexual fantasies (e.g., porn, TV, movie, sex in advertising), it is important to examine the consequences of sex fantasies on individuals. Many popular media suggest that sex fantasies can spice up people's romantic relationships, such that fantasies add more fun and steam to romantic encounters and provide erotic stimulation to routine sex life. However, an increasing number of popular press reports suggest that many men would rather watch pornography and fantasize about unrealistic sex than engage in romantic dating and enjoy real sex with their partners. Nonetheless, academic research on the consumption of sexual content and its impact on individuals' romantic relationships is limited and mostly correlational in nature (for a review, see Leitenberg and Henning 1995). This research is to investigate the causal impact of sex fantasies on individuals' romantic relationships with a focus on adult males.

We hypothesize that sex fantasies can decrease individuals' attraction to potential romantic dates and demotivate them to engage in romantic dating. This hypothesis is based on past goal research showing that the activation of a goal might lead to devaluation of stimuli that are inconsistent with or irrelevant to this activated goal (e.g., Ferguson 2007; Brendl, Markman, and Messner 2003). For example, participants who were primed with an academic goal generated negative evaluations of words that were related to a social goal that might undermine the activated academic goal. Brendl and colleagues (Brendl et al. 2003; Markman and Brendl 2000) have suggested that such "devaluation effects" occur when the activation of a given goal renders as negative those objects that might draw resources away from this activated goal. For example, when a goal of getting food is activated by hunger, individuals would devalue goal irrelevant objects, such as movie tickets. Even though movie tickets do not directly undermine the goal of getting food, they do so indirectly by drawing limited resources away from the focal pursuit (Shah, Friedman, and Kruglanski 2002).

In the current context, we propose that fantasizing about sex can activate the goal to engage in sexual activities. Romantic dating, although it might lead to sex, draws too many resources (e.g., time and effort) that are not directly relevant to sexual activities. Thus, we propose that engaging in sexual fantasy tends to decrease attraction to potential romantic dates and that this decrease is driven by a devaluation of the goal to engage in romantic dating.

In Experiment 1, 169 single Chinese heterosexual males between the ages of 20 to 35 living in the Chicago area were invited by email to register for a famous Chinese dating show hosted in Chicago. This dating show provides single heterosexual males the chance to find female dates. Before they began to read the invitation, they were assigned to two conditions (fantasy and control) by fantasizing (or not) about a sexual encounter with a celebrity. Then they evaluated the attractiveness of 12 female participants for this dating show. Lastly, they decided whether to register for the dating show. The results showed that engaging in sexual fantasy decreased male participants' attraction to potential female dates (M=3.42, SD=1.55 vs. M=3.84, SD=1.52; F(1,101)=4.31, p<.05) and fewer participants in the sex fantasy condition actually registered for the dating show (M=2% vs. M=10%, χ2(1)=4.06, p<.05).

To rule out contrast effect, Experiment 2 tested whether the impact of fantasy on attraction depends on the fantasy content. 37 single male undergraduates were randomly assigned to two conditions by engaging in a highly vs. mildly sexual fantasy then evaluated the attractiveness of 3 females. The results showed that engaging in a highly sexual fantasy decreased participants' attraction to females (M=2.27, SD=1.29 vs. M=3.09, SD=1.26; F(1,35)=6.88, p<.01).

Experiment 3 was to examine the mechanism of the impact of sex fantasy on attraction. 491 heterosexual adult males recruited from Mturk were assigned to two conditions (fantasy vs. control) by looking at sexual vs. non-sexual pictures of the same celebrities and then fantasize. We measured their attraction to 5 females and their valuation of romance by their agreement with the statement--dating is a waste of time and money for guys. Results showed that fantasy produced significantly lower attraction to potential female dates (M=3.27, SD=1.55 vs. M=4.12, SD=1.52; F(1,489)=82.55, p<.001) and also produced a devaluation of romance (M=3.65, SD=1.75 vs. M=3.16, SD=1.72; F(1,489)=6.41, p<.01). A mediation analysis showed that the devaluation of romance mediates the effect of fantasy on attraction.

In Experiment 4, 426 heterosexual adult males (82% unmarried) recruited from Mturk were assigned to two fantasy conditions similar as Experiment 1. Then they were assigned to two scenarios: looking for a date on a dating website or looking for a one-night stand in a bar. Within each scenario, they were asked to rate either two average looking females or two Victoria's Secret models. This constituted a 2 (fantasy: fantasy vs. control) x 2 (target goal-fit: dating vs. sex) x 2 (target attractiveness: average looking women vs. Victoria's Secret models) between-subject design. The results showed that no matter for the average looking women or the VC models, fantasy decreased attraction when male participants were looking for a date but increased attraction when they were looking for a one-night stand. The findings of experiment 4 support the idea that fantasy activates a sex goal, and that sex and dating tend to operate as conflicting goals. As a result, engaging in sexual fantasy increases attraction to sexual targets, but decreases attraction to romantic targets.

This research adds to the literature on sex fantasy, attraction, and offers practical implications on porn watching, sex in advertising, and relationships.

Happiness From Experiences: It's All in the Mind(set)

Shilpa Madan, Nanyang Technological University, Singapore
Elison Lim, Nanyang Technological University, Singapore
Sharon Ng, Nanyang Technological University, Singapore

EXTENDED ABSTRACT

"Want to be happy in life? Buy experiences instead of things."
(Dunn, Gilbert, and Wilson 2011, p. 115)

Extant research on happiness and well being shows that the first principle of using money to increase happiness is to spend it on experiences and not possessions (Van Boven and Gilovich 2003). Experiences (going to a Broadway show, hiking) bring more happiness than possessions (designer dress, electronic gadget). There are several reasons underlying this preference – experiences are less prone to adaptation (Nicolao, Irwin, and Goodman 2009), more amenable to positive re-interpretation (Van Boven and Gilovich, 2003), more social (Caprariello and Reis 2013) and less prone to comparison (Carter and Gilovich 2010). Thus far, research seems to suggest that preference for experiences is almost universal – with few purchaser characteristics (lower income consumers and those high in materialism, Van Boven and Gilovich 2003; Zhang et al. 2014) and a solitary purchase characteristic (valence of the purchase, Nicolao et al. 2009) leading to a lack of preference for experiences (over material possessions).

However, we propose that this may not be true for all consumers. Not all consumers will derive similar happiness from experiential consumption. Specifically, mindsets or, belief in malleability (vs. fixedness) of personality will drive the preference for experiential purchases (over material possessions). Incremental theorists, who believe in malleability of self and others, are actively seeking opportunities for self-growth and advancement (Elliot and Dweck 1988). Hence, they would likely derive greater value from experiential consumption, as they believe that experiences add to their personalities and help them grow as individuals. In contrast, entity theorists who believe in the immutability of the world (Dweck 2000) are less likely to view experiences as a tool for self-development, thus not preferring experiences over material possessions. Hence, incremental theorists will be more positively disposed towards experiences (over material goods) than entity theorists. Further, we propose that incremental theorists' preference for experiences is driven by the belief that experiences contribute to self-growth. Even a negative experience may be construed positively as a learning opportunity.

We test these hypotheses across three studies. Driven by the belief that experiences contribute to self-growth, incremental theorists (vs. entity) are more likely to favor experiences over material goods. We show this by measuring the general tendency to make experiential purchases (Study 1), self-generated purchase (Study 2) and manipulating the type of purchase to be recalled (Study 3). Participants were from US and recruited via MTurk.

Study 1 measured participants' habitual propensity to buy experiences using the Experiential Buying Tendency Scale (EBTS; α=.89) by Howell et al. (2012). This 4-item scale was developed to measure the general tendency to make experiential rather than material purchases. We measured implicit theory orientation (α=.96) using the 3-item measure (Levy et al.1998). As hypothesized, incremental theory orientation and experiential buying tendency were positively correlated, r(49)=.36,p<.05. Specifically, entity theory orientation (+1SD) was linked with a lower propensity to buy experiences (M_{ENT}=3.6) compared to incremental theory orientation (-1SD,M_{INC}=4.74,p<.05).

In line with prior research, Study 2 asked participants to self-generate a recent purchase that they "*thought would make them happier*" (Guevarra and Howell 2014, p. 31), with the prediction that incremental theorists will be more likely to recall an experiential purchase. Implicit theory orientation (α=.93) was measured using the 8-item scale (Levy at al. 1998). We measured materialism (Richins 2004) and asked for wealth and income details as prior research shows that these two variables moderate the relationship between purchase type and happiness (Van Boven 2005). Participants' purchase descriptions were coded into two categories - material(1) and experiential(0) using the Van Boven and Gilovich's (2003) definition. Ordinal logistic regression using this coding as dependent variable, implicit theory score as predictor, and controlling for materialism and wealth/income levels, revealed an overall significant model (Chi square=8.46,p<.05,df=3) and significant effect of implicit theory orientation on type of purchase recalled (Chi square=3.94, p<.05). As hypothesized, participants with incremental theory orientation were more likely to recall an experiential purchase.

Study 3 manipulated purchase type in a post-consumption recall task. Participants were asked to recall a recent purchase, either material or experiential (Nicolao et al. 2009). Then they evaluated the subjective economic value of the purchase (Guevarra and Howell 2014). To investigate the role of self-growth as the mechanism, we asked participants to respond to "To what extent did this purchase help you grow as a person?" from 1 (not at all) to 9 (very much). Participants completed the implicit theory (Levy et al. 1998) and materialism (Richins 2004) scales.

Regressing type of purchase, participants' score on implicit theory scale, their interaction, and belief in materialistic values (as control variable) on subjective economic value (SEV) resulted in a significant interaction (F(2,136)=9.46, p<.05). Spotlight analysis showed that incremental theorists assigned higher SEV to their experiential purchases (M_{INC}=8), compared to entity theorists (M_{ENT}= 6.67,p<.05). No such difference was found for material purchases (M_{INC}=7.15,M_{ENT}=7.59,p=NS). Further, incremental theorists derived higher economic value from their experiential purchases vis-à-vis material objects (M_{EXP}=8, M_{MAT}=7.15, p<.05) whereas entity theorists rated their material purchases (M_{MAT}=7.59) to be more economically beneficial than experiential purchases (M_{EXP}=6.67, p< .05). To test self-growth as the process, we performed moderated mediation analysis using Hayes' (2012) Model 7. Bootstrapping with 5000 iterations revealed a significant indirect effect (95%CI=[.07,.53]) and was significant only for incremental theorists.

The experience-over-goods effect is thought to be near universal with only a few moderators investigated till date. Our research shows that difference in mindsets or implicit theory orientation has a tangible impact on consumers' preference for experiences. Our research contributes to happiness and well-being literature by highlighting a key difference that drives value derivation from experiential purchases. Further, we show experiential purchase's ability to contribute to self-growth as the underlying mechanism. We contribute to growing consumer research that establishes implicit theory as a meaningful individual difference variable with impact on choice and preferences (Mathur et al. 2015). This research

has practical relevance for developing compelling products and communication for different consumers. While we used chronic and post-consumption measures, future research may look at predicting choice and also manipulate mindsets.

Choice Overload or Time Stress: What Determines Purchase Decisions for Airline Tickets?

Ammara Mahmood, City University London, UK
Boshuo Go, Imperial College London, UK
Catarina Sismeiro, Imperial College London, UK

ABSTRACT

Previous research has identified choice overload as a potential cause for purchase deferral. Researchers suggest that the decision difficulties and frustration consumers experience when processing significant amounts of information can lead to decision avoidance and have also found that, consistent with such explanation, that time constraints act as a moderator: approaching deadlines seems to amplify choice overload due to an increased cognitive burden. Identifying moderators of choice overload and discovering contexts in which choice overload occurs is a promising research direction and more importantly it is still unclear whether this phenomenon exists in real business contexts. With the present study, we address this gap and study the interaction between assortment size and time constraints in a purchase context dominated by uncertainty. We conducted two studies to investigate how number of options and time pressure influence purchase decisions. Past research in time effects vary in understanding of time pressure and focus on either real decision deadlines (physical time) or subjective feeling of pressure associated with time (sense of urgency or psychological time). We test both the moderating effect of physical time and psychological time and compare their impact.

In Study 1, we investigate the effect of number of choices and purchase deadlines (physical time limit) on consumers' purchase decisions using secondary data on consumers' purchase and search of airline tickets. We collected secondary data from a European online travel agency, an ideal context with large number of options and in which both deadlines and subjective feeling of time pressure can have influence on people's decisions. Our results are consistent with the presence of choice overload: we find a negative relationship between number of options and purchase probability. Due to nature and detail of the data, we are also able to exclude alternative explanations including option filtering as consumers go through the purchase funnel. However, our results suggest an alternative mechanism behind the choice-overload phenomenon. We then test for the potential moderating effect of time pressure: further away from departure we expect consumers to experience little if any time pressure leaving sufficient cognitive resources to process the available information as a result choice overload is less likely to impact purchase. In contrast we find that further away from departure the negative effect of having more options is stronger. This means that purchase deferral is more likely when consumers face greater options far from departure. Closer to departure, the negative impact of number of options is not as strong. These results suggest that it is likely that number of options, though negatively impacting purchase decision (i.e., leading to a postponed purchase) is not the result of choice overload but perhaps the result of other alternative psychological mechanisms. This mechanism is the temporal shift of choice preferences. While processing information of an activity in a near future, decision makers tend to use a lower level construal that is more concrete, detailed and includes "contextual and incidental features" (Trope and Liberman, 2003) of the activity. Decision makers prefer the desirability to the feasibility of a decision outcome when they are distant from the decision deadline, because decision makers are able to postpone their choice till they are closer to the decision deadline and therefore postpone thinking of the information that can be used to evaluate the feasibility of the decision, such as details, concrete aspects and context of the

decision. When the decision deadline approaches, however, decision makers prefer feasibility to desirability. In the context of purchasing airline tickets online, desirability of a decision is finding an ideal option such as lowest price, most convenient departure / arrival time etc. Feasibility of the decision, however, is to have one airline ticket before planned departure date and avoid missing the travel plan. The interaction between number of options and decision time limit (number of days till planned travel date) has a negative effect on purchase probabilities. This negative effect indicates that when purchase deadline is distant and there are numerous options, customers tend to construct a higher-level construal and are attracted by desirability of the decision and therefore prefer to defer choice and continue to search for the best option. While purchase deadlines are near or number of options decrease, customers form a lower-level construal, prefer feasibility of the decision and are more likely to make a purchase to avoid having no options or missing planned travel dates. The uncertainty regarding alternatives and recent price changes, seem to contribute to shifts to lower-level construal. We find also that consumers' subjective sense of urgency, or *psychological time*, has a greater impact on this shift than physical time and the number of options. Despite controls for heterogeneous personal characteristics that may influence people's psychological time pressure, these effects exist.

In Study 2, we conducted an experiment to further verify the effect of sense of urgency. We constructed a mock website of an online travel agency, providing either 6 or 12 options of flight tickets to choose from. We set up two planned travel dates (purchase deadlines) for participants: 7 days till departure and 30 days till departure. We randomly assign participants to each of these departure dates. In order to manipulate sense of urgency, we established four scenarios of scarcity: flight departure in 7 days; flight departure in 7 days with limited seats available; flight departure in 30 days; flight departure in 30 days with limited seats available. An icon of "3 seats left" was shown to participants in scenarios of scarcity for example a scenario of "flight departure in 7 days with limited seats". Participants' sense of urgency of making a purchase will be activated when customers observe this scarcity icon. These scenarios were randomly presented to participants. Participants were asked to make a decision of either "Confirm and Purchase Now" or "Cancel and Make Purchase Later" on last page of this mock website. 205 respondents show that in scenarios with same level of scarcity, average purchase rate is higher when purchase deadline is near (7 days till departure) than when deadline is distant away. However, both scenarios with scarcity have higher purchase rates than scenarios without scarcity. Our experimental results verify that while decision time limit moderates the effect of number of options on purchase decisions, perceptions of time stress play a greater role in changing behaviour.

Through this study we highlight that a sense of urgency or *psychological* time play a significant role both in the shift of decision makers' temporal construal levels and in moderating the impact of number of options on purchase deferral. We also suggested that the shift of consumers' temporal construal levels is the mechanism behind the choice overload effect in a context where customers have a purchase deadline. As information gathered while searching could influence the perceived time pressure resulting in a sense of urgency and a shift to prevention focus resulting in less choice deferral despite large assortments. Thus there is a close association between a

consumer's real o psychological perceptions of time and assortment size. Our findings suggest that managers can manipulate consumers' sense of urgency by showing different numbers of options, different varieties, price increase/decrease to customers in order to decrease choice deferrals.

A Consumer Theory of Acquisitions

Elisa Maira, Erasmus University Rotterdam, The Netherlands
Christoph Fuchs, TU Munich, Germany
Stefano Puntoni, Erasmus University Rotterdam, The Netherlands

EXTENDED ABSTRACT

Acquiring other firms is a common way for companies to grow. In 2015, the global value of acquisitions was five trillion dollars, a record since the late 2000s' financial crisis (J.P. Morgan 2016). What draws the attention of acquirers is often the brand and market position that the target firm was able to develop. Acquirers often possess the resources to create new brands, but they find it difficult and time-consuming to build brands with unique identities. Given the weight of brand assets in motivating acquisitions, one would expect that academic research on the topic carefully examined how acquisitions impact consumers' attitudes towards acquired brands. However, the extant literature on acquisitions—in accounting, finance, strategy, organizational behaviour, and in marketing —adopts a predominantly internal, supply-side view on acquisitions (e.g., Capron and Hulland 1999; Moeller, Schlingemann, and Stulz 2005). Therefore, the literature is silent regarding the impact of acquisitions on consumer response towards the acquired brand.

In this paper, we address this gap by focusing on consumer reactions to acquisitions.

Given today's ease of access to information about companies via the Internet and social media, it is particularly important to study if and how acquisitions have downstream consequences for consumer behavior.

From an information economics view, we would expect that consumers respond positively to acquisition news. According to signaling theory (Boulding and Kirmani 1993; Spence 1974), consumers should interpret an acquisition as a quality signal regarding the acquired firm and reason heuristically ("if the firm was bought up, it must be good"). As a consequence, they should exhibit increased attitudes and purchase intentions.

However, we argue that acquisitions do not only prompt positive but also negative consumer reactions. In particular, we hypothesize that acquisitions lead to decreased attitudes towards brands and products of acquired firms that operate in identity-relevant product categories. The reason for these negative response is that acquisitions dilute the identity of the acquired brand in the eyes of consumers. Thus, the very asset that motivated the acquisition–the brand–can be damaged by it.

Six studies document the existence of a negative effect of acquisitions on a series of consumer response measures (i.e., attitude towards the acquired brand, choice, online posting behavior), and support identity loss as the process driving the negative effect of acquisitions. The pattern of results in our study allow us to rule out alternative explanations for the negative effect of acquisitions such as consumers' sympathy towards small firms.

Study 1 shows that consumers' preference for products from independent vs. acquired firms is contingent on the identity relevance of the product category in which the acquired firm operates. In product categories characterized by high identity relevance, participants preferred products sold by independent firms, while in categories low on identity relevance they opted for products sold by acquired firms.

Study 2 documents the negative effect of acquisitions on product choice in a real setting. When asked to choose between two chocolate brand–one acquired and one non-acquired- the majority of participants chose the non-acquired brand. Revealing that an acquisition took place was detrimental because it reduced the choice share of the acquired brand compared to the non-acquired one.

Study 3 complements the results of Study 2 and provides evidence that the negative effect of acquisitions holds in the field. To test our main prediction, we retrieved user comments on online newspaper articles about craft beer. Using sentiment analysis, we find that the sentiment expressed in user comments is more negative when the main subject of the news article is craft beer acquisitions rather than craft beer in general.

Study 4a shows that when consumers are informed that founders are still involved in the acquired firm after the acquisition, the negative effect of acquisition is attenuated.

Study 4b provides further support to our identity loss account by showing that the identity of the acquired brand becomes weaker as a result of the acquisition, and such weakening brings forth a decrease in consumer attitudes.

Study 5 shows that consumers' reactions to acquisitions vary depending on the positioning of the acquired brand. We find that an acquisition is especially detrimental for a brand that leverages identity-related aspects (e.g., uniqueness or style) in its positioning. That is, however, not the case for a brand with a positioning focused on non identity-related aspects (e.g., technological sophistication).

In sum, this set of studies advances research on acquisitions by giving insights on the consumer perspective, which, despite its importance, has been largely ignored by previous literature.

The Population Penalty:
Why Common Brands Benefit from Dense Populations Less than Uncommon Brands

Ted Matherly, Oklahoma State University, USA
Zachary Arens, Oklahoma State University, USA
Todd Arnold, Oklahoma State University, USA

EXTENDED ABSTRACT

The population of an area underlies many marketing decisions, such as sales strategies and retail site selection. Although the basis for these decisions are based on a well-established relationship between population and expected sales (Christaller 1935; Craig et al. 1984; Ingene and Lusch 1980; Ingene and Yu 1981; Kumar and Karande 2000; Reinartz and Kumar 1999) we show that this relationship is not always straightforward. One factor that may moderate this relationship is brand commonness - the number of units associated with a particular brand in the marketplace at a given time. Consumers often avoid common brands, such as stores with many locations, as a way to maintain a distinct identity (Ariely and Levav 2000; Berger and Heath 2007). According to Brewer's (1991) optimal distinctiveness theory consumers derive their identity, in part, from belonging to social groups, but large groups tend to be inclusive and indistinct, and do a poor job of satisfying an innate need for distinctiveness. An important group is the community where consumers reside, and thus residents of densely populated areas are likely to have a greater need for distinctiveness than residents of sparsely populated areas. Sociologists have consistently found that urban residents are more heterogeneous than rural residents (Fischer 1984; Wirth 1938) and are more likely to belong to distinct religious organizations (Ogburn and Duncan 1964) and more likely to prefer unique art, fads and fashions (Fischer 1975; Weber 1976). Thus, we predict that consumers in densely populated areas have heightened motivation to express their distinctiveness, reducing their preference for common brands. Thus common brands suffer from a "population penalty" in which the effect of population density on sales is weaker than it is for uncommon brands.

Our first study analyzed brand commonness as a moderator of alcoholic beverages sales. The data included 11 years of alcoholic beverage sales (beer, wine and spirits) for all bars and restaurants in Texas. We modeled sales with county population density, commonness – the total number of locations – and their interaction. As predicted there was a negative interaction between brand commonness and population density on sales indicating that the population-sales relationship grows weaker with commonness. We conducted multiple versions of this model, examining population rather than population density, and controlling for cannibalization and number of competitors, but they did not change the conclusion.

While the empirical analyses provided direct measures of population density, the many factors associated with density create potential alternative explanations. Therefore, study 2 used an experimental design, manipulating density by asking participants to imagine people moving into or away from their hometown. Study 2 also examined whether the desire to be distinct was the underlying process. We manipulated the desire to distinguish from others using a task adapted from Escalas and Bettman (2005) in which participants wrote about an experience in which they were associated with/separate from a close knit social group. Afterwards, participants rated their interest in shopping at a common furniture chain. As predicted, shopping interest depended on both density and disaffiliation. In the disaffiliation condition, as well as the control condition where there was no motive prime, participants were less interested in the common store when they imagined living in a densely populated area

than a sparsely populated area. However, participants primed with affiliation showed no effect of population density, supporting the social identity process underlying these effects.

Although the evidence suggests that common brands may pay a population penalty, it does not necessarily mean that they should avoid densely populated areas. Common brands may be able to reduce the population penalty by sub-branding, which involves creating a new brand that is partially independent but affiliated with an established family brand (Aaker 1994; Milberg, Park and McCarthy 1997). Consumers mentally categorize sub-brands differently than family brands (Sood and Keller 2012) creating an appearance of an uncommon brand. Our third study examines whether sub-branding may be used to help brands overcome the population penalty. As in the previous study, participants imagined a large population moving into or away from their hometown. Next, participants read a brief description of a new hair salon that was considering opening in their area. In the sub-branding absent condition, the salon was described as a "Great Clips" salon with over 3,700 locations. In the sub-branding present condition, the salon was described as a "Trend Styles by Great Clips" salon, a new salon with a single location, but owned by Great Clips which had 3,700 locations. Consistent with the previous studies, without a sub-brand, the common store (Great Clips) elicited marginally greater purchase intention among participants who imagined living in a sparsely populated area than those who imagined living in a densely populated area. However, population density had no significant effect on the sub-branded store (Trend Styles by Great Clips). These results suggest that sub-branding may offer a way for common brands to avoid the population penalty.

Many marketing decisions are based on the assumed financial benefits of operating in densely populated areas. Yet despite its importance, there is little research on the factors that affect the strength and direction of the population-sales relationship. The results presented here demonstrate that this relationship varies with the commonness of the brand. Based on optimal distinctiveness theory, our results indicate that common brands, such as large chain retailers, pay a population penalty by failing to benefit from dense populations as much as uncommon brands. Indeed for the most common brands sales may be actually lower in areas with dense populations than sparse populations. Although it is common practice for marketers to prefer market areas based on their large populations, these results imply that common brands should carefully reexamine this criterion, or consider strategies to avoid this population penalty, such as sub-branding. We hope that this research raises awareness of the variability of population's relationship with sales, and look forward to future research examining marketing strategy from a social psychological lens.

Framing Wait Time Changes Time Perception and Patience

Frank May, Virginia Tech, USA
Ashwani Monga, Rutgers University, USA

EXTENDED ABSTRACT

In intertemporal choice settings, patience is driven by perceptions of the larger-later relative to the smaller-sooner reward (Loewenstein 1996; Zauberman and Lynch 2005), and by perceptions of wait time (Zauberman et al. 2009). Considering patience for receiving a larger-later (LL) reward of $150 in one week (vs. $100 now), increasing LL (e.g., from $150 to $600) is known to increase patience. Thus, increased patience can result from increasing LL magnitude. We show that this effect of LL magnitude may arise via contracted wait time perception, particularly under certain frames of wait time.

Wait time may be viewed using a *long* frame (e.g., "how long the time until X day seems") or a *far* frame (e.g., "how far X day seems"). Intertemporal choice research has assessed time perceptions primarily using *long* (Kim, Zauberman, and Bettman 2012; LeBoeuf 2006) while other research has primarily used *far* (Ross and Wilson 2002; Jiga-Boy et al. 2010). Although these frames appear similar, research on semantic framing suggests that similar words may lead to different judgments (Fillmore 1976; Patrick and Hagdtvedt 2012).

THEORY

Similar semantic frames may evoke different judgments (Fillmore 1976; Patrick and Hagtvedt 2012). In our context, given a one week wait, people may think of how long the week seems, or how far the end of the week seems. Given the mapping between space and time (Boroditsky and Ramscar 2002; Kim, Zauberman, and Bettman 2012), we argue that although both *long* and *far* refer to the "distance" of wait time, *far* is associated more with the LL available at the end—the "destination."

Long is the root of the word "length," and refers to the distance itself ("extending a great distance"), with its antonym being short ("not great in distance"). Thus, a long-short continuum conveys distance by referring to the distance itself. In contrast, far alludes to distance in terms of the destination ("at or to a great distance"), and so does its antonym near ("close to someone or something in distance."). Thus, a far-near continuum conveys distance by referring to the object that is at that distance.

Due to repeated co-occurrence, *far* rather than *long* should have a stronger association with "destination" (Anderson and Bower 1973; Collins and Loftus 1975). This difference in association will lead to different weights in judgment (Srull and Wyer 1979). Specifically, "destination" should receive more weight in judgment for those who encounter a *far* rather than *long* frame. Differential weight given to "destination" should influence perceptions of wait time because destinations are known to appear closer when they are physically larger (Sousta, Smeets, and Brenner 2013; Raghubir, Morwitz, and Chakravarti 2010) and affectively prominent (Balcetis and Dunning 2010; Alter and Balcetis 2010). Thus, a week may seem similarly *long* whether the eventual reward is $150 or $600. However, the end of the week may seem *far* when the reward is $150, but less so when it is $600. We propose that in the case of *far* (vs. *long*), a destination of larger magnitude (e.g., LL=$600 vs. $150) contracts wait time perception, leading to higher patience.

STUDIES

In Study 1, we verified that *far* (vs. *long*) is more associated with destination-related words. In Implicit Association Tests, reaction times were faster when the predicted associations were matched (far-destination and long-distance) rather than mismatched (far-distance and long-destination).

In study 2, we used a 2 (frame: far vs. long) x 2 (LL magnitude: low ($125) vs. high ($200)) design. Participants first created sentences using either *far* or *long*. Supporting the predicted associations, destination words were mentioned more frequently in *far* (vs. *long*) sentences. Additionally, when faced with receiving $100 today or the larger reward ($125 vs. $200) in one month, the effect of a larger magnitude LL leading to higher patience was stronger for the *far* (vs. *long*) frame.

In study 3, we used a design similar to study 2. Participants faced the prospect of receiving $100 today or a larger reward ($125 or $200) in two months, and indicated their perceptions of wait time by answering a *far* (i.e., How far away does that day seem?) or *long* (i.e., How long does the time until that day seem?) question. The effect of a of magnitude (i.e., higher magnitude→greater patience) was stronger for the *far* (vs. *long*) frame, and time perception mediated this effect.

In study 4, we used a design similar to study 3, and framed the questions in terms of "how near" and "how short". Participants faced a lottery with a $10 payoff today or a larger payoff ($12 or $15) in one week, and indicated perceptions of wait time by answering a *near* or *short* question. Again, the effect of magnitude (i.e., higher magnitude→greater patience) was stronger for the *near* (vs. *short*) frame, and time perception mediated this effect

In study 5, we utilized a product context: an iPad Air shipped today versus a superior version shipped in 2 months. Again, we manipulated frame and LL magnitude. Frame was manipulated with an advertisement: "The new iPad Air. How far (long)? Not very far (long). April 18, 2014." The effect of magnitude (i.e., higher magnitude→greater patience) was stronger for the *far* (vs. *long*) frame, and perceptions of the aversiveness of wait time mediated this effect.

In study 6, we showed that the *far-long* asymmetry dissipates if all participants consider the destination when providing wait time judgments. We used a design similar to that used in study 3, with an additional increased LL salience condition. In this condition, we prefaced time perception questions with "Considering the larger amount…". In the low-destination salience condition, the effects mirrored study 3. However, in the high-destination salience condition, the interaction was not significant and only a main effect of magnitude emerged (i.e., higher magnitude→greater patience). Again, time perception mediated these effects.

DISCUSSION

Two frames of wait time—*far* versus *long*—seem equivalent, but yield different consequences. Destination (i.e., magnitude of the LL) influences patience more strongly when the wait time frame is *far* (vs. *long*). We reveal a new antecedent of intertemporal choice: semantic framing of wait time.

Objective Measures of Design Typicality that Predict Aesthetic Liking, Fluency, and Car Sales

Stefan Mayer, Goethe University Frankfurt, Germany
Jan R. Landwehr, Goethe University Frankfurt, Germany

EXTENDED ABSTRACT

Visual typicality is a general principle of product design aesthetics, and ample research suggests that humans prefer prototypical designs over atypical ones (Veryzer and Hutchinson 1998). The link between typicality and aesthetic preferences has been demonstrated in various domains such as paintings (Purcell 1993) and automobile designs (Landwehr, Labroo, and Herrmann 2011; Landwehr, Wentzel, and Herrmann 2013); and one of the most influential explanations for typicality's positive effects is based on the concept of processing fluency (Reber, Schwarz, and Winkielman 2004).

However, studies establishing associations between typicality and aesthetic preferences have been criticized based on potential circularity in their measurements since only the subjective percept of both constructs is usually measured (Boselie 1995). That is, directly asking people about their typicality perception may yield a biased measure because the answer is partly driven by the overall aesthetic impression. Hence, the answer captures the subjective response towards the stimulus instead of the objective stimulus characteristics. An unbiased measure of design typicality, in contrast, would optimally capture solely the stimulus' typicality.

Against this background, we examine the relationships between design typicality, processing fluency, aesthetic liking of consumers, and car sales using 3D models of cars. In accordance with previous studies on car design (e.g., Landwehr et al. 2011), we argue that consumers will experience greater fluency when processing typical rather than atypical designs and will interpret the fluency signal as their aesthetic liking. We further expect the effect of typicality on car sales to be sequentially mediated by processing fluency and aesthetic liking.

In order to capture all possible aspects of typicality, we compare four objective measures of design typicality. In line with previous research on prototypicality (Langlois and Roggman 1990), we consider a prototype as possessing the average values of the visual features of a specific category. Thus, all of our four measures follow the idea that the prototype is a representation of the common characteristics of all designs within a category. A car's design, for example, is typical if the distance to the prototype's design is low, and atypical if the distance to the prototype's design is high. The specific calculation of the prototype and the distance measure, however, differs between our four measures: Two are based on feature points, two are based on a grid that is placed over the image.

The two feature point-based measures rely on the identification of characteristic design features. The first approach applies an established measure that has been used in prior studies on car designs (Landwehr et al. 2011) where predefined characteristic feature points (e.g., the vertex of headlights) are manually set for each image (*manually coded feature point measure*). The second approach follows the same idea of characteristic feature points. However, in contrast to manually coding the feature points, we use a new, algorithmic approach based on perceptual image hashing (Monga and Evans 2006). The advantage of this new approach is that feature points do not have to be set manually but are found automatically (*algorithmic coded feature point measure*).

The two grid-based measures are computationally very simple and do not rely on characteristic feature points; hence they are also applicable to less standardized shapes. In both approaches, we rely on the key idea of perceptual image hashing to reduce an image to its perceptually relevant parts. In particular, we first divide the image into grid cells and calculate the average gray value within each grid. We repeat this for all images and create average grid cells over all images to construe a morphed grid prototype (i.e., a cross-blended image). The typicality of a particular image is then simply the correlation of the grayscale values of its grid with the grayscale values of the morph's grid. We use two versions of the above grid approach. For the first version, we vary the grid size from a 2x2 grid up to the full pixel information to capture all levels of visual typicality (coarse structures, finer details). Typicality is calculated as the average across the typicality values over all grids (*grid measure*). For the second version, we only use the full pixel resolution and calculate typicality simply as the correlation of the grayscale image with the mean image (*grid measure at full resolution*).

We apply the proposed measures to a database consisting of 77 automobile designs from four segments, and compare them to subjectively rated design typicality. As outcomes, we use ratings of aesthetic liking, processing fluency, and cumulative sales.

The comparison with subjectively rated typicality indicates that all objective typicality measures but the manually coded feature point measure correlate significantly with the subjectively rated design typicality scores. For the cumulative sales data, we estimate OLS regressions (one for each typicality measure) at the individual image level, predicting sales from typicality. Subjectively rated typicality and the grid measure of typicality predict sales. Both feature point measures and the full resolution grid measure are, however, not significantly associated to sales. The liking and fluency ratings of the car models are analyzed using a Linear Mixed-Model approach. For aesthetic liking, the models yield significant positive effects of typicality for all but the algorithmic feature point measure. Fluency experience, in contrast, is only associated with the subjective typicality measure and both grid measures. Using a serial mediation analyses based on the PROCESS Macro for SPSS (Hayes 2013), we further show that the underlying processes of the positive effect of typicality on sales are processing fluency and aesthetic liking. In sum, a recommendation would be to use the subjective typicality measure if one is interested in the psychological process. However, if one's goal is to econometrically model the effect of (pure) typicality, it seems adequate to use the unbiased grid measure, thereby avoiding the reversed causality problem.

Overall, our findings demonstrate the possibility to use algorithmic, objective measures of design typicality to predict consumers' aesthetic preferences. Our research thereby contributes to marketing theory and practice by providing algorithmic, objective approaches to assess design typicality that can be used from the very first step of the product design process.

Compensatory Contagion: A Psychological Defense Against Threat

Justin McManus, York University, Canada
Sean Hingston, York University, Canada
Peter Darke, York University, Canada
Theodore Noseworthy, York University, Canada

EXTENDED ABSTRACT

A substantial body of research has demonstrated that people are able to respond to psychological threat with interchangeable defenses, a phenomenon broadly referred to as fluid compensation (Baumeister and Jones 1978; Sobol and Darke 2013; Heine et al. 2006; Steele 1988; Tesser 2000). Drawing on this work, we find that self-esteem threat augments preference for objects that have come into contact with a celebrity who is unrelated to the threatened domain--an effect we call compensatory contagion. Across four experiments, we make several theoretical contributions. First, we provide the first evidence, to our knowledge, that contagion can serve a defensive function. Second, we extend prior work by demonstrating a coping strategy that is unrelated to social signaling (cf. Lee and Shrum 2013; Rucker and Galinsky 2013). We also find that this response is not an avoidance of products related to threat (White and Argo 2009), but rather an approach motivation directed towards positive contagion. Third, we provide process evidence that contagion is the underlying mechanism driving these effects. Fourth, we identify two key moderators--self-affirmation and constrained cognitive resources--to further isolate the role of threat and contagion, respectively. Lastly, we find that compensatory contagion is not explained by positive or negative affect and, similar to other compensatory responses (Rucker et al. 2011), it is dominantly exhibited by consumers who feel connected to the celebrity's domain.

Research suggests preferences for celebrity memorabilia are largely due to seeking an essence--the underlying or unobservable qualities in an object (Newman et al. 2011). In the face of discomfort, many people seek relief in retail therapy as a means of boosting various aspects of the self (Gao et al 2009). Yet another response to threat is to compensate through self-enhancement by emphasizing desirable traits which are not currently under threat (Baumeister and Jones, 1978; Greenberg and Pyszczynski 1985). Bringing these two methods of coping together, we propose that people can compensate from threats to self-esteem by purchasing their desirable traits. If the purchase of celebrity objects is ultimately driven by the desire to acquire the essence of positive figures, can contaminated products act as a compensatory vehicle?

In study 1, participants ($N = 218$) were randomly assigned to a 3 (threat: athletic vs. business vs. control) × 2 (celebrity: Bill Gates vs. LeBron James) between-subjects design. Participants first wrote about a time when they failed in an athletic or business context. Then in an ostensibly separate study, participants viewed a product from an online auction on celebrity memorabilia. Participants reported their valuations for an unbranded cotton sweater that was described as being previously *owned and worn* by Bill Gates or LeBron James. Results showed that valuations varied by celebrity in the athletic threat and business threat conditions but not in the control condition. Consistent with our theorizing, when the sweater was owned by LeBron James, participants in the business threat condition were willing to pay more compared to participants in either the athletic threat condition or the control condition. Critically, the athletic threat was no lower than the control. Conversely, when the sweater was owned by Bill Gates, participants in the athletic threat condition were willing to pay more compared to participants

in either the business threat condition or the control condition. These results provided initial evidence to suggest that people compensate for ego-threat by paying more for celebrity-contaminated memorabilia from domains outside that of the initial threat.

Study 2 directly investigated the role of contagion by (1) manipulating contact, and by (2) demonstrating the underlying intuitive nature of the phenomenon (Kramer and Block 2011). Participants ($N = 159$) were randomly assigned to a 2 (threat: athletic vs. business) × 2 (contagion: no contact vs. contact) × 2 (cognitive load: high load vs. no load) between-subjects design (procedures similar to study 1). Participants viewed a sweater supposedly worn by Sidney Crosby. Consistent with Study 1, when the celebrity had physical contact with the object, valuations in the business threat condition were significantly elevated compared to the athletic threat condition. As predicted, when the celebrity touched the product, valuations in the business threat condition were even further elevated under load (vs. no load). This suggests that the observed effects are automatic and not being driven by a cognitive association.

Study 3 conceptually replicated our findings, isolated the role of threat by manipulating self-affirmation, and further confirmed the role of contagion using statistical mediation. Participants ($N = 121$) were randomly assigned to a 2 (threat: volunteer vs. business) × 2 (self-affirmation: yes vs. no) between-subjects design. Participants evaluated a sweater owned by Mark Zuckerberg. As predicted, contagion (e.g., wanting to shake hands with Zuckerberg) only mediated the relationship between threat and valuations when participants did not self-affirm. Hence, without the shield of self-affirmation (Steele 1988), participants sought compensatory contagion. Together, these results suggest that compensatory contagion is a defensive response.

Study 4 assessed the connection to the compensatory domain, included a negative control condition, and examined the role of affect in our compensatory contagion effect. Participants ($N = 132$) were randomly assigned to one of two between-subjects conditions in a 2 (threat: dental pain vs. business) × domain connectedness (measured trait) design. Participants then evaluated a sweater owned by LeBron James. As predicted, simple slopes revealed that when participants had high levels of domain connectedness, valuations were elevated for those who experienced a business domain threat compared to dental pain threat. These findings suggest that, on some level, people must value the traits imbued in the celebrity contaminated object for them to hold compensatory value. That is, threat leads to compensation in other important domains, not just any domain.

In sum, we contribute to the literature by showing positive contagion can serve a defensive psychological function. Although the desirability of positive contagion is thought to be universal and stable—George Clooney's sweater will be desired by many and for the foreseeable future—the current research suggests that threat can alter preference for an otherwise desirable essence.

The Push and Pull of Attachment Styles on Romantic Consumption

Martin Mende, Florida State University, USA
Maura Scott, Florida State University, USA
Aaron Garvey, University of Kentucky, USA
Lisa Bolton, Pennsylvania State University, USA

EXTENDED ABSTRACT

The modern experience of romantic love is interlocked with the consumption of commodities and leisure goods (Illouz 1997). Consumers engage in romantic consumption routinely (e.g., romantic movies) and for exceptional events (e.g., weddings). Accordingly, romantic consumption is of crucial economic importance. For example, weddings are a $50+ billion business per year (IBISWorld). Surprisingly, given its ubiquitous nature, romantic consumption has received scant attention in consumer research.

We examine how and why consumers engage in romantic consumption. We posit that consumers' attachment styles explain systematic differences in their romantic consumption. Individuals function in relationships differently through their *attachment styles*, defined as the systematic pattern of relational expectations, needs, emotions, and behaviors that results from the internalization of a particular history of attachment experiences (Bowlby, 1969/1982; Mikulincer & Shaver 2007). Attachment styles are conceptualized through two dimensions: Attachment anxiety is the extent to which a person worries and ruminates about being abandoned; attachment avoidance is the extent to which a person possesses an excessive need for self-reliance (Brennan, Clark, & Shaver 1998). Because people can experience varying levels of each of these dimensions, the literature distinguishes four attachment styles (e.g., Brennan, Clark, & Shaver 1998).

We propose that attachment anxiety and avoidance trigger systematic patterns of romantic consumption. Given that attachment anxiety and avoidance are linked to engagement in or flight from romantic love, we argue that romance-themed offerings will trigger the attachment system. Specifically, a hyperactivated (deactivated) attachment system related to the anxious (avoidant) attachment style should result in distinct responses to romantic offerings:

Hypothesis 1: *Consumer preference for, and consumption of, offerings that evoke romantic love (a) increase with an increasing level of attachment anxiety, but (b) decrease with an increasing level of attachment avoidance.*

As the two dimensions interact, we propose that the positive effect of attachment anxiety in the context of romantic consumption counteracts the negative effect of avoidance:

Hypothesis 2: *Attachment anxiety and attachment avoidance interact to influence romantic consumption, such that the negative effect of attachment avoidance declines with an increasing level of attachment anxiety.*

People have a fundamental motivation to form interpersonal bonds, to fulfil their need for belongingness (Baumeister & Leary 1995). Fulfilling this need has been shown to mediate the effect of attachment styles on psychological well-being. We explore whether romantic consumption helps fulfil the motive to achieve emotional intimacy.

Hypothesis 3: *The effects triggered by attachment anxiety, attachment avoidance, and their interplay in response to offerings that evoke romantic love will be mediated by a motive for emotional intimacy.*

We test these hypotheses in two studies. The first study is a survey of married women who report on their actual wedding spending. Results indicate that, at low levels of anxiety, avoidant consumers spend far less than secure consumers). At high levels of anxiety, avoidance has no effect: anxious and fearful consumers do not differ in their spending, which also does not differ from the spending of secure consumers. These results support H1-H2: attachment avoidance reduces romantic consumption (in the form of wedding spending)—but less so as attachment anxiety increases. That is, attachment avoidance pushes consumers away from romantic consumption, but attachment anxiety pulls them back.

In the second study, participants watch a preview to a romantic movie and indicate their intentions to watch the rest of the romantic movie (or a non-romantic movie alternative). At low levels of anxiety, intentions to watch the romantic movie decline as avoidance increases; at high levels of anxiety, avoidance has no effect (anxious and fearful consumers do not differ in their intentions, nor from secure consumers). These results support H1-H2: Avoidance deters romantic consumption whereas anxiety pulls consumers back toward romantic consumption (and outweighs the effect of avoidance). Moreover, mediation analyses support H3: Attachment effects on romantic consumption arise from differences in the desire for emotional intimacy by attachment style.

Together, this research contributes to the literature in several ways. First, we contribute to consumer attachment research (e.g., Thomson & Johnson 2006; Thomson, Whelan, & Johnson 2012) by demonstrating the influence of the interplay between attachment anxiety and avoidance on romantic consumption. Second, we expand the examination of romantic consumption beyond gift-giving (Belk & Coon 1993; Huang & Yu 2000) as romantic consumption frequently is not gift-giving (e.g., watching a romantic movie). Third, our work helps inform the psychological process driving romantic consumption: Desire for emotional intimacy—an arguably ironic motive inasmuch as the consumption of products that evoke romantic themes (e.g., watching a romantic movie alone) may not necessarily create close connections with others.

Paying Up for Fair Pay:
Consumers Prefer Firms With Lower CEO-to-Worker Pay Ratios

Bhavya Mohan, University of San Francisco, USA
Tobias Schlager, University of St. Gallen, Switzerland
Rohit Deshpande, Harvard Business School, USA
Michael Norton, Harvard Business School, USA

EXTENDED ABSTRACT

Starting on January 1, 2017, public companies in the United States will be required to disclose the ratio of the total compensation of the CEO to the average annual compensation of all other employees in their annual reports. We propose that disclosing high pay ratios will have a marked impact on consumer behavior, given that previous research shows that consumers believe pay ratios are far lower than they actually are (Kiatpongsan and Norton 2014). In fact, consumers' ideal ratio of CEO pay to average unskilled worker pay is 4.6 to 1, while their estimated actual ratio of CEO pay to average unskilled worker pay is 10 to 1 (Kiatpongsan and Norton 2014). Note that these estimated ratios are far lower than the average pay ratio across US firms, which is estimated to be approximately 331 to 1 (AFL-CIO 2014). Perceived fairness plays a critical role in shaping consumer behavior; generally speaking, individuals prefer equitable to inequitable distributions of outcomes (Adams 1965). Fairness increases individuals' happiness (Tabibnia, Satpute, and Lieberman 2008) and reduces negative affect (Sanfey et al. 2003). Thus, we hypothesize that the CEO-to-worker pay ratio spurs fairness considerations and that consumers perceive high pay ratios to be less fair than low ratios. Perceived wage fairness, in turn, will drive consumers' purchase intentions and willingness to pay, thus mediating the effect of high (vs. low) CEO-to-worker pay ratios on consumers.

Disclosing pay ratios is not without potential downsides to the firm. It is possible that while disclosing low pay ratios enhances firm perceptions among some consumer segments, it may backfire with others. Political ideology is an important individual-specific factor: for instance, liberal Americans are more likely to support increases in the minimum wage (and therefore lower pay ratios) than conservative Americans (Kuziemko Norton, Saez, and Stantcheva 2015). Given the central role that political ideology plays in consumption (Crockett and Wallendorf 2004; Hirschman 1993) and the fact that different persuasive messages have different appeal to different political affiliations (Kidwell, Farmer, and Hardesty 2013; Winterich, Zhang, and Mittal 2012), it is possible that while low pay ratios may appeal to liberal consumers, they may serve as a deterrent to more conservative consumers.

In this paper, we test the effect of disclosure of pay ratio on product and brand desirability in three experiments.

In Study 1 we tested whether the disclosure of pay ratios can causally affect consumers' willingness to pay in a controlled, incentive-compatible context. We sold gift cards to two retailers that vary in their real-world pay ratio – Urban Outfitters (with a pay ratio of 15:1) and GAP (with a pay ratio of 456:1; AFL-CIO 2014) – and varied the presence of pay ratios by revealing this information or not. Participants ($N = 232$, $M_{Age} = 35.63$, 42% male) completed this online experiment in exchange for $0.50. We used the log of the amount participants bid on the gift cards. We also measured perceived wage fairness: participants indicated their perception of wage fairness on a 7-point scale.

We conducted a 2(Ratio Presence: Absent vs. Revealed) by 2(Pay Ratio: High vs. Low) ANOVA on the amount participants bid on the gift card. A linear regression with an interaction between both factors showed that revealing the pay ratio lowers the amount par-

ticipants bid for the gift card when the pay ratio was high relative to when the pay ratio was low (β_{Low} = -0.153, t = -0.833, p = 0.41; $\beta_{Revealed}$ = -0.049, t = -0.272, p = 0.79; $\beta_{Revealed \times Low}$ = 0.579, t = 2.230, $p < 0.05$).

We used moderated mediation to examine whether perceived wage fairness mediated the effect of high and low pay ratio on the amount participants bid on the gift card depending on pay ratio presence. A 5,000-sample bootstrap analysis revealed that the 95% bias-corrected confidence interval for the indirect effect did not exclude zero when no pay ratio was revealed [-0.01, 0.16] but excluded the zero when the pay ratio was revealed [-0.60, -0.48]. The direct effect of the pay ratio (high vs. low) became insignificant [-0.44, 0.26], indicating moderated mediation (Preacher and Hayes 2008).

In Study 2, we tested whether these effects hold across different product categories and price ranges. Within subjects, participants assessed 12 products. The products represented a wide range of categories and prices: listed retail prices for similar products sold online ranged from $3.99 (cereal box) to $499.99 (flat screen television). Between subjects, we once again manipulated pay ratio to be either low or high. We again found a significant main effect on willingness to buy of disclosing a high pay ratio (F(1,149) = 5.43, p = 0.02). Importantly, the interaction between product type and pay ratio was not significant (F(9,141) = 0.66, p = 0.75), indicating that the impact of pay ratio disclosure was not significantly different across product categories.

In Study 3, we tested whether a low pay ratio will alienate certain customer subgroups. Prior research shows that people have varying perceptions of inequality; for instance, Republican voters desire relatively less equal distributions of wealth than their Democratic counterparts (Norton and Ariely 2011). We find that in three of the four subgroups by political affiliation (Democrat, Independent, Other) there were significant differences in willingness to buy between the high-pay-ratio and the low-pay-ratio retailer, with participants more willing to buy in the high-pay-ratio condition (p's < 0.02). In the Republican subgroup, there was no significant difference in willingness to buy between the high-pay-ratio and the low-pay-ratio retailer (M_{Low} = 5.36, SD = 1.32 vs. M_{High} = 5.36, SD = 1.68; $t(45)$ = -0.01, p = 0.99). Thus, a low pay ratio increases positive perceptions of most customers without harming perceptions of other customers.

In sum, our results suggest that pay disclosure can have benefits: firms with low pay ratios stand to garner improved consumer perceptions via disclosure relative to firms with very high ratios.

Alternative Consumption Experiences Via Imaginative Fantasy Creation

Kimberley Mosher, Queen's University, Canada
Peter A. Dacin, Queen's University, Canada

EXTENDED ABSTRACT

Consumers often wish to have consumption items or experiences, which they also realize may be unattainable for them. Consumption-related research suggests consumers who want an item or an experience engage in various activities to prepare for the anticipated benefits eventual consumption will bring. However, when consumers believe the item or experience is unattainable, can they ever gain some of the benefits of consumption without actually engaging in consumption? That is, might perceptions of unattainability motivate consumers to develop imaginative fantasies of their consumption items to gain consumption-related outcomes without physically experiencing or engaging with the item? In this exploratory research, we examine whether consumers who engage in pre-consumption activities, such as mental imagery (MacInnis and Price 1987, 1990), wish list creation (Fournier and Guiry 1993), consumption visions (Phillips, Olson, and Baumgartner 1995; Phillips 1996), and consumption dreaming (d'Astous and Deschênes 2005), for unattainable consumption items or experiences integrate these pre-consumption processes within an imaginative fantasy creation resulting in a mental experience that, while not a physical consumption experience, provides them with feelings of excitement, satisfaction and satiation akin to a physical consumption experience.

We suggest that consumers, as a result of imaginatively exploring their unattainable consumption items, gain outcomes associated with consumption even if they do not experience consumption. Consumers may be able to develop clear, cogent reasons that pertain to their inability to consume, providing a catalyst to develop an alternative to actually experiencing what they want via engaging in imaginative fantasy creation. Although the fantasy experience is specific to the individual and may not offer a true representation of what the actual experience may be, consumers integrate their prior knowledge and stored mental imagery within the fantasy creation to explore what they wish to actually experience. Although this suggested process is devoid of traditionally understood consumption stages and does not involve the consumer actually interacting with the item or experience, consumers may still be able to develop an enjoyable experience, satiate their wanting for the item without investing or transacting for the actual object, and also alter their feelings towards the brand, potentially affecting their knowledge and impressions of the brand in addition to future consumption interactions. This suggestion draws on the work of Holbrook and Hirschman (1982) who recognize that consumers do not just participate in consumption to satisfy needs and wants but for the feelings of fantasy and fun that are part of the experience.

To gain an initial understanding of whether consumers who perceive consumption as unattainable are engaging in activities that may contribute to a consumption experience within the mind of the consumer, an exploratory interview-based study was conducted. Findings from our exploratory study suggest consumers are able to identify consumption items they perceive as unattainable yet still engage in imaginative fantasy creations that offer consumers a consumption "experience" within the mind. Consumers who recognize what they want is unattainable appear to develop imaginative mental experiences involving the consumption experience they wish to have. These occurrences incorporate known pre-consumption processes yet are more developed and complex, suggesting that coupled with imaginative fantasy creation, consumers develop a consumption-like experience that does not involve physically interacting with the actual item they want.

While exploratory in nature, preliminary findings suggest the marketing literature's present understanding of consumption is often limited to the suggestion that consumers engage in these types of behaviors specifically for the purposes of engaging in actual consumption experiences and this understanding should be adjusted to accommodate these types of experiences as part of how we view consumption. These types of fantasy creations offer consumers an alternative consumption experience as well as benefits typically associated with actual consumption experiences, which provides an interesting basis for future exploration of how we view consumption and the ways in which consumers may be able to interact with the things they want without actually experiencing those things. Consumers are likely already benefiting from the creation of these types of experiences, thus understanding more about how consumers engage with what they want through imaginative fantasy creations can only benefit both marketers and consumer researchers, as well as consumers.

Righteous Indignation: When Anger Consumption Makes You Feel Better

Nira Munichor, The Hebrew University of Jerusalem, Israel
Yael Steinhart, Tell-Aviv University, Israel

EXTENDED ABSTRACT

"Half of all Americans are angrier today than they were a year ago," says a new survey (Esquire 2016). In addition, 68% of the respondents also reported hearing or reading something in the news that makes them angry at least once a day. Why do people consume things (e.g., news) that make them angry? Is getting angry always negative?

Anger is defined as a strong negative feeling of being upset or annoyed (Averill 1983), and one might therefore expect people to refrain from consuming anger-eliciting items. However, we suggest, and show, that sometimes people deliberately engage in, rather than avoid, the consumption of items that elicit anger. Based on findings about the instrumentality of anger in protecting the self in confrontational contexts (McCullough et al. 1997; Parrott 2001; Tamir et al. 2008; Tamir and Ford 2011; Tiedens 2001), we propose this consumption of anger-eliciting items may happen when a conflict accompanies the consumption. Specifically, we suggest that when people experience a conflict between their personal attitudes and the message conveyed by a consumed item, anger will increase that item consumption. We further suggest that in such cases, the anger-involved consumption may help people feel better about themselves, sustaining their sense of righteous indignation.

A set of studies provides empirical support for the consumption of anger-eliciting items, its underlying mechanism, and the favorable consequences of such consumption in terms of self-perceptions.

A pilot study (n=116) demonstrated consumers deliberately consume items they expected to elicit anger. Participants reported that even when they expect the consumption to make them angry, they read articles (78%; significantly greater than 50%, $p<.001$) and blogs (62%; significantly greater than 50%, $p=.01$) and watch television programs (48%; not different from 50%, $p>.7$).

Study 1 (n=90) showed consumers might consume more of an anger-eliciting item when they experience a conflict between their attitudes and the message conveyed by that item. Participants, who voted for either a left-wing or a right-wing party in the last pre-election survey, rated a satirical television program, which was known for its left-wing political bias. After participants watched a short clip of that program, we played an additional section and let participants decide at which point to withdraw from watching. We regressed the log-transformed watching time on political opinion, anger ratings, and their interaction, while controlling for conventional motivations to consume a satire—fun and interest. The results showed a significant interaction between political opinion and anger ($F(1,84)=5.89$, $p=.02$). As predicted, the more anger eliciting the program was, the more time right-wing voters (who were in higher conflict) watched it ($\beta=.22$; $SE=.09$; $t(84)=2.44$; $p=.02$). However, anger did not affect left-wing voters' watching time ($p>.3$). This effect remained significant after we controlled for participants' television-watching habits and general interest in politics.

Study 2 (n=145) further supported the effect of anger on consumption of conflictual items, and showed the instrumentality of anger-involved consumption for self-perceptions. Study 2 therefore revealed a link between conflict, anger, consumption, and self-perceptions. Participants read about a parliament member who accused another parliament member with muscular dystrophy of double voting. Participants who were assigned to the low-conflict condition also read that the focal parliament member had been genuinely concerned about double voting, whereas participants in the high-conflict condition read that this parliament member had been repeatedly teasing the disabled member. Participants reported their level of anger and then received an article that provided additional information about the incident. After reading, they indicated how much they elaborated on the article (as a proxy to consumption), and reported their self-perceptions. We regressed elaboration on conflict, anger, and their interaction. The results showed a marginally significant interaction between conflict and anger on elaboration ($F(1,141)=3.53$, $p=.06$). As predicted, the angrier participants in high-conflict were, the more they elaborated on the article ($\beta=.35$; $SE=.12$; $t(141)=2.91$; $p=.004$). However, anger did not affect elaboration of participants who were low in conflict ($p>.5$). We also conducted a moderated-mediation analysis with self-perception as the dependent variable, anger as the independent variable, elaboration as the mediator, and conflict as the moderator. As expected, greater anger increased elaboration only in high (vs. low) conflict, which in turn elevated participants' self-perceptions ($\beta=.04$, $SE=0.03$; 95% CI: 0.04 to 0.12). By contrast, we found no significant indirect effect when conflict was low (95% CI: -0.02 to 0.05).

If people in conflict consume the anger-eliciting item to feel better about themselves, then only when the message the consumed item conveys is relevant (vs. non-relevant) to the conflict anger should increase consumption among people who experience a conflict. Study 3 (n=129) tested this hypothesis by manipulating both conflict and the extent to which the consumed message was relevant to the conflict. We told residents of a specific city about either a politician's acts that impair the city's unique identity or tourist activities in the city, and then asked them to report their willingness to read an article about either topic. A regression analysis revealed a significant three-way interaction between conflict, relevance, and anger ($\beta=1.01$; $t(121)=2.23$, $p=.03$). As expected, we found anger increased participants' willingness to read the article only when they experienced a conflict and the article was relevant to that conflict ($\beta=.55$; $t(121)=3.63$, $p=.004$; all other $ps>.1$).

Taken together, these results provide evidence for deliberate consumption of anger-eliciting (conflictual) items, and they suggest the anger involved in the consumption of conflictual items provides consumers with a sense of righteous indignation: when consumers experience a conflict between their attitudes and the message an item conveys, anger-involved consumption of that item seems to prompt improved self-perceptions.

Our research contributes to a better understanding of the evasive interplay between emotions and consumption, identifying situations in which the experience of anger—a negative emotion—causes people to consume more, rather than less, of the anger-eliciting item. From a practical perspective, our findings undermine the commonly held view that people are only motivated to avoid unpleasant feelings in general, and anger in particular.

Semantic Price Claims and Discount Expectations

Patricia A. Norberg, Quinnipiac University, USA
Albert J. Della Bitta, University of Rhode Island, USA
Stephen A. Atlas, University of Rhode Island, USA

EXTENDED ABSTRACT

Extant research on "semantic price cues" employed in sale ads has focused almost exclusively on the effects of words that refer to externally supplied reference prices and offer prices. However, with the exception of Barnes (1975), there has been no exploration into how phrases that describe sales affect value perceptions and purchase intention. In this paper, we investigate whether consumers have consistent numeric interpretations of semantic price claims. We find that claims and numeric price information jointly influence purchase intentions and that this interaction occurs through expectancy-disconfirmation.

The 'encoding-complex' model (Campbell and Clark1988) views individuals as developing numerous cognitive representations of numerical data (verbal, visual, magnitude, etc.), depending on the modality/format of the inputs. This framework suggests that numbers, in addition to words and phrases, will be associatively connected to other words and phrases in semantic memory. A considerable body of research evidence is consistent with this model (e.g., Bernado 2001; Campbell 1994; Campbell and Epp 2005; Campbell, Parker, and Doetzel 2004; Lee and Kang 2002; Sciama, Semenza, and Butterworth 1999). We suggest that expectations stemming from word-number associations are activated when consumers view sale information, since such messages typically combine a verbal phrase (semantic claim) with numeric discount information. Based on this:

Hypothesis 1: *Consumers expect greater numeric discounts following exposure to high value semantic price claims than when they are exposed to low value semantic claims.*

The evaluation of the "value of a deal" requires a relative comparison to other available information, and we expect that claims cue internally held comparison standards for discounts and therefore influence perceptions of deal value, or transaction value. We also hypothesize that the effect on acquisition value will work through transaction value, consistent with Grewal et al. (1998) who found that price influenced acquisition value through transaction value. Based on this:

Hypothesis 2: *Semantic claim and numeric discount information will affect perceived transaction value, which will mediate the effect of claim and numeric discount information on acquisition value.*

Originating from Helson's (1948) adaptation level theory, expectancy disconfirmation suggests that one's evaluation of an object is based on the discrepancy between expectations which develop over time and a performance outcome (Oliver 1980). Disconfirmation is typically applied in marketing to satisfaction, but has also been applied to other contexts, such as its effect on new product quality expectations (Kopalle and Lehmann 1995; Olshavsky and Miller 1972) and price recall (Helgeson and Beatty 1987). Zeithaml and Graham (1983) suggest that a reference price can be thought of as a price expectation. Mazumar, Raj and Sinha (2005) suggests that in addition to integrating previously encountered price information into price expectation (internal reference price), consumers also integrate contextual information into that expectation. Consequently we propose:

Hypothesis 3: *Differences between expectations based on semantic cues and actual discount information impact purchase intentions.*

Study 1, a 2 (special [low], blowout [high]) modifier x 2 (sale, deal) core word between-participants design, tested the effects of claims on discount expectations and value perceptions. Chosen claims resulted from a content analysis on newspaper sale ads. Claims were pretested for numeric discount associations. One hundred undergraduates were asked to fill in the numeric discount they believed would be in an ad for a watch based on the semantic claim displayed. They also answered questions on perceived value and purchase intention. ANOVA revealed significantly different numeric discount expectation by phrase ($F(3, 95) = 16.45$, $p < .001$). Pairwise comparisons showed that discount perceptions of high value phrases were different from low value phrases ($p < .01$), supporting H1. Transaction value significantly differed by condition ($F(3, 96) = 3.92$, $p = .01$) and was found to fully mediate the relationship between semantic claim/numeric discount and acquisition value, supporting H2.

Study 2 replicated and extended these results by investigating the discount associations between more core words (cool, smart, blowout, unbeatable) and modifier words (deal, sale, savings). 357 participants drawn from an online panel viewed one of 12 possible ads, and then answered questions to assess expected discount, acquisition value and transaction value. We again found support for H1 and H2, as semantic claims were again linked to numeric discount expectations, and transaction value mediated the relationship between claim/numeric discount and acquisition value.

Study 3 tested whether semantic price claims interacted with explicit discount information to influence purchase intentions through expectancy-disconfirmation and fluency, as predicted by Hypothesis 3. 297 participants recruited from Amazon's Mechanical Turk read a promotional advertisement for sunglasses, normally priced at $149, and read one of six conditions in a between-participants design manipulating semantic discount claims (blowout savings [high] vs. cool savings [low]) and actual discount levels (5%, 30%, 70%). Participants rated likelihood of buying the sunglasses, fluency questions, and controls.

Consistently with Study 1, participants expected a greater discount after reading that the savings were "blowout" than "cool" ($M\_blowout = 39.38$, $SD\_blowout = 17.4$; $M\_cool = 27.81$, $SD\_cool = 13.77$; $F(1, 295) = 40.15$; $p < 0.0001$), supporting H1. Purchase likelihood is a function of expected discount ($p < 0.001$), unexpected discount ($p < 0.001$) and fit ($p < 0.001$). In jointly-estimated simultaneous equations with three mediators (fluency, expected savings, unexpected savings) the indirect effects of expected and unexpected discount each mediate semantic price and purchase intentions (expected discount: $\beta = 0.45$, 95% CI = {.26, 0.67}, $p < .001$; unexpected discount: $\beta = 0.52$, 95% CI = {.35, 0.71}, $p < .001$) while fluency does not ($p > 0.30$ and CI includes 0). Notably, semantic prices lead to disconfirmed expectations which impacts purchase intentions.

Together, these studies provide support for the ideas that semantic price claims affect not just price expectations, but that these

expectations interact with actual discount information to influence purchase likelihood. We tested and found that semantic price claims influence expected savings, unexpected savings, and fluency. Notably, we find that semantically-induced discount expectations and disconfirmations influence purchase intentions. This research highlight the need to carefully consider wording in sale ads.

The Tipping Point Of Perceived Change:
Asymmetric Thresholds In Diagnosing Improvement Versus Decline

Ed O'Brien, University of Chicago, USA
Nadav Klein, University of Chicago, USA

EXTENDED ABSTRACT

Things change. From private fluctuations in health and habits to broader cycles in the climate and economy, people must continually respond to the possibility of something being different now than it was before. Responding effectively, however, requires people to first come to the conclusion an entity has indeed changed in some substantive manner. We refer to this moment as the perception of the tipping point—the point at which people begin to perceive noise as signal. Four studies reveal a pervasive asymmetry: things change, but they are perceived as actually tipping at different rates and in different ways depending on whether people think about change for the better or change for the worse.

Study 1 established the basic effect. Participants evaluated changes related to athletic performance, academic performance, health, mood, luck, habits, friendship, or personality, described in different hypothetical scenarios. For each, "decline" participants were given a positive starting point and indicated how many observations of the next 10 must be bad for them to be convinced in genuine change for the worse. For example, in the athlete scenario, they indicated how many games of the next 10 must a good athlete play poorly to signal official decline. "Improvement" participants rated the opposite. Participants demanded about twice as much positive evidence to tip for improvement than for decline. For example, a handful of awkward encounters, failed exams, bad games, gained pounds, and lost bets led people to judge romantic prospects, academic performance, athletic ability, health, and luck as having "officially" changed for the worse; yet corresponding positive developments were dismissed as fickle flukes.

Study 2 replicated these findings via mere framing. Participants perused a static image of a graph, allegedly depicting real fluctuations in an index of the United States economy over time. The depicted trend line was slightly and ambiguously sloped, and participants' task was to interpret it. Participants were told that lower values suggest things are getting worse on this particular index ("decline" condition), or that things are getting better ("improvement" condition). Note that everyone saw the exact same graph. And yet, it was interpreted as more "real" when framed as decline versus improvement. We replicated this effect in the domain of public health (rather than the economy) and also when inverting the slope direction, suggesting that the effect asymmetry generalizes.

Study 3 significantly expanded this basic effect by assessing real consequential behavior. Participants played three completely random, completely independent card-flipping games. The games were rigged such that some participants lost the first two ("decline" participants) and others won the first two ("improvement" participants). Before the third game, they were invited to bet on the outcome using their participation payment: "decline" participants were invited to bet that their third game would be another loss, while "improvement" participants were invited to bet that their third game would be another win. While exactly 50% of "improvement" participants gambled on a third win in a row, nearly 75% of "decline" participants gambled on a third loss in a row. A hot streak apparently runs out quickly (positive signals are perceived as a passing fluke) while an identical cold streak seems here to stay (negative signals are perceived as a lasting trend).

Study 4 sought to explain this asymmetry, in particular going beyond hedging. Participants imagined repeated social interactions, one at a time. "Decline" participants read about a morally good person who, at Interaction #1, behaved slightly immorally. At this point, they could choose to click to the next page to find out how the person behaved at Interaction #2, or indicate they had seen enough evidence to conclude the person had truly changed. "Improvement" participants evaluated a bad person who behaved morally. Here we replicated the asymmetry: participants amassed a pair of bad behaviors before tipping for decline but twice as many good behaviors before tipping for improvement. In another version, however, participants role-played as "Evil Evaluators" and imagined needing to find a fallen saint who indeed changed for the worse, and that they would be penalized if the person was misdiagnosed. And yet, participants were still twice as fast to tip for decline. This suggests the asymmetry is not driven by hedging alone. Participants had to be especially cautious in their diagnosis of decline but still tipped just as readily as they normally do; signals of decline are overweighted not only to hedge against costs but because capacities to change for the worse (hit floor) may seem more universally likely.

Taken together, an asymmetry at the tipping point of change not only fills missing gaps in the change perception literature, but also raises significant practical implications.

People might be overly quick to punish others but overly slow to reward others who are trying to change, and likewise too slow to appreciate their own progress but too quick to feel hopeless from equivalent regression. In general, people should bear in mind how suddenly cold streaks can (appear to) form and consider the fickleness of reputation; in our studies, being moral or having a happy relationship at the start counted for less than one might hope.

Finally, our framework as a whole also invites a novel perspective for re-thinking important policy debates over broader societal changes, such as climatic, economic, and viral cycles. Traditionally, "effective persuasion" is first and foremost thought to involve convincing the other side that a chosen problem indeed exists and should be addressed, even if one's exact method of convincing (e.g., central/peripheral routes) might vary. We suggest a more crucial (and, to date, overlooked) piece: as difficult as it is to convince others that one's chosen issue is a problem (a negative change likely demanding little evidence), it may be even harder to convince others that policy solutions will be effective (a positive change likely demanding greater evidence). Policy-makers should put more effort into this back-end of the persuasion process and emphasize the gradual nature of improvement following a proposed intervention, beyond the mere existence of decline.

The Effect of Processing Modes and Lighting Types
on Shoppers' Engagement in a Store

So-Yeon Yoon, Cornell University, USA

EXTENDED ABSTRACT

When perceiving physical environments, Westerners tend to use a local processing mode by focusing on foreground objects with a narrowed scope of attention, whereas East Asians tend to see contexts through a global processing mode that includes a broadened scope of attention (Miyamoto, Nisbett, & Masuda, 2006). Patterns of attention associated with cultures exhibit predispositions toward approaching and exploring an environment (Masuda et al. 2008). In stores, shoppers either zoom out to see a whole store (global processing) or focus in on a product for its details (local processing). The type of lighting (holistic vs. focused) guides the shopper's attention toward focusing on gestalt or detail in a store; therefore, lighting can potentially interact with shoppers' processing modes. Despite the potential benefits of enhanced retail store lighting, little is known about how specific lighting decisions influence shoppers' in-store behaviors (Quartier, Vanrie, and Van Cleempoel 2014).This study assesses the influence of focused versus holistic lighting. In this study, we posit that a person is more likely to approach and explore a store when a store environment arranges an attentional scope to match the person's processing style.

Hypothesis 1: *Global processors will show a higher intention to spend time in a store with holistic lighting, whereas local processors will show a higher intention to spend time in a store with focused lighting.*

We investigate H1 by comparing Westerners (Americans) and Easterners (Koreans) in Study 1. We manipulate a temporary processing mode in Study 2 and Study 3 to confirm the fit effect between processing mode and lighting type on shopping behavior. Of practical significance, we test whether a positive mood can enhance the fit effect. Two different predictions can be proposed, depending on two opposite views of mood effect: fixed view or flexible view. According to the fixed view, positive moods lead people to perceive gestalt by broadening their attention (Gasper & Clore, 2002). Likewise, negative moods lead shoppers to view detail by narrowing their attention. Also, positive moods can override local processing and lead to preferences for holistic lighting. In contrast, according to the flexible view, positive moods empower momentarily dominant attentional focus (Huntsinger et al., 2010). Then, positive moods will confer the local Western processing style and lead to preferences for focused lighting. Adopting the flexible view on positive moods, we hypothesize that the fit effect remains with positive moods (H2). We test H2 with people from Western (American) culture in Study 4 and with people from both Western and Eastern cultures in Study 5.

Hypothesis 2: *The fit effect on the enhanced intention to spend time in a store is likely to occur in the positive mood condition.*

We conducted five experimental studies using the same lighting stimuli. In a store for digital products, holistic and focused lighting displays were developed. Both a perception study (n = 17) and an eye-tracking study (n = 33) demonstrated the different attentional scopes between holistic lighting and focused lighting. In Study 1, 236 students (127 Americans and 155 South Koreans) participated. After reporting their moods and shopping orientation, participants were shown a store with holistic or focused lighting and asked to indicate their intention to spend time in the store. Supporting H_1, a culture x lighting interaction ($F_{[1,278]} = 7.97$, $p = .008$) suggested that Americans prefer focused lighting ($M_{focused} = 4.51$, $M_{holistic} = 3.98$, $F_{[1,278]} = 4.204$, $p = .045$) and Koreans prefer holistic lighting ($M_{holistic} = 4.93$, $M_{focused} = 4.35$, $F_{[1,278]} = 3.96$, $p = .048$).

In Study 2, we directly manipulated processing mode using Navon letters (Navon, 1977), which consist of large letters composed of small letters. A total of 187 American participants were asked to identify global letters in the global mode condition, local letters in the local mode condition, and both global and local letters in the neutral condition. Supporting H_1, a processing prime x lighting type interaction was significant, $F_{(1,180)} = 5.51$, $p = .005$. The intention to spend time was higher for the holistic lighting ($M_{holistic} = 5.86$, $M_{focused} = 5.13$; $F_{[180]} = 5.08$, $p = .025$) in the global mode condition, and for the focused lighting in the local mode condition ($M_{focused} = 5.62$, $M_{holistic} = 4.85$; $F_{[180]} = 4.63$, $p = .033$). There was no difference in the neutral condition ($p = .210$).

Study 3 replicated the fit effect by using a map-viewing task (Friedman et al. 2003which in turn bolsters or undermines creative generation. In the first two experiments, participants completed visual tasks that forced them to focus perceptual attention on a comparatively broad or narrow visual area. As predicted, broad, compared to narrow initial focusing of perceptual attention subsequently led to generation of more original uses for a brick (Experiment 1). A total of 179 MTurk participants were instructed to look at a map's shape in the global processing condition, the map's details in the local processing condition, or both details and shape in the neutral condition. Then, participants were asked to report their intention to spend time in a store. An interaction was significant: $F_{(2,170)} = 5.15$, $p = .007$. Participants in the global processing condition preferred the holistic lighting ($M_{Focused} = 4.36$, $M_{Holistic} = 5.01$; $F_{[1,170]} = 3.88$, $p = .051$), whereas participants in the local processing condition preferred the focused lighting ($M_{Focused} = 4.55$, $M_{Holistic} = 3.87$; $F_{[1,170]} = 6.53$, $p = .012$). Participants in the neutral condition showed no difference ($p = .995$). The variations in attention from culture (Study 1) and temporary priming in Study 2 and Study 3 support H1, suggesting processing fit as a driver of shoppers' intentions to spend time in a store.

In Study 4, a total of 141 American students listened to Mozart's *Eine kleine Nachtmusik* (positive mood induction) or Mahler's *Adagietto* (negative mood induction). Supporting H2, there was a significant mood x lighting interaction: $F_{(1,133)} = 9.80$, $p = .002$. Positive mood enhanced local processors' approach intention toward the focused lighting store ($M_{focused} = 5.34$, $M_{holisitc} = 4.57$), $F_{[1,133]} = 5.19$, $p = .024$), whereas negative mood induced the opposite results ($M_{holistic} = 5.26$, $M_{focused} = 4.44$, $F_{[1,133]} = 4.38$, $p = .038$).

Study 5 replicated Study 4 using both North Americans (n = 69) and East Asians (n = 96). A significant three-way interaction ($F_{[1,153]} = 7.42$, $p = .007$) indicated that positive moods drove prefer-

ence for lighting type aligned with the culturally dominant processing mode. Americans in positive moods preferred focused lighting ($M_{focused}$ = 5.75, $M_{holistic}$ = 4.77, F [1,157] = 6.94, p = .009), whereas Koreans in positive moods preferred holistic lighting ($M_{focused}$ = 4.53, $M_{holistic}$ = 5.34, F [1,157] = 8.06, p = .005).

Our research points out that the attentional scope shaped by lighting type influences the ways people engage in a store. The fit in lighting type and processing style facilitates engagement in a store as shoppers more attentively process information aligned with their processing style in a given moment.

Defining and Differentiating Marketplace Tranquility

Cele C. Otnes, University of Illinois at Urbana-Champaign, USA

Ravi Mehta, University of Illinois at Urbana-Champaign, USA

EXTENDED ABSTRACT

Recently, demand has increased for products, services, and experiences that facilitate consumers' ability to withdraw from a technology-driven, multitasked, fast-paced, and typically urban world. For example, over 20,000 spas in the U.S. generate $15.5 billion in revenue (International Spa Association, 2014). More recently, coloring books for adults, which enable them to achieve respite from stress-filled, overstimulated lives, dominate lists of bestselling books (Harrison, 2016). Increasingly, people who seek respite from an "age of incessancy" (Prochnik, 2011, 12) are turning to the marketplace for solutions.

But despite the increase in demand for such offerings, there is little understanding of how and why consumers acquire them. Rather, the long-dominant paradigm of the "experience economy" (Pine II and Gilmore 1999) advocates offering consumers sensory-laden, stimulating marketplace experiences. Likewise, most research on retail atmospherics centers on how to keep customers excited, thrilled, and stimulated (Fulberg 2003; Lesser and Kamal 1991; Wakefield and Baker 1998), implying these outcomes yield optimal outcomes for firms and consumers. Yet the increased demand for offerings such as Bose noise-reducing headphones, Amtrak Quiet Cars (Gallagher 2014), and even monastic retreats may indicate that the experience economy paradigm is overlooking consumers' needs to leverage the marketplace to achieve peace, quiet, and associated consumer-welfare benefits.

We address this theoretical and empirical gap by exploring an emergent construct that we label "marketplace tranquility" (MT). In so doing, we explore these questions: 1) How do consumers understand tranquility in general (GT), and how do they perceive it differs from MT? 2) What marketplace resources and practices do they identify as potential sources of tranquility? 3) What motivates consumers to seek out these sources? Our main contributions of this admittedly exploratory study are to demonstrate the salience of MT to consumers, and to show how they perceive MT as meaningfully different from GT. In short, while consumers perceive GT as abstract and often unattainable in a hyper-urbanized, hectic world, they conceptualize MT as a "practical" form of tranquility – one both accessible and useful in their pursuit of life goals. Furthermore, consumers now seem to take it for granted that the commercial sphere will, and should, provide opportunities for them to try and achieve tranquility-related outcomes.

Below, we discuss current academic understandings of tranquility, and differentiate it from distinct but related constructs. We then explicate our methods, analyze our research questions, discuss the paradoxes inherent in MT, and offer ideas for future research.

BACKGROUND

Tranquility

The OED ("Tranquility," 2016) defines tranquility as "free from disturbance [and] calm." Research supports this delineation, explaining tranquility as a state symbolized by emotional ease and lack of anxiety (Ellison, Burdette, and Hill 2009; Yager 1982). Along similar lines, Herzog and Bosley (1992) refer to tranquility as calmness, serenity, and peace. Other research highlights the importance of the external environment in achieving these outcomes. Eliovson

(1971) interprets tranquility as a desirable state of mind, promoted by certain components of a natural environment (Herzog and Bosley 1992). Likewise, Hunter et al. (2010) detail tranquility as a mental state likely occurring in the presence of sensory inputs from the natural environment. Thus it appears tranquility stems from two components, feelings of calmness and peace (or low-arousal positive affect; Russell 1980) and the external environment that supports it. Consolidating the above characterizations, we offer a cohesive definition of general tranquility (GT) as a state of mind resulting from the experience of low-arousal positive emotions, emerging from immersion in an external environment typified by lack of disturbance.

Related But Dissimilar Constructs

Some studies (e.g., Puccinelli et al. 2009) argue it is critical to understand the role of atmospherics in consumers' marketplace experiences. However, no extant research explores how consumers seek or leverage marketspaces or resources to achieve tranquility. Nevertheless, GT can be compared to similar constructs studied within consumer behavior. For example, *consumption simplicity* pertains to consumers' voluntary simplification or reduction of consumption levels through downshifting (Schor 1998), and may involve consumers foregoing maximum consumption and income-earning opportunities (Shaw and Newholm 2002). Such simplicity may remove consumers' burdens, enabling them to enjoy "non-materialistic satisfaction…from slowing down to enjoying nature…to reading of challenging books to watching…classic[s] on television" (Etzioni 1998, 637). Although tranquility and consumer simplicity may appear similar, we believe simplicity is more accurately understood as an antecedent to tranquility. Furthermore, *solitude* (or aloneness) may seem related to tranquility—but the two may not be the same. Previous research argues that togetherness, as manifest through healthy human relationships, may actually contribute to tranquil outcomes (Stoilova et al. 2014; Williams, Page, and Petrosky 2010). On similar lines, although *silence* shares common features with tranquility, we argue it is also distinct. Indeed, some types of sounds (especially those emanating from nature; e.g., wind and water) may contribute to tranquil experience (Herzog 1985).

METHOD

Given our goal to explicate a new construct (MacInnis and De Mello 2005), we chose in-depth interviews as our primary research technique. These enable consumers to articulate their own experiences, understandings, and meanings pertaining to GT and MT. We began with an initial, broad question, "What comes to mind when you hear the word tranquility?" We then asked them to describe how they sought tranquility in their lives, and to discuss any marketplace entities they thought could (or could not) contribute to their tranquility. We also allowed informants to discuss other aspects of MT they believed to be important.

We interviewed six informants (three males, three females) from September-October 2015. All were acquaintances. Interviews were conducted face-to-face or via Skype. All but one informant is Korean, and all are graduate students in their 20s. Each read and signed consent forms prior to the interviews, permitting us to transcribe the text and use excerpts when disseminating research, while protecting their anonymity. Interviews lasted 60-90 minutes and

were audiotaped and transcribed, yielding almost 100 pages of typed transcripts. We supplemented these interviews with two one-hour observations of marketplace offerings designed to foster tranquility – a yoga class and a class held at a Japanese teahouse in the Midwest, contributing twelve pages of field notes to the data set. The research team read the data set individually, seeking codes and patterns across the text, and discussed and negotiated emergent themes pertaining to general and marketplace tranquility. Our discussion led us to devise the following definition of MT, as distinct from general tranquility (GT): "Marketplace tranquility is an outcome consumers acquire when leveraging products, services, and experiences that enable them to enjoy peace, quiet, and related benefits."

FINDINGS

Our first research question is: How do consumers understand tranquility in general (GT), and how do they perceive that it differs from MT? Similar to the elements emanating from previous research, informants associate GT with the experience of low-arousal, positive emotions such as peace, serenity, and calmness. In addition, they emphasize that immersion in a natural environment is necessary for tranquility to emerge. In fact, many "define" GT by offering vivid, nature-laden descriptions: [GT is] "feeling like flowers, like a plateau, and lying on it". Yet they express skepticism as to whether GT is attainable, or in any sense permanent. Summer notes, "I know…[GT] is…good for my mind, but in reality [it] feels…distant from me." Likewise, Paul notes GT can last "that day, that few hours… you [can't] be tranquil for 50 years (laughs)… likely there are chunks of time [in which to feel] complete and utter peace."

Also consistent with the literature, informants note GT requires escape from crowded, fast-paced environments such as city living, which David equates with a "chicken cage." Especially salient is their desire to escape from crowds of people in general, and from stress-inducing social groups in particular: "you don't have people over your shoulder saying, 'you should do it a certain way'" (Paul). Yet while escaping oppressive others was prevalent in the text, some of our informants' descriptions of GT do feature small groups of intimate others, typically enjoying themselves in natural settings.

General Tranquility vs. Marketplace Tranquility

Asked whether the marketplace can offer tranquility, our informants concur, offering many examples of this phenomenon. But contrary to their more abstract, elusive conceptualizations of GT, we assert they perceive MT as *practical and goal-oriented*. We root this assertion in the emergence of three key aspects of MT: its ability to help informants feel nostalgic, informants' beliefs that the marketplace should socialize them in where and how to attain tranquil offerings, and the ability of MT to help informants achieve goals related to coping with their stressful daily lives.

First, although scholars recognize nostalgia as driving many forms of consumption (Holbrook 1993; Holbrook and Schindler 2003), we are unaware of any studies linking nostalgia and tranquility. However, Paul clearly links the two constructs, noting about bookstores that "they could be peaceful 'cause it's quiet usually. And very soft music. When I was a child my [parents] would take me to a bookstore a lot…I remember I was sad when it closed. I think that the tranquility thing is something that takes you to your childhood." Likewise, other informants equate the simplicity of certain retail atmospherics, or marketplace offerings (e.g., adult coloring books) with simpler times in their lives.

Furthermore, informants rely upon the marketplace to educate and train them on offerings that can help them achieve tranquility. As the table reveals, they identify a plethora of offerings contribut-

ing to this outcome. Joy avers: "we absolutely need these kinds of books [about] peacefulness and enjoying the present…. you don't know how to do it by yourself. I think it's good to purchase the methods…." However, many offerings entail mastering rituals and behaviors that informants realize they should incorporate into their daily lives for maximum effect (e.g., meditation, yoga). For example, at a calligraphy class at the Japanese teahouse, students first engage in a purification ceremony, then pay their respects to sacred scrolls prior to entering the class. Furthermore, prolonged instances such as Buddhist "Temple Stays" in Korea feature monks schooling their visitors in specific "ritual utterances" (e.g., "blessings;" Otnes, Ilhan, and Kulkarni, 2012) to promote tranquility during and after the visit.

Finally, informants often seek out commercial offerings to help them cope with the stress of their everyday lives, using words like "heal" and "refresh" to reflect their motivations. Summer notes "if [marketers] can make…really good places where people in this modern society can rest or find peace, it will be good for [us], and profitable too." Nicole notes marketplace offerings enable people to "purify…so that you can do your work hard." The yoga class we observed reflects consumers' desires for such outcomes. Offered as part of a program promoting wellness in general (and held outside), its instructor encouraged participants to incorporate yoga practice into their lives to help them deal with daily stress.

Marketplace Aspects and Resources

Our second research question explores the elements consumers identify as contributing to MT. As the table reveals, they mention brands, products, retailers, services, and experiences they believe do so. Three important characteristics of these entities emerge: 1) muted features/atmospherics; 2) quietude; and 3) privacy. First, consumers perceive market offerings as tranquil when they are less intrusive upon the senses. Paul mentions Banana Republic as a tranquil retail space due to its "smooth" and "beach tone and black" colors. Likewise, the simplicity associated with a lack of patterns or labels contributes to consumers' perceptions of brands as tranquil. Furthermore, quietude is also a critical element contributing to MT— although quietude does not equal silence. Many informants note soft, instrumental music can play an important role in fostering a calm, peaceful mindset. Together with muteness and quietude, privacy also contributes to MT. Securing a private commercial place or space helps consumers feel secure, safe, and comfortable. In fact, many informants use the word "safe" when describing retail outlets that protect them somewhat from the outside world, offering nooks or spaces where they can feel secluded in a (relatively) noise-free, comfortable environment.

Motivations for Seeking MT

Not surprisingly, informants' goals for seeking MT correspond to the issues discussed above: namely, coping and managing the pressures of their stress-filled, hectic lives. Specifically, our analysis reveals three specific goals they pursue when seeking commercial offerings to gain peace and quiet. We discuss these briefly below.

Escape

We mention above that informants often use the word "safe" to describe marketspaces and resources that enable them to experience MT. Indeed, we were intrigued that almost all of our informants used the word "safe" as an outcome for experiencing MT. However, they do not use the term to denote concerns over their personal safety. Instead, safety appears to refer to their ability to enjoy personal freedom and exercise agency in an otherwise-demanding world. Nicole notes she feels safe at a particular area of a coffee shop "'cause it's

small, blocked a little bit, so …it feels like I have my own space? It's still public, but I feel like I have some private space in there so…I can do my own thing." Ironically, some retail spaces such as Starbucks that were originally designed to offer consumers a "caffeine-induced oasis" (Kim and Mauborgne, 1999, 90) in their lives may have become so popular, they can no longer offer MT as a viable benefit.

Engagement

It may seem paradoxical that consumers use tranquility to foster engagement. However, the type of engagement is not typically social, but mental. Our informants note their jam-packed lives do not afford them opportunities to pursue creative activities, or to engage with their authentic selves. In pursuing MT, consumers are very specific about leveraging products and services that help them delve into passions in a creative manner. Paul observes of his photography hobby that it is "a more active way I seek tranquility…I am creating a new shot. I am…exploring the city while I am doing it. And I say, "Oh wow, I captured that moment…. it's kind of the same buzz people get when they learn something." Thus, our informants demonstrate that the "flow" they seek when engaged in creative pursuits (Csikszentmihalyi 1996) both requires tranquility, and can prolong it as well.

(Marketplace) Emancipation

As we note above, our informants often discuss how they wish to free themselves from the confines of their stressful and typically urbanized existence. Ironically, however, one context they specify describe as wanting to escape – and where they believe the MT can offer a solution – are overstuffed, overstimulating retail outlets themselves. Many of our informants describe the information overload they experience when engaged in retail stores (Eroglu, Machleit, and Chebat, 2004). However, Paul extends his discussion of the oppressive nature of the marketplace by remarking on the drain on self-esteem he believes women must endure, given the strict norms governing beauty in American culture that retail outlets often reflect: "I think clothing [purchasing] is more tranquil to guys…because body image [is] very obvious in clothing….and girls are constantly comparing themselves with the models in a very unfair standard…. that's not fair. Not a very safe environment. You feel very insecure." In short, informants contrast tranquil marketspaces with the overabundant and normative retail spaces that characterize contemporary consumer culture. Furthermore, they imply there may be a moral imperative to offer alternatives to these marketspaces to enhance consumer welfare – an issue that may interest marketers and practitioners whose agendas intersect with that of transformative consumer research (e.g., Mick et al., 2012).

DISCUSSION

The present work advances current understanding of tranquility, and how consumers may perceive it as integral to marketplace offerings. Specifically, we explore three main research questions that pertain to consumers' understanding of GT and its distinction from MT. We find that consumers perceive MT as meaningfully different from GT and actively seek products, services and experiences that enable tranquility. Further, three main motivations emerge as driving the need for tranquility from marketplace offerings. It appears consumers want to escape from sensory-laden external environments (including retail environments), and find environments typified by relative peace and quiet where they can engage with their authentic selves.

Interestingly, our findings illuminate intriguing paradoxes that not only enhance the current understanding of MT, but offer significant implications and open research avenues for academics and practitioners. The first paradox is that consumers use the marketplace to try and escape the overabundance and cacophony of the marketplace. Second, it appears consumers seek to leverage MT to clear their minds so they can then engage their minds. Third, consumers detail that they rely on MT because they may find GT increasingly unattainable; in fact, MT be their only available resource in a world where nature is increasingly detached from everyday experience, and where time pressures mean they must seek tranquility from sources available to them in urban settings—such as the marketplace.

This research thus highlights implications for both consumers and marketers. It appears tranquil retail spaces may wield implications for consumer well-being and mental health. Currently, retail environments focus on providing stimulating rather than calm and peaceful environments. In addition, our research offers new insights for practitioners, with respect to customer needs and expectations from marketplace offerings. Marketers can adopt new strategies to satisfy this emerging customer need. Furthermore, implications for pricing strategies may be salient; e.g., are consumers willing to pay more for tranquil marketplace experiences?

Other future research implications emerge from these findings. For example, it would be valuable to understand the effect of product types on tranquility experiences. For example, many luxury products or hedonic consumption offerings promise calmness and hint at tranquil experiences; is it possible then that hedonic and compared to utilitarian consumption may lead to higher tranquil experiences? Another interesting future research question may entail understanding how consumers reconcile undelivered promises by service providers with respect to tranquility. For example, how would loud conversations and other distracting sensory input at a "tranquil" service provider (e.g., a spa) impact customer expectations, service evaluations and brand loyalty? These and many other interesting questions arising from this research may merit further attention.

The Role of Employee Physical Dominance on
Male Customers' Status-Signaling Consumption

Tobias Otterbring, CTF, Service Research Center, Karlstad University, Sweden
Christine Ringler, University of Alabama, USA
Nancy J. Sirianni, University of Alabama, USA
Anders Gustafsson, CTF, Service Research Center, Karlstad University, Sweden

EXTENDED ABSTRACT

Abercrombie & Fitch has become known for hiring physically fit male employees to pose at store entrances shirtless. However, it is not clear whether this strategy is effective in enticing male or female customers to make purchases.

Research has shown that youth, health, and attractiveness are important characteristics for men in a mate; whereas status, wealth, and dominance are priorities for women (Burd 1986). One way to understand gender differences in mate preferences is through Darwin's (1871) principle of sexual selection. A heterosexual man will search for young, healthy and attractive female mates because they are generally more fertile, which increases the probability that the man's genes can be passed on (Kenrick & Griskevicius 2013). Women place greater importance on a potential mate's capacity for investment (Trivers 1972); in terms of time, effort, and ability to provide resources. It is therefore unsurprising that women value a mate's status, as this has been linked to survival (Geary 2000).

Just as male peacocks with the most impressive feathers are more successful at attracting females, some men communicate fitness to potential mates and demonstrate competitiveness to rivals through flashy and noticeable displays (Buss 1988). Given that two of the most important cues in making inferences about people's status are the cost and noticeability of the products they buy (Belk, Bahn, & Mayer 1982), men are also more prone than women to use consumption as a way to signal status (Sundie et al. 2011). Men without large resources may attempt to signal status through the consumption of conspicuous brand logos, tipping more at dinner, or buying a more expensive brand than their peers.

The current research investigates whether physically dominant male employees can increase male customers' status-signaling consumption. We expect that men whose status is threatened by a physically dominant male employee will show a greater willingness to spend money on products associated with status.

391 members of an online research panel completed Study 1 and were randomly assigned to a 2 (participant gender: male vs. female) × 2 (customer gender: male vs. female) between-subjects design. All participants read a scenario: "Retail companies have started to hire athletic, fit male employees to attract customers. These employees stand at the store entrances, where they greet arriving customers." Participants then indicated their agreement on the following: "I think female [male] customers will spend more money in the store compared with male [female] customers" and "purchase more expensive products in the store than male [female] customers." Respondents then answered demographic questions including gender (independent variable).

Conducting a two-way ANOVA with participant gender and customer gender as between-subjects factors, we found a main effect of customer gender ($F(1,387) = 131.55$, $p < .001$). Participants predicted that female customers would spend more money ($M_{female} = 6.22$) than male customers ($M_{male} = 3.84$) in the presence of a dominant male employee. Similarly, we found a significant main effect of customer gender on purchasing more expensive products ($F(1,387) = 65.54$, $p < .001$), indicating that female customers would purchase more expensive products ($M_{female} = 5.77$) than male customers ($M_{male} = 3.92$) in the presence of a dominant male employee.

Study 2 included 369 customers in a 2 (customer gender: female vs. male) × 2 (dominant employee: absent vs. present) between-subjects design. Customers in the dominant employee present condition entered the store where a dominant male employee greeted them. Customers in the dominant employee absent condition entered the store, but were not greeted by an employee. They then continued with their normal shopping. After checking-out, customers were asked if they would be willing to participate and their gender was recorded. A photograph was taken of their receipt to count the number of items purchased and the amount spent. To measure status-signaling consumption, we used the average price paid per item (Eastman, Goldsmith, & Flynn 1999).

Conducting a two-way ANOVA with customer gender and dominant employee as between-subjects factors on price paid per item, we found a main effect of the dominant employee condition ($F(1,341) = 3.64$, $p = .05$) and a main effect of gender ($F(1,341) = 6.88$, $p = .009$). These were qualified by an interaction ($F(1,341) = 3.67$, $p = .05$). The average price per item purchased by men (M = 18.33) was approximately 94% more expensive than the average price per item purchased by women (M = 9.43) in the presence of the dominant male employee ($t(172) = 2.61$, $p = .010$). When the employee was absent, we found no difference ($t < 1$).

Study 3, a 2 (participant gender: male versus female) × 2 (employee: dominant versus non-dominant) between-subjects design utilized 114 undergraduate students. They were given a photograph depicting the male employee, who was either dominant or non-dominant (but equally attractive). Participants were told the study would investigate participants' ability to form impressions of employees. Participants answered questions consistent with the story and indicated their logo size preferences on clothing as research has demonstrated that a desire for larger logos indicates a willingness to engage in status-signaling consumption (Lee & Shrum 2012). Finally, participants indicated demographic information.

We conducted a two-way ANOVA on logo size preferences. We found a significant main effect of employee condition ($F(1,110) = 5.84$, $p = .017$) and of participant gender ($F(1,110) = 6.67$, $p = .011$). These effects were qualified by an interaction ($F(1,110) = 8.28$, $p = .005$). Male participants in the dominant employee condition ($M_{dominant} = 5.20$) preferred significantly larger logos compared with male participants in the non-dominant employee condition ($M_{non-dominant} = 3.52$; $t(54) = 3.57$, $p < .001$); female participants did not differ between conditions ($t < 1$).

Collectively, we found that a dominant male employee motivates male customers to spend more money and buy more expensive products than female customers – while lay theory would suggest that female customers' purchase behavior should be more positively influenced under such conditions. While previous research has focused on the effect that attractive women have on men's status-signaling consumption, our main theoretical contribution is the finding that dominant male employees assert real-world consequences on men's purchase behavior.

The Elaboration of Ethical Brand Crises on Social Media

Stefano Pace, Kedge Business School, France
Matteo Corciolani, Università di Pisa, Italy
Giacomo Gistri, Università di Macerata, Italy

EXTENDED ABSTRACT

A crisis is a severe occurrence in the life of an organization threatening its own existence (Coombs 2007). Crises that breach the ethical values of a brand can impair the root values of the company. Marketplace resources – including brands – can be highly contested by opposing views of society (Luedicke, Thompson, and Giesler 2012). Disadvantaged or stigmatized segments of society adopt marketplace resources as an intermediate step to affirm their legitimacy before a wider legitimacy is reached in other sectors of the society.

Most of the extant literature on consumer identity politics (Sandikci and Ger 2010; Scaraboto and Fischer 2013; Thompson 2013; Üstüner and Holt 2010) focuses on situation of normal market practices. In these situations, consumers affirm their identity rights by using (or boycotting) products and brands, and by adopting consumption practices as identity markers. Yet, the marketplace inertia tends to weaken and postpone the effects of the consumer identity political change. A brand crisis brings instead a sudden and serious break in the normal life of a brand and thus opens the opportunity for a radical change in the brand meanings and it may represent an occasion for the stigmatized segments to prove their discrimination and assert a change in society.

Conventional crisis communication adopts a Public Relations approach (Coombs 2007). This top-down managerial approach is effective and consolidated. However, social media publics ask for a renewed mindset that would take into account the power of the audience. Social media require companies to adopt a stakeholder theory (Xu and Li 2013) to approach crisis communication, so that what the audience say about the crisis is as relevant as what the organization says. The research question is how consumers debate online around the apology by the company after an ethical brand crisis.

In 2013, during an interview, the president of the Barilla group expressed a view that triggered intense protests. According to his declaration, the advertising by Barilla will never feature a family of gay persons, because the brand Barilla – though it respects gays – would represent the traditional idea of family. After the interview, Guido Barilla released a video where he apologized and reassured that he and the company have the utmost respect for gays.

Through a qualitative content analysis (Spiggle 1994; Strauss and Corbin 1990), using Atlas.ti, we analyzed the Facebook comments published for a period of three months under the video of apologies by Barilla. The corpus of data is made of 41.000 words. We complemented the content analysis with an examination – inspired by netnography (Kozinets 2015) – of the online material generated around the crisis.

A good part of the comments obviously concerns in a direct way the issue of civil rights. Other comments take a different approach in their defense or criticism of the brand. Comments expressing agreement with the Barilla position adopt two major discursive strategies: sublimation and minimization of the crisis. In the first strategy (sublimation), commenters defend the right of the brand representative to express any opinion, even unpopular and questionable ones. Minimization consists in considering the statement by Barilla simply as a marketing strategy that would be neutral in terms of ethics, reducing the crisis to a simple marketing affair without a real infringement of ethics. The critics combine and reverse the sublimation and reduction strategies employed by the brand defenders. In this critical position, marketing is not a simple company function detached from ethics;

marketing is instead a powerful ideology (Firat 2012), that has to be updated and cleaned from biases. The two sides of sublimation and minimization are tied together by critics to affirm a holistic vision of marketing, which should express the higher values of civil rights through its tools and techniques.

The online audience here analyzed does not show the dynamic of change in their rhetorical positions, differently from professional stakeholders directly touched by a crisis (Vallaster and von Wallpach 2013). The online interaction is often limited to reiteration of one's own opinion and a series of attacks and counter-attacks with no further articulation. There is no synthesis, but rather a positional battle of opposing ideas. This structure of the conversation may be due to the structure of the social network analyzed. On social networks, in occasion of a crisis, it may happen that comments add to each other, without a real interaction and there is a risk of polarization (Yardi and boyd 2010), preventing the formation of a discussion generating new ideas that synthesize opposite views.

The emerging findings may provide some contributions. First, in most extant studies, the subjects affirm their identity politics via a personal use of products (Sandikci and Ger 2010; Scaraboto and Fischer 2013; Thompson 2013; Üstüner and Holt 2010). In the case examined, the subjects are not necessarily consumers of the brand; they are interested in the ethical issues raised during the crisis. In addition, the product (pasta) is a fast-moving consumer good, which is not able per se to signal the identity project of the individual. In this situation, the subjects focus more on the ethical discussion and less on product-related issues. Differently from other more complex products, fast-moving consumer good may have less intense ethical or political underpinnings. The crisis gives the opportunity to reassert that a product is just a product (the reduction strategy of the brand defenders) or, on the contrary, to discover that fast-moving consumer goods can be useful to a project of consumer identity politics. The unfolding discussion can be a rich elaboration of different positions. Second, to affirm their legitimate identity, consumers normally build a whole lifestyle through many brands. In the case of the brand crises, consumers pick one single brand and a specific crisis and scale it up to a wider discussion. Consumption in a normal setting seems to need an aggregation of different brands to state an identity position, while a brand crisis allows for a sharper focus on a single brand, used to state a wide identity politics strategy.

Old, But Gold! The Role of Aging Stereotypes on Consumers' Purchase Intentions in Second-Hand Marketplaces

Felipe Pantoja, IESEG School of Management (LEM-CNRS), France
Marat Bakpayev, University of Minnesota, Duluth, USA
Patricia Rossi, IESEG School of Management (LEM-CNRS), France
Sukki Yoon, Bryant University, USA

EXTENDED ABSTRACT

The global population is aging. Due to a combination of increased life expectancy and reduction in fertility rates (Lutz et al. 2008), the percentage of people over 60 years old is expected to double in the next few years (United Nations 2013). Therefore, marketers should be attentive to this new growing market of senior consumers.

The online presence of seniors is rapidly expanding as well. In Europe alone, Internet usage has doubled among people over 65 years old (Edwards et al. 2015). The "silver surfers" are increasingly subscribing to online social networks (Choudrie and Vyas 2014) and also turning to Internet to earn additional income (Winch 2014).

Online second-hand markets are one of the fastest growing markets (Walia and Zahedi 2013). Websites such as Ebay and Amazon are just a few examples. Such markets are peculiar to the extent that available products are pre-owned by someone that buyers rarely know. Evidence suggests that people perceive certain invisible properties of previous owners to be transferred to goods (Kapitan and Bhargave 2013).

Age is one of the three primary dimensions of interpersonal categorization (North and Fiske 2012). Previous research shows that consumers often use stereotypes as heuristics to judge elderly people (Fiske et al. 2002; Cuddy, Norton and Fiske 2005), both in positive (e.g. warm) and negative ways (e.g. less competent) (Couto and Koller, 2012). In addition, the theory of consumer contamination (Argo, Dahl and Morales 2006, 2008) suggests that a physical contact between a product and a given source (e.g. person) can contaminate the referred product with the source's essence (Argo, Dahl and Morales 2006, 2008).

In this scenario, does the seller's age has an impact on consumers' purchase intentions toward a second-hand product? Considering the mixed-nature of age stereotypes, to what extent does an elderly seller contaminate their used goods? Does the contamination lead to a positive or negative outcome in terms of purchase intentions?

In study 1, we primed participants with a picture of either a young or an old seller of a second-hand product. Participants saw the same product and the same details for the seller (e.g. seller rating). We used purchase intentions as the main dependent variable. A one-way ANCOVA using physical attractiveness as a covariate shows a significant main effect of age condition on purchase intentions. Participants showed higher intentions to purchase the armchair when the seller was an old (vs. young) lady.

In study 2, we use a similar procedure as in study 1. To control for seller attractiveness, in this study we use a written description of the seller. Again, we used purchase intentions as the main dependent variable and included interpersonal warmth as a mediator. The results suggest a positive effect of seller's age on purchase intentions toward a second-hand product. Using a 5,000 bootstrapped samples (Preacher and Hayes 2008; Zhao, Lynch, and Chen 2010), results show that age has a marginally significant effect on purchase intentions ($\beta = 0.37$; $t(114) = 1.88$, $p = .06$). Additionally, the effect of interpersonal warmth on purchase intention is significant ($\beta = 0.38$; $t(114) = 2.68$, $p < .01$). Finally, when controlling for interpersonal warmth, age no longer has a significant impact on purchase intentions ($\beta = 0.28$, $t(114) = 0.93$, $p > .3$), which confirms that interpersonal warmth mediates the effects of age condition on purchase intentions (95%, CI 0.005 to 0.3783). These findings suggest that consumers have higher intentions to purchase second-hand goods that were pre-owned by senior (vs. young) people.

While referring to the warmth dimension in elderly stereotyping, it is interesting to test boundary conditions. Prior research connects social exclusion with warmth-seeking behavior (Zhong and Leonardelli 2008; Li and Liao 2013). When a person is feeling lonely and socially excluded, he/she literally experiences interpersonal coldness, which leads to a need for warmth (Zhong and Leonardelli 2008). Thus, in situations where consumers feel socially excluded, it is expected that senior sellers of second-hand products will be preferred because they would be perceived as adding a warmth dimension to the product. That is, because social exclusion prompts consumers to search for social warmth, an older seller with a stereotypical image of warmth would better fulfill the need of socially excluded buyers. In contrast, those who do not feel socially excluded are not likely to be in a great need for warmth.

Study 3 uses a 2 (seller age: young vs. old) x 2 (social exclusion: excluded vs. control) between-subjects experimental design. The experimental procedure was very similar to the one of study 1 (using pictures). To manipulate social exclusion, we asked participants to take part in an unrelated task, which consisted in the "Southampton Loneliness Scale" (Wildschut, Sedikides and Cordaro 2011). Once the participants completed this task, we gave them their Loneliness Score. Participants received either a negative result (informing that they scored above the average on loneliness compared with the other undergraduates) or a positive result (informing that they scored very low on loneliness compared with the other undergraduates). Then, participants gave their opinion about a second-hand product (an armchair) that was being sold on Ebay. We used purchase intentions as the main dependent variable. A two-way ANOVA showed a marginally significant interaction between sellers' age and social exclusion conditions on purchase intentions ($F(1,106) = 3.41$, $p = .068$). When feeling socially excluded, participants showed higher intentions to purchase the armchair when the seller was an old lady ($M_{young} = 1.50$; $M_{old} = 2.06$; $F(1,106) = 3.02$, $p = .085$). However, when participants do not feel socially excluded (i.e. control condition) the preference for the old seller dissipates ($M_{young} = 1.98$ and $M_{old} = 1.71$; $F(1,106) = 0.76$, $p = NS$).

Finally, across three studies we provide preliminary evidence that the age of the seller in second-hand markets has an important role on consumers' purchase intentions. Specifically, the results show higher purchase intentions toward a product that was pre-owned by a senior (vs. young) seller and perceived interpersonal warmth mediates this effect.

Does Suspense Spur or Hamper Consumer Creativity?

Sungjun (Steven) Park, Korea Advanced Institute of Science and Technology, Korea
Yong J. Hyun, Korea Advanced Institute of Science and Technology, Korea
Page Moreau, University of Wisconsin, USA

EXTENDED ABSTRACT

A mixed emotion arises from simultaneously experiencing two or more discrete emotions opposite in valence (Aaker, Drolet, & Griffin, 2008). Any time consumers decide to engage in a creative activity (i.e., when they solve an ill-defined problem), they are accepting ambiguous conditions that often foster mixed emotions. Then, their creativity may be influenced by such mixed emotions.

Past research focuses mainly on the effect of univalent emotions on creativity. Positive emotions facilitate creativity (Amabile, Barsade, Mueller, & Staw, 2005; Baas, De Dreu & Nijstad 2008; Isen & Daubman, 1984) while negative emotions do so under certain circumstances (Baas, De Dreu, & Nijstad, 2008; Van Kleef, Anastasopoulou, & Nijstad, 2010). Little effort has been made, however, to examine how mixed emotions influence creativity (for exceptions, Amabile et al., 2005; Fong, 2006). This research examines the relationship between consumer creativity and suspense as a mixed emotion.

Suspense is a mixture of hope and fear (Alwitt, 2002; Madrigal & Bee, 2005) which is coupled with "a cognitive state of uncertainty" (Ortony, Clore, & Collins, 1990, p.131), frequently arising in consumption settings (Alwitt, 2002; Madrigal & Bee, 2005; Moulard, Kroff, & Folse, 2012). For example, when assembling an IKEA do-it-yourself product, h/she may feel hope (a positive emotion) in the prospect of successfully assembling and benefiting from the product. At the same time, h/she may feel fear (a negative emotion) as h/she is uncertain of how to assemble the product.

Suspense may bring about a psychological discomfort or conflict as its two components, hope and fear, are opposite in valence (Hong & Lee, 2010; Williams & Aaker, 2002). To resolve the felt conflict, the consumer may adopt a flexible mindset, which enhances his/her creativity (Huang & Galinsky, 2011; Miron-Spektor, Gino, & Argote, 2011).

Four online experimental studies were conducted, using Amazon's Mechanical Turk (MTurk). In Study 1, 92 participants were randomly assigned to either of the two conditions (suspense vs. control) in a between-subjects design. The suspense group read a scenario, recalled similar life events, and described them in writing. Then, creativity was measured by using the method of Duncker's candle problem (Duncker & Lees, 1945). Results show that the suspense group felt hope, fear, suspense, and emotional ambivalence more than the control group. A logistic regression analysis indicates that more participants correctly solved the candle problem in the suspense condition (23/44, 52%) than the control condition (15/48, 39%; $\chi^2(1, 92) = 4.21$, $p < .05$).

Study 2 differs from Study 1 in the ways of mood induction and creativity measurement. 122 participants were randomly assigned to either of the two conditions (suspense vs. control) in a between-subjects design. A gambling task was applied to arouse suspense. The winning probability and amount differ between the two groups. Then, the participants were asked to list in writing as many creative uses for a block of brick within three minutes. The creative uses listed by each participant were evaluated in terms of novelty, meaningfulness, and fluency (Amabile et al., 2005; Moreau & Dahl, 2005). Results show that the suspense group is higher in novelty (M_suspense = 3.07 vs. M_control = 2.97; $p < .05$), meaningfulness (M_suspense = 5.05 vs. M_control = 4.69; $p < .01$), and fluency (M_suspense = 7.30 vs. M_control = 6.02; $p < .05$) than the control group.

Study 3 compares suspense with multiple univalent-emotions in consumer creativity. 191 participants were randomly assigned to one of the four conditions (suspense, happy, sad, and affect-neutral) in a between-subjects design. For mood induction, participants were asked to recall and describe an affectively charged past experience corresponding to the condition to which they were assigned. Ten problems from the Remote Associates Test (RAT; Mednick, 1962) were used to measure consumer creativity. Each problem presents three seemingly unrelated words (e.g., Cottage, Swiss, Cake), and asks participants to think of a fourth word that relates to all three words (e.g., Cheese). Results show higher creativity scores in the suspense condition (M = 7.22) than in the sad (M = 5.83, $p < .001$) and control conditions (M = 6.18, $p < .002$). The creativity difference between the suspense and happy conditions (M = 6.63) is marginally significant ($p = .059$). In addition, the happy condition produced higher creativity scores (M = 6.63) than the sad condition (M = 5.83, $p < .05$).

Study 4 aims to identify a mediating role of felt conflict between suspense and creativity. 118 participants were randomly assigned to either of the two conditions (suspense vs. control) in a between-subjects design. The mood manipulation procedure in Study 2 was used to induce suspense, and creativity was measured by using the method in Study 3. Participants were asked to rate how much conflict they felt while describing the life events they had recalled (1 = not at all, 11 = very much; α = .84). Results show that the creativity score is higher in the suspense group (M = 5.94) than the control group (M = 5.10; $p < .05$). A mediation analysis reveals that felt conflict significantly (CI = - .22 to - .06) mediates the effect of suspense on consumer creativity (Preacher & Hayes, 2008).

Findings of the four studies indicate that suspense enhances consumer creativity via felt conflict. Results provide a basis for further work on how mixed emotions relate to consumer creativity. In this aspect, it is important to discuss shortcomings of the four studies and directions for future research. This discussion is developed mainly in four ways as follows.

First, online experiments compromise internal validity and thus laboratory experiments should be considered in future studies. Second, mediators between felt conflict and creativity need to be examined. For example, a flexible or an abstract mindset to resolve felt conflict could be a mediator. Third, future studies should attend to mixed emotions other than suspense (e.g., guilty pleasure, bittersweetness). Lastly, mixed emotions may be felt and interpreted differently across cultures (William & Aaker, 2002), and thus cultural factors should be considered in future studies.

Preference Versus Freedom:
Two Psychological Meanings of Scarcity and Their Influences on Consumer Choice

Hanyong Park, University of Texas at San Antonio, USA
David Silvera, University of Texas at San Antonio, USA

EXTENDED ABSTRACT

Marketers frequently use scarcity appeals, such as "while supplies last" and "nearly sold out." The key message is that product *units* will soon become unavailable. However, some natural settings may create the feeling of scarcity even when item units are not limited. For example, a store may offer a price discount on only a subset of the entire product category. In this case, even assuming that all sale and non-sale items are fully stocked, the restricted sale promotion may make consumers feel that *options* available for sale are scarce. Despite this conceptual distinction, prior literature has largely focused on unit scarcity, concealing potential differential effects of the two types of scarcity behind the broad label of "scarcity effects." This article seeks to address this issue by examining how they may exert different influences on consumer choice, particularly their tendency to seek variety.

We posit that *unit scarcity* and *option scarcity* may trigger distinct psychological processes. Based on the finding that scarcity (as operationalized by limited availability of units) polarizes preferences (Zhu and Ratner 2015), we argue that unit scarcity highlights one's preferences, leading consumers to narrow their item selections to choices that they strongly prefer. Conversely, option scarcity highlights consumers' freedom of choice (Kim and Drolet 2003), leading them to widen their item selections to re-attain their restricted behavioral freedom (Brehm 1966). Accordingly, we propose that unit scarcity decreases choice variety, while option scarcity increases choice variety.

Study 1 (N=489) tested and contrasted the two scarcity effects. Participants in the control condition read a scenario about a store offering a price discount on 9 soda brands (with pictures), all of which were fully stocked. Participants in the option scarcity condition read the control scenario and were also told that the store had been offering the discount on all of its 21 soda brands but starting this week the discount is limited to 9 brands. Participants in the unit scarcity condition read the control scenario, but were told that there are not many units remaining for each brand. To control for potential confounds due to varied set sizes/brands, the same choice set was used in all three conditions. Participants then indicated which brand(s) of soda and how many bottles of each they would select. There was no restriction on total purchase quantity. Two choice variety measures were used: (1) proportion (i.e., number of different brands chosen relative to total number of brands); and (2) Herfindhal index (Nowlis et al. 2010). The Herfindhal index measure was additionally used because it controls for purchase quantity. As predicted, the results using the proportion/Herfindhal index revealed that compared to those under no scarcity (control), participants made a less varied selection of soda brands under unit scarcity ($F(1, 330) = 8.89/5.19$, $p < .01/.05$; for proportion/Herfindhal-index, respectively), while participants made a more varied selection of soda brands under option scarcity ($F(1, 321) = 9.12/10.56$, $p < .01/.01$), supporting the existence of two scarcity effects that exert opposite influences on variety seeking.

Study 2 (N=191) provided real-world evidence for the proposed scarcity effects. A field experiment was conducted at an Asian supermarket. Four brands of cookies were selected as the target brands, and were placed together in an endcap display. A total of 411 boxes of cookies across 191 purchase cases were checked during a two month period. The control (product display) setting only used a regular sale tag. The unit scarcity setting used, in addition to the regular

sale tag, a tag saying "Limited Quantity." One option scarcity setting used, in lieu of "Limited Quantity," a tag saying "Sales Limited to Four Flavors." A second option scarcity setting only included three out of the four brands of cookies and only used the regular sale tag as in the control setting. As earlier, the unit scarcity setting yielded less choice variety than did the control setting ($F(1, 94) = 5.86/6.69$, $p < .05/.05$ for the proportion and Herfindhal-index variety-seeking measures, respectively), while the option scarcity setting yielded more choice variety than did the control setting ($F(1, 91) = 4.95/5.37$, $p < .05/.05$, for first option scarcity setting; $F(1, 85) = 14.54$, $p < .01$, for second option scarcity setting).

Study 3 (N=290) examined participants' focus on preference (for unit scarcity) and focus on freedom of choice (for option scarcity) as factors underlying the relation between the two types of scarcity and variety seeking. Separate mediation analyses were conducted for each process. The indirect negative effect of unit scarcity on choice variety was significantly mediated by focus on preference (95% CI = [.0010, .0281]/[.0017, .0414] for the two variety-seeking measures). The indirect positive effect of option scarcity on choice variety was significantly mediated by focus on freedom of choice (95% CI = [.0005, .0279]/[.0035, .0212]).

Study 4 (N=570) examined the presence of the favorite option as a boundary condition. If our theorizing regarding the process is correct, we should observe both scarcity effects only when the favorite option is included in the set. A 3(type of scarcity: control vs. unit scarcity vs. option scarcity) x 2(inclusion of favorite: favorite included vs. favorite not included) design was used. As expected, there was a significant interaction between scarcity and inclusion of favorite ($F(2, 564) = 3.07$, $p < .05$; proportion measure). Both scarcity effects were replicated when the favorite was included ($F(1, 210) = 2.87$, $p < .08$ for unit scarcity; $F(1, 228) = 4.20$, $p < .05$ for option scarcity). However, scarcity had no impact on variety seeking among participants whose favorite was not present ($Fs < 1$).

To conclude, our work extends the scope of scarcity research by conceptualizing a new dimension of scarcity. Further, it provides an integrative framework suggesting why unit scarcity decreases variety seeking (preference mechanism), while option scarcity increases variety seeking (freedom mechanism). A successful manipulation of option scarcity in the retail environment may provide potential benefits, including balanced sales, prevention of stock-outs, inventory cost reduction, and customers' increased frequency of visiting the store.

Don't Believe the Hype

Erin Percival Carter, University of Colorado Boulder, USA
Lawrence E. Williams, University of Colorado Boulder, USA
A. Peter McGraw, University of Colorado Boulder, USA

EXTENDED ABSTRACT

Championships. Series finales. Award shows. Televised events that draw millions of viewers. Many viewers—even those without intrinsic interest—tune in because of the surrounding *hype*: intense, coordinated, multi-pronged, and exaggerated publicity efforts driven by commercial interests. Indeed, millions of people who care little about boxing, period dramas, or filmmaking watched Mayweather fight Pacquiao, the Mad Men finale, and the Academy Awards. We ask how consumers' decisions to give in to the hype (or not) affect their well-being.

There are good reasons to believe that hype both helps and hinders well-being. On one hand, pursuing hyped events can expose people to novel experiences (Keinan & Kivetz 2011), allow them to bond with others through a shared experience (Bhargave & Montgomery 2013), or simply draw their attention to something that they otherwise might have missed. However, hype can also inflate expectations and lead to disappointment (Anderson, 1973; Oliver, 1980; Mellers and McGraw 2001). Social pressure to experience hyped events and a "fear of missing out" (aka fomo; Grohol 2011) might cause people to switch away from activities that are more in line with their interests, goals, and values.

Our inquiry examines responses from nearly 7,000 people, across 16 hyped television events. We found that people who experienced hyped events reported less positive effects on their well-being than people who engaged in alternative activities. While the magnitude of the difference varied based on individual preferences, the effect persisted in all but the most extreme cases.

Although giving in to the hype did not improve people's well-being compared to pursuing alternative activities, there was one exception: social well-being. Drawing from recent work in positive psychology demonstrating the importance of considering well-being as an evaluation based on multiple distinct dimensions (Baumeister, Vohs, Aaker, & Garbinsky 2013; Seligman 2011), we examined effects on each dimension separately and found that engaging in hyped (versus alternative) events could benefit well-being by way of social relationships. This effect occurred primarily when participants' experiences were solitary. It seems that when people are alone, hyped events offer a kind of shared experience that is socially rewarding. We find support for this effect using both correlational (Study 1) and experimental (Study 2) data.

The first study was a long-term field survey conducted across 15 hyped events. The first event occurred in February of 2015 (Super Bowl XLIX) and the last event occurred in November of 2015 (final game of the World Series). We recruited all participants (n= 6,406, M_{Age} = 33.4, 60% male) on Amazon's Mechanical Turk (MTurk) via study postings that specifically recruited people who had watched the hyped event or done something fun and entertaining for themselves in the previous 24 hours. We find that engaging in a hyped versus alternative activity has significant negative effects on well-being. This pattern of results is diminished but persists when hyped activities are social and alternative activities are not, and is diminished but never reverses when participants are general fans of the event or fans who "won." However, hype does seem to offer unique social benefits for some people. When we analyzed the effect of engaging in hype on the distinct underlying dimensions of well-being, we found that solitary participants found hyped events to be more beneficial than alternative activities when it came to social well-being.

In our second study, we examined whether it is possible to improve people's experience with hyped events by drawing their attention to the social elements of the experience. This study was a three-part quasi-experimental field study, with data collected before, during and after a single hyped event: Super Bowl 50. The first survey occurred before the game started. We asked participants whether or not they planned to watch the Super Bowl. We randomly assigned participants who indicated they planned to watch the Super Bowl to one of two conditions, one featuring instructions to focus on the specifics of the game and another featuring instructions to focus on the social aspects of watching the game. We conducted our analyses using only participants who watched the game and thus, received our manipulation (*N*=485). Our analyses supported our prediction. A mixed effects model allowinºg for random effects of participant and time period during which the measure was taken revealed a significant interaction of the manipulation to focus on the details of the game or the social elements of the game and whether participants watched the game alone or with others (*t* (442.07) = -2.38, *p* = .02). Decomposing the interaction, we find that when participants watched the game alone, focusing on the social benefits of the game resulted in higher reported well-being than focusing on the details of the game (*t*(120.79) = 2.37, *p* = .02) while the manipulation had no effect when participants watched the game with others (*t* (20.09) = -0.6 *p* = .57). Analyses for each time point using a simple linear model revealed consistent results both using only half time responses (half time: interaction *t* (234) = -2.13, *p* = .03, condition simple effect among participants who watched alone *t* (234) = 2.28, *p* = .03, condition simple effect among participants who watched with others *t* (234) = -0.10, *p* = .71), and using only post-game responses (half time: interaction *t* (395) = -1.80, *p* = .07, condition simple effect among participants who watched alone *t* (395) = 1.61, *p* = .11, condition simple effect among participants who watched with others *t* (395) = -0.82, *p* = .41).

Hype is everywhere, but modern life also features a tremendous amount of choice over how we spend our time. Giving into the hype comes at a cost, most notably the opportunity cost of not pursuing other non-hyped, intrinsically motivating interests. Given the limited benefits of hype, our data lend themselves to a straightforward recommendation: unless you are alone and want to feel connected to others, don't believe the hype.

Volume Estimation as Simulated Judgment

Hannah Perfecto, University of California, Berkeley, USA
Clayton R. Critcher, University of California, Berkeley, USA

EXTENDED ABSTRACT

While standing in line at a coffee shop, consumers can eye different-sized cups on display, trying to determine which size looks ideal. While at a container store, consumers may peruse various storage boxes, trying to determine which is the right size to store the junk that has been accumulating on one's dining room table.. Previous research has examined different sources of bias when estimating volume—either the shape of the object to be judged (e.g., Anderson & Cuneo, 1978; Wansink & van Ittersum, 2003; Ordabayeva & Chandon, 2013), or the psychological states of the judge (Cornil, Ordabayeva, Kaiser, Weber, & Chandon, 2014). Although such work has identified robust sources of estimate error, they largely remain "as-if models"—algorithms that can predict when consumers' judgments will err, but that remain agnostic about the actual process by which those judgments are made. We instead propose a specific mental process by which volume estimations often unfold, thereby allowing us to make two novel predictions about what biases such judgments.

We posit that volume estimation is often made through *simulated judgment*. This proposal draws on diverse literatures that converge to suggest the key role of mental simulation in judgments and forecasts. For example, features that make it easier to imagine what global warming would feel like can make the simulations seem sharper and thus more likely (Risen & Critcher, 2011). Closer to physical judgments, Profitt and colleagues (1996, 2003) demonstrate that being weighted down makes hills appear steeper: Because the weight would make the climb more difficult, people simulate the climb (and thus the slope) as steeper.

Building on these literatures, we suggest that estimating a receptacle's volume can involve simulating an interaction with it: how much one can imagine pouring into the container. But given that pouring happens with the flow of gravity—from top to bottom—we suggest that two features can (and do) influence such judgments. First, we hypothesize an *orientation effect*—that the same glass will appear bigger right-side-up than upside-down. We test whether this is explained by the simpler mental simulation of filling an upright cup. Second, we posit a *cavern effect*—that imagining pouring through a narrow top into a wide base (as though into a cavern) makes the volume seem bigger than pouring through a wide top into a narrow base. More precisely, we suggest that—all else equal—a container with a small top-to-base ratio will look bigger than one with a large top-to-base ratio.

Study 1 focuses on the *orientation effect*. Participants (N = 302) were presented with a sequence of 24 images of 12 actual glasses (taken from Google Images) that varied in shape (e.g., plastic cup, coffee mug, stemless wineglass), size, and color. Each image was presented twice—once right-side-up, and once upside-down. In all studies, participants saw a reference cylinder of a specified size (in order to make the scaling clear) before being shown the target cup. Consistent with hypotheses, the exact same cup looked bigger when right-side-up than upside-down $t(5989.90) = 2.92$, $p = .004$.

Study 2 (N = 250) built on Study 1 in two primary ways. First, whereas Study 1 used images of actual glasses (for purposes of external validity), Study 2 used computer-generated images. This allowed us to hold the shape of a cup constant, but vary whether the wide or narrow end was depicted as the open top or the closed base. Second, we modified the images so that the cup appeared empty, or entirely full of water. We then asked participants how much they could pour into the *empty* cup, or pour out of the *full* cup. We observed main effects of orientation and the top-to-base ratio, $ts > 4.70$, $ps < .01$,

consistent with the orientation effect (right-side-up cups looked bigger) and cavern effect (cups with narrow tops and wide bases looked bigger), respectively. Showing the key role of simulation in these judgments, both effects were larger when participants imagined filling up (as opposed to emptying) the cup, $ts > 4.19$, $ps < .01$.

Study 3 (N = 209) delved more deeply into both the orientation and cavern effects. First, we asked participants about the ease of the simulation ("To what extent did you find it easy or difficult to mentally simulate filling up the cup?") Participants' higher volume estimates of right-side-up cups were partially mediated by simulation ease. Second, we held the volume of the cups constant, but varied the top-to-base ratio. This permitted us to observe that the cavern effect emerges only when there is a sufficient mismatch between a narrow top and wide base (versus the reverse), and not from the size of the top or base alone.

Study 4 (N = 388) more precisely tested the role of mental simulation (versus mere container shape) in producing the cavern effect. Participants saw open or lidded cups. In filling an open cup, the size of the top is the size of the aperture through which the cup can be filled. But for the lidded cups, which always included only a small hole through which to fill the cup, this link was disrupted. Showing the key role of simulated judgment (as opposed to mere shape), the lidded nature of the cups moderated the cavern effect: narrow tops and wide bases exaggerated the size of containers, but only when open.

Although considerable attention has been given to biases in psychophysical judgments, the present work is among the first to propose a specific psychological process by which such judgments are made. The present findings suggest that restaurant and store owners would do well to display containers right-side-up. Furthermore, packaging designers may be wise to design products with low top-to-base ratios (e.g., Yoplait yogurt) as opposed to the reverse (e.g., snowcones). Through this talk, we will emphasize the complimentary roles that basic and applied research can play: Only by offering and testing a new theoretical process account of how volume estimation unfolds were we able to make predictions for what externally-valid features should distort such judgment.

Education, Liberalism and Consumers' Response to Luxury Brands

Francine E. Petersen, ESMT Berlin, Germany
Keith Wilcox, Columbia University, USA

EXTENDED ABSTRACT

This research examines the relationship between education and consumers' response to luxury brands. Previous research finds that people who are higher in education are more likely to hold liberal values compared to those with less education (Deary, Batty, and Gale 2008; Hastie 2007; Pascarella and Terenzini 2005). Social liberalism is defined as being concerned about equality and having the desire to act in a socially responsible manner (Graham, Haidt, and Nosek 2009).

While highly educated people are more likely to be socially liberal, evidence suggests that luxury brands are inconsistent with liberal values. Although there are positive associations with luxury brands, they are also associated with excess, exclusivity, wealth, and self-enhancement (Dubois, Czellar, and Laurent 2005; Torelli, Monga, and Kaikati 2012). Luxury consumption can lead consumers to choose personal interests over the concern about the society (Chua and Zou 2009), which adds to the perception of luxury as undemocratic and elitist. Additionally, luxury consumption is often considered a selfish behavior (Griskevicius, Tybur, and Van den Bergh 2010). These negative concepts associated with luxury brands are inconsistent with liberal values, the values of highly educated consumers.

When people evaluate a target, they often form their judgment by comparing the target to relevant information in memory, such as one's personal beliefs and values (Markus 1977). These concepts can serve as a standard for evaluating the target (Tourangeau and Rasinski 1988). When a target is inconsistent with the standard of comparison, it often results in a contrast effect such that judgment of a target shifts away from the standard (Schwarz and Bless 1992). In the context of a luxury brand, this suggests that when people judge how socially conscious a luxury brand is perceived to be, they may form their evaluation by comparing the luxury brand to their personal values. Thus, we predict that:

Hypothesis 1: *Consumers with higher education will perceive luxury brands to be less socially conscious compared to those with less education.*

Hypothesis 2: *Liberalism mediates this relationship.*

Luxury brands, however, are increasingly positioning themselves as socially responsible (e.g. Davies et al. 2012). Our theory suggests that highly educated consumers may be more responsive to a luxury brand that adopts a socially responsible positioning strategy. As stated, when judging how socially conscious a luxury brand is perceived to be, consumers use their values as a standard of comparison. When a luxury brand is positioned as socially responsible, the brand's positioning is consistent with liberal values. When a target is consistent with the standard of comparison, it often results in an assimilation effect such that the judgment of the target shifts toward the standard. Thus:

Hypothesis 3: *Consumers with higher education will perceive a socially responsible luxury brand to be more socially conscious compared to those with less education.*

Hypothesis 4: *Liberalism mediates this relationship.*

Study 1 (N=319) employed a 2 (luxury vs. non-luxury brand) by 2 (real vs. mock brand) between-subjects design. In the real brand, luxury (non-luxury) condition participants saw an advertisement for Gucci (Zara). We included a mock brand (Rami) as a replicate. Participants indicated the extent to which they associated the brand with social justice, social well-being, and social concerns. Education was measured with a 5-point scale. In a regression, we found the predicted interaction between education and brand positioning (β = -.14, $t(311)$ = -2.25, p < .05). In the luxury brand condition, education had a negative and significant effect on perceived social consciousness, supporting H1. Education did not have a significant effect for the non-luxury brand. The three-way interaction was not significant.

Study 2 (N=178) employed a 2 (control vs. socially responsible) between-subjects design. Education was measured. Liberalism was measured with two items (social and political liberalism). Participants then saw one of two ads for Parmigiani Fleurier watches. The control ad promoted typical luxury brand attributes. The socially responsible ad promoted commitment to social equality. Participants indicated the brand's social consciousness on the same previous scale. We found the predicted interaction between education and positioning (β = .37, $t(174)$ = 2.81, p < .01). When participants saw the control ad, education had a negative and significant effect on the luxury brand's social consciousness. Consistent with H3, when participants saw the socially responsible ad education had a positive and marginally significant effect. We also found an interaction between liberalism and positioning (β = .23, $t(174)$ = 3.45, p < .001). When participants saw the control ad, liberalism had a negative and significant effect, but when participants saw the socially responsible ad, liberalism had a positive and significant effect. Mediation analysis suggested that liberalism mediates both in the control condition and in the socially responsible conditions.

Study 3 (N=150) employed a 2 (control vs. socially responsible) by 2 (high vs. low liberal values) between-subjects design. We primed liberal values. To manipulate brand positioning participants saw one of two ads for the Rolex brand of watches similar to the previous study. Participants completed the same previous social consciousness scale. An ANOVA revealed a main effect of positioning and the predicted interaction ($F(1, 146)$ = 11.00, p <.01). When liberal values were high, those exposed to the socially responsible (vs. control) ad perceived Rolex as more socially conscious. When liberal values were low, perceptions of Rolex' social consciousness were not significantly different.

Study 4 (N=934) was a survey. We measured perceived social consciousness, willingness to buy luxury products with two items, willingness to spend on luxury brands, and actual behaviors regarding luxury brands with three items. Regressions showed a negative and significant effect of education on perceptions of luxury brands as socially conscious, willingness to buy luxury brands, willingness to spend on luxury brands, and actual behavior regarding luxury brands (all p < .05). Perceived social consciousness mediated the effect of education on behavioral measures.

Gifting an Identity: The Effect of Gifts on Receiver Identity

Matthew Philp, HEC Montréal, Canada
Laurence Ashworth, Queen's University, Canada
Nicole Robitaille, Queen's University, Canada
Suzanne Rath, Queen's University, Canada

EXTENDED ABSTRACT

Existing work on gift-giving has tended to focus on how and why givers' choose the gifts that they do. One of the central findings of this research is that givers frequently choose gifts for their symbolic meaning (Belk 1976; McCracken 1986). Gifts can be chosen to communicate a valued relationship (Sherry 1983), shared identities and interests (Larsen and Watson 2001), and even how the giver would like the receiver to perceive them (Larsen and Watson 2001). Little research, however, has examined the impact of such gifts on receivers, despite several calls for more research on this topic (Joy 2001; Larsen and Watson 2001; Minowa and Gould 1999).

The current work suggests that receivers often see gifts as indicative of how the giver views them. Receiving a certain team's hockey jersey, for example, suggests that the giver perceives the receiver as a fan. Or receiving a coffee cup suggests the giver must view the receiver as a coffee drinker. And because gifts have the potential to convey such information (i.e., reflected appraisals; Tice and Wallace 2011), they should also be capable of affecting individuals' self-appraisals (Cooley 1902; Mead 1934; Shrauger and Schoeneman 1979). In short, the current work investigates the idea that gifts can alter aspects of individuals' identity because of what they convey about how others view them.

GIFTS AS REFLECTED APPRAISALS

Schwartz (1967) first suggested that gifts might act as "generators of identity," where at a young age parents use gifts to push gender identities (e.g., dolls for girls, guns for boys). Such gifts could potentially affect identity via selective exposure, but they could also affect identity by communicating information about how the giver perceives the receiver to be. This latter suggestion is consistent with the looking glass view of self, where individuals come to learn about themselves through the eyes of others (Cooley 1902; Mead 1934; Shrauger and Schoeneman 1979). According to this perspective, beliefs about how others view us (i.e., reflected appraisals) can directly influence how we see ourselves (i.e., self-appraisals).

Gifts should be capable of providing a very clear picture – from the receivers' perspective – about what the giver thinks of them. Even gifts that receivers dislike should presumably convey information about what the giver *thought* the receiver might like. As such, receivers might often see gifts as diagnostic of how the giver views them. This is not to say that this view is necessarily *accurate*. The giver may have chosen the gift for reasons that have nothing to do with what they thought the receiver would like. Our suggestion is simply that gifts are often likely to be seen as indicative of what a giver thinks the receiver would like, and therefore, that they provide information about how the giver views the receiver.

Given the possibility that gifts might be interpreted this way (i.e., as information about how one is seen by other people), we suggest that they provide a strong context in which to study the effect of reflected-appraisals on self-appraisals. Extant work has largely investigated this relationship in naturalistic settings, and therefore relied on correlational data, or else has examined contexts in which actual appraisals are highly ambiguous (e.g., Kenny and DePaulo 1993; Tice and Wallace 2003). Gift receipt is one context where we believe we might find evidence of the impact of reflected appraisals on self-appraisals. This would contribute to the gift-giving literature by investigating the impact of gifts on receivers' reflected appraisals and, in turn, on identity formation, but would also contribute to the literature on reflected appraisals by providing an experimental demonstration of the role of reflected appraisals on self-appraisals.

OVERVIEW OF STUDIES

To test these ideas we conducted a series of studies examining how receiving gifts can influence both self-identity and beliefs about how the giver perceives the receiver (i.e., reflected appraisals). Across four experiments and a field study we find support for our predictions.

Experiment 1 demonstrated that receiving a team jersey (Experiment 1a) or a city branded mug (Experiment 1b) as a gift vs. receiving the same item as a randomly drawn prize increased gift-congruent identity and reflected appraisals. In other words, people who received these items as gifts vs. as a prize identified more strongly with the sports team (Experiment 1a) or city (Experiment 1b). This effect is mediated by the receiver's belief that the giver views the receiver as possessing the identity signaled by the gift (i.e., reflected appraisals).

Experiment 2 and 3 replicates the effect and demonstrates moderation of process by manipulating whether the gift is diagnostic for how the giver sees the receiver or not. Specifically, Experiment 2 found that the effect of receiving an identity-signaling gift on identity was larger when the gift was personal and not given to anyone else (diagnostic) compared to when the same gift was given to multiple people (non-diagnostic). Similar results were found in Experiment 3 where the effect of receiving an identity-signaling gift on identity is larger when given by a close (diagnostic) vs. distant (non-diagnostic) other. Evidence is provided that this moderated effect is mediated by the receiver's belief that the giver views the receiver as possessing the identity signaled by the gift.

Lastly, in Experiment 4 we examined this effect outside the laboratory in a natural experiment. Specifically, during the new naming of a business school in the Fall of 2015, students on campus were given t-shirts with the new name and logo by the schools' administration. Survey results later found that receiving the t-shirt (vs. not) resulted in higher self-identity perceptions aligning with the new school name.

CONCLUSION

Overall, by showing that gifts can drive recipients' identity, we highlight an important consequence of gifts from the receiver's perspective. Across five studies we provide evidence that receivers use gifts to inform them of how the giver views them. We demonstrate that these reflected appraisals can then influence how the receiver perceives themselves, influencing their own identity perceptions.

Feeling Stupid About Nothing:
Inferring Competence From Externally Caused Negative Outcomes

Matthew Philp, HEC Montréal, Canada
Laurence Ashworth, Queen's University, Canada

EXTENDED ABSTRACT

It is easy to think of personally dissatisfying consumption experiences. Maybe it was from receiving horrible service at a restaurant, a product not living up to its claims, or being ripped off by a salesperson. In either case, these experiences are typically unexpected and essentially random. Sometimes, they just happen. Since they are firm-caused, consumers should not feel any self-blame (e.g., Folkes 1984; Weiner 1980; 1995; 2000). There is, however, research that has examined how victims of horrible crimes and diseases sometimes blame and feel worse about themselves for having these externally caused experiences. We seek to clarify this discrepancy and provide evidence for when people feel worse about themselves (i.e., decreased self-esteem and feel incompetent) following externally caused consumption outcomes.

In this current research, we argue that consumers can feel incompetent for firm-caused dissatisfying outcomes, while simultaneously feeling dissatisfied with the firm for causing the dissatisfying outcome. Although these ideas have not received much attention in the context of consumer decisions, there is variety of evidence in the victimization and health literatures that is consistent. For example, victims of rape typically take some responsibility for the attack (Littleton, Magee, and Axsom 2007). Similar attributions of self-blame have been shown for victims of spinal cord injury and cancer, even when the objective circumstances indicate the victim had little control over their outcome (e.g., Bearison et al. 1993; Bulman and Wortman 1977; Burgress and Haaga 1998; Davis et al. 1996; Fogel 2004; Glinder and Compas 1999; Malcarne et al. 1995). Overall, existing work has shown that victims of various misfortunes, from real life crime, accidents, and illness, will take some blame for what happened to them, even when the outcome was caused entirely by another party or was essentially random. From this, we ask, can consumers blame and feel worse about themselves for firm-caused dissatisfying outcomes? If so, when is this likely to occur? And what impact can this have on the consumer?

Reasons behind blaming the self appear to be mixed (Littleton et al. 2007). However, in the victimization literature, Davis et al. (1996), provides evidence that after controlling for causal attributions, individuals who perceived the negative outcome to be more avoidable were more likely to foster feelings of self-blame. This is because attributions of causality (i.e., the who or what that caused the negative outcome) should be conceptually different from what the victim believes they could have done in hindsight to *avoid* the negative outcome. We suggest many analogous situations can exist in a consumer context. For example, consumers having the freedom to choose whatever store they want versus being restricted in their choice will increase the perception that a negative outcome was, in hindsight, avoidable. From this, we predict that consumers will feel incompetent following firm-caused dissatisfaction when they believe, in hindsight, that they could have done something to avoid it. In other words, even though the consumer blames and is dissatisfied with the firm, under conditions of increased perceptions of avoidability consumers will also feel as an incompetent consumer.

SUMMARY OF STUDIES AND RESULTS

Three studies were conducted to demonstrate that firm-caused dissatisfaction can lead to feelings of incompetence (Study 1, 2, 3),

that this effect is moderated by perceived avoidability (Study 2 and 3), and that these perceptions can arise from truly random negative outcomes (Study 3).

In study 1, participants were asked to either describe four Satisfying or four Dissatisfying firm-caused consumption experiences they recently had for which the outcome was unforeseeable, unintended, unexpected, and/or they could not have planned for it to have occurred. Results find that recalling firm-caused dissatisfying experiences compared to satisfying ones increase self-reported feelings of incompetence (Ms = 3.09 vs. 2.42; $F(1, 60) = 6.77$, $p < .05$).

In study 2, participants read a scenario depicting them having a lot of time (Avoidable) or little time (Less-Avoidable) to make a necessary purchase that later turned out to be a firm-caused dissatisfying or normal experience. A significant Dissatisfaction X Avoidability interaction ($F(1, 96) = 7.55$, $p < .01$) indicated that the effect of a firm-caused dissatisfying experience on feelings of incompetence is smaller when the situation is perceived to be non-avoidable (Ms = 3.92 vs. 3.22; $F(1, 96) = 2.07$, $p > .10$) than when it is perceived to be avoidable (Ms = 4.78 vs. 2.68; $F(1, 96) = 39.81$, $p < .001$).

Study 3 was a behavioral experiment that manipulated participants actual outcome to be a random negative or neutral outcome and also manipulated whether the situation was perceived to be more vs. less avoidable. Specifically, all participants entered into a lab and were given a chocolate bar to keep. However, all participants then drew from a lottery (Avoidable) or had a ticket drawn for them (Less-Avoidable) to see if they would keep their chocolate bar or not. Results showed a significant Random Outcome X Perceived Avoidability interaction ($F(1, 131) = 4.17$, $p < .05$) indicating that the effect of randomly losing a chocolate bar, versus not, on feelings of incompetence is larger when participants pick their own lottery ticket (Ms = 3.08 vs. 2.33; $F(1, 131) = 8.47$, $p < .01$) and smaller when participants had their ticket picked for them (Ms = 2.80 vs. 2.79; $F < 1$).

CONCLUSION

These results demonstrate that consumers can feel incompetent for negative outcomes they did not cause. Since perceptions of competence is a central component to self-identity, self-esteem, and self-efficacy, demonstrating that this can be influenced by firm-caused dissatisfaction is very interesting. Existing research examining firm-caused dissatisfaction would assume the consumer to be a blame externalizer. However, we provide evidence that consumers' sense of self is fragile and under certain circumstances they can feel incompetent for essentially random and uncontrollable negative outcomes. Future research examining consumer reactions to firm-caused dissatisfaction should consider these findings and how feelings of incompetence can influence their reactions and future behaviors.

Human Brand Identity Types and Dynamics: The Role of Incongruent Extensions and Legitimacy Mechanisms - The Case of Film Directors

Camille Pluntz, ISG International Business School, France
Bernard Pras, Université Paris Dauphine and ESSEC Business School, France

EXTENDED ABSTRACT

Professional human brands have become substantial research objects. Scholars have already focused on professional human brand building strategies (Parmentier, Fischer and Reuber, 2008, 2013; Dion and Arnould, 2016) but have neglected to raise the question of human brand identity evolution. This issue needs to be addressed, as branded individuals are seen undertaking incongruent extension strategies in their careers, which come to alter their human brand's identity.

Previous research suggests that only human brand identities resting on expertise associations (the chameleon conformist), or on expertise and creativity associations (the archetype) are viable (Parmentier et al., 2013). On the contrary, we assume that a human brand identity solely rooted in creativity associations can exist socially, and is thus also viable such as it is for artists (Becker, 1988) or charismatic creative persona (Dion and Arnould, 2011). Furthermore, we link the social existence of human brands to the legitimacy they hold (Arnould and Dion, 2013) in regards to various constituencies, that is, inside members of the industry (specific legitimacy), critics (bourgeois legitimacy) and the public (popular legitimacy) (Bourdieu, 1983). By conceptualizing incongruent extensions as sources of legitimacy loss/gain, the aim of our paper is thus to understand the legitimacy mechanisms which are activated by incongruent human brand extensions and which bring a branded individual to evolve from one professional human brand identity type to another. We focus on film director who are key human brands in the film industry (Kerrigan, 2010). We conduct two studies to answer two research questions: What are the professional identities available to human brands? What are the dynamics of professional human brand identities? The first study is based on an analysis of American Western film directors (1909-2011). The second study is based on in-depth interviews conducted among French film directors, critics, producers, and filmgoers.

Study 1

In order to have a comprehensive view of the existence of human brand categories, we chose to analyze American Western film directors by following a "study of context" approach (Askegaard and Linnet, 2011), that is by confronting personal trajectories to historical and institutional trajectories (Brown, Hirschman, and Maclaran, 2001). From an analysis of 570 American westerns, we identified four western waves (1909-1928: Silent Western movies; 1929-1962: Classic movie westerns and Golden age; 1963-1980: Era of anti-heroes; 1981-2011: Episodic movie westerns). In light of these cycles, we then analyzed the patterns of the 281 filmographies comprised in our database. We selected 20 film directors representative of the various patterns available and conducted deeper analysis of their filmographies with qualitative data (Eisenhardt, 1989).

Our results confirmed the existence of the two human brand identities present in the literature: (1) The "chameleon conformist" who builds its brand by directing highly commercial films (e.g. Andrew V. McLaglen). He forges his professional image by cultivating strong expertise and by giving evidence of performance. (2) The "archetype" director who makes films that fit into a pre-existing socially inscribed definition of the western genre. He follows the rules by cultivating his expertise but also bends them in a creative, yet legitimate manner (e.g. Ralph Nelson).

Our analysis also unveils two other film director types, supporting our assumption: (1) the archetype niche director whose identity rests entirely on the creative attributes of his atypical films (e.g. Fritz Lang) which appeal to a small public of film lovers; and (2) the film director influencing the social definition of the western genre (e.g. John Ford).

Study 2

We define human brand legitimacy as a sociological attribute through which a human brand is perceived as matching an identity inscribed in a socially constructed system (Weber, 1971; Suchman, 1995; Dion, 2013). We propose that film director human brands exist socially because they benefit mainly from specific, bourgeois and popular legitimacy (Bourdieu, 1983) allocated by producers, critics and the public. These different legitimacy types, and thus each human brand, evolve according to the characteristics and success of the director's newest film. But film directors often make incongruent extensions (Heckler and Childers, 1992): with an "unexpected extension", that is a film in a new genre (e.g. a thriller directed by a romance film director) or an "irrelevant extension", which is a film different from its director's original identity (e.g. a conformist film directed by a niche auteur film director).

In order to study the dynamics of professional human brand identities, we conducted eight in depth interviews, comprising 2 film directors, 2 producers, 2 critics and 2 film goers. Film directors were asked to give a detailed history of their careers, while other respondents were asked to create film director categories and extensively talk about directors' filmographies and changes in film director identities. We used the grounded-theory methodology (Glaser and Strauss, 1967) to analyze the data.

The 4-tiered professional human brand categorization emerged again, with the appearance of a new variable: eclecticism. Conformist (high specific legitimacy) and niche (high bourgeois legitimacy) auteur human brands appeared as non eclectic; auteurs for the masses (bourgeois and popular legitimacy) were mostly eclectic, and the consecrated (high specific, bourgeois and popular legitimacy) auteurs were highly eclectic. Respondents highlighted four types of identity dynamics. "Conformist" film directors can evolve towards a niche auteur identity by gaining bourgeois legitimacy with an auteur film (incongruent extension), but they perceive this move as extremely risky for their specific legitimacy. "Niche auteur" directors who attempt to evolve towards the wide public auteur category through incongruent commercial extensions incur low risks on bourgeois legitimacy and can benefit from specific and popular legitimacy gains. "Wide public auteurs" can use risk-free incongruent "commercial" film extensions to reinforce specific and popular legitimacy. But only very successful congruent films may be efficient to also enhance bourgeois legitimacy and attain the "consecrated" human brand category. The "consecrated" human brand type runs the least risk of losing its legitimacy by directing any incongruent film.

In sum, our findings extend Parmentier et al.'s framework (2013) by adding two other viable human brand types (i.e. niche archetype human brand and consecrated human brand) and by showing that human brand identities and evolution depend on the legitimacy forces at play in a given field of practice.

Contagious Endowment Effect

Tae-Hyung Pyo, SUNY New Paltz, USA
JaeHwan Kwon, Baylor University, USA
Thomas Gruca, University of Iowa, USA
Dhananjay Nayakankuppam, University of Iowa, USA

EXTENDED ABSTRACT

Endowment effect has typically been conceptualized as a phenomenon that occurs within a transaction at a specific point in time wherein the buyer and seller have differing perspectives that result in different reservation prices: the buyer's willingness-to-pay (hereafter WTP) and the seller's willingness-to-accept (hereafter WTA). There is little in prospect theory to predict any carry-over of the endowment effect to another transaction. However, recent research (e.g., Nayakankuppam and Mishra 2005) has affirmed that the endowment effect is not due to shifts in response language (e.g., buy low, sell high) but reflect actual differences in mental representations of the item by sellers and buyers. Since mental representations are associative networks in memory (Anderson 1983), such associations that have been primed in memory are more accessible. Greater accessibility is likely to bias subsequent information processing and influence subsequent judgments (Houston and Fazio 1989). Therefore, we propose that an endowment, once experienced, can exert an influence the valuations of similar objects in a subsequent transaction.

STUDY 1

One hundred and nineteen undergraduate students (male=58.45%, M_{age}=20.61) were randomly assigned to a 3 (buyer-first, seller-first vs. control) X 2 (reservation price in first task vs. second task) X 2 (order: blue mug first vs. red mug first) mixed factorial design. In the buyer first condition, participants were given $5 cash, randomly assigned to see a mug of a particular color, and asked to provide their WTP. After reporting their WTP, however, the participant was told that the mug was unavailable. S/he was then shown the mug of the other color and asked to provide his/her WTP for this mug. In the seller-first condition, a participant was given a mug of a color and asked to provide their WTA price. Then, s/he was told that the assigned color mug was unavailable. S/he was given $5 cash instead of the mug and asked to provide his/her WTP for the mug of a different color. In the control condition, participants were given $5 cash, randomly assigned one of the mugs (blue or red), and asked for their WTP. Next, without the cover story of unavailability, they were asked for their WTP for the other color mug.

Reservation prices in the first task

A one-way (buyer first vs. seller first vs. control) ANOVA yielded a main effect of role on reservation prices in the first task ($F(2, 116)$=5.768, p=.004. Planned comparisons showed that sellers reported significantly larger reservation prices than buyers ($F(1, 116)$=7.880, p=.006) and the control condition ($F(1, 116)$=5.114, p=.027). The classic endowment effect is replicated in these results.

Reservation prices on the second task

A main effect emerged for the role in the first task on the reservation prices quoted in the second task ($F(2, 116)$=3.169, p=.046). Planned analyses revealed that participants who had been sellers in the first task reported greater WTP in the second task than those who had been buyers in the first task ($F(1, 116)$=3.268, p=.075) and those in the control ($F(1, 116)$=4.287, p=.041).

Repeated measure comparisons

Of importance, a role versus task (i.e., first vs. second WTP) analysis yielded only a main effect for the role in the first task ($F(2, 232)$=9.224, p<.001) but neither the task nor the interaction term. A planned comparison of the reservation prices quoted by participants who had been sellers in the first task (and buyers in the second task) yielded no significant effect ($F(1, 232)$=1.233, NS). These individuals changed roles between tasks. In contrast to the predictions of a significant change in reservation prices predicted by prospect theory, we observed no significant change in reservation prices. This result is not a function of the unavailability of the mug in the first task. If that were the case, there would be a difference between the WTP of the "buyers first" participants in their first task and the control condition. In other words, the fact that WTP amounts are higher when one happened to be a seller earlier for a similar object is consistent with the idea of a carry-over of the endowment effect.

STUDY 2

We analyze data from eBay.com. We predict that the experience of being a high bidder on an item creates a change in the bidder's internal representation of the object in much the same way that ownership or possession does. We further argue that if the bidder fails to win the item, his or her reservation price in subsequent auctions for similar, but different, items will be higher than those bidders who never enjoyed the status of being the highest bidder—in other words, the endowment effects are contagious and spread to other products. Our model to estimate the influence of experiences from *prior* auction (*j-1*) on the bidding price of individual bidder *i* in a *current* auction *j* is as follows:

Model 1

Indicator Variable for the Endowment Carry-over Effect

$$Bid\ Amount_{ij} = \beta_0 + \beta_1 Pseudo\text{-}Endowment_{ij-1} + \beta_2 ln\ Bid\ Time_{ij} + \beta_3 Bidder's\ Feedback\ Score_{ij}$$
$$+ \beta_4 Frequency\ of\ Previous\ Auction_{ij} + \beta_5 Duration\ of\ Auction_{ij}$$
$$+ \beta_6 Starting\ Price_{ij} + \beta_7 Shipping\ Cost_{ij} + \beta_8 Seller's\ Reputation_{ij}$$
$$+ \beta_9 Posting\ Per\ Day_{ij} + \beta_{10} BIN\ Price_{ij} + \beta_{11} Closed\ Auction + \varepsilon_{ij}$$

Model 2

Continuous Measure of the Endowment Carry-over Effect

$$Bid\ Amount_{ij} = \beta_0 + \beta_1 Top\ Bidder\ Duration_{ij-1} + \beta_2 ln\ Bid\ Time_{ij} + \beta_3 Bidder's\ Feedback\ Score_{ij}$$
$$+ \beta_4 Frequency\ of\ Previous\ Auction_{ij} + \beta_5 Duration\ of\ Auction_{ij}$$
$$+ \beta_6 Starting\ Price_{ij} + \beta_7 Shipping\ Cost_{ij} + \beta_8 Seller's\ Reputation_{ij}$$
$$+ \beta_9 Posting\ Per\ Day_{ij} + \beta_{10} BIN\ Price_{ij} + \beta_{11} Closed\ Auction + \varepsilon_{ij}$$

The estimated coefficient of *Pseudo-Endowment* shows that a bidder increases her or his bid by 4.0% of buy-it-now price if s/he had been a high bidder in a prior auction. In addition, we found that the longer the time spent as the top bidder in the prior auction, the higher the subsequent WTP for the same item (*Top Bidder Duration*). These results show that the endowment effect caused by being a top bidder is transferred to a similar object.

GENERAL DISCUSSION

Recent research documents the differences in mental representations of the object in transaction (e.g., Carmon and Ariely 2000;

Johnson et al. 2007). In the current research, we questioned whether the biased mental representations and emotional attachment (which appears to be the source of the endowment effect) wither away once the specific item being transacted is gone for good or it can find its way to a new home to infect another transaction. Our study finds that individuals do appear to transfer their biased mental representations to similar other objects, and thus the endowment effect contaminates future transactions.

Breaking Free From the Sunk Investment: The Role of Positive Affect and Instrumental Attitude toward Resource Investment in Reducing Sunk Cost Bias

Jin Seok Pyone, University of Kansas, USA
Kyle J. Emich, University of Delaware, USA

EXTENDED ABSTRACT

Sunk cost bias is a pervasive problem in consumer decision making that occurs when people continue allocating resources to failing endeavors (Arkes and Blumer 1985; Staw 1976, 1981). This tendency exists because people often focus on prior investments without considering the possibility of failed future returns. While many suggested interventions to attenuate this bias involve altering cognitive processes, the current research examines an alternative affective route. Specifically, we propose that inducing positive affect can mitigate consumers' tendency to rely on sunk costs when making future commitment decisions.

We posit that sunk cost bias is associated with people's attitude toward previously invested money or other economically construed resources. That is, normatively people tend to view their own resource investments as an ultimate asset to conserve or maximize (terminal attitude), and thus salvaging a prior investment is more likely to be prioritized in the decision process. We propose that positive affect naturally attenuates this terminal attitude toward resource investment. Prior work suggests that positive affect enhances people's cognitive flexibility (Ashby, Isen, and Turken 1999; Isen 2008; Pyone and Isen 2011) and thus broadens their scope of thinking (Fredrickson 2001).

In the context of present research, we suggest that positive affect allows people to consider their prior investment in the context of a long-term gain, and thus it will enable consumers to view their prior monetary investment as an instrumental resource to be used for the long-term gain (vs. terminal resource that needs to be salvaged). Thus, when a prior monetary investment is useful in bringing about a long-term gain, people experiencing positive affect will continue to invest in a prior endeavor. However, when a monetary investment is dissociated from a long-term gain, people experiencing positive affect will acknowledge that their prior investment has no instrumental value and thus disregard it in their reinvestment decision, stopping their commitment to it (i.e., reducing sunk cost bias).

We tested our hypothesis over four studies. In Study 1, we test the influence of positive affect on a typical sunk cost problem in everyday consumer decisions involving money. Participants watched either an amusing film clip or a neutral clip depending on their affect condition and then made a commitment decision about an apartment. Specifically, they were asked to choose between an apartment for which they already paid a non-refundable deposit and a new apartment which provide a better long-term benefit. The results showed that the majority of the neutral affect condition chose to keep the old apartment as they planned. However, this commitment tendency was significantly decreased in the positive affect condition.

In Study 2, we test our core effect in a real choice setting and examine if positive affect can attenuate sunk cost bias involving a behavioral resource (effort). Participants were asked to choose their own pen to take after the study. They were led to invest either a high or low amount of effort in choosing their own pen. After making their initial choice, respondents were presented with one more decision. Specifically, the experimenter asked if respondents would like to trade the pen they chose for a superior pen that received a higher rating than their current option. Respondents' decision to switch or not was recorded and all respondents received their choice of pen after the experiment. The results showed that when participants invested a minimal amount of effort (low sunk cost), the neutral and positive affect conditions did not differ in their decision to keep their original pen. However, when respondents had to spend the extra effort choosing their pen, those in the neutral affect condition showed a greater tendency to keep their initial choice. In contrast, those in the positive affect condition were more willing to switch to the better alternative.

In Study 3, we investigate whether the proposed attenuating effect of positive affect depends on the decision context: specifically, whether the previously incurred cost is redeemable into a long-term gain or not (whether it has instrumental value or not). The results showed that those who were experiencing positive affect were successfully able to disregard their prior investment in their decision making when it was irredeemable (sunk). However, when it was redeemable, they showed continued commitment as controls did.

Finally, in Study 4, we examine our proposed mechanism. We found that participants experiencing positive affect were less likely to view their monetary investment as terminal but more as instrumental resources, and this attenuated terminal attitude toward money mediated the relationship between positive affect and the reduction of sunk cost bias. Taken together, the results of four studies involving hypothetical as well as real consumer choices provide consistent evidence that inducing positive affect reduces sunk cost bias in consumer decision making.

Morality-based Blame for Victims of Harmful Product Failures

Brandon Reich, University of Oregon, USA
Troy Campbell, University of Oregon, USA
Robert Madrigal, University of Oregon, USA

EXTENDED ABSTRACT

Imagine an automobile accident resulting from faulty brakes. To what extent would the driver be blamed if he was driving to meet his mistress rather than his wife? The objective reason for the accident in both cases is brake failure, yet the moral nature of the driver's behavior is likely to color our assessment of blame to either the victim or company. Victim blaming is an impediment to social change (Ryan 1976) because it stunts market forces that would otherwise punish the company's bad behavior, thus threatening market self-regulation. Victim blame is therefore an important topic that has received little empirical attention in the consumer behavior literature.

Alicke's (2000) theory of culpable control posits that following a harmful event, people automatically assess blame based partly on character evaluations. We propose that product failures harming an immoral (vs. neutral or moral) victim will produce (H1a) more victim blame and (H1b) less company blame. Further, due to its role in predicting victim derogation (Kogut 2011; Lerner and Simmons 1966), we propose that Belief in a Just World (BJW; Lerner 1980) will potentiate the enhanced blame for the immoral (vs. neutral or moral) victim (H2). We also propose that the morality × BJW interaction will reduce company blame, mediated by victim blame (H3).

STUDY 1

We recruited 182 attentive participants from MTurk (M_{Age} = 35.87, SD_{Age} = 11.87; 51.1% female). Half the sample began with Lipkus' (1991) seven-item BJW scale (α = .903), whereas the other half ended with this scale. Because BJW scale order influenced victim and company blame (both ps < .095), we retained it as a dichotomous covariate in all studies. Participants were randomly assigned to read one of two scenarios about a person named Mark in a 2-cell (morality: immoral vs. neutral) between-participants design. In the (immoral) [neutral] scenario, Mark's brakes failed and he crashed into a tree while driving to see his (mistress) [wife]. Participants then responded to two attention checks, a three-item manipulation check of immorality perceptions (α = .946), and three-item scales for each of victim blame (α = .879) and company blame (α = .931).

Independent samples t-tests showed that perceptions of immorality and victim blame were higher and company blame was lower in the immoral (vs. neutral) condition (all ps < .013), supporting H1. Moderated mediation analysis (PROCESS model 7; Hayes, 2013) supported H2 and H3, such that the morality × BJW interaction increased victim blame which in turn decreased company blame (*index* = -.265, *SE* = .151, *95% CI* [-.586, -.001]). Though Study 1 provides initial support for our hypotheses, it is not yet clear whether a *moral* victim will be blamed less than a morally neutral one, or if victim blaming will influence choice of real brands.

STUDY 2

We recruited 278 attentive participants from MTurk (M_{Age} = 34.74, SD_{Age} = 10.79; 54.3% female), all of whom indicated at least moderate liking for Chipotle, the brand used in this study. Participants were randomly assigned to read one of three stories – ostensibly reported by other respondents – about a coworker named Darren, in a 3-cell (morality: immoral vs. neutral vs. moral) between-participants design. The (immoral) [moral] story described Darren as (lazy, rude, and unpleasant) [hardworking, kind, and fun]; Darren's char-acter was not described in the neutral story. All stories explained that Darren got food poisoning from Chipotle. We used similar measures of BJW (α = .892), manipulation check (α = .886), victim blame (α = .852), and company blame (α = .790). We also offered participants an actual choice between a $10 gift card to either Subway or Chipotle.

A one-way MANOVA with Bonferroni-corrected contrasts showed that Darren (the victim) was perceived as more immoral in the immoral (vs. neutral) condition (p < .001), and more immoral in the neutral (vs. moral) condition (p < .001). Supporting H1a, Darren was blamed more in the immoral (vs. neutral or moral) condition (both ps < .001), but blamed equally in the neutral and moral conditions (p > .999). We dummy-coded morality into dummy1 (0 = neutral; 1 = immoral) and dummy2 (0 = moral; 1 = immoral), and used PROCESS (model 7) to test moderated mediation (X = dummy1, M = victim blame, W = BJW, Y = company blame), showing good fit (*index* = -.186, *SE* = .113, *95% CI* [-.484, -.018]) and supporting H2 and H3. Based on this model, we used SEM to examine choice as an outcome of company blame, which exhibited excellent fit ($\chi^2(10)$ = 8.569, p = .573, CFI > .999, RMSEA < .001, PCLOSE = .836). Similar results emerged using dummy2 in PROCESS and SEM. Study 2 replicated and extended Study 1, but did not distinguish between moral and neutral victims. Based on Nadler (2012), we expected negligence to moderate the effect of morality, such that a moral (vs. neutral) victim will be blamed less only when he is not negligent (H4).

STUDY 3

We recruited 269 attentive participants from MTurk (M_{Age} = 35.52, SD_{Age} = 11.92; 49.1% female). Participants were randomly assigned to one of four conditions in a 2 (morality: moral vs. neutral) × 2 (negligence: yes vs. no) between-participants design. As in Study 2, stimuli were based on a story about Darren, with a similar manipulation of morality. The (negligent) [not negligent] stories explained that Darren was at a bar with his phone on the counter, and (Darren's phone was gone when he returned from the bathroom) [a thief grabbed Darren's phone and ran while Darren was there]. Darren later discovered that his private information was stolen, even though the mobile provider guaranteed identity-theft protection. We used similar measures of BJW (α = .919), morality manipulation check (α = .830), victim blame (α = .905), and company blame (α = .786), as well as a three-item negligence manipulation check (α = .954).

A 2 × 2 MANOVA showed that participants in the moral (vs. neutral) conditions perceived the victim as less immoral (p < .001), and participants in the negligent (vs. not negligent) conditions perceived the victim as more negligent (p < .001). Supporting H4, we observed a morality × negligence interaction on victim blame (p < .001), such that participants blamed the moral (vs. neutral) victim less when he was not negligent (p < .001), but not when he was negligent (p = .143). PROCESS (model 7) showed that the morality × negligence interaction reduced company blame, mediated by victim blame (*index* = -.295, *SE* = .154, *95% CI* [-.683, -.058]. Thus, consumers only blamed the moral (vs. neutral) victim less when they are explicitly told that the victim was not negligent.

The Untouchables: The Sacredness of Brand Logos

Maria A. Rodas, University of Minnesota, USA
Carlos J. Torelli, University of Illinois at Urbana-Champaign, USA
Shirley Y. Y. Cheng, Hong Kong Baptist University, Hong Kong

EXTENDED ABSTRACT

Companies spend millions of dollars redesigning their logos, often only to revert to the old logo, given consumer backlash. Tropicana, for example, spent $35 million to unveil a drastically new design, only to go back to the old logo after consumers complained. While Tropicana might be a well-known example, it is hardly the only one. That is not to say that all logo redesigns fail. So what determines whether a brand's logo is "untouchable"? In this research we propose and find evidence that one determinant of how protective consumers are of a brand's logo is the extent to which the brand is collectively considered sacred.

We define brand sacredness as the extent to which brands are perceived as having an extraordinary dimension and are associated with an endless time and space (Belk, Wallendorf, and Sherry 1989; Kesebir, Chiu, and Pyszczynski 2011). Additionally, brand sacredness is conceptualized here in terms of consumers' views about the shared understanding of such transcendence and boundlessness meanings. We propose that brand sacredness is a construct that exist in the mind of consumers, which emerges from an understanding of how sacred meanings are collectively drawn by consumers to construct crucial parts of the self (see McCracken 1986). Thus, we focus on brand sacredness that emerges through external sanctioning by experts and reference groups, i.e., the collective understanding of brand sacredness, instead of on sacredness that might emerge through personal experiences (e.g., rituals, gift giving, or inheritance, Belk, Wallendorf, and Sherry, 1989).

We propose and find evidence in five studies that brand sacredness is a distinct construct that can uniquely predict how protective consumers are of a brand's logo, so that a collective understanding about a brand's level of sacredness can drive consumers' own personal experience of moral outrage as a response to changes to the brand's logo, even when there is a weak connection with the brand. Furthermore, we find evidence that the process underlying this effect is consumers' desire to protect the essence of a brand perceived to have high levels of sacredness.

Given that past research on sacredness consumption has focused more on consumption experiences in general as opposed to brands in particular, we conducted Study 1 with the goal of developing a reliable and valid measure of brand sacredness. A first sample rated different brands on a 5-item sacredness scale. An EFA showed that all items loaded on a single factor, with a high level of internal consistency. A second sample rated another set of brands on sacredness, self-brand connection (SBC), and cultural symbolism (CS). A CFA with the three constructs as separate factors offered a good fit to the data and better than a model with a single factor, suggesting that brand sacredness is a distinct construct that is partially correlated with the other two brand measures.

Study 2 was designed to investigate the impact of brand sacredness on the outrage in response to the logo redesign of a familiar brand (Under Armour). Participants rated the brand in terms of brand sacredness, SBC, and CS. Participants were then shown visual representations of changes to the brand's logo and were asked to rate their own personal emotions (anger and disgust) towards them. Results demonstrate that after controlling for self-brand connection and collective beliefs about cultural symbolism, brand sacredness predicts consumers' experience of moral outrage in response to changes to the symbols of a brand.

Study 3 was designed to provide further evidence of our main prediction using a more controlled environment by manipulating perceptions of sacredness of an unfamiliar brand of chocolates (Milka). Participants were randomly assigned to either the sacredness condition, where they read brand information aimed at manipulating collective beliefs of brand sacredness, or to the control condition (neutral information). Then participants rated the brand in terms of sacredness and reviewed 2 different changes to the most visible element of the brand (i.e., color of the logo). Results from an ANCOVA on ratings of emotions toward the changes with manipulated sacredness as a fixed factor (SBC and CS as covariates) demonstrated that participants in the sacredness (vs. control) condition experienced stronger negative emotions toward the proposed changes to the logo.

Study 4 aimed to provide initial process evidence, namely the desire to protect the essence of the brand. To rule out that the effect is just driven by the possibility that a logo change is simply perceived as ill-conceived to the marketing of the brand, participants rated their reactions to hypothetical changes to the logo as well as other similar ill-conceived changes to the brand strategy as related to new products and target market expansions—that we argue are less essential and central to the brand meaning. As predicted, simple contrasts for the logo-related actions revealed that collective perceptions of brand sacredness were positively related to feelings of anger and disgust in response to changes to the brand logo and not to ill-conceived changes to less essential elements of a brand strategy.

To obtain direct evidence of the underlying mechanism, participants in Study 5 rated the *Columbia* brand in terms of sacredness (as well as on SBC and CS) and then indicated their anger and disgust toward several changes to the brand's logo. Immediately after, they also indicated their level of agreement with statements that reflect a desire to protect the brand's essence (e.g., "It is important for *Columbia* to protect its brand essence"). A mediation analysis with SBC and CS as covariates suggested that the heightened desire to protect the brand's essence mediated participants' negative emotions toward the logo changes of a more (vs. less) sacred brand.

This research aims to contribute to the brand logo literature by empirically investigating a novel construct, namely brand sacredness, to help determine when a brand's logo redesigning efforts might backfire, regardless of consumers' personal connection to the brand. Furthermore, our work has important managerial implications. Every year companies spend millions of dollars redesigning their logos. Our research provides guidance on when these efforts should be avoided, which could prevent a situation like Tropicana's.

Marketing "Raunch Culture":
Sexualisation and Constructions of Femininity Within the Night-Time Economy

Frances Rogan, Birmingham University, UK
Maria Piacentini, Lancaster University, UK
Isabelle Szmigin, Birmingham University, UK

EXTENDED ABSTRACT

Since the 1990s, there has been significant academic interest in "porn chic", that pornography and sexualised entertainment permeate almost all aspects of our popular culture and everyday lives. This "pornographication" or "raunch culture" (Levy 2005) relates to numerous social and cultural shifts, and Maclaran (2015) argues that we need to have a better understanding of marketing's role in this is needed. We focus on one marketing context (the nightclub venue), and examine the role of the venue in supporting and perpetuating the mainstreaming of this sexualised or "raunch" culture.

The mainstreaming of sexualisation relates to more than just sexualised images in advertising or the use of women's bodies to sell products. The contemporary culture of sexualisation relates to the ways in which these images have entered our everyday lives, resulting in the 'mainstreaming of sexual explicitness for women' (Evans et al 2010: 115). One major commercial space where we see evidence of this is the night-time economy (NTE), and particularly the context of nightclub management. Griffin et al (2012) have exposed the contradictions involved here for young women, particularly when inhabiting the current "culture of intoxication" in the UK (Measham and Brain, 2005), where the construction of "femininity" in relation to drinking cultures is problematized, particularly when situated within a post-feminist context. These contradictions are integral to "new" idealised images of femininity (McRobbie 2009).

Research on alcohol consumption amongst young people has focused mainly on public health risks, bodily harm and anti-social behaviour (Szmigin et al, 2008; Measham, 2006), but less has been written on situating these risks in gendered terms. Young men have tended to consume more alcohol than women (Plant, 2008) with heavy drinking traditionally considered a sign of "masculinity" (Willott and Lyons 2012; Dempster 2011). Heavy drinking is also an aspect of contemporary "lad cultures" which may "intensify attempts to put women in their place through misogyny and sexual harassment" (Phipps and Young, 2015, 1). Women participating in the excessive drinking culture has raised concerns about the potential violence, threats, and health risks that women face by entering a historically "masculine" domain (Sheard 2011; Day et. al. 2004). This paper investigates the role of nightclub venues in perpetuating the wider mainstream sexualised culture, and the ways that these environments allow sexual harassment to take place.

The study took place across two UK cities, one in the Midlands (City A) and the other in the North of England (City B). Phase 1 was a social media tracking study, involving selecting and following a number of drinking venues via popular social media sites. For Phase 2, we conducted 10 focus groups with young people (aged 18-28, 13 men and 28 women, students and working adults). The focus was on exploring drinking habits, perceptions of risk in relation to alcohol consumption, venues frequented and social media usage. For Phase 3, we set up a Facebook page where we invited participants (19 members) to post their thoughts on subjects related to alcohol consumption and venues, and where we further explored themes emerging from the focus group data.

The social media analysis showed venues were slightly more active than brands in their postings. Focus groups and Facebook discussion also focused on venues, and findings were organised around two main themes: (1) sexual discourses and "raunch culture" and (2) sexualisation, harassment and violence.

Sexual discourses and "raunch culture" Club venues regularly use images of female patrons, staff or models to market their nights out. One club in particular appeared to be marketing their events around particular images of hypersexualised femininity, regularly posting images of their female staff wearing revealing "uniforms", and dancing provocatively. The club uses sex to appeal to a young audience, referring to itself as the "sexiest night out in City A" putting this claim immediately next to an offer for "£1.50 drinks", linking the notion of "cheap" drinks" with "sexiness".

Participants highlighted both the sexualised nature of nights out, and the underlying "lad culture" that permeates them. Heteronormative constructions of sexuality dominate in the marketing of mainstream drinking venues. This "hyper-sexualisation" marks a shift away from what feminist scholars might traditionally have understood as "objectification" (Gill, 2007), as the depiction of women as silent, passive objects has in some cases been replaced by a more explicit, active, knowing female sexual subject where self-sexualisation is a route to success (Levy, 2005).

Sexualisation, harassment and violence Data showed how sexual harassment and the threat of violence were often very "real" aspects of a night out for young women. Many of the Facebook comments highlighted that the sexualised images and language used had a more harmful sub-message, related to the promise of sexualised interactions for men entering these spaces, without repercussion for the men. For young people inhabiting this NTE it was striking how some form of violence is to be expected although not accepted. A consequence of the mainstreaming of sexualised culture is a potential normalising of sexual harassment and assault (Phipps and Young, 2015). Women reported that men tried to make them complicit in their violent interactions through suggesting that it was a 'game' or 'joke' and being instructed to 'lighten up' when they resisted their advances. The hegemonic masculinity associated with contemporary laddism can be viewed as a defence mechanism, and this sexual harassment is one aspect of this (McLaughlin et al, 2012).

Our study has shown how marketing communications serve to ensure that images of femininity are seen and understood against a backdrop of neoliberal, post-feminist discourse of individual choice(s) and empowerment. Nightclubs are contributing to the mainstreaming of porn culture, and thus shaping the ways that young women dress and act in particular situations, in order to fit in with these norms. A consequence of this hyper-sexualised culture is the normalising of sexual harassment and violence towards women (McLaughlin et. al., 2012). Our analysis shows how these marketing materials set up the conditions that are conducive to the normalisation of sexual harassment and violence.

Seeking Justice: How Harmful Brands Cause Consumers to Punish, Cheat, and Steal

Jeff D. Rotman, Ivey Business School, Western University, Canada
Mansur Khamitov, Ivey Business School, Western University, Canada
Scott Connors, Carson College of Business, Washington State University, USA

EXTENDED ABSTRACT

In July of 2015, a group known as The Impact Team hacked into Avid Life Media (AshleyMadison.com, EstablishedMen.com) and then released the names of 37 million users (Watson 2015). While this event caused a whirlwind of media attention, the marketing literature is relatively silent on what might motivate these types of attacks. Why would individuals spend their time, demand no financial incentive, and risk severe imprisonment to attack a company that had not personally wronged them?

Extant research has argued that unethical consumer behavior is a function of two competing motivations: self-interest versus protection of one's positive self-concept (Mazar, Amir, and Ariely 2008). However, a distinct mechanism that has received less attention within the marketing literature is that of moral justification. Unlike the research that has stressed the absence of moral considerations, the current research focuses on moral justification which implies that consumers are acting on a moral imperative in which targets are perceived to be deserving negative treatment (Bandura 1999) – an effect that we argue can impact a brand regardless of any directly attributable personal transgression. There may be no moral intuition more fundamental than the rejection of unwarranted harm and the subsequent need for justified punishment (Greene 2012; Khamitov, Rotman, and Piazza 2016). When entities are perceived as harmful, an individual comes to believe that they possess lower moral worth and subsequently are deserving of moral mistreatment.

Across six studies the current research examines consumers' punishment of brands that they perceive to be harmful. We argue that consumers perceive these brands as being of lower moral worth, and therefore less deserving of fair and ethical treatment. As such, consumers are more willing to lie, cheat, and steal to punish a harmful brand – regardless of whether the brand's harmfulness stems from direct, personal transgressions or a more general harmful reputation.

Study 1 establishes that perceptions of harmfulness predict unethical retribution in the form of real-world theft and fraud across a variety of industries. Results demonstrate that perception of harmfulness was a significant positive predictor of retail fraud (r = .086, *p* < .05) and that the effect held while controlling for perceived size, profitability, ease and riskiness of committing fraud.

Study 2 examines the underlying psychological mechanism and shows that perceptions of a brand's harmfulness translates into increased punishment through lower moral worth. We held the brand constant (Nike) and asked participants about their perceptions of its harmfulness, moral worth, as well as punishment and marketplace aggression (adapted from Grégoire, Laufer, and Tripp 2010). Participants then completed measures of brand attitudes, likeability, and were asked to report whether they could recall Nike having committed any specific transgression towards them personally. Results demonstrate that perceptions of harmfulness predicted both punishment, β = .46, *p* < .001 and marketplace aggression, β = .33, *p* < .01 while controlling for brand attitudes, perceptions of the brand's likeability, and experience of specific transgressions. Importantly, the influence of perceptions of harmfulness on both punishment and marketplace aggression scores was significantly mediated through moral worth attributions, β = .05, 95% CI = [.00, .14] and β = .08, 95% CI = [.04, .18].

Study 3 explores this effect by manipulating the level of perceived harmfulness in a more controlled setting using a fictitious brand. Participants were randomly assigned to either a more harmful or less harmful brand condition. The results again supported our moral worth mechanism. Specifically, in the more (vs. less) harmful condition, the brand was attributed lower moral worth, which in turn led to higher punishment intentions (β = .24, 95% CI = [.02, .68]) and marketplace aggression (β = .17, 95% CI = [.02, .54]).

Study 4 explores and extends this effect using a behavioral dependent measure of cheating, demonstrating that individuals are more likely to financially cheat harmful brands than less harmful brands. Participants were randomly assigned to one of four conditions: (harmful brand with harmful policy; harmful brand with good policy; non-harmful brand; control). Participants in all four conditions were then asked to complete a matrix task (Mazar et al. 2008), and number of matrices solved was thus used as a proxy for our dependent measure of cheating behavior. Consistent with our predictions, there was a significant main effect of condition on the magnitude of cheating, *F*(1,202) = 4.83, *p* = .003. Specifically, participants in the control and non-harmful brand condition cheated less than both participants in the harmful brand with harmful policy condition and those in the harmful brand with good policy condition.

Study 5 manipulates the ethicality of consumers' retributional behavior to show that while individuals feel bad lying and cheating a non-harmful brand, they feel no worse off after cheating a harmful one. We randomly assigned participants to a 2 (harmful vs. non-harmful brand) x 2 (lying vs. not lying). The interaction was significant *F*(1,166) = 5.86, *p* = .017. Simple effects revealed that participants in the no harm condition felt significantly worse in the lying consumer action condition compared to the not lying condition. However, when the brand was manipulated to be harmful there was no statistically significant difference regardless of whether consumers lied or not.

Lastly, Study 6 identifies justice sensitivity as an important moderator of our effect and explores the concept of harmfulness contamination by demonstrating that the mere presence of a harmful product category can color a brand's reputation as harmful. The interaction between the harmfulness of the product category and one's justice sensitivity was significant for both punishment and aggression (*p*s < .001) and were mediated by perceptions of moral worth.

The results of six studies confirm our moral worth account of consumer punishment of harmful brands. We show that consumers view harmful brands as being less deserving of fair moral treatment leading to greater punishment intentions. Importantly, as our moral worth account would predict, a directly attributable personal transgression is not a necessary requirement to lead to the brand being perceived as deserving of lower moral worth and thus greater punishment.

Brand Logo Salience as a Signal of Brand Status

Justin Saddlemyer, KU Leuven, Belgium
Sabrina Bruyneel, KU Leuven, Belgium

EXTENDED ABSTRACT

In our work we seek to address an interesting contradiction in the literature. Although research has consistently demonstrated the positive effects of visual attention on consumer behavior (i.e. Chandon, Hutchinson, Bradlow, & Young, 2009), there is some research that suggests that subtlety is associated with higher status brands and products (i.e. Berger & Ward, 2010). Our work investigates why brands might utilize subtle logos, despite benefits that attention-grabbing qualities (such as color or brightness) might confer. More specifically, we propose that the use of a subtle logo is a signal that high status brands employ as a sign of quality (i.e. the product should speak for itself), wherein the costs associated with decreased visibility and attention are recouped through quality inferences.

The benefits of visual saliency are well-documented. Researchers have revealed a visual saliency bias (Mormann, et al., 2012), which is the finding that low-level properties associated with salience can positively affect consumer preferences and choice. For example, adjusting the brightness of a product increases the likelihood that it will be chosen in a choice task.

Despite this finding, there are reasons to suggest that consumers may draw positive inferences from non-conspicuous attributes. For example, researchers have consistently (Jacobs et al., 1991) found that people associated the color black with expensiveness and power, despite the attention-grabbing qualities of color (Wolfe & Horowitz, 2004; Frey, Honey, & König, 2008). Similarly, researchers have revealed a negative relationship between the extent to which a logo or brand is displayed and the price or status of a brand or product (Berger & Ward, 2010; Han, Nunes, & Dreze, 2010).

We believe these findings are best interpreted within a signaling framework (Kirmani & Rao, 2000). Brands often use a variety of marketing signals to represent quality, at varying costs. For example, a firm may offer a product warranty, which may incur costs to the brand at a later point in time, but is viable for firms with high quality (i.e. Boulding & Kirmani, 1993). A key implication of this interpretation of marketing signals is that only brands that are of higher quality should engage in such signaling, as they are expected to recover (or avoid) the financial penalties sustained as a result of the strategy.

We regard logo subtlety to be another costly signal, wherein the subtle logo may reduce visibility and attention in the marketplace. For high status brands, this penalty should be recovered in the form of increased status perceptions (the product is good enough to speak for itself, apparently); for low status brands, this penalty will not be recovered, as such signals set unreasonably high expectations for products (that will likely not be fulfilled), and they will also lose out on the benefits of increased attention. We thus designed a study to test whether existing brands already adhere to such principles, and then designed original logos to test how manipulated salience affects status perceptions.

In our first study, we asked a sample of participants to gauge the conspicuousness of 14 logos from a consulting firm's 2014 list of top global companies. Critically, seven of these brands were categorized as luxury, and participants estimated seven other randomly selected non-luxury brands. As expected, we found that the average conspicuousness of the luxury brands was lower (M = 4.71,

SD = 1.13) than the non-luxury brands (M = 5.39, SD = .96, $t(57)$ = 5.90, $p < .001$). This provides evidence that luxury brands do tend to use less salient logos than non-luxury brands.

In our second set of experiments aimed to show that logo salience would reduce brand status perceptions. We presented participants with two similar logos that differed in salience via color (Study 2a) or brightness (Study 2b). As expected, both studies revealed a significant main effect of conspicuousness on perceived status of the brand, ($F(1, 136)$ = 15.62, $p < .001$, d = .67) and ($F(1, 90)$ = 9.14, p = .055, d = . 40), such that the black and white indicated higher status than the color logo ($M_{B\&W}$ = 4.32, $SD_{B\&W}$ = 1.28; M_{COLOR} = 3.48, SD_{COLOR} = 1.22) and the dark logo indicated higher status than the bright logo (M_{DARK} = 4.70, SD_{DARK} = 1.55; M_{BRIGHT} = 4.07, SD_{BRIGHT} = 1.57). Controlling for liking did not eliminate these effects, indicating that salient logos can signal lower brand status.

Lastly, we intended to show that the status inferences demonstrated in the previous two studies would be mediated by reduced credibility. If, as we predict, salient logos signal a reliance on eye-catching logos, then brands that utilize such techniques should be seen as less credible. Thus, we ran a variant with two pre-tested logos (equal in liking and familiarity, but different in salience), and asked participants to evaluate both the status of the brand and a measure of brand credibility (Kirmani, 1997). Consistent with our predictions, a mediation analysis using the macro PROCESS (Hayes, 2012) confirmed that this effect was indeed driven by brand credibility, such that the salient logo negatively affected credibility, which in turn affected perceived brand status. There was a significant indirect effect of conspicuousness on brand status (ab = -1.01; LLCI = -1.50, ULCI = -.55), but the direct effect was not significant (p = .734), indicating that credibility fully mediated the negative effect of conspicuousness on status perceptions.

Thus, across four studies we demonstrated that luxury brands tend to utilize less conspicuous logos, that a less conspicuous logo leads consumers to infer that the brand is of higher status, and that this effect is mediated by brand credibility. Our work has implications not just for new firms seeking to design a logo to fit their image, but also brands looking to update their logo.

Duration of Restrictions Influences Information Processing:
The Role of Perception of Control

Gülen Sarial-Abi, Bocconi University, Italy
Sadaf Mokarram Dorri, Bocconi University, Italy
Aulona Ulqinaku, Bocconi University, Italy

EXTENDED ABSTRACT

Restrictions are a part of people's daily lives and they are constraints that limit or confine individual choices. (Botti et al 2008).

Because of the importance and salience of restrictions in daily life, researchers in economics, psychology, and consumer behavior have extensively investigated the antecedents and consequences of having restrictions (Mullainathan and Shafir 2013). However, most of these studies, though not explicitly stated, focus on restrictions of limited duration (i.e., temporary restrictions). This paper investigates how the duration of restrictions influences information processing. Extant research supports the idea that the same event or object can be construed in more or less abstract or concrete ways (Liberman and Trope 1998; Trope and Liberman 2010). Research also shows that these different levels of mental representation enable expansive and contractive thinking, respectively (Trope and Liberman 2010).

In current research, we investigate the possibility that the duration of restrictions influences the way people contract or expand their mind-sets. Specifically, we posit that those who have temporary restrictions tend to process information with a contracted mind-set, focusing on the psychologically proximal situation of having a temporary restriction. In contrast, those who have permanent restrictions tend to process information with an expanded mind-set such that they expand their mental horizons to think about psychologically far-away objects or events. Furthermore, we identify a theoretically derived mediator: perception of control. Those with permanent restrictions perceive more control than those with temporary restrictions and therefore, they tend to have a more expansive mind-set.

Using three studies in the field and one online study, we predict and demonstrate that people with permanent restrictions have a more expansive mind-set and, consequently, process information more abstractly than those with temporary restrictions. Previous research demonstrates that those with permanent restrictions are more self-accepting and less neurotic than those with marginal restrictions (Colman 1971). People with chronic illnesses have to deal with uncertainties about their situation and its accompanying symptoms as well as the ambiguities about the future course of their illness. Research shows that one way in which these feelings of vulnerability and helplessness can be offset is by generating a sense of personal control over the chronic illness, its accompanying effects, and life more generally (Taylor 1983). We suggest that when people with permanent restrictions perceive control over their lives, they focus less on their restrictions. We posit that those who have temporary restrictions tend to process information with a contracted mind-set, focusing on the psychologically proximal situation of having a temporary restriction. In contrast, those who have permanent restrictions tend to process information with an expanded mind-set such that they expand their mental horizons to think about psychologically far-away objects or events.

The first study determines whether those who have permanent restrictions (i.e., those who use wheelchair) have a more expansive mind-set than those with no permanent restrictions. We tested our prediction in the field, specifically, a supermarket. Previous research demonstrates that those who construe events with an expanded mind-set use larger categories to classify objects (Liberman, Sagristano, and Trope 2002). In line with this research stream, we predicted that those who have permanent restrictions would have fewer items on their shopping list than those with no restrictions.

The second study has a similar aim. Patients of a diabetes clinic and clients of a diet store indicated their preferences for different descriptions of the same brand in five product categories. We inferred participants' mind-sets from their preferences for brand-product category information or brand-product attribute information.

The third study tests our predictions in a controlled environment, in which we manipulated having permanent or temporary restrictions using a restriction on parking scenario. We determine participants' information processing by using an adapted version of the Behavioral Identification Form (BIF). Study 3 also tests the proposed mechanism of perception of control.

Study 4 investigates the information processing of people with permanent and temporary restrictions by testing their preferences for product shelves in retail settings. As a behavioral measure of preference, we asked participants to indicate their preferences for different supermarket shelf formats. We predicted that because a contracted mind-set would cause participants to focus more on details and product features, temporary-restriction participants (i.e., dieters) would prefer shelf formats that contain only gluten-free products. Study 4 also tests for the underlying mechanism of perceived control.

The current work contributes to the budding literature on restrictions by building on and contributing to construal level theory. We provide evidence that people with permanent restrictions have more expansive mind-sets than those with temporary restrictions; consequently, those with permanent restrictions process information more abstractly than those with temporary restrictions. We further provide evidence that people with permanent restrictions perceive more control than those with temporal restrictions and that this perception of control leads to different information processing.

Descriptive Social Norms Enhance Pro-Environmental Behavior:
A Bayesian Reanalysis of Hotel Towel Reuse

Benjamin Scheibehenne, University of Geneva, Switzerland
Tahira Jamil, University of Amsterdam, Netherlands
E.-J. Wagenmakers, University of Amsterdam, Netherlands

EXTENDED ABSTRACT

Descriptive social norms indicate which behavior is typical or normal in a given situation (Cialdini, Reno, & Kallgren, 1990). Such information can influence people's behavior in important ways (Schultz et al. 2007). A prototypical and widely-cited example for the effectiveness of descriptive social norms concerns the reuse of hotel towels (Goldstein, Cialdini, & Griskevicius, 2008). In the original study, hotel guests received one of two messages that encouraged them to reuse their towels. One message simply informed the guests about the benefits of environmental protection (i.e., the control condition) and another message indicated that the majority of guests actually reused their towels in the past (i.e., the descriptive social norm condition). The results suggested that the latter message facilitated reuse (i.e., Experiment 1: 44.1% versus 35.1% reuse, $p = .05$; Experiment 2: 44.5% versus 37.2% reuse, $p = .03$).

In recent years, however, five replication experiments with a total sample size of 2,466 participants have arguably failed to obtain the original finding of an increased proportion of towel reuse (i.e., all ps > .14; Bohner & Schlüter, 2014; Mair & Bergin-Seers, 2010; Schultz, Khazian, & Zaleski, 2008). Here we resolve the apparent contradiction by a Bayesian reanalysis of the data that tests for independence in contingency tables (Gunel & Dickey, 1974; Jamil et al., 2015; see also jasp-stats.org). Bayesian hypothesis tests allow researchers to quantify evidence for both the null and the alternative hypothesis. One prominent advantage of the Bayesian test is that it can distinguish between evidence for absence versus the absence of evidence (e.g., Dienes, 2014).

As a basis for the reanalysis, the number of participants and the proportion of towel reuse in each experimental condition were recorded[1]. Figure 1 displays the posterior distribution of the log odds ratio and the default one-sided Bayes factor for a test of equality of two proportions[2]. The bottom row of Figure 1 displays the same information for the data when collapsed across all seven experiments.

Figure 1 reveals, first, that when considered in isolation none of the experiments provide compelling evidence in favor of the descriptive social norm hypothesis. The strongest Bayes factor comes from Experiment 2 of Goldstein et al. (2008) and yields a modest $\text{BF}_{10} = 2.02$, meaning that the data are only about twice as likely under the descriptive social norm hypothesis than under the null hypothesis. Three replication attempts also yield only weak evidence. Thus, the apparent contradiction in the literature may be partly attributed to the infamous p value "cliff effect" (Rosenthal & Gaito, 1963), that is, the tendency to believe that findings with $p < .05$ are qualitatively different from those with $p > .05$.

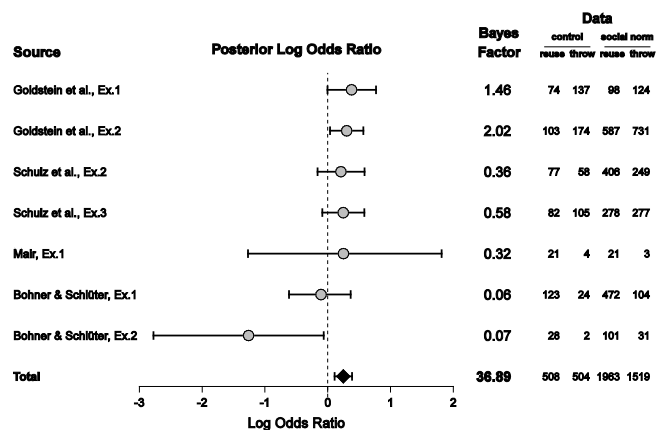
Figure 1 also reveals that, when collapsed across experiments, the data do provide strong evidence in favor of the social norm hypothesis: $\text{BF}_{10} = 36.89$, meaning that the data are about 36 times more likely under the descriptive social norm hypothesis than under the null hypothesis. For the combined data, the mean log odds ratio is 0.25. The 95% Bayesian credible interval ranges from 0.11 to 0.39. In absolute terms, the data indicate an average 6% increase in towel


Figure 1: Bayesian reanalysis of seven experiments on the effectiveness of social norms on reuse of hotel towels, separately for each experiment and ordered by publication date. To the left, grey circles indicate the posterior mean of the log odds ratio and error bars indicate 95% credible intervals. To the right are the corresponding Bayes factors in favor of the descriptive social norm hypothesis, as well as the raw data. Positive log odd ratios and Bayes factors greater than 1 indicate evidence for the effectiveness of social norms. The bottom row indicates the same information for the combined data across all experiments.

reuse in the social norm condition. The effect size is modest, but—if it is a veridical reflection of the true effect size—the presence of millions of guest rooms worldwide suggests that its impact can nevertheless be substantial.

Although other statistical models can be specified to analyze these findings, we found the qualitative patterns of results to be robust: When analyzed individually, none of the experiments provides compelling evidence for the effectiveness of descriptive social norms on towel reuse, but together the studies provide strong support for the hypothesis. The analysis on the combined data assumes a fixed effect; with only seven studies and in the absence of strong prior knowledge, we feel a random effects analysis is overly ambitious.

In sum, our Bayesian reanalysis brings good news and bad news. The bad news is that when analyzed individually, the current experiments on towel reuse are evidentially weak. The good news is that when analyzed together, the data provide compelling support for the fact that descriptive social norms can prompt people to alter their behavior ways that help the environment.

The Psychophysics of Price Perception: Evidence from the Lab and From the Field

Benjamin Scheibehenne,University of Geneva, Switzerland

EXTENDED ABSTRACT

The results of a lab (n=40) and a field study in a grocery store (n=966) indicate a systematic underestimation of shopping basket values that follows a compressive power function. The bias depended on the sequential order but not on the shape of the underlying frequency distribution or simple rounding strategies.

THEORETICAL BACKGROUND

The subjective perception and integration of discrete numerical information is an elementary cognitive process that is highly relevant in a consumer context, where purchase decisions often depend on price estimations. Such integration processes also provides the basis for other relevant measures such as expected utility and the evaluation of risky prospects and keeping track of spending during a shopping trip or at a restaurant can help prevent overspending. Given this importance, the paper at hand presents a lab experiment and a field study to gain a better understanding of how people perceive and aggregate sequentially presented price information and what factors influence their estimation accuracy.

METHOD

In the lab experiment, Local university students ($N = 40$) repeatedly estimated the total sum of 24 numbers described as the prices of fictitious items in a shopping basket. The numbers were sequentially displayed on a computer screen for 0.5 s each. After observing each sequence, participants typed in their best estimate for the total sum before proceeding to the next trial. For each sequence, the shape of the underlying frequency distribution, the sequential order in which the numbers were displayed, and the range of these numbers were subject to experimental manipulation. All sequences were presented in random order in a within-subject experimental design.

As facilitation toward subjectively estimating the sum rather than actually adding the exact numbers, participants also completed a secondary working memory task. To incentivize accuracy, participants received a bonus at the end of the experiment that depended on their estimation accuracy. The accuracy of participants' estimations ($\hat{y}$) was quantified as a bias measure indicating over- or underestimation proportional to the true sum (y):

$$\text{bias} = \frac{\hat{y} - y}{y} \qquad (1)$$

To test if the results from the lab experiment generalize to real-world scenarios, a field study was conducted at a grocery store where customers who lined up at the checkout gave a spontaneous estimate of the total value of their shopping basket. After the checkout, this estimate was compared to the actual value indicated on their sales receipt. Besides testing for a possible estimation bias, this design also allowed testing a possible influence of the underlying price distribution, the number and types of items purchased, customers' age, whether they payed cash or credit, if they purchased potential impulse items such as sweet and fatty snacks that could be more prone to underestimation, or if they used shopping lists and thus planned their purchases. A total of 966 customers participated in the study, 545 in the first session and 421 in the second session.

RESULTS

In the lab experiment, 65% of all sequences were underestimated. The mean bias across participants was -.055 ($SD = .066$; Cohen's $d = 0.8$), and for 35 of 40 participants, the bias was negative, indicating underestimation. This proportion of participants was highly unlikely under the null hypothesis of no bias as indicated by a binomial test ($p < .001$). The corresponding Bayes factor (BF) was greater than 10,000, indicating extreme evidence for the alternative hypothesis. Results further indicate that underestimation became slightly stronger for higher sums. For the lowest quintile, participants on average underestimated the true value by about 3.4% while for the highest quintile it was about 7.7%. Further analyses indicated that the bias varied depending on the sequential order.

The main results were confirmed in the field study. Here, the median basket value was 49.9 Swiss Francs (CHF). The median bias was -0.05 (interquartile range = -0.19 to 0.13; $M = -.02$; Cohen's $d = 0.2$). In total, 60% of all baskets were underestimated (first session: 62%, second session: 57%), which was unlikely under the null hypothesis of no bias as indicated by a binomial test ($p < .001$; BF > 10,000). Results further indicate that underestimation got stronger for larger sums, while small values were slightly overestimated. In particular, a 10% increase in the true basket value yields only a 9% increase in the estimated value. In other words, a basket worth 51 CHF (the average basket value) was underestimated by 3 CHF or 8% while a basket worth 79 CHF (the upper 75% quantile) was underestimated by 8 CHF or 10%.

A stepwise linear regression with bias as dependent variable further indicated that underestimation was stronger for older participants and that underestimation increased for baskets that contained a few (relatively expensive) as compared to many (relatively inexpensive) items. The mode of payment (cash vs. credit) or properties of the distribution of items, including its variance and skewness, did not influence the bias. Under the assumption that items bought first were scanned last by the cashier, the analysis further indicated that underestimation was stronger for sequences that ended with more expensive items.

DISCUSSION

Taken together, the results indicate that basic research on the mental representation of numbers also applies to a consumer context. Thus, even with plenty opportunities for feedback, people still have a bias to underestimate the sum of a sequence of numbers.

From an applied perspective, the results suggest that estimation accuracy can be improved by separately integrating different parts of the number sequence (such as different accounts or product categories) and then adding these separate estimates in a second Likewise, the observed sequence effect indicates that accuracy may increase when expensive items are encountered early on.

Cultural Engagement in the Age of Social Media

Joachim Scholz, Cal Poly, USA
Henri Weijo, Bentley University, USA

EXTENDED ABSTRACT

On April 12, 2015, 9:24 AM local time, London, UK, Hannah Atkinson pulled out her smartphone to make a public stance against how advertisers objectify women's bodies. She stands on the platform of an underground subway station, in front of a bright yellow, gigantic advertisement for Protein World's Weight Loss Collection. Featuring a toned model in a yellow bikini, the ad asks: "Are you beach body ready?" (see image 1). Hannah types "This advert pretty much sums up everything that I despise about how we treat and value women's bodies," snaps a photo, and tabs "Tweet." Her's is the second post about Protein World's newest advertising campaign, and the first one to go viral: Five hundred and fifty-seven retweets, 505 favorites.

Conventional social media wisdom suggest that Protein World should have taken immediate action to appease the crowd of over 500 people who retweeted Hannah Atkinson's angry tweet. Protein World, however, did not apologize when it was called out by Hannah Atkinson and others who complained about their portrayal of women's bodies. Instead, it antagonized critics with tweets like "@dazburn [strong arm emoticon] - here is a shoulder for you to cry on [kissing emoticon and heart]" ~ @ProteinWorld, April 27. Responses like this further fueled the controversy: By the end of April, advertisement posters have been vandalized, 70,000 people signed an online petition to remove the ads, and about 100 people gathered in Hyde Park to protest the campaign (Boland 2015; Sweney 2015). Protein World found itself in the midst of one of the fiercest social media storms in history, and even received a bomb threat to its headquarters. However, and to the surprise of many observers, Protein World's engagement strategy paid off. Thousands of Twitter users voiced their support for the brand, whose Twitter follower base grew by 15% over three weeks. Fanning the flames also brought in new sales: Protein World claims to have gained 30,000 first-time customers and a profit of £2 million since the campaign began (Daubney 2015).

We analyze the Protein World case through qualitative (Kozinets 2010; Weijo, Hietanen and Mattila 2014) and quantitative analysis of tweets and other online publications in order to develop the notion of *distributed infuriation* as a social media strategy. As we discuss below, current conceptualizations of consumer engagement cannot explain why Protein World has been successful (at least initially) with its distributed infuriation strategy. In order to fill this gap in the consumer engagement literature, we expand the cultural branding paradigm (Holt 2016; Holt and Cameron 2010) to explain the dynamics of the distributed infuriation strategy. In particular, the purpose of our research is to explore (1) how brands can orchestrate distributed narratives that are ideologically informed, and (2) how the distributed narratives impact the ideological alignment of the brand itself.

We used both qualitative and quantitative analysis techniques in order to answer our research questions. Most of our data for the qualitative analysis is collected by searching for tweets that contained "@proteinworld," "#proteinworld", or "Protein World." Because of the large volume of tweets, only a subset of data from nine different days was used for the qualitative analysis. During this analysis, certain keywords (e.g., #fitshaming, #growupharriet, and #gamergate) emerged as particularly important. In addition, we viewed and read images, articles and Facebook posts that were attached to these tweets. We used the Sysomos software application in order to conduct a qualitative analysis the Protein World controversy. We analyzed the frequency of keywords mentioned in combination with @Protein-World mentions in order to better understand what different factions emerged over time. Finally, we visualized the different ideological camps that emerged during the Protein World controversy through interactional clustering analysis (figures 1).

Our findings have practical implications for marketers who wish to employ this strategy. As our analysis revealed, purposefully antagonizing critics on social media in order to mobilize brand supporters can be beneficial for a brand. However, there are inherent risks involved in this strategy: The focal brand can easily become associated with, or even accidentally endorse, extremely polarized narratives (e.g., rape threats) that would harm its image in the eyes of most customers. When using this strategy, brand managers should (1) frame both sides of the ideological battlefield according to their needs, (2) enable supporters to engage with critics from across the clearly defined ideological fault line, and (3) prevent fragmentation and hyper-polarization of the ideological battlefield. The last step not only involves banning critic-trolls, but also banning and marginalizing support-trolls whose actions would harm the original ideological fault line.

Aside from these managerial implication, our study advances the cultural branding paradigm by highlighting how it can be adapted to the age of social media and its emphasis on consumer-to-consumer interactions. While others have pointed out that cultural branding becomes even more suitable to position a brand in the age of social media (Holt 2016), our research is concerned with how the cultural branding paradigm can help marketing managers to *tell* their brand stories and *engage* consumers via social media (i.e., *cultural engagement*). We highlight how marketers can use cultural framing strategies (i.e., creating a clearly marked ideological fault line) in combination with established cultural branding tactics (e.g., cultural jujitsu and evoking ideological flashpoint; Holt and Cameron 2010) in order to facilitate brand supporters' interactions with brand critics across the ideological fault line. And most importantly, we show how the distributed narratives that are exchanged in cultural engagement strategies can impact the ideological alignment of the brand itself.

The Global Surf Narrative: Using Narratives in Global Market Strategy

Rodrigo Costa Segabinazzi, Federal University of Rio Grande do Sul, Brazil
Hope Jensen Schau, University of Arizona, USA
Walter Meucci Nique, Federal University of Rio Grande do Sul, Brazil
Melissa Archpru Akaka, University of Denver, USA

EXTENDED ABSTRACT

Twenty years ago, Appadurai (1996) presented us with dimensions of globalization: ideoscapes, technoscapes, mediascapes and financescapes. Stressing the opportunities that companies should consider in this globalized world, Alden, Steenkamp and Batra (1999) further the concept of Global Consumer Culture (GCC) to Global Consumer Culture Positioning (GCCP). Contexts and paths to such positioning remain elusive. Following Consumer Culture Theory CCT (Arnould and Thompson, 2005) tradition, extant research identifies how local or "glocal" characteristics are integral to consumer behavior. Coffee consumption in Denmark (Kjeldgaard and Askegard 2006) highlighted resistance to the Starbucks global brand. Cova, Pace and Park (2007) identify important differences between French and US customers of the Warhammer brand, leading the authors to suggest different strategies to attract customers in those countries. We posit that cultural approaches could add value to global market strategy, specifically, how companies could act globally in a "glocalized" world.

Penaloza (1998) finds that, more important than the product display, is the story that is told to the consumer as they enter *Niketown*. Action and adventure are some of the meanings created by texts, high ceilings and memorabilia (Penaloza 1998). Kozinets et al (2002) notice that, through the use of lavish décor and sleek finishes, consumers are presented with a stage behind the storefront of ESPN zone in Chicago.

Narratology, the study of narratives, addresses the fundamental role narratives have in our daily lives (Josselson and Lieblich1999). To narrate something is to tell a story (Miller 1999), and people give meaning to their experiences by telling stories. As Abma (1999) claims, "Storytelling is a socially and situated language performance. Stories imply actions toward others" (Abma 1999, p. 170). Mediascapes (Appadurai 1996) have global reach, and can be carriers of storytelling, imagination and action.

We employ an ethnographic approach to investigate the reigning surf narrative and identify meanings and symbols used within surf retail environments and advertising. We use a mix of techniques (participant observation, naturalistic observation, and in depth interviews) to collect data in Brazil and the US (California and Hawaii) from 2009 to 2016.Our data consist of in excess of 458 photographs from 18 stores observed, combined with more than 30 in depth interviews (store and brand managers, consumers) and field notes from on site observation. Each element of the data set contributes unique insights to the surf retailscape (retailer tactics, brand strategies and consumer perceptions). Together they weave a narrative tapestry that scaffolds the surf market.

Our data reveal counter–intuitive findings around the surf market. We find that actually non surfers are the main consumers of the surf-related products, being responsible for between 50 to 90% of all consumption, according to brand and store managers from all locations observed. This consumption relates basically to apparel (shorts, hats, t-shirts). A specific narrative is created to attract this consumer.

Central to the narrative of surf retail is selling California. Managers from all locations mention that a "Californian scenario" is constructed in their stores, and that the Australian major global surf brands (Rip Curl, Quicksilver and Billabong) are perceived by buyers as originally from this US state. Importantly, it is not only contemporary California that is sold by surf companies, but an imagined California of the 1960s. Our data shows that movies such as "The Endless Summer" (1966), magazines (*Surfer*) and music (The Beach Boys) were some of the carriers of this imagined reality. This association is perceived in surf stores "scenarios" in pictures of old woodies (wood-paneled station wagons) and VW vans on t-shirts, photographs and ads in all locations observed. This means that California's imagined reality was spread through mediascapes and is re-imagined, accepted and accessed in different parts of the world.

Within this scenario, executives reveal that selling surfing is also selling an idealized lifestyle. This story involves a good life around the beach, with majestic beachscapes, everlasting summer and beautiful people. These images are presented on storefronts and inside the stores.

Local and global stores use the surfboard merely as a symbol to obtain credibility, to be recognized as a surf store. All surf store and brand managers interviewed claim that the sporting goods (surfboards, wetsuits) are not a significant source of revenue. They make far more profit selling any variation of apparel.

Having surfboards, "the Californian scenario" and photographs of surfers performing extreme practices is a strategy openly realized and developed by surf stores and brand managers to attract non surfers. Consumers (from both countries) clearly articulate that buying apparel is a way of living this great life suggested by surf companies. One consumer (who does not surf – has never tried, nor wishes to) opened his wardrobe and pointed out to all of his items, saying that came from different surf brands. He revealed that all of these brands connected him to a cool, easy going lifestyle, which he always felt related to.

Summarizing our contributions, the narrative around surf retailing is not attached to a single brand or location. Local and global brands, as consumers from different countries engage in the surf narrative in a similar way. Previous work around GCCP(Alden et al 1999) and CCT stressed brand or glocal related phenomena (Kjeldgaard and Askegard 2006; Penaloza 1998; Kozinets et al 2002). Within our multi-brand, multi-national context, we offer Global Narrative Positioning as a possible intersection between GCCP (Alden et al 1999) and glocal realities addressed in CCT (Arnould and Thompson 2005) studies.

We introduce the global narrative as way for companies to position in the market. If the story has meaning and global reach, the narrative could be attached to any brand, local and global. The main advantage of the global narrative is that is not related to a specific brand or place, e.g., surf-related companies do not face local resistance to their products. We suggest that managers identify possible narratives that have global meaning, that is, consumers from different locales find the narrative resonating. Tattooing, fitness programs and farmer's markets seem to carry such characteristics.

The Achilles Heel of Centrality:
Group Identification Makes the Central Susceptible to Influence

Edith Shalev, Technion University, Israel
Hadas Eiges, Technion University, Israel

EXTENDED ABSTRACT

The groups and communities to which a consumer belongs influence his attitudes and decisions (Escalas & Bettman, 2003). Nowadays, with growing possibilities to form communities online, it is important to understand how groups influence consumers, and in particular – who is most influential and who is most susceptible to influence. Our research focuses on the latter, and examines whether susceptibility to group influence (henceforth labeled 'SGI') depends on centrality.

Central consumers, defined as those holding a large number of social ties within their group, are known to be "influentials." Consequently, one may expect them to resist social influence. However, extant research yields mixed findings; some find the central resistant (Hu & Van den Bulte, 2014), others find him susceptible (Lee, Cotte, & Noseworthy, 2010), yet others report no association between centrality and SGI (Iyengar, Van den Bulte, & Valente, 2011). The seemingly opposing findings call for deeper understanding of the conditions under which centrality increases as opposed to decreases SGI.

We propose that centrality may instigate two distinct processes, resulting in opposite effects on SGI. The 'status mechanism' lowers the central's SGI. Compared to the marginal, the central ranks high in the group's social hierarchy, and therefore should experience more autonomy (Kifer et al. , 2013), and less sensitivity to social pressures (Galinsky et al., 2008). Indeed, research demonstrates that centrality and status are negatively associated with conformity (Bellezza, Gino, & Keinan, 2014; Hu & Van den Bulte, 2014). We acknowledge the status mechanism, but introduce a different process via which centrality increases SGI – the 'group-identification mechanism'.

We posit that centrality increases group-identification, i.e. that the central identifies with the group more than the marginal does (H1). Due to his numerous relationships in the group, the central obtains a strong sense of belonging (Baumeister & Leary, 1995). The marginal, in contrast, obtains very limited benefits from the group. Thus, the same group is psychologically more rewarding and appears more appealing to the central than to the marginal. Since group-identification facilitates conformity to group norms (Cialdini & Goldstein, 2004), the central should exhibit higher SGI than the marginal (H2). If the group-identification process is driven by belonging motives, it may depend on self-construal - the extent to which the self is defined independently of others or interdependently with others (Markus & Kitayama, 1991). Centrality should increase SGI when the individual is interdependent, rather than independent (H3).

Finally, we posit that the group setting may determine whether centrality instigates a status or a group-identification process. Group settings generally bolster belonging motives (Gardner, Gabriel, & Lee, 1999). However, groups vary in their effect on status motives. While social groups reward egalitarian behavior and inhibit status motives, achievement groups foster inequality and status aspirations. Therefore, in achievement (social) groups, status mechanism will weigh more (less), and centrality would decrease (increase) SGI (H4).

Study 1 tested the association between centrality and SGI using real social groups. We assigned 175 students to 14 groups, and opened a social networking website for each group. Centrality represented the number of friends that each participant had in his group/ social network. During two weeks, aside from freely interacting online, participants responded to opinion polls on their social networking website. The SGI measure was derived from numeric responses to these polls. Prior to expressing their personal opinion, participants saw the cumulative response distribution of preceding respondents from their group. For each participant, we calculated the mean deviation of his answer from the preceding mean opinion, across the 7 polls. Lower deviations indicate greater SGI. Consistent with H2, centrality was negatively associated with deviation from group opinion. In contrast, subjective-status correlated positively with deviation from group opinion. Therefore, a positive association between centrality and SGI is evident, and cannot be attributed to status effects.

Next we explored the effect of centrality on group-identification. Participants in studies 2a and 2b (N2a = 103; N2b = 174) imagined attending a private movie screening with a group of 24 viewers. They rated various aspects of their movie going experience, including how they felt about themselves and about the group of viewers. We told participants in the high (low) centrality condition they were friends with 13 (2) of the other moviegoers. Supporting H1, in both studies central participants showed stronger group-identification than marginals. In study 2a, sense of belonging mediated the effect of centrality on group identification. In study 2b, self-construal moderated that effect. Centrality increased group identification more among interdependents than among independents. Studies 2a&2b demonstrate that centrality increases group identification due to belonging needs. Subjective status, mood, or self-image could not explain these findings.

Study 3 tested whether group-identification mediates the effect of centrality on SGI. Participants (N = 104) imagined residing in a community neighborhood. In the low (high) centrality condition, participants hardly knew any (knew many) of the other neighbors. They imagined voting on three topics during a neighbors meeting. For each topic, participants indicated their preference between two options after learning about the preference of the majority. Supporting H2, central participants showed stronger agreement with the group and greater group-identification than marginal participants. Furthermore, group-identification mediated the effect of centrality on agreement with the group, but subjective status did not. Study 4 (N = 189) employed the same procedure with a self-construal scale. It revealed that among interdependents (independents), centrality increased (decreased) agreement with the group.

Study 5 tested whether group type moderates the effect of centrality on SGI. Participants (N = 207) imagined being tennis club members. Pretest participants perceived club members as tennis fans, so we operationalized SGI using tennis attitudes; more favorable attitudes reflected higher SGI. We described the tennis club as either social or achievement-oriented. Supporting H4, among social (achievement) group participants, centrality enhanced (lowered) tennis attitudes.

Taken together, these studies elucidate the vulnerable side of centrality. Despite their status, central group members depend on the group to satisfy belonging needs, which increases their SGI. The finding that group-identification is more likely to prevail in social than in achievement groups reconciles the seemingly contradictory findings in the literature.

The Role of Choice Set Size on Consumers' Preference for Unconventional Goods

Marissa A. Sharif, University of California Los Angeles, USA
Elizabeth C. Webb, Columbia University, USA

EXTENDED ABSTRACT

Choice set size and composition have been the topic of much consumer research in recent years (for a review see Chernev 2011). To-date the majority of the work on this topic has examined the experience of choosing from larger versus smaller choice sets, revealing both advantages and disadvantages. For example, although larger choice sets have been shown to increase option value, flexibility, opportunities for variety, perceptions of choice freedom, and enjoyment related to the overall shopping experience (Kahn, Moore, and Glazer 1987; Simonson 1990; Kahn and Lehmann 1991; Kahneman and Snell 1992; Ratner, Kahn, and Kahneman 1999; Botti and Iyengar 2004; Shin and Ariely 2004), they also lead to increased consumer cost, higher rates of choice deferral, choice overload effects, increased choice difficulty, and lower choice satisfaction (Broniarczyk, Hoyer, and McAlister 1998; Iyengar and Lepper 2000; Schwartz et al. 2002; Chernev 2003).

However, relatively little work has investigated the effect of choice set size on the specific option chosen. Some work has demonstrated that larger choice sets lead to greater variety-seeking and diversification (Read and Loewenstein 1995; Kahn and Wansink 2004). Additionally, Sela et al. (2009) found individuals are more likely to choose easy-to-justify options, such as virtuous products over vice products, in larger choice sets compared to smaller choice sets (Sela, Berger, and Liu 2009). The authors suggest that larger choice sets increase choice difficulty, inducing consumers to focus their decision process on choosing an option supported by good reasons. This suggests that larger choice sets can induce different psychological strategies to deal with choice.

In this paper, we assess whether consumers are more likely to choose an unconventional product in a larger choice context than in a relatively smaller one. Simonson & Nowlis (2000) find that providing reasons for choice promotes more unconventional choices. This occurs because reasons for expressing uniqueness are easier to think of, more accessible, and more persuasive (Simonson and Nowlis 2000). Based on the findings of both Sela et al. (2009) and Simonson & Nowlis (2000), we propose that consumers should be more likely to choose unconventional options in large choice sets than in small choice sets due to a greater reliance on reason-based choice.

In three studies we demonstrate that larger choice sets lead to more unconventional choices compared to smaller choice sets. We show this main effect across ice cream flavor choice in two studies, and through choice shares of a compromise option in a third study. We rule out any moderating effects for two individual-level variables: Need for Uniqueness (NFU) (Snyder and Fromkin 1977) and Intolerance of Ambiguity (IOA) (Budner 1962). Taken together, our empirical findings suggest that choice set size is an important situational variable in determining choice.

STUDY 1

In this study, we show the main effect—that larger choice sets increase choice shares for more unconventional options relative to smaller choice sets. We demonstrate this effect over ice cream flavors. Participants were randomly assigned to one of two choice set size conditions (Large vs. Small). Participants in the Large condition evaluated twelve ice cream flavors, half of which were identified in a pretest as more unconventional, while participants in the Small condition evaluated four ice cream flavors, again half of which were more unconventional. All participants were asked to choose one flavor to purchase. Our dependent variable of interest is the type of ice cream flavor selected (unconventional or conventional). In addition to our dependent variable, we also measured choice difficulty, IOA, and participant demographics (gender and age). We predicted that participants would choose more unconventional choices in the larger choice set condition.

Pretest

Fifty participants were asked to rank order fifteen ice cream flavors from most conventional to least conventional. Conventionality was defined by the number of people that would be predicted to choose each flavor, such that the more popular flavors were to be identified as more conventional. The ice cream flavors with the lowest average rankings on this pretest were identified as the more conventional flavors, while the flavors with the higher average rankings were identified as the less conventional flavors. For example, the ice cream flavor that had the lowest average ranking (most conventional) was Cookie Dough (M_{rank} = 5.56), while the flavor that had the highest average ranking (most unconventional) was Honey Avocado (M_{rank} = 12.14).

Method

Two-hundred participants (M_{age} = 35.2 years, 55.5% male) on Amazon's Mechanical Turk (mTurk) were randomly assigned to one of two choice set size conditions (Large or Small). All participants were asked to imagine they were choosing an ice cream flavor to purchase. Participants in the Large condition evaluated twelve flavors, while participants in the Small condition evaluated four. The Small choice set was a subset of the twelve flavors used in the Large condition. The flavors used for the Small condition were randomized across participants such that all participants in the Small condition saw a different subset of flavors. We used this method so that across participants in the Small condition all possible combinations of flavors were evaluated, thus controlling for potential individual differences in flavor preferences.

Half of the ice cream flavors were unconventional (as identified in the pretest) while the other half were more conventional. The flavors were not explicitly labeled as conventional or unconventional for participants, instead participants were given the names of the flavors and a brief description. Our dependent measure of interest was whether a participant chose an unconventional ice cream flavor. We also measured choice difficulty ("How difficult was it for you to choose a single flavor to purchase?") and a subscale of the IOA scale related to the preference for novelty (sample question: "What we are used to is always preferable to what is unfamiliar").

Results and Discussion

Participants in the Large choice set condition were significantly more likely to choose an unconventional flavor than participants in the Small condition. Specifically, participants in the Large condition chose an unconventional flavor 37.8% of the time, while participants in the Small condition chose an unconventional flavor only 20.6% of the time (($1) = 7.15, p < 0.01). We also found that choice difficulty was rated higher (more difficult) in the Large condition than the Small condition (2.43 vs. 1.93, t(190.13) = -2.39, p < 0.02). Finally, we ran a logistic regression of unconventional choice (1 = chose an unconventional flavor, 0 = chose a conventional flavor) on a dummy

variable for the Large condition, choice difficulty, IOA index, and participant controls. This analysis shows a significant positive effect for the Large condition (= 0.97, $p < 0.01$) such that participants in the Large condition were more likely to choose an unconventional flavor than participants in the Small condition. This effect holds even controlling for choice difficulty (= 0.01, $p > 0.10$), and individual-level differences in IOA (= -0.55, $p > 0.10$).

These results provide initial evidence that larger choice sets lead to different choices than smaller choice sets. Specifically, consumers making a choice in a larger choice set are more likely to choose an unconventional option than consumers making a choice in a smaller choice set. While larger choice sets lead to more choice difficulty, increased choice difficulty does not significantly affect unconventional choice shares. Thus, choice difficulty did not mediate our effect.

STUDY 2

In Study 1, half of the options were unconventional flavors and half were conventional flavors. However, it's possible consumers perceive the choice set differently depending on the choice set size as well as the composition of the choice set (e.g., ratio of conventional and unconventional options), leading to different choices. In order to ensure that the effect from Study 1 is not specific to a certain ratio of unconventional to conventional choices within a choice set, we designed Study 2 to directly manipulate the ratio of unconventional flavors.

Method

Participants ($N = 605$, $M_{age} = 35.2$ years, 55.5% male) on mTurk were randomly assigned to one of four between-subjects conditions (Size: Large, Small; Ratio: Half, Fourth). The Large-Half and Small-Half conditions were equivalent to the Large and Small conditions in Study 1. Participants in the two Large conditions viewed twelve ice cream flavors, while participants in the two Small conditions viewed four flavors. In the Large-Fourth and Small-Fourth conditions, the choice sets were comprised of one-fourth unconventional flavors (i.e., three flavors in the Large-Fourth condition and one flavor in the Small-Fourth condition). The Small conditions were again a subset of the Large conditions as in Study 1. Further, the flavors were identified as unconventional or conventional via the same pretest described above.

We predict that the main effect for choice set size found in Study 1 was not the result of the composition (half conventional vs. half unconventional). Thus, we hypothesize that there will be no significant interaction between choice set size (Large vs. Small) and choice set ratio (Half vs. Fourth) and that we will replicate our finding that participants choose more unconventional choices (across both the Half and Fourth conditions) in large choice sets than in small choice sets. Our dependent measure of interest is again unconventional choice share. In addition to this measure, we also measure choice difficulty.

Results and Discussion

We ran a logistic regression of unconventional choice (1 = chose an unconventional choice, 0 = chose a conventional flavor) on a dummy variable for the Large choice set conditions, a dummy variable for the Fourth ratio conditions, and the interaction between choice set size and ratio. We found no significant interaction between choice set size (Large vs. Small) and ratio (Half vs. Fourth), b = -0.62, (1)= 1.98, $p = 0.16$. As expected, we did find a significant main effect of choice set size (Large vs. Small) controlling for ratio (Half vs. Fourth). Overall, 25.0% of participants in the Large conditions chose an unconventional choice, compared to only 18.0% of participants in the Small conditions, b = -0.44, (1)= 4.61, $p < .05$.

Additionally, we found a significant main effect of ratio: participants were significantly more likely to make an unconventional choice in the Half condition versus the Fourth condition, b = -1.41, (1)= 23.81, $p < 0.001$. These effects hold when controlling for the significant positive effect of choice difficulty (= 0.21, $p < 0.01$) and participant demographics (= 0.41, $p < 0.04$; = -1.06, $p < 0.001$). As in Study 1, choice difficulty did not mediate our effect.

Overall, Study 2 replicates the findings from Study 1 regarding choice set size. Specifically, we still find that participants are significantly more likely to choose an unconventional choice in the larger choice set than in the smaller choice set. Study 2 also extends the findings of Study 1 by demonstrating that this main effect is not specific to the ratio of unconventional to conventional options available within the choice set.

STUDY 3

While Studies 1 and 2 have shown the main effect of choice set size on the preference for unconventional options, they did so in one product category (ice cream). We seek to replicate this finding over a different product (televisions) and through a different operationalization of conventionality (preference for a compromise option). In their work on unconventional choices, Simonson & Nowlis (2000) operationalize unconventional choice as choice for a non-compromise option. Specifically, because the compromise option is the least extreme option in a choice set, it is more conventional relative to the non-compromise options. Following this set-up, we measure preference for compromise options between small and large choice sets. We hypothesize that individuals will be more likely to choose a compromise option in a smaller choice set relative to a larger choice set.

Method

Participants ($N = 390$, $M_{age} = 33.3$ years, 53.3% male) on mTurk were randomly assigned to one of two choice set size conditions (Large, Small). Participants in each size condition were then further randomly assigned to either a "2-Group" or "3-Group" option set, creating a total of four between-subjects conditions. The 2-Group and 3-Group conditions are necessary to measure the compromise effect. Specifically, in order to assess whether the compromise effect exists in both choice set size conditions, we have to compare shares for the compromise option when it's in a binary choice set-up (2-Group) to shares for the compromise option when it is in a trinary choice set-up (3-Group). The number of options varied across all conditions. Participants in the Small-2-Group condition viewed two options; participants in the Small-3-Group condition viewed three options; participants in the Large-2-Group condition viewed eight options; and participants in the Large-3-Group condition viewed twelve. The Small conditions represent the traditional compromise effect set-up.

In each condition, participants are asked to imagine they are buying a television that varies is picture quality and price. The televisions vary from lower price/lower quality to middle price/middle quality (compromise options) and to higher price/higher quality. In the 2-Group conditions, participants chose between the middle price/middle quality option(s) and the higher price/higher quality option(s), while in the 3-Group conditions the lower price/lower quality option(s) were added to the set. The compromise effect exists if participants are more likely to choose the middle price/middle quality option(s) in the 3-Group conditions than in the 2-Group conditions. In the Small conditions, there is one television model for each price/quality tier. This option is randomized from the full set of options (represented by the Large-3-Group condition). In the Large conditions, there are four options for each price/quality tier. Thus,

the choice of any of the four middle price/middle quality options is considered a compromise choice.

To measure if participants are less sensitive to the compromise effect (and thus less likely to choose conventional options), we measure the difference in the shift in choice share for the middle price/middle quality option(s) between the 2-Group and 3-Group conditions for the Small choice set and for the Large choice set size separately. We hypothesize that participants in the Small condition will be more likely to choose the compromise option in the 3-Group condition than in the 2-Group condition (e.g., the classic compromise effect) but participants in the Large condition will not be more likely to choose the compromise option. This pattern would support our claim that participants choose conventional options more in smaller choice sets than in larger choice sets.

While our main dependent measure is the difference in the compromise effect between the Large and Small conditions, we also measure choice difficulty and participant demographics (age and gender) as in the previous studies. Further, we also included the NFU Scale in case this individual difference variable moderates the effect of choice set size on the compromise effect. We would expect a possible moderation since individuals who have higher NFU scores are more likely to choose less conventional options overall.

Results and Discussion

We found a marginally significant interaction between choice set size (Large vs. Small) and option set (2-Group vs. 3-Group), b = 0.88, (1)= 3.62, p = 0.057. Simple effect analysis revealed that participants were significantly more likely to choose the compromise option in the 3-Group option set than in the 2-Group option set in the Small condition, b = 0.65, (1)= 4.22, p = 0.04; however, they were directionally less likely to choose the compromise option in the 2-Group option set in the Large condition, b = -0.24, (1)= 0.49, p = 0.48. This significant interaction suggests that the compromise effect is reduced in larger choice sets, which can also be thought of as a reduction in the choice of a conventional option.

Looking at choice difficulty, there is a main effect of choice set size on choice difficulty ratings such that participants in the Large conditions find making a choice more difficult than participants in the Small conditions (3.32 vs. 2.55, $t(367.443)$ = -4.69, p < 0.001). However, if we run a logistic regression predicting choice of a compromise option (1 = chose a compromise option, 0 = did not choose a compromise option) from a dummy variable for the Large choice set conditions, a dummy variable for the 3-Group option conditions, an interaction between the Large conditions and the 3-Group option conditions, and choice difficulty, we see that choice difficulty has a significant positive effect on the probability of choosing a compromise option (= 0.27, p < 0.001). This means that greater choice difficulty leads to a higher probability of choosing a compromise option. The opposite pattern that we would expect if choice difficulty was the reason why participants were choosing more conventional options. Yet, even controlling for the significant positive effect of choice difficulty, the interaction between the Large dummy variable and the 3-Group dummy variable is significantly negative (= -1.00, p < 0.05). This implies that the decrease in the compromise effect is due specifically to the contextual choice set size variable separate from changes in choice difficulty.

We also ran two similar models of the regression described above, also including the NFU Scale. We evaluated two models: one with a three-way interaction between Large choice set size, the 3-Group option set, and the NFU Scale and one with no three-way interaction, just the NFU Scale as an independent measure. The first model found no significant three-way interaction (p > 0.10), sug-

gesting that NFU does not moderate the effect of the Large choice set size on the compromise effect. The second model did show a significant negative effect of NFU on choice of the compromise option = -0.54, p < 0.05). This implies that individuals with higher NFU are less likely to choose a compromise option overall. However, the interaction between the Large choice set size and 3-Group option set still remains significant and negative (= -1.03, p < 0.05) even when including the NFU Scale. This suggests that choice set size still significantly reduces the compromise effect even when controlling for individual-level differences in NFU.

Overall, Study 3 has replicated the main effect of choice set size on the preference for unconventional choice options in a different product category and via a different operationalization of conventionality. Further, the finding that larger choice sets reduce the compromise effect is not moderated by NFU or diminished when controlling for either choice difficulty or NFU. This suggests that choice set size has an independent and separable effect that is specific to the number of options available.

GENERAL DISCUSSION AND CONCLUSION

Across three studies we have demonstrated that larger choice sets lead to a greater preference for unconventional items relative to smaller choice sets. We have shown this effect in two product categories (ice cream and televisions) and across two operationalizations of conventionality (an independent pretest and the compromise effect). We also demonstrated that this effect is not attributable to changes in choice difficulty or individual-level differences in NFU or preference for novelty.

In our studies, we only examined two relative choice set sizes (four versus twelve). It is possible that the difference in preferences may be attenuated with smaller or larger choice sets. Further, we were only able to rule out potential mechanisms for the difference in conventional choice share between choice set sizes (choice difficulty, NFU) and we were not able to specifically identify a mechanism for the main effect of choice set size. While we hypothesize that this is the result of a greater reliance on reasons and the preeminence of reasons related to uniqueness, we have not confirmed this empirically. Despite these limitations, this paper still contributes to the literature on choice set size and provides compelling evidence that choice set size significantly affects preference and can explain why consumers experience negative post-choice outcomes. The results of this paper have strong implications for marketers determining which options and how many options they should have in stock.

Word of Mouth vs. Word of Mouse: The Effect of Communication Channel on Subsequent Reactions to the Brand

Hao Shen, the Chinese University of Hong Kong, China
Jaideep Sengupta, the Hong Kong University of Science and Technology, China

EXTENDED ABSTRACT

With the increasing popularity of the internet, more and more word of mouth is generated online. Consumers not only talk face-to-face to their friends, but also write online reviews, provide comments or text messages to others about their view of a product or a brand. This research examines whether a communicator's own reactions to and behavior towards a favored brand might change as a consequence of discussing it orally vs. in writing.

We propose that oral communication is more likely to invoke the self than written communication. The communications literature suggests that this might occur, because of multiple reasons. First, because oral communication is more involving than written communication, speakers refer to themselves more frequently than writers (Chafe 1982, 1985; Jahandarie 1999). Second, writing often serves to "disembody the written text from the writer" (Rubin 1987, pg. 10). Speech, in contrast, is ephemeral and therefore cannot be separated from the speaker (Jahandarie 1999; Rubin 1987). Third, oral communication is typically more spontaneous than written communication; accordingly, it is more likely to be a truer reflection of the self, rather than being corrected by a consideration of social norms (Berger and Iyengar 2013; Klesse, Levav and Goukens 2015).

These findings suggest that consumers who talk (vs. write) about a brand are more likely to evoke thoughts about the self, as manifested in heightened ego-involvement (Chafe 1985; Jahandarie 1999), increased self-expressiveness (Rubin 1987; Chafe 1982) and a greater inclusion of personal experiences (Chafe 1982; Tannen 1985). We argue that this in turn should strengthen the self-brand connection, which captures the extent to which the brand is integrated into the consumer's self-representation (Escalas 2004). The positive consequences of a strong self-brand connection should therefore also be obtained, such as a greater resistance to an attack on the brand (Cheng, White and Chaplin 2012) and a greater willingness to wait for the brand in cases – e.g., in case of stockout (Sprott, Czellar, and Spangenberg 2009).

Study 1 provided evidence for our predictions, showing that participants reported a greater self-brand connection with a positively-viewed brand (Apple) after discussing it orally than after writing about it. In support of the premise that this effect of communication channel arises because of greater self-activation in the oral case, this effect disappeared if participants, across conditions, were explicitly instructed to focus on the self when discussing the brand. Exactly the same pattern was observed for the frequency of "I" mentions during the communication, which serves as a proxy for self-activation. Finally, willingness to wait for the discussed brand (in stockout situations) also followed this pattern: oral (vs. written) communication had an advantage in the control condition, which disappeared in the self focus condition.

Study 2 examined whether the effect of speech vs. writing will disappear if the discussion is with the reference to a second party's views. Participants in the control condition either talked about their views of a positively-viewed brand (Samsung) to a voice recorder or wrote about it on a piece of paper. In the other-person condition, they were instead asked to think of someone else who uses "Samsung" products, and discuss this person's views of the brand. After participants provided their initial attitudes towards Samsung, they then read a consumer critique of Samsung, and reported their attitudes again. As predicted, in the control condition, talking once again produced

a higher SBC than writing, which also translated into a greater resistance to attack. Both of these differences disappeared, however, when discussing Samsung from another person's perspective. Finally, a protocol analysis of the communication content also provided evidence supportive of our theorizing: participants in the control condition mentioned more self-relevant positive thoughts about the brand during oral than written communication, but this difference disappeared if they discussed someone else's perception of the brand.

Having found good support for our basic premises in these studies (as well as others not reported here), Study 3 investigated when writing about the brand will benefit it more than talking about it. We suggest that a reversal of earlier results will obtain when consumers have an explicit goal of persuading the recipient as to their opinions about the brand. Given such a goal – as opposed to simply sharing thoughts on a brand – consumers might themselves believe that they have done a more persuasive job if given the opportunity to write out their message (even if this does not reflect actual recipient persuasion) because of greater opportunity to refine and structure the message (Berger and Iyengar 2013). This belief should increase their own certainty about their already-favorable attitudes towards the brand (Visser and Mirabile 2004), which in turn is likely to not only increase self-brand connection, but also bring about other benefits such a willingness to wait for the favored brand (Tormala et al. 2006). Study 3 found support for these ideas by manipulating the communication goal: sharing vs. persuasion. Previous results were replicated when participants were simply required to share their views: talking produced a stronger SBC and a higher willingness to wait for the favored brand (in this case, Adidas). However, given a persuasion goal, not only did the SBC difference disappear, but certainty in post-communication attitudes was higher for the writing (vs. talking) condition – in turn, this produced a greater willingness to wait for the brand.

In our final study, we explore whether this link is bi-directional. Because the self-expressive function served by brands with a high SBC is more likely to be fulfilled in the oral rather than the written modality. We predict, therefore that not only does talking vs. writing about a favored brand increase the self-brand connection (which is the central thesis of this research), but also, an enhanced self-brand connection increases the likelihood that consumers will choose to talk rather than write about the brand. Study 4 provided support for this argument.

This research contributes both to the communications literature in highlighting novel consequences of talking vs. writing and also to consumer scholarship by addressing the relatively understudied issue of how the communication channel used for word-of-mouth can influence the consumer's own reactions to a brand. The findings also contain applied implications in terms of informing managers as to when it might be beneficial to encourage consumers to talk (vs. write) about a brand – and also when it might be useful to encourage the reverse.

Playful Consumption: A Physical Perspective

Olivier Sibai, Birkbeck, University of London, UK

EXTENDED ABSTRACT

Playfulness is ubiquitous in consumption, pervading every stage of the consumption process (Grayson 1999; Jantzen et al. 2012). While physically playful consumption has become a widespread phenomenon, existing conceptualizations of play in consumer research are disembodied. In this paper I conceptualize (1) why consumers engage in physically playful consumption and (2) how they do it. This research contributes to the literature on playful consumption and consumer expertise.

Previous research has conceptualized playful consumption as a non-productive, intrinsically motivated, voluntary consumption experience involving an optimal level of arousal and feelings of fun, and anchored at the border between the real and the imaginary (Holt 1995; Holbrook 1999; Kozinets et al. 2004). Two trends have developed in playful consumption. One the one hand, consumers increasingly engage in mental play. For example, consumers revel in the actualization of impossible fantasies in video games (Denegri-Knott and Molesworth 2010) and engage in "screen play" (Kozinets et al. 2004 p. 668). On the other hand, consumers also engage in physical play. Descriptive accounts show that consumers playfully explore their bodies through a wide range of consumption activities, from sports (Coakley and Dunning 2000), to yoga (Ertimur and Coskuner-Balli 2015), DIY (Wolf and McQuitty 2011) and the latest generation of video games (Benford, Magerkuth and Ljungstrand 2005). However, these descriptive accounts have not conceptualized the processes and purposes of physically playful consumption.

The study was conducted in the juggling community. The community members practice as consumers rather than professionals the circus crafts involving the manipulation of objects, a set of highly physical and playful activities (Palacios 1991). The study follows an ethnographic research design based on participant-observation in two London juggling clubs. Over 2015, 11 jugglers were interviewed (200 transcript pages), members' online discussions were continuously scrutinized (over 100 conversations downloaded) and field notes were taken at 25 juggling gatherings (40 transcript pages).

Physical play emerges as a mode of consumption whereby consumers appropriate material reality. I distinguish four types of physically playful consumption practices allowing consumers to appropriate different aspects of material reality. Each practice is characterized by specific doings, uses of objects and physical meanings. In skill playing, consumers train to develop new physical abilities, using the toy as a tool, and derive feelings of self-improvement from it. Skill playing allows consumers to appropriate their body. In artistic playing, consumers improvise long sequences of movements, viewing the toy as an extension of their body, allowing them to express themselves. Through artistic playing, consumers unite with surrounding objects. In collaborative playing, consumers play physical games with others , using the toy as a communication medium, to gain feelings of mutual incorporation, perceptions of being in physical harmony with others. Consumers thus integrate the bodies of fellow consumers in their inner worlds. In performance playing, consumers present their physical abilities to an audience in a choreography, using the toy as a theatrical property. By defying the rules of gravity, the player produces feelings of magic in the audience. In performance playing, consumers enchant the world, reshaping material reality as they wish. The range of physical play practices consumers can engage in expands overtime as their expertise develops. Beginners start with skill playing as all other forms of play require mastering a number of basic movements. Then, they can engage in artistic and collaborative playing. In the last step consumers can become performance players.

While in previous research consumers were viewed as playing to escape material reality (Deighton and Greyson 1995), this research indicates that consumers play to connect with material reality and characterizes four ways in which it does. This study also contributes to the literature on consumer expertise. It offers an embodied account of consumer expertise contrasting with existing cognitive ones (von Wallpach and Kreuzer 2013). While cognitive expertise allows consumers to select the experiences which enhance their expertise the most, leading expert consumers to engage in less varied experiences than novices (Clarkson, Janizewski and Cinelli 2013), physical expertise unlocks new experience opportunities, leading expert consumers to engage in more diverse experiences than novices.

Toward a Framework for CCT Research on Consumer Emotion

Anton Siebert, The Open University, UK
Andrew Lindridge, The Open University, UK
Ahir Gopaldas, Fordham University, USA
Cláudia Simões, The Open University, UK

EXTENDED ABSTRACT

CCT research on consumer emotion dates back to the 1980s, following passionate pleas by interpretive researchers to highlight the emotional, experiential, and expressive aspects of consumer behavior (Belk 1987; Hirschman and Holbrook 1982; Holbrook 1987). Although CCT has made valuable inquiries into emotion, the field has tended to employ different theoretical perspectives of emotion, to situate concepts of emotion at differing levels of analysis, and often to subordinate emotion under parallel theoretical notions, such as, ideology and community. As a result, CCT research on consumer emotion is rather fragmented (Gopaldas 2014; Illouz 2009; Rafferty 2011), having produced a large unconnected array of piecemeal insights. Consequently, there has been a call for more social-, cultural-, and management-related conceptualizations of emotions in marketing and consumer research (Bagozzi, Gopinath, and Nyer 1999; Moisio and Beruchashvili 2010). This article proposes an integrative framework for CCT research on consumer emotion. We develop a framework that captures the distinctions and possible links among the macro-cultural, the meso-market, and the micro-individual level as they relate to emotion. Such integrative framework extends existing theorizations of consumer emotion by establishing important connections among different levels (macro, meso, micro) of analysis.

To develop our framework we collected CCT articles from the *Journal of Consumer Research*; *Journal of Consumer Culture*; *Consumption, Markets, and Culture;* and *Marketing Theory*; along with relevant texts from other journals, books, and edited volumes on consumer emotion, focusing primarily on sociocultural perspectives (Belk and Coon 1993; Belk, Ger, and Askegaard 2003; Beruchashvili and Moisio 2012; Beruchashvili, Moisio, and Gentry 2015; Bonsu, Darmody, and Parmentier 2010; Celsi, Rose, and Leigh 1993; Gopaldas 2014; Jantzen et al. 2012; Kuruoglu and Ger 2015; Otnes and Pleck 2003; Sandlin and Callahan 2009; Siebert 2013, 2014; Thompson 2005). Next, we iteratively went back and forth between landmark emotion research in the social sciences (Hochschild 1979; Illouz 1997; Stearns and Stearns 1985; Stets and Turner 2008) and our collection of CCT work on consumer emotion. From this process, we built up and created common themes, assumptions about emotion, and an overall framework integrating and connecting recent CCT research on consumer emotion along a macro-meso-micro spectrum of analysis.

We resort to the notion of "emotionology" (Stearns and Stearns 1985) to distinguish between the cultural and market elements that shape consumer emotion, and individual emotional experience and expression itself. Although the term in its original formulation is largely limited to social rules regarding emotion, we adapt it to capture the macro and meso levels of analysis. We suggest the label "cultural emotionology" for macro-level ideational resources pertaining to emotion, such as, emotion discourses, values, and norms. In addition, we suggest labeling "marketplace emotionology" the material and symbolic resources related to emotion that result from the use and reworking of cultural resources by actors in market and consumption settings (e.g., brand-centered "emotion cultures," Beruchashvili et al. 2015) and the market-mediated assemblages formed by resources, concrete emotions, and market actors (e.g., "emotional economies," Kuruoglu and Ger 2015). At each level, emotionologi-cal formations may serve as resources and regulating structures for consumers.

Next we describe the main findings emerging from our analysis at the three levels: macro, meso, and individual. The key elements at the macro level of *cultural emotionology* (e.g., emotion ideals, vocabularies, ideologies) usually exist in plural form in societies and are often contradictory, creating tensions at the cultural level that animate much of the dynamism in human emotional activity. However, these elements can also form "emotional regimes" (Jantzen et al. 2012; Reddy 2001) that enforce particular emotional norms, values, and techniques guiding consumers in desirable emotional directions.

The key elements at the meso level of *market emotionology* are market offerings and actors, symbolic marketplace resources, and consumer collectives. These elements become variously assembled in the emotion concepts that prior research has created or applied. For instance, the concepts "emotion culture" (Beruchashvili et al. 2015; Gordon 1989) and "structures of feeling" (Thompson 2005; Williams 1997) were used to reveal how emotional consumer behavior is normatively shaped. We further locate at the meso level, emotional or "affective economies" (Kuruoglu and Ger 2015; Ahmed 2004) and "marketplace sentiments" (Gopaldas 2014). These latter concepts although paying little explicit attention to normative content about emotions, they represent more concrete assemblages that encourage collective thoughts, feelings, and actions. Much research at this level tends to perceive emotions as being collectively evoked in and through the interactions of consumers (and other market actors and actants) in shared consumption settings.

The cultural and marketplace levels provide scripts and resources for individuals as socially situated emotion interpreters to make sense of and (make efforts to) deal with their emotional experiences and expressions. Research at the *micro-individual* level emphasizing emotion as a central element in consumers' identity projects tends to be based on the premise that emotion and identity are interlinked and broadly governed by similar structures and processes (Beruchashvili and Moisio 2012; Hochschild 1983). Emotions are seen as being orientated or managed toward, motivating, reassuring, or hindering particular identity goals and prescribed consumer positions (and vice versa) within cultural contexts and marketplace structures (Belk et al. 2003; Siebert 2013; Thompson 2005; Thompson and Coskuner-Balli 2007).

Overall the proposed framework helps broadening scholarly debates from specific concepts and dichotomizations between cultural and psychological work to connections among existing concepts at different levels of analysis. By taking such a perspective, researchers will have a more comprehensive view of consumer emotion. The framework further clarifies the different emotionological levels, and the links between the socio-culturally constructed (i.e., emotionology) and the messy realm of the individually experienced.

The Paradox of Social Television:
The Effects of Connectedness and Distraction on Enjoyment

Cansu Sogut, Boston University, USA
Frédéric Brunel, Boston University, USA
Barbara Bickart, Boston University, USA
Susan Fournier, Boston University, USA

EXTENDED ABSTRACT

Social television (social TV) - the use of social media to communicate with other viewers while watching television - allows the sharing of experiences with close or distant others. People can share via live-tweeting, posting Facebook status updates, or reading other viewers' comments (Nielsen 2014; Wagner 2013). In this paper, we examine how communicating online with other consumers while watching a television broadcast affects enjoyment of the viewing experience.

Broadcast networks have two major incentives to encourage social TV: (i) increasing engagement and word-of-mouth about the TV programs and (ii) bringing back traditional TV, where viewers are not able to fast-forward the commercials. These motives call broadcasters to action; yet, research on the downstream effects of social TV on viewing experiences shows conflicting results. While some industry research suggests that this behavior can increase program and brand engagement (Nielsen 2015; Russell 2012), other findings suggest that it might be distracting (Pearce 2014).

Our goal is to understand how the nature of TV consumption changes while people are engaging in social TV. Specifically, we examine the effects of social TV on (i) the enjoyment of the content and (ii) the enjoyment of the overall experience. Our theorizing suggests that social TV has both a positive effect on enjoyment via a feeling of social connectedness and a negative effect on enjoyment via distraction.

The positive outcomes of consuming experiences with social others suggest that the benefits may also extent to social TV. Thus, we predict that social TV will enhance the overall enjoyment of the consumption and this effect will be mediated by social connectedness.

Our hypothesis is based on the connections between (i) the felt synchrony with social others induced by viewers' online communication (Sogut, Brunel, and Bickart 2015), (ii) people's preference for social experiences (Caprariello and Reis 2013; Raghunathan and Corfman 2006; Ramanathan and McGill 2007), and (iii) the impact of social connectedness on well-being and positive emotions (Mauss et al. 2011).

Social TV requires multi-tasking as viewers need to use a second screen device (e.g., smartphones, tablets) while watching the program on TV. Thus, we predict that participating in social TV may also lead to distraction, which negatively affects the enjoyment of the content. We also predict that the effect of distraction on content enjoyment will depend on the type of the viewed content. On the one hand, communicating with others requires attentional resources, which may reduce consumers' ability to process the program content. Experiences can be evaluated less favorably when attention is divided (e.g., Green and Brock 2000; Langer 1997). On the other hand, some findings suggest that distraction while watching TV does not necessarily make the experience less enjoyable, especially if the affective component (compared to the informational component) of the viewed content is dominant (Nelson et al. 2009; Shiv and Nowlis 2004)we present a two-component model, which predicts that distraction may decrease subsequent choices for the sampled item. The model asserts that the ultimate pleasure arising from the taste of a food sample depends on two components, one informational and the other affective. Further, the model proposes that distraction increases (decreases. Therefore, we predict that people will perceive participation in social TV as distracting when the viewed content is predominantly informational, but not if the viewed content is predominantly affective.

In two studies, we examined whether social TV affected overall experience enjoyment and viewed content enjoyment. In Study 1, participants watched a clip from a talent show (high affect), while in Study 2 they watched a clip from a documentary (high information). In both studies, we manipulated whether or not audience members participated in social TV while watching the clips. Lab sessions were randomly assigned to one of two experimental conditions. In the "TV + Social TV" condition participants watched the video while communicating with each other using a chat room interface, and in the "TV only" condition, they watched the video without communicating. In the TV + Social TV sessions, each participant was assigned an anonymous username and was instructed to share at least five posts in the chat room. After viewing the video, participants rated their *enjoyment of the experience* and *enjoyment of the content*. We also measured social connectedness and distraction.

In Study 1, where content was predominantly affective, social TV enhanced experience enjoyment, which was driven by social connectedness. Further, regardless of engaging in communication, all participants enjoyed the clip equally. In other words, participating in social TV did not enhance or diminish the enjoyment of the intrinsically enjoyable *content itself* per se, but rather, enhanced the enjoyment of the *overall experience* for the participants.

In Study 2, where content was predominantly informational, we found that participating in social TV resulted in less enjoyment of the video content. Although social TV increased the felt connection with other audience members, the negative effect of distraction on content enjoyment was stronger than the positive effect of connectedness. For experience enjoyment, the effects of distraction and connectedness balanced each other out, resulting in no difference in overall experience enjoyment between the two conditions.

In two experiments, we find that participating in social TV (vs. TV only) increases social connectedness, which enhances the enjoyment of the overall experience. When social TV is not distracting, the positive effect of feeling connected to social others positively affects the overall experience. When communication leads to distraction (occurring when content is predominantly informational, rather than affective), social TV hinders the enjoyment of the viewed content.

Our work contributes to the literature on experiential and hedonic consumption by providing a theoretical framework that reconciles the paradox of social TV – the tension between connection and distraction. We believe that understanding the effect of social TV on different aspects of enjoyment also has important practical implications for content producers, broadcast networks, and advertisers. Specifically, content producers and advertisers should encourage online conversation among consumers, especially when the program content is emotional. When the content is mainly informational or requiring more attention, it might make more sense to encourage viewers to share their thoughts during the ad breaks rather than dur-

ing the program. Finally, because feeling connected enhances viewing experiences, promotions encouraging online conversation should also highlight the importance of being part of a group or community.

Multitasking: Perception and Performance

Shalena Srna, University of Pennsylvania, USA
Rom Y. Schrift, University of Pennsylvania, USA
Gal Zauberman, Yale University, USA

EXTENDED ABSTRACT

In today's tech-heavy environment, multitasking has become an integral part of our lives (Jumio 2013; Ophir, Nass, and Wagner 2009; Wang and Tchernev 2012). Consumers frequently go back and forth between tabs on their smartphones, messages, and websites. Moreover, nowadays, many workplace environments necessitate working on multiple projects under time pressure that may lead workers to shift back and forth between several tasks that they are engaged in (e.g., Leroy, 2009). In the current paper, we first propose and demonstrate that multitasking is often about people's perceptions. Second, we demonstrate that the mere perception of multitasking improves performance compared to the perception of single-tasking, holding the task constant. Finally, we suggest that the perception of multitasking reduces boredom and increases engagement with the task, which drives this improvement in performance and increase in persistence.

The definition of multitasking, which originated in computer-engineering, is the engagement in two or more tasks simultaneously (Witt and Lambert 1965). However, it is generally accepted that humans cannot really perform more than a single task concurrently. That is, for non-automatic activities that require active attention, people shift back and forth between activities and process only a single task at any given time (Conard and Marsh 2014; Leroy 2009; Pashler 1994). Thus, multitasking is more about perception than actual engagement in multiple tasks concurrently (we limit our attention to non-automatic activities). When engaging in a given activity that requires several distinct tasks, one may construe such activity as either multitasking or single-tasking. This brings up important questions: what factors would make individuals perceive a certain activity as multi- versus single-tasking? Further, holding the actual activity constant, would the mere perception of multitasking impact performance? If so, why?

First, we examine what may be the factors that would prompt individuals to construe a certain activity as either multi- or single-tasking. In two studies, we demonstrate the malleability of people's perception of their activity. For example, in one study(N=80) participants were asked to imagine that they were working on two word-puzzles. In one condition the puzzles were described as being part of a single study while in another condition each puzzle was said to relate to a distinct and different study. Indeed, participants in the latter condition construed such an activity as being more consistent with multitasking than those in the former condition(p<.001). In additional studies, we find that participants' perception of multitasking is also influenced by task relatedness, topics, importance, and switching frequency (p's<.05). Thus, even the simple framing of an activity can make people construe a given activity as either multitasking or single-tasking.

Next, we tested whether the mere perception of multitasking increases persistence and performance. In one study (N=237), participants worked on two types of word-puzzles presented side-by-side. The tasks were framed as part of a single study (single-tasking-framing) or as part of two separate, distinct studies (multi-tasking-framing). Manipulation checks ensured that the framing manipulation worked as intended. We find that participants in the multitasking condition worked significantly longer and performed better compared to those in the single-tasking condition(p's<.001).

Across 12 studies, we replicated this effect with different tasks, and regardless of whether participants felt they had a choice of whether to multitask or not. For example, in an additional study, participants(N=162) were asked to transcribe what they heard when watching an educational video. This activity was framed as either a single activity (e.g., transcribing), or as two concurrent activities (listening and typing). Participants in the multitasking-condition transcribed more and performed significantly better on a subsequent quiz relating to the video content(p's<.05). Additionally, we did not find consistent results that would support that the effect was driven by a change in mind-set (i.e., a productivity mindset Keinan 2007) or overall perceptions of engagement in the task. Furthermore, the perception of multitasking did not seem to heighten the perception of self-efficacy, need for closure, confidence, or control, which could also be advocated as a mechanism driving improvement on task performance (Rotter 1966; Sherer et al. 1982).

In additional studies, we explore other mechanisms for the observed effect. In particular, we test whether it is possible that individuals' belief that multitasking is generally more difficult is causing them to gear up toward working on this supposedly more difficult activity. Such heightened preparedness would ultimately leads individuals to persist longer and perform better. In a study(N=200), we manipulated the degree to which participants would feel they needed to prepare for the study by informing them that the stud(ies) are simple and easy, in addition to our task-perception framing manipulation. Thus, the study was a 2(multitask-framing vs. single-task-framing) × 2(easy vs. control). Although we replicated the effect in which the perception of multitasking improves performance, we did not find an interaction that would support that the main driver is participants' tendency to get geared towards a more difficult task.

Several additional studies demonstrate that the multitasking framing improves performance because of increased engagement in the task(s). Specifically, participants who felt like they were multitasking reported being less bored when watching a gallery tour or working on puzzles (*p's*<.05). We more directly test the mechanism underlying this effect using eye-tracking. By measuring people's pupil dilation as a proxy for arousal (Beatty and Lucero-Wagner 2000), we find that when an activity is framed as multitasking, switching between the tasks increases arousal more so, compared to when the same activity is perceived as a single task.

To summarize, across 22 studies, with 4686 subjects, and employing five different types of tasks, we find that the mere perception of multitasking substantially improves performance. That is, while doing more at the same time might hurt performance, doing the same activity but perceiving it as more, improves it. This research has important implications because consumers have many opportunities to multitask as they navigate between tabs on their web browser, watch television, waiting in line, or shop in stores. In these contexts, consumer's perception of multitasking can increase engagement with a certain marketing activities like watching commercials or a tour.

Physical Transformations and Visual Practices in the Fitblr Community

Yannik St.James, HEC Montreal, Canada
Sarah-Jade Lacoursière, HEC Montreal, Canada

EXTENDED ABSTRACT

The appearance of one's body is a central aspect of self-identity and transforming the body to enact identity projects constitutes a common theme in contemporary consumer culture (Thompson and Hirschman 1995). In Western societies, achieving the cultural ideal of a slender and fit body has become a primary concern (Heisse-Biber 2007) and consumer researchers have examined how consumers' interpretation of sociocultural discourses shape their efforts to exert control over their body (Thompson and Hirschaman 1995), how consumers cope with cultural expectations of weight control (St.James, Handelman, and Taylor 2011), and the role of support groups in pursuing weight-loss goals (Moisio and Beruchashvili 2010).

As computer-mediated environments become increasingly popular sites where consumers construct identities (Belk 2013), research seeking to understand consumers' weight-control efforts has turned to the analysis of blogs (Leipämaa-Leskinen 2011) and online communities (Ballantine and Stephenson 2011). These studies largely focus on consumers' discursive practices by analyzing the verbal texts consumers produce and share. We argue that investigating consumers' visual practices is a fruitful avenue to expand our understanding of their weight-related identity projects in online communities, a proposition that is premised on two observations: First, the body is a visible cultural object (Thompson and Hirschman 1995) and visual images play an important role in producing and reproducing meanings associated with specific physical forms and identities (Schroeder and Borgenson 1998). Second, social media is intensifying the visual nature of the Internet environment (Belk 2013), so that new forms of visual objects and practices such as selfies become meaningful ways for consumers to construct and express identities (Iqani and Schroeder 2015). The purpose of this study is thus to investigate consumers' visual practices as they pursue physical transformation projects in a virtual community.

To examine this question we conducted an 18-month qualitative investigation in the *Fitblr* community. *Fitblr* is a virtual fitness and weight-loss community on the social media platform Tumblr. It is loosely structured as an informal network of microbloggers who follow each other's account and who identify themselves through the hashtag "fitblr" (contraction of *fitness* and *Tumblr*) and related hashtags such as "fitspo" and "fitspiration" (contractions of *fitness* and *inspiration*). The *Fitblr* community is largely composed of young women and its multimedia content is highly visual. Data collection entailed content analysis (Gleeson 2011; Fairclough 2003) of 19 blogs over a 2-month period – for a total of 480 posts – as well as depth interviews (McCracken 1988) with 9 bloggers.

Our analysis reveals that bloggers' visual practices and community interaction practices evolve synergistically to form a system of inspiration that shapes and sustains physical transformations projects at the individual and community levels. As bloggers undertake, pursue, and achieve physical transformation goals, these practices correspondingly move from consuming inspiration, to sharing inspiration, and finally becoming a source of inspiration in the community.

Our participants joined the *Fitblr* community by creating a blog on Tumblr dedicated to achieving weight-loss or related physical transformation goals. Bloggers initially *consume inspiration* to develop their blog as a motivational board that helps them visualize their goals and to keep these goals salient amidst the various demands of their everyday lives; reposting visual content from other blogs is the main visual practice they use to this end. Reposting leads to creating a highly uniform visual landscape in the *Fitblr* community, composed mainly of four types of images: (1) "bodyspo" (body inspiration), which refers to images of ideal bodies or body parts that depict bloggers' physical goals; (2) images of lifestyle activities associated with bloggers' physical transformation projects, namely exercise or food choice; (3) pictures of various products and brands bloggers associate with their physical transformation project; and (4) stylized images of motivational quotes. As they build their motivational board, bloggers begin to interact and create relationships with other members in the community by following other accounts, reposting material, "liking" or commenting on a post.

As bloggers adopt lifestyle activities directed towards their goals and as they grow more comfortable in the community, they often begin to *share inspiration* by posting original content. These posts document the efforts bloggers deploy towards reaching their goals and include post-workout selfies, workout charts and statistics, meals and food diaries. By posting original content, bloggers reveal themselves to the community, thus transforming the nature and intensity of interactions. Indeed, original content attracts a larger base of followers, more reposts, as well as comments and personal messages. This is a source of affirmation for bloggers but it also sometimes experiences as pressure to post new content frequently and to live up to the image they have created on their blog. Others hesitate to post original content in the fear that it might not be embraced if it does not conform to the community's implicit norms.

Finally, bloggers who have transformed their bodies *become inspiration* for the community. These success stories are presented and shared through the visual practice of "before and after" pictures which are reposted by a large audience, conferring a unique status (Moisio and Beruchashvili 2010) to the featured blogger whose "expertise" is sought by other members looking to achieve similar goals. Transformation pictures also lend solidity to the blogger's new identity and becomes a source of motivation to maintain this lifestyle.

Our findings contribute to the literature examining how visual practices contribute to the production and reproduction of identities (Schroeder and Borgenson 1998). Indeed, practices such as reposting content and dominant visual tropes such as "before and after" pictures ultimately create a highly homogeneous taste regime (Arsel and Bean 2013). This study also contributes to our understanding of the "visual culture of the self" (Dinhopl and Gretzel 2016, p.126) and the notion of extended self in digital environments (Belk 2013). We show how participants' transformation goals can be re-negotiated in the community, and how perception that they are successfully progressing towards and achieving their objectives is not only shaped by their own private observation of their body but also by visual practices of sharing pictures that document their progress.

The Effects of Framing Subscription Benefits as Price Discounts or Time Bonuses on Time Preferences

Florian Stahl, University of Mannheim, Germany
Daniel M. Bartels, Booth School of Business, University of Chicago, USA
Veronica Valli, University of Mannheim, Germany

EXTENDED ABSTRACT

When consumers make choices about subscriptions, they face an intertemporal decision and have to make choices about a stream of consumption and payments over time. The current paper examines how consumers' time preferences change with changes in the framing of subscriptions' benefits. Subscriptions are attractive to companies because they allow for security in planning and enhance customers' loyalty. Therefore, to induce consumers to choose longer-term, subscriptions, firms might either offer a price discount (e.g., "save 25% off the monthly price when you sign up for a year")—lowering the per-time-unit cost for longer contracts—or offer a bonus time (e.g., "pay for 9 months and get 3 months free") —giving consumers an additional subscription time "for free" rather than lowering the unit price. In this paper, we investigate the different effects of price discounts and bonus time promotions on people's preferences for longer-term subscriptions.

Our research builds on and contributes to the literature on intertemporal discounting (Frederick et al. 2002; Read 2004; Zaubermann et al 2009) and specifically, the literature on framing effects in intertemporal decisions (Loewenstein 1988; Loewenstein and Prelec 1992).

Our main contribution results from studying time preferences in the context of subscriptions and from documenting a new kind of preference reversal, where consumers prefer longer-term (vs. short-term) subscriptions when presented with a bonus time (vs. price discount) promotion.

To preliminary investigate the different impact that promotions' framing may have on consumers' choice for subscriptions and to have a first impression of actual purchase behaviors we conducted a 2x2 (2-months vs. 6-months subscriptions/ bonus time vs. price discount) online controlled experiment (Kohavi et al. 2009) with a major Italian news publisher offering digital subscriptions to their daily newspaper. Randomized allocation of respondents to the 4 conditions ensured external validity of the study. Each condition (in form of a different digital landing page) has reached about 2.5 million impressions and two-sample tests of proportions revealed that in the short-term condition, price discount promotions increase the likelihood of a sale relative to bonus time promotions (.578 vs. .422, z= 2.303, p= .021) while in the long-term condition we observe a preference reversal as bonus time promotions increase the likelihood of a sale relative to price discount promotions (.546 vs. .454, z=-1.828, p= .068).

To better investigate this behavioral phenomenon, we conducted 6 survey-based experimental studies that represent data collected from more than 1,500 participants on different platforms, in different countries and in different languages. We focus on different theoretical constructs varying parameters that might be expected to change the preference reversal pattern that we have found. These include: time of payment (monthly installments vs. upfront lump sum), time at which the free months are offered (beginning vs. end of subscription), size of the base subscription rate (magnitude effect of the monthly fee of 10$ vs. 50$ or customization of this value via adaptive surveys), type of service offered (Internet vs. mobile phone) and whether the monthly price reduction is framed as discount or rebate. Results reveal that consumers prefer price discounts to bonus time up to contract durations of approximately 11 months and prefer bonus time over price discounts thereafter. Furthermore, the preference reversal is stable with regard to different methods for the elicitation of individual discount rates (matching-based measures vs. choice-based measures), is not significantly affected by individuals risk aversion and can be found for subjects with lower as well as with higher numeracy. However, teaching the subjects how to translate the overall cost of the bonus time frame into the price discount frame through calculation tasks or added information, leads to elimination of this preference reversal and to stable preferences for offers framed as price discount.

In conclusion, this paper provides empirical evidence of a new impact of promotions' framing on time preferences with implications for optimal contract promotion design. From a managerial perspective our findings suggest that, since monthly discount rates are lower under the *Price Discount* condition for contract durations up to a certain period (of approximately 11 months) and the opposite is true for longer contract durations, firms should offer short-term contract promotions with price discounts and long-term promotions with bonus time.

Resource Scarcity, Socioeconomic Status and Conformity: The impact of Resource Scarcity on Responses to Social Influence Depends on Childhood Environments.

Angelos Stamos, KU Leuven, Belgium
Sabrina Bruyneel, KU Leuven, Belgium
Siegfried Dewitte, KU Leuven, Belgium

EXTENDED ABSTRACT

The economic turmoil of the past years has increased the number of people experiencing financial insecurity (World Health Organization, 2014). Research has shown that resource scarcity can have a significant impact on different aspects of individuals' behavior (e.g. Shah et at al. 2012). We focus on the responses to social influence. Social influence can have substantial impact on consumers' decision making (Wood and Hayes, 2012) as it is used as a tool for changing behaviors (e.g. Goldstein et al. 2009). Earlier findings suggest that financial constraints might enhance consumers' sensitivity to social influence (e.g. Drèze and Nunes 2011) but it is not clear how general this phenomenon is. Recent studies have suggested that individuals' responses to resource scarcity can be adaptive. These studies used life-history theory to show that behavior of individuals facing adversities such as resource scarcity depends on their childhood socioeconomic background (Ellis, et. al., 2009). In this paper, we use life-history theory to examine the joint impact of childhood socioeconomic background and current resource scarcity on conformity.

Life-history theory addresses the issue of how organisms make use of limited resources to maximize fitness (Roff, 2002). Life-history strategies vary along a slow-to-fast continuum (Ellis et al., 2009). With regard to psychological reactions, fast strategies are linked with immediate gratification, disregard for future consequences, and opportunism, whereas slow strategies are associated with long-term planning and delaying gratification to increase future payoffs. Previous studies proposed that lower-socioeconomic status (SES) in early-life environments sensitizes people to adopt faster life-history strategies, whereas higher-SES early-life environments sensitize people to adopt slower life-history strategies (Miller et al., 2009). Their findings indicate that the expression of fast and slow strategies is especially likely to emerge in stressful situations, for instance, in situations of resource scarcity (Griskevicius et al,. 2013).

We focus on the joint impact of childhood socioeconomic background and current resource scarcity on conformity. In evolutionary literature, conformity is defined as a form of social learning (Boyd and Richerson 1985). According to that literature, individuals have two different ways to acquire information: Individual learning in which humans acquire information through experimentation and trial-and-error, and social learning which involves the acquisition of information by copying others. Individual learning is more costly and time consuming but it is in most cases more accurate and reliable. On the other hand, social learning is less costly but also less accurate and reliable (Boyd and Richerson 1985). Individuals use both types of learning interchangeably depending on which type of strategy is more suitable to the circumstances they live in.

Harsh and unpredictable environments are characterized by increased dangers and mortality. This makes the acquisition of information through individual learning difficult and in many cases dangerous. When information is highly costly to be acquired with individual learning, individuals turn to social learning to acquire information (Boyd and Richerson 1998; Morgan et al 2011). As a result, we expect individuals raised in harsh childhood environments to be sensitized to acquire information through social learning. On the other hand, in less harsh environments, risks and mortality are less salient. In such situations, individual learning can be an adaptively more efficient strategy as it is considered to be more accurate and

might therefore yield better results (Boyd and Richerson 1998; Morgan et al 2011). This can lead people living in those environments to acquire information mostly through individual learning; therefore we expect people raised in less harsh environments to have been sensitized to learn relatively more through individual experience. To summarize, we expect that people who grew up in low-SES backgrounds will be sensitized to use the opinion of others and thus resource scarcity cues will make them more conformist, whereas people coming from high-SES backgrounds will be sensitized to use their own information and resource scarcity cues will not have an impact on their tendencies to conform. We tested these predictions in three studies.

In study 1 participants were assigned to one of two conditions: resource scarcity were they read an article describing the highly uncertain economic climate or the control condition were they read an article describing a man searching for his father in a metro station. Childhood SES was assessed with three questions concerning the economic situation of participants' household in their childhood (Griskevicius et al. 2013). Conformity was assessed by giving a product description accompanied by user ratings (9.25 out of 11), and asking participants to rate the product (higher rates showed more conformity). Resource scarcity cues made participants from poor childhood backgrounds conform more (they rated the product significantly higher than in the control condition), whereas these cues did not influence high-SES people's tendencies to comply.

In the scarcity condition of study 2, participants had to list their monetary expenditures from the past 30 days, whereas in the control condition participants had to describe the weather (Zhou, Vohs and Baumeister 2009). We also tested our hypothesis for negative social influence (we gave part of the sample low products ratings: 2,58 out of 11). We again found that resource scarcity stimulated people from low SES backgrounds to confirm more (both when provided with high and low average product ratings), whereas it had no influence on people from high SES backgrounds.

Study three used the same resource scarcity manipulation but assessed conformity in a different way. Specifically, participants were asked whether they would endorse an online survey policy where respondents who do not pay proper attention to the instructions are not paid. They were informed that so far, there was a 70% compliance rate with the punishing policy. We used a different way to assess childhood SES (Hill et al. 2013). Resource scarcity again only stimulated conformity in people from low SES backgrounds but not in people from high SES backgrounds.

Our findings show that whether or not resource scarcity has an impact on people's responses to social influence depends on childhood background. We contribute to the literature by showing that the extend of conformism in some occasions depends on individual differences (and specifically on childhood SES).

Inking Immortality: Exploring the Relations Between (Tattooed) Bodies, Time, and the Permanence/Change Dialectic

Chloe Steadman, University of Manchester, UK
Emma Banister, University of Manchester, UK
Dominic Medway, Manchester Metropolitan University, UK

EXTENDED ABSTRACT

Introduction

Time and bodies are intertwined. Our everyday embodied lives are shaped by temporal frameworks, such as the modern idea of linear clock time (Adam 1995). We experience internal bodily rhythms like the beating heart (Birth 2012), and we carry time on our bodies when we wear wedding rings. The body's surface also captures multiple marks of time, including unintentional temporal indicators such as wrinkles, alongside intentional temporal inscriptions like tattoos (Velliquette, Murray, and Evers 2006). Due to this embodied and temporal existence we are ultimately beings-toward-death (Heidegger 1927/2010). Within many cultures it is understood that time flows forwards from birth to death, and thus that we have a finite lifespan. Throughout history persons have striven to transcend their temporal boundaries and attain permanence for the self/others through various means, such as via placing their faith in religious belief systems, maintaining healthy bodies, and creating symbolic legacies (Bauman 1992; Cave 2012). Yet, the links between bodies and time remain underexplored, particularly from a consumption perspective, as is human (im)mortality. We thus explore the following research questions within the context of tattoo consumption: First, does permanence still matter to people in a transient world? And second, how and why might people endeavour to attain a sense of permanence for themselves/others via tattooing the impermanent body?

Research Design

An ethnographic research design was employed. The first author conducted participant observation at three tattoo studios (*Alfie's Tattoos*; *North West Tattooing*; and *M1 Tattoos*); two tattoo conventions (*Manchester Tattoo Show*; *Liverpool Tattoo Convention*); and three museum/art exhibitions (*Body Worlds*, Amsterdam; *death: the human experience*, Bristol; *Time: Tattoo Art Today*, London). Multiple biographical/elicitation style interviews (Wengraf 2001) were also conducted with 18 tattoo consumers (Appendix 1). The first interview involved participants telling an uninterrupted story of their life followed by prompting for further narratives about their key life events. The second interview involved participants telling the story of their tattoos, with subsequent questions concerning tattooing the past, future tattoo plans, permanence, memory, and ageing. Interviews were audio-recorded and transcribed verbatim. Photographs of participants' tattoos were taken with their permission, and they chose their own pseudonyms. The first author also kept an ongoing tattoo consumption diary which thus incorporates an introspective element (Gould 2012).

Data was analysed/interpreted using a hermeneutic approach (Arnold and Fischer 1994). Each interview was read through and initial interpretations were noted. Next, each transcription was uploaded onto NVivo software and categorised into inductively generated themes (Braun and Clarke 2006) which were related to the cultural context, including cultural notions of time. Narrative analysis was also employed (Sparkes 1999), whereby key narrative features such as plot; sequence; characters; temporal modes; and key life events and turning points were identified within participants' narratives.

Fieldnotes were also analysed using a thematic approach and related to interview themes and the cultural context.

Key Findings

Participants often experienced their bodies as what we term *autobodyographies* (Appendix 2). Namely, supporting extant research (e.g. Shelton and Peters 2006; Velliquette et al. 2006), despite their fragmented lives they often used tattoos to create a sense of temporal linearity on their skin by threading together their past, present, and anticipated future. Their bodies narrated partial and fluid accounts of their biographies, and the dynamic contexts in which they are entangled. Participants were thus seemingly creating a personal *symbolic legacy* on their skin. The concept of a symbolic legacy stems from the Ancient Greeks, who held the dualistic belief that culture did not suffer the same decay as nature (Bauman 1992; Cave 2012). Hence, in contrast to the mortal body, the cultural realm is often considered as an enduring space in which to transcend one's temporal boundaries and attain immortality (*ibid*).

Likewise, participants frequently acquired memorial tattoos to create a symbolic legacy for *others* on their bodies following their physical deaths, and thus to transport that person through time into the future to engender continuing bonds (see Turley and O'Donohoe 2012). Given the transient body represents the locus of our physical mortality (Bauman 1992; Cave 2012), this creation of symbolic legacies for self/others on the skin appears rather paradoxical. However, in the backdrop of a seemingly 'accelerated' and ephemeral cultural world (Bauman 2000; Giddens 1999), perhaps the body provides people with an apparently more predictable, stable, and safer surface on which to attain a sense of permanence for self/others today. Indeed, akin to the practice of refreshing family heirlooms (Türe and Ger 2016), participants also engaged in ongoing tattoo maintenance and repair work (Graham and Thrift 2007), such as regularly moisturising their tattooed skin, to protect their tattoos from the ravages of time and preserve their permanence. This finding indicates the desirability of permanence for many of our participants.

Conclusions

Existing literature observes that we are living within an accelerated and transient world (Bauman 2000; Giddens 1999). It has been suggested that people continuously re/deconstruct multiple identities (Firat and Venkatesh 1995; Gergen 1991); persons partake in ephemeral consumer tribes (Cova and Cova 2001; Maffesoli 1996); and that we have increasingly transient relationships with our possessions in a globalised world (Bardhi, Eckhardt, and Arnould 2012; Figueiredo and Uncles 2015). However, our participants used tattoos to craft symbolic legacies for the self and others on their temporal bodies, and thus to create a sense of symbolic immortality. This paper, therefore, challenges this literature by indicating how permanence, durability, and a sense of temporal continuity remain important for persons living within a seemingly accelerated and transient world. It also contributes to the slowly growing, yet somewhat sparse, literature concerning bodies and time, in addition to death and consumption, within consumer research, thus responding to calls for a more embodied appreciation of time (Toyoki, Schwob, Hietanen, and Johnsen 2013). Future research could further investigate how multiple marks

of time intermingle on the body in narrating people's biographies by drawing on multiple contexts, for example anti-ageing surgeries and scarification. Moreover, future research could further explore death and consumption within diverse contexts, such as health crazes and religion, to importantly engender a more open discussion about this often sequestered feature of the human condition.

How Consumer Power Affects Recommendations in the Online Environment

Inbal Stockheim, Tel Aviv University, Israel
Shai Danziger, Tel Aviv University, Israel
Liat Levontin, Technion, Israel Institute of Technology, Israel

EXTENDED ABSTRACT

Online recommendations exert a strong influence on consumer choice (Chevalier and Mayzlin 2006). Most research on online recommendations has focused on how they affect receivers (Senecal and Nantel 2004). Less work has examined the factors that facilitate or deter consumers from generating recommendations (Berger 2014).

We propose that consumers' perceived power affects their proclivity to post online recommendations and influences recommendation content (e.g. instructions vs. opinions). Consumers who feel powerful are more likely to express their views freely compared to those who lack power (Anderson and Berdahl 2002). Accordingly, we hypothesize that those with high power will generate more online recommendations than those who lack power (**H1**).

Power can be associated with an influence over others (Lammers, Stoker, Rink and Galinsky 2016). Since powerlessness is aversive and, in contrast, high power promotes confidence, optimism and self-importance (Anderson and Galinsky 2006; Rucker, Dubois and Galinsky 2011), people with power strive to maintain their powerful states (Garbinsky, Klesse and Aaker 2014). In offline interactions, power can be identified through status and is relatively stable. In the online environment, consumers have less means to display power. Providing others with recommendations that include instructions is a form of acting directed at gaining influence. We therefore hypothesize that recommendations provided by those with high power will include more instructions to influence others, compared to recommendations provided by those with low power (**H2**). We further hypothesize that the need to influence others will mediate the effect of power on the likelihood to post online recommendations (**H3**). Finally, we predict, the potential influence of a recommendation will moderate the effect of power on the generation of online recommendations such that consumers with high power will generate more recommendations when those have a high potential for influence compared to when the potential for influence is low (**H4**).

We tested these hypotheses in four studies. Study 1 (N=180, M_{age}=23.08, 52% females) tested H1 and H2. Participants performed a power manipulation and two other tasks (Galinsky, Gruenfeld and Magee 2003). Then, participants rated the likelihood that they would post an online recommendation to future participants about the tasks they performed. Those willing to recommend, wrote their recommendations. As expected, participants primed with high power (68%; 65 out of 94) were more likely than those primed with low power (51%; 45 out of 86) to post recommendations (χ^2 (1,N = 180) = 5.75, p = .016). Next we analyzed recommendation content. Recommendations rated as instructions were dummy coded as 1 ("follow instructions!"), and recommendations rated as opinions (e.g. "fun game"), were dummy coded as 0. The recommendations of those primed with high power (vs. those with low power) were more likely to include an instruction as opposed to an expression of opinion (χ^2 (1, N = 110) = 4.98, p = .026).

Studies 2 and 3 tested our mediation hypothesis (H3). In study 2 (N= 146, M_{age} = 37.19, 55% females) we manipulated power by allocating participants to power roles (Anderson and Berdahl 2002). Participants then indicated the likelihood of posting an online recommendation about a restaurant experience. An ANOVA showed that, as expected, those in the high power role (M_{high}=3.78, SD=1.56) were more likely to post a recommendation than those in the low power role (M_{low}=3.17, SD=1.86; $F(1,145)$= 4.37, p=.038). The results of the mediation analysis (PROCESS, model 4) showed that both power (95% CI [.20, 1.06], B=.63, SE=.21, p=.004]) and need to influence (95% CI [.30, .72] B=.51, SE=.10, p=.000]) significantly affected the likelihood to generate online recommendations. Importantly, participants' need to influence mediated the effect of power on the likelihood to recommend (95% CI [.0.11, 0.63]).

Participants (N=70, M_{age}=31.69, 51.4% females), who hold high power positions (managers with over 10 employees, N = 32) or non-managerial positions (Control, N=38) participated in Study 3. Participants were asked whether they would post an online recommendation about an excellent hotel they had stayed at, on a site like TripAdvisor.com. As expected, participants' power position predicted the tendency to recommend (t(70)=2.20, p=.031). Participants' need to influence was measured using two items: "how important is it was for you to be recognized for you recommendation?" and "how important is it for you to receive as many likes as possible following your recommendation" anchored on a 1-7 scale (α=.88). Mediation analysis (PROCESS, model 4) showed that need to influence mediated the effect of power position on the likelihood to recommend (95% CI[.03,.79]).

Study 4 (N=135, M_{age}=25.54, 68% females) tested our moderation hypothesis (H4). We manipulated power using a modified dictator game and operationalized the potential to influence by either making participants feel their recommendation is the only rating of the game available (high potential to influence) or that many others have already posted their rating of the game (low potential to influence). An ANOVA revealed no main effects, and as expected, a significant interaction between power and the potential to influence ($F(1, 134)$=4.74, p =.031). Participants with high power were more likely to post recommendations when their potential to influence was high (M=3.38, SD=.27) than when it was low (M=2.56, SD=.26, $F(1,134)$= 4.77, p =.031). Among participants with low power, there was no significant difference between potential to influence conditions.

Our research offers both theoretical and practical contributions. First, despite the abundance of research on power, little is known about its consequences in the online environment. Second, the power literature has focused mainly on its negative consequences (Zimbardo 1973). We show how power can be harnessed to help others. Last, by demonstrating that consumers' power can boost the quantity, and influence the content of online recommendations, we offer marketers a practical tool to promote their offering.

When Bigger Isn't Better: How Perceptions of Market Dominance Interact with Existing Brand Images to Impact Brand Favorability

Jennifer L. Stoner, University of Minnesota, USA
Carlos J. Torelli, University of Minnesota, USA

EXTENDED ABSTRACT

Brands often communicate their dominance through slogans and advertisements. Although business publications often refer to dominant brands as powerful brands, research has not explicitly acknowledged that consumers might perceive power in market dominant brands. This research directly assesses this possibility and demonstrates that communicating dominance can have unintended consequences for consumers' reactions to these communication messages.

Research by Fragale, Overbeck, and Neale (2011) demonstrate that powerful people are perceived to lack warmth. Powerful people are known to behave in ways inconsistent with what is expected from a warm person (Galinsky et al. 2006; Rucker, Dubois, and Galinsky 2011). Therefore, we propose and find in four studies that a message communicating market dominance which is seen as an embodiment of power dilutes the image of a warm brand and hence are negatively evaluated by consumers.

Study 1 investigated our hypothesis using a fictitious soap brand. Participants viewed a description of the brand that positioned it as having a warm brand image. After reading the description, participants viewed an advertisement for the brand that either communicated the brand's dominance over competitors or one that communicated an equal amount of competence (but not dominance). Participants then completed 4-items measuring their attitudes towards the brand. An ANOVA showed that participants evaluated less favorably the warm brand promoted with a market dominant (vs. competent though not market dominant) message ($M = 3.89$ vs. 4.41, $F(1, 79) = 4.14$, $p < .05$).

Study 2 replicated this effect using a stricter version of the control advertisement, one that communicated only a brand logo and product image. This study also used fictitious brands from three different product categories and explored the mediating role of dilution of the brand image. After viewing a warm brand description, participants viewed either a market dominant or control ad. They completed the same favorability measures from Study 1 as well as 3 items of brands image warmth. An ANOVA revealed a main effect of type of advertisement ($F(1, 164) = 6.23$, $p < .05$) with the market dominant (vs. control) message receiving less favorable brand evaluations ($M = 4.27$ vs. 4.77). This effect was significantly mediated by the warmth of the brand's image (95% CI of the indirect effect = -64 to -.20).

Given that market leadership has its benefits (Kamins, Alpert, and Perner 2003) in Study 3 explores a way for marketers of warm brands to communicate market leadership without the negative effect of market dominance. By framing the brand's market dominance as a descriptive norm (e.g. "More people buy Brand X"), marketers can avoid the power associations of a market dominant message. Study 3 used a real brand with a warm image, *Johnson's* baby shampoo. Participants viewed an ad that either communicated either market dominance or descriptive buying norms. They then completed the favorability and brand warmth measures. An ANOVA revealed that participants liked the brand less after viewing the advertisement communicating the brand's dominance over the competition ($M = 5.00$ vs. 5.66, $F(1, 71) = 4.68$, $p < .05$). Furthermore, we find that this effect was mediated by perceptions of the brand's warmth (95% CI of the indirect effect = .01 to 1.06).

Study 4 explored the boundary condition of category warmth. Research by LaBoeuf and Simmons (2010) suggests that attributes shared by a product category allow brands to differentiate on conflicting attributes. We propose that for brands associated with a high-warmth category, advertisements communicating a brand's dominance do not trigger negative consumer attitudes. This study also demonstrated that the negative impact of market dominance occurs only for warm brands and not non-warm brands. The experiment was a 3 (brand: warm brand in warm-neutral category/warm brand in warm category/non-warm brand in warm-neutral category) × 2 (ad: market dominant/descriptive norms) between subjects design. Participants viewed a fictitious soap brand description for the warm-neutral category and a fictitious greeting card brand for the warm category. Participants then viewed either a market dominant or descriptive norms advertisement and completed ratings of favorability. An ANOVA revealed a significant brand × ad interaction, ($F(2, 115) = 3.10$, $p < .05$). Planned contrasts revealed that the dominant (vs. descriptive norms) ad triggered less favorable brand evaluations for the warm brand in the warm-neutral soap category ($M = 4.37$ vs. 5.01, $F(2, 115) = 2.72$, $p < .05$, one-tailed). There was no difference in evaluations of the warm brand in the warm category ($M = 3.93$ vs. 3.46, $F(2, 115) = 1.65$, ns) nor the non-warm brand in the warm-neutral category ($M = 4.51$ vs. 4.11, $F(2, 115) = 1.37$, ns).

The final study replicates the findings of Study 4 by again showing that the negative impact of market dominance occurs only for warm brands and not for non-warm brands. This study used a warm rice brand and ads from Study 2 but also included a non-warm rice brand. Additionally, we theorize that the incongruity between warmth and dominance will be weakened (heightened) for participants that endorse values of self-enhancement less (more) than self-transcendence. After completing brand favorability items, participants completed measures of their endorsement of these values (Schwartz et al. 2001). A score was computed for each participant's endorsement of self-transcendence values relative to self-enhancement values. An ANOVA revealed a significant 3-way interaction ($F(1, 123) = 4.32$, $p < .05$). Consistent with Study 4, participants at the mean level of self-transcendence importance evaluated the warm brand less favorably when viewing the market dominant (vs. control) advertisement ($M = 4.50$ vs. 5.17, $F(1,123) = 6.50$, $p < .05$). Participants had equally favorable reactions towards the non-warm brand when viewing either ad ($M = 4.50$ vs. 4.39, $F(1,123) = 0.20$, ns). Spotlight analysis showed that for participants valuing self-enhancement more than self-transcendence, favorability for the warm brand was lower for those viewing the market dominant (vs. control) ad ($M = 5.38$ and 3.83, $F(1, 123) = 16.13$, $p < .001$). However, this difference disappeared for those valuing self-transcendence more than self-enhancement ($M = 5.17$ and 4.96, $F(1, 123) = 0.21$, ns).

EXTENDED ABSTRACT

Miserable products are used to "wallow in misery" (Pollack 2014). Although counter-hedonic consumption exists, it has been relatively neglected by research. When and why do people choose miserable products?

We define wallowing as the perpetuation of negative self-views that can occur after threatening experiences. An example of wallowing would be engaging in miserable activities (eating disgusting food, staying at home) instead of uplifting ones (eating nice food, meeting friends) after a romantic breakup. Most existing theories would predict that threats cause self-gifting to mollify the sting of the threat (Mick and DeMoss 1991) or engage in compensatory consumption to bolster the threatened part of the self (Gao et al. 2009; Rook 1987). Why would consumption be used to cultivate negative self-views rather than to counteract them?

This research tested whether wallowing is a form of self-verification. Self-verification describes the need to be understood and to act in accordance with one's firmly held self-views (Sedikides and Strube 1997). Self-verifying actions align self-perceptions and environment to create predictability and facilitate relationships. Research demonstrated that engrained negative self-views trigger verification rather than enhancement: People who thought poorly of themselves preferred condescending interaction partners (Swann et al. 1992) and roommates that liked them less (Swann and Pelham 2002).

This project proposes that consumers with low self-esteem use miserable products like disgusting food, or low-tier brands, to self-verify. Low self-esteem consumers perceive miserable products as self-congruent and therefore appealing. We predict that negative self-verification is chronic and persists after threats because failures and setbacks reaffirm engrained negative self-conceptions (Dogson and Wood 1998). Success experiences urge low self-esteem people to update their self-views which should temporarily attenuate the desire for miserable products. We further expect that low self-esteem consumer's choosing of miserable products is explained by undeservingness – convictions of being unworthy of quality products (Cavanaugh 2014).

STUDY 1A

Study 1a examined whether lower self-esteem is positively associated with choosing miserable products. Participants completed a measure of trait self-esteem (Rosenberg 1989) and then chose among six food product pairs: one miserable and one non-miserable alternative (e.g., canned pulled pork in water vs. pulled pork from the meat counter). Next, we measured our mediator deservingness (Cavanaugh 2014) and trait frugality (Kasser 2005) to exclude money-saving goals as an alternative explanation. A linear regression indicated that self-esteem was negatively associated with choosing miserable products ($\beta = -.274$, $p = .04$). A mediation analysis revealed a significant indirect relationship between self-esteem and product preferences through deservingness (95% LLCI = .0324; 95% ULCI = .2722). Frugality did not mediate.

STUDY 1B

Study 1b tested if low self-esteem consumers actively seek out miserable products using a within-subjects design. We selected damaged and undamaged versions of eight different food products (e.g., a brown vs. a yellow banana). Participants completed the Rosenberg self-esteem scale and then rated eight unique food products (four damaged and four non-damaged) one at a time. A mixed linear regression model revealed the predicted interaction between self-esteem and quality on choice; $\beta = -.395$, $p < .001$. Consumers' self-esteem was negatively associated with choosing undamaged products ($\beta = .192$, $p = .04$) and positively associated with choosing damaged products ($\beta = -.203$, $p = .06$).

STUDY 2

Study 2 tested whether low self-esteem consumers' desire for miserable products is chronic. Self-esteem was measured before or after product choice in a 2X2 between-subjects design. The product choice measure contained six alcohol product pairs, one miserable and one non-miserable (e.g., $6 plastic bottle vs. $25 glass bottle vodka). Lastly, we measured deservingness, frugality, and self-punishment motivations. We regressed self-esteem, the order dummy, and their interaction on alcohol choice. As expected, the interaction was non-significant ($p = .99$). Instead, low self-esteem consumers chose more miserable alcohol regardless of whether they completed the self-esteem scale before or after product choice ($\beta = -.290$, $p = .03$). Self-esteem was positively related to frugality ($p = .04$) and therefore frugality cannot explain the aforementioned effect. A parallel mediation model including self-punishment and deservingness indicated a significant indirect effect through deservingness but not self-punishment (95%LLCI = -.4893; 95%ULCI = -.1853).

STUDY 3

Study 3 tested whether positive feedback that counteracts negative self-views can attenuate low self-esteem consumers' desire for miserable products. Also, we examined whether low self-esteem consumers verify negative self-views similarly on a chronic basis and after threat. We manipulated task feedback (failure vs. success vs. no feedback) and measured self-esteem in a 3X2 between-subjects design. Participants completed the self-esteem scale. Next, they solved items of the Remote Association Test after which they receive success, failure, or no feedback. Then, participants chose between two types of popcorn for a film-clip watching study: Fresh popcorn and somewhat stale popcorn. On sliders from 0 to 100, participants indicated how much they would like to eat each type. They believed to receive whichever popcorn they rated highest.

We subtracted stale- from fresh-popcorn-liking. Higher values reflected greater preference for fresh over stale popcorn. Next, we regressed this measure on experimental condition (dummy coded to compare the success to each of the other two conditions), self-esteem, and all interactions. As expected, two significant interactions between self-esteem and failure vs. success and control vs. success emerged. Simple effects for participants high and low in self-esteem (1SD above and below the mean) revealed that low self-esteem participants liked stale popcorn more after failure than after success feedback ($\beta = -.331$, $p = .02$), and after no feedback than after success feedback ($\beta = -.289$, $p = .02$). Popcorn preferences of high self-esteem participants did not differ between conditions (all $p > .08$).

CONCLUSION

In summary, four studies demonstrated "wallowing in misery" - paradoxical behavior where low self-esteem people pursue actions that cultivate negative self-views. Low self-esteem consumers' chronic and threat-induced negative self-views led them to choose miserable food. In support of theorizing, these consumers' sense of un-deservingness explained their choices while alternative accounts like frugality, and self-punishment were ruled out. We detailed when consumers verify ("wallow") and when they self-enhance in the wake of threat. This work adds to emerging knowledge on consumers' pursuit of counter-hedonic experiences (Andrade and Cohen 2007).

The Sociocultural Dynamics of Consumer Entanglement

Maribel Suarez, Federal University of Rio de Janeiro, Brazil
André de Castilho Costa Pinto, Federal University of Rio de Janeiro, Brazil

EXTENDED ABSTRACT

Okay, you may not agree with Facebook, but everyone is on Facebook: straight, gay, black, white, Jewish, Palestinian, socialist, capitalist. If Karl Marx were alive today he would certainly be on Facebook, because you have to propagate your ideas. I think nobody lives without Facebook today. Especially now, that I will start to work. I have to be back on social networks. Companies always ask for your social network profile. I started to think that recruiters would consider it strange that I don't have a social media network. Until today I think, I'm on Facebook, but I do not want it. But I get it because if I deactivate it, I lose contact with people.
(Jane, 24 years, student)

Certain consumption patterns remain in consumers' lives grudgingly, perpetuating their presence even in the cases where consumers want to move away from these patterns. Some consumption entangles and, in extreme cases, entraps consumers. As in the example above, consumer entanglement occurs when a particular consumption pattern is difficult to suppress or escape when so doing constrains the consumer's modes of living, including his or her social relations and other types of consumption. The consumer entanglement phenomenon arises when consumption articulates dependence and dependency relationships, creating benefits and value, but also constraining and limiting.

Loyalty studies attempt to capture the nature and stability of the connections formed between the consumer and previous consumption. Although suggesting different dimensions to the loyalty construct, research focusing on attitudinal and affective aspects has the implicit assumption that repeated consumption is mainly volitional and based on positive commitment (Chaudhuri and Hoolbrok, 2001; Sirdeshmukh et al, 2002; Oliver, 1999). Other studies delineate loyalty as repetitive purchase highlighting economic and cognitive aspects that prevent switching behavior. Lock-in theories provide evidence that consumers tend to decrease their propensity to search for alternatives and give up previous choices after an initial investment – whether economic (Zauberman, 2003) or an investment in related skills acquisition (Johnson et al. 2003; Murray and Haubl 2007).

These explanations, however, do not fully explain consumer entanglement phenomenon. Why don't consumers like Jane abandon their previous consumption when they would like to or could so? What explains consumption continuation in the absence of direct economic, physiological, or cognitive barriers for switching?

The goal of this study is to complement economic and cognitive explanations by examining sociocultural underpinnings of continued patronage. This research investigates what we refer as entanglement dynamics - the sociocultural mechanisms that entangle and entrap consumers in their previous consumption.

The limiting and constraining nature of entanglement is best revealed by consumers' efforts to move away from previous consumption. Based on this premise, we used a multimethod approach incorporating long interviews (McCracken 1988) and observational Netnography (Kozinets, 2002) to investigate consumers' efforts to quit Facebook. Besides Facebook's relevance in contemporary society, it presents as a rich context to expand our understanding about consumers' lock-in since the app and alternative social media offers are both costless and intuitive to use. Generally, users maintain profiles on various social networks. Accordingly, learning how to use an alternative app is not a barrier to abandonment.

Instead of dyadic relations between consumers and consumption objects, this paper theorizes continued patronage as complex assemblages, resulting from the dialectic of dependence and dependency between consumers and things (Hodder, 2012). Dependence exists because consumers rely on things to live. Dependency, in turn, arises when a specific consumption becomes a key part on existing assemblage and make a change at this part has important impacts on its stability. Future consumption is limited and constrained by these previous relations, perpetuating certain patterns. The dependence and dependency dialectics frame loyalty as relational and contextual, with overlapping alliances including other people, things and different consumption practices.

Entanglement involves weblike conditions that arise when consumer cannot manage without a specific consumption We identify four entanglement dynamics: 1) *Centrality* occurs when consumption attains a pivotal role in a crucial domain of consumers' lives; 2) *Pervasiveness* occurs when certain consumption is pervasive and integrative, permeating different domains of consumer's lives. 3) *Others interdependencies* occur when giving up certain consumption significantly affects consumers' ability to relate to other people; and 4) *Things interdependencies* occur when giving up certain consumption significantly affects consumer's ability to relate to other products and perform other consumption activities.

EXTENDED ABSTRACT

Imagine you want a new T.V. As you point out options that you like to a friend, your friend comments that it's interesting that all the T.V.s you are considering show the price on the right side of the T.V. This research examines how price location impacts price perception and product evaluations, as moderated by engagement.

A survey of 727 prices for six different retailers show that electronics retailers, which tend to offer more engaging products, price information was on the right ($p < .001$). For discount retailers, which tend to offer less engaging products, the price information was shown more on the left ($p < .001$).

STUDY 1: VISUAL FIELD EFFECTS IN THE MARKETPLACE

Pretest

Consistent with our predictions, participants showed greater purchase intention for the product, when the product's price was in the right visual field compared to the left ($p < .05$).

Method

The study was a single three-level factor (visual field location: left, right, control) between design. We featured a promotion for a product (i.e., Arizona iced tea) by posting a large sign on the front of a product cooler. To ensure realism, the price on the promotion represented a discounted price ($.89; regular price $.99). During the first promotional week the price was shown on the right side of the sign. In the second promotional week, the price was shown on the left side of the sign.

Results and Discussion

Sales. To assess the effect of visual field location on consumer response, we examined the number of units of the target product that were sold on average in each of the two-hour intervals. While, a price featured in the left visual field led to a non-significant increase in sales ($p > .22$), a price featured in the right visual field led to significantly more sales ($p < .05$).

STUDY 2: EVIDENCE OF VISUAL PRICE DOMINANCE

Method

Sixty-six right-handed students participated in a 2 (engagement: low, high) x 2 (visual field location: left, right) between-subjects design. The level of engagement was manipulated using scenarios adapted from Howard and Kerin (2006) and Suri and colleagues (2012). Half of the participants saw the description of the television and its price in the left visual field while the other half saw the same information in the right visual field. Participants were then asked to first recall the price of the television and recognize the slogan. Response times were measured using DirectRT software.

Results and Discussion

Response latencies. We examined the effect of visual field location and engagement on participant response time using ANOVA. As expected, under low engagement, participants responded faster when the price was located in the left visual field ($p < .01$). Further, under high engagement, participants responded faster when the price was located in the right visual field ($p < .05$).

STUDY 3: HOW PRICE LOCATION AND ENGAGEMENT ACTIVATE THE BRAIN

Method

Ten right-handed people participated in a 2 (engagement: low, high) x 2 (visual field location: left, right) mixed design.

Procedure. Participants were told that as part of a marketing study they would see six prices in a row on the screen in front of them and be asked to remember the location of one of the six prices shown. To assess the relative level of activation in the left versus right hemisphere during the task, we measured the blood flow in the prefrontal cortex at 16 different points across the participant's forehead. To examine asymmetric activation in the prefrontal cortex we used functional near-infrared spectroscopy (fNIR; Ayaz et al., 2012).

Results and Discussion

Location recall. In study 3 we expected that during low engagement (first five trials) we would see a leftward bias in recall of a price's location compared to high engagement (last five trials). Mouse clicks for each trial were coded as to the left (1) or to the right (0) of the actual price location (no participant selected precisely the original location of the price). No significant main effects were observed. The clicks were analyzed via a 2 (location of click: left, right) x 2 (trial timing: first five, last five) within-subjects design. A significant interaction of direction of clicks (left/right) and trial timing (first/last) was observed ($p < .05$). As expected participants showed a leftward bias in recall of the price location under low engagement (first five trials) but not high engagement (last five trials).

Hemispheric activation. As participants grow more engaged in the task activation of the left prefrontal cortex associated with such high engagement will increase. Supporting our prediction, greater oxygenated-hemoglobin concentration changes were observed in the anterior left dorsolateral prefrontal cortex (DLPFC) ($p < .01$).

STUDY 4: VISUAL FIELD EFFECTS ON EVALUATIONS

Method

One hundred five right-handed students participated in a 2 (engagement: low, high) x 2 (visual field location: left, right) between-subjects design. Half of the participants saw this information with the product's price on the left while the other half saw this information with the product's price on the right.

Results and Discussion

Perceived value. As we predicted, under low engagement, consumers viewed the product to offer higher value (Grewal, Monroe, and Krishnan 1998) when its price was located in the right visual field (p < .05), and under high engagement, consumers viewed that the product offered higher value when its price was located in the left visual field (p < .05).

Monetary sacrifice. As expected, under high engagement, consumers perceived lower monetary sacrifice when the price appeared in the left visual field (p < .01).

Using PROCESS Model 8 we show that moderated mediation indicates that the effects of price location were mediated by sacrifice perceptions in the high engagement condition (with a 95% confidence interval excluding zero: = -1.29 to -1.7) but not in low engagement condition (the 95% confidence interval included zero: -.28 to .58).

The Blender Effect:
Physical Food State Influences Consumers' Perceptions and Consumption

Courtney Szocs, Portland State University, USA
Sarah Lefebvre, Universy of Central Florida, USA

EXTENDED ABSTRACT

It is increasingly common to find the same food available in multiple physical states (i.e., solid, liquid) including the raw (i.e., non-mechanically altered) physical state as well as other physical states that represent different degrees of processing (i.e., mechanical alteration). For instance, at a grocery store a consumer might find apples in their raw physical state as a solid (i.e., whole fruit), in a processed physical state as a semi-solid (i.e., applesauce), and in a processed physical state as a liquid (i.e., apple juice). Additionally, companies often place images of foods on packages, and the foods in these images can be in different physical states (e.g., an orange versus a glass of orange juice). Sometimes changing the physical state of a food involves adding ingredients. In this research, we hold the ingredients constant. We ask: would altering the physical state of a food product, a food pictured on a package, or a food on display influence consumers' product perceptions and consumption decisions?

We build on research which shows that consumers mentally categorize foods as healthy or unhealthy (Chernev 2011), and these categories have a graded structure (Barsalou 1983; 1985) so that foods that are more representative of the category would be perceived as healthier than foods that are less representative of the category. We link this work related to categorization with work in the domain of non-food products, which shows that physical product differences influence categorization (Trudel and Argo 2013). We predict that a blender effect will occur such that altering the physical state of a food will influence how representative the food is of the broader evaluative category (healthy or unhealthy) and ultimately healthiness perceptions.

We demonstrate the blender effect in four experimental studies. First, in Study 1A we have participants view equal volumes of food in a raw/solid state (i.e., an apple), a processed/solid state (i.e., apple slices), or a processed/semi-solid (i.e., apple sauce). We show that individuals perceive the food as healthier in the raw physical state (vs. either of the processed states). We also show that this blender effect is mediated by category representativeness. Then, in Study 1B we rule out an alternative explanation related to healthiness perceptions being tied to a specific physical state.

In Study 2 we vary the physical state of the food displayed on a package (rather than the state of the food itself) and examine healthiness perceptions. In addition, we examine whether making the ingredients in the food salient will attenuate the blender effect. That is, we vary both the physical state of the food displayed on the package as well as the ingredient salience. We have participants view a carton of apple juice displaying either an image of apples or an image of a glass of juice. In the ingredient salient conditions, participants are reminded that the apple juice contained 100% juice. No such reminder was given in the ingredient not salient conditions. The results showed that when the ingredients were not made salient, individuals perceived the apple juice as healthier when the carton displayed an image of the food in a raw (vs. processed) physical state. However, when the ingredients in the apple juice were made salient there was no difference in healthiness perceptions based on the physical state of the food displayed on the package.

In Study 3 we examine the influence of the blender effect on consumption volume. We predict that because individuals perceive foods in less processed physical states as healthier, they should consume a greater volume of the food when the ingredients are displayed in a less (vs. more) processed physical state. Additionally, we examine whether priming individuals to mindfully evaluate the healthiness of the food before consumption would attenuate the effects of physical food state on consumption. Study 3 had a 2 (physical food state: raw vs. processed) x 2 (mindful healthiness evaluation: absent vs. present) between subject design. Participants were shown the ingredients in a new juice smoothie either in the raw/unprocessed physical state or in a processed physical state. Then, they were allowed to consume as much of a sample of the juice as they wanted. The results showed that, as predicted, individuals consumed a greater volume of the juice when the ingredients were displayed in the raw (vs. a processed) physical state. However, mindful healthiness evaluations did not moderate this effect.

The results of our studies demonstrate a blender effect whereby individuals perceive foods as healthier when the foods are displayed in a raw or less processed physical state (vs. a more processed) physical state. This blender effect is driven by perceived category representativeness with foods in their raw state being perceived as more representative of the broader evaluative category (healthy or unhealthy), and is attenuated when the ingredients are made salient.

The findings of our studies have implications for theory and practice. From a theoretical standpoint this is possibly the first research to examine the effects of physical food state on consumers' healthiness perceptions as well as the first to show that the physical state of the food depicted on a package can influence consumers' healthiness perceptions. From a practical standpoint, our findings suggest that managers should take care when deciding the physical state of the food they display on packages, menus etc. as it can have unintended consequences in terms of influencing consumer perceptions.

The Upside of Randomization:
The Influence of Uncategorized Product Display on Consumers' Shopping Evaluation

Tao Tao, The Chinese University of Hong Kong, China
Leilei Gao, The Chinese University of Hong Kong, China

EXTENDED ABSTRACT

Although organizing products by category is a common marketing practice and has been shown to increase consumer satisfaction (Mogilner, Rudnick, and Iyengar 2008), presenting products in a randomly arranged set (e.g. flea market and store sales) may also lead to pleasant shopping experiences. The present research demonstrates the positive influence of random product presentation on shopping evaluations.

In this research, we define a categorized set as a group of products that are sorted according to product type. A randomized set is a set of products displayed randomly with no a priori categorization. Accordingly to research on environmental psychology, environmental complexity and unpredictability signals greater amount of information to be processed, which induces feelings of arousal (Berlyne 1971; Mehrabian and Russell 1974). Hence, we propose that consumers would experience greater arousal when browsing a randomized product set than a categorized set. In addition, research has shown that arousal can serve as a magnifier of emotions and evaluations (Reisenzein 1983; Russell and Mehrabian 1976). Because shopping is generally considered a positive activity (Bloch and Richins 1983; Holbrook and Hirschman 1982), we propose that greater arousal elicited by a randomized set will intensify the pleasantness associated with the shopping experience and subsequently result in greater choice satisfaction and more enjoyable shopping experiences. We refer to this effect as the positive product randomization effect.

This randomization effect, however, hinges on two conditions. First, a complex environment could elicit arousal because it signals increased amount of information that one needs to process (Berlyne 1960). Therefore, when individuals have a motivation to screen off unnecessary information and only process important or relevant information, they are less likely to feel aroused even in a complex environment (Mehrabian 1977). We thus propose that when consumers have a priori shopping goal, motivating them to search and selectively focus on a subset of products rather than exploring the choice set, they are less likely to be aroused by a randomized set. In addition, since categorization facilitates product searching and enhance perceived variety when consumers engage in goal-oriented shopping (Hoch et al. 1999; Mogilner et al. 2008), we should observe a positive categorization effect in this condition. The second prerequisite condition is that shopping should be considered as a pleasant experience. If shopping is considered unpleasant, such as when the product options are unattractive, the polarizing effect of arousal (Reisenzein 1983) is expected to result in more negative affective reactions, and subsequently lead to more negative shopping evaluations.

Experiment 1 examined the randomization effect and obtained evidence for arousal being the mediator. Participants firstly browse 64 stationery products arranged in four columns and 16 rows. The products were either sorted into 16 sub-categories or displayed randomly. After browsing, participants rated their feelings of arousal and pleasure. After that, participants saw the same product set again and indicated the products they would like to buy. Then, they rated choice satisfaction and shopping experience. Independent-samples t-tests showed that participants reported greater choice satisfaction when the set was randomized than categorized (6.81 vs. 5.70; $t(69) = 2.61$, $p < .05$). Similar results were detected on shopping experience (6.53 vs. 5.66; $t(69) = 2.09$, $p < .05$), arousal (5.50 vs. 4.86; $t(69)$

$= 2.06$, $p < .05$) and pleasure (6.61 vs. 5.86; $t(69) = 2.60$, $p < .05$). Mediation analyses revealed that arousal mediates these randomization effects.

Using 54 different chocolates and 64 stationery products, respectively, Experiment 2 and 3 manipulated consumers' ideal point availability and task-oriented shopping motivation to demonstrate that when consumers had target product(s) to purchase, relative to a categorized set, a randomized set reversely decreased choice satisfaction. Experiment 3 further demonstrated that arousal and perceived variety mediated the randomization and categorization effect, respectively.

Experiment 4 then tested that the valence of the stimuli moderated the valence of the impacts of elicited arousal on shopping evaluations. An animal donation scenario was employed and the stimuli valence was manipulated the by using either 40 good-looking endangered animals or 40 creepy-looking ones. ANOVA analysis of stimuli valence and set organization on arousal feeling revealed the main effect of organization ($M_{randomized} = 6.22$ vs. $M_{categorized} = 5.65$; $F(1, 139) = 7.43$, $p < .01$), which did not depend on stimuli valence. However, the valence of the influences of organization on choice satisfaction depends on the stimuli's valence ($F(1, 139) = 7.77$, $p < .01$). Specifically, for attractive animals, participants reported greater satisfaction when the set was randomized than when it was categorized (7.31 vs. 6.45; $F(1, 139) = 4.90$, $p < .05$); the effect was reversed for aversive animals (4.16 vs. 4.84; $F(1, 139) = 2.99$, $p = .09$).

Lastly, based on research findings that visual information is more information-rich and verbal information is less complex (Townsend & Kahn 2014), we propose that the randomization effect would be less likely to occur when the products were only presented verbally. Experiment 5 tested this proposition by employing 48 magazines which are presented either verbally in text or visually in pictures. The results showed that the randomized set elicited arousal, and thus enhance the pleasurable feelings, choice and experience evaluations only in the visual present condition rather than in the verbal condition. Further, in the visual present condition, arousal feeling mediates the positive influences of randomization on choice evaluation and shopping experience.

With five experiments, this research demonstrates the influence of product randomization on arousal feelings and its positive influences on shopping evaluations. Our findings enrich the extant knowledge about the impacts of product display method (Diehl et al. 2015; Kahn and Wansink 2004; Mogilner et al. 2008) on shopping evaluations. Our findings also add to the growing body of literature examining the influence of shopping environment on consumers' evaluative judgments (Kaltcheva and Weitz 2006; Milliman 1986; Muro and Murray 2012; Spangenberg et al. 1996). The findings of this study may have useful marketing implications for store arrangements.

Topic Controversy and WOM: The Effect of Opinion Extremeness on Sharing

Vito Tassiello, LUISS, Italy

Cesare Amatulli, University of Bari, Italy
Michele Costabile, LUISS, Italy

EXTENDED ABSTRACT

Due to its profound impact on consumers' daily purchasing decisions, word-of-mouth (hereafter WOM) is considered among the most effective marketing communication tools (Arndt 1967; Berger 2014; De Angelis et al. 2012). In particular, proliferation of websites and social media platforms has also increased the pervasiveness of peer-to-peer communications, thus stimulating the interest of marketing scholars in investigating electronic word-of-mouth (hereafter eWOM; Godes & Mayzlin, 2004; Hennig-Thurau et al., 2004; King, Racherla, & Bush, 2014; Sweeney, Soutar, & Mazzarol, 2014), that is any positive or negative statement made by consumers about a product or a company, and available to a multitude of people and institutions via the Internet (Hennig-Thurau et al. 2004). Another phenomenon, strongly characterizing current society, is represented by controversial topics, that is topics on which people tend polarizing opinions (Chen & Berger, 2013). However, to the best of our knowledge, no research has investigated the relationship between WOM and controversial topics, except for a study by Chen and Berger (2013) that shows a curvilinear relationship between the degree of a topic's controversy and WOM tendency to engage in conversations about that topic.

The present research is aimed at investigating how people share, via the Internet, information about topics that are controversial in nature. Our objective is to shed light on what drives people's decision to share their opinions about controversial topics through different online platforms. More specifically, and differently from previous studies, the present research investigates how eWOM is affected by the extremeness of the opinion one holds about a controversial topic, that is how extremeness influences the online platform consumers prefer when sharing information about high controversial topics.

While people might be naturally led to develop extreme opinions about controversial topics, they might not be as much naturally led to share such extreme opinions with others. Indeed, sharing extreme opinions might be more likely to expose the sharer to the risk of social rejection than sharing more moderate opinions (Buss 1990; Hogg, Turner & Davidson 1990). Thus, as a consequence, we argue that individuals' likelihood to share their extreme opinions on controversial topics depends on how severe they perceive the risk to be negatively judged by other people. One factor that might make social disapproval perceived as more or less severe by the sharer of an extreme opinion is the channel he/she uses to communicate his/her opinion. Indeed, we expect that people are likely to share more versus less extreme opinions about controversial topics when sharing via email, whereas we expect such an effect to be less likely to manifest when sharing via post on social network pages. We argue this might happen because sharing an extreme opinion about a relatively highly controversial topic via post on one's social network page might carry a higher risk of social disapproval and rejection for the sharer than sharing the same opinion via email. Our hypotheses are empirically supported by three experiments.

Experiment 1 had the goal to test if individuals show a general tendency to share extreme opinions about high controversial topics. Hundred twenty respondents were recruited online were randomly assigned to one of two conditions. In the "high controversy" condition, participants read a scenario about a hypothetical announce-

ment appeared at a bakery store reporting that the store neglects to prepare cakes for homosexuals. In the "low controversy" condition, the announcement participants read reported that consumers had to book their wedding cake with no less than thirty days before the wedding (M_{high} = 6.35, SD = 0.92 vs. M_{low} = 3.10, SD = 1.60, $F(1, 119)$ = 196.05, p<.001). WOM likelihood served as dependent variable, level of controversy as independent variable and the opinion extremeness as mediator. Using the PROCESS SPSS macro (Hayes, 2013; model 4), results showed that level of controversy positively affects opinion extremeness (b=1.86; t=5.62; p<.001) with the marginal effect of level of controversy on WOM likelihood (b=.67, t=1.91, p=.06). The indirect effect of level of controversy on WOM likelihood was significant (b=.69, 95% C.I. = .31, 1.18).

Experiment 2 aimed at introducing a boundary condition, whereby we expected to find an interaction between opinion extremeness and type of platform. Hundred one respondents have been randomly assigned to either a condition in which they were told they could access their email account or their Facebook page to share their opinion. Before being exposed to the sharing platform manipulation, respondents read an advertisement about the effectiveness of slimming pills, and were asked to rate the level of controversy of it ($M_{controversy}$ = 5.19, SD = 1.42). When regressing WOM likelihood on both opinion extremeness and sharing platform results showed that both factors had a significant and positive effect on WOM, and their interaction was significant (b=-.71, t=-2.83, p<.01). Conditional effects of opinion extremeness on WOM likelihood revealed that when prompting respondents to use email for sharing, the effect of opinion extremeness was significant (b=.62, 95% C.I. =.22, 1.02) respect the other condition (b=-.09, 95% C.I. =-.39, .21).

Experiment 3 aimed at providing convergence with Experiment 2. With the same setting of experiment 2, 119 respondents were randomly assigning to one of two conditions (email vs social networks). We included level of controversy (measured as a single item) as an independent variable in the regression, in addition to sharing platform (manipulated) and opinion extremeness (measured), with WOM likelihood as dependent variable. Procedure (Hayes, 2013) proved the existence of a significant 3-way interaction (b=-.37, t=2.42, p=.02). Analysis of the conditional effects of the two-way interaction between level of controversy and opinion extremeness on WOM likelihood revealed that individuals were more likely to share their highly extreme opinion about a topic perceived to be highly controversial via email (b=.28, 95% C.I. =.02, .55), but not via social networks (b=-.09, 95% C.I. =-.23, .05).

Findings show the mediating role of the opinion extremeness related to the controversial topics and the moderating role of online platform, thus shedding light on how eWOM about extreme opinions regarding controversial topics depends on the type of communication channel.

When Having a Trick Up Your Sleeve Is a Bad Thing:
Highly Effective Self-Control Strategies Can Be Demotivating

Ding (Allen) Tian, Wuhan University, China
Gerald Häubl, University of Alberta, Canada

EXTENDED ABSTRACT

Consumers differ in their dispositional capacity to exercise self-control. Compared to those high in trait self-control, individuals low in trait self-control are more likely to place themselves in a temptation-rich environment (Ent, Baumeister, and Tice 2015; Hofmann, Baumeister, Förster, and Vohs 2012) and to act on impulses triggered by temptations (Baumeister and Heatherton 1996). As a result, low self-control is associated with numerous personal and societal problems, such as binge eating, substance abuse, aggression and crime, weak academic performance, poor psychological adjustment, and poor interpersonal relationships (Baumeister, Heatherton, and Tice 1994; DeWall, Baumeister, Stillman, and Gailliot 2007; Duckworth and Seligman 2005; Gottfredson and Hirschi 1990; Shoda, Mischel, and Peake 1990; Tangney, Baumeister, Boone 2004; Wiebe 2006). Due to their chronic vulnerability to self-control failures, it is crucial to inform consumers low in trait self-control about effective strategies for resisting temptations. As such, companies often seek to convince consumers of the effectiveness of products that serve as strategies to facilitate self-control, ranging from debt consolidation programs to smartphone applications like MyFitnessPal.

Although perceived strategy effectiveness can stimulate preferences and purchases (Chae, Li, and Zhu 2013; Sheth and Talarzyk 1972), it remains less clear how perceived strategy effectiveness might affect consumer self-control. Intuitively, greater perceived strategy effectiveness should boost self-regulatory strength of those low in trait self-control. However, building on prior research on justification-based self-control failure (De Witt Huberts, Evers, and De Ridder 2014; Khan and Dhar 2007), we propose that greater perceived strategy effectiveness can ironically undermine the motivation to exercise self-control among those low in trait self-control who are, ironically, most in need of help, because greater perceived strategy effectiveness reduces anticipated guilt associated with indulgence, thereby increasing their susceptibility to temptations. We conducted four studies to test this theoretical framework.

Evidence from four studies provides converging support for our hypothesis. In study 1a, participants initially learned about a (purportedly) more versus less effective strategy for controlling calorie intake. Next, in an ostensibly unrelated study, participants reported their desire to eat each of three unhealthy food items. The three responses were averaged into a composite measure of self-control (larger values indicate less interest in unhealthy food). Finally, participants completed a series of control measures, in which a trait self-control scale specific to eating (Giner-Sorolla 2001) was embedded. As predicted, greater perceived strategy effectiveness reduced self-control (i.e., increased interest in unhealthy food) in participants low in trait self-control, whereas this effect reversed among those high in trait self-control. We replicated this finding in study 1b by using the domain-general scale (Tangney et al. 2004) to measure chronic self-control as well as addressed alternative explanations.

In study 2, we tested our predictions by using a behavioral measure of self-control. Participants first read about a (purportedly) more versus less effective behavioral strategy for overcoming procrastination. Next, participants performed two tasks within a time window of 10 minutes, which created a procrastination situation. The first of these was to play an enjoyable yet inconsequential computer game (Tetris), whereas the second task was to work on a boring but consequential writing task for which the top 50% performers would qualify for an opportunity to earn a performance-based bonus payment. We operationalized self-control in terms of the amount of time spent on the writing task (more time spent on the writing task reflects greater self-control). As hypothesized, greater perceived strategy effectiveness reduced self-control (i.e., less time spent on the writing task) in participants low in trait self-control, whereas it had the opposite effect among participants high in trait self-control.

Study 3 sheds light on the psychological process underlying this effect by including a measure of anticipated guilt (adapted from Dahl, Honea, and Manchanda 2003). Participants initially completed the brief self-control scale (Tangney et al. 2004) embedded in other scales. Then, they read about a (purportedly) more versus less effective strategy for becoming more patient. After reading about the strategy, participants completed a filler task. Upon the completion of the filler task, they were asked to make a consequential choice between a smaller immediate payment and a larger payment that was delayed by 8 days. In line with our theorizing, greater perceived strategy effectiveness led to a higher probability of choosing the immediate smaller payment for individuals low in trait self-control, but had no such effect among those high in trait self-control. Critically, the anticipated guilt associated with choosing the smaller immediate payment mediated the effect observed among those low in trait self-control.

In sum, this research shows that providing people who are chronically low in self-control with highly effective self-control strategies may have unintended adverse consequences.

Planned to Miss: The Use of Two-Method Measurement Design in Experimental Marketing Research

Broderick Turner, Florida International University, USA
Jonthan Hasford, Florida International University, USA

EXTENDED ABSTRACT

Although people's behavior is shaped by many factors, psychological research typically attempts to isolate the effects of one construct of interest (or sometimes a small number of constructs). In focusing on a key predictor, it is not always clear how to best account for the possibility that other factors may also affect the outcome variable. While statistically controlling for valid covariates in correlational or experimental analyses can yield more accurate estimates and significance tests of focal effects, including unnecessary covariates can also be problematic, and can even be misused.

In this paper, we present a two-step method using lasso regression (Belloni, Chernozhukov, & Hansen 2014) as a practical solution to the problem of principled variable selection for covariates, drawing on recent advances in statistics and econometrics. We apply this method to four datasets drawn from recent literature to illustrate double-lasso variable selection in both correlational analyses and experimental designs.

THE COVARIATE SELECTION PROBLEM

Analyses that fail to take into account valid predictors of the dependent variable can suffer from multiple problems. In correlational analyses, omitted variables that predict the dependent variable and are correlated with the focal independent variable(s) can cause bias in estimated parameters (Darlington, 1990; Mauro, 1990). When valid covariates are excluded, the estimated coefficient of interest may either be artificially strong (when the covariate is a confound), or may be artificially weak (a suppression effect; MacKinnon, Krull, & Lockwood, 2000; Thompson, 2006).

A common way of avoiding this problem is to use experimental manipulations as independent variables. When randomization is successful, the experimental independent variable should be uncorrelated with any omitted variables, precluding bias in estimating the effect of the independent experimental variable. However, in practice, attempted random assignment may not always yield the desired independence (Darlington, 1990; Zhou & Fishbach, 2016), and formal tests are rarely conducted to confirm randomization (Wilkinson, 1999). Even when randomization is successful, failure to statistically control for valid predictors of the dependent variable reduces the statistical power of the experiment (Darlington, 1990; Judd, McClelland, & Ryan, 2011), exacerbating the already typically low likelihood of detecting a true effect of the independent variable (Rossi, 1990).

Given these benefits of controlling for covariates, it may seem surprising that the practice is not consistently applied in the literature. The ad hoc practices related to including covariates are likely attributable to several factors. As a practical concern, researchers may rely on rules of thumb (e.g., Green, 1991) and conclude that their sample size is too small to support including more predictors. In the extreme case when the dataset has more potential covariates than participants, including all variables in a regression is not possible.

Furthermore, it is not always clear how to go about selecting covariates and discussions of best practices in psychological research provide little guidance on this issue (Cumming, 2014; Wilkinson, 1999). Automatically controlling for a standard set of variables, such as demographics, is not recommended (Meehl, 1971). Automated methods, particularly stepwise regression, are widely recognized to perform poorly (i.e., over-fitting the data, selecting non-optimal models, inflating R^2; Freedman, 1983; Thompson, 1995; Thompson, 2006) and are rarely used.

In fact, recent work on research integrity has cautioned that the decision of whether or not to control for covariates can contribute to the problem of researcher degrees of freedom and false positives. Simmons, Nelson, and Simonsohn (2011) provide an elegant example of how selective reporting of only those analyses including controls that contribute to a significant focal result can lead to spurious findings. In fact, Simonsohn, Nelson, and Simmons (2014) use presence of covariate controls as a suspicious characteristic to distinguish between studies more or less likely to have been "p-hacked", and report evidence supporting this suspicion. Thus, some researchers may feel that it is simpler and more conservative to report main effects without covariates. Even when controlling for covariates could be beneficial, the lack of established principled methods for doing so may discourage researchers from doing such analyses.

DOUBLE-LASSO VARIABLE SELECTION

We propose that recently developed methods based on lasso regression (e.g. Tibshirani, 1996) provide a useful solution to these problems. We describe a "double-lasso" approach (Belloni et al., 2014) that can help researchers select variables for inclusion in analyses in a principled manner that avoids inflated Type I errors. The goal is to identify covariates for inclusion in two steps, finding those that predict the dependent variable and those that predict the independent variable. The second step is important, because exclusion of a covariate that is a modest predictor of the dependent variable but a strong predictor of the independent variable can create a substantial omitted variable bias. In experimental data, the second step also serves as a test of randomization. While we recommend using lasso regression, calibrated to avoid over-fitting, in these variable selection steps, we also discuss similarly-performing alternative methods. The variables selected in either step are then included in the regression of interest.

A lasso regression minimizes the sum of squared errors in the regression equation with an additional penalty term based on the absolute magnitude of the coefficients in the regression. The penalty term results in the lasso regression shrinking the estimated regression coefficients towards zero and potentially setting coefficients for some variables exactly to zero, both of which help reduce over-fitting. By setting some coefficients to zero, the lasso performs variable selection, and can be used even when the number of observations is small relative to the number of predictors (James, Witten, Hastie, & Tibshirani, 2013).

However, directly using lasso regression can be problematic. Those lasso-estimated coefficients that are actually non-zero are typically underestimated, and lasso may mistakenly exclude variables with non-zero coefficients, particularly variables with moderate effects. Each of these phenomena generally causes significant regularization bias that adversely affects estimation and inference about the coefficient of interest. The omission of covariates with moderate but non-zero coefficients is especially problematic and results in omitted variable bias when these covariates are relevant predictors of the focal variable. In order to overcome such biases, we recommend using the "double-lasso" variable selection procedure (Belloni, et al., 2014), which was explicitly designed to alleviate both sources of bias, as follows:

Step 1: Fit a lasso regression predicting the dependent variable, and keeping track of the predictors with non-zero estimated coefficients.

Step 2: Fit a lasso regression predicting the focal independent variable (or variables), keeping track of the predictors with non-zero estimated coefficients. If the indendepent variable is an effectively randomized treatment, no covariates should be selected in this step.

Step 3: Fit a linear regression of the dependent variable on the focal independent variable, including the covariates selected as predictors in either of the first two steps. This regression could also include a small set of additional covariates identified a priori as necessary. Interpret and report the coefficient estimates and significance tests on the focal variable(s) as the final results.

While implementation is fairly straightforward and extends easily to multiple focal variables by repeating Step 2 for each, the choice of the tuning parameter l is very important for successfully avoiding over-fitting. Dedicated code for this procedure is available for use with STATA. We also provide details and examples for how to apply this method in both STATA and in the R statistical package, and how to closely approximate the results using modified forward-selection in SPSS (Kozbur, 2015).

SIMULATION RESULTS

We ran a simple simulation to illustrate the practical benefits of double-lasso variable selection. We generated 10,000 datasets from eight known sets of parameters, varying the number of available covariates and the sample size. We compare the double-lasso procedure to five alternatives: regression including no covariates ("none"), including all the covariates when possible ("all"), including all covariates selected in a step-wise regression ("stepwise"), choosing covariates to maximize the chances of the independent variable being significant ("p-hacking") and, as a baseline, using the correct variables ("true").

On average, the double-lasso selected close to the right number of covariates (2.6 vs. 2 actual), and far fewer than stepwise (5.5) or p-hacking (4.9). The average error in estimating the coefficient of the dependent variable in the double-lasso was very close to the true baseline (RMSE=.261 vs. .246), lower than including no covariates (RMSE=.356) or all covariates (RMSE=.383) and much lower than p-hacking (RMSE=.496). The significance test for the focal independent variable was well calibrated in the double lasso, rejecting the null hypothesis 5.4% of the time, similar to "none" and "all" (5.3% and 5.6%, respectively) and much better than "stepwise" (11.8%) or p-hacking (29.8%). Perhaps most importantly, using the double-lasso yielded substantial benefits in statistical power compared to those other methods that also did not over-reject (.579 vs. .626 for the "true" baseline, compared to .323 for "none" and .396 for "all").

We also tested two procedures that roughly approximate the double-lasso. Two-step multiple regression (including all potential covariates, and then re-running the regression removing non-significant covariates) provides reasonable solutions, but underperforms the double-lasso and is infeasible in settings with more available covariates than observations. Double-forward regression (using forward regression to do both steps, with modified p-value cutoffs) yields results quite similar to the double lasso.

Notably, the double-lasso performs well even in demanding situations. For example, with a sample size of 60, it is impossible to include 120 covariates in a standard regression, and researchers in this situation might therefore not include any covariates. However,

double-lasso variable selection identifies covariates and improves on the no-covariate model in this situation, with both lower error (RMSE=.276 vs. .390) and higher statistical power (.422 vs. .261). Next, we illustrate the proposed variable selection method by using it to analyze four datasets discussed in the literature.

ANALYSIS 1: CORRELATIONAL ANALYSIS OF PARENTS' LIFE SATISFACTION

Nelson, Kushlev, English, Dunn, and Lyubormirsky (2013) concluded, based on analyses of three datasets, that parents report relatively higher levels of life satisfaction, happiness, and meaning in life than do nonparents, contrary to some prior research. Their analyses were based on mean comparisons (t-tests) and correlations, without including any covariates as statistical controls. These conclusions were criticized by Bhargava, Kassam, and Loewenstein (2014), who re-analyzed the data and found that the satisfaction and happiness were not higher for parents, controlling for demographics.

In Study 1, Bhargava et al. (2014) reported a significant positive relationship between parental status and life satisfaction in the World Values Survey data without any controls (b=0.224, p<.001), similar to Nelson et al. (2013). This suggests that parents are more satisfied with their lives than non-parents, on average. However, they also find that the relationship is instead negative when controlling for marital status, age and gender (b=-0.144, p=.04), and is non-significant when controlling for income as well (b=-0.065, p=.34).

Thus, whether the relationship between life satisfaction and parenthood was significantly positive, non-significant or significantly negative depended on whether and which covariates were included. One important consideration is whether the potential covariates should be considered controls, on theoretical and logical grounds (e.g, as opposed to being analyzed as potential mediators). Assuming that the variables are valid potential controls, it is not clear which covariates should be included and what conclusion should be drawn. In fact, the lack of difference found by Bhargava et al. (2014) could potentially even be spurious, a result of multiple testing of many potential covariates. The double-lasso addresses this concern by identifying whether there is sufficient empirical justification for including the published covariates and potentially identifying other covariates.

To be comprehensive and test the ability of the method to handle many potential covariates, we began with 9 demographic variables, created dummy codes from the categorical variables and computed powers of the variables and interactions, yielding a total of 524 potential covariates. Using the procedure described above, we then identified a subset of 17 covariates for which there was sufficient empirical support to be included in the final test. These were covariates that were either strong predictors of life satisfaction or of being a parent.

In particular, our analysis using double-lasso variable selection confirms that there is sufficient evidence to include the variables identified by Bhargava et al. (2014) (age, gender, marital status and income) as covariates, as well as several other variables and interactions. In the resulting model, we find a significant negative relationship between parental status and life satisfaction (b=-0.196, p=.006), controlling for the identified covariates. Note that it is important for the results to conduct both variable selection steps. If we only use covariates identified as predictors of the dependent variable (life satisfaction) and leave out those identified as predictors of being a parent, we instead find a weaker negative relationship between parental status and life satisfaction (b=-0.127, p=.051).

While this analysis tells us which potential covariates have empirical support for inclusion, it cannot determine which variables make logical sense or are theoretically justified to include. As an

example, one potential concern with this analysis is that parenthood might causally impact some of the variables, particularly income and employment status. When we re-run the regression excluding these variables as potential covariates, we still find a significant negative relationship between parental status and satisfaction (b=-.221, p=.002), controlling only for marital status, age, gender and interactions of those covariates.

Nelson et al. (2013) and Bhargava et al. (2014) also debated whether demographics moderated the effect of parenthood on life satisfaction, with the latter paper arguing that evidence of such moderation was weak. In separate analyses, we find that marital status (b=.362, p=.015) and age (b_{age}=3.281, p=.009; $b_{age-squared}$=-3.107, p=.045) moderates the effect of being a parent, controlling for selected covariates, but gender does not.

Overall, our findings parallel those of Bhargava et al. (2014). The higher self-reported life satisfaction of parents may be explained primarily by the differing demographic characteristics of parents vs. nonparents, disguising lower life-satisfaction among parents, all else equal.

ANALYSIS 2: MEDIATION ANALYSIS OF CONSERVATIVE HAPPINESS

Next, we look at how double-lasso regression can be used to inform variable selection when conducting a mediation analysis. Napier and Jost (2008) report that conservatives demonstrate higher levels of subjective well-being than liberals do. Using large secondary data sets, they identify rationalization of inequality as a mediator of this difference, in accordance with system-justification theory. However, a potential concern is that the mediation result may be spurious, if the mediator is merely a proxy for other factors that relate to political orientation and subjective well-being. While the paper reports mediations including selected demographic controls, we can use lasso regression to test whether inclusion of the covariates is supported by the data.

We reanalyzed the 1,192 participants in the 2000 American National Election Survey who had completed the measures analyzed in Study 1 of Napier and Jost (2008). We confirmed that conservatives were happier (b=.282, t(1190)=4.70, p<.001), and the difference was partially mediated by the rationalization of inequality scale (indirect b=.062, bootstrap CI=[.0004,.1246], p=.049, Preacher & Hayes, 2004).

The dataset also includes a large number of demographic variables that could be potentially confounding the mediation result. We chose 35 demographic variables, including all the variables used in the paper, and created dummy codes for all categorical variables. We conducted a double-lasso analysis to test the resulting 141 demographic variables for inclusion, and identified four covariates (church attendance and dummy codes for employment, being married and African-American ethnicity). Controlling for these covariates, the effect of political orientation on happiness is only marginally significant. While the coefficient of political orientation decreases when rationalization of inequality is included, the mediation is not significant (indirect b=.045, bootstrap CI=[-.011,.102], p=.116). This suggests that the proposed mediation in the original study is sensitive to the inclusion of a more complete set of covariates, which are identifiable using the double-lasso procedure.

ANALYSIS 3: SPURIOUS EXPERIMENT ON CHRONOLOGICAL REJUVENATION

While controlling for covariates can be helpful, as in the prior analyses, Simmons et al. (2011) have shown that opportunistically controlling for covariates can contribute to spurious findings. The

potential for controls to distort the primary findings is a particular concern in experimental studies, where successful randomization addresses issues of confounding. We re-analyzed the data from Study 2 of their paper to test whether using the double-lasso would reduce the likelihood of including spurious covariates.

In Study 2, Simmons et al. (2011) present an intentionally spurious finding, reporting that a randomized experimental intervention (having people listen to "When I'm Sixty Four" by the Beatles vs. a control song) had a significant effect on the participant's age, controlling for father's age (M=20.1 vs. 21.5 years old, b=-521.85, t(17)=2.22, p=.040). The covariate was also significant in the regression (b=98.34, t(17)=3.86, p=.001).

We identified nine potential covariates in the dataset. Dummy-coding a categorical variable yielded 10 variables. The double-lasso takes into account not only the multiple comparisons, but also the small sample size (N=20), setting a higher bar for covariates to be included. As a result, the double-lasso analysis revealed insufficient empirical support to include any of the potential covariates in the regression. The resulting single-variable regression accurately revealed no significant effect of the experimental manipulation (b=-305.30, t(18)=1.00, p=.329). Simply using a principled variable-selection method eliminated the spurious finding.

ANALYSIS 4: SUGGESTED DEFAULTS EXPERIMENT IN DONATION

In the last analysis, we demonstrate that the double-lasso method can be used to identify valid covariates in a randomized experiment, testing whether randomization was successful, and increasing the statistical power to detect a result. Goswami and Urminsky (2016) conducted a field experiment on the effect of recommended amounts in donation appeals. Each appeal letter included three donation amounts (low, medium and high) that were based on the recipient's most recent donation amount. In the four focal conditions, appeal letters were randomly assigned to include a recommendation to give the low amount, medium amount, high amount or to not include any recommended amount.

One of the hypotheses tested was a "scale-back" effect, in which donors would anchor on the recommended amount and give less when the low amount was recommended, compared to the control condition with no recommendation. People who chose to donate gave less in the low-recommendation condition (vs. control), but the difference was not significant (M=$162 vs. $283, t(46)=1.38, p=.175). Ten potential covariates were available, to which we added non-linear transformations and interactions, for a total of 196 potential covariates. There was a strong a priori rationale for including one of the potential covariates, the prior amount donated, since the choice options in the appeal letter actually differed depending on the most recent donation.

We used a double-lasso regression to identify which covariates had empirical support for inclusion. First, none of the covariates had a significant relationship with experimental condition. While is expected since the conditions were randomly generated, it can be problematic to simply assume effective random assignment (Darlington, 1990). Thus, this step provides a valuable tool for validating the effectiveness of randomization.

Based on the relationship to amount donated, three covariates were identified (most recent donation amount and two interactions) in the lasso step predicting donation amount. As noted above, no covariates were selected in the step predicting experimental condition, revealing no evidence of failed randomization based on the covariates. A linear regression including the identified covariates (as well as orthogonal experimental conditions), confirmed that there was a

significant effect of the low recommendation condition on log donation amount relative to control (b=-.365, t(67)=3.03, p=.004). This analysis demonstrates how double-lasso regression can be used to identify valid covariates, increasing the power of experimental tests.

CONCLUDING REMARKS

The simulation and re-analyses demonstrate the potential benefits of using a principled variable selection method, such as the double-lasso, for better identifying which covariates to include and not include in analyses across a range of situations. It is important to emphasize that the analytic method presented here cannot determine either the role that selected variables should play, or how their effects on the relationship of interest should be interpreted. A confound, a manipulation check and a mediator may all have similar statistical relationships in the data (MacKinnon, Krull, & Lockwood, 2000; Zhao, Lynch, & Chen, 2010), and these distinctions should typically be made on theoretical grounds.

However, either including all covariates or ignoring covariates entirely, either because of the conceptual difficulty of identifying the theoretical role of the variable or because of the potential for covariates to be used improperly (i.e., in p-hacking), is no solution. Failing to control for valid covariates can yield biased parameter estimates in correlational analyses or in imperfectly randomized experiments and contributes to underpowered analyses even in effectively randomized experiments. As demonstrated in the analyses, double lasso variable selection can be useful as a principled method to identify covariates in analyses of correlations, moderation, mediation and experimental interventions, as well as to test for the effectiveness of randomization. While variable selection methods are no substitute for thinking about what the variables mean, the approach presented here can provide an empirical basis for determining which variables to think hard about.

Love Food, Hate the Brand That I Waste:
The Effects of Product Waste on Brand Evaluations

Erica van Herpen, Wageningen University, the Netherlands
Ilona de Hooge, Wageningen University, the Netherlands

EXTENDED ABSTRACT

Product waste involves a huge loss of resources and of 'unused utility': throwing away of functioning appliances, unused products, and edible foods. Wasting is not a carefree activity for consumers. Consumers follow complex procedures in managing the residual value of discarded food items to lessen anxieties about wastage (Evans, 2012; Graham-Rowe et al., 2014; Parizeau et al., 2015). Moreover, a distaste for waste affects consumers' choices, such as favoring options with less unused utility (Bolton and Alba, 2012) or persevering in a failing project when stopping would involve waste (Arkes, 1996). The current research provides insights into this contradiction between wasting a lot and not wanting to waste, and reveals the consequences of waste for brand evaluations.

Waste can be understood as the result of not using a product to its full capacity. Whereas both throwing away a food container that still holds leftovers and throwing away an emptied food container would lead to the generation of waste, there is an important difference in the unused utility that is wasted, in this example in the form of uneaten food. This salient unused utility is aversive for consumers (Bolton and Alba, 2012). According to cognitive dissonance theory (Festinger, 1957), the occurrence of "nonfitting" relations among cognitive elements (which could entail attitudes, beliefs, and behaviors) is unpleasant and leads to psychological discomfort (also termed dissonance). Thus, consumers would like to solve this dissonance in the current waste situation. Because attitudes can be altered more easily than previously displayed behaviors, attitude change is a common way in which people reduce dissonance (Galinsky et al., 2008; Simon et al., 1995; Starzyk et al., 2009). Therefore, we expect that wasting a product with left-over utility would generate cognitive dissonance, and that this dissonance would be solved by decreasing evaluations of the wasted brand.

Importantly, when a product with left-over utility is discarded, the left-over utility is not necessarily wasted. Different disposition behaviors are possible: throwing it away, giving it away, trading it, and selling it (Jacoby et al., 1977). If unused utility can be transferred to another person, the level of psychological discomfort should be lower than if unused utility is lost. Thus, we expect that wasting a product with left-over utility leads to more cognitive dissonance and more decreased brand evaluations than other ways of disposing a product.

Finally, the predicted effect should depend on brand salience. Dissonance reduction through brand evaluations should be less likely when the brand itself is not salient when wasting the product (i.e., when the brand is not visible, and there is thus no reminder of the brand name).

We tested our hypotheses in four experiments. The first three experiments were scenario studies. Experiment 1 examined the effect of different ways of disposing products on dissonance feelings. Results showed that wasting a product (irrespective of whether it was thrown away or recycled) lead to more dissonance than transferring utility to another person (irrespective of whether the product was used in its original intended purpose). Experiment 2 tested the effects of wasting on brand evaluations. Participants imagined that they had purchased a drink they could not consume entirely, and that they either threw the remaining product in the bin (waste condition) or gave it to a friend (no-waste condition). Brand evaluations were lower in the waste condition than in the no-waste condition. Experiment 3 ruled out alternative explanations (transfer of disgust, cf. Morales and Fitzsimons, 2007, and attribution of waste to the brand).

Experiment 4 investigated waste in a situation with real product consumption, to generalize our results beyond imagined situations. It also tested the moderating effect of brand salience. Participants prepared and ate a salad in the lab. In the brand-salient condition, product containers with the same brand name were placed next to bowls with ingredients, whereas in the brand-not-salient condition only unlabeled bowls were provided. In both conditions, participants were aware of the brand through the instructions. The amount of ingredients provided ensured that there were leftover ingredients. As dissonance is more likely when people believe that they freely choose their behavior (Harmon-Jones, 2000), in the waste condition participants could ask for sandwich bags to take leftover ingredients home or put leftover ingredients in a bin (only six participants asked for bags). In the no-waste condition, participants could take leftover ingredients home or leave these on the table for future participants (none took ingredients home). All participants then evaluated the brand.

Our results showed the expected waste x salience interaction effect ($F(1, 120) = 5.32$, $p = .023$). When the brand was not salient, wasting did not affect brand evaluations ($p = .156$). In contrast, when brand was salient, brand evaluations were marginally higher when ingredients were left on the table ($M = 5.19$) than when these were wasted ($M = 4.75$, $p = .069$). Mediation analyses showed that dissonance was a mediator when salience was high but not when salience was low.

Our research shows that consumers can reduce dissonance from wasting a product with unused utility by decreasing their brand evaluations. This was found both in scenario studies and in a food consumption context. Results furthermore reveal that brand devaluation does not occur when the brand is not salient at the moment of wasting. This provides new insights to literature on consumer disposition behavior that help clarify the paradox in which consumers both waste products and do not want to waste. It also has important managerial implications. The realization that brand evaluations suffer when consumers waste products with unused utility could inspire companies to spend additional efforts on preventing this. Companies can do so by ensuring that products do not contain excess utility beyond what consumers need (e.g., small package sizes), helping consumers to use all product utility (e.g., easy storage of partially used products), and providing mechanisms for the collection of products with remaining utility (e.g., collection points for appliances).

Planning to Fill The Gap:
The Efficacy of Forming Implementation Intentions in Healthy Eating

Irene Vilà, Universidad Pontificia Comillas, Spain
Isabel Carrero, Universidad Pontificia Comillas, Spain
Raquel Redonde, Universidad Pontificia Comillas, Spain

EXTENDED ABSTRACT

Healthy eating is becoming an increasingly important behavior since obesity is a major public health concern and has become more widespread in the past five years (OECD, 2014). Our role as consumer researchers is to develop, test and perfect the instruments which are used to design social policies aimed at increasing healthy eating. The main goal of this research is to study the effectiveness that forming implementation intentions has on healthy eating through a meta-analytic review.

Implementation intentions are action plans subordinate to goal intentions that specify the "when, where, and how" of responses leading to goal attainment. They have the structure of "When situation x arises, I will perform response y!" and thus link anticipated scenarios with goal-directed responses. Implementation intentions delegate the control of goal-directed responses to anticipated situational cues which (when actually encountered) elicit these responses automatically. Because implementation intentions imply the selection of a suitable response applicable to a future situation (i.e., a good opportunity), it is assumed that the mental representation of this situation becomes highly activated and thus more easily accessible (Gollwitzer, 1999).

In particular, this review has two research objectives related to the type of intended behavior. Our first objective is to test the effect of using the intervention for promoting healthy behaviors versus its effect on decreasing unwanted behaviors. Past evidence shows that the effect-size seems to be lower when the intervention aims at reducing unhealthy behaviors (e.g. Adriaanse, Vinkers, De Ridder, Hox & De Wit, 2010; Verplanken & Faes, 1999)it was investigated whether the quality of the outcome measures and the quality of the control conditions that are used in these studies influence implementation intentions' effectiveness. Methods: Twenty three empirical studies investigating the effect of implementation intentions on eating behavior were included. In assessing the empirical evidence, a distinction was made between studies that aim to increase healthy eating (i.e., eating more fruits, but the results are still inconclusive due to limited sample sizes of previous meta-analyses. Second, it will test the efficacy of implementation intentions in different eating domains since past evidence is not conclusive in this respect. In healthy eating, the average effect of forming implementation intentions is small to medium (Adriaanse, van Oosten, de Ridder, de Wit & Evers, 2011). However, in recent years there has been a substantial increase in research focused on specific healthy eating domains with mixed results (Hagger & Luszczynska, 2014).

The literature search and data extraction were performed in February 2015. We searched for studies published in the Web of Science (Core Collection) and MEDLINE (1990 - December 2014). Application of the inclusion criteria resulted in 71 relevant articles describing 80 empirical studies, involving 15,944 participants. This study represents the largest meta-analysis performed in the healthy diet domain pertaining to the efficacy of forming implementation intentions.

Our findings show that the overall effect of the intervention is small to medium ($d = .34$). Compared with other behaviors, the effect that implementation intentions have on achieving a healthy-diet goal is lower (Gollwitzer & Sheeran, 2006). These differences confirm the hypothesis, "the effect of implementation intentions varies across different types of health-related behaviors" (Bélanger-Gravel, Godin, & Amireault, 2013: 45). Coherent with previous research, this meta-analysis shows significant differences between reducing ($d= .23$) or promoting ($d= .42$) a certain behavior. Therefore, it could act as a moderator variable.

However, the study of other moderator variables resulted in unexpected findings. When testing the efficacy of implementation intentions in different eating domains, values of d were calculated for different healthy eating behaviors in order to search for moderator effects. The meta-analysis showed that the efficacy of the interventions is similar when it is used to reduce fat intake ($d=.36$), increase fruit consumption ($d=.45$) or promote healthy snacking ($d=.44$). However, when the individual forms implementation intentions to diminish unhealthy snacking, the effect-size is .14, significantly smaller than the effect found for fat intake. Being that both are unwanted behaviors, the efficacy of implementation intentions should be similar. It leads us to conclude that future researchers cannot assume that forming implementation intentions in all cases is more efficient at promoting healthy behaviors than at decreasing unwanted behaviors.

Our results suggest the possible moderating effect of a new variable unused in previous meta-analysis, goal complexity. Although some authors had pointed out their possible influence on the intervention (e. g. Luszczynska, Scholz, & Sutton, 2007). We define complex goals as those in which the course of action to achieve the goal is unclear due to there being more than one alternative and each course of action having a different degree of effectiveness (De Vet, 2007).

The contribution of this work to the theory of implementation intentions is that it clarifies the moderation role of the type of intended behavior, promoting versus decreasing, adding the mediator role of a new variable, goal complexity. Although by itself goal complexity does not have a moderating role, it seems that along with the type of intended behavior, it sheds light on the actual role of implementation intentions in different types of healthy eating behaviors. The effect-sizes show that on one hand, the intervention is significantly more efficient when used for complex goals, aims to decrease a behavior ($d= .35$), and is also more efficient in simple goals that promote behaviors ($d= .45$). On the other hand, implementation intentions are less efficient for complex goals promoting a behavior ($d= .17$) and simple goals decreasing a behavior ($d= .14$).

Our findings imply that future researchers cannot assume that forming implementation intentions in all cases is more efficient at promoting healthy behaviors than at decreasing unwanted behaviors. This opens up a new line of research to help understand and improve the performance of implementation intentions since there is literature which discusses the role of each variable separately, but not jointly.

From the Transformative Consumer Research perspective, it is important to do practical research that can be used to increase the wellbeing of consumer citizens (Mick, 2006; Ozanne et al., 2011). In this vein, the ultimate purpose of our research is to help policy makers design interventions intended to help people achieve their goals of healthy eating. Implementation intentions will be reasonably helpful when used for reducing fat intake or increasing the consumption of fruit, vegetables or healthy snacks. However, for other behaviors, such as diminishing unhealthy snacking or promoting a global healthy diet, the intervention would not be suitable.

How and Why Wearing Sunglasses Makes for Cool Consumers

Lili Wang, Zhejiang University, China
Amy Dalton, Hong Kong University of Science and Technology, China

EXTENDED ABSTRACT

The question of how cool becomes active in directing thought and action has received little theoretical analysis and empirical attention. Critical to understanding what drives cool, then, is identifying which aspects of our day-to-day consumer experiences mentally activate cool and affect how people think and act with respect to coolness. We posit that using a symbolically cool product may activate cool, thus making the source of activation a consumer's own actions. We rely on sunglasses to study this issue.

Study 1 surveyed consumers regarding the behaviors and products they consider cool. We found that sunglasses were the most commonly listed "cool product" and were rated cooler than other fashion accessories and garments (e.g., scarves and jeans). In terms of cool behaviors, factor analysis established two dimensions: emotional composure (e.g., calmness under pressure) and nonconformity (e.g., slacking at school). These findings prompted us subsequently to manipulate cool activation using sunglasses, and to measure cool activation using emotional composure and academic underachievement.

Our first experiment, however, tested whether consumers wearing sunglasses pay more attention to people and brands that are cool over those that are neutral with respect to coolness. This study provides a strong test of cool activation because attention is less controllable than behavior, and because attention to cool stimuli is less subject to alternative explanations than behavioral measures. Attentional bias was examined in a dot probe task (MacLeod et al. 1986), which presents pairs of images simultaneously on a computer monitor. After the images disappear, a dot appears in place of one of the images and participants indicate whether the dot is on the right or left. If participants attend more to one image over the other, they will be faster to detect the dot when the dot replaces that image. Thus, response times should be faster when the dot replaces a cool image (e.g., Johnny Depp or Harley-Davidson) versus a neutral image (e.g., Mickey Mouse or Volvo). The results confirmed that people wearing sunglasses exhibited a greater attention bias to cool images compared to people in a control condition, for whom the sunglasses were visible on the desk but were not worn during the task (F (1,170) = 3.89, p = .05; note: Satterthwaite adjusted df). In addition, people wearing sunglasses exhibited a greater attentional bias on trials where cool images were present compared to control trials where cool images were absent (F (1,95) = 3.28, p = .07). These findings suggest that wearing sunglasses guides attention toward perceptual input that is cool.

Study 3 tested whether consumers wearing sunglasses underperform academically and exhibit emotional composure, hallmarks of cool behavior. Again under the guise of product evaluation, half were instructed to wear sunglasses throughout the study and half simply saw the sunglasses on their desk. Participants completed an "English language ability test" in which they received 5 minutes to generate as many words as possible from a set of scrambled letters (Dewall et al. 2011). Next, they were randomly assigned to receive positive or negative performance feedback and subsequently completed measures of shame, guilt and pride (Tangney and Dearing 2002). Compared to control participants, those who wore sunglasses performed worse on the test (t(99) = − 1. 96, p = .05), consistent with the notion that cool kids reject achievement norms and slack at school. They also maintained their composure, expressing less intense feelings of shame (F (1, 97) = 8.92, p < .004), guilt (F(1, 97) = 6.64, p = .01), and pride (F(1, 97) = 25.10, p < .001) in response to performance-related feedback. Importantly, performance did not predict emotions; rather, and as predicted, wearing sunglasses produced two independent effects: academic underperformance and emotional composure.

Study 4 tested whether these behavioral effects depend on the perception that sunglasses are cool. Participants were randomly assigned to sunglasses or control conditions before viewing a web-blog and advertisement that portrayed sunglasses either as cool or healthy (i.e., for UV-protection). Next, they completed a so-called filler task, a math matrices task (Gino et al. 2010), before answering questions about the website. Performance on the filler task was our dependent variable. As predicted, fewer matrices were solved in the sunglasses condition than the control condition but only when sunglasses were portrayed as cool (F(1, 162) = 10.76, p =.001) and not healthy (F < 1). Thus, as predicted, sunglasses' symbolic meaning is critical to obtaining effects on cool behavior. Moreover, because wearing sunglasses did not affect performance in the healthy condition, we rule out the possibility that sunglasses impair performance through cognitive load or distraction.

Study 5 teased apart three completing underlying mechanisms – stereotype/construct activation, implicit self-perceptions, and explicit self-perceptions – by testing moderation by self-awareness and mediation by self-perceptions. Participants were assigned to the sunglasses or control condition. Self-awareness was manipulated in a "me/not me" self-description task (Markus 1977) in which participants indicated whether a series of personality and behavioral traits describes them ("me") or not ("not me"). The low self-awareness condition was instructed to respond to items quickly, while the high self-awareness condition was instructed to respond accurately. Thus, self-perception was based on accessibility (introspection) in the low (high) self-awareness condition. All accounts make similar predictions under low self-awareness, predicting cool traits are more accessible in the sunglasses (vs. control) condition. Critically, predictions vary under high self-awareness. The explicit self-view account predicts that people wearing sunglasses continue to perceive cool traits as self-descriptive and to underperform academically. That is, a process whereby people consciously infer they possess cool traits and thus behave cooler would not be weakened by self-awareness (Bem 1972). Conversely, the two accessibility-based accounts predict that high self-awareness attenuates the effect of wearing (vs. not wearing) sunglasses, consistent with the notion that self-awareness undermines accessibility effects (Wheeler et al. 2008). The accessibility-based accounts can, however, be teased apart. Stereotype/construct activation implies a direct effect but implicit self-perception is indirect, with self-perception mediating behavior. Our findings supported the implicit self-perception account: people wearing sunglasses automatically internalize self-perceptions associated with coolness, and this drives cool behavior.

The Insidious Effects of Smiles on Social Judgments

Ze Wang, University of Central Florida, USA
Huifang Mao, Iowa State University, USA
Jessica Li, University of Kansas, USA
Fan Liu, Adephi University, USA

EXTENDED ABSTRACT

Smiles are widely used as a marketing tool to produce positive impressions. Sales assistants, restaurant servers, and store cashiers are often trained to smile when they interact with customers (Hennig-Thurau et al. 2006), probably because smiles positively influence interpersonal judgments in a myriad of ways. People who smile are perceived to be kinder, more sociable, more honest (Thornton 1943), more pleasant (Mueser et al. 1984), more carefree (Deutsch, LeBaron, and Fryer 1987), and more polite (Bugental 1986) than people who do not.

Such associations may lead one to believe that smiles always convey positive information and hence, the bigger the smile, the better. Indeed, research has documented that people deliberately intensify positive emotional displays to receive favorable social feedback (Andrade and Ho 2009). In this research, however, we caution that bigger and broader smiles sometimes bring forth undesirable consequences. Well-intended broad smiles are not always beneficial, and can even have a boomerang effect on consumers' judgments and behaviors.

THEORY AND HYPOTHESES

We integrate research in two areas – the stereotype content model (SCM) and the social-functional perspective on emotion – to develop our framework and hypotheses. The SCM proposes that interpersonal judgments are captured by two fundamental dimensions of social perception—warmth and competence—that likely reflect evolutionary pressures (Fiske 2002). In order to survive and reproduce, social animals must quickly determine others' intentions (e.g., to help or harm), and their ability to act on them. Warmth judgments reflect the first of the two dimensions, and typically include evaluations of kindness, friendliness, trustworthiness, and helpfulness (Aaker et al. 2010). Competence judgments relate to evaluations of the target's capability of carrying out his/her intentions, and include perceptions of effectiveness, intelligence, power, and skillfulness (Hoegg and Lewis 2011).

The social-functional perspective on emotion asserts that emotions have evolved to help facilitate social interactions by signaling important information about the expresser (Fridlund 1992; Keltner and Haidt 1999). People are able to make quick and spontaneous inferences from facial expressions to understand the expresser's internal emotional states and social intentions (Fridlund 1994; van Kleef et al. 2004). Smiles, in particular, are believed to have evolved to assist group living by facilitating cooperation among unrelated individuals (Owren and Bachorowski 2001). Smiles communicate positive intent, agreement, or assent, and are often used to encourage and support social interactions (Abe Beetham and Izard 2002).

Not only do facial expressions convey the expresser's emotions and intentions, but also the intensity of those feelings, with more intense facial expressions connoting more intense emotions and desires (Ekman, Friesen, and Ancoli 1980). Broad versus slight smiles may have different social consequences. Women with the most intense smiles in photographs are more likely to be married by age 27 (Harker and Keltner 2001) and people with more intense smiles in photos are less likely to divorce later in life (Hertenstein et al. 2009). This may be because, compared to slight smiles, broad smiles

deliver stronger signals that the expresser desires to make social connections, which increase the perception that the expresser is friendly and approachable. Hence, we propose that broad (vs. slight) smiles enhance warmth perceptions.

On the flip side, broad smiles may also signal that the individual is less competent. Research has connected broad smiles with reduced aggression, performance, and dominance—traits that help one achieve status and power (Dabbs 1997; Kraus and Chen 2013; Mazur and Booth 1998). For example, Dabbs (1997) found a negative relationship between smile intensity and dominance, which they define as "a quality that helps one win whatever one wants to win" (p. 46). These findings are in line with the competition hypothesis of smiling and laughter, which proposes that smiles function to implement social hierarchies and signal low motivation to compete for status (Mehu and Dunbar 2008). For instance, bared-teeth display in chimpanzees is often an indicator of submission and acceptance of subordinate status (de Waal and Luttrell 1985). Thus, a broad smile may suggest that the individual is content with the current situation (Fridlund 1994) and unmotivated to change or improve the status quo (Bodenhausen, Kramer, and Süsser 1994). Consequently, we hypothesize:

Hypothesis 1:   *Compared to a slight smile, a broad smile will lead to higher perceptions of the marketer's warmth, but lower perceptions of the marketer's competence.*

We also propose a boundary condition—perceived consumption risk, or the magnitude and/or probability of experiencing adverse consequences after purchasing a product or service (Oglethorpe and Monroe 1987). When perceived risk is high, consumers are motivated to adopt strategies that help reduce the risk to a manageable level (Dowling and Staelin 1994). For example, high risk leads consumers to rely on familiar or well-known brands (Erdem 1998) and corporate reputations that signal product functionality and performance (Gürhan-Canli and Batra 2004). Similarly, we propose that when perceived risk is high, consumers should focus more on perceptions of competence (rather than warmth), because this trait reduces risk and increases consumer confidence that the marketer can successfully deliver the outcome.

On the other hand, when perceived risk is low, negative consequences of consumption are minimal (Oglethorpe and Monroe 1987) and consumers are less concerned about product or service failure (Gürhan-Canli and Batra 2004). Instead, they tend to focus on having a positive and satisfying consumption experience, which is largely dependent on employee helpfulness and friendliness (Surprenant and Solomon 1987; Tsai and Huang 2002). Taken together, we propose:

Hypothesis 2:   *The effect of smile intensity on social judgments is moderated by the risk level of the consumption context such that (a) a broad (vs. slight) smile is more likely to enhance warmth perceptions when consumption risk is low (vs. high); (b) a broad (vs. slight) smile is more likely to undermine competence perceptions when consumption risk is high (vs. low).*

Research suggests warmth and competence perceptions are important predictors of consumers' behavioral responses (Aaker et al. 2010; Cuddy et al. 2007). As discussed above, consumers are likely to focus on the marketer's competence when perceived risk is high. Thus, compared to a slight smile, a broad smile, which signals lower competence, is expected to decrease consumers' intentions to purchase or use the product or service in a high-risk context. In contrast, low perceived risk is predicted to shift consumers' focus to warmth. Thus a broad (vs. slight) smile should increase consumers' behavioral intentions through enhanced warmth perceptions in a low-risk context.

Hypothesis 3: *Compared to a slight smile, a broad smile will lead to more favorable consumer behavioral responses through warmth perceptions when consumption risk is low, but less favorable consumer behavioral responses through competence perceptions when consumption risk is high.*

STUDY 1

Stimulus

We used photos of slight and broad smiles from a validated set of affective stimuli – the Montreal Set of Facial Displays of Emotion (MSFDE) created by Beaupré and Hess (2006). The MSFDE consists of digitally-morphed photos of facial expressions displaying different emotions at five levels of intensity. We selected two photographs from the MSFDE, with level 2 (slight) and level 5 (broad) smiles of the same displayer. Smiles in the two selected photos vary on the level of zygomatic major muscle movement, producing more or less intense smiles. The two photos are consistent in other appearance cues, such as head orientation (Farroni, Menon, and Johnson 2006), brow position (Sekunova and Barton 2008), and gaze direction (Adams and Kleck 2003).

Participants and Procedure

We recruited 123 individuals from Mturk (M_{age} = 31.28, ranging from 18 to 65; 55 females). Participants were shown one of the two photos and asked to report warmth and competence perceptions of the target (warmth: warm, kind, friendly, sincere; α = .94; competence: competent, intelligent, capable, skillful; α = .93; 1= not at all, 7 = very much so; Aaker et al. 2010; Cuddy Fiske and Glick 2007). Next, we collected data on two confound checks. Prior research suggests that smiles may vary in authenticity—the degree to which the smile is consistent with the expresser's internal feelings (Hennig-Thurau et al. 2006), and that smiles may influence the perceived attractiveness of the target (Mueser et al. 1984). To ensure our smile intensity manipulation did not inadvertently affect these variables, we asked participants to report smile authenticity and attractiveness of the target (Gorn et al. 2008; Mueser et al. 1984). Finally, participants responded to additional questions including a manipulation check of smile strength (1 = displays no smile, 7 = displays a broad smile; Barger and Grandey 2006) and demographics.

Results

We first conducted analyses on the manipulation and confound checks. Independent sample t-test showed that ratings of smile intensity were significantly higher when the target displayed a broad rather than a slight smile (M_{broad} = 5.28, M_{slight} = 4.61, t = 2.60, p = .01). Ratings of perceived authenticity did not differ across the two conditions.

A 2 (smile intensity) × 2 (social judgment) repeated-measures ANOVA revealed a significant interaction F (1, 121) = 26.90, p < .001. Planned contrasts showed that broad smiles elicited higher ratings of warmth (M_{broad} = 5.28, M_{slight} = 4.53; F (1, 121) = 23.28, p < .001), but lower ratings of competence (M_{broad} = 4.43, M_{slight} = 4.83; F (1, 121) = 6.29, p = .01). The same pattern of results was observed when we included smile authenticity and perceived attractiveness as covariates in the analysis, and the effects of covariates were not significant.

STUDY 2

Stimulus

We purchased and downloaded two stock photos from istock.com showing the same woman displaying a slight and a broad smile. We examined the zygomatic major movement in the two photos to ensure that the two smiles differed on intensity levels and were comparable to the level 2 and level 5 smiles in the MSFDE. In addition, we assessed and ensured the two photos were equivalent on other facial cues (e.g., head orientation, gaze direction). Participants were told the woman is a nutritionist. To manipulate consumption risk, the high-risk condition included a statement emphasizing the magnitude and probability of experiencing adverse consequences from nutrition coaching, "misleading advice or inappropriate dietary adjustment from a nutritionist could lead to serious health-related issues." This statement was omitted in the low-risk condition. A pretest (N=51) showed that the participants in the high (vs. low) risk condition, perceived the nutrition coaching service to be significantly riskier (M_{high} = 4.08, M_{low} = 3.38, t = 2.24, p < .05).

Participants and Procedure

Two-hundred and eighty-one participants (M_{age} = 36.29, ranging from 18 to 78; 155 females) were recruited from Mturk. Participants were randomly assigned to read the high or low-risk version of the nutrition coaching manipulation. Subsequently, they were asked to provide their zip codes so that they could ostensibly be matched with a local nutritionist. After a brief delay, participants were informed that the nutritionist they were matched with is trying to attract new customers. They viewed the nutritionist ad and reported their social judgments as well as intentions to use her services. Warmth and competence perceptions were measured using the same scales as study 1 (warmth: α = .94; competence: α = .96). Consumption intention was measured using a four-item scale (e.g., I am interested in the coaching program by this nutritionist; It is likely for me to pay for the coaching program offered by this nutritionist; 1= "strongly disagree" 7 = "strongly agree"; α = .96; Dodds, Monroe, and Grewal 1991). Participants were asked if they would like to sign up for a special promotion package of the coaching program by leaving contact information. Sign-up behavior (present, absent) was used as a behavioral measure of consumption likelihood. Finally, we collected confound checks on perceived persuasive intent, perceived appropriateness of the persuasive attempt, smile authenticity, and target attractiveness.

Results

Social judgments

A 2 (smile intensity) × 2 (consumption risk) × 2 (social judgment) mixed ANOVA revealed a three-way interaction F (1, 277) = 3.93, p = .05, which persisted after controlling for potential confounds. In the low-risk condition, the interaction between smile intensity and social judgments was significant (F (1, 277) = 6.29, p < .01). Judgments of warmth were greater in the broad smile condition

than the slight smile condition (M_{broad} = 5.35, M_{slight} = 4.70; F (1, 277) = 7.31, $p < .01$). However, smile intensity did not impact perceptions of competence (M_{broad} = 4.64, M_{slight} = 4.43; *p.n.s.*). The interaction between smile intensity and social judgments was also significant in the high-risk condition, (F (1, 277) = 25.32, $p < .01$). However, competence was lower in the broad smile condition than the slight smile condition (M_{broad} = 4.40, M_{slight} = 5.08; F (1, 277) = 6.95, $p < .01$) and smile intensity had no effect on warmth perceptions (M_{broad} = 5.08, M_{slight} = 4.82; *p.n.s.*).

Consumer responses

A 2 (smile intensity) × 2 (risk level) between-subjects ANOVA revealed a two-way interaction on behavioral intention (F (1, 277) = 15.01, $p < .01$). In the low-risk condition, participants reported more favorable behavioral intentions in the broad smile condition (M_{broad} = 3.75, M_{slight} = 3.28; F (1, 277) = 3.28, $p = .07$). The opposite was true for the high-risk condition (M_{broad} = 3.35, M_{slight} = 4.37; F (1, 277) = 12.99, $p < .01$). Inclusion of covariates did not change the results (F (1, 277) = 12.07, $p < .01$).

Next, we analyzed the behavioral measure. A binary logistic regression was conducted that included smile intensity, risk, and their interaction as predictors. The smile intensity × risk interaction was significant (χ^2 (1) = 6.84, $p = .01$). Participants in the low-risk condition were more likely to sign up for the nutrition coaching program if the nutritionist displayed a broad smile (M_{broad} = 32.9%, M_{slight} = 19.2%; χ^2 (1) = 3.60, $p = .05$); those in the high-risk condition were more like to sign up if the nutritionist displayed a slight smile (M_{broad} = 17.9%, M_{slight} = 31.8%; χ^2 (1) = 3.28, $p = .07$). The interaction effect remained significant after including potential confounds as covariates.

Moderated mediation

A moderated mediation analysis (5,000 resamples; Hayes 2013) showed that, in the low-risk condition, the indirect effect of smile intensity on purchase intention through warmth perceptions was significant (efficient = .20, 95% [CI]: .07, .42), but the indirect effect through competence perceptions was not significant (efficient = .08, 95% CI: -.02, .22). In the high-risk condition, the indirect effect of the interaction on behavioral intentions through competence perceptions was significant (efficient = -.48, 95% CI: -.80, -.22), but the indirect effect though warmth perceptions was not (efficient = .15, 95% CI = -.14, .50).

Participants' sign up behavior showed similar effects. In the low-risk condition, the indirect effect of smile intensity through warmth perceptions was significant (efficient = .18, 95% [CI]: .00, .52), while the indirect effect through competence perceptions was not (efficient = .07, 95% CI: -.05, .34). In the high-risk condition, the indirect effect through competence perceptions was significant (efficient = -.24, 95% CI: -.57, -.04), but the indirect effect though warmth perceptions was not (efficient = .07, 95% CI = -.01, .29).

STUDY 3

To take our investigation out of the lab into a field setting, we collected data from Kickstarter.com, one of the world's largest crowdfunding platforms for creative projects. Many project creators on Kickstarter.com provide profile photos featuring themselves, which allow us to code the smile intensity level displayed in these photos. We collected publicly available panel data on projects in the "Technology" category, which had the largest number of projects (i.e., 924 projects) at the time of data collection (November 2014). A total of 393 projects included a clear headshot of a smiling creator.

Measurements

Smile Intensity

For each profile photo of the project creator, two coders independently classified the facial expression into one of three categories: 0 = no smile, 1= slight smile, and 2 = broad smile (Cupchik and Poulos 1984). As part of the training process, coders examined sample photos from the MSFDE (Beaupré and Hess 2006). The inter-coder reliability was .87 and differences in coding were resolved by a third coder.

Backer Behavior Driven by Competence Perceptions

Research on crowdsourcing identifies the desire to collect rewards as one of the primary motivations of backers (Cholakova and Clarysse 2015; Gerber and Hui 2013). When a Kickstarter creator is perceived as competent, backers have greater confidence that the creator will be able to successfully complete the project and deliver what is promised. As such, we anticipate that a slight smile, which leads to greater perceived competence than a broad smile, will lead backers to contribute more money to the project, hence increasing total pledged amount to the project and average pledged amount per backer.

Backer Behavior Driven by Warmth Perceptions

The desire to help others is another important motivation for backers to support crowdfunding projects (Gerber and Hui 2013). People's intention to provide help or social support to others is determined by a variety of factors (Becker and Asbrock 2012), including warmth (Cuddy et al. 2007). People tend to like and feel positive emotions toward individuals perceived as warm and friendly (Fiske et al. 2002), and are more likely to extend help or assistance to these individuals (Cuddy et al. 2007).

Consumers tend to balance the desire to help others with the desire to protect self-interest, and hence helping behavior is more likely to be observed when the cost associated with helping is relatively low (Wagner and Wheeler 1969). In Kickstarter, visitors can support a project by liking the project page on Facebook, which is a low cost way of helping the creator. Hence, we predict that a broad (vs. slight) smile in the profile photo, which elicits warmth perceptions, should be positively related to the number of shares a project receives on Facebook.

Backer Behavior Driven by Both Competence and Warmth Perceptions

Project creators on Kickstarter can set multiple reward categories, providing different rewards for backers pledging different amounts. On Kickstarter, an average required contribution for the first reward category is $7.97. The average required contributions for the second and third category are $27.1 and $98.6, respectively. Based on these statistics, we classified pledges lower than $25 as small contributions, pledges between $25 and $100 as medium contributions, and pledges higher than $100 as large contributions. As discussed earlier, a broad (vs. slight) smile is more likely to elicit low cost forms of helping behavior, and thus project creators wearing a broad (vs. slight) smile should receive a greater number of small-scale contributions as an indicator of social support. In contrast, compared to a slight smile, a broad smile may undermine the perceived competence of the project creator, which may lead to fewer large-scale contributions, which are likely viewed as investment on promising projects.

Results

Backer Behavior Driven by Competence Perceptions

When the creator displayed a broad (vs. slight) smile in the photo, the total amount pledged by backers plunged by more than 50% (M_{broad} = \$10947.72, M_{slight} = \$24519.93, t = -2.01, p = .05), and average contributions per backer was reduced by more than 30% (M_{broad} = \$96.12, M_{slight} = \$156.14, t = -2.19, p = .03).

Backer Behavior Driven by Warmth Perceptions. On the other hand, smile intensity positively predicts number of Facebook shares. A project page with a profile photo featuring a broad (vs. slight) smile received nearly twice as many Facebook shares (M_{broad} = 414.44, M_{slight} = 220.78, t = 1.87, p = .06).

Backer Behavior Driven by Both Competence and Warmth Perceptions

A 2 (smile intensity) × 2 (size of contribution) repeated-measures ANOVA revealed a significant two-way interaction (F (1, 200) = 7.41, p < .01). The number of small-scale contributions was significantly greater in the broad smile condition than in the slight smile condition (M_{broad} = 68.25, M_{slight} = 32.90; F (1, 200) = 3.79, p = .05). The opposite pattern was found for the number of large-scale contributions—broad smiles led to significantly lower number of large contributions than slight smiles (M_{broad} = 16.86, M_{slight} = 51.45; F (1, 200) = 5.14, p = .02).

Robustness checks

Given the correlational nature of this data, we took extra caution to rule out the possibility that the observed effects might be caused by factors other than smile intensity. To this end, we examined and ruled out the possibility that the results were due to, and (with the exception of funding goal) did not interact with, these control variables: creator gender, total funding goal, creator's entrepreneurial experience (whether the entrepreneur was an experienced or first-time project creator on Kickstarter.com), whether the project was promoted by Kickstarter as "staff pick," and whether the project had a video demonstration.

GENERAL DISCUSSION

Marketers routinely use facial expressions as a persuasion tool to engage customers, but little is known about how varying intensity levels of the same emotion expression can lead to differences in social judgments. Three studies revealed that brief exposures to facial expressions in still images are sufficient for consumers to form a preliminary impression of the marketer, and that, contrary to intuition, broader smiles do not always lead to more positive interpersonal judgments. Specifically, greater smile intensity enhances perceptions of warmth, but undermines perceptions of competence. This effect is bounded by level of consumption risk. The results of this research demonstrate that when it comes to smiles, bigger isn't always better.

Drawn to the Light:
Loneliness Predicts a Preference for Products in Brightness But Not Darkness

Yanan Wang, Bishop`s University, Canada
Fuschia Sirois, University of Sheffield, UK

EXTENDED ABSTRACT

Today's consumers are lonelier than ever. Between 1985 and 2004, the number of people who said there was no one with whom they discussed important matters tripled, to 24.6 percent (McPherson, Smith-Lovin, & Brashears, 2006). As the size of this segment of consumers grows, more research is called for to understand the impact of loneliness on consumption. Recent research has begun to address this gap. For example, it has demonstrated that loneliness can contribute to materialism (Pieters, 2013), willingness to try an illegal drug (Mead, Baumeister, Stillman, Rawn, & Vohs, 2011), choice of an unappealing item favored by a peer (Mead et al., 2011), and preference between minority- or majority-endorsed products (Wang, Zhu, & Shiv, 2012). There is also evidence that loneliness and related negative states such as hopelessness can literally translate common metaphors for these states into sensory perceptions and, accordingly, elicit preferences for warmer food (Zhong & Leonardelli, 2008) and brighter light (Dong, Huang, & Zhong, 2015) perhaps to compensate for the negative states. In this paper we extend research on the product preferences of lonely people by examining the extent to which darkness, a metaphor often linked to loneliness, might also influence lonely people's preferences for products presented with dark or bright ambient lighting. In testing this proposition, we draw upon three theoretical frameworks, semantic network models of emotion (Bower, 1981; Ingram, 1984), conceptual metaphor theory (Lakoff & Johnson, 1980), and self-product congruency theory (Sirgy, 1982).

Everyday metaphors and literary references suggest a close association between loneliness and the concept of darkness. Phrases such as "left in the dark" and "in the shadows" are often used to communicate social exclusion and isolation, states which are conceptually linked to loneliness. In Robert Frost's poem "Acquainted with the Night", the night (a time of darkness) is used as a metaphor for loneliness and depression. From a more concrete perspective, being in darkness literally means that people cannot see their surroundings nor if anyone else is nearby, which can be analogous to feeling alone and socially isolated. Semantic network models of emotion (Bower, 1981; Ingram, 1984) suggest that we store information about emotions in organized nodes that encapsulate the beliefs and antecedents associated with a particular emotion, and that emotions and their semantic nodes are dynamically and bidirectionally linked. Thus, experiencing an emotion activates the associated node and its information, and activating the nodal information can elicit the associated emotion (Niedenthal, Winkielman, Mondillon, & Vermeulen, 2009). Importantly, the processing of this information occurs via an automatic and non-conscious rather than a conscious route (Bower, 1981). From this perspective, the emotional experience of loneliness may be represented psychologically by darkness and the absence of light, and darkness itself may in turn activate feelings of loneliness.

Conceptual metaphor theory (Lakoff & Johnson, 1980) provides further explanation as to how darkness and feelings of loneliness may become metaphorically linked. This theory suggests that our understanding of higher level, abstract concepts is informed by our lower level more concrete experiences in the world, such that the easily grasped lower concepts (e.g., darkness) are used to gain a better understanding of higher level concepts (e.g., loneliness) for which we may have less experiential knowledge. Research applying this theory found that induced hopelessness, an emotional state that

is strongly associated with loneliness (Chang, Sanna, Hirsch, & Jeglic, 2010), resulted in an increased desire for a brighter room (Dong et al., 2015).

The literal translation of the metaphors associated with negative states into metaphorically-linked perceptual changes illustrated in this and other research implies that feelings of loneliness evoke conceptual metaphors that may influence consumers' preferences for products that metaphorically reflect loneliness. Following this logic, products that have a dark ambient lighting may be viewed by lonely people as being consistent with their own emotional state, which could have the effect of heightening awareness of feeling lonely, a state which is unpleasant to most people (Hawkley & Cacioppo, 2010). This proposition is consistent with self-product congruency theory (Sirgy, 1982), which states that products serve as cues that activate self-schemas about actual self-image, and ideal self-image. Products that are congruent with actual self-image reflect self-congruity, and products that are congruent with ideal self-image reflect ideal-congruity.

According to this theory either form of self-product congruity can motivate preferences for a product, but the nature of the product preference depends also on how both the self and the product are evaluated. Sirgy (1985) proposes that the self-esteem motive (a need to act in ways that enhance self-esteem) and the self-consistency motive (a need to act in ways consistent with self-image) are key for understanding how self-product congruity influences product preferences when self-image is negative or positive. For someone who is lonely, actual self-image would be negative (Jones, Freemon, & Goswick, 1981), and a product that has dark ambient lighting, and thus evokes the conceptual metaphor of loneliness, would also be viewed as negative. This negative self-congruity would result in a product preference conflict because motivation to enhance self-esteem would promote product avoidance, whereas motivation to maintain self-consistency would promote product approach. However, we argue that because loneliness is associated with low self-esteem (McWhirter, 1997; Olmstead, Guy, O'Mally, & Bentler, 1991), the self-enhancement motive will outweigh the self-consistency motive and a product associated with darkness will be avoided because it evokes negative self-referent feelings. Sigly (1985) has also demonstrated that people who are low in self-esteem tend to be more influenced by ideal-congruity in their product preferences, as products that activate ideal self-schemas offer the promise of seeing oneself in a positive light and are therefore self-enhancing. If we consider that lightness is the absence of darkness, then products presented with bright ambient light may be similarly viewed as metaphorically reflecting the absence of loneliness, and therefore be viewed as desirable by lonely people. Taken together, this theory and research provides support for the proposition that when lonely people are presented with the choice of a product with either dark versus bright ambient lighting, they will show a preference for the product with bright ambient lighting because of a congruency between their ideal self-image and the product (Sirgy, 1985).

Across five studies employing several different product types we tested whether chronic (Study 1) and situational (Study 2) loneliness would be linked to a preference for products that were presented with bright versus dark ambient lighting. In Studies 1 & 2 we also tested the effect of loneliness on preference for products with dark and light colours to rule out the possibility that the effects were due

to the darkness or lightness of the product itself rather than the background lighting. Study 3 replicated the results from the first two experiments and further tested whether negative feelings towards products with dark ambient lighting explained non-preference for these products. Consistent with the automatic processing of emotional information suggested by semantic network models of emotion (Bower, 1981; Niedenthal et al., 2009), in Study 4 we asked participants to consciously think and write about the product presented with dark ambient lighting. We expected that doing so would eliminate the effects of loneliness on product preference through negative emotions proposed and tested in Study 3. Finally, in Study 5 we tested the proposition that the effects of loneliness on product preference would only be present for products that were personally relevant for the individual, and that she/he would personally use rather than purchase for someone else.

STUDY 1

The goal of Study 1 was to test the effects of chronic loneliness on preferences for products presented with either dark or bright ambient lighting. We also tested the effect of loneliness on product color preferences to demonstrate that the loneliness is psychologically represented as darkness (e.g., a product in dark ambient lighting) rather than simply to a product having a dark colour.

Methods

Undergraduates at a Canadian liberal arts university voluntarily participated in exchange for three dollars. After completing personality filler questions, participants were told to think about the product as if they were shopping for themselves, and then were presented two different IKEA product pairs in a counterbalanced order: one pair with a desk in bright or dark ambient lighting, and one with a shelving unit of dark or light colour. Participants indicated their product preference across three items rated on a 7-point scale (1=not at all; 7=very much): 1) How do you like the product? 2) How interested are you in the product? 3) How likely are you to get this product in the future? Participants completed the 20-item revised UCLA loneliness scale (Russell, 1996).

Results and Discussion

Regression analysis predicting product preference for the desk from chronic loneliness found significant main and interaction effects as a function of bright versus dark ambient lighting. Spotlight analysis at 1 standard deviation above and below the mean of loneliness scores revealed that lonely participants reported higher product preference for the desk with a bright background. Regression analysis predicting product preference for the shelf from chronic loneliness found no significant main or interaction effects as a function of product color. Together these findings indicate that the lonely participants preferred a product with bright versus dark ambient lighting, but the colour of the product had no effect on their preferences.

STUDY 2

The goal of Study 2 was to replicate the findings from Study 1 using a measure of situational loneliness.

Methods

Participants recruited via Mechanical Turk participated in an online experiment in exchange for 75 cents. Participants were randomized to either a loneliness or non-loneliness condition, and first completed personality filler questions as in Study 1. Those in the loneliness condition wrote an essay about a time in which they felt socially isolated, whereas those in the non-lonely condition wrote an essay about a time that they felt a sense of social belonging. A self-perception scale, which included two items assessing state loneliness, served as a manipulation check. Participants were presented the product pairs (desk and shelf; Figures 1a and 1b) and rated their product preferences as in Study 1.

Results and Discussion

Participants in the loneliness condition reported significantly higher levels of loneliness than those in the non-lonely condition. Results of the 2X2 ANOVA revealed a significant interaction between loneliness and ambient lighting, with pairwise comparisons indicating that lonely participants reported significantly higher preference for the desk with bright ambient lighting. The ANOVA on product colour revealed nonsignificant main and interaction effects. Overall, the results are consistent with those in Study 1 in that lonely participants prefer a product with bright ambient lighting.

STUDY 3

The goals of Study 3 were to replicate the results from the first two experiments and further test whether negative feelings towards products with dark ambient lighting explained lonely participants non-preference for these products, as Middlestandt (1990) found that ambient background colour conveys emotion.

Methods

Participants recruited via Mechanical Turk participated in an online experiment in exchange for $1.30. Participants were randomized to either a loneliness or non-loneliness condition, and completed the same filler questions, writing task, and manipulation check as in Study 2. They were then presented the images of the desk as in Study 1 and asked to rate their current level of negative emotion associated with the desk (1=not at all; 7=very much). Participants then rated their product preferences as in Study 1.

Results and Discussion

Participants in the lonely condition reported significantly higher levels of loneliness than those in the non-lonely condition. Consistent with Study 2, the 2X2 ANOVA and pairwise comparisons revealed a significant interaction between loneliness and ambient lighting, with lonely participants reporting significantly higher preference for the desk with bright ambient lighting. A bootstrap analysis of the indirect effects of loneliness on product preference via negative affect for the lonely participants was significant indicating that higher levels of negative affect for the desk presented with dark ambient lighting explained their lower preference ratings.

STUDY 4

The goal of Study 4 was to test the proposition that the link from loneliness to negative affect to product preference demonstrated in Study 2 reflected an automatic, unconscious process rather than a conscious one.

Method

Participants recruited via Mechanical Turk participated in an online experiment in exchange for $1.50. Participants were randomized to either a loneliness or non-loneliness condition and completed filler questions, a writing task, and manipulation check questions as in Study 2. They were then presented the image of the desk in dark or bright ambient lighting. To engage participants in a conscious information processing route, participants were asked to write down any thought that came to mind when seeing the product image. They then completed a measure of negative affect associated with the product and rated their preference for the product as in Study 3.

Results and Discussion

Participants in the loneliness condition reported significantly higher levels of loneliness than those in the non-lonely condition. A 2X2 ANOVA revealed no significant or interaction effects of loneliness and ambient lighting on product preference after participants deliberated over the product. The ANOVA on negative affect as a function of loneliness and ambient lighting was also non-significant. Together these results indicated that negative mood was not associated the product on a dark ambient background after engaging in conscious information processing of the product image.

STUDY 5

The goals of Study 5 were to replicate the findings regarding loneliness and product preference from Studies 1 to 3, and to test the moderating effect of product authorship. The study employed loneliness (continuous) by authorship (for self vs. for other) by ambient lighting (dark vs. bright) between-subjects design, where loneliness was measured and authorship and ambient lighting were manipulated.

Method

Undergraduates at a Canadian liberal arts university voluntarily participated in exchange for three dollars. After completing filler questions about personality and lifestyle, participants were presented an image of a pair of gender neutral T-shirts, one with a dark ambient lighting and one with bright ambient lighting. They were told to imagine that they were shopping for the product either for themselves or for others, and then rated their emotional perceptions (socially isolated, pure, extroverted, warm, sophisticated) of the featured product one a 7-point scale (1=not at all; 7=very much). Participants then completed the 20-item revised UCLA loneliness scale (Russell, 1996).

Results and Discussion

The regression analysis with product preference toward the t-shirt as the dependent variable and loneliness (mean-centered), authorship (0=for self; 1=for others), ambient lighting (0=bright; 1=dark), and all their interactions as predictors revealed a marginally significant main effect of authorship, a significant two-way interaction between authorship and loneliness, and a significant three-way interaction. A simple slope analyses of the effects of loneliness on product preference toward the t-shirt as a function of product ambient lighting indicated that when shopping for self, lonely (vs. non-lonely) participants reported higher product preference toward the t-shirt when it was in bright versus dark ambient lighting. However, shopping for others, the product preferences of lonely participants was the same as non-lonely participants for both dark and bright ambient lighting.

Spotlight analyses at 1 standard deviation above and below the mean of loneliness scores revealed that when shopping for self, lonely participants reported higher product preference toward the t-shirt when the product ambient lighting was bright than when it was dark, whereas non-lonely participants' product preference was not impacted by product ambient lighting. When shopping for others, both lonely participants and non-lonely participants showed equal levels of product preference when the product ambient lighting was bright and dark. Overall, the results revealed that the effects of loneliness on product preference were only present for products that participants would personally use rather than purchase for someone else.

GENERAL DISCUSSION

Our findings extend and advance research on the product preferences of lonely people and

the metaphorical mapping of loneliness by demonstrating for the first time that loneliness, whether chronic or situational, is associated with a preference for products presented with bright rather than dark ambient lighting. Importantly, our findings suggest that negative feelings towards a product in dark ambient lighting explains why lonely people do not prefer products presented in dark ambient lighting. We also provide supportive evidence that the activation of the metaphoric link between loneliness and product preference through negative mood reflects an unconscious information processing route rather than a conscious one. Our findings also suggest that the effects of loneliness on product preference occurs only when the product has self-referent salience, supporting the notion that lonely people's preferences for products with bright but not dark ambient lighting reflect congruity between the ideal self and the product, and helps them avoid a state of motivational conflict (Sirgy, 1985). This is consistent with the notion that by avoiding products associated with a threatened aspect of identity, lonely people are able to view the self more positively (White, Argo, & Sengupta, 2012).

The current research should be considered in the context of several limitations and strengths. First, although we presented two different products in ambient lighting, it is unknown if the effects found will generalize to other product types and classes; they could be particular to desks/furniture. Future research is needed to address this issue. Second, the effects of product authorship on preferences were only tested for one product, a clothing item, as it was expected that preferences for clothing may more readily activate ideal-product congruity. Further research is needed to understand if this effect generalizes to other products. Despite these limitations, replicating the results across several studies with both chronic and situational loneliness and with large community and student samples are clear strengths of the research. Ruling out the competing hypotheses of product colour in Studies 1 and 2 also provides additional support for the hypotheses that the effects were due to the ambient lighting. Testing and ruling out the alternative hypothesis that the effects found were due to depression rather than loneliness is another clear strength of this research.

Our research provides novel insights into the meaning of background color in marketing that has important implications for marketing practice. Product ambient colors can be manipulated by 1) displaying a product in a bright (versus a dim) place in a retail setting, and 2) by featuring a product in an advertisement with bright or dim background color. Our research suggests that advertisement or retailing display featuring a product in a bright ambient lighting can be more effective if marketers consider the target segments' loneliness orientations. Marketing practitioners normally consider that white background color signifies cleanliness and purity, and black background color is positively associated with authority, prestige and exclusivity (Gorn, Chattopadhyay, Yi, & Dahl, 1997). Thus, in general, dark background color is used to denote cool sophistication and a powerful sense of extreme luxury or expense. Our research offers a caveat in using dark background color for advertisement or retailing product display. Because our findings indicate that lonely consumers prefer a product in a bright rather than dark background because the dark background activates negative feelings towards the product, they may not view products presented with dark ambient lighting as desirably as would non-lonely consumers. Accordingly, marketers need to be cautious in presenting products with a dark ambient background color as it may not have the intended effects on consumer preferences if their targeted market segment includes a substantial portion of lonely consumers.

Does Priming a Sense of Powerfulness Encourage Consumers to Buy Healthy Foods?

Cindy Wang, University of Oregon, USA
Jiao Zhang, University of Oregon, USA

EXTENDED ABSTRACT

Growing concerns about obesity and the associated health conditions including type II diabetes behoove researchers to study how consumers make food-related decisions. This research aims to further explore what factors influence individuals' perception and choices when they make decisions on what types of food to purchase and consume. We investigate how sense of power and message framing jointly influence individuals' willingness to engage in healthy eating and healthy food consumption in an effort to have an impact on the growing obesity epidemic.

In general, high power increases the processing fluency, directs consumers' attention to an option's positive features, and leads to a higher level of construal and a tendency to see "big picture. On the other hand, low power concentrates on the lower level of construal and shorter psychological distance (e.g. Magee Milliken, &Lurie, 2010). Healthy eating focuses on the long-term benefits of the food consumption, while indulgent eating focuses on the immediate benefits of food. As a result, we can infer that high power individuals are more likely to consume healthy food than indulgent food, while low power individuals are more likely to consume indulgent food than healthy food.

Recent research on message framing finds that an assertive (non-assertive) message is more effective in communications involving hedonic (utilitarian) products, (Kronrod, Grinstein, &Wathieu, 2012). Previous research also indicates that imperative and forceful messages tend to be perceived as a threat to personal freedom and foster reactance toward the message (Quick &Considine, 2008).

Healthy food consumption, which requires effort to comply, is normally easier for high power individuals. Tasty food consumption, which brings instant joy, is more preferred by low power people. This is because of the matched construal level between food types and power levels as we stated earlier. We suggest that when the food is promoted with an assertive tone, it can backfire because it raises reactance for people. When the reactance is activated, the consumption pattern will be reversed. However, when construal level of the product type and the individual's power states are inconsistent, assertive messages could be more motivating than baseline non-assertive messages. Therefore, we propose:

Hypothesis 1A: *High power individuals will exhibit higher purchase intention toward healthy (tasty) food when the message is non-assertive (assertive); low power individuals will exhibit higher purchase intention toward healthy (tasty) food when the message is assertive (non-assertive).*

Hypothesis 1B: *The reactance/motivation elicited by the assertiveness of the message is the underlying mechanism.*

STUDY 1

We proposed a one way (Assertive vs. Non-assertive) between subject design. 91 American undergraduate participants (M_{age}=20.6, 53.1%Male) participated for partial course credit. At the beginning of the lab session, we measure participants' chronic sense of power (Anderson, John, &Keltner, 2012). Then, participants were presented with a print ad about chocolate. We manipulate the assertiveness of the message at the bottom of the ad by saying "You must try our chocolate" or 'it's worth trying our chocolate". Then we ask participants to report their purchase intention. The spotlight analysis results showed that there is significant interaction effect of chronical power and message assertiveness on purchase intention. For one standard deviation above (below) the mean on chronical power, in other words, high (low) power participants, they were more likely to purchase the chocolate truffle product when the message is assertive (non-assertive).

STUDY 2

We proposed 3(Powerful vs. Powerless vs. Control) x2(Assertive vs. Non-assertive) between subject design. 244 American undergraduate participants (M_{age}=21.1, 56.3%Male) participated for partial course credit. We manipulated sense of power by using headlines of "we all feel powerful in the morning" or "we all feel powerless in the morning" (Adapted from Dubois et al., 2012). In the control condition, we do not have headline. We manipulate the assertiveness of the message as in study1. Then we ask participants to report their purchase intention and the motivation/reactance. For participants primed with powerfulness, the non-assertive message is preferred for healthy food consumption ($p<.01$). For participants primed with powerlessness, the assertive message is more preferred for healthy food consumption ($p =.19$). For control condition, the pattern resembled low power condition. The effect in high power group is partially significantly mediated by motivation/reactance to buy products from the brand.

STUDY 3

A 2(Powerfulness vs. Powerlessness) x2(Assertive vs. Non-assertive) x2 (chocolate vs. salad) between subject design was adopted. 231 North American adult participants (M_{age}=28.3, 60.5% Male) from Amazon Mechanical Turk participated and financially compensated for $.60. Study 3 adopted same design and similar stimuli with study2, only replaced cereal picture with chocolate truffles and salad pictures. We also included several potential process measures from previous literature and alternative explanations including information process fluency measures, message compatibility, ad perception, and ad evaluation. The results showed that when manipulated with powerfulness (powerless) feeling, participants were more likely to purchase the chocolate (salad) when the ad presented with assertive message, and were more likely to purchase salad (chocolate) when presented with non-assertive message. The mediation analysis results show that motivation/reactance to buy from advertised brand significantly mediate the moderation effect.

Study 4. We propose a 2(High vs. Low) x2(Assertive vs. Non-Assertive) x2(Positioning: Tasty vs. Healthy) between-subject design. 244 American undergraduate participants (M_{age}=21.9, 58.2% Male) participated for partial course credit. We used a pretested role-imaging task in an educational context (Garbinsky, Klesse, &Aaker, 2014) to manipulate participants' sense of power. Half of the participants were presented with the tasty (healthy) version of a yogurt where we added a headline saying "Sander's Mixed Berries Yogurt, The Tastiest (Healthiest) Yogurt!" The rest of the design was the same as study 3. Results showed that when the product was positioned as tasty, participants primed with high (low) power were

more likely to purchase the yogurt if it were assertive (non-assertive) message. When the product was positioned as healthy, the pattern reversed. Motivation to eat, and motivation to buy are significant mediators.

Across four studies, we showed that under high (low) power, individuals are more likely to consume healthy (tasty) food when the message is non-assertive and tasty (healthy) food when the message is assertive.

Politicized Purchasing: Consumer Responses to Divisive Corporate Political Activity

T.J. Weber, Washington State University, USA
Jeff Joireman, Washington State University, USA
David Sprott, Washington State University, USA

EXTENDED ABSTRACT

In the 2010 Citizen's United decision, the Supreme Court of the United States (SCOTUS) ruled companies can spend unlimited amounts of money on political causes. Consequently, companies have been making donations to causes that are not directly related to their financial performance. For example, Amazon, Chick-Fil-A, and Target have used resources to influence the debate over same-sex marriage, policy ostensibly unrelated to firm performance. More importantly, the position companies take on divisive issues has the potential to communicate to consumers that these companies have an underlying political orientation, which may or may not be in line with that of consumers.

The present research addresses this emerging issue by examining how divisive firm political involvement can alter consumer preferences. We find that consumers respond negatively when companies support causes that are inconsistent with the consumer's political orientation across three different public policy contexts. In addition, we demonstrate that perceived value overlap is the underlying mediator explaining consumer responses to divisive firm political involvement.

In the present research, we make three main contributions. First, we demonstrate that consumers typically respond negatively to firm political involvement implying a political orientation inconsistent with their own, but rarely respond positively to firm political involvement consistent with their own political values. Second, we demonstrate that divisive firm political involvement can affect product evaluations, such as perceived taste and quality of a cupcake, through perceived value overlap with the firm. Third, we offer practical implications for policy makers, practitioners, and consumer advocacy groups looking to better understand divisive firm political involvement.

THEORETICAL DEVELOPMENT

Corporate political activity (CPA) is consistently associated with positive financial implications for firms. However, if a company engages in political activity that cannot be directly tied to firm financial interest, it is likely that such activities will convey to consumers that the firm holds a particular political orientation. This adoption of an identifiable political orientation represents a paradigm shift in the influence, purpose, and nature of interaction between the public and private sectors. While firms historically engaged in firm political involvement exclusively for self-interest, firms now routinely donate to causes outside their obvious interests. Importantly, these forms of "political signaling" could also allow consumers to determine preferences based on the perceived political orientation of the company, supporting firms with similar political values and/or punishing firms that differ. Despite this, no studies have explored how this new wave of CPA affects consumer behavior, or why these effects may occur.

STUDY 1

270 participants read a news story detailing a fictional firm donating $500,000 to fight immigration reform (conservative condition), or support immigration reform (liberal condition). Participants in two additional conditions read that the firm was uninterested in joining the immigration debate (not interested condition) or moving offices (control condition). After reading the news story, participants responded to a manipulation check by indicating their impression of the political orientation of the firm as well as their brand attitudes and purchase intentions toward the firm. Lastly, participants indicated their political orientation.

Analyses revealed the liberal (conservative) condition was seen as significantly more liberal (conservative) than the control and conservative (liberal) conditions, providing support for a firm's ability to adopt a political orientation identifiable to consumers. Moderated regression analyses further demonstrate that consumers respond negatively when a company adopts a political orientation that is at odds with the consumers' political orientation, and limited support for a positive effect among very liberal consumers when a company is engaged in liberal CPA. Next, Study 2 tests for generalizability within a different policy domain (abortion).

STUDY 2

301 participants read a news story detailing a fictional firm donating $500,000 to support a policy limiting abortion rights (conservative condition) or opposing a policy limiting abortion rights (liberal condition). Participants then responded to the same items as Study 1. Results again indicated support for our manipulation check. Moderated regression analyses next found mostly negative effects for both conditions relative to the control and limited positive effects within the liberal condition for very liberal consumers. Next, Study 3A/3B tests the generalizability of this pattern with a different form of divisive firm political involvement (politically motivated business policies) in a third policy context (gay marriage).

STUDY 3A/3B

In Study 3A (n = 320) and Study 3B (n =327), participants viewed a fictional bakery's website detailing their policy toward serving LGBT weddings. Study 3A and 3B were run as identical studies before and after the SCOTUS decided Obergefell v. Hodges (2015) legalizing gay marriage. The bakery indicated they "proudly serve traditional marriages between women and men" (conservative condition), 'proudly serve marriages for customers of all sexual orientations' (liberal condition), or made no mention of LGBT marriage. Moderated regression analyses yielded a significant interaction term for each interaction on brand attitudes, purchase intentions, boycotting likelihood, positive word-of-mouth intentions, the dependent variables, and value overlap, the proposed mediator. Analyses of consumer reaction pre- v. post-SCOTUS suggests a reactive nature to consumers after the decision, with reactance driving significant changes to brand attitudes after the decision.

Next, we examined value overlap, the proposed mediator. Results revealed a significant indirect effect of the interaction on brand attitudes, purchase intentions, boycott likelihood, and positive word of mouth intentions through value overlap for both conditions, providing support for value overlap as the mediator. Study 4 tested whether this pattern extended to evaluations of an actual product.

STUDY 4

180 participants were assigned to one of the three conditions described in Study 3. Consistent with Study 3A/3B, results revealed a significant indirect effect of each interaction term on each dependent variable through identification with the bakery. Finally, results suggest the interactive effect of consumers' political orientation and the CPA related to gay marriage predicts perceived quality and taste of a cupcake, through value overlap, the mediator.

Study 4 provides strong support as both a replication of earlier results as well as our model's ability to predict downstream consequences on actual product evaluations. Together, Studies 1-4 strongly support of our conceptualization of divisive firm political involvement, and how it affects consumers.

The Bright Side to Cuing Consumerism: Consumer Primes Make Individuals with Low Childhood Socioeconomic Status More Prosocial

Jodie Whelan, York University, Canada
Sean Hingston, York University, Canada

EXTENDED ABSTRACT

There is no shortage of research detailing the dark side of cuing consumerism. Advertisements for and images of luxury consumer goods, descriptions of people shopping, and consumer terminology have all been shown to activate a proself orientation that ultimately undermines personal and social wellbeing. For example, after being exposed to consumer primes, people become more competitive, more solitary, more selfish, more likely to give up on difficult tasks, more dissatisfied with their appearance, and less interested in social relationships—including getting married and having children (Ashikali and Dittmar 2012; Bauer et al. 2012; Ku, Dittmar, and Banerjee 2014; Li et al. 2015).

Importantly, this literature assumes that consumer cues mean the same thing to everyone and consequently, affect everyone the same way. Here, we question this assumption. We draw on a growing body of research that demonstrates people's childhood social and economic environment can shape cognition in important and persistent ways and hypothesize that childhood socioeconomic status (SES) influences how people respond to consumer primes (e.g., Laran and Salerno 2013; Mittal and Griskevicius 2014). Specifically, because consumers with low childhood SES grow up with economic and social constraints that limit personal choice and instead, require mutual acts of interdependence (e.g., relying on, paying attention to, and trusting other people; Adams, Bruckmüller, and Decker 2012; Snibbe and Markus 2005; Stephens, Fryberg, and Markus 2011; Stephens, Markus, and Townsend 2007), we predict that individuals with low childhood SES will become more prosocial in response to consumer primes. Through testing this hypothesis, we offer a more nuanced understanding of the effects of consumer primes and provide one way to reconcile the budding controversy surrounding the replicability of these findings—particularly those of Bauer and colleagues (2012) (Francis 2014; Klein et al. 2016).

Four experiments provide support for our hypothesis. **Experiment 1** provides initial support for our premise by demonstrating that MTurk participants ($N = 79$) become less trusting and more competitive (as indicated by increased jealousy) after being exposed to brand logos. While we suspect this effect was driven by the lower childhood SES of our MTurk sample (an assumption that is confirmed by a post-test with 200 MTurk workers), we do not measure or test for the role of childhood SES. The remaining studies address this limitation

In **experiment 2**, American participants recruited from Prolific Academic ($N = 108$) were randomly assigned to a consumer or a control condition in a between-subjects main-effect design, wherein they either viewed advertisements (consumer) or shapes (control). Then, all participants completed the same jealousy task used in study 1, a five-item measure of competitive orientation (Roux, Goldsmith, and Bonezzi 2015; Ryckman et al. 1990), and a three-item measure of childhood SES (Griskevicius et al. 2011, 2013). Analyses revealed a main effect of condition, such that participants in the consumer condition were less competitive and less jealous. Importantly, these effects were moderated by childhood SES. When childhood SES was low (-1 SD) or at the mean, being exposed to the consumer prime made participants more prosocial. When childhood SES was high (+1 SD), the effect was not signifi-
cant. Mediation analysis also revealed that a decrease in competitive orientation fully mediated the effect of the consumer prime x childhood SES on jealousy, thus providing initial evidence for our proposed mechanism—the activation of a prosocial orientation.

In **experiment 3**, American MTurk workers ($N = 136$) were randomly assigned to a consumer or a control condition in a between-subjects main-effect design, wherein they either viewed images of brand logos (consumer) or vegetables (control). Participants then completed the Triple-Dominance Measure, designed to assess whether people are prosocial or proself (Van Lange, Otten, De Bruin, & Joireman, 1997). Analyses revealed a main effect of condition, such that participants in the consumer condition were more likely to be prosocial (vs. proself). Furthermore, this effect was moderated by childhood SES. When childhood SES was low (-1 SD) or at the mean, being exposed to the consumer prime made participants more prosocial. When childhood SES was high (+1 SD), the effect was not significant.

In **experiment 4**, undergraduate business students ($N = 94$) were randomly assigned to a consumer or a control condition in a between-subjects main-effect design. The procedure, manipulation, and dependent measures were the same as those of experiment 2, with the exception of our measure of childhood SES. Instead of asking participants to report their perceived childhood SES, we asked participants to indicate their household family income when they were growing up (Griskevicius et al. 2013; Mittal and Griskevicius 2014). Analysis revealed a significant interaction of condition and childhood family income on jealousy and competitive orientation. When childhood family income was low, participants in the consumer condition were less jealous and less competitive than those in the control condition. When childhood family income was high, participants in the consumer condition were more competitive and more jealous than those in the control condition. Mediation analysis also revealed that competitive orientation fully mediated the effect of the consumer prime x childhood SES on jealousy.

DISCUSSION

Although prior work has consistently shown that consumer primes result in more proself and less prosocial outcomes, the results of four experiments suggest these effects may be limited to individuals who grew up relatively wealthy. In particular, consistent with prior work demonstrating that childhood SES can shape cognition in important ways, our findings suggest that low childhood SES consumers may have different models of responding to consumer primes. Rather than becoming more proself after being exposed to consumer primes, in four experiments we find that low childhood SES individuals become more prosocial.

Direct and Indirect Signals of Demand in Retail Displays

Sarah Whitley, Boston University, USA
Remi Trudel, Boston University, USA

EXTENDED ABSTRACT

Consumers use scarcity cues as signals of quality and popularity to guide their consumption decisions (Caminal and Vives 1996; Jeong and Kwon 2012; Van Herpen, Pieters, and Zeelenberg 2009; Verhallen 1982). A well-documented scarcity cue is that of empty shelf space, which provides a visual signal of product demand, leading consumers to infer that a product's limited availability is a *direct* result of prior consumers' purchases (Van Herpen, Pieters, and Zeelenberg 2009; Van Herpen, Pieters, and Zeelenberg 2014). However, not all retail display strategies allow for the observation of direct signals of demand. Without direct signals of demand, it is not clear how uncertain consumers react to and utilize product displays as a source of information.

We investigate this question by exploring how consumers interpret product availability in an efficient assortment retail environment characterized by demand-based shelf allocations (Jenkins and Kornfeld 2003; Kurt Salmon Associates 1993) and fully-stocked shelves (Convenience Store Decisions Staff 2011; Flick 2012) which do not allow for the observation of direct signals of demand. We propose that when examining the aisle of an efficient assortment retailer, consumers will use allocation quantity as a cue of consumer demand. Efficient assortment retailers allocate more shelf space to popular products (Broniarczyk, Hoyer, and McAlister 1998; Curhan 1973; Kurt Salmon Associates 1993), and we expect that consumers will infer those highly available products displayed to be high in popularity. In this manner, we believe that consumers will interpret retailer product allocation quantities as an *indirect* signal of consumer demand by basing their assumptions on retailers' experience and sales expectations.

Overall we show that retailer inventory strategies dictate whether consumers can observe direct or indirect signals of demand from product displays, which ultimately lead to contrasting interpretations of product popularity from displayed product availability, impacting product choice. This work contributes to a growing understanding of consumer inferences from product displays and serves to inform both retailers and marketers about the consequences and compatibility of their inventory and signaling strategies.

To examine how retail environment impacts consumer choice, 197 Mturk participants viewed one of two displays of masked pasta sauce brands and select which sauce brand they would choose to purchase. The direct signal of demand display condition featured a shelf containing two brands with an equal number of potential shelf facings, yet one brand exhibited empty space, where a few jars had been removed, creating a cue of scarcity. The indirect signal of demand display condition featured a fully-stocked shelf of two sauce brands with one of the brands having a greater number of facings than the other; this condition is consistent with an efficient assortment inventory strategy. Across both conditions, we refer to the brand with the highest number of facings as being more available and the brand with the least number of facings as less available. Results featured a main effect of display condition on brand choice ($\chi^2(1) = 7.03$, $p < .01$); consumers in the direct signal condition were more likely (61%) to choose the less available brand while those in the indirect signal condition preferred (58%) the more available brand.

To further the generalizability of our effect of retail environment on choice, we conducted a study where participants made a real choice from an assortment of sodas. 78 business students filled out a short survey and were invited to select a free soda from an assortment of two brands of strawberry Japanese Ramune soda. The focal product was chosen under the assumption that subjects would not have prior brand associations; the two soda brands had similar bottles and colors to deter the potential for either brand garnering extra attention (Janiszewski 1998). Students chose from either a soda display arranged with a direct signal of demand (empty space) or an indirect signal of demand (fully-stocked but with disparate allocation quantities). Complementing the results of study 1, display condition significantly affected soda brand choice ($\chi^2(1) = 5.23$, $p < .05$); participants in the indirect signal condition were more likely (67%) to choose the most available brand, while participants in the direct signal condition were more likely (60%) to choose the least available brand.

We then performed a mediation study to show that the information consumers were gaining from product availability in our conditions was indeed informative of product demand and driving choice. Using the same stimuli as study 1, 124 Mturk participants saw a product display exhibiting either a direct or indirect signal of demand; participants then specified how popular they believed each sauce to be and indicated their preferred choice. A main effect of choice between display conditions was confirmed ($\chi^2(1) = 16.86$, $p < .01$) as well as significant differences in perceived popularity of the more ($F(1,116) = 35.81$, $p < .01$) and less ($F(1,116) = 5.78$, $p < .05$) available brands between display conditions. A mediation analysis showed that popularity ratings of more available and less available brands successfully mediated the link between display condition and product choice; consumers in the indirect signal condition perceived the more available brand to have high popularity which induced choice of that brand while consumers in the direct signal condition perceived the less available brand to have high popularity, driving choice of the less available brand.

Lastly, we tested the strength of direct versus indirect signals of demand. 114 undergraduates viewed a display of pasta sauces containing either an indirect signal of demand or mixed signals of demand. The mixed signals of demand condition contained both a direct demand cue of empty shelf space and an indirect demand cue of disparate allocation quantities; cues were arranged in opposition to each other to test the strength between the two signals. Display condition had a significant effect on brand choice ($\chi^2(1) = 7.03$, $p < .01$). Participants in the indirect signal condition chose the more available brand more often (66%). In the mixed signals condition, participants were more likely to choose the less available brand (59%); this result illuminates consumers' tendency to defect to direct signals over indirect signals of demand.

Anecdotal versus Statistical Evidence in Risk Communication Messages: The Moderating Effects of Comparative Optimism and Message Framing

Marina I. Wieluch, Bundeswehr University Munich, Germany

EXTENDED ABSTRACT

Social marketing messages often seek to persuade individuals to cease or reduce risky behavior, for instance, speeding or smoking (Lee and Kotler 2011). The present study focused on the relative effectiveness of two different evidence types that social marketing messages may use to support their appeals, that is, anecdotal evidence and statistical evidence. Both evidence types appear regularly in risk communication messages. With regard to the relevant question of which evidence type is more effective, the literature reports contradictory findings (e.g., Allen and Preiss 1997, De Wit, Das, and Vet 2008, Greene and Brinn 2003). Thus it seems relevant to search for conditions under which one of the evidence types may have a persuasive advantage–potentially leading to recommendations when to use anecdotal evidence and when to use statistical evidence.

This research examines the moderating effects of message framing and comparative optimism. Previous research shows that an important driver of risky behavior is comparative optimism (Weinstein and Klein 1996): Some individuals perceive themselves, compared to others who show the same risky behavior, to have a lower risk of experiencing certain negative life events (Armor and Taylor 1998). However, previous research suggests that these individuals are challenging to reach and that statistical evidence may not be effective in persuading this important target group (Czerwinka and Praxmarer-Carus 2014).

The present study compares the persuasiveness of positively and negatively framed anecdotal and statistical evidence in risk communication messages and takes comparative optimism as a potential moderating variable into account. Based on prior research (e.g. White, MacDonnel, and Dahl 2011) it was predicted, that the combination of anecdotal evidence and negative message framing as well as the combination of statistical evidence and positive message framing should be easier to process and thus be more persuasive compared to positively framed anecdotal and negatively framed statistical evidence.

Furthermore, it was predicted that this effect would depend on comparative optimism. Based on prior research (e.g. Schwarz 2004), the persuasive advantage of negatively framed anecdotal and positively framed statistical evidence was expected to increase with increasing comparative optimism. Finally, it was proposed that, as comparative optimism increases, the persuasive advantage of negatively framed anecdotal evidence over positively framed statistical evidence should increase. This effect was not expected to occur among non-optimistic individuals.

Hypothesis 1: *Message framing and evidence type interact, such that*
a. *Negatively framed anecdotal evidence leads to higher compliance with risk communication messages than positively framed anecdotal evidence.*
b. *Negatively framed statistical evidence leads to lower compliance with risk communication messages than positively framed statistical evidence.*

Hypothesis 2: *Comparative optimism, message framing and evidence type interact:*
a. *When comparative optimism increases, the persuasive advantage of negatively framed anecdotal evidence over negatively framed statistical evidence increases.*
b. *When comparative optimism increases, the persuasive advantage of positively framed statistical evidence over positively framed anecdotal evidence increases.*
c. *When comparative optimism increases, the persuasive advantage of negatively framed anecdotal evidence over positively framed statistical evidence increases.*

A study in the context of smartphone usage while driving (N=401) was conducted online. The study used a 2 (evidence type) x 2 (message framing) between subjects design. Before participants saw one of the messages, comparative optimism was measured as the difference between the personal risk assessment and the risk assessment for a similar other. Respondents indicated their intention to reduce their smartphone usage while driving on a 7-point likelihood scale. A regression-analysis following the procedure for moderated moderation by Hayes (2013) was conducted to test the proposed interaction between evidence type and message framing as well as the moderating effect of comparative optimism. In line with hypothesis 1, results showed a significant interaction effect between evidence type and message framing [$b = 3.12$, $t(391) = 2.897$, $p = .004$].

In addition, the three-way interaction between evidence type, message framing and comparative optimism was significant [$b = .65$, $t(391) = 3.203$, $p = .002$]. Results showed that the conditional effect of the interaction between evidence type and message framing differs depending on comparative optimism. Table 1 reports the estimated values of behavioral intention for two groups: individuals high in comparative optimism and individuals low in comparative optimism (mean +/-1sd).

Further analysis of these estimated values supported the assumption, that negatively framed anecdotal evidence and positively framed statistical evidence is especially persuasive for the highly optimistic target group (hypotheses 2a and 2b). Differences between these estimated values indicated the proposed pattern: the persuasive advantage of negatively framed anecdotal over positively framed statistical evidence increased with increasing optimism (hypothesis 2c).

The current study contributes to previous research on the effectiveness of anecdotal and statistical evidence as it sheds light on conditions for the persuasive effect of the two evidence types. In addition, this research advances knowledge on information processing as it shows the influence of comparative optimism on information processing. Findings suggest that social marketers should use negatively framed anecdotal evidence in their risk communication messages, when the target group is highly optimistic. This may particularly be the case for risky behaviors individuals perceive as highly controllable by taking preventable actions (Weinstein 1984), such as speeding, smoking, binge drinking, sexually transmitted diseases and the like.

Consumption Skill Acquisition in Ski Schools:
Towards a Theory of Embodied Learning

Niklas Woermann, University of Southern Denmark & University of Constance, Germany
Verena E. Stoeckl, University of Innsbruck, Austria

EXTENDED ABSTRACT

Consumption skills are vital prerequisites for realizing identity projects, community membership, and value co-creation. Consumer researchers have repeatedly acknowledged the benefits of skills—the bodily capacity to do something well—and the importance of skill acquisition to consumers with regard to experiences, identity construction, or status (e.g., Arnould and Price 1993; Golding, Shankar, and Canniford 2012; Tumbat and Belk 2011).

However, while many studies in consumer research find that consumption skill level is variable and can be acquired over time, no systematic study has focused on how consumers acquire skills in dedicated learning settings. Most studies assume that skills 'automatically' increase with experience, or that consumers acquire skills through trial-and-error. Hence a broad range of market offerings remains understudied that seek to teach consumers new skills through dedicated exercises and various forms of instruction.

In this paper, we review how existing studies conceptualize skill acquisition and find a number of quite different acquisition modes described in the consumer research literature. We complement existing research with an exploration of how consumption schools enable and facilitate consumption skill acquisition through different schooling practices. Focusing on the context of ski schooling, we find that none of the different skill acquisition modes described in the literature dominates, but rather that instructors alternate between schooling practices that entail a variety of different acquisition modes. We systematize these modes and compare them to prior literature in order to lay the foundation for a more systematic theory of embodied learning.

Bodily skills form the bedrock on any human activity (Merleau-Ponty 1962) and thus appear in many different contexts and range from basic and ubiquitous to highly specialized and difficult. We discuss skill acquisition using a tri-part scheme that acknowledges the interconnected domains of 1) bodily or muscle movements, 2) the conscious state of skillful coping, and 3) the socially assembled (learning) situation. Being skilled means to experience one's bodily doing as suitable to deal with the practical demands of the situation at hand, and hence restricting the analysis to either domain would lead to an impoverished understanding of the phenomenon.

1. *Bodily or muscle movements:* Developmental psychologists (Burton, Brown, and Fisher 1984), sport scientists (Duesund and Jespersen 2004), and consumer researchers presenting both experimental (Murray and Häubl 2007) and cultural studies (Joy and Sherry 2003) agree that at the core of skill acquisition or bodily learning we find a basic mechanism of repetitive sequential learning. The more a body or its muscles repeat a certain movement, the better they 'remember it' and the movement then becomes refined.

2. *The conscious state of skillful coping*: Following the lead of Joy and Sherry (2003), we draw on the phenomenology of embodiment (Merleau-Ponty 1962) to conceptualize skill and skill acquisition. In doing so, we seek to understand possessing skill as being tied to an experience of being skilled at something. We neither look at the body as a kinetic machine that is functionally or ontologically independent from conscious experience or merely executing

commands; nor do we conceive of the conscious mind as independent from, or prior to, the moving body.

3. *The socially assembled (learning) situation:* Skillful conduct requires a socio-material assemblage organized towards affording the activity (e.g., Canniford and Shankar 2013; Hill, Canniford and Mol 2014). The assemblage enwrapping the situated body must allow details of body movement to recede into the background of experience to give the practitioner a sense of skill and control. The learning situation is arranged so that focus is directed towards details that require control and change—such as the shoulder rotation in skiing—and away from other that can block progress—such as the fear of falling.

To explore modes of skill acquisition in an empirical and systematic manner we conducted a video-based ethnographic study in several ski schools. Our data base encompasses 18 hours of video from observations of different classes in two ski schools, 16 interviews with instructors and experts in the ski industry, and 16 informal interviews with skiers. In several rounds of moving between explanations of bodily movement by skill instructors, to consumers' descriptions of critical learning moments, to situational examples from our video material, a recurrent set of modes of skill acquisition emerged.

We find that skill acquisition in ski schools happens primarily in carefully assembled learning situations which combine a number of socio-material resources such as space, ski equipment, social roles and norms, verbal instructions, gestures, and interaction orders. We identify six types of skill acquisition modes that represent different constellations of bodily movements, conscious focus, and the social structure of the learning situation, in particular the relation between the instructor's and learners' doings. We organize these practices into two groups:

I. Learning by Doing in which skill acquisition and refinement happens (consciously or pre-consciously) over the course of performing the aspired practice: Repetition, Reflection and Emulation.

II. Forms of Training, understood by us as learning practices in which learners do something else than performing the activity they eventually seek to learn: Demonstration, Instruction, and Exercise.

Three key implications stand out. First, the sensory-motor system, conscious experience and social assemblage are structurally coupled but separate in that none has full control over the other. Since skillful coping requires the three to be in a state of smooth alignment (Woermann and Rokka 2015), teaching a skill requires well-placed interventions into the learner's performance. Second, consciousness functions as a pivot between the situational assemblage (including the task at hand, the spatial, and material setting, and the interaction with the teacher) and the learner's motor system. The ski instructor cannot teach consumers' bodies directly, but must work via their conscious experience. Third, this means that an adequate understanding of consumption skill acquisition must pay special attention to consumer experience and particularly emotional states such as fear, failure, and frustration. Overall, we encourage consumer researchers to pay particular attention to the powerful interactive forms of skill acquisition which seem to be instrumental for acquiring skills, and, ultimately, for gaining access to abundant rewarding consumption experiences.

Mental Traveling Along Social and Temporal Distances: The Influence of Cultural Syndromes on Construal Level

Vincent Chi Wong, Lingnan University, China
Robert S. Wyer Jr., Chinese University of Hong Kong, China

EXTENDED ABSTRACT

A formulation of the way people construe the implications of events is provided by Trope and Liberman (2010). This formulation, known as construal level theory, specifies the manner in which an event's psychological distance (which can be temporal, social, spatial, or uncertainty) affects the abstractness of the constructs that are typically applied to it. People are assumed to construe the world from an egocentric reference point that includes oneself and one's immediate surroundings and to perceive the distance of objects and events in relation to this point. Thus, psychologically distal events and objects are represented in terms of more general features, whereas psychologically proximal stimuli are construed in terms of more concrete, situation-specific features.

However, the impact of cultural orientation on the nature of these construals has seldom been investigated and moreover has had inconsistent implications. Some studies suggest that individualists (Westerners) think more abstractly than collectivists (Easterners) (e.g., Cousins 1989), whereas others suggest the opposite (e.g., Spassova and Lee 2013).

We provide an integrated framework in examining the antecedents of construal level that implies interactive effects of general cultural orientations (e.g., individualism/collectivism and short/long-term orientation) and psychological distance on construal level.

People are mental travelers along social and temporal distance, and can imagine themselves at different points along these dimensions (e.g., Kross and Grossmann 2012). Specifically, it is possible that when estimating egocentric distance, people actually mentally travel away from themselves in the here and now and stop when they feel that they have reached far enough (Liberman and Forster 2009). Individual differences, however, in the flexibility of perspective shifting may exist.

When making decisions for others or predicting others' decisions (a socially distant situation), persons may construe the decision-related events more concretely if they shift flexibly into the others' positions (thus perceiving them as socially closer) than if they are less flexible to shift perspective. When making decisions for selves, however, flexible persons traveling into others' positions may view themselves from a distance and construe the decision-related events more abstractly than persons without this disposition.

Individual differences of flexibility of shifting can also exist along a temporal dimension. People who shift flexibly in to the future context should construe future events more concretely than inflexible individuals. Also, flexible people who shift to a future time point may view present events from a temporal distance and construe them more abstractly than those who view present events from the perspective of the present (i.e., inflexible travelers).

Previous research has examined how cultural orientation shapes individuals' tendency to shift perspective along social and temporal dimensions (Lastovicka et al. 1999; Oyserman, Coon and Kemmelmeier 2002). Specifically, members of a collectivist culture may tend to adopt the perspective of another in order to understand social environment and maintain interpersonal harmony, and thus, cultivate a tendency to shift to others' positions. Individualists, on the other hand, are more likely to take a self-centered perspective, and thus, travel inflexibly to others' positions. Moreover, representatives of a long-term orientation (LTO) culture may be disposed to project themselves into the future when making decisions, developing a flexible shifting along temporal dimension. Comparatively, members of a short-term orientation (STO) culture may attach more importance to here and now, and shift inflexibly when projecting themselves into future (Bearden, Money, and Nevins 2006).

These considerations suggest that collectivists will construe events more concretely than individualists do when the events pertain to others, but will construe them more abstractly than individualists do when the events concern themselves. Similarly, persons with a long-term temporal orientation should construe events more concretely than those with a short-term orientation when the events occur in the future but more abstractly than the latter individuals when the events occur in the present.

Experiment 1 investigated the interactive effects of individuals' temporal orientation (short- vs. long-term orientation) and temporal distance. We first primed short- vs. long-term orientation by a writing task in which they wrote either experience that focused on treasuring here and now (short-term orientation condition), or planning for the future (long-term orientation condition; Kopalle, Lehmann, and Farley 2010). We then described an apartment with desirable abstract but negative concrete features and asked participants either to report intention to move into it now or 1 year later. As expected, long-term orientation participants evaluated the apartment more favorably than short-term orientation participants when they made decision for immediate, but less favorably than short-term orientation participants for moving intention of future.

Experiment 2 investigated the interactive effects of individuals' social orientation (individualism/collectivism) and social distance. We first primed individualism/collectivism following Gardner, Gabriel and Lee's (1999) Pronouns Circle Task. We then described the same apartment as in experiment 1 and asked participants either to evaluate it for themselves or to predict a stranger's reactions to it. As expected, collectivists evaluated the apartment more favorably than individualists when they made decision for themselves, but less favorably than individualists when they predicted the reactions of a stranger.

The effects of temporal and social orientations on construal level that I observed in Studies 1 and 2 were specific to the dimension to which these orientations directly pertained. According to my conceptualization, however both social orientation and temporal orientation influence determine the flexibility of perspective taking along dimensions to which they are not directly related. That is, temporal orientation should influence the abstractness of concepts applied along a social dimension in much the same way it influences concepts applied along a temporal dimension. Correspondingly, social orientation should also influence the abstractness of construals along both social and temporal dimensions. Studies 3 and 4 investigated these possibilities, and the results echoed to our conceptualization and results of study 1 and 2. Across the four studies, bootstrapping analyses were performed using process Model 14 (Hayes 2009) confirmed the mediation role of perspective flexibility,

The present research reconciles the mixed findings of previous research on the effects of cultural orientation on construal level. Moreover, it provides preliminary evidence that CLT may not be universal across cultures.

Preference Gap Matters: When Scarcity Polarizes versus Converges Preferences

Yuechen Wu, University of Maryland, USA
Meng Zhu, Johns Hopkins University, USA
Rebecca K. Ratner, University of Maryland, USA

EXTENDED ABSTRACT

Previous research suggests that scarcity polarizes preference (Zhu and Ratner 2015), consequently increasing consumers' liking of the already more-preferred alternative and decreasing the liking of the less-preferred alternative. But, what if a priori the customer does not have a strong preference for one option over the other? Will scarcity polarize, or alternatively converge, the consumer's preference towards the two similarly preferred options?

The goal of the present research is to examine when and why scarcity might converge versus polarize consumer preferences.

Scarcity has become a widespread marketing strategy. Extant literature on scarcity has focused on scarce supply of a single item and how object-specific scarcity increases desirability of the particular item (Amoldoss and Jain 2005). Yet, our understanding of how consumers make choices among a set of items which are all scarce or abundant remains limited. In a notable exception, Zhu and Ratner (2015) show that overall scarcity of items increases the attractiveness of the a priori most-preferred item but decreases the attractiveness of the less-preferred items, leading consumers to choose more of the favorite item. However, Zhu and Ratner employed choice sets in which consumers have rather strong preferences for one option over the others. In the current work, we extend our investigation to situations where individual do not have a priori more-preferred choice alternative.

Consumers are faced with numerous choices. Sometimes they have a strong preference for one option over the other, but other times their prior preference gap among the choice alternatives is small. The primary objective of this research is to examine whether the impact of scarcity on preference within a choice set is affected by the extent to which consumers prefer one choice alternative over another. Building on several streams of research suggesting a possible connection between scarcity and attention narrowing (Cialdini 2009; Mullainathan and Shafir 2013), we predict that while scarcity polarizes preferences when consumers' prior preference gap is large, scarcity converges preferences when consumers' prior preference gap is small. Further, we explore whether the preference convergence arising from scarcity leads to negative downstream consequences, such as increased decision difficulty and decreased decision satisfaction.

We also explore the underlying process from scarcity to preference polarization and preference convergence. Prior research has theorized a connection between scarcity and attention narrowing (Cialdini 2009; Mullainathan and Shafir 2013). Building on findings that consumers have the propensity to reduce the processing strain by basing their choice on the most important attributes (Tversky, Sattath, and Slovic 1988), we suggest that consumers faced with narrowed attentional focus induced by scarcity are even more likely to selectively attend to cues that have high information value at the expense of cues that have limited information value when making decisions (Mandler 1975; Mano 1992, 1994; Paulhus and Lim 1994). The disproportionate attention given to primary (vs. secondary) attributes subsequently leads to either preference polarization or preference convergence, depending on the size of prior preference gap.

Study 1 supports our hypothesis that scarcity converges preference when the initial preference gap for options is small. Participants were asked to choose between two similarly liked candies that were customized for each participant based on their initial likings towards six types of candies. Participants were told that we had either limited quantities (scarcity condition) or large quantities (abundance condition) of each type of candy. As expected, when consumers have close prior preferences towards the options, scarce versus abundant supply of each alternative reduces the discrepancy between the likings of the choice alternatives, subsequently increasing perceived decision difficulty.

In study 2, we employed an incentive-compatible test to investigate whether scarcity leads to preference convergence and preference polarization respectively, when the prior preference gap is small versus large. Participants were presented with four pairs of gift cards with four different levels of initial preference gaps. Each pair of gift cards was customized for each participant based on their initial likings towards gift cards from eight different apparel retailers. Participants were told only a few (scarcity) or many (abundance) gift cards from each store are remaining. After choosing a gift card from each of the four pairs, participants were asked to rate their likings towards the gift cards again. The results show that compared to abundance, scarcity leads to preference polarization when the initial preference gap is large; more importantly, we find that with the initial preference gap declining, preference polarization attenuates and ultimately reversed. As preference convergence emerges, consumers experience lower satisfaction when making the decision.

Study 3 directly tests the premise that scarcity leads to a narrowed attentional focus on primary versus secondary attributes. Participants were asked to imagine that they were looking for a new apartment and had narrowed down to two options. After the scarcity manipulation, participants were informed that they had access to information of the two apartments on two attributes and they could check on the information only when they hover their mouse on the attribute of interest. As predicted, we find consumers under the constraint of scarcity devoted a larger share of their time checking on information of the primary (vs. secondary) attribute.

Study 4 further examines the attention-narrowing process, demonstrating that preference convergence triggered by scarcity can be attenuated by experimentally expanding participants' attention on other attributes. Attention expansion was manipulated by presenting the participants with unrelated examples of how people compare multiple attributes to make a decision. Adopting similar protocol of study 2, participants were presented with two customized pairs of gift cards with large and small initial preference gaps. Results show that when participants are primed to allocate their attention more evenly on primary vs. secondary attributes when making choices, preference convergence effect attenuates, which in turn leads to lower decision difficulty.

To summarize, we find scarcity polarizes or converges preferences, depending on the size of prior preference gap towards options. Preference convergence arising from scarcity consequently increases decision difficulty and decreases decision satisfaction. Process evidence show that scarcity narrows consumers' attention on primary (vs. secondary) attribute, leading to these effects.

Hypothesis 1A: *When consumers have small prior preference gap towards the options in the choice set, scarcity converges preferences, decreasing the discrepancy between the liking of the choice alternatives.*

Hypothesis 1B: *When consumers have large prior preference gap towards the options in the choice set, scarcity polarizes preferences, broadening the discrepancy between the liking of the choice alternatives.*

Hypothesis 2:   *Overall scarcity versus overall abundance of options contained in a choice set narrows consumers' attention on primary versus secondary attributes of the choice alternatives.*

Hypothesis 3:   *The impact of scarcity on preference within a choice set will be attenuated when consumers broaden their attention to secondary attributes of the choice alternatives.*

Disfluency Effects on Inference and Evaluation

Ruomeng Wu, University of Cincinnati, USA
Esta D. Shah, University of Cincinnati, USA
Frank R.Kardes, University of Cincinnati, USA

EXTENDED ABSTRACT

Prior research shows that fluency leads to positive consequence, while disfluency leads to negative consequence (Schwarz, Bless, Strack, Klumpp, Rittenauer-Schatka and Simons 1991; Reber, Winkielman and Schwarz 1998; Reber and Schwarz 1999; Winkielman and Fazendeiro 2003; Reber, Schwarz and Winkielman 2004; Unkelbach 2006, 2007; Novemsky, Dhar, Schwarz and Simonson 2007; Song and Schwarz 2008; Tsai and McGill 2011). For example, disfluency can lead to disliking (Reber et al. 1998).

Our research confirms prior research by showing that compared to normal information which is easy to process, difficult-to-process information lead to unfavorable evaluation and reduced purchases.

Although Consumers are usually insensitive to missing information by focusing on given information to form judgment and make decision (e.g. Sanbonmatsu, Kardes, and Sansone 1991), our research suggest that disfluency increases the sensitivity to incompleteness by encouraging individuals to question their first impressions during problem solving (Alter et al. 2007; Song and Schwarz 2008). This sensitivity to incompleteness contributes to disliking of disfluency.

In Study 1, we showed that difficult-to-read contrast color led to lower perceived information sufficiency, contributing to lower product evaluation and purchase intention.

Despite the negative consequence of disfluency, prior research shows that disfluency may be neglected or even valued under some circumstances (Galak and Nelson 2010; Deval, Mantel, Kardes and Posavac 2012).

Prior research demonstrates that the negative consequence of disfluency can be reduced or eliminated through debiasing technique, such as making consumers attribute the processing difficulty to the disfluency itself rather than the information or the product (Schwarz et al. 1991; Novemsky et al. 2007). Explicitly warning people of the difficulty (a debiasing technique) undermines the informational value of the disfluent experience, leading to a similar consequence as in the normal condition (Novemsky et al. 2007). Yet, only a limited number of literatures looks at conditions when debiasing techniques do not function or even backfire (Sanna and Schwarz 2003, 2006; Sanna, Schwarz and Stocker 2002). And hardly has any literature looked at how personal traits function on debiasing techniques. In the present research, we explore how individual traits influence how people attribute processing difficulty. Specially, we study how need for cognitive closure (Kruglanski and Webster 1996) and consistently time pressure (Heaton and Kruglanski 1991) influence consumers' evaluation based on warning of disfluency.

Our research shows that when brand information has been known, highs would base their evaluation on this earliest judgmental cue by neglecting the disfluency of the product information. When they are warned of the disfluency, their attention would be transferred to disfluency by using it as the primary judgment cue. Lows would avoid the influence of disfluency on evaluation when warned, since they have consider the product information at the first place.

In Study 2, Study 3a and Study 3b, we explored the role of explicit warning of disfluency based on need for cognitive closure (NFCC). In all 3 studies, disfluency was manipulated via easy-to-read font versus hard-to-read font.

Study 2 shows that when brand information had been known, consumers high and low in NFCC would differ in attribution based on warning. Consumers low in NFCC would adjust evaluation as more favorable after being warned. Consumers high in NFCC would form even more moderate evaluation when warned, as warning transferred their attention from brand to disfluency. Study 3 manipulated NFCC through high or low time pressure, and the results confirmed the findings in Study 2. In Study 3b, we deleted information about the brand, and found that when no brand information is shown, the difference between participants would disappear, such that all participants would adjust evaluation to higher when warned of disfluency. Different responses to warning of disfluency of participants high and low in NFCC or under time pressure, is based on whether brand has been known prior to disfluent information.

Nevertheless, warning of disfluency has no function on sensitivity to incompleteness. We believe that is because sensitivity to incompleteness is an implicit cognition. When a cognition (i.e. sensitivity to incompleteness), is implicit however, explicit warning may not function on correct attribution at all, since it's hard for individuals to adjust the deeply rotted implicit attitude (e.g. Forehand and Perkins 2005). When warned of disfluency, participants may realize disfluency impacts their evaluation so that they can adjust evaluation accordingly, but may not be able to adjust their sensitivity to incompleteness due to its impliciticness.

In Study 4, a response latency task was used to further test disfluency's influence on sensitivity to incompleteness. Disfluency was manipulated via easy-to-read versus hard-to-read word-background contrast color. When the information was easy to read, participants responded more slowly to previously absent information than to previously present information, indicating an insensitivity to incompleteness in normal cases. When the information was hard to read, however, the difference disappeared. Participants responded equally fast to both present and absent information, indicating an increased sensitivity to incompleteness. Study 4 confirms findings of former studies, such that disfluency increases sensitivity to information incompleteness, attributing to unfavorable evaluation. This sensitivity is an implicit cognition.

The Effect of Self-Target Comparison in Perspective Taking on Judgment of Dishonesty

Guang-Xin Xie, University of Massachusetts Boston, USA
Hua Chang, Towson University, USA
Tracy Rank-Chrisman, University of Wisconsin - Milwaukee, USA

EXTENDED ABSTRACT

The act of lying occurs when people provide others with false information (Burgoon et al. 1999), which, at times, involves self- or other-benefiting dishonesty (Argo and Shiv 2012). Recent research suggests that people in general, consumers, and marketers alike, lie without deeming themselves dishonest, as long as the lie is small enough (Mazar, Amir, and Ariely 2008). People assume that small lies are perceived inconsequential and sometimes unintentional; thus, they can distance themselves from otherwise severe condemnations (Shu, Gino, and Bazerman 2011). In effect, people can then manage or maintain an honest self-concept despite having told a lie. In the present research, we examine an intriguing question through the lens of "perspective taking." If consumers and marketers both lie, how do consumers judge marketers' act of lying? More specifically, do consumers apply the rule of reciprocity and tolerate dishonesty to some extent? Or do they dissociate themselves from marketers regardless of potentially similar acts of dishonesty?

In four studies, we explore the effects of self-target assimilation and contrast in perspective taking and their effects on social judgments of a dishonest target. Study 1 used a measurement-of-mediation approach to investigate the effects of self-target assimilation and contrast on observers or buyers' attitudes toward a dishonest seller. Study 2 manipulated assimilation and contrast directly and categorized a car salesperson's dishonesty as ambiguous (vs. blatant). Study 3 replicated the differential effects of assimilation and contrast in a different context (i.e., covert marketing). Finally, study 4 revealed the role of self-anchoring in self-target contrast by measuring the degree of perspective-takers' vicarious honesty.

The findings contribute to the literature in three ways. Foremost, this research introduces a novel concept, self-target comparison, to the perspective taking literature; and empirically demonstrates the differential effects of two distinct underlying mechanisms: self-target assimilation and contrast. Ku, Wang, and Galinsky (2015) conclude that previous studies mainly rely on "self-other overlap" to explain the perspective taking effects under circumstances where perceivers' self-concepts are accessible (e.g., Ames, Jenkins, Banaji, and Mitchell 2008; Davis, Conklin, Smith, and Luce 1996). The present research suggests that perspective-takers project themselves acting similarly (e.g., lie) or differently (e.g., do not lie) when compared to a dishonest seller in marketplace exchanges. We conceptualize this mechanism with parsimonious terms of assimilation and contrast. Both concepts refer to perspective takers' cognitive activities to consider resembling or diverging from the dishonest target's actions. In particular, we argue that "self-other overlap" is a metaphorical term describing perspective takers' mental processes of associating with the target's prototypical traits (e.g., race, age, profession) at a subconscious level. By contrast, we argue that self-target assimilation or contrast is a context-specific mental projection of how the perspective taker would consciously act given a particular situation. Acknowledging that perspective-takers do not necessarily "merge" self-descriptive traits (positive or negative) with the target's, will open up new avenues of research.

Another important implication is that we distinguish "elaborative-" from "intuitive-" perspective taking. We noticed that the perspective taking manipulations in some study designs encourage participants to engage in an automatic, less thoughtful, and pro-target process. A classic example is when researchers ask participants to take the perspective of another person by asking them to "put yourself in his or her shoes." We argue that while these instructions encourage participants to take the target's perspective, the semantics of such instructions may prime perspective-takers to align their stances with the target's (i.e., assimilation) intuitively. By contrast, when the perspective taking manipulation encourages participants to engage in more elaborative thinking, new findings may emerge. For instance, Trötschel et al. (2011, p. 775) asked participants during personal negotiations to "focus on other party's perspective, such as the other party's intention and interests in the negotiation." Perspective-takers were more likely to exchange concessions on low- vs. high-preference issues by identifying the potential of integrative gains (i.e., mutually-beneficial).

In line with these recent findings, this work provides further evidence of the effects that result with more elaborative reasoning, when participants were asked to think about acting similarly or differently compared to the dishonest target (study 2). In particular, study 3 shows that when the degree of taking the target's perspective was held constant, contrast and assimilation caused different attitudinal responses towards the dishonest seller. In study 4, when perspective takers thought of a particular dollar amount to tell the buyer, those who indicated they would act dishonestly (vs. honestly) appeared to have a more positive attitude towards the seller. In essence, these results together suggest that perspective taking may involve a deeper, more effortful, and more deliberate type of processing. We argue that this process in perspective- taking is different from favoring the target based on easy-to-access heuristics, which appears to be largely influenced by research designs in the literature (see more examples in Hoever, Knippenberg, van Ginkel, and Barkema 2012).

Last, this research provides an unconventional approach to examining how consumers react to marketplace dishonesty. Most studies in the literature suggest that consumers naturally guard themselves against deceptive practices in the market (e.g., Darke and Ritchie 2007). The present research shows a less intuitive type of response - when consumers consider acting similar to (vs. dissimilar to) a dishonest seller, they are more inclined to react less negatively. However, this effect appears to be salient only when the sellers' dishonesty is ambiguous (vs. blatant). Further, if primed to think about honesty, perspective-takers are more likely to experience the contrast effect. As a result, they apply a harsher evaluative standard when judging a dishonest seller. Together, the results from four studies suggest that consumers tend to follow the rule of reciprocity and tolerate dishonesty, but only to a limited extent.

Sweet or Sweat, Which Should Come First:
The Sequence Effect of Justification

Shaoguang Yang, Fudan University, China

Liyin Jin, Fudan University, China

EXTENDED ABSTRACT

People are around of vices and virtues. When we plan our meals, we constantly hesitate about whether to eat something tasty but unhealthy, like fried chips, or something healthy but tasteless, like a green salad. When we plan our schedule, we are constantly torn by whether to work or to play. Most of previous research explored what determines the choice between a vice and a virtue. In this case, choosing one option means giving up the other one. For instance, researchers find that when consumers decide which to give up, they value the vice item more than the virtue one, whereas when they choose which to acquire they value the virtue one more (Dhar & Wertenbroch, 2000).

Some other research offered participants a chance to have both a virtue and a vice simultaneously to explore how it is different from a single choice. Fishbach and Zhang (2008) demonstrate that when vice and virtue are presented together in one picture and seem to complement each other, the vice is preferred over the virtue; while when they are presented apart and seem compete with each other, the preference is reversed. Besides, researchers try to bundle vice and virtue together to examine consumer's preference. They suggest that people like the bundle with 75% virtue and 25% vice most in that the virtue part can help them justify the guilt of consuming the vice (Liu, Haws, Lamberton, Campbell, & Fitzsimons, 2015).

However, if we adopt a dynamic point of view, all these choices compose a series of vices and virtues. For instance, we may intend to go shopping online for the first one hour and then read papers after that; or vice versa. Therefore, we not only choose content of options, but also their sequence. The current research proposes that the sequence of consuming can exert great influence on consumer experiences. Existent evidence about how sequence matters includes that when the last chocolate is emphasized, it is more enjoyable and tastes better than the previously eaten chocolates (O'Brien & Ellsworth, 2012). Also, sequential evaluation of calories in a vice or a virtue can lead to different calorie estimations (Chernev, 2011).

Nevertheless, why does the sequence of consuming vice and virtue influence consumer experiences? Previous research illustrates that, inherently, it is more difficult to justify vice goods or activities compared with virtue ones. Okada (2005) shows that the vice is preferred over the virtue when either is presented separately, but the virtue is preferred over the vice when the two are presented jointly. This finding demonstrates that when people are reminded that there is a virtue, it is hard for them to justify choosing a vice. In addition, it has been confirmed that people love having fun, and they are more likely to have fun if the situation allows them to justify it. For example, Kivetz and Simonson (2002) find that after people exert effort to acquire vice goods, they feel that they have earned the right to indulge.

Based on these findings, the current research hypothesized that consuming or doing things in the sequence of vice-virtue (vice first and then virtue) leads to better experience than that in a reversed sequence. In particular, if individuals consume or do something vicious first, the guilt increases. And then if they consume or do something virtue, the subsequent virtue can help justify the guilt, which in turn leads to a better overall experience. However, if they try in a reversed sequence, the preceding virtue is not able to justify the latter vice,

which in turn lowers the overall experience. Four studies were conducted to test the hypothesis as well as the underlying mechanism.

Study 1 (N=101) adopted a two-cell scenario-based between-subject design. The results showed that the willingness to pay (WTP) for the entire meal containing the same vice (e.g. cheesecake) and virtue (e.g. green salad) food was significantly higher in the vice-virtue condition than that in the virtue-vice condition (t (99) = 2.63, p = .01). Besides, WTP for the vice didn't differ between the two conditions (t (99) = 1.24, p = .22), but WTP for the virtue was significantly higher in vice-virtue condition (t (99) = 4.00, p = .00), which means that the sequence effect of justification is mainly driven by the virtue part. These results suggest that the virtue induces greater positive value when consuming after a vice, which can help justify guilt induced by the vice part.

Study 2 (N=69) used similar materials and procedure as in study 1, with three differences. First, we introduced satisfaction and taste as different measurements of subjective experience. Second, we measured guilt. Third, we asked a different set of participants to indicate their preference of eating sequence (N=38). The last change was introduced to rule out the alternative explanation that the results were affected by eating habits. It replicated the basic effect as well as the contribution of each part (virtue vs. vice food) to the overall experience (p s < .05). In addition, having a vice then a virtue induced significantly less guilt than that in the virtue first condition (t (67) = -2.48, p = .02), which means the latter virtue can better justify the guilt induced by the preceding vice, but the magic power of virtue disappeared in the reversed sequence. Study 2 also suggested that there was no dominated preference of eating sequence (χ^2(1, N = 38) = .42, p =.52).

Study 3 (N=105) adopted a 2 (sequence: vice-virtue vs. virtue-vice) × 2 (viciousness: strong vice vs. weak vice) between-subjects design. The strong vice condition is similar to study 1 and study 2, while in the weak vice condition, we adopted similar manipulation from Chernev and Gal (2010) to reduce the viciousness of the vice food. By framing the vice part into a weak vice, there should be no need to justify guilt in either sequence, which in turn eliminates the sequence effect of justification on the overall experience. The data supported our induction. It replicated the sequence effect in the strong vice condition, where participants in the vice-virtue condition indicated higher WTP for the meal than those in the virtue-vice condition (t (46) = 2.54, p = .01). While in the weak vice condition, where the vice food was no longer vicious and didn't need to be justified anymore, there was no difference in WTP between different sequences (t (54) = .13, p = .90). In addition, such results help to rule out the alternative explanation that it is the recency effect of the virtue that enhances the subsequent measured experience. If so, in the weak vice condition, WTP won't be similar between reversed sequences.

Study 4 (N=313) employed similar design as study 3 but generalized the situation to daily activities. Participants were asked to imagine that a student was required to complete an urgent homework, which means study is a virtuous activity. Given time was limited, any other activities can undermine goal fulfillment of completing the urgent homework, which meets the definition of vices. In such a case, workout can be a vicious activity. We framed workout

as either a strong vice by emphasizing its hedonic value, or a weak vice by emphasizing its utilitarian function. The measurement of the overall experience in this study was how much the person suffered after workout and study (reverse coded). The results suggested that if workout was framed as a strong vice, participants predicted that the student who went to gym first suffered less, compared to the students who did homework first (t (154) = -2.57, p = .01). However, if workout was framed as a weak vice, then there was no sequence effect of justification (t (155) = 1.29, p = .20).

Our research suggests that if individuals have to or want to have both vice and virtue, they should have the virtue after the vice. Such a specific sequence can better justify their guilt and in turn improve their experience.

When Diversity in Advertising Leads to Activism vs. Aversion

Linyun Yang, University of North Carolina - Charlotte, USA
Enrica Ruggs, University of North Carolina - Charlotte, USA
Jennifer Ames Stuart, University of North Carolina - Charlotte, USA
Steven Shepherd, Oklahoma State University, USA

EXTENDED ABSTRACT

The purpose of our research is to understand not only how consumers respond to diversity in advertising, but also to examine why consumers respond differently to ads portraying diversity in a subtle manner relative to ads that make stronger statements regarding their stance on diversity. We wish to extend prior research by examining consumers' responses to other traditionally excluded groups (i.e., interracial couples, overweight women) and provide a more systematic examination of when increased diversity in advertising may lead to positive or negative consequences for the promoted brand. We suggest that consumers respond negatively to certain portrayals of diversity not necessarily because of overt prejudice (as shown in prior research), but because such portrayals go against their schemas or expectations.

STUDY PROCEDURE OVERVIEW

A similar procedure was used for all our studies. Participants recruited through Amazon's Mechanical Turk were asked to view an ad that targeted a consumer group (families in Studies 1 and 3, women in Study 2) and randomly assigned to view an either more or less diverse ad. Next, participants used seven-point scales to rate their interest in purchasing (1=low, 7=high), opinion of (1=very bad, 7=very good), and liking (1=dislike very much, 7=like very much) for the advertised brand. Then participants completed Paharia et al.'s (2015) Purchase Activism Scale which measured the extent to which participants were willing to purchase the advertised brand because it aligned with their personal beliefs (e.g., "The product embodies the ideals I live by.") In Studies 2 and 3, participants also rated the extent to which viewing the ad made them feel disgusted, angry, revolted, irritated, accepting, affectionate, happy, and pleased (last 4 items reverse-scored; Bhat et al. 1998). Participants also provided their gender, age and race, which had no significant effects on our results (with the exception of gender in Study 2).

STUDY 1: INTERRACIAL PARENTS

Method

Study 1 had a 2(Target consumer: Parents (target) vs. Nonparents (nontarget) x 2(Ad diversity: Interracial vs. white parents) between-subjects design ($N=90$). In Study 1, the more diverse ad featured a family with an African American father, white mother, and biracial child while the less diverse ad featured a family with white, heterosexual parents and a white child. The promoted brand Cheerios was positioned as offering "convenient breakfasts for busy families." Parental status was determined by asking participants to indicate whether or not they had children at the end of the study.

Results

We conducted a 2(Target consumer: Parents vs. Non-parents) x 2(Ad diversity: Interracial vs. white parents) ANOVA on our dependent variables with modern racism as a covariate.

Brand evaluations (α=.86)

Analysis revealed only a main effect of ad diversity ($F(1, 85)=5.79$, $p<.05$), where the more diverse ad elicited more favorable evaluations overall. Further contrasts indicated that parents evaluated Cheerios more favorably after viewing the ad containing interracial parents ($M=4.90$) relative to the one containing white parents ($M=4.14$; $F(1, 85)=5.79$, $p=.05$). However, ad diversity had a weaker effect on non-parents' evaluations ($M_{Interracial}=4.73$ vs. $M_{White}=4.38$; $F(1, 85)=1.85$, NS).

Purchase activism (α=.89)

Analyses yielded only a main effect ad diversity ($F(1, 85)=6.47$, $p<.05$). Further contrasts found that parents indicated greater purchase activism after viewing the more diverse interracial parents ad ($M=2.52$) relative to the white parents ad ($M=1.66$; $F(1, 85)=4.86$, $p<.05$) while this effect was weaker for non-parents ($M_{Interracial}=2.34$ vs. $M_{White}=2.02$; $F(1, 85)=1.55$, NS).

STUDY 2: OVERWEIGHT FEMALE MODELS

Method

Study 2 had a 2(Target consumer: Female (target) vs. Male (nontarget)) x 2(Ad diversity: Overweight vs. Thin Model) between-subjects design ($N=117$). Participants viewed a print ad promoting Dasani water that featured either a thin or overweight female.

Results

We tested our predictions by conducting a 2(Target consumer: Female vs. Male) x 2(Ad diversity: Overweight vs. Thin Model) ANOVA on each dependent variable with antifat attitudes and BMI as covariates.

Brand evaluations (α=.91)

Analysis revealed a only a significant two-way interaction ($F(1, 111)=4.83$, $p<.05$). For female participants, the overweight model ad ($M=3.79$) garnered less favorable evaluations relative to the thin model ad ($M=4.47$, $F(1, 111)=4.39$, $p<.05$). However, this was not the case for male participants ($M_{Overweight}=4.33$ vs. $M_{Thin}=4.00$; $F(1, 111)=2.29$, NS).

Negative emotions (α=.85)

Analysis revealed a significant two-way interaction ($F(1, 111)=5.82$, $p<.05$). Contrasts indicated that the overweight model ($M=3.79$) elicited more negative emotions from female participants compared to the thin model ($M=2.05$; $F(1, 111)=6.34$, $p<.05$). However, this was not the case for male participants ($M_{Overweight}=2.93$ vs. $M_{Thin}=3.27$; $F(1, 111)=1.24$, NS).

STUDY 3: GAY PARENTS

Method

Study 3 had a 2(Consumer target: Parents vs. Non-parents) x 2(Ad diversity: Gay vs. Straight Parents) by 2(Schema activation: Busy vs. Wholesome families) between-subjects design. Participants ($N=173$) viewed a Cheerios ad that featured an image of either a nontraditional family with white, homosexual parents (two fathers) or a traditional family with white, heterosexual parents (one father and mother). We positioned Cheerios as offering "convenient breakfasts for busy families" (activating the "busy family" schema) or a "wholesome breakfasts for wholesome families" (activating the

"wholesome family" schema). Again, we asked participants to indicate whether or not they had children to determine parental status.

Results

We conducted a 2(Consumer target: Parents vs. Non-Parents) x 2(Ad diversity: Gay Parents vs. Straight Parents) by 2(Schema: Busy vs. Wholesome Families) ANOVA on each of our dependent variables. Prejudice toward homosexuals was also included as a covariate for all analyses.

Brand evaluations (α=.75)

Analysis revealed only a significant three-way interaction ($F(1, 164)$=11.93, $p<.01$). We first examined contrasts for parents. When the "busy families" schema was activated, the ad featuring gay parents (M=5.23) was more persuasive for parents than the ad featuring straight parents (M=4.26, $F(1, 164)$=3.15, $p<.01$). In contrast, when the "wholesome families" schema was activated, the gay parent ad (M=4.01) was less persuasive for parents than the heterosexual parent ad (M=4.76, $F(1, 164)$=4.72, $p<.05$). However, we found a different pattern of effects for non-parents. Whether gay or straight parents were depicted did not affect non-parents' brand evaluations in the "busy family" conditions (M_{Gay}=4.68 vs. $M_{Straight}$=4.50; $F(1, 164)$=.03, NS). Interestingly, in the "wholesome family" conditions, non-parents actually responded more favorably to the gay parents (M=4.73) relative to straight parents ad (M=4.15, $F(1, 164)$=3.04, $p<.05$).

Purchase activism (α=.86)

Analyses found a main effect of ad diversity ($F(1, 164)$=16.18, $p<.01$), which was qualified by a three-way interaction ($F(1, 164)$=3.62, p=.05). For parents viewing the "busy families" ads, the portrayal of gay parents (M=3.01) garnered higher ratings on purchase activism relative to the portrayal of straight parents (M=1.81; $F(1, 164)$=4.00, $p<.01$). However, when viewing the "wholesome families" ads, portraying gay (M=2.28) versus straight parents (M=2.36) did not elicit different levels of purchase activism from parents ($F(1, 164)$=.02, NS). For non-parents, the gay parents ad elicited higher levels of purchase activism compared to the straight parents for both the "busy families" (M_{Gay}=2.84 vs. $M_{Straight=}$1.97 $F(1, 164)$=5.13, $p<.05$) and "wholesome families" ads ($M_{Gay=}$2.96 vs. $M_{Straight}$=1.96; $F(1, 164)$=5.75, $p<.05$).

Negative emotions (α=.84)

Analysis yielded the following effects: schema ($F(1, 164)$=8.18, $p<.01$), target consumer by ad diversity interaction ($F(1, 164)$=4.10, $p<.05$), and target consumer by schema ($F(1, 164)$=9.08, $p<.01$). These lower order effects were qualified by a significant three-way interaction ($F(1, 164)$=9.44, $p<.01$). Examining the responses of parents first, we found that ad diversity had no effect on the negative emotions of parents in the "busy family" conditions (M_{Gay}=2.28 vs. $M_{Straight}$=1.93; $F(1, 164)$=1.07, NS). However, in the "wholesome family" conditions, the portrayal of gay parents (M=3.87) elicited more negative emotions from parents compared to the portrayal of straight parents (M=2.64; $F(1, 164)$=7.67, $p<.01$). In contrast, for non-parents, ad diversity had no effect on negative emotions in either the "busy family" conditions (M_{Gay}=2.56 vs. $M_{Straight}$=2.65; $F(1, 164)$=.01, NS) or the "wholesome family" conditions (M_{Gay}=2.34 vs. $M_{Straight}$=2.82; $F(1, 164)$=2.23, $p>.15$).

Taken together, our findings suggest that promoting diversity and inclusiveness can be an effective way for brands to garner support from consumers. However, marketers must have a good understanding of how the portrayal of diverse groups relates to consumers' schemas.

Consumer Donations: the Roles of Implicit Theories and Appeal Types

Ozge Yucel-Aybat, Pennsylvania State University-Harrisburg, USA
Meng-Hua Hsieh, Pennsylvania State University-Harrisburg, USA

EXTENDED ABSTRACT

Giving USA 2015 reports show that Americans contributed 358.38 billion dollars to charities in 2014. Existing literature has examined the impact of sympathy and empathy (Rick, Cryder, and Loewenstein 2008), guilt (Strahilevitz and Myers 1998), happiness (Liu and Aaker 2008), social identity (Aaker and Akutsu 2009), and awareness about one's mortality (Cai and Wyer Jr 2015) on prosocial behavior. However, studies linking personality traits to charitable donations have been limited. The current research suggests that an individual's implicit theory may affect that person's likelihood to donate money to charities.

Entity theorists believe that characteristics are definite and unchangeable; whereas incremental theorists perceive them in a more dynamic and flexible way (Plaks, Grant, and Dweck 2005). When analyzing others' behaviors, entity theorists focus their attention on personal and psychological traits without taking situational factors into account. However, incremental theorists interpret others' actions based on changing situations (Levy, Stroessner, and Dweck, 1998). The primary focus of the current article is to understand how entity and incremental theorists differ in terms of their donations to charities, especially to those that fight health problems caused by personality traits, as in lifestyle diseases such as obesity, versus charities that fight health problems which mostly occur due to situational factors such as cancer. We expect that entity theorists would be more likely to donate to a cancer (vs. obesity) charity that helps those who suffer due to inevitable/situational (vs. controllable/personality) factors for which they cannot (vs. can) be held responsible. However, since incremental theorists usually take both situational and personality factors into account and do not judge others based on their personality traits only, they would be equally likely to donate to both charity types.

Research has shown that charities may use two types of appeals (White and Peloza 2009). A self-benefit appeal emphasizes how people's donation will enhance their own life and make them feel that they are good citizens, while an other-benefit appeal emphasizes how their donation will enhance the lives of those who suffer. Current research explores under which conditions these appeals are more effective for each type of implicit theorists. For cancer charities that fight health problems which occur due to situational factors, we show that incremental theorists are more persuaded by other-benefit (vs. self-benefits) appeals. For obesity charities that fight problems caused by controllable factors/personality traits, incremental theorists are more persuaded by self-benefit (vs. other-benefits) appeals. However, results show that entity theorists are more persuaded by the cancer (vs. obesity) charity ads, regardless of appeal type.

In our first study, implicit theory was manipulated by presenting participants with three proverbs that either supported entity (You cannot teach an old dog new tricks) or incremental theory (It is never too late to learn; Poon and Koehler 2006). Participants were then presented with one of the two charity ads fighting against obesity or cancer and were asked to indicate their likelihood to donate money and recommend the charity to others. The results revealed that entity theorists were significantly more likely to donate to the cancer (vs. obesity) charity; however charity type did not impact incremental theorists' donation likelihood.

In Study 2, we sought to examine what would influence incremental theorists to donate more to charities via self-benefit versus other-benefit appeals. Implicit theory was manipulated by presenting articles emphasizing change versus no change (Levy et al. 1998) followed by an ad for a cancer charity. In the self-benefit (vs. other-benefit) condition, the ad ended with the tagline "Just imagine how your donation will enhance your life and make you feel (vs. enhance lives of those affected by cancer)." We found that incremental theorists were more likely to donate when the ad used other-benefit (vs. self-benefit) appeals. However, appeal type did not impact the donation likelihood for entity theorists.

Study 3, with a 2 (implicit theory: entity vs. incremental) x 2 (charity type: obesity vs. cancer) x 2 (appeal type: self-benefit vs. other-benefit) between-subjects design, not only showed differential effects of charity and appeal types, but also examined their subsequent outcomes on additional measures. After implicit theory manipulations (as in Study 1), participants evaluated the charity ad, indicated attitudes towards the charity, and likelihood of donating money to the charity, recommending it to others, and finding more about the charity. The results revealed that incremental theorists had more positive attitudes towards the ad if the obesity charity used self-benefit (vs. other-benefit) appeals. However, they had more positive attitudes towards the ad if the cancer charity used other-benefit (vs. self-benefit) appeals. Also, they preferred other-benefit appeals more if a cancer (vs. obesity) charity was using them. A similar pattern was observed with attitudes towards the charity if the obesity charity used self-benefit (vs. other-benefit) appeals, and if the cancer charity used other-benefit (vs. self-benefit) appeals. Moreover, incremental theorists' donation likelihood was greater if the obesity charity used self-benefit (vs. other-benefit) appeals, and if the cancer charity used other-benefit (vs. self-benefit) appeals. On the other hand, entity theorists had more positive attitudes towards a cancer (vs. obesity) charity ad, had more positive attitudes towards a cancer (vs. obesity) charity and were more likely to donate to a cancer (vs. obesity) charity, regardless of appeal type.

Current research contributes to literatures on donations, implicit theory, and advertising by suggesting that entity theorists are more likely to donate to cancer charities (situational factors) regardless of the benefit appeals used in ads, whereas incremental theorists prefer other-benefit appeals in this case. Conversely, obesity charities (personality traits) may benefit more from using self-benefit appeals since incremental theorists are more likely to be persuaded and entity theorists would be indifferent. In future, we aim to explore processes for these effects, such as whether consumers believe that it would be too selfish (irritating) to use self-benefit appeals that stress how good the giver would feel after donating to a cancer charity.

As Many As 9, but As Few As 11:
On a Hypothesis Testing Process of Evaluating Inevaluable Quantities

Y. Charles Zhang, UC Riverside, USA
Yunhui Huang, Nanjing University, China

EXTENDED ABSTRACT

Numerous research has documented that people are insensitive to the magnitude of numbers. Consequently, they usually provide indistinguishable evaluations toward objectively close quantities. For example, consumers' evaluation of the speed of a 3D printer that prints 11 mm/s does not differ from that of 9 mm/s. Research has also suggested that such quantities can indeed be distinguished when proper reference point is offered. For example, Thomas and Morwitz (2005) show that a product rating of 2.99 is perceived as significantly lower than 3.00 when both numbers are compared to 4.00.

In the present research, we find a new context in which evaluations between close pair of numbers are distinguishable, namely, when the communicator of the numerical information conveys whether this number is supposed to be considered as large or small. Such context is 1) free of reference points, 2) leads to reversed evaluations between the numbers, and 3) is an extremely common situation in which the numbers are presented in everyday life – we examined 868 articles in the New York Times and found that 48.6% of the total of 6,421 numbers that appear in these articles are presented in such a context.

In such contexts, an objectively smaller number consists of large digits (e.g., 98) can be judged to be larger than an objectively larger number consists of small digits (e.g., 112), an effect we call "the digit paradox." We argue that recipients evaluate the focal number by drawing on the communicator's position and validate that position against the magnitude of the *individual digits* of the number; large/small digits extend greater support for the position that the number is large/small.

In study 1, 222 undergrad students read a short article about 3D printer, in which the current speed of 3D printing, either 9mm/s (large digit) or 11mm/s (small digit), is described either as fast (e.g., "as fast as 9 [11] mm/s"), or neutral (i.e., without magnitude claims). As a result, the communicator's position increased the perceived magnitude of 9mm/s to a greater extent than they did to 11mm/s ($F(1, 218) = 4.59$, $p = .033$, $\eta^2 = .021$). In the meantime, 9mm/s was perceived to be subjective faster ($M = 5.0$ vs. 4.5, $F(1, 218) = 4.46$, $p = .036$, $\eta^2 = .020$) than 11mm/s in the presents of large magnitude claims but not when magnitude claims are absent ($M = 3.8$ vs. 4.1, $F < 1$, *ns.*).

In persuasion, numbers are usually presented to support arguments. When the communicator's opinion stands against the recipients', recipients may resist the persuasion from that communicator, and become unwilling to adopt any positions that the communicator attempts to convey. In this case, the digit paradox should be eliminated. Study 2 tests this boundary condition. 214 undergraduate students prepared a debate on whether using social networks facilitates or hinders social interaction. Immediately after, they read a "research article" claiming that using social networks actually hinders social interaction as "frequent social network users on average are only involved in as few as 98 [112] incidences of face-to-face interaction with others every year." Participants then reported their perceived magnitude of the 98 [112] incidences, with an expectation that those who prepared for the "facilitate" position were likely to counter-argue with the communicator; therefore, their judgments should not be affected by the digit paradox. As a result, for participants in the hinder conditions, 98 incidences was perceived to be larger than 112 incidences, replicating the digit paradox. For participants in the fa-cilitate condition, however, this reversal did not happen ($F(1, 204) = 4.61$, $p = .033$, $\eta^2 = .022$). Different from study 1, the digit paradox was eliminated without changing the content of the communication; what was manipulated was participants' willingness to validate and adopt the communicator's position as hypothesis. It therefore rules out any alternative explanations that are based on the different content of information that participants receive during the judgment process.

Because using digit as evidence is a heuristic, the digit-as-evidence effect should only be observed among those who do not feel that they have the knowledge. Study 3 examines this moderator. Participants read that a governor had either created as many as 96,000 [112,000] jobs or as lost as many as 96,000 [112,000] jobs. Participants first judged the governor's performance. Then, they reported their familiarity in politics, which serves as a measure of feeling of knowing (FOK). We ran a linear regression including the following predictors: the magnitude of the digits, the valence, FOK, all the two-way interactions among these three variables, and the three-way interaction. As a result, the digit*valence interaction was significant ($\beta = 0.079$, $t(203) = 2.67$, $p = .008$), suggesting a strong digit paradox: the performance of creating/losing as many as 96,000 jobs was judged to be better/worse than creating/losing as many as 112,000 jobs. Further, the coefficient of the three-way interaction was negative and also significant ($\beta = -0.075$, $t(203) = -2.54$, $p = .012$), suggesting that the effect was moderated by how recipients feel that they know of the target of judgment: the strong this feeling was, the lesser the extent to which his/her judgment was affected by the magnitude of digits.

Providing numbers is a common approach of presenting a quantity – "Let the data speak for themselves." The current research, however, we find that the subjective magnitude of a number is affected by the communicator's position, the extent to which depends on whether the focal number consists of large or small digits. Importantly, the fact that recipients are not influenced by the digits in the absence of magnitude claim suggests that this effect goes beyond a simple digit-magnitude association. While prior literature is largely silent on how people evaluate inevaliable quantities (e.g., in single evaluation), our research suggests a plausible approach – hypothesis testing with heuristic-based evidence. Essentially, holding a hypothesis about the target, judgment and evaluation may draw on remote associations that are otherwise meaningless in the absence of the hypothesis.

When Lacking Awareness Arises:
The Role of Unconscious Thought on Brand Extension Evaluations

Yuli Zhang, Drexel University, USA
Hyokjin Kwak, Drexel University, USA
Marina Puzakova, Lehigh University, USA
Charles Taylor, Villanova University, USA
Trina Andras, Drexel University, USA

EXTENDED ABSTRACT

Prior brand extensions research provided insights into multiple factors that influence consumers' brand extension judgments. Important factors such as brand-characteristics (Meyvis and Janiszewski 2004), individual consumer differences (Monga and John 2007), as well as various contexts (Monga and Gurhan-Canli 2012), and communication strategies (Bridges, Keller, and Sood 2000), can all enhance consumer evaluations of weak-tie brand extension (i.e., the extension that has a low fit with the brand). In this research, we examine an important cognitive mechanism – an unconscious thought process – that impacts consumers' perceptions of weak-tie brand extensions. In this regard, prior research in psychology has shown that unconscious thought influences people's choice, decision making, attitude formation and change, impression formation, problem solving, and creativity (Bos, Dijksterhuis, and van Baaren 2011; Dijksterhuis and Nordgren 2006). However, in this research, we demonstrate that unconscious thought increases consumers' evaluations toward weak-tie brand extensions. Further, we show that unconscious thought is divergent and associative in nature, which can potentially influence consumers' abilities to establish possible connections of remotely associated information between the brand and the weak-tie extension. Additionally, we explore the role of consumers' agency-communion orientation, which determines the extent to which people have a focus either on the self or relationships with others (Abele and Wojciszke 2007).

Our hypotheses were tested in three studies. In study 1 and 2, participants were exposed to brand information. Then they were exposed to one of two versions of brand extension announcements (i.e., strong-tie vs. weak-tie) and then were asked to engage in one of two thoughts (i.e., unconscious thought vs. conscious thought). As expected, participants in the unconscious thought condition were more likely to evaluate a weak-tie brand extensions more favorably than those in the conscious thought condition. In study 3, participants read a WSJ article that introduced the brand information. Next, they were exposed to the weak-tie extension stimuli and then were asked to engage in one of two thoughts (i.e., unconscious thought vs. conscious thought). We used gender as a proxy for the agency-communion orientation. The analysis revealed that the weak-tie extension was more favorable in the unconscious thought (vs. conscious thought) condition. In particular, for female participants, they evaluated the weak-tie more favorably in the unconscious thought (vs. conscious thought) condition. For male participants, there was no significant difference.

Through a series of three experiments, our research demonstrates that unconscious thought results in more favorable attitude toward weak-tie brand extensions than conscious thought. Also, unconscious thought increases weak-tie brand extension evaluations for female but not male consumers. These findings contribute to the literature by providing theoretical and empirical documentation of the unconscious thought effect on consumers' evaluations of brand extensions.

The Unintended Consequences of Long Deadlines on Goal Pursuit

Meng Zhu, Johns Hopkins University, USA
Rajesh Bagchi, Virginia Tech, USA
Stefan J. Hock, George Mason University, USA

EXTENDED ABSTRACT

Imagine that Mr. Long and Mr. Short each just bought a house in a recently-developed local community. The houses are practically identical. As it so happens, both admire the kitchen in the upgraded model home of their community, and decide they would like to renovate their own kitchens accordingly before moving in. While both want to commence work on their respective projects immediately, they set different deadlines for their goal of completing the renovation task, basing it on their move-in dates. Mr. Long (Short) expects to move in after six (three) months as his current lease expires then, and so wants to complete the project within the next six (three) months. They both need to assess the amount of resources (time and money) that they would devote to this renovation. Will the difference in the length of the two deadlines—long (six months) versus short (three months)—impact the level of resource committed by each individual? If so, why?

Given the similar nature of their goals—that is, with an identical current and (supposedly identical) desired end state of the kitchens—a naïve perspective may suggest that differences in deadlines should not impact resource commitment. An alternative hypothesis can also be offered. Prior research has consistently demonstrated that individuals form different mental representations of the same information depending on temporal distance (Trope and Liberman 2003). In particular, people categorize objects associated with distant future events in fewer, broader categories (Liberman et al. 2002). Unpacking a complicated task into fewer (vs. more) steps could lead to the inference that the task is easier, thus increasing optimism about task completion, and to underestimation of resources (time and money) needed to complete the task (Buehler et al. 1994; Kahneman and Lovallo 1993). Together, this suggests that a longer (temporally distant) deadline might lead consumers to unpack a pre-set goal into fewer steps (due to broader categorization), which might lower resource commitment.

We propose yet another contrarian hypothesis. We argue and show that longer deadlines increase, rather than decrease, resource commitment. Our theorization is based on prior research suggesting that consumers tend to rely on salient, non-diagnostic contextual cues to make inferences (Broniarczyk and Alba 1994; Dick et al. 1990; Harris 1981; Kardes et al. 2004) and that constraints draw attention. For example, research on activation suggests that attention is typically drawn to inputs that are constrained and limited (Berlyne 1969; Pribram and McGuinness 1975). Mullainathan and Shafir (2013) suggest that resource constraints yield a "focus dividend"; this occurs because inputs associated with constraints impose themselves on us, capturing our attention above all else. Given that deadlines are inherently a constraint requiring one to complete a task within a specified time window, deadlines should emerge as a salient cue in the local decision-making environment. Thus, we expect consumers to rely on deadlines to make inferences about the focal goal. Given that longer deadlines imposed for a pre-set goal would allow one to incorporate more of subtle aspects (e.g., the finish, aesthetic composition, texture, quality of appliances) into the focal goal (e.g., the kitchen renovation), we expect that a long versus short deadline will lead consumers to infer the focal goal as more difficult, even when the deadline length is resultant from an unrelated exogenous constraint, and when the current and desired end states of the goal are supposedly the same. Further, because a more difficult goal frequently requires more resources (e.g., time and money), we expect that longer deadlines will lead individuals to commit to spending more resources.

Experiment 1 provides support for our main thesis that a long versus short deadline of a pre-set goal increases the amount of resources committed to the goal. Participants in this study indicated the deadlines they imposed on themselves when shopping during the past Christmas season. They also reported the total amount of time and money they spent. Consistent with our predictions, the longer the deadline (i.e., the more months in advance participants started shopping before last Christmas), the more time and the more money they spent. These effects hold even after controlling for importance of Christmas shopping and the number of immediate family members.

Experiment 2 directly manipulated the length of the deadlines to examine the consequential effect of deadline length on resource commitment. In this experiment, we recruited students from an undergraduate class and asked them to complete the same extra credit assignment in either six weeks' or in four weeks' time. We find that the longer the deadline, the more time students committed to this assignment. Importantly, more participants failed to complete the assignment in the long deadline condition. Normatively, with more time, participants should have found it easier to complete the assignment in time. Yet, this seemingly counter-intuitive result is consistent with our proposed inference-making account that longer deadlines increase perceived goal difficulty. This increased goal difficulty arising from longer deadlines might have been responsible for the escalation of resource commitment and subsequently led to the increased likelihood of quitting.

Experiment 3 provides direct evidence for the proposed mediating role of perceived goal difficulty. We find that incidental deadlines resulting from an unrelated exogenous constraint (i.e., a friend's availability) are sufficient to change the perception of goal difficulty, consequently affecting the level of resources committed to the focal goal. Experiment 4 tests whether the impact of deadline length on the amount of resources committed to a pre-set goal is moderated by the objective difficulty of the goal. Consistent with the proposed difficulty-based inference-making account, we find that when the objective goal difficulty was high versus low, the difference in deadline length produced a more pronounced impact on the level of resources participants committed to the focal goal. Finally, Experiment 5 provides further process evidence by demonstrating the moderating role of goal familiarity, showing that longer deadlines led to greater resource commitment only when the requisite knowledge necessary for making inferences about goal difficulty was available (i.e., high vs. low goal familiarity).

Getting in Touch with Your Thinking Style: How Touchscreens Influence Purchase

Ying Zhu, University of British Columbia, Canada
Jeffrey Meyer, Bowling Green State University, USA

EXTENDED ABSTRACT

Affordable, easy-to-use touchscreen technology dramatically alters human–machine interfaces, and consumers have readily accepted this dramatic change, as indicated by the skyrocketing demand for touchscreen devices. Predictions indicate that the touchscreen market will experience compound annual growth rates of 41% from 2013 to 2018 and reach a value of $51.77 billion by 2018 (Research & Markets, 2013). The prevalence of touchscreen devices sends a clear signal: Consumers enjoy tactile communication tools.

These nearly ubiquitous touchscreen interfaces spawn a new stream of questions for academia and industry. The use of touch potentially represents a new influence on behavior and consumption decisions, because consumers use their fingers to complete shopping processes; to zoom in and out to manage photo albums; and to tap, drag, slide, swipe, pinch, and rotate while playing games on touchscreen devices. Their intuitive interfaces also make touchscreens easy to use. Although this phenomenon is observable, the rapid growth of touchscreen usage has not been accompanied by academic theory. The way tactile uses on touchscreens affect consumer behavior and decision making in various activities is uncertain, suggesting the need for advanced tactile research.

To address this gap, the current study investigates touchscreen devices and the underlying psychological drivers that contribute to consumers' responses to products presented on different devices. We identify differential effects of device types on purchase intentions, such that consumers are more likely to purchase hedonic products on handheld touchscreen devices but favor utilitarian products when using desktop computers (study 1). We then validate situation-specific thinking style (Novak and Hoffman 2009) as an underlying mechanism that contributes to the differences between the devices. Specifically, compared to desktop users, touchscreen users apply a more experiential but less rational thinking style (study 2). We also demonstrate that these situation-specific thinking styles mediate the relationship between device type and purchase intentions, and this mediation is moderated by the nature of the product (study 3).

STUDY 1 DEVICE TYPE AND PRODUCT NATURE

Ninety-nine students from a North American university (41% female; M_{age} = 19.6) participated in exchange for course credit. We randomly assigned participants to one of four conditions in a *2 (device type: handheld touchscreen device vs. desktop computer) × 2 (product nature: hedonic vs. utilitarian)* between-subjects experimental design, with device type and product nature as independent variables and purchase intentions as the dependent variable.

An analysis of covariance revealed a significant interaction effect between device type and product nature on purchase intentions ($F(1, 95)$ = 11.82, p = .001). Most importantly, as predicted by H1, the simple effects revealed that, participants have significantly higher purchase intentions for *hedonic products* when buying on touchscreens than on desktops (M_{Touch} = 5.26, M_{PC} = 4.17; p = .012) and significantly higher purchase intentions for *utilitarian products* on desktops than on touchscreens (M_{PC} = 5.53, M_{Touch} = 4.53; p = .024).

STUDY 2 DEVICE TYPE AND THINKING STYLE

Undergraduate students at a North American university (N = 90; 37% female; M_{age} = 19.6) participated for course credit. We use *a single factor (device type) between-subjects design*, with device type as the between-subjects independent variable, thinking style as the dependent variable. An ANOVA analysis revealed a significant effect of device type on experiential thinking style ($F(1, 88)$ = 9.47, p = .003). Specifically, touchscreen users exhibited a significantly higher experiential thinking score than desktop users (M_{Touch} = 3.70 vs. M_{PC} = 3.22, p = .003). We again used an ANOVA analysis, revealing a significant effect of device type on rational thinking style ($F(1, 88)$ = 10.62, p = .002). Desktop users exhibited a significantly higher rational thinking score than touchscreen users (M_{PC} = 3.77 vs. M_{Touch} = 3.35, p = .002).

STUDY 3 DEVICE TYPE, PRODUCT TYPE, AND THINKING STYLE

Study 3 mirrors the study design of Study 1. It used a *2 (device type: handheld touchscreen vs. desktop computer) × 2 (product nature: hedonic vs. utilitarian)* between-subjects design, with device type and product nature as independent variables and purchase intentions as the dependent variable. Undergraduate students at a North American university (N = 100; 40% female; M_{age} = 19.4) participated for course credit.

A two-way ANOVA revealed a significant device type and product nature interaction ($F(1, 96)$ = 9.46, p = .003). The results closely resembled those of study 1. Importantly, simple effects tests of the device type within product nature showed a significant difference for both hedonic and utilitarian products. Specifically, participants are more likely to purchase hedonic products when on a touchscreen than on a desktop (M_{Touch} = 4.95, M_{PC} = 4.01; p = .039). The results also showed participants are more likely to purchase utilitarian products on a desktop than on a touchscreen (M_{PC} = 4.22, M_{Touch} = 3.25; p = .026).

GENERAL DISCUSSION

Traditional touch research focuses on the functionality of touch and haptic information collected through fingers when consumers touch the surface of products directly (e.g., Peck & Shu, 2009). When using a touchscreen device to shop online, consumers cannot touch the product, yet touch remains an active part of their information search and facilitates purchase processes. In such a context, touching performed by fingers substitutes for traditional tools (e.g., mouse, keyboard). The functionality of touch as an evaluation tool during consumer decision making has received some academic attention (e.g., Krishna, Elder, & Caldara, 2010; Peck & Childers, 2003a, 2003b), but non-product touching remains an underexplored research area.

This research addresses the gap in tactile research by hypothesizing and testing different tactile effects of traditional computers and touchscreen devices on consumers' purchase intentions toward products of a certain nature (e.g., hedonic vs. utilitarian). We also reveal that handheld touchscreen devices are more likely to evoke an experiential thinking style, whereas desktop computers align better with a rational thinking style. Finally, we show that situation-specific thinking style mediates the impact of the two types of devices on consumers' purchase intentions, and this mediation effect is moderated by the nature of the product.

How Embarrassing For You (and me): The Nature of Observer Embarrassment

Alexander Ziegler, University of Kentucky, USA
John Peloza, University of Kentucky, USA
Alexis Allen, University of Kentucky, USA

EXTENDED ABSTRACT

Research on embarrassment finds that the presence of observers is a necessary requirement that all embarrassing situations share (Dahl, Machanda, and Argo 2001; Blair and Roese 2013; Grace 2007, 2009). The effect of the embarrassing situation on the observer, however, has been largely ignored. This research aims to address the question: How are observers impacted by the embarrassing situation? We define observer embarrassment as the observer's emotional reaction to an intentional or accidental norm violation of an actor. Because one actor's embarrassment is often witnessed by multiple observers, observer embarrassment is more ubiquitous then actor embarrassment. In spite of the potential impact this imposes for marketers, the consumer literature at large has not examined observer embarrassment.

Drawing on Cognitive Appraisal Theory (Lazarus 1993), we examine the nature of observer embarrassment in a series of three experiments. In study 1, we show that observer embarrassment impacts consumers' consumption experience, and embarrassed observers exhibit the same avoidance strategies as embarrassed actors. Next, we introduce social identity congruence between observer and actor, as well as the social presence of other observers, as moderators that provide additional support for our conceptualization of observer embarrassment.

In study 1, one hundred and eighty-six undergraduate students at a large North American university imagined themselves in a hotel lobby observing the check-in process of an unrelated customer. Actor embarrassment is created when the checking in customer has a credit card declined. Analysis demonstrates an indirect effect of observing an embarrassing situation, through observer embarrassment, on avoidance intentions (total indirect effect: 95% CI = .0004 to .1816). This analysis provides evidence supporting the positive relationship between observing an embarrassing situation and experiencing observer embarrassment, as well as the subsequent avoidance intentions of the observer.

Study 2 provides further evidence of the underlying process behind the generation of observer embarrassment. The study uses a 2 (Perceived actor embarrassment: yes/no) X 2 (Actor identity: congruent/incongruent). We manipulate observer embarrassment and introduce social identity congruence (university affiliation: home versus rival) as a boundary condition for the presence of observer embarrassment. We recruited 210 undergraduate students at a large North American university who imagined themselves standing in the self-check-out lane at a store. Another customer purchases an embarrassing product (genital wart remover cream, pretested as an embarrassing product). We manipulate perceived actor embarrassment by having either the customer or a store clerk inquire about the price of the product. Analysis reveals a significant interaction between perceived actor embarrassment and social identity of the actor ($F(1, 209) = .86, p = .05$). Furthermore, the impact of the perceived actor embarrassment on observer embarrassment is only present for participants in the identity incongruent condition ($M_{cong} = 4.92$ vs. $M_{incong} =4.26, F(1, 209) = 4.65, p < .05$). Thus, study 2 provides further evidence in support of our conceptual framework.

Study 3 had two main objectives. The first objective is to rule out a possible alternative explanation by demonstrating that observer embarrassment can occur without the presence of empathy. Further, we examine the role of social presence of others on observer embarrassment. This distinguishes observer embarrassment from other related interpersonal emotions.

One hundred sixty-two undergraduate students at a large North American university participated in the study as part of a course requirement. The design was a 2 (Presence of Others: crowded/not crowded) X Continuous (Observer Embarrassment: Measured) design. Participants imagined an incident of customer rage directed at the front-desk employee during a hotel check-in process due to a lack of an available room. Social presence was manipulated by describing the lobby as virtually empty versus crowded. Analysis reveals a significant interaction between observer embarrassment and social presence ($F(1, 161) = -.23, p = .04$). We conducted a simple slopes analysis to qualify this interaction. Observer embarrassment leads to lowered observer satisfaction in a crowded environment. Satisfaction ratings were not impacted if the setting was not crowded. This underlines the impact that a social presence has on observer embarrassment.

The results across three studies highlight the nature and consequences of observer embarrassment. Thus, consumer embarrassment impacts their behavior as well as the behavior of others who observe the embarrassment. The mere observation of an embarrassing situation is enough to create observer embarrassment and observer embarrassment can, in turn, impact observers in ways unfavorable for marketers. Namely, observer embarrassment leads to avoidance intentions (Study 1) and lowered satisfaction (Study 3). Furthermore, we introduce boundary conditions for the antecedents of observer embarrassment as well as for the impact that observer embarrassment has on the observer in the form of identity congruence (Study 2) and social presence (Study 3). The social nature of observer embarrassment presents a particular challenge for marketers because crowded retail setting provide many benefits for marketers, but can also exacerbate negative consumer emotion.

Not Just For Your Health:
How Regular Physical Activity Influences Processing of Irrelevant Product Information

Laura Zimmermann, London School of Economics and Political Science, UK
Amitav Chakravarti, London School of Economics and Political Science, UK

EXTENDED ABSTRACT

We document a novel "spillover" benefit of regular physical activity (RPA) on decision-making. Specifically, RPA seems to aid people's ability to ignore irrelevant information. In the consumption domain, when evaluating products, consumers often face a wide range of information - some relevant and informative, while other information might be irrelevant for evaluating the benefits of a product. Exposure to irrelevant information typically weakens consumer's belief in a product's benefit and results in less extreme product ratings - the dilution effect (Nisbett, Zukier and Lemley 1981; Meyvis and Janiszewski 2002). The dilution effect represents a judgmental bias since non-diagnostic information is taken into account when it should be ignored to make the optimal choice.

Health research shows that RPA improves the ability to inhibit irrelevant distractors in psychometric tasks (e.g., Hillmann et al. 2014, Hillmann et al. 2004). Besides the positive impact on physical and emotional health, RPA also benefits cognition, particularly executive functions (Barenberg, Berse and Dutke 2011). However, the extant research has not looked at whether RPA also benefits information processing in completely unrelated domains.

The aim of this research was to investigate whether RPA affects information processing in 'real-life' decision domains, such as product judgments that require ignoring irrelevant information. We hypothesize that physically active individuals are less susceptible to dilution effects in consumer decision-making and investigate underlying mechanisms.

In Study 1 we combined an experimental manipulation of product information with an individual differences approach to investigate dilution effects in sedentary vs. RPA individuals. Two hundred and ninety-four US participants (age range: 18-65 years) completed an adapted version of Meyvis and Janiszewski's (2002, experiment 1) consumer product test of the dilution effect. A 2 (information: informative vs. informative + irrelevant) x 7 (product replicates) mixed design was used and crossed with measured RPA, using the International Physical Activity Questionnaire (Hallal and Victora 2004). Participants were randomly assigned to one of two between-subjects factors and saw descriptions of seven products in random order. For each product, participants were first given the desirable benefit ("You are looking for a safe apartment") and then received the product description. In the control condition, participants received one piece of supportive and diagnostic information ("24 hour on-site security"). In the dilution condition, this was followed sequentially by three pieces of irrelevant information (e.g., "complex name: Haywood Park"). Finally, participants rated the product's benefit. We collected various control variables to account for differences between people with varying levels of RPA (affect, Big-5, lay beliefs in the effects of RPA, creative and analytical reasoning).

Study 2 was designed to 1) replicate the findings from study one; 2) shed light on underlying mechanisms; and 3) eliminate additional confounding variables as competing explanations. Two hundred eighty-nine US participants completed the same procedure as in study 1. Additionally, participants completed a reaction time recognition test of the product information, two inhibition measures (Stroop test, Necker Cube Pattern Control), two decision-making measures (intertemporal choice, self-control scenarios) and several controls (TIPI, lay beliefs in the effects of RPA, demographics).

In study 3 we tested two hundred and twenty-seven exercisers during their gym visit to address physical activity self-report issues. We used the same procedure but added a quasi-experimental manipulation of physical activity, by varying the timing of the testing (before vs. after workout).

In study 1, adding irrelevant information significantly weakened participant's beliefs in the product's benefit, thus demonstrating the classic dilution effect ($M_{Control} = 75.02$, $M_{Dilution} = 70.57$, $t(292) = 3.44$, $p < .001$). More importantly, we found support for our hypothesis. A two-way ANOVA showed a significant interaction between the dilution condition and RPA, $F(1, 290) = 4.37$, $p < .05$. Simple effects showed that sedentary subjects significantly diluted their product judgments when faced with irrelevant information ($p = .006$). There was no difference in product judgments for RPA individuals ($p = .899$). This finding persisted after controlling for various characteristics that could explain individual differences, including reasoning scores, socioeconomic status, mood, personality traits and lay beliefs in the effects of RPA.

In study 2 the positive "spillover" benefit of RPA on product judgments was replicated. A two-way ANOVA showed a significant interaction between the dilution condition and RPA, $F(1, 285) = 4.67$, $p < .05$. Sedentary subjects significantly diluted their judgments when faced with irrelevant information ($p < .001$). There was no dilution effect for RPA individuals ($p = .402$). Again, this remained after controlling for potential confounds. Further, we could rule out differences in memory for the product information and improved inhibitory control as mediating factors.

Study 3 revealed a significant three-way interaction between the dilution condition, RPA and time of testing, $F(1, 219) = 4.31$, $p < .05$. Planned contrasts showed that regular exercisers did not dilute their product judgments when faced with irrelevant information after they had just exercised, $p = .206$. All other groups showed a significant dilution effect, $p < .001$. Summary statistics of all studies across condition and RPA groups.

This research documents a novel effect: Regular exercisers are significantly less prone to dilute their judgments when faced with irrelevant product information. This effect remains after controlling for a number of confounds and also appears after a situational manipulation of physical activity with regular exercisers at a gym.

Our findings have important theoretical and practical implications. First, they are one of the first to establish the positive effect of RPA on cognition, particularly decision-makers' ability to ignore irrelevant information. This can be useful to promote RPA among people who aren't motivated to exercise by health benefits. Second, they extend the benefits of RPA to a new and unrelated domain – consumer product judgments. Marketers can take this into account when promoting products to regular exercisers. Finally, our findings shed light on potential remedies against the dilution effect as a judgmental bias. This is important considering the number of studies demonstrating the dilution effect in various applied domains including legal decision-making (Smith, Stasson and Hawkes 1998), negotiations (Wiltermuth and Neale 2011) or climate change (De Vries, Terwel and Ellemers 2014).

Film Festival 2016

Vegetarianism: A Video-Ethnography of Conflicts Within and Outside the Movement That Affects The Market Dynamics

Renata Andreoni Barboza, FGV-SP/Escola de Administração de Empresas de São Paulo, Brazil
Tania Modesto Veludo de Oliveira, FGV-SP/Escola de Administração de Empresas de São Paulo, Brazil

This film approaches several types of conflicts in the consumer social movement of vegan and vegetarians. The realistic conflict theory serves as the basis to understand how hostility within and outside the movement arise as a result of conflicting goals and competition and how it affects the market. (19.34 min)

Meaningful Things: Exploring the Symbolic Meaning of the Material Environment and its Impact on Happiness

Mafalda Casais, Delft University of Technology, Netherlands
Ruth Mugge, Delft University of Technology, Netherlands
Pieter M. A. Desmet, Delft University of Technology, Netherlands

Symbolically meaningful possessions have the ability to make intentions tangible to remind of aspirations and to keep successes fresh. This videography is a compilation of stories about objects with symbolic meaning reflecting on the contribution of the material environment to the subjective well-being of individuals. (14.37 min)

Skoros: Anti-Consumption in Crisis

Andreas Chatzidakis, Royal Holloway University of London, UK
Pauline MacLaran, Royal Holloway University of London, UK

Skoros is an anti-consumerist collective in Athens Greece that runs a space where people give take or give and take goods and services for free. Soon after came the "Crisis" and with it a need to cater for people that are increasingly below the poverty line… (19.24 min)

Dedicated Followers of Fashion: The Role of Cultural Mythologies in Product Adoption

Skye-Maree Dixon, University of Bath, UK

Fashion is undergoing a shift in narrative. The rise of bloggers and the proliferation of social media have shifted power relations democratising a previously elitist industry. This film presents the initial pilot study into how marketplace-myths develop within a fashion context and their impact on product adoption. (24.21 min)

Shopping: A Retail Experience

Joao Fleck, Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre, Brazil
Stefania Ordovas de Almeida, Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre, Brazil
Vinicius Brasil, Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre, Brazil
Jose Afonso Mazzon, FEA - USP, Brazil
Giuliana Isabella, Insper - Institute of Research and Education and FEA-USP, Brazil

Shopping: A Retail Experience is a videography made with the goal of analyzing purchasing motivations. The consumers reflected upon their purchase choices by participating in a shopping experience using an HD Camera Glasses and later on they were interviewed while viewing their on-store videos. (20.26 min)

Evil Eye: The Business of Anticipated Malicious Envy in India

Tanvi Gupta, Indian Institute of Management Bangalore, India
Preeti Krishnan Lyndem, Indian Institute of Management Bangalore, India

The evil eye belief (anticipated malicious envy) which fuels the $40 billion Indian ritual market is studied from the academic lens using the 'theory of magic' 'compensatory control' 'information cascades' and more. This visual journey engages with sellers and buyers of cultural symbols used to cope with anticipated malicious envy. (35.32 min)

Living the Stream: A Study of Voyeuristic Consumption in Video Game Live Streaming

Jacob Hiler, Ohio University, USA
Andrew Kuo, Louisiana State University, USA
William Northington, Idaho State University, USA

Video game live streaming has seen explosive growth in the past few years and has become a multi-billion dollar industry. This film explores the phenomenon through the eyes of the consumers of live streams and furthers the theory of voyeuristic consumption. (26.21 min)

Further Away = Higher Willingness to Pay?

Karina Isaak, ESCP Europe, Berlin, Germany
Elena Dinkevych, ESCP Europe, Berlin, Germany
Robert Wilken, ESCP Europe, Berlin, Germany

Consumers' willingness-to-pay is influenced in many ways - psychological distance is one of them. Advertisements for instance can present products from a high distance or in a close-up. We empirically show that this spatial distance to a product does not only affect consumers' mean willingness-to-pay... (12.08 min)

Dodo Lé Là - From Beer Consumption to Heritage Edification

Julie Leroy, University La Réunion, France
Baptiste Cléret, University of Rouen, France
Michel Boyer, University La Réunion, France

This research studies the role of consumers in the edification of a convenience good as a patrimonial object of consumption. Through the practices representations and values they insert in the good and its context they transformed a regional product into an iconic brand; the beer "La Dodo". (40.43 min).

E-book. Just a small gadget?

Cecilia Lobo-de-Araujo, Fundaçao Getulio Vargas, Brazil
Patricia SM Boaventura, Fundaçao Getulio Vargas, Brazil
Suzana Battistella-Lima, Fundaçao Getulio Vargas, Brazil
Renata Andreoni-Barboza, Fundaçao Getulio Vargas, Brazil
Adriana Arcuri, Fundaçao Getulio Vargas, Brazil

E-books. How a new way of consumption – e-book reader opposed to physical book – is changing our understanding and relation with extended-self cultural capital transference reference of knowledge (treasure) sacredness of things and also the consumption of books itself. Interviews and questions to think about this apparent small technological change. (14.09 min)

Darth Vader, May I Take a Picture with You?

Rafael Mello, Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre, Brazil
Rafael Bronzatti, Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre, Brazil
Renan Sahity, Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre, Brazil
Joao Fleck, Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre, Brazil
Stefânia Almeida, Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre, Brazil
Vinicius Brasil, Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre, Brazil

We analyzed the experience of consumption of cosplayers in events of the geek subculture as well as aspects related to the process of character choice formation of groups feelings before and after the events and other characteristics of this activity. (22.25 min)

Shopping: A Study on Motivations

Stefania Ordovas de Almeida, Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre, Brazil
Joao Pedro Fleck, Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre, Brazil
Vinicius Brasil, Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre, Brazil
José Afonso Mazzon, FEA - USP, Brazil
Giuliana Isabella, FEA - USP and Insper - Institute of Research and Education, Brazil

This videography aims at understanding what motivates people to shop nowadays. Our interviewees lead us to find four main influencers on shopping behavior: shopping malls store design and shopping environment; Atmospherics of Stores and Store Employees. (14.29 min)

Wonders of Waste. The Ideological Diffusion of the Upcycling Consumer Movement

Grace O'Rourke, University College Cork, Ireland
Stephen R. O'Sullivan, University College Cork, Ireland

This videography explores the ideological diffusion of the upcycling movement a movement attempting to restore the balance between production consumption and waste. The upcycling movement marks a new form of working consumer – creative deconsumers – working towards altering the ideological identification with waste. (22.25 min)

Empowerment Through Social Entrepreneurship

Thayse Schneider, Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre, Brazil
Denise Telli, Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre, Brazil
Tatiana Bolzoni, Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre, Brazil
Guilherme Mattos, Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil
Stefânia Ordovás de Almeida, Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre, Brazil
João Pedro Fleck, Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre, Brazil

Our goal with this videography is to connect Social Entrepreneurship and Consumer Behavior. We intend to show how Social Entrepreneurship can be used as a weapon to fight social exclusion empowering the less fortunate. (15.08 min)

Walking with Zombies – Insights into the Subculture of the Undead

Sascha Steinmann, University of Siegen, Germany
Frederic Nimmermann, University of Siegen, Germany
Hanna Schramm-Klein, University of Siegen, Germany
Andreas Rauscher, University of Siegen, Germany
Judith Ackermann, University of Siegen, Germany
Gunnar Mau, University of Siegen, Germany

This movie provides insights into the "zombie community" and by showing how zombie archetypes have evolved in media over time especially in movies and computer games. Furthermore we show how the zombie archetypes have influenced the way community members dress and perform during the Cologne Zombie Walk in 2015. (21.18 min)

Roundtable Summaries

ROUNDTABLE
Conceptualizing Consciousness in Consumer Research:
A Holistic Look at Consumers' Mental Lives

Chairs:
Lawrence Williams, University of Colorado Boulder, USA
Kathleen Vohs, University of Minnesota, USA

Participants:
Jonah Berger, University of Pennsylvania, USA
Kristina Durante, Rutgers University, USA
Chris Janiszewski, University of Florida, USA
Juliano Laran, University of Miami, USA
Rik Pieters, Tilburg University, Netherlands
Andy Poehlman, Clemson University, USA
Sharon Shavitt, University of Illinois at Urbana-Champaign, USA
Itamar Simonson, Stanford University, USA
Michaela Wänke, University of Mannheim, Germany
Alex Genevsky, Erasmus University, Netherlands
Lan Chaplin, University of Illinois at Chicago, USA
Bob Fennis, University of Groningen, Netherlands

Consumer researchers long have questioned how unconsciousness shapes behavior. This roundtable redresses the field's neglect of consciousness's influence. Scrutinizing consciousness from evolutionary developmental cultural neurological methodological and applied approaches this session offers diverse perspectives on one of the more enigmatic aspects of human existence.

ROUNDTABLE
Consumer Neuroscience: Conceptual, Methodological, and Substantive Opportunities for Collaboration at the Interface of Consumer Research and Functional Magnetic Resonance Imaging

Chairs:
Martin Reimann, University of Arizona, USA
William M. Hedgcock, University of Iowa, USA
Adam Craig, University of Kentucky, USA

Participants:
Maarten Boksem, Erasmus University Rotterdam, The Netherlands
Raquel Castaño, Tecnológico de Monterrey, Mexico
Moran Cerf, Northwestern University, USA
Angelika Dimoka, Temple University, USA
Ming Hsu, University of California Berkeley, USA
Hilke Plassmann, INSEAD, France
Akshay Rao, University of Minnesota, USA
Ale Smidts, Erasmus University Rotterdam, The Netherlands
Carolyn Yoon, University of Michigan, USA

During this roundtable the results of the first Pre-Conference Workshop on Consumer Neuroscience are discussed especially the findings from three "design thinking challenges" on conceptual methodological and substantive issues concerning functional magnetic resonance imaging (fMRI). The roundtable aims to develop directions for research on the role of neurophysiology in consumption.

<div align="center">

ROUNDTABLE
Boundary Research: Tools and Rules to Impact Emerging Fields

Chairs:
Koert Van Ittersum, University of Groningen, The Netherlands
Brian Wansink, Cornell University, USA

Participants:
Adam Brasel, Boston College, USA
Jeff Inman, University of Pittsburgh, USA
Ajay Kohli, Georgia Tech, USA
Cait Lamberton, University of Pittsburgh, USA
Connie Pechmann, University of California Irvine, USA
Rik Pieters, Tilburg University, The Netherlands
Linda Price, University of Arizona, USA
Stefano Puntoni, Erasmus University Rotterdam, The Netherlands
Aric Rindfleisch, University of Illinois at Urbana-Champaign, USA
Roland Rust, University of Maryland, USA
Peeter Verlegh, Free University of Amsterdam, The Netherlands
Luk Warlop, K.U. Leuven, Belgium
Ellen Van Kleef, Wageningen University, The Netherlands

</div>

Boundary research can be risky but it can also move academic disciplines into wider areas of influence. To help reduce the risk and increase the reward this roundtable brings together researchers interested in engaging in boundary research sharing experiences and best practices with regards to conducting and publishing boundary research.

<div align="center">

ROUNDTABLE
Luxury Brands, Conspicuous Consumption and Social Signaling

Chairs:
Yajin Wang, University of Maryland, USA

Participants:
Darren Dahl, University of British Columbia, Canada
David Dubios, INSEAD, France
Kristina Durante, Rutgers University, USA
Lan Chaplin, University of Illinois at Chicago, USA
David Gal, University of Illinois at Chicago, USA
Barbara Kahn, University of Pennsylvania, USA
Anat Keinan, Harvard Business School, USA
Nailya Ordabayeva, Boston College, USA
C. W. Park, University of Southern California, USA
L.J. Shrum, HEC Paris, France
Amna Kirmani, University of Maryland, USA
Keith Wilcox, Columbia University, USA
Carlos Torelli, University of Minnesota, USA
Jennifer Stoner, University of North Dakota, USA
Lisa Cavanaugh, University of Southern California, USA
Yajin Wang, University of Maryland, USA

</div>

One of the biggest trends in consumer behavior over the last two decades has been the growth of luxury consumption. The goal of this roundtable session is to discuss the new trends and novel research questions in luxury consumption and to develop collaborative relationships.

ROUNDTABLE
Liquid Consumption: How Can We Use It in Consumer Research?

Chairs:
Fleura Bardhi, City University of London, UK
Giana Eckhardt, Royal Holloway University of London, UK

Participants:
Linda Price, University of Arizona, USA
Eric Arnould, University of Southern Denmark, Denmark
Russel Belk, York University, Canada
Eileen Fischer, York University, Canada
Cele Otnes, University of Illinois at Urbana-Champaign, USA
Adam Arvidsson, University of Milano, Italy
Rebecca Watkins, Cardiff University, UK
Aric Rindfleisch, University of Illinois at Urbana-Champaign, USA
Nancy Wong, University of Wisconsin-Madison, USA
Sofia Ulver, Lund University, Sweden
Soren Askegaard, University of Southern Denmark, Denmark
Christian Eichert, City University of London, UK
Jacob Ostberg, Stockholm Business School, Sweden

We introduce the concept of liquid consumption and discuss how it differs from 'solid' consumption as well as postmodern consumption. We focus on how liquid consumption can reinvigorate research agendas for a wide variety of consumer behavior constructs such as consumer attachment brand communities materialism and digital consumption.

ROUNDTABLE
Question-Behavior Effect Roundtable

Chairs:
Eric Spangenberg, University of California Irvine, USA

Participants:
David Sprott, Washington State University, USA
Ioannis Kareklas, University at Albany, State University of New York, USA
Berna Devezer, University of Idaho, USA
Katie Spangenberg, University of Washington, USA
Vicki Morwitz, New York University, USA
Paul Dholakia, Rice University, USA
Siegfried Dewitte, University of Leuven, Belgium
Chris Janiszewski, University of Florida, USA
Elise Chandon, University of South Carolina, USA
Andy Perkins, Washington State University, USA
Bianca Grohmann, Concordia University, Canada
Richard Yalch, University of Washington, USA

For 40 years consumer psychologists have explored the nature of the question-behavior effect (QBE). A new meta-analysis of the QBE (Spangenberg et al. 2016) finds varying support for four over-arching theoretical mechanisms (attitudes consistency fluency and motivations). The roundtable will challenge theoretical perspectives and facilitate further collaboration on the QBE.

Working Papers

Effects of Face and Gaze Direction in Print Advertisements

Safa Adil, Rennes 1 University, France
Sophie Lacoste-Badie, Rennes 1 University, France

This study assesses the effects of face presence and gaze direction in print advertisements on attention to and memorization of the product and the advertisement. Our main finding is that advertisements are more effective in "gaze towards the product" condition than in "gaze towards the observer" and "no face" conditions.

Virtue in Vice: Benefits of Conspicuous Consumption for the Powerless

Sumaya AlBaloohsi, BI Norwegian Business School, Norway
Mehrad Moeini-Jazani, BI Norwegian Business School, Norway
Bob M. Fennis, University of Groningen, The Netherlands
Luk Warlop, Katholieke University Leuven, Belgium & BI Norwegian Business School, Norway

Lacking power motivates people to consume conspicuously to signal status. However beyond the desire to signal status little is known about the positive consequences of conspicuous consumption for the powerless. In this ongoing research we provide initial evidence that powerless' acquired status through conspicuous consumption enhances their cognitive abilities.

Social Valuation and Neoliberal Ideology in Postfeminist Digital Spaces

Mikael Andéhn, Aalto University, Finland
Joel Hietanen, Stockholm University, Sweden
Thom Iddon, Stockholm University, Sweden

The online community labeled "the red pill" is growing rapidly and references to it in mainstream media are becoming commonplace. Delving into the community we uncover traces of an ideology in which social relations operate under market-like conditions and where management of the self is the key to marketplace success.

Should I Copy Her? A Meta-Analytic Synthesis Of Mimicry Effects

Susan Andrzejewski, California State University Channel Islands, USA
Krista Hill, Babson College, USA
Dhruv Grewal, Babson College, USA
Nancy Puccinelli, University of Bath and Oxford University, UK

We quantitatively synthesize the work on mimicry effects (i.e. effects of copying another's behavior). The results suggest for example that mimicry can increase favorable behavior by as much as 82% over a non-mimicry baseline. Importantly these effects are significantly attenuated by behavior that is mimicked and goals.

#NoBoysAllowed: Consumer Response to Brand Infidelity

Justin Angle, University of Montana, USA
Kathryn Mercurio, University of Oregon, USA
Eric Setten, University of Oregon, USA

This research explores consumer response to brands that shift their focus to different customers a concept we term brand infidelity. We propose that consumers who identify strongly with a brand experience more betrayal - yet are more likely to forgive - when a brand "cheats" on them with other customers.

Showing Off More For Less on Social Media:
The Changing Dynamics of Conspicuous Consumption and Value While Renting

M. Eda Anlamlier, University of Illinois at Chicago, USA
Lez Trujillo Torres, University of Illinois at Chicago, USA
David Gal, University of Illinois at Chicago, USA

We examined consumers' online display of status products when renting not owning. Preliminary analyses of the "Rent the Runway" hashtag in Instagram show a) use value for products remains high while exchange value is dramatically lower due to renting and b) consumers conspicuously embrace the renting firm above specific brands.

Examining the Co-construction of Belonging between Consumers and Service Providers

Robert Arias, University of Illinois at Urbana-Champaign, USA

This research examines how consumers' sense of belonging (SB) develops within a consumption community supported by firms. The researcher conducted interviews with both consumers and service providers. The aim of the paper is to develop a theoretical framework explicating how consumers' SB experiences are co-constructed by themselves and marketing agents.

Can Food (Waste)-related Lifestyle Segments Explain Food Waste?
– The Example of Denmark

Jessica Aschemann-Witzel, Aarhus University, Denmark

Identifying consumer differences in their relation to food in everyday life allows marketers and policy makers to efficiently design campaigns against consumer food waste. We adapt the food-related lifestyle concept to waste and through a survey and segmentation analysis find five segments deriving different recommendations for targeted social marketing action.

The Effect of Product Type on Consumers' Preference for Ambiguous vs. Precise Ratings

Amin Attari, University of Kansas, USA
Promothesh Chatterjee, University of Kansas, USA
Yexin Jessica Li, University of Kansas, USA

We investigate whether when and why consumers prefer precise information over ambiguous information. We hypothesize that when buying a utilitarian product consumers prefer precise product ratings over ambiguous ones. However due to the motivation inherent in hedonic purchases we propose this preference gets attenuated when consumers consider such products.

Emotional Well-Being in Stressful Situations: the Effect of Luxury Brands

Leonardo Aureliano-Silva, ESPM, Brazil
Suzane Strehlau, ESPM, Brazil

Stress is a problem in contemporary societies thus the use of luxury brands might help consumers feel better. The purpose of this research is to verify the impact of luxury brands consumption on emotional well-being and brand attachment in stressful situations. A set of 4 experiments between subjects was conducted. In high stress context luxury brand has a powerful impact on emotional well-being and attachment level compared to non-luxury brand.

When, How, and Why Hedonic Adaptation Generates a New Consumer Desire

Rodolfo Azambuja, Universidade Federal do Rio Grande do Sul, Brazil
Vinicius Andrade Brei, Universidade Federal do Rio Grande do Sul, Brazil
Leonardo Nicolao, Universidade Federal do Rio Grande do Sul, Brazil

This work shows preliminary results of a model developed from a 10-month longitudinal study designed to test whether the emergence of a new desire comes from consumer hedonic adaptation processes. Partial results show such an effect. The current level of enjoyment with a product consequence of hedonic adaptation influences desire.

How Ownership Judgments Affect Brand Extension Evaluations

Aaron Barnes, University of Illinois at Urbana-Champaign, USA
Tiffany White, University of Illinois at Urbana-Champaign, USA

We find evidence suggesting that when brands extend into contexts where the user's ownership is ambiguous brand extension evaluations operate through how observers evaluate the user. We also demonstrate that these effects disappear when the consumer does not have a strong self-brand connection.

When Causes Change How We Think and License Indulgence

Aaron Barnes, University of Illinois at Urbana-Champaign, USA
Minkyung Koo, University of Illinois at Urbana-Champaign, USA

We investigate the psychological consequences of cause-related marketing (CM) and demonstrate that cultural differences in thinking style affect and are affected by CM. We identify cultural orientation as an important moderator of previously documented licensing effects because of differences in consumers' attribution of virtuosity.

Deny the Voice Inside:
For Collectivists, Attitude Accessibility May Hinder Decision Making

Aaron Barnes, University of Illinois at Urbana-Champaign, USA
Sharon Shavitt, University of Illinois at Urbana-Champaign, USA

Although accessible personal attitudes are generally seen as desirable and helpful we present evidence that for collectivists compared to individualists such attitudes may have more negative or dissonance-inducing consequences particularly when those attitudes appear to be at odds with prevailing norms and thus interfere with adapting to normative expectations.

In The "I" of The Beholder:
Improving Health Communication by Using The First Person Perspective

Frederic Basso, London School of Economics, UK
Benjamin Voyer, ESCP Europe, France
Olivia Petit, INSEEC Business School, France
Kevin Le Goff, Aix Marseille Université, Marseille, France
Olivier Oullier, Aix Marseille Université, Marseille, France

The present research draws from studies on food psychology and embodied cognition to investigate the effect of the attribute of the message (pleasure vs. health) and the visual perspective (first vs. third-person perspective) on persuasion using behavioral and neuroimaging (fMRI) experiments.

Not Just a Pretty Face! The Impact of Model Facial Expression and
Body Mass Index on The Effectiveness of Health Advertising

Kerrie Bertele, University of Hertfordshire, UK
Ariadne Kapetanaki, University of Hertfordshire, UK
Paul Connell, Stoney Brook University, New York,USA

We examine the presentation of models in health advertisements. Eye-tracking experiments investigate the impact of: (1) facial expression (serious vs. fake smile vs. Duchenne smile) and (2) low versus high BMI on consumer's visual attention and intent to eat healthy. Recommendations to guide the design of health advertisements are developed.

Don't Freak, I'm a Sikh: Stigma, Styled Identities and
Social Distancing of the Turbaned Sikh Male

Anoop Bhogal-Nair, University of Northampton, UK
Andrew Lindridge, Open University, UK

This working paper investigates how Sikh men utilise social distancing strategies in developing distinct identities not narratives. Grounded in social identity theory we examine how global discourses of 'Islamophobia' have prompted 'Sikh projects' as strategies to de-stigmatize cultural symbols and ultimately socially distance one 'Other' from another 'Other.'

A Trip to Your Past: The Effect of Ending on Preference for Nostalgic Products

Sheng Bi, Renmin University of China, China
Jun Pang, Renmin University of China, China

This research proposes the ending effect on consumers' preference for nostalgic products. Across three studies we show that the ending of a time period increases consumers' preference for nostalgic products. In addition we identify the perceptions of the passage of time as the underlying process that accounts for this effect.

What's in the Box? Risk in Surprise Subscription Models.

Severin Bischof, University of St. Gallen, Switzerland
Tim Boettger, University of St. Gallen, Switzerland
Thomas Rudolph, University of St. Gallen, Switzerland

Assessing subscription models in retailing we seek to identify the drivers that influence consumers' attitude towards product subscriptions. Using Prospect Theory we find that consumers prefer subscription boxes with surprise content in lower frequencies and subscription boxes with predefined content in higher frequencies.

Using The Aesthetic Design Principle 'Autonomous, Yet Connected'
to Increase Purchase Intention of Radical Innovations by Consumers

Janneke Blijlevens, RMIT University, Australia
Wilfred Horig, RMIT University, Australia
Ruth Mugge, Delft University of Technology, The Netherlands

We find that both autonomy and connectedness simultaneously influence purchase intention mediated by aesthetic appreciation. We expected that the aesthetic design principle 'autonomous yet connected' principle would work to increase appreciation for radical innovations and sway the preferred balance to connectedness. These expectations were not confirmed and implications are discussed.

Experiencing the Self through Products:
How Direct Product Experiences Paired with Abstract Product Construals
Increase Consumers' Identification with and Evaluation of Products

Silke Blumer, University of St. Gallen, Switzerland
Philipp Scharfenberger, University of St. Gallen, Switzerland
Gerald Häubl, University of St. Gallen, Switzerland
Torsten Tomczak, University of St. Gallen, Switzerland

Consumers frequently use products to manifest their selves. We hypothesize that products fulfill this self-oriented function particularly when they are experienced directly and perceived on a high construal level at the same time. Evidence from two experiments supports this theorizing.

The "GMO" Halo Effect:
How Labeling Products as Genetically Modified Influence Calorie Judgments

Nicolas Bochard, Université Grenoble Alpes, France
Dominique Muller, Université Grenoble Alpes, France
Norbert Schwarz, University of Southern California, USA

In the same way as organic or fair trade labels GMO can lead to misperceptions on the caloric content of the food products (health halo effect). Depicting food as not containing GMO lead to positive evaluation (less caloric). Depicting food as containing GMO conversely lead to negative evaluation (more caloric).

Live in Your World - Play in Ours: How Pre-Configurations Based on
Preference Articulation Affect Consumer Product Configuration Processes

Daniel Boller, University of St. Gallen, Switzerland
Tobias Schlager, University of St. Gallen, Switzerland
Andreas Herrmann, University of St. Gallen, Switzerland

Firms face the challenge that product configurators are often perceived to be complex. This research proposes a novel format of product configuration that tackles these issues specifically providing consumers the opportunity to articulate their preferences and offering them an initial product configuration based on these articulated preferences.

Controversial Advertising: Reflections from Professionals

Jan Brace-Govan, Monash University, Australia

This study examines the work practices of advertising professionals through in-depth interviews to gather their views on controversial advertising specifically adverts that depict violence against women. The fragmentation of the advertising industry especially around digital channels has reduced opportunities for internal review leading to increases in unintentional controversy.

"You Shouldn't Have!" Facework and Disposal in Gift Receiving as a
Way to Manage Interpersonal Relationships

Ines Branco-Illodo, Nottingham Trent University, UK
Teresa Heath, Nottingham University, UK
Caroline Tynan, Nottingham University, UK

Drawing on Attachment Theory this research addresses the neglect of the ways in which recipients use gift receiving to manage relationships with givers. By pretending reducing dissonance and being honest in their gift responses and by using different disposal strategies recipients deal with the emotional anxiety of receiving unwanted gifts.

Uncertainty and the Provision of Online Reviews for Services

Leif Brandes, University of Warwick, UK
Rosa Cacabelos, Universität Zürich, Switzerland
Egon Franck, Universität Zürich, Switzerland

We study the effect of uncertainty about a service's true quality level after purchase on the provision and content of online reviews. We show that such uncertainty reduces the number of posted reviews and makes posted reviews more negative such that reviews no longer reflect true product quality levels.

The Consumer as an Artist Citizen: The Emancipatory Potential of Art in the Formation of the Self and Public Sphere in the 21st Century Consumer Culture

Zafeirenia Brokalaki, King's College London, UK

This research amalgamates consumer and cultural studies literature to explore self-expressive art practices in consumption settings. Using Habermas's public sphere conceptualisation and an ethnographic case-study we demonstrate the critical role of authorship in art-stimulated dialogical discourses impacting consumers' multi-layered activation public expression and marketplace conversions into late modern public spheres.

Toward an Improved Understanding of the Privacy Paradox

Mirja Bues, University of Muenster, Gemany
Wayne D. Hoyer, University of Texas at Austin, USA

The current research seeks to understand why consumers disclose vast amounts of personal information online despite high concerns of privacy a phenomenon known as the privacy paradox. We show that consumers' willingness better predicts their actual disclosure behavior than do behavioral intentions and also which factors influence the situation-specific willingness.

Why Customers Get Even?
The Predicting Role of Vengeful Customer's Negative Emotions

Phuong Thao Bui Nguyen, Toulouse 1 Capitole University, France

This research clarifies two categories of negative emotions that vengeful customers can feel: one of which targets the firm and the other targets the final user of the defective product. The proposed typology highlights different roles of a vengeful customer (victim vs. guilty party) which will predict his revenge action.

The Impact of Visual Imbalance on Consumers' Donation Behavior

Fengyan Cai, Shanghai Jiao Tong University, China
Christopher K. Hsee, Chicago University, USA
Jieru Xie, Shanghai Jiao Tong University, China

Two lab studies and one field experiment together demonstrate that a visually imbalanced donation device could increase people's donation intention even real donation behavior. And this impact of visual imbalance on consumers' donation intention is mediated by their motivation to seek for balance.

The Collective Aggregation Effect:
Aggregating Potential Collective Action to Motivate Prosocial Behavior

Adrian Camilleri, RMIT University, Australia
Richard Larrick, Duke University, USA

Is the statement "If X people all do Y action then Z outcomes will be achieved" motivating? We answer this question by conducting a series of laboratory experiments focused on motivating pro-social actions. It turns out that such statements are motivating by boosting perceptions of outcome efficacy.

The Power of Meaningful Stories over Happy Ones and the
Moderating Role of Implicit Theories

Marina Carnevale, Fordham University, USA
Ozge Yucel-Aybat, Pennsylvania State University-Harrisburg, USA

In the current research we explore whether and how meaningful versus happy stories about a brand may influence consumers' attitude towards that brand. Results suggest that meaningful stories might lead to higher attitude towards the brand because of its perceived trustworthiness. However these effects occur only for incremental theorists.

Reactions Towards Wasted Food. Experimental Data on Food Appreciation and Sales

Luca Casetti, Bern University of Applied Sciences, Food Science & Management, Switzerland
Thomas A. Brunner, Bern University of Applied Sciences, Food Science & Management, Switzerland
Aline E. Stämpfli, University of Bern, Switzerland

In this experimental study we examine the reactions of consumers towards wasted food under two different conditions. Having an organic product and a more personal relation to the food provider evokes more self-related responsibility whereas having bought the product on sale shows no effect.

Political Affiliation Moderates Attitudes Towards Artificial Intelligence

Noah Castelo, Columbia University, USA
Adrian Ward, University of Texas at Austin, USA

Despite the inexorable march towards human-level artificial intelligence almost nothing is known about how consumers perceive the risks and benefits of this revolutionary trend. We report 2 studies exploring these issues finding that consumers' attitudes are strongly influenced by political affiliation and by anthropomorphism of computers.

Who Gets Nudged? How Choice Architecture Interventions Interact with Preferences

Noah Castelo, Columbia University, USA
Crystal Reeck, Temple University, USA
Jon Jachimowicz, Columbia University, USA
Eric Johnson, Columbia University, USA
Elke Weber, Columbia University, USA

We explore how default effects are moderated by decision makers' pre-existing preferences. Default effects are significantly enhanced when the intent of the choice architecture intervention is consistent with the preferences of the decision maker and when existing preferences are uncertain.

The Risk of Virtue

Boyoun (Grace) Chae, Temple University, USA
Hyun Young Park, China Europe International Business School, China
Katherine White, University of British Columbia, Canada

While prior research has examined the impact of corporate social responsibility (CSR) on consumers' attitude toward the company and its products no extant research has investigated how CSR affects consumers' risk-taking decisions. The current research explores how CSR influences consumers' financial risk-taking depending on their belief in a just world.

The Donation to The Emergent-poor and to The Prolonged-poor Victims

Chia-Chi Chang, NCTU, Taiwan

Study one suggests distinct processing modes lead to different levels of willingness to donate money to the emergent-poor vs. the prolonged-poor. Study two shows preference of donating to the emergent-poor over to the prolonged-poor is also found to be affected by raising appeals (sympathetic vs. inspiring).

Consumer Responses to Green Messages: The Mediating Role of Perceived Personal Contribution

Ming-Yi Chen, National Chung Hsing University, Taiwan

This research explores how congruous attributes claim in green product communication elicit perceived personal contribution and brand attitudes by considering two boundary conditions (i.e. appeal type and message frame). Research on this topic has the potential to provide a more comprehensive and meaningful account of green advertising than currently exists.

The Reversed Endowment Effect in Living-Goods Transactions

Rui Chen, Xiamen University School of Journalism and Communication, China
Leonard Lee, National University of Singapore Business School, Singapore
Yuhuang Zheng, Tsinghua University School of Economics and Management, China

Prior research has shown that the endowment effect is sizable and robust. However the results of four studies suggest that the endowment effect may be reversed in transactions involving living objects implicating the role of psychological ownership—in particular perceived accountability and anticipated costs of ownership—in this effect reversal.

The Effect of Power on Consumers' Preferences for Nostalgic Products

Huan Chen, Renmin university of China, China
Sheng Bi, Renmin university of China, China
Jun Pang, Renmin university of China, China
Lingyun Qiu, Peking University, China

This research proposes the effect of power on consumers' preferences for nostalgic products. Results from two studies show that consumers with lower power are more likely to purchase nostalgic products. In addition the motivation to search for meaning in life works as the underlying mechanism that accounts for this effect.

The Effect of Smiling Expression on Status Perception and Product Evaluation

Yunqing Chen, the Chinese University of Hong Kong, China
Robert S. Wyer, the Chinese University of Hong Kong, China

We examined the effects of an endorser's facial expression on consumers' reactions to endorsers used in print ads and the consequent impact of these reactions on evaluations of the products being promoted. One study showed that people perceive a smiling female to have lower social status than a nonsmiling female but perceive a smiling male to have higher status than a nonsmiling male. These attributions in turn influenced evaluations of the products that the endorsers promoted. However smiling also influenced consumers' liking for the endorser and thus had a direct effect on product evaluations independently of status.

#ConsumerActivism: How Online Consumer Activism Impacts Brand Change

Amber M. Chenevert, St. John's University, USA
Aleksandr V. Gevorkyan, St. John's University, USA

The authors sought to understand the motivations actions and expectations of both online consumer activists and brand executives who have encountered consumer activist campaigns. This research contains online consumer activism implications for brand managers economics and marketing theory integration and introduces qualitative research to a largely quantitative area of study.

Voters' Processing Mindsets and Construing Modes of Campaign Advertising

Hsuan-Yi Chou, National Sun Yat-sen University, Taiwan

Based on theories on attitude change resistance to persuasion and construal-level theory this study examines how party consistency and the timing of broadcasting campaign advertisements affect voters' processing mindsets and construing modes of advertising messages and therefore investigates their responses towards advertisements. The findings contribute to political-marketing research and practice.

Being an Underdog or a Frontrunner: The Effects of Candidate Labels on Voters' Responses

Hsuan-Yi Chou, National Sun Yat-sen University, Taiwan

Despite pervasive use of the underdog and frontrunner labels in elections related studies are still scant. This study examines the relative effects of labeling candidates as underdogs vs. frontrunners in political communications and explores the moderation of candidate-related and voter-related variables. Research results contribute to political-marketing theories and practices.

The Price is Right – Activation of Mating Goals as Driver of Price-Based Quality Inferences

Fabian Christandl, Fresenius University of Applied Sciences, Germany
Mario Pandelaere, Virginia Tech, USA
Sebastian Berger, University of Bern, Switzerland

Three studies demonstrate that activation of mating goals may strengthen the belief that price signals quality. They further show that this effect is mediated by feelings of prominence and status that higher prices signal to people and in line with evolutionary psychology that the effect is limited to male participants.

Consumers' Motivations for Engagement in the Sharing Economy

Jaeyeon Chung, Columbia University, USA
Gita Johar, Columbia University, USA
Oded Netzer, Columbia University, USA
Matthew Pearson, Airbnb, USA

We use Airbnb host rent-out database (N = 24053) to suggest that consumers who are driven by intrinsic motivations (e.g. meeting people and sharing beauty) are more likely to be successful in renting out their properties than hosts who are driven by extrinsic motivations (e.g. earning cash).

Reflexive Habitus and Consumption: Negotiation and (Re)Stabilization of Social Class in Czech Republic

Zuzana Chytkova, University of Economics, Prague, Czech Republic

The concept of reflexive habitus (according to which self-reflexivity can become habitual and thus a "second nature") is used as a conceptual tool to describe how consumption is used to negotiate and (re)stabilize social class in a context in which the social structure has been disrupted by a neoliberal transformation.

How Health-based Body Image Stereotypes in Advertising Perpetuate Unhealthy Consumption Decisions Among at Risk Populations

Scott Connors, Washington State University, USA
Katie Spangenberg, University of Washington, USA
Andrew Perkins, Washington State University, USA
Mark Forehand, University of Washington, USA

The use of health-based body image stereotypes in advertising is shown to lead overweight consumers to make unhealthy product choices as a function of their own self body-image. An overweight implicit body image drives perceptions of product-model fit leading to more positive (negative) attitudes towards unhealthy (healthy) products.

Making Salient Immediate Post-consumption Affects Promotes Healthy Food Choices

Olivier Corneille, Université catholique de Louvain, Belgium
Claudia Toma, Université libre de Bruxelles, Belgium
Marcel Zeelenberg, Tllburg University, Netherlands

Three studies show (1) that consumers expect more instant than post-consumption satisfaction when choosing hedonic over healthy food items (2) more post-consumption than instant satisfaction when choosing healthy over hedonic food items and (3) that orienting consumers' attention on immediate post-consumption affects redirects their choice towards more healthy food options.

How Appropriate is Appropriation as a Branding Tool?
Commercialization and the Value of Experiences

Gert Cornelissen, Universitat Pompeu Fabra, Barcelona, Spain
Galli Maria, ESADE Business School, Spain
Joan Serra, Universitat Pompeu Fabra, Barcelona, Spain

Previous research has demonstrated how advertising and branding efforts that appropriate valued aspects of life are successful in building a favorable brand image. In this paper we study whether such efforts can crowd out the pleasure inspiration or value that people derive from those areas in life.

Finding the Right Corporate Social Responsibility:
How Identity Goals Influence Brand CSR Strategies

Diego Costa Pinto, ESPM Business School, Brazil
Márcia Maurer Herter, FADERGS Business School, Brazil
Dilney Gonçalves, IE Business School - IE University, Spain
Eda Sayin, IE Business School - IE University, Spain

Past research implies that sophisticated brands may not benefit from CSR. We demonstrate that priming consumers' identity goals moderates the effect of brand personality on perceived brand social consciousness. When social (personal) identity goals are primed consumers choose CSR with focus on self-(other) benefits for sophisticated (sincere) brands.

Signal with Cost: When and Why Identity Signals Are Perceived to Be Authentic

Katherine M. Crain, Duke University, USA
James R. Bettman, Duke University, USA
Mary Frances Luce, Duke University, USA

Punks signal with mohawks and piercings but sometimes they are called poseurs. How do observers judge the authenticity of a signaling consumer? We suggest that observers judge a signaling consumer's authenticity by inferring his or her willingness to accept the costs associated with his or her signal which is directly moderated by the positivity of the identity being signaled.

Message Not Received - The Effects of Creditor Pressure in Consumer Debt Management

Anna Custers, University of Oxford, UK

Survey data suggests that avoiding creditors is a common behavior by over-indebted consumers and is positively associated with debt levels negative emotions towards debt and creditor pressure. This behavior cannot be explained by observable individual characteristics. The results suggest that creditor pressure can increase avoidance and therefore can be counterproductive.

The Early Bird Gets the Worm:
The Effect of Habituation on the Effectiveness of Counter-Attitudinal Appeals

Steven Dallas, New York University, USA
Gavan Fitzsimons, Duke University, USA

In a lab study and a field study the current research finds that counter-attitudinal persuasive appeals can have a greater impact on behavior after people habituate to them. This flies in the face of current practice which typically involves making counter-attitudinal appeals as in-your-face and attention-grabbing as possible.

The Effect of Moral Identity on Compensation Evaluation:
Is Monetary Compensation Always Better?

Ahmad Daryanto, Lancaster University, UK
Felix Martin, Lancaster University, UK
Laura Salciuviene, Lancaster University, UK

We demonstrate how moral identity affects consumers' evaluation of damages vs. free repair compensation in a product moral crisis situation. Our findings reveal that it impacts the evaluation differently contingent upon the duration of product ownership.

Marketplace Mythology and the Politics of Identity

Ronnie Das, Coventry University, UK

This study recalls how the interdisciplinary field of cultural research has prioritised the investigation of 'Politics of Consumer Identity work' as a developing field of enquiry. Following this theoretical lead this study sought to understand the consequences of cultural branding in generating identity politics surrounding men and their two-wheeler machines.

Materialism and Participation in Sharing Practices

Alexander Davidson, Concordia University, Canada
Mohammad Reza Habibi, California State University Los Angeles, USA
Michel Laroche, Concordia University, Canada

The current research demonstrates that materialistic values are strongly associated with willingness to participate in sharing practices (i.e. couch surfing) due to the appeal of social status display. Because of a lack of appeal this effect does not carry over towards practices referred to as 'pseudo-sharing' (i.e. Airbnb).

A Theoretical Perspective on Guilt and Materialism in Helping Behavior

Ramona De Luca, FGV-EAESP, Brazil
Delane Botelho, FGV-EAESP, Brazil
Mateus Ferreira, FGV-EAESP, Brazil

In this theoretical paper we discuss the positive effect of a negative emotion such as guilt on individuals' attitudes toward charitable giving. In particular we propose that this effect is stronger for individuals with high levels of consumer materialism when compared with their low-materialism counterparts.

To Share or Not to Share: Coupon-sharing as a Way to
Increase Expenditures of Face Concerned Consumers

Eline de Vries, University Carlos III of Madrid, Madrid, Spain
Sha Zhang, University of Chinese Academy of Sciences, Beijing, China

Unlike previous literature focusing on traditional non-shareable coupons this study highlights a new form of coupons that can be shared with friends. Across studies conducted in the U.S. and China we find convergent results that high face concerned consumers are willing to spend more to obtain shareable than non-shareable coupons.

Research Reflections on Mobile Phone Visual Ethnography in Ghana, West Africa:
Bridging Mobile Phone Ethnography and Transformative Photography

Benét DeBerry-Spence, University of Illinois at Chicago, USA
Akon Ekpo, Rutgers University, USA
Dan Hogan, University of Illinois at Chicago, USA

While the proliferation of mobile phones in developing countries has been well documented researchers have not fully capitalized on this technology to inform ethnographic inquiries. Based on a study with consumer-merchants in West Africa we present mobile phone visual ethnography as a promising methodology for consumer research in emerging markets.

728 / Working Papers

How Thinking Style Impacts Consumer Reactions to Corporate Social Responsibility

Yoshiko DeMotta, Fairleigh Dickinson University, USA
Catherine Janssen, IÉSEG School of Management, France
Sankar Sen, Baruch College, USA

We examine how consumers' thinking style may impact their evaluation of CSR. We show that analytical thinkers evaluate companies more positively when the company-cause fit is high (vs. low) holistic (vs. analytical) thinkers evaluate companies more positively when the fit is low. CSR attributions mediate these effects.

How Youtube Storytelling Can Win Consumers' Hearts: The Case of Nivea

Laurence Dessart, Kedge Business School, Dep. of Marketing, Bordeaux, France
Valentina Pitardi, Luiss University, Dep. of Business Management, Rome, Italy

The study explores the role of storytelling in generating positive consumer responses to video ads compared to fact-based ads. The findings support the relevance of storytelling in enhancing consumer-brand relationship and show how a co-creation process in the evolution of a brand's storytelling content contributes to large and positive consumer responses.

The Effect of Visual Transparency on Taste Perception

Isabel L. Ding, National University of Singapore, Singapore
Miaolei Jia, National University of Singapore, Singapore

We demonstrate that individuals perceive the same beverage to be thicker when it is served in a visually opaque (vs. transparent) container. This effect arises because individuals attribute the perceived thickness of the beverage to the visual density of the container that it is served in.

The Effect of Gender-Scent Congruity on Product Evaluation and Purchase Intention

Isabel L. Ding, National University of Singapore, Singapore
Ming Ming Loo, National University of Singapore, Singapore
Xiuping Li, National University of Singapore, Singapore

Gender-scent congruity (e.g. female consumers exposed to feminine scents) enhances consumers' product evaluation purchase intention and willingness to pay for gender-neutral products (e.g. backpacks) when consumers engage in self-expression considerations. This effect is further moderated by the gender of the spokesperson in the product advertisement.

The Effect of Feedback Frequency on Goal Performance

Isabel L. Ding, National University of Singapore, Singapore
Leonard Lee, National University of Singapore, Singapore

Frequency of feedback given to individuals when pursuing a goal has an effect on their goal performance. Long-interval feedback (feedback given at longer regular intervals) leads to higher goal performance than short-interval feedback (feedback given at shorter regular intervals).

Do You Cut In Line?
Predicting Individuals' Compliance to Social Norms From Day-to-Day Behavior.

Michael Dorn, University of Bern, Switzerland
Adrian Brügger, Universität in Cardiff, Wales
Claude Messner, University of Bern, Switzerland

This paper demonstrates the predictive validity of a recently developed conformity scale in which consumers self-report day-to-day behavior. This conformity scale is the only one constructed on a Rasch model hence incorporating both the probability of the behavior and the costs related to reporting engagement in this behavior.

Exploring Food Waste: The Role of Health Motivation

Marit Drijfhout, Research Master Student, Rijksuniversiteit Groningen, The Netherlands
Jenny van Doorn, Associate Professor of Marketing, Rijksuniversiteit Groningen, The Netherlands
Koert van Ittersum, Professor of Marketing and Consumer Well-Being, Rijksuniversiteit Groningen, The Netherlands

We propose that consumers' intentions to eat healthy impact food waste. A field experiment measuring actual food waste and a household food waste diary study both consistently show that consumers with a higher degree of autonomous health motivation waste less food.

Reward-Based Crowdfunding: The Roles of Funders

Natalia Drozdova, Norwegian School of Economics, Norway
Ingeborg Kleppe, Norwegian School of Economics, Norway

In different types of crowdfunding projects the nature of relations between founders and funders can differ significantly. Our analysis of the Oculus Rift case demonstrates how funders negotiate their roles in a reward-based crowdfunding project as the project evolves from social towards commercial logic dominance.

Why Giving to Others Can Both Help and Hinder Persuasion: The Influence of Product Type on One For One Promotions

Riley Dugan, University of Dayton, USA
Joshua Clarkson, University of Cincinnati, USA
Joshua Beck, University of Oregon, USA

Despite considerable acclaim little is known regarding the efficacy of one for one promotions. This research demonstrates that these promotions have differential effectiveness on the basis of product type (hedonic v utilitarian). Furthermore we find that an individual's competing needs of belonging and uniqueness underlie the effectiveness of this model.

On The Cutting Edge: The Relationship Between Expertise and Social Influence in Evaluating Normative and Innovative Opinion

Riley Dugan, University of Dayton, USA
Joshua Clarkson, University of Cincinnati, USA
Cammy Crolic, University of Florida, USA

The present research examines the importance of the social knowledge signaled by statistical majorities and minorities (i.e. normative adherence versus innovative thought). In particular we posit that the majority position signals reliance on the socially-accepted position whereas the minority position signals reliance on an alternative to the socially-accepted position.

A Fresh Light on Choice Regret

Marcel Escher, University of Bamberg, Germany
Steffen Wölfl, University of Bamberg, Germany

Choice regret is a retrospect experience with important implications for consumer behavior in future decision situations. This research uses polynomial regression analysis and response surface analysis to deepen the understanding of choice regret. A study in the higher education context shows how an expectation-performance discrepancy affects choice regret.

Chirping Birds and Freshly-Cut Grass: The Role of Incidental Sensory Cues on Pro-Environmental Purchases

Sina Esteky, University of Michigan, USA

Can sensory factors in a retail store subtly nudge consumers towards green products? There is reason to believe so. This research investigates auditory and olfactory cues and finds evidence that incidental exposure to nature-related sensory cues may indeed influence product preferences and pro-environmental choices.

Shedding Light on the Influence of Illumination on Social Behaviors

Sina Esteky, University of Michigan, USA
David Wooten, University of Michigan, USA
Maarten Bos, Disney Research Pittsburgh, USA

Three studies provide empirical evidence that illumination affects social behaviors. We find that participants in bright (versus dim) settings demonstrate greater consideration of others' opinions needs rights and viewpoints; public self-consciousness mediates the effect of illumination on social behaviors; and the effect is reversed when social desirability is not relevant.

Sensitivity to Price Changes: A Study Within the Prospect Theory

Andrzej Falkowski, SWPS University of Social Science and Humanities, Warsaw, Poland
Robert Mackiewicz, SWPS University of Social Science and Humanities, Warsaw, Poland
Nina Chrobot, SWPS University of Social Science and Humanities, Warsaw, Poland

Prospect theory assumes that people derive utility from the perspective of gain or loss. We present two experiments that show that consumers are more price sensitive when they provide the price that would discourage them from the purchase in comparison with the price that they would accept

Social Crowding and Consumer Reactance toward Service Providers

Linying Fan, Hong Kong Polytechnic University, Hong Kong
Yuwei Jiang, Hong Kong Polytechnic University, Hong Kong

Two experiments revealed that a crowded environment increase consumers' reactance toward service providers who are perceived as warm and caring compared with consumers in uncrowded environments. Moreover this effect of crowding on reactance toward warm service providers is mediated by a heightened desire for social distance from others.

Financial Constraint Decreases Consumers' Variety Seeking Behavior

Yafeng Fan, Renmin University of China, China
Jing Jiang, Renmin University of China, China
Lin Jiang, Renmin University of China, China

This study examines the effect of financial constraints on consumer' variety-seeking behavior. Using different measures of variety-seeking choice we conducted three experiments to demonstrate that financial constraints increase consumers' insecurity which in turn decreases their variety seeking behavior. The moderating role of materialism in this effect was also examined.

On Aesthetic Pleasure: The Uncertainty-Reducing Role of Processing Fluency

Ali Faraji Rad, Nanyang Technological University, Singapore
Michel Tuan Pham, Columbia University, USA

We propose that the effect of fluency on aesthetic pleasure relates to fluency's role in reducing uncertainty: resolution of uncertainty is pleasurable; fluency contributes to faster uncertainty resolution and creates aesthetic pleasure. Three studies show that the effect of fluency on aesthetic pleasure attenuates when people are certain (vs. uncertain).

How One-Step (vs. Gradual) Presentation of Change Affects its Perceived Magnitude - The Role of Identity

David Faro, London Business School, UK
Emre Ozdenoren, London Business School, UK
Anja Schanbacher, London Business School, UK

Overall change in a stimulus is perceived to be larger when presented in one step vs. gradually but only when the changing stimulus has an underlying identity (e.g. a person or brand). Our findings suggest this is because one-step (vs. gradual) change causes stronger perceived disruption of the underlying identity.

Health is Up, Indulgence Down. Effects of the Vertical Location of Food Product Claims on Consumer Response

Alexandra Festila, MAPP Centre, Department of Management, Aarhus University, Denmark
Polymeros Chrysochou, MAPP Centre, Department of Management, Aarhus University, Denmark

Our research indicates that the position of specific food claims along the vertical dimension (of ads and packages) influences consumers' response such that products will be preferred when health-related claims are at the top and indulgence-related claims at the bottom.

The Dark Side of Connected Health Technology: How Connectivity Creates Exercise Addiction among Conscientious Users

Sandy Fitzgerald, RMIT University, Australia
Luke Kachersky, Fordham University, USA
Natalya Saldanha, RMIT University, Australia
Emily Chung, RMIT University, Australia
Lisa Farrell, RMIT University, Australia
Gaurangi Laud, RMIT University, Australia
Kaleel Rahman, RMIT University, Australia
Mike Reid, RMIT University, Australia
Linda Robinson, RMIT University, Australia

For many users connected health technologies (CHTs; e.g. diet and fitness apps) promote positive behavioral changes through simple psychological mechanisms. Yet emerging evidence suggests CHTs may compel some users to pursue health goals at unhealthy levels. This research examines if how and for which users CHTs foster exercise addiction.

The Effects of Selective Attention on Choice: An Eye-Tracking Study

Arnd Florack, University of Vienna, Austria
Martin Egger, University of Vienna, Austria

We conducted an eye tracking experiment to examine the effects of selective attention on consumer choice. We showed that selective attention influences preferences in consumer choice and provide new insights into the understanding of the mechanisms underlying the effects of selective attention on preferences.

Illusion of Illustration: The Impact of Picture Style on Dieters' Perception of Vice Food

Pei-Wen Fu, National Sun Yat-sen University, Taiwan
Pei-Chi Chen, National Sun Yat-sen University, Taiwan
Ying-Ying Li, National Sun Yat-sen University, Taiwan
Chun-Tuan Chang, National Sun Yat-sen University, Taiwan

This research investigates how different picture styles (photograph versus illustration) and dieting tendency influence consumers' perception of vice food. The results show that illustrated rather than photographic picture results in a healthier perception of vice food for dieters. Besides dieters' attention focus serves as the underlying mechanism.

Regaining Control or Avoiding Risk: When Social Crowdedness Inhibits versus Encourages Preference of DIY Product

Pei-Wen Fu, National Sun Yat-sen University, Taiwan
Chun-Ming Yang, Ming Chuan University, Taiwan
Chi-Cheng Wu, National Sun Yat-sen University, Taiwan

This paper proposes an important outcome of social crowdedness loss of control which results in the motivation of control restoration and the preference for control regaining products (DIY product). The results also showed that when DIY product fails to be a mean of control restoration avoidance motivation dominates consumers' choice.

Materialism, Green Values, and Well-Being: A Conflicting Values Perspective

Pia Furchheim, HEC Lausanne, Switzerland
Christian Martin, HEC Lausanne, Switzerland
Felicitas Morhart, HEC Lausanne, Switzerland

People can endorse simultaneously green and materialistic values. Across two studies we show that the resulting latent value conflict is associated with increased psychological tension and reduced well-being. Moreover latent value conflict impacts psychological tension in part through experienced value conflict.

Magnitude Matters: The Role of Anger Intensity in Interpersonal Perceptions

Celia Gaertig, University of Pennsylvania, USA
Alixandra Barasch, University of Pennsylvania, USA
Emma Levine, University of Pennsylvania, USA
Maurice Schweitzer, University of Pennsylvania, USA

How does the magnitude of an anger expression influence interpersonal perceptions? We find that extremely angry people are perceived to be less competent and warm and receive less status in interpersonal interactions. Our results demonstrate that magnitude matters: the social consequences of emotion hinge on the magnitude of emotional expressions.

Using EEG to Understand The Brain Processing Mechanism of Irrational Consumption Bias Rooted in Different Income Sources

Fei Gao, HEC Paris, France

This research first explores consumer's cognitive neural mechanism of irrational consumption bias rooted in different income sources. Different income sources set up different brain processing mechanisms of mental accounting. P3 and LPC are the specific components which reflect different types of consumption preferences in different income source accounts.

Unintended Negative Consequences of Product Recommendations Among Prevention Focused Consumers

Arezou Ghiassaleh, University of Lausanne, Switzerland
Bruno Kocher, University of Lausanne, Switzerland
Joseph Lajos, University of Lausanne, Switzerland

Results of a behavioral experiment involving real product choices show that the provision of product recommendations decreases consumers' choice commitment when they have a prevention focus but not when they have a promotion focus and that this moderating effect of regulatory focus is mediated by decision difficulty.

Towards Better Understanding and Managing of Online Trolling Behaviors

Maja Golf Papez, University of Canterbury, New Zealand
Ekant Veer, University of Canterbury, New Zealand

Trolling is a pervasive phenomenon performed by 'real' perpetrators and at the expense of 'real' targets (people or brands). Our study defines how trolling is different from other online misbehaviors and it demonstrates how understanding the factors involved in trolling may help social marketers and managers addressing it more successfully.

Creating a Hyper-Place: How Refugee Helpers Create a Place for Their Values

Johanna F. Gollnhofer, University of St. Gallen, Switzerland

This ethnography of voluntary refugee helpers shows why and how a meaningful place is produced. By drawing on spatial theory we map out how activist consumers create a hyper-place: Embedded in the dynamics of demarcating and linking voluntary helpers set a place apart from the surrounding space and other places.

Consumers' Dissociation Responses to Incidental Similarity of Products in Different Product Domains

Xiushuang Gong, School of Business, Renmin University of China, China
Jing Jiang, School of Business , Renmin University of China, China
Lin Jiang, School of Business, Renmin University of China, China
Yan Wang, China Unicom Research Institute, China

The current research examines the effect of incidental similarity of products on consumers' dissociation responses in different product domains. Across three experiments we find that consumers' dissociation responses are higher for the incidental similarity of high symbolic products. This effect is mediated by embarrassment and moderated by group belongingness.

Linear or Nonlinear? The Effect of Product Aesthetics on Consumers' Post-purchase WOM Generation and Repurchase Intentions

Xiushuang Gong, School of Business, Renmin University of China, China
Jing Jiang, School of Business, Renmin University of China, China
Yan Wang, China Unicom Research Institute, China

The present research examines the effect of product aesthetics on consumers' post-purchase WOM generation and repurchase intentions. Across two studies we find that for products with medium quality product aesthetics of hedonic and utilitarian products both positively influence consumers' WOM generation while their effects on consumers' repurchase intentions are quite different.

How Shall I Thank Thee? Giver-Recipient Discrepancies in Preferences for Public or Private Expressions of Gratitude

Lauren Grewal, University of Pittsburgh, USA
Mary Steffel, Northeastern University, USA
Dhruv Grewal, Babson College, USA

This research examines how people prefer to give and receive gratitude and whether recipients accurately predict and respond to givers' preferences for receiving thanks. Across three studies we show that recipients fail to anticipate gift giver responses to public gratitude; causing recipients to miss opportunities to enhance gift givers' experiences.

Head in the 'Cloud': Online Information Search Inflates Consumers' Self-Confidence in Personal Decision-Making Ability

Tito L. H. Grillo, Federal University of Rio Grande do Sul, Brazil
Adrian F. Ward, University of Texas at Austin, USA
Cristiane Pizzutti dos Santos, Federal University of Rio Grande do Sul, Brazil

Consumers increasingly rely on the Internet to prepare for future decisions and experiences. This study shows that accessing information through online search (vs. accessing without online search) elicits a false sense of "already knowing things" which increases consumers' confidence in their own decision-making abilities.

Does This Dog Make Me Look Fat? The Liberating Effect of Choices Made for Others on Subsequent Choices for the Self

Kelley A. Gullo, Duke University, USA
Peggy Liu, University of Pittsburgh, USA
Lingrui Zhou, Duke University, USA
Gavan J. Fitzsimons, Duke University, USA

Consumers frequently make consumption choices for others. We propose that those choices affect subsequent choices made for the self. We show that a choice made for a pet's consumption that is congruent with a primary personal goal liberates subsequent pursuit of an opposing secondary goal for the self.

Two Shades of Green: Unravelling the Composition, Antecedents and Consequences of Benign and Malicious Envy on Brand Attitude

Tanvi Gupta, Indian Institute of Management Bangalore, India
Preeti Krishnan Lyndem, Indian Institute of Management Bangalore, India

Malicious (benign) envy is conceptualized as a cluster of relatively high (low) envy and low (high) admiration. Three antecedents to envy-type are identified namely deservingness relationship type and foul-play. These contextual factors differentially activate the assimilative (contrastive) emotion of admiration (envy) by influencing self-other congruence and significantly impact brand attitude.

Experiential Bridges - An Alternative Perspective on Acculturation

Aditya Gupta, University of Nebraska-Lincoln, USA
Xin Zhao, Lancaster University Management School, Lancaster, UK

This paper presents an expanded view of experiential consumption in trying to understand the consumer acculturation process for international students and uncovers three underlying themes which help explain how such individuals adjust and adapt to their different consumption context which they have to inhabit for the medium-term.

Promoting Ethical Consumption: Effects of Self Regulatory Focus on Evaluation of Multifinal Ethical Products

Rishad Habib, University of Guelph, Canada
Towhidul Islam, University of Guelph, Canada

As more companies profess their desire to fulfill ethical and functional goals the research on ethical products from a multiple goals perspective remains scant. This paper looks at ethical products as multifinal means and seeks to explore the effect of regulatory focus on evaluation of means and resource allocation.

Spending Predictions: The Effects of Unpacking Based on Typicality

Konstantinos Hadjichristidis, University of Trento, Italy
Kishore Gopalakrishna Pillai, University of East Anglia, UK
Bidisha Burman, University of Mary, Washington, USA

Spending predictions are key drives of important life decisions so it is critical to understand the underlying psychology. We demonstrate that unpacking a target category of spending can increase decrease or leave predictions unaffected based on the typicality of the unpacked components and the perceived spending on them.

The Effect of Perceived Learning Opportunity on Consumers' Evaluations of Really New Products

Ajmal Hafeez, University College of Southeast Norway, Norway
Marit Gunda Gundersen Engeset, University College of Southeast Norway, Norway
Radu Dimitriu, Cranfield School of Management and University College of Southeast Norway, UK

We propose that consumers who are oriented towards future opportunities (learning) rather than focused on the attributes that maybe difficult to understand in the present will enhance consumers' evaluation of really-new products. Unlike previous research which has studied immediate costs-benefits we focus on consumers' long-term considerations of adopting really-new product.

Becoming an Insectivore: Results of an Experiment

Christina Hartmann, ETH Zürich, Switzerland
Michael Siegrist, ETH Zürich, Switzerland

Insects are considered as a sustainable alternative to conventional meat-based animal products however are not accepted as food by Western consumers. In this eating-experiment we explored whether or not offering insects in a processed form may facilitate the acceptance of insects in the diet in industrialized countries.

The Effects of Perspective Taking on Consumer Uniqueness-Seeking Tendency

Dongjin He, Hong Kong Polytechnic University, Hong Kong
Yuwei Jiang, Hong Kong Polytechnic University, Hong Kong

This research shows that incidental perspective-taking experiences lead consumers to become less attracted by unique products in subsequent consumption compared with those who do not take others' perspective. Moreover self-construal moderates this effect such that the effect is more salient for interdependent consumers.

Firm Power: On Its Construction and Consequences

Sharlene He, Northwestern University, USA
Derek Rucker, Northwestern University, USA

Firm power is an important aspect of the marketplace however the consumer behavior literature has limited understanding of how consumers represent firm power and the consequences of such perceptions. This research introduces and tests a model of antecedents to potential biases in and consequences of consumers' perceptions of firm power.

How Nudity in Advertising Affects Donation Behavior

Marloes Heijink, Hong Kong Polytechnic University, China
Yuwei Jiang, Hong Kong Polytechnic University, China
Jaideep Sengupta, Hong Kong University of Science and Technology, China

This research finds that exposure to nudity in advertising causes consumers to engage in more altruistic behavior as manifested both in monetary donations and intentions to donate blood. This effect is found to be mediated by the feeling of guilt elicited by viewing nudity.

The Ethical Consumption Gap in Fairtrade Consumption: How Price Importance, Habit and Ego Depletion Affect Attitude-Choice Incongruence

Atar Herziger, University of Cologne, Germany
Erik Hoelzl, University of Cologne, Germany

We examine an individual-level measure for the ethical consumption gap. In two studies involving incentive-compatible or hypothetical choices between Fairtrade and conventional products attitude-choice incongruence was significantly associated with reported price importance. In the incentive compatible design Fairtrade consumption habit and ego depletion tended to reduce the ethical consumption gap.

Shared Offline and Online Spaces of Ethical Consumption Communities

Vera Hoelscher, University of London - Royal Holloway, UK

This paper explores how the sharing of both physical and digital spaces impacts ethical consumption communities. Considering three independent sites in the London Borough of Camden through ethnography it studies the qualitative differences between offline and online spaces as well as the networks that form therein.

How Do They Feel: Categorial Sentiment Analysis of Emojis for Social Media Communication

Lisa Carola Holthoff, University of Duisburg-Essen, Germany

In electronic communication consumers increasingly use emoticons to express their emotions. We develop a categorial emoji sentiment analysis tool on the basis of a qualitative study with 900 participants and validate it with a second quantitative study. The tool simplifies the identification of emotional consumer reactions in social media communication.

Pain-Free Funeral: Creating the Market for the Bereaved in South Korea

Soonkwan Hong, Michigan Technological University, USA

This study illuminates the transformative process by which Koreans have been converted due to regulations with respect to funerary practice and unconsciously endorse the new experience industry that caters unprecedented "convenience" to the bereaved. The socio-politico-cultural patterning of funeral experience is characterized as de-Confucianization which involves de-emotionalization hyper-symbolization and vulgarization.

When There's Nothing You Can Do, an "Expansive" Window is For You: The Interaction Effect of Feelings of Personal Control and Promotion Period Framing on Promotion Evaluation

You Jeong Hong, Seoul National University, South Korea
Kyoungmi Lee, Seoul National University, South Korea

This research shows that when personal control is threatened consumers exhibit a more favorable attitude toward and a higher likelihood of participating in a promotion using expansive frame('anytime through Tuesday and Thursday') than non-expansive frame('from Tuesday to Thursday') to restore feelings of personal control.

Contemporary Art Consumer Experience: Using Video-Elicitation to Understand the Feeling of Strangeness

Richard Huaman Ramirez, Aix-Marseille University, France
Juan David Pinzon, Aix-Marseille University, France
Aranzazu Gaztelumendi, Aix-Marseille University, France

We analyze the feeling of strangeness of eleven visitors to a contemporary art museum by utilizing the "video-elicitation" technique combining video recording and in-depth interviews. We identified the participants values registers the terms they use to designate strangeness from artworks and the relation between the feeling of strangeness and satisfaction.

Creativity from Chaos: Disorder Material Display and Consumer Creative Success

Rong Huang, Shanghai University of Finance and Economics, China
Weiling Ye, Shanghai University of Finance and Economics, China
Darren Dahl, University of British Columbia, Canada
Yuqian Chang, Shanghai University of Finance and Economics, China

Our research demonstrated that when the materials to be used creatively are displayed in a disorderly manner people feel that they are more creative (i.e. subjective creativity) and objectively rated more creative in accomplishing a creative task. Subjective creativity also increase evaluations of the products/tools they are using.

Feeling of Luck Drives Preference for High-Effort Products and Activities

Feifei Huang, Chinese University of Hong Kong, China
Meng Zhang, Chinese University of Hong Kong, China
Yuwei Jiang, Hong Kong Polytechnic University, China

The current research examines the effect of incidental feeling of luck on consumers' preference for high-effort products and activities. We find that feeling of luck increases consumers' action tendency which in turn leads consumers to prefer high-effort products and activities over low-effort ones.

Responses to Injustice: Affect, Threats to Social Self-Esteem, and Materialism

Feifei Huang, Chinese University of Hong Kong, China
Robert S. Wyer Jr., Chinese University of Hong Kong, China

Five experiments demonstrate that people become more materialistic when the retributive and distributive justice of their misfortune are both high or both low. These effects are driven by the intention to boost social self-esteem and to eliminate the negative affect that results from the loss of this esteem.

The Effect of Personal Relationships on Pro-social Giving Behavior: Faith Based Giving

Jane Hudson, Plymouth University, UK
Jen Shang, Plymouth University, UK

How does the nature of our religious and personal relationships impact on our pro-social faith based giving behavior? We explore through experimental research how 'knowing' and 'caring' relationships with others influences financial generosity. Findings suggest 'caring' about siblings spouses and friends makes us more generous.

A Finite Pool of Worry

Brian Huh, Columbia University, USA
Ye Li, University of California Riverside, USA
Elke Weber, Columbia University, USA

People have finite cognitive resources in dealing with news. We tested the "finite pool of worry" hypothesis: Does worrying about one issue reduce worrying for other (perhaps more) important issues? We show that inducing concerns about an issue increases worry for that issue at the expense of other important issues.

Creative Power of Unique Fashion: Identifiable by Others or Exclusive for Yourself

San Young Hwang, Korea University, Korea
Nara Youn, Hongik University, Korea
Min Jung Koo, Sungkyunkwan University, Korea

We find that extraversion moderates the behavioral priming effect of unique fashion on wearers' creativity. "Self-awareness of being in the social spotlight" mediated the relationship for extraverts wearing bluntly unique clothing and "self-awareness of own distinctiveness that others don't notice" explained the effect for introverts wearing clothe with hidden uniqueness.

Retailer Pricing as Reassurance:
Discounts and the Transaction Utility of Conflicted Consumers

Chris Hydock, Georgetown University, USA
Luc Watieu, Georgetown University, USA

Retailers often either follow "every-day low pricing" (EDLP) or "high-low" (Hi-Lo) models; recent research finds that consumers' perceive the EDLP model to be cheaper. This research indicates that despite the price perceptions Hi-Lo pricing offers consumers particularly price-quality conflicted consumers transaction utility not available through EDLP.

Food Label Use by Functionally Low-Literate Consumers
in a Rural South African Context

Fay Irvine, North-West University, South Africa
Daleen Van der Merwe, North-West University, South Africa
Hanlie Van Staden, North-West University, South Africa
Magdalena Bosman, North-West University, South Africa
Susanna Ellis, North-West University, South Africa

This study investigated food label use by functionally low-literate consumers in a South African rural area. Respondents sometimes read labels and understood simple label information but struggled with more complex information and symbols. The provision of easily understandable labels for low-literate consumers to facilitate informed decisions will also benefit manufacturers.

Self-Reference as a Trigger of the Inner Prosecutor: The Moderating Role of the
Self-Reference Effect on the Relationship between Consumers and Transgressor Brands

Didem Gamze Isiksal, Istanbul Technical University, Turkey
Elif Karaosmanoglu, Istanbul Technical University, Turkey

This study analyzes the interplay between self-reference effect and corporate brand transgressions on consumer punishing behavior. By a 2x2 experimental design it is found that the interaction effect between self-reference and no self-reference groups and transgression levels causes a dramatic increase in punishing behavior under mild transgression rather than severe transgression.

Delegitimation of a Cultural Product: The Case of Turkish TV drama Behzat C.

Anil Isisag, University of Wisconsin - Madison, USA

This study examines the process of marketplace de-legitimation during which consumption practices are challenged and eliminated from the marketplace as a consequence of their inability to comply with become associated with and alter the definitions of legitimacy.

Patterns of Emotional Brand Experiences Across Cultures:
The Role of Context and Social Orientation of Emotions

Alexander Jakubanecs, Norwegian School of Economics, Norway
Magne Supphellen, Norwegian School of Economics and Business Administration, Norway
Hege-Mathea Haugen, Telenor Research, Telenor Group, Norway
Njål Sivertstøl, Telenor Research, Telenor Group, Norway
Nhat Le, Norwegian School of Economics, Norway

There is a lack of frameworks predicting under what conditions different brand emotions will be observed across cultures. We address this limitation by focusing on the social orientation of emotions and field dependency theories. One important finding is that brands evoke theoretically atypical emotions in an interdependent culture.

Effects of Dialecticism on Consumer Responses to Products With Conflicting Goals

Alexander Jakubanecs, Norwegian School of Economics, Norway
Alexander Fedorikhin, Indiana University, USA
Nina Iversen, BI Norwegian Business School, Norway

Research on drivers of consumer reactions to healthy vices (indulgent products with healthy claims) has been limited. We focus on dialecticism to predict and explain responses to these products within and across cultures. One important finding is that dialectical consumers (vs.non-dialectics) are significantly more accepting of products with conflicting goals.

Mortality Beliefs Distorted: Magnifying the Risk of Dying Young

Peter Jarnebrant, BI Norwegian Business School, Norway
Kristian O. R. Myrseth, University of St Andrews, UK

We explore mortality beliefs by eliciting individual-level belief distributions for participants' remaining lifespans. We find simultaneous great pessimism (about dying at < 50 years) and great optimism (about dying at > 100 years) compared to demographic data. This has important implications for a range consumer behavior including intertemporal choice.

Can the Color Value Affect Perceptions on Homosexual Images?

Eunmi Jeon, Sungkyunkwan University, South Korea
Myungwoo Nam, Sungkyunkwan University, South Korea

The current research examines how can color value affects perceptions on homosexual images. Our research aims to evaluate how an increased in color value results to a morally upright perception on homosexual images. A homosexual image on lighter tone yielded a positive attitude than that on a darker tone.

Seeking Indulgence by Involving Others

Miaolei Jia, National University of Singapore, Singapore
Gita Venkataramani Johar, Columbia University, USA
Leonard Lee, National University of Singapore, Singapore

We demonstrate that consumers are more likely to strategically involve others when they seek indulgence. This effect is mediated by the feeling of guilt. Accordingly promotions that involve others (e.g. "Buy one and get one free for your loved one") increase purchase intention for vice but not virtue products.

Lack of Control and Preference for Tangible Products

Li Jiang, UCLA, USA

We show consumers cope with lack of control by choosing tangible products over intangible counterparts. In three studies we show individual differences in desirability of control predicted choices of tangible products over intangible counterparts and participants who were made to feel lack of control chose tangible products over intangible counterparts.

Pride and Dishonesty-Why does Authentic Pride Lead to More Dishonesty?

Jinfeng (Jenny) Jiao, SUNY Binghamton, USA
Cathy Cole, University of Iowa, USA
Gary Gaeth, University of Iowa, USA

This paper focuses on authentic pride and hubristic pride as antecedents to consumer dishonesty and has both theoretical and empirical implications. We further examine the moderating role of cognitive resources in influencing pride effects on dishonesty. We demonstrate that it is moral disengagement that mediates the found effect.

Buyers Are More Impatient Than Sellers: The Timing of Peak Influences Satisfaction in Experiential Purchase

Zhenyu Jin, Shanghai Jiao Tong University, China
Wei Lu, Shanghai Jiao Tong University, China
Meng Duan, Shanghai Jiao Tong University, China
Jin Luo, Shanghai Jiao Tong University, China

Previous research demonstrated that the later the peak occurs the greater happiness people feel (Baumgartner et. al. 1997; Fredrickson and Kahneman 1993). We proposed that experience-buyer becomes more impatient than experience-seller while waiting for the delayed peak of an experience due to varying construal levels.

I Bought That First And You Know It:
The Influence of Ambivalent Mimicry on the Desire for Social Approval

Sunghee Jun, Seoul National University, Korea
Y. Jin Youn, Seoul National University, Korea
Kiwan Park, Seoul National University, Korea

Prior research shows that mimicry can lead to dissociation responses due to its threat on uniqueness as well as a sense of social approval. However we argue that consumers who experience ambivalent mimicry will not value the product less nor dislike it but will seek ways to gain social approval.

Fathers are not Like Mothers: How Males and Females Differ in the Effect of
Political Identity on Their Children's Educational Spending

Jihye Jung, Rice University, USA
Vikas Mittal, Rice University, USA

Through four studies this research examines the effect of parents' political identity on their spending decision on child's education. We find that conservatives prefer conformance-style education whereas liberals are more supportive of independent-style education. Further we identify this matching effect differs by individuals' self-versus other focus.

This Brand is MINE: Brand Psychological Ownership as a Distinct Construct and
Powerful Driver of Consumer Behavior

Bernadette Kamleitner, Wirtschafts University, Austria
Sophie Süssenbach, Wirtschafts University, Austria
Carina Thürridl, Wirtschafts University, Austria
Ruta Ruzeviciute, Wirtschafts University, Austria

Marketers often aim to make consumers experience a brand as "mine" i.e. they hope to initiate psychological ownership (PO) for their brand. Across three studies we show that brand PO is a conceptually distinct construct with explanatory power above and beyond other brand relationship constructs such as attachment.

Do I More (or Less) Deeply Process Messages When I Am the Source?
The Effect of Customization on Information Processing Mediated by
Perceived Control, Perceived Identity and Self-Control Resources

Hyunjin Kang, Nanyang Technological University, Singapore

By customizing their own media technologies consumers become active sources rather than passive audiences in communication processes. The study investigates the effect of customization on how consumers process product-related information. The study also tests how psychological outcomes of customization (i.e. perceived control and identity) and self-control resources mediate this effect.

"Prosociality Lies in the Mind of the Believer":
Differential Impacts of God and Religion on Prosocial Intentions

Mustafa Karatas, Koc University, Turkey
Zeynep Gürhan-Canli, Koc University, Turkey

We examine distinct cognitive consequences of two important religious concepts –God and religion– as they pertain to prosocial intentions. We show that God (vs. religion) reminders lead to higher (vs. lower) mind-set abstraction and increase compliance with abstractly (vs. concretely) framed messages and heightens prosocial tendencies toward psychologically distant (vs. close) targets.

Entitled to Spend:
Discourse Analysis as a Framework for Understanding Student Buying Behaviour

Matthew Kearney, Ulster University, Ireland
Lorna Stevens, University of Westminster, UK
Pauric McGowan, Ulster University, Ireland

Drawing on discourse analysis this qualitative exploratory study identifies a discourse of entitlement amongst student consumers enabling them to justify compulsive buying and other maladaptive spending habits. Three sub-themes Deservedness Defiance and Desire for Distinction were identified within this framework highlighting the wider societal context within which individual spending occurs.

Sexualized but not Objectified -
When do Women React Negatively Towards Sexualized Advertisements

Matthias Keller, University of Basel, Switzerland
Leonie Reutner, University of Basel, Switzerland
Mirella Walker, University of Basel, Switzerland
Rainer Greifeneder, University of Basel, Switzerland

Sex-Sells is a commonly used strategy which is often received negatively by women. Two studies investigated the underlying processes and indicate that it is not the sexualization per se but the objectification of the model that causes negative evaluations especially when oneself feels close to the model.

Do We Truly Like Those Who Work for It?
The Effects of Consumption on Evaluations of Others Spending Earned Wealth

Corinne Kelley, Florida State University, USA
Martin Mende, Florida State University, USA
Maura Scott, Florida State University, USA

Two studies demonstrate that under automatic processing attitudes toward successful others with earned wealth decline when the target's consumption behavior is made salient. This effect is attenuated with systematic processing. The effect is mediated by jealousy and a decline in belief in a just world.

Involving Others in Sustainable Consumption:
The Positive Impact of Exemplary Behavior

Corinne Kelley, Florida State University, USA
Martin Mende, Florida State University, USA
Maura Scott, Florida State University, USA

Drawing on theories of social observability impression-management and role-modeling we find experimental support for the idea that encouraging others to engage in sustainable behavior causes consumers to take on social role model responsibilities. This has downstream effects on their motivation to engage in other exemplary behaviors (e.g. healthy food choices).

Ethicality in Direct to Consumer Advertising of Prescription Medicines:
Consumers' Autonomy and Safe Decision Making

Neda Khalil Zadeh, University of Otago, New Zealand
Kirsten Robertson, University of Otago, New Zealand
James Green, University of Otago, New Zealand

Self-regulation of DTCA assumes consumers can make autonomous decisions. Two population-based studies examined responding to DTCA based on attitudes knowledge and health behaviors. Attitudes and unhealthy behaviors predicted responding to DTCA so raised concerns regarding regulations on DTCA. Further research exploring factors that contribute to consumers' safe decision-making is described.

Seeking a Green City to Live in: The Differential Impact of Innovation-Based Versus Regulation-Based Environmental Policy on Willingness to Live

Sukhyun Kim, HEC Paris, France
Jaehoon Lee, Southern Illinois University, USA

In three studies we show that innovation-based policy leads to a greater willingness to live than regulation-based policy. Using a serial mediation analysis we further show that this effect is mediated by perceived innovativeness and then by perceived quality of life resulting in an increased willingness to live.

Human Model Effect? Online Visual Presentation of Fashion Merchandise

Jae-Eun Kim, Massey University, New Zealand
Kyeongheui Kim, SKK GSB, Korea
Jungkeun Kim, Auckland University of Technology, New Zealand

Fashion retailers use human models to present their merchandise. The purpose of this research is to investigate the effects of using human models on product evaluations. The results showed that it can vary depending on the level of individual's dispositional or situational visualization ability which further should be domain specific.

The Illusion of Processing Fluency on Pro-social Campaigns: Unjustifiable Efforts Produce Guilty Feelings

Yaeeun Kim, Temple University, USA
Yae Ri Kim, Seoul National University, South Korea
Vinod Venkatraman, Temple University, USA
Kiwan Park, Seoul National University, South Korea

This study provides evidences that attitudes in processing pro-social campaigns are moderated by different goals. We found that if one's goal is dishonorable putting extra effort into difficult processing fluency (DPF) campaigns causes negative effects. The increase in guilt when dealing with DPF campaigns explains the underlying mechanism.

Proudly Going Green: Emotional Appeals Influence Outcomes for Environmental Marketing Challenges

Yaeeun Kim, Temple University, USA
Crystal Reeck, Temple University, USA

We examined the effect of goal progress and emotional appeal messages. Findings support that emotional appeal messages increase the feeling of helping the environment and intentions to complete the marketing challenge. Subsequent experiments investigate the effect of progress in social goals on the attitudes toward pro-social behavior.

The Interplay of Happiness and Control on Reliance on Feelings versus Reasons in Decision Making

Moon-Yong Kim, Hankuk University of Foreign Studies, Korea
Sungjun Park, KAIST, Korea

Previous research has demonstrated that happy moods are known to promote feeling-based processing whereas sad moods promote reason-based processing. The current research shows that a high (vs. low) level of control in a happy situation can promote a greater reliance on feelings (vs. reasons) in making judgments and decisions.

You Stepped on My Toes:
When Does Psychological Ownership Lead to Territorial Responses?

Colleen Kirk, New York Institute of Technology, USA
Scott Swain, Clemson University, USA
Joann Peck, University of Wisconsin - Madison, USA

Results of three experiments reveal that when consumers psychologically own a product they perceive infringement and behave territorially as another person signals control intimate knowledge or investment of self in the product. Infringement and territorial responses intensify when consumers believe they have more clearly signaled (i.e. "marked") their psychological territory.

Understanding Consumer Skepticism Towards Sustainable Innovations

Jan Koch, University of Groningen, The Netherlands
Koert van Ittersum, University of Groningen, The Netherlands
Jan Willem Bolderdijk, University of Groningen, The Netherlands

We offer a novel account for explaining consumers' skepticism towards sustainable innovations (e.g. insect consumption electric vehicles). We argue that adopting these innovations requires consumers to violate internalized norms which triggers negative emotions (e.g. disgust) and thus stimulating consumers to reject radical behavioral changes.

The Emotional Dynamics in Online Customer Reviews

Clara Koetz, Rennes School of Business, France
Renaud MacGilchrist, Rennes School of Business, France

Our objective is to model the nature of emotional dynamics in online customer reviews. Our findings demonstrate that rather than a diffusional process emotions switch between stochastic regimes through time. These regimes are characterized by significant changes in the temporal frequency of reviews and the transition probabilities of emotions.

Consumer Discrimination: How a Choice Mindset
Influences Fairness Perceptions of Insurance Premiums

Michail Kokkoris, University of Cologne, Germany
Krishna Savani, Nanyang Business School, Singapore

We examined consumers' fairness perceptions of insurance policies that discriminate premiums based on individual behaviors or outcomes. We found that a choice mindset decreases perceptions of fairness among consumers who feel disadvantaged by the policy but increases perceptions of fairness among those who feel favored by the policy.

When do Consumers Feel More Authentic?
The Interplay of Self-Control Choices and Thinking Styles

Michail Kokkoris, University of Cologne, Germany
Erik Hoelzl, University of Cologne, Germany
Carlos Alós-Ferrer, University of Cologne, Germany

We examined how consumption self-control affects authenticity for consumers with different thinking styles. Making a high self-control choice made participants with a higher (vs. lower) preference for deliberation feel more authentic whereas making a low self-control choice made participants with a higher (vs. lower) preference for intuition feel more authentic.

Do Consumer Choices Make Us Narcissists?
The Role Of Self-Referencing And Self-Affirmation

Michail Kokkoris, University of Cologe, Germany
Ulrich Kühnen, Jacobs University Bremen, Germany
Constantine Sedikides, University of Southampton, UK

We examined two pathways from consumer choices to maladaptive narcissism operating in parallel. Choice yields both self-referencing and self-affirmation which in turn have opposing effects on narcissism: Whereas self-referencing increases maladaptive narcissism self-affirmation reduces it. Therefore consumer choices can simultaneously augment maladaptive narcissism via self-referencing and attenuate it via self-affirmation.

When Does Anxiety Make Consumers More Careful About Conserving Resources?

Shruti Koley, Texas A&M University, USA
Caleb Warren, Texas A&M University, USA
Suresh Ramanathan, Texas A&M University, USA

Anxiety is a multi-dimensional emotion that can be broken down into narrower categories. Individuals experience active-anxiety when they're lagging behind on goals they feel responsible for while they experience passive-anxiety when they perceive global threats that are outside their control. Active-anxiety unlike passive-anxiety increases choice for discounted products and activities.

Applications of the Need for Smell-Scale

Monika Koller, WU Vienna, Austria
Thomas Salzberger, WU Vienna, Austria
Arne Floh, University of Surrey, UK
Alexander Zauner, WU Vienna, Austria
Maria Sääksjärvi, Delft University of Technology, The Netherlands
Rick Schifferstein, Delft University of Technology, The Netherlands

Little is known about the individual propensies of consumers to actively engage their senses in purchase decision-making. This is especially true for the sense of smell. The current paper presents field applications of the Need for Smell-scale. Moreover common patterns of need for touch and need for smell are identified.

Functional Near-infrared Spectroscopy (fNIRS): A New Tool for Consumer Research?

Caspar Krampe, Heinrich Heine University Düsseldorf, Germany
Enrique Strelow, Justus Liebig University Giessen, Germany
Peter Kenning, Heinrich Heine University Düsseldorf, Germany

As a new method for consumer research our study aims to validate the functional Near-Infrared Spectroscopy (fNIRS) in a laboratory experiment. Preliminary results indicate that the fNIRS is indeed a reasonable neuroscientific method to study consumer behaviour.

Precise Like a Swiss Watch: Semantic Precision in Marketing Communication

Ann Kronrod, Boston University, USA
Vincent Xie, University of Massachusetts, USA

Three studies reveal that semantic precision (verbally describing things exactly as they are) influences perceptions and attitudes towards products. This effect is mediated by perceived conversational cooperativeness and trustworthiness of the source. Further we find that the salience of the effect of semantic precision depends on context (hedonic/utilitarian).

The Environmental Impact of Anti-Consumption Lifestyles and Environmentally Concerned Individuals

Maren Ingrid Kropfeld, ESCP Europe, France
Marcelo Vinhal Nepomuceno, HEC Montreal, Canada
Danilo Dantas, HEC Montreal, Canada

Our findings indicate that certain anti-consumption lifestyles (i.e. voluntary simplicity and tightwadism) have lower environmental impact than being concerned with the environment suggesting that resisting consumption offers an alternative way towards more sustainable consumption. Voluntary simplicity has the lowest environmental impact of the lifestyles studied frugality the highest

Boomerang Effect of Conditional Promotions in Shopping Cart Abandonments

Atul Kulkarni, University of Missouri, USA
Cindy Wang, University of Oregon, USA
Hong Yuan, University of Oregon, USA

We find that shoppers' propensity to abandon shopping carts in response to unfulfilled conditional promotions is influenced by the interaction of promotion framing and distance-to-threshold. We found support for perceived fairness (perceived attractiveness) of the promotional offer as a driver of abandonment intention when distance-to-threshold is relatively far (close).

Taste Competitions in an Online Community: The Case of Yeni Gelin Evleri in Turkey

Alev Pinar Kuruoglu, Independent researcher, Turkey
Gulay Taltekin Guzel, Bilkent University, Turkey

This research aims to understand how the interplay of gender and class inflect taste displays and competitions in an online community. We conduct netnography on a Turkish facebook group "Yeni Gelin Evleri" in which lower-middle class newlywed women share photos and receive comments on their homes.

Doctoring Happiness: An Ethnographic Study on Plastic Surgery in Turkey

Alev Pınar Kuruoğlu, Independent Researcher, Turkey
Berna Tarı Kasnakoğlu, TOBB ETU, Turkey

This ethnographically informed research investigates the entwinement of elective plastic surgery with the pursuit of happiness. We approach happiness as a "self-disciplining technique" that drives practices related to cosmetic surgery and which we argue constitutes part of broader dynamics related to being a "proper" woman living a worthwhile life.

How Thinking about Society's Past Influences Optimism towards its Future

Canice M. C. Kwan, Sun Yat-Sen University, China
Shirley Y. Y. Cheng, Hong Kong Baptist University, China
Alex S. L. Tsang, Hong Kong Baptist University, China

Consumers would feel nostalgic not only when reminiscing about their own past but also when reflecting on a historic era of their society. This research probes into the latter type exploring its impacts on optimism toward the society's future and decisions for the society (e.g. endorsement of risky public policy).

Resistance, Conformance, And Stigma in The Consumption of Music

Gretchen Larsen, Durham University, UK
Maurice Patterson, University of Limerick, Ireland

This paper delineates the nature of the stigma of conformity in music consumption. Such stigma is associated with too close an adherence to social norms as made manifest in popular culture and fashion. Thus this stigma is attached to that which is superficial and is seen to lack authenticity.

Thinking Creatively through Hands

Jeong Eun Lee, Hongik University, South Korea
Nara Youn, Hongik University, South Korea

Through four studies this research empirically demonstrates that physical hand movement and the elicitation of the embodied metaphor of hands enhance creativity. The relationship between using hands and creativity is mediated by the symbolic metaphor of the "craft-making" and "curiosity and imagination."

Time and Conformity:
The Effect of Temporal Distance on Consumers' Responses to Word-of-Mouth

Ran Li, The Chinese University of Hong Kong, HK, China
Yiren Dong, Nanjing University, China
Guocai Wang, Nanjing University, China

This paper examines the effect of temporal distance on consumers' responses to word of mouth. Two studies demonstrate that when participants buy a product for future use (vs immediate use) they will feel more similar and close with other consumers and conform more to their word of mouth.

Whom Do Incentives Motivate and Whom Do They Deter?
The Role of Group Identity in Incentivizing Charitable Behavior

Charis Li, University of Florida, USA
Yanping Tu, University of Florida, USA
Ayelet Fishbach, University of Chicago, USA

The role of material incentives in prosocial domain has long been arguable. This research suggests that group identity changes how people view personal gains through charitable behaviors thus altering the role of incentives: incentives motivate charitable behavior among in-group donors or fundraisers but undermine charitable behavior among outgroups.

Work With Me or For Me: The Influence of
Implicit Self-Theories on the Preference of Anthropomorphized Products

Chien-Wei Lin, State University of New York at Oneonta, USA
Dipankar Rai, LeMoyne College, USA

Three studies show that consumers' implicit theories of personality interact with anthropomorphized product roles when relating to consumer preference. Specifically incremental (entity) theorists prefer a product that portrays as a partner (servant) more since it fits their mastery (performance) goal orientation. This effect is moderated by task difficulty.

Heavy vs. Light TripAdvisor Reviewer Behavior

Heather Linton, Cornell University, USA
Robert Kwortnik, Cornell University, USA
Jay Russo, Cornell University, USA

Existing research on motivations behind engaging in online word of mouth (eWOM) has offered multiple discrepant lists of the reasons travelers choose to leave a review online. In this paper existing data from TripAdvisor reviews is analyzed to further investigate the behavioral differences of heavy versus light TripAdvisor reviewers.

On the Accuracy of Consumer Future Usage Estimations: Evidence From the Car Sharing Industry in Germany

Daniel Lippe, Karlsruhe Institute of Technology (KIT), Germany
Sven Feurer, Karlsruhe Institute of Technology (KIT), Germany

Estimations of future usage plays an important role in consumer decision-making. Drawing on real consumption data this study illuminates the accuracy with which consumers estimate future usage and provides evidence that involvement and need for cognition drive this accuracy.

It Feels Good and Bad to Be Fake: The Effect of Counterfeit Consumption on Consumer Feelings and Purchase Preference

Joyce Jingshi Liu, Hong Kong University of Science and Technology, China
Amy Dalton, Hong Kong University of Science and Technology, China
Jiewen Hong, Hong Kong University of Science and Technology, China

We find that using counterfeits in public elicits mixed feelings particularly for consumers with a high status-signaling motive. These mixed feelings in turn reduce the appeal of counterfeits relative to genuine products. Accordingly ads that highlight counterfeit consumption experience in the present of others effectively reduce consumers' counterfeit demand.

Focusing Only on Satisfying Customers? --- Negative Word of Mouth from Insiders

ShihHao Liu, Saint Louis University, USA
SangBong Lee, Saint Louis University, USA

The ongoing research proposes and identifies a systematically neglected source of negative word-of-mouth (NWOM). The current two studies revealed that feedback on service performance causes employees' to exert NWOM which is mediated by negative affect but not to make change in work-related behaviors.

'My Beautiful Self': An Exploration of the Effects of Advertising Campaigns on Female Empowerment

Cristina Longo, Université Lille, France
Meltem Türe, Université Lille, France

This study explores the effects of the recent advertising trend that promotes women's self-acceptance. We find that while these brands create a space of empowerment for women within a market that works with beauty standards they also subtly contribute to the powerless and insecure women myth they claim to challenge.

The Role of Visual Attention in Product Selection

Ruxandra Luca, Imperial College London, UK
Mirjam Tuk, Imperial College London, UK
Andreas Eisingerich, Imperial College London, UK

The cognitive impact of pop-up ads is not well known: while designed to inform they also interfere with online browsing behaviour. The purpose of this project is to investigate how the visual system filters ads depending on their location colour and duration and how this subsequently affects preferences for products.

How Companies' CSR Motivation Influences Consumers to Adopt Pro-social Behavior

Danielle Mantovani, Federal University of Parana, Brazil
Lucas Magalhães de Andrade, Federal University of Parana, Brazil
Angela Negrão, Federal University of Parana, Brazil

This paper proposes that CSR motivation impacts consumers' pro-social behaviors based on consumer-brand social distance. Consumers close to the brand are positively (vs. negatively) influenced by benevolent (vs. self-interest) CSR motivation (experiments 1and 2). Experiment 3 provides evidence that this effect is mediated by consumers' skepticism about the CSR action.

Matte Is the New Green:
The Influence of Matte Packaging on the Perceived Greenness of Products

Eva Marckhgott, WU Vienna, Austria
Bernadette Kamleitner, WU Vienna, Austria

In two studies we show that products in matte packages are perceived to be greener than products in glossy packages and that this cue is particularly strong in competitive presentation settings. Our findings draw attention to the importance of packaging surface and may inform packaging design.

Age-Related Changes in Materialism in Adults – A Psychological Insecurities Perspective

Christian Martin, HEC Lausanne, Switzerland
Sandor Czellar, HEC Lausanne, Switzerland

It has been reported frequently that materialism declines with age during adulthood. The reasons for this however have not yet been studied. In two studies we find that this effect can be partially explained by age-related changes in self-uncertainty. Implications for theory are discussed.

A Threatened Relationship Makes More Positive Consumers:
The Effect of Romantic Jealousy on Advertising Effectiveness

Olga Martin, University of Washington, USA
Lea Dunn, University of Wasahington, USA

This research examined the effect of romantic jealousy on advertising effectiveness and found that romantic jealousy increased overall favorability of attitudes toward advertisements and advertised products as well as purchase intention. Mediation analyses confirmed that the effect of jealousy on confidence is the mechanism by which jealousy affects advertising effectiveness.

Consumer Engagement with Luxury Foods

Ewa Maslowska, Northwestern University - Medill, USA
Vijay Viswanathan, Northwestern University - Medill, USA
Mototaka Sakashita, Keio University, Japan

Luxury foods are often purchased for their experiential and identity benefits and hence can enhance consumer engagement. Preliminary analysis of purchase transactions from an ultra-luxury department store show that food purchases contribute to reducing the time elapsing between two shopping trips and thus increase engagement with the store.

The Voice From Afar: Reverberation in Spoken Advertising Messages "Influences Consumer Information Processing

Johann Melzner, NYU Stern School of Business / LMU Munich Institute for Market-based Management, Germany
Jochim Hansen, University of Salzburg, Austria

We provide first evidence that the sound design of an advertisement can have more than an aesthetic function as it affects consumers' cognition. When reverberation was added to an announcer's voice participants put more weight on statistical (versus individualized) product information. This effect influenced evaluation willingness to pay and choice.

"It Might Fit But Cost More":
Similarity, Skepticism, and Regulatory Focus in Cause-Related Marketing

Monica Mendini, Università della Svizzera Italiana, Switzerland
Paula C. Peter, San Diego State, USA
Michael Gibbert, Università della Svizzera Italiana, Switzerland

A key issue in CRM is how fit and skepticism are related. Our findings suggest that even if consumers perceive higher fit with taxonomic partnerships they are more skeptical and expect companies to contribute more to the cause. To lower this effect a promotion (vs. prevention) focus strategy is suggested.

Motivating Persistence and Risky Choice: Beyond Monetary Incentives

Rachel Meng, Columbia University, USA
Ran Kivetz, Columbia University, USA

Incentives motivate us. While considerable research has focused on monetary rewards our evidence suggests that non-monetary hedonic rewards may induce greater persistence—and better performance—in real-effort tasks. Participants facing hedonic (vs. monetary) incentives were also more likely to invest effort to earn a larger-uncertain reward over a smaller-surer one.

White and Clean: How Disease Avoidance Affects Color Preferences

Uwe Messer, University of Bamberg, Germany
Daniel Hein, University of Bamberg, Germany
Steffen Woelfl, University of Bamberg, Germany
Alexander Leischnig, University of Bamberg, Germany

This research examines how an activated disease avoidance system influences preferences for products with light-colored surfaces. Light-colored surfaces facilitate the detection of impurity which is a fundamental goal when consumers are motivated to protect themselves from contamination. The results of two experiments allow for important theoretical and managerial implications.

Online Retailing is Here to Stay -
The Effects of Product-Context Levels On Consumer Decision Making

Jan Meyer, Tecnológico de Monterrey, Mexico
Eva Gonzalez Hernandez, Tecnológico de Monterrey, Mexico
Paz Toldos Romero, Tecnológico de Monterrey, Mexico

We investigate the role of context (with or without) in online product presentations and its influence on the consumer's value perception. High context presentations generate increased value through increased mental imagery. The level of involvement and the consumer's implicit theory moderate the relationship. Our results help improving online shopping experiences.

Resources Availability and Explicit Memory Largely Determine Evaluative Conditioning…
Even in a Paradigm Conducive of Implicit EC Effects.

Adrien Mierop, Université catholique de Louvain, Belgium
Mandy Hütter, Universität Tübingen, Germany
Olivier Corneille, Université catholique de Louvain, Belgium

Three studies used a multinomial processing tree model to examine the impact of attentional load on implicit and explicit learning processes involved in Evaluative Conditioning. Results yielded evidence for explicit learning but no support for implicit learning processes even though studies relied on sensitive experimental and analytic procedures.

When a Change in Institutional Logics Does Not Lead to Market Evolution:
The Case of Fertility Services Market

Laetitia Mimoun, HEC Paris, France
Francesca Sobande, University of Dundee, UK
Lez E. Trujillo Torres, The University of Illinois at Chicago, USA

Using institutional theory we investigate the lack of market evolution despite change in guiding institutional logics. The 15-year historical analysis of the fertility services market reveals how marketers use various strategies to maintain market and logics legitimacy despite conflicting scientific moral commercial and gendered logics surrounding the quest for parenthood.

Self-Awareness Fit and Consumer Product Evaluation

Bora Min, University of Southern California, USA
Cheryl Wakslak, University of Southern California, USA

Consumers increasingly engage in activities that can situationally increase self-awareness (e.g. taking selfies). Across two experiments we find that situationally increasing self-awareness via self-focusing stimuli (i.e. video and mirror) enhances (vs. hinders) experiences with products among consumers with high (vs. low) public self-consciousness.

The Effect of Spending Intentions on Windfall Use

Joshua I. Morris, Stanford University, USA
Jonathan Levav, Stanford University, USA

We show that receiving a windfall decreases the likelihood of choosing an option with a price exceeding the windfall amount when one does not have prior spending intentions for the purchase category. However receiving a windfall increases the likelihood of choosing such an option when prior spending intentions are present.

Do Deals Really Help Save: Deal Salience And Increased Consumer Spending

Sudipta Mukherjee, Virginia Tech, USA
Mario Pandelaere, Virginia Tech, USA
Daniel Villanova, Virginia Tech, USA

Consumers have the lay belief that looking for deals helps in saving money. In this paper we find that deal salience decreases self-control and increases consumer spending. Further we get the surprising result that deal salience has a greater influence on the spending behavior of tightwads than spendthrifts.

Is Altruism Perilous? Consumer Benevolence and Risk Taking

Sudipta Mukherjee, Virginia Tech, USA
Samuel Bond, Georgia Tech, USA

Our research examines the relationship between consumer benevolence and risk taking. Based on theory of less deliberative processing and optimism bias we hypothesize and find across three 3 studies that at both trait and situational levels benevolence is related to increased risk taking due to decreased risk perceptions.

Ambivalent Attitudes do Not Induce Confusion among Collectivists

Andy H. Ng, University of Illinois at Urbana-Champaign, USA
Sharon Shavitt, University of Illinois at Urbana-Champaign, USA
Hazel R. Markus, Stanford University, USA

People of Asian (vs. European) background perceived context-dependent attitudes as more socially desirable which led to a higher tendency to evaluate objects both favorably and unfavorably without context. This led to feeling of confusion only for those who did not strongly endorse collectivistic values and when independent self-construal was primed.

Goal Failure Enhances Creativity

Luke Nowlan, University of Miami, USA
Juliano Laran, University of Miami, USA

We examine the cognitive consequences of failed goal pursuit and demonstrate that goal failure leads to the consideration of an array of alternative goals which induces a flexible mindset and enhances creativity. Contributions to both the goal pursuit and creativity literatures are discussed.

Empirical Generalizations of Brand Personality Dimensions: Longitudinal Analysis of a Robust Six Factor Model

Travis Tae Oh, Columbia University, USA
Michel Tuan Pham, Columbia University, USA
Kamel Jedidi, Columbia University, USA

Since Aaker's seminal paper on brand personality the validity of this proposition has not been fully investigated. We analyze 15 years of proprietary panel data with 17000 subjects and 3000 brands per year provided by BAV. We find in fact a six dimension brand personality structure that evolves over time.

The Relationship between Happiness and Perception of Purchases: Experiential Versus Material

Hyewon Oh, University of Illinois at Urbana-Champaign, USA
Incheol Choi, Seoul National University, Korea

We examine two unanswered questions regarding happiness and the fuzzy boundary between experiential purchases and material purchases. Using a multi-method approach we found that happy people perceive their purchases as more experiential than less happy people do and people become happier when they practice 'experiential framing' of their purchases.

When Gift Giving is Stressful: The Role of Relationship Style

Lale Okyay Ata, Koc University, Turkey
Zeynep Gurhan Canli, Koc University, Turkey
Nicole Verrochi Coleman, University of Pittsburgh, USA

In two studies this research explores relationship attachment style as an antecedent of gift giving stress and investigates the differential impact of separate insecure attachment styles on consumers' attitudes toward various stages of gift giving. Implications for theory and practice are discussed.

Towards a Better Understanding of Sales Promotions' Impact on Impulsive Purchases

Mahshid Omid, Université Laval, Canada
Frank Pons, Université Laval, Canada

Although previous research emphasized that a significant percentage of impulsive purchases comes from sales promotions the psychological mechanisms at the origin of this influence have been understudied. To address this gap this paper investigates the mediating role of consumer affective and cognitive responses on impulse buying process of promoted products.

Webrooming or Showrooming? A Matter of Involvement

Carlos Orús, University of Zaragoza, Spain
Raquel Gurrea, University of Zaragoza, Spain
Carlos Flavián, University of Zaragoza, Spain

We examine two cross-channel behaviours formed by the integration of the online and physical channels: showrooming (information offline purchase online) and webrooming (information online purchase offline). We find that involvement is higher in webrooming than in showrooming and determines the channel preferences to search for information and buy the product.

When Beauty is Bad: Attractive Faces Alter People's Food Choices

Tobias Otterbring, Karlstad University, Sweden

Directly contradictory to individuals' lay beliefs prior exposure to attractive (versus unattractive) opposite-sex faces made people choose unhealthy rather than healthy food products. This effect primarily influenced people with a low (versus high) concern for healthy eating but did not generalize to exposure of attractive (versus unattractive) same-sex faces.

Attention to Country-of-Origin Information

Johanna Palcu, University of Vienna, Austria
Arnd Florack, University of Vienna, Austria
Adamantios Diamantopoulos, University of Vienna, Austria
Georgios Halkias, University of Vienna, Austria

The present study applies eye-tracking to establish the conditions under which country-of-origin (COO) information moves into the center of consumers' attention. Moreover applying the Stereotype Content Model to a COO context we demonstrate that consumers' warmth and competence country stereotypes are reflected in their warmth and competence product judgments.

Consumer Suspicion as a Communicational Opportunity in Ethical Consumption

Artemis Panigyraki, Imperial College Business School, UK
Claudia Jasmand, Imperial College Business School, UK

This paper proposes the notion of suspicion as a unique opportunity for persuasion in ethical consumption. Can suspicion be more efficient than trust for marketers to achieve persuasion? Information search might be triggered by a certain level of suspicion and give to ethical companies the opportunity to overcome generalized distrust.

Customer Engagement: Conceptualization, Distinctiveness and Testing the Nomological Network

Prateeksha Parihar, Indian Institute of Management Raipur, India
Jagrook Dawra, Indian Institute of Management Raipur, India
Vinita Sahay, Indian Institute of Management Raipur, India

We have conceptualized & distinguished Customer Engagement (CE) from other constructs by extant literature review. We observed the mediation effect of CE between Involvement and Loyalty with the positive effect of Involvement on CE and CE's positive effect on Loyalty but No direct effect of Involvement on Loyalty.

Deliberate First or Act First? The Effect of Self-Construal on Goal Pursuit

Hanyong Park, University of Texas at San Antonio, USA
David Silvera, University of Texas at San Antonio, USA
Ashok Lalwani, Indiana University, USA

This research examines cultural differences in goal pursuit. Independent self-construal is associated with cost-benefit analysis which leads to emphasis on assessment-related goal pursuit activities. Conversely interdependent self-construal is associated with agreeableness which leads to emphasis on locomotion-related goal pursuit activities.

What Happens When the Company is the Unfairly Treated Party in Online Review?

Maria Alice Pasdiora, Universidade Federal do Rio Grande do Sul, Brazil
Cristiane Pizzutti, Universidade Federal do Rio Grande do Sul, Brazil
Natalia Englert, Universidade Federal do Rio Grande do Sul, Brazil

We show that consumers who perceive unfairness in an online review towards a company behave against the unfair review and reviewer and in favor of the wronged company. This effect is explained by the negative emotions caused by the episode reader's inferences about reviewer's motivations and empathy towards the company.

When Usage Repetition Leads to Predictions of Faster Adaptation

Maria Alice Pasdiora, Universidade Federal do Rio Grande do Sul, Brazil
Vinicius Andrade Brei, Universidade Federal do Rio Grande do Sul, Brazil
Leonardo Nicolao, Universidade Federal do Rio Grande do Sul, Brazil

We show how and when the perception of repetitive consumption leads consumers to predict hedonic adaptation. Results suggest that repetition salience stimulates consumers to predict diminishing enjoyment over time weakens the impact of assortment variety on predicted enjoyment and strengthens the impact of attention drawn by product on predicted enjoyment.

The Association Between Digit Ratios and Conspicuous Consumption, and the Moderating Role of Intrasexual Competition

Cristina Maria de Aguiar Pastore, Pontifical Catholic University of Paraná, Brazil
Marcelo Vinhal Nepomuceno, HEC Montreal, Canada
Eric Stenstrom, Miami University, USA
Eliane Cristine Francisco Maffezzolli, Pontifical Catholic University of Paraná, Brazil

We investigated the effects of hormones on conspicuous consumption. Low digit ratios (high prenatal testosterone exposure) were associated with greater conspicuous consumption in men particularly when intrasexual competition was high. In women high digit ratios (high prenatal estrogen) were only associated with greater conspicuous consumption when intrasexual competition was high.

From Consumers to Producers: The Identity Evolution of Food Bloggers

Gabrielle Patry-Beaudoin, HEC Montréal, Canada
Yannik St.James, HEC Montréal, Canada

Drawing from the professional identity and serious leisure literatures this study examines consumers' identity as they engage in production activities. A qualitative investigation of food bloggers documents three identity forms – novice amateur and professional – consumers integrate as they participate in production practices as well as identity tensions they must negotiate.

Pornographication and the Advertising of Sexual Services

Maurice Patterson, University of Limerick, Ireland
Gretchen Larsen, University of Durham, UK

This research reports on an analysis of advertising cards used by prostitutes in London from 1992 to 2008. It depicts a shift in such advertising described in terms of pornographication; a visual regime that relies heavily on the representational codes of pornography and an industrialization and commodification of sex work.

The Influence of Contextual Minority Status on Privately-Held Evaluations of Identity-Linked Products

Iman Paul, Georgia Institute of Technology, USA
Jeffrey R Parker, Georgia State University, USA
Sara Loughran Dommer, , Georgia Institute of Technology, USA

Does being the lone female in a group of males influence women's evaluations of female identity linked products? Two studies find that when gender identity is activated by being in the numerical minority of a group women report less positive attitudes toward products associated with negative aspects of their gender.

I Aspire to Give to Your Needs, I am Responsible to Give to Your Aspirations: Persuasion of Philanthropy Functions Through Regulatory Non-fit

Sara Penner, University of Manitoba, Canada
Olya Bullard, University of Winnipeg, Canada

This research examines philanthropic giving from a goal-directed perspective. Applying the framework of Regulatory Focus Theory (Higgins 1997) a persuasion through regulatory non-fit phenomenon is identified. Individuals' promotion focus motivates giving to prevention-focused causes whereas individuals' prevention focus motivates giving to promotion-focused causes. Implications for theory and practice are discussed.

Brand Extensions - It's all About Managing Accessibility

Adrian Peretz, Kristiania University College, Norway
Lars Olsen, Kristiania University College, Norway

We demonstrate that using benefit-based brand extensions and selecting extension categories that can be subsequently subsumed into more abstract categories reduces interference in memory from category associations–allowing for easier retrieval of diagnostic of brand benefit associations.

The Interaction between Moral Behavior and Social Norms

Dikla Perez, Tel Aviv University and Technion, Israel
Ayelet Gneezy, University of California San Diego, USA

This research uses the case of digital-content piracy to examine the behavioral consequences of engaging in socially acceptable immoral behaviors. We suggest that consumers' willingness to pay for digital content piracy is driven by negative emotions linked to their perceived dishonesty and relevant when social norms against piracy are strong.

Comparing Prices Then and Now – the Store Price Image Determines Reference Price Dominance

Anne Odile Peschel, Aarhus University, Denmark

When evaluating product prices consumers compare the observed prices to an internally retrieved or externally suggested reference price. Using scanner panel data I show that while in high price image store formats the internal reference price dominates in low price image formats consumer rely more on externally suggested reference prices.

When Governmental Regulation Causes Price Increases: Is Communicating a Good Cause Always Beneficial?

Doreen Pick, University of Applied Sciences Merseburg, Germany
Stephan Zielke, University of Wuppertal, Germany
Wayne D. Hoyer, University of Texas at Austin, USA

Price increases can occur as the result of governmental regulations which support a good cause. Firms can justify the increase by highlighting the good cause (environment framing) or they could blame the government for the regulation (government framing). We analyze the impact of such strategies in a field scenario experiment.

Distant but Local: Border-Based Perceptions of Localness and Effects on Food Preference

John Price, University of Oregon, USA
Brandon Reich, University of Oregon, USA

We first introduce and validate the Locavore scale. We then show experimentally that consumers exhibit a "border bias" in which distant (vs. proximal) food is perceived as more local when it is sourced from within their political borders and how localness perceptions interact with Locavorism to influence food choices.

The Role of Social Endorsement in a Repeated Exposure Context

Suntong Qi, Lingnan University, Hong Kong
Yu-Jen Chen, Lingnan University, Hong Kong

We examine how social endorsement asymmetrically influence message persuasibility in a context of repeated information exposure. We show how subsequent social endorsement is more effective than initial one because message recipients inhibit pursuit of goal initially but rebound to a higher desirability level at subsequent exposure stage.

Friend or Firm: When Friendliness Reduces Comfort Perceptions During Sales Interactions

Suzanne Rath, Queen's University, Canada
Laurence Ashworth, Queen's University, Canada
Matthew Philp, HEC Montreal, Canada
Nicole Robitaille, Queen's University, Canada

It is generally believed that friendly firms facilitate positive consumer responses. However this may not always be true. This research suggests that friendly firms may make consumers feel less comfortable as consumers may not view firms as especially meaningful relationship partners even though friendliness is normally a desirable interpersonal exchange.

Money and Me: Thoughts of Money Change Individuals' Self-View

Leonie Reutner, University of Basel, Switzerland
Mirella Walker, University of Basel, Switzerland
Rainer Greifeneder, University of Basel, Switzerland

We show that money thoughts shift individuals' self-view (study 1) towards more agency and less communion when accuracy is central but does not similarly affect the way other people are viewed (study 2). When accuracy is not central money shifts self-view towards an ideal agentic and communal self (study 3).

The 'Flower Men' Phenomenon: Exploring the Cultural Encoding of Masculinity in South Korean Cosmetics Advertising

Ann Kristin Rhode, ESCP Europe & Université Paris 1 Panthéon-Sorbonne, France

Given the cultural relativity of masculinity and attractiveness representations of masculinity are likely to vary across cultures. This study explores images of masculinity in South Korean print advertising for men's cosmetics. Findings of a content analysis suggest a notion of 'soft masculinity' that may widen traditional gender lines around cosmetics.

Clicking Decisions and the Coexistence of Insufficient and Excessive Checking

Yefim Roth, Technion University, Israel
Michaela Wänke, University of Mannheim, Germany
Ido Erev, Technion University, Israel

We examines the impact of past experiences on the tendency to use easy "single-click checking" options in simplified settings. The results reveal the co-existence of insufficient and excessive checking. The direction of the deviation is captured with the hypothesis that consumers exhibit oversensitivity to the best in retrospect outcome.

When Choosing the Best Brings out the Worst:
Maximizing Increases Cheating Due to Greater Perceptions of Scarcity

Caroline Roux, Concordia University, Canada
Jingjing Ma, Peking University, China
Kelly Goldsmith, Northwestern University, USA

Striving for the best or a maximizing mindset is often advocated as an ideal in many life domains. But how far are consumers willing to go when striving for the best? Three studies demonstrate that activating a maximizing mindset increases cheating behavior because it elicits greater perceptions of scarcity.

The Effects of Envy on Scarcity Appeals in Advertising:
Moderating Role of Product Involvement

Rajat Roy, Curtin University, Australia

Results from two laboratory experiments show that when subjects experience benign (malicious) envy they exhibit higher value perception and purchase intention for the product showcased in a demand (supply) appeal over the supply (demand) appeal. This effect held under conditions of high product involvement but disappeared under low involvement.

Social and Behavioral Consequences of Feedback When Participating in Brand Pages

Salvador Ruiz de Maya, University of Murcia, Spain
Mariola Palazon, University of Murcia, Spain
Maria Sicilia, University of Murcia, Spain

This study combines data from Facebook and two experiments to show that (a) the content of consumers' posts on brand pages in social networks determines the feedback they obtain in the form of likes and comments and (b) how that feedback impact their perception of social recognition and behavioral intentions.

The Effects of Consumers' Identification and Disidentification in the Case of
Corporate Misconduct – Exploring the Mediating Role of Emotions

Christopher Ruppel, University of Vienna, Austria
Sabine Einwiller, University of Vienna, Austria

Due to higher self-relevance corporate misconduct should elicit stronger emotions in identified and disidentified consumers compared to non-identified which mediate different consumer reactions. In a first study particularly disidentified consumers' adversarial behaviors were mediated through disapproving emotions and schadenfreude whereas sympathy elicited in identified consumers resulted in higher perceived trust.

Taking the Easy Way Out:
The Structure of Complex Assortments Navigates Consumers Towards Different
Product Choice Locations Under the Condition of Broad Attentional Scope

Sebastian Sadowski, University of Groningen, The Netherlands
Bob M. Fennis, University of Groningen, The Netherlands
Koert van Ittersum, University of Groningen, The Netherlands

Across two studies we show that assortment complexity affects consumers with a broad but not with a narrow attentional scope. Consumers with a broad attentional scope not only take longer to choose most preferred product from a complex assortment they also select products from different locations depending on assortment structure.

Advertising Effectiveness: Examining the Role of Latent Themes on Advertising Success

Prakash Satyavageeswaran, Doctoral Student, Indian School of Business, India
M G Parameswaran, FCB Ulka, India
Sridhar Samu, Great Lakes Institute of Management, India

We extract two latent themes from transcripts of television advertisements using latent topic modelling. Their impact on the advertisements' success is assessed using a multinomial logit model. We contribute methodologically and substantively by introducing a novel latent theme approach for understanding impact of textual themes on consumer's ranking of advertisements

Lost in the Supermarket: Searching for Products on Crowded Shelves

Ana Scekic, HEC Paris, France
A. Selin Atalay, Frankfurt School of Finance and Management, Germany

Crowded scenes make it more difficult to differentiate otherwise distinct objects. We study how the positions of products on the vertical range of the visual field affect consumers' search experience in a retail context. We provide initial evidence for shelf location based effects on consumer search in crowded scenes.

The Monetary Value of Ethical Attributes: Preference Reversal Effects Among Cause-Related Marketing Campaigns

Christina Patricia Schamp, University of Hamburg, Germany
Mark Heitmann, University of Hamburg, Germany
Julia Stehmann, University of Hamburg, Germany

The momentum of cause-related marketing allows the transfer of the norm theory of category-bound thinking on market scenarios evaluating the actual value of ethical attributes. Our results show that the importance of causes and subsequent choices reverse when two isolated campaigns are implemented jointly and brand-cause fit moderators this reversal.

Consumer-Expert Interactions in the Medical Domain: Exploring When and How Patients with Prostate Cancer Ask Their Physicians for Advice

Karen Scherr, Duke University, USA
Mary Frances Luce, Duke University, USA
Peter Ubel, Duke University, USA

With the increasing consumerization of healthcare the role of physician recommendations has become more complex and uncertain. Using data from patients with prostate cancer we find significant variation in how patients request recommendations how physicians respond to those requests and identify factors (e.g. anxiety) that predict whether patients request recommendations.

Using Humor to "Sell" Good Life Choices

Julie L. Schiro, University College Dublin, Ireland

What is the effect of humor on public service ads? On one hand humor could hurt by trivializing the problem. On the other humor could help by making the ad more likable. Using SEM I model these factors simultaneously to find the net effect of humor on behavior.

Close Alternatives: The Influence of Spatial Proximity on Choice Difficulty

Iris K. Schneider, VU University Amsterdam, the Netherlands
Norbert Schwarz, University of Southern California, USA
Sander L. Koole, VU University Amsterdam, the Netherlands

Decision difficulty is often expressed in spatial language for instance when people say "the choice alternatives are close". We explore the consequences of this metaphor for consumer decision-making. Our findings reveal that choices are harder when alternatives are presented spatially close together compared to far apart.

To Share or Not to Share?
Social Distance as The Underlying Mechanism to Explain Sharing Behavior

Nadine Schreiner, Heinrich Heine University Düsseldorf, Germany
Peter Kenning, Heinrich Heine University Düsseldorf, Germany

Sharing is a fundamental part of human behavior but still lacks empirical research. Field theory suggests social distance as one of the underlying mechanism affecting sharing behavior. Using an experimental design preliminary results show a decrease of sharing ratio as a function of social distance resulting in a hyperbolic shape.

Humanizing Products Through Typeface Design

Roland Schroll, University of Innsbruck, Austria
Benedikt Schnurr, University of Innsbruck, Austria
Dhruv Grewal, Babson College, USA

Across three experimental studies the authors show that using handwritten (vs. machine-written) typefaces on product packaging positively affects consumers' product evaluations. This effect is driven by perceptions of social presence imbued in the product which increase consumers' emotional attachment to the product. Further the authors examine an important boundary condition.

Food Fight! A Comparative Analysis of the
Portrayal of Food in Cartoons Targeting Girls and Boys

Eric Setten, University of Oregon, USA

This study shows significant differences in the number and meaning of food references in cartoons for girls versus those for boys. Girls' shows reinforce the message "food is love" while boys' shows reinforce the message "food is fuel." This has important implications for the development of identity-based attitudes towards food.

A Visual Consumption of Desserts: The Impact of Subtle Food Cues on Dieters

Donya Shabgard, University of Manitoba, Canada
Kelley Main, University of Manitoba, Canada

This research examines the differences between dieters and non-dieters in response to subtle consumption cues. Participants were presented with an image of a bitten cut or whole dessert. The results show that dieters in comparison to non-dieters respond more favourable to the bitten and cut desserts.

The Ending Effect on Positive Illusion

Ziqi Shang, Renmin University of China, China
Jun Pang, Renmin University of China, China
Lingyun Qiu, Peking University, China

This research proposes and demonstrates the ending effect on individuals' positive illusions. Across two studies we show that individuals have a lower level of positive illusion at the end of a time period than at other time points and this effect is mediated by the perceptions of resource depletion.

I Like It Because I Imagined The Scent: Olfactory Imagery Improves Product Evaluation

Varun Sharma, Bocconi University, Italy
Zachary Estes, Bocconi University, Italy

We show that visual image of a pleasant scent-inducing object in advertisements and packages improve (reduce) product evaluation for scent-relevant (scent-irrelevant) product categories. First study demonstrates this effect in product packages. Second study shows that this effect is mediated by generation of olfactory imagery while extending the applicability to advertisements.

Asymmetric Conformity to Positive and Negative Advice

Henry Shen, University of California, Riverside, USA
Ye Li, University of California, Riverside, USA

The ubiquity of online ratings has facilitated word-of-mouth transmission but researchers have yet to fully understand whether and how rating valence interacts with intrinsic product quality to affect consumer's ultimate product evaluation. We show that positive and negative WOM advice asymmetrically influences the evaluation of good and bad experiential products.

Leaps and Tweaks: The Impact of Version Numbers on Product Attractiveness

Meyrav Shoham, Technion - Israel Institute of Technology, Israel
Yael Steinhart, Tel-Aviv University, Israel
Sarit Moldovan, The Open University of Israel, Israel

When consumers evaluate products with version numbers smaller numerical gaps between version numbers can enhance product appeal. Three studies show that this effect occurs when the existing version has a decimal number while the new version has a whole number suggesting a more substantive leap after several incremental ones.

Mental Representation of Attitudinal Ambivalence

Amit Surendra Singh, Ohio State University, USA
H. Rao Unnava, Ohio State University, USA

An ambivalent attitude has both positive and negative reactions associated with it. In this research the underlying structure of oppositely-valenced components is investigated. Preliminary evidence indicates positive and negative thoughts about an object being stored together in memory. Further effect of situational relevance on accessibility is studied.

The Telepresence Effect:
Changing Attitudes via Virtual Tours in Marketing Communications

Nathalie Spielmann, NEOMA Business School, France
Antonia Mantonakis, Brock University, Canada
Barry J. Babin, Louisiana Tech University, USA
Aikaterina Manthiou, NEOMA Business School, France

Virtual online tours enable a consumer to immerse themselves in environments without physically being in them usually in the hopes of encouraging positive attitudes toward the advertiser. Two studies demonstrate how consumer and advertiser interactivity unique to virtual tours leads to telepresence (e.g. immersion) which then leads to positive attitudes.

How Hunger Facilitates Dieting: The Paradoxical Effect of Hunger When Individuals are Primed With an Environmental Dieting Cue

Aline E. Stämpfli, University of Bern, Switzerland
Thomas A. Brunner, Bern University of Applied Sciences, Switzerland
Sabrina Stöckli, University of Bern, Switzerland
Claude Messner, University of Bern, Switzerland

This research examines the influence of an environmental dieting cue in interaction with hunger. Results reveal that the cue a screensaver showing thin human-like sculptures by the artist Alberto Giacometti reduced unhealthy food intake especially in hungry individuals. Thus the dieting cue was effective when it was actually needed.

The Role of Mimicry in Charity Advertising

Sabrina Stöckli, University of Bern, Switzerland
Aline Stämpfli, University of Bern, Switzerland

This research explores the effect that charity ads induce more empathy when showing sad versus neutral and happy children's faces. Assuming mimicry to be involved face reader analysis reveals that people mimic happy but not neutral and sad faces. This suggests that mimicry only partially facilitates emotional contagion.

Choosing an Inferior Alternative: The Case of Disappearing "Inherited Options"

Rusty Stough, University of Wisconsin - Madison, USA
Evan Polman, University of Wisconsin - Madison, USA

We extend work on subsequently unavailable options by examining items that consumers acquire despite their preferences. We found that when people experience a loss of an inherited option they recoup the loss with a similar option to the extent they choose an option that is inferior to other available options.

Eye Buy: Broad Visual Attention Increases Unplanned Purchases

Mathias Streicher, University of Innsbruck, Austria
Oliver Büttner, University of Vienna, Austria
Zachary Estes, Bocconi University, Italy

We investigate whether manipulating the scope of visual attention influences subsequent attention to products and unplanned purchases. We find that a broad vs. a narrow scope of attention increases attention to products in the visual periphery and that this may lead to more unplanned purchases and spending.

Social Exclusion and Consumer Switching Behavior: A Control Restoration Mechanism

Lei Su, Hong Kong Baptist University, China
Yuwei Jiang, Hong Kong Polytechic University, China
Zhansheng Chen, University of Hong Kong, China
C. Nathan DeWall, University of Kentucky, USA

Four studies reveal that socially excluded consumers exhibit more switching behaviour than those who do not. This effect is mediated by a decreased sense of personal control after social exclusion. It diminishes when the switching behaviour cannot restore personal control or when other resources compensate the desire for internal control.

When Shared Joy is Lessened:
Comparing Psychological Costs Between Online and Offline Positive Word of Mouth

Ana Suárez Vázquez, University of Oviedo, Spain
Manuel Chica Serrano, Open University of Catalonia, Spain

This research examines the difference in drivers of online and offline WOM. We suggest the existence of an emotional pain associated with the spreading of others' positive experiences that could have a deterrent effect over online positive WOM. That effect does not exist in the case of offline positive WOM.

The No-Pain, No-Gain Heuristic: The Effect of a Creator's Tragic Biography and Construal Levels on Quality Inferences

Yeonjin Sung, Seoul National University, Korea
Seojin Stacey Lee, Seoul National University, Korea
Kiwan Park, Seoul National University, Korea

Extending the effort heuristic we propose that people utilize a creator's tragic biography as a cue for high quality judgment of the creation. We demonstrate that this effect is observed at low construal level which facilitates process focus and is attenuated at high construal level which activates outcome focus.

Caveat Voluntas: Exploring the Dark Side of Volunteering

Stefan Suppanschitz, Viena University, Austria
Verena Gruber, HEC Montreal, Canada
Jonathan Deschenes, HEC Montreal, Canada

Academics have mainly focused on the positive consequences of volunteering. This paper explores its potential negative side through a review of literature and a preliminary analysis of interviews with 14 current or past volunteers working at the Vienna Red Cross.

Constructing Hybrid Identity: the Consumption of Brit-Asia Bhangra Music

Dr. Amandeep Takhar, University of Northampton, UK
Dr. David Chitakunye, AMA International University, Kingdom of Bahrain

We propose that the consumption of the Brit-Asian music genre plays a pivotal role in the lives of young British Sikhs in the UK. It acts as a sub-cultural force that reinforces the British Sikh identity but also mediates cultural and intergenerational tensions therefore acting as a catalyst for change.

Consuming a Transfusion of Fashion: Constructing Hybrid Identity amongst the Third Generation British Indian Community

Amandeep Takhar, University of Northampton, UK
David Chitakunye, AMA International University, Kingdom of Bahrain

This study contributes to an understanding of how migrating communities consume a transfusion of clothing and fashion. We adopt an interpretivist approach to explore how third generation British Indians consume fashion and found that fashion was consumed as an expression of their hybrid identities.

Complicitous Consumers? Deconstructing Online "Fertility Testimonials"

Jennifer Takhar, Novancia Business School, Paris, France
Kelly Pemberton, The George Washington University, USA

Our discursive analysis of American women's online customer testimonials on two "fertility wellness" websites reveals how this advertising strategy makes women unwittingly complicitous in the medical and marketing discourses that stigmatise them as solely responsible for procreative challenges and simultaneously undermines the tenets of fourth-wave feminism.

Effects of Task Routinization on Consumer Creativity

Jasper Teow, National University of Singapore, Singapore
Li Xiuping, National University of Singapore, Singapore

Our research posits that routine tasks lead to mental rigidity. It is demonstrated that after typing a string of letters repetitively participants were more likely to employ a local processing style and performed worse in a remote association task assessing creativity. Furthermore participants' psychological reactance moderates the effect of routinization.

Role of Mood in Cause-Related Marketing Effectiveness

Ali Tezer, Concordia University, Canada
Onur Bodur, Concordia University, Canada

Brands promise to donate certain amount of sales prices per product sold in cause-related marketing (CRM) promotions. Contrary to common wisdom we show that CRM is effective when consumers are in a bad mood but not when they are in a good mood.

Do Children Perceive Links Between Physical Attractiveness, Possessions, and Aggression?

Tabitha Thomas, Univesty of Otago, New Zealand
Kirsten Robertson, Univesty of Otago, New Zealand
Maree Thyne, Univesty of Otago, New Zealand

We examine beauty stereotypes in children and the associations they make between physical attractiveness possessions and aggressive behaviour. Across four studies we find that children perceive attractive children to own expensive possessions and display prosocial behaviour whereasunattractive children were perceived to own cheap possessions and display antisocial behaviour.

Does Visual Heaviness Convey Rich Flavor?
Effect of Product Image Location on Consumers' Taste Expectation

Taku Togawa, Chiba University of Commerce, Japan
Jaewoo Park, Chiba University of Commerce, Japan
Hiroaki Ishii, Seikei University, Japan

This research found that product images' location on packaging affects consumers' perception of food products. In consumers with low autotelic need for touch product images placed at the bottom (vs. top) of packaging positively affected perception of flavor density. Additionally perceived heaviness mediated this effect.

Affective Influences on Activation of Social Network Type:
The Effects of Social Motivations and Anticipated Audience Responses

Dandan Tong, Chinese University of Hong Kong, China
Jianmin Jia, Chinese University of Hong Kong, China
Robert Wyer, Chinese University of Hong Kong, China

This research investigates how event-elicited affective states (positive vs. negative) and relevance (self vs. other) give rise to activated social network types. We found that what people share in social media is driven by self-presentation motivation and emotion regulation motivation that are differentially associated with different types of social network.

'Compete or Cooperate'– How Motivational Mindsets Affect Facial Beauty Judgments

Natalie Truong, Nanyang Technological University, Singapore
George Christopoulos, Nanyang Technological University, Singapore

The present research examines the effect of competition versus cooperation mindset on facial beauty judgments and face processing style. Initial results show that a competitive state leads to higher evaluations of female faces compared to a cooperative state. We hypothesize a social comparison resulting in self-threat as the underlying process.

Theorizing Authority Relinquishment in Agency Relationships:
Conditions and Consequences

Gulnur Tumbat, San Francisco State University, USA
Kent Grayson, Northwestern University, USA

According to agency theory exchange agreements range from where the buyer has high authority over the seller to where both are relatively independent. Some principal-agent agreements reverse this relationship by allowing the seller to exercise authority over the buyer. We study this unexplored type of agency agreement: "authority relinquishment."

Low Construals Prefer Atypical Colors

Jiyoon Uim, Hongik University, Republic of Korea
Nara Youn, Hongik University, Republic of Korea

The current research examines how atypical (vs. typical) color affects consumer information processing and examines the moderating role of construal level. Through three studies we demonstrate that atypical color would lead to favorable evaluation of product more for consumers with low level than for those with high level construals.

Genealogies of Consumers' Resistance

Carmen Valor, Universidad Pontificia Comillas, Spain
Eleni Papaokinoumou, Universitat Rovira i Virgili, Spain

This paper examines the subjectification process in the sustainable consumers' resistance movement. By applying the Foucault's genealogical method we aim to unveil the discursive roots and anchors of the sustainable subject and how such subject is opposed to the consumerist subject.

"I Deserve to Help!" Effects of Entitlement and Social Influence Appeals on Prosocial Motivations

Martine van der Heide, University of Groningen, The Netherlands
Bob Fennis, University of Groningen, The Netherlands
Koert van Ittersum, University of Groningen, The Netherlands
Debra Trampe, University of Groningen, The Netherlands

Entitlement—a sense that one deserves more than others—typically reduces prosocial motivations. We further investigate this relationship by considering the interplay between entitlement and social influence appeals. We demonstrate that a consistency appeal reinforces the negative effect of entitlement on prosocial motivations while a scarcity appeal fully attenuates it.

Non-price Determinants of the Purchase Intention Towards Counterfeit Global Brands: An International Comparison of Respondents as a Moderator of Behavior

Claudia Velez-Zapata, Universidad Pontificia Bolivariana, Colombia

This study analyzes the determinants of intention to purchase of counterfeit clothing global brands in Bologna Madrid Chicago and Medellin. This research shows the relevance of non-price factors (i.e. perceived quality public and private prejudice). Additionally it presents evidence which support city of the respondents as a moderator of behavior.

Communicating Less/No Meat Consumption: Dialogue between Meat Lovers and Avoiders

Handan Vicdan, EMLYON Business School, France

Despite the scientifically proven need for adoption of less/no meat diets few people adopt such diets. We explore the counterproductive communication that hinders the promotion of these diets between meat lovers and avoiders. Focus group and depth interviews identify ways to establish constructive dialogues in order to promote these diets.

Peeping on Poverty: Groupness and Moral Considerations in Slum Tourism

Julia von Schuckmann, ESADE Business School, Spain
Lucia Barros, EBAPE-FGV, Brazil
Eduardo Andrade, EBAPE-FGV, Brazil

Slum tourism is a prevalent tourist attraction in the Global South that brings a fierce ethical debate. In two field experiments in Rio de Janeiro we show that groupness and its impact on moral considerations help explain why some consumers (out-groups) find it appealing whereas others (in-groups) find it appalling.

"Love Accounting": The Effect of Love Messages on Gift Budgeting

Yanan Wang, Bishop's University, Canada
Ashesh Mukherjee, McGill University, Canada

Through three studies it is found that when people give a gift they engage in 'love accounting' so that they will spend less on it if they include a written expression of love with it. The amount of effort expended on preparing the message did not account for the effect.

Approach or Avoidance? The Dual Role of Face in Fashion Consumption

Wangshuai Wang, Shanghai Jiao Tong University, China
Xin-an Zhang, Shanghai Jiao Tong University, China

We propose face affects fashion consumption in two ways. Desire to gain face boosts fashion consumption whereas fear of losing face demotivates it. Moreover these effects are mediated by need for uniqueness and moderated by social visibility. Data from one survey and four experiments provide support for these hypotheses.

With A Little Help From My Friends:
How Product and Website Socialness Drive Online Word-of-Mouth Persuasion

Yiru Wang, Kent State University, USA
Cesar Zamudio, Kent State University, USA

Consumers' online review information processing depends on the social nature of the object under review and website used. When the object is consumed privately readers rely on both review content and writers' social profile. However when the object is consumed socially readers rely on social profile alone.

Information-Searching Task Type and Searching Effort:
the Mediating Role of Self-Efficacy

Feiqiong Wei, Renmin University of China, China
Yafeng Fan, Renmin University of China, China
Jing Jiang, Renmin University of China, China

This article examines information searching behavior under different searching tasks (general vs. specific) and the mechanism. Two experiments demonstrate that consumers make more efforts under general searching task than under specific searching task which is mediated by self-efficacy. We also explore this effect under different scenarios (material vs. experiential product).

When Detailed Information Works Better:
Comparison Between 3-Colors and 5-Colors Traffic-Lights Nutritional System Labels

Carolina O.C. Werle, Marketing Department, Grenoble Ecole Management, France
Kévin Roche, Marketing Department, Grenoble Ecole Management, France
Olivier Trendel, Marketing Department, Grenoble Ecole Management, France

Two studies using implicit (i.e. automatic) tasks show that nutritional traffic light systems facilitate the recognition of the healthiest option among a pair of food products. Furthermore a more subtle system (traffic light with five colors instead of three) works better independently of consumers' knowledge about the food nutritional value.

Creating the Flawed Hero: Consumer Movement Framing in the Online Environment

Jeff Wiebe, Queens University, Canada
Jay Handelman, Queens University, Canada

Employing a New Social Movement perspective we conduct a netnographic analysis to examine how members frame consumer movements in the online environment. We find that rather than adhering to traditional activist roles members position themselves as persistent "flawed heroes" who inform others of important truths.

What You Smell is What You See?
The Effect of Ambient Scent on Stimulus Ambiguity in Product Aesthetics

Xiaoxuan (Farrah) Wu, Temple University, USA
Martin Reimann, University of Arizona, USA
Maureen (Mimi) Morrin, Temple University, USA
Angelika Dimoka, Temple University, USA

Can the olfactory and visual senses cooperate to resolve ambiguity? Two scent experiments aim to understand if and how pleasant ambient scent (e.g. eucalyptus) can mitigate stimulus ambiguity in visual product aesthetics (e.g. abstract artwork) and how consumers' perceptions and evaluations are influenced as a consequence.

Icing on the Cake or Not:
The Impact of Positive In-Group Members' Advice on individuals' Preference on Choice

Yinghao Wu, Renmin University of China, China
Jing Jiang, Renmin University of China, China

Based on the optimal distinctiveness theory this study proposes that anticipated in-group similarity becoming excessive due to too much positive advice will make individuals feel emotional ambivalent which will evoke subsequent negative behavioral responses-preference decrease or shift. The situation will be even more intense when individuals are independent self-construal.

Do the powerful prefer the "Brand-As-Leader"?
Gender Difference in the Power Effect on Brand Role Preference

Jiang Wu, Nanjing University, China

In the current research we investigated the gender difference in the power effect on brand role preference. Specifically we proposed that men with lower sense of power and women with higher sense of power would prefer "brand as leader" to "brand as partner".

The Impact of Corporate Environmental Transgressions on Consumer Support for
Non-profits: The Role of Negative Moral Emotions and Moral Identity

Chunyan Xie, Stord/Haugesund University College, Norway
Richard P. Bagozzi, University of Michigan, USA

We add to research on pro-social decision making by providing a new psychological mechanism underlying consumer support for non-profits upon exposure to corporate environmental transgressions. Results showed that contempt anger and disgust mediate the relationship between corporate transgressions and consumer support. Further moral identity regulates such a mediation process.

"Slim-as-Luxury" Effect: The Influence of Product Shape on Product Luxury Perception

Ji (Jill) Xiong, National University of Singapore, Singapore
Yu Ding, National University of Singapore, Singapore

Based on anthropomorphism theory that people tend to imbue characteristics of human beings such as personalities emotions and facial features onto products we found that people also attribute their implicit belief about slim human body shape and its signaling of high status and luxuriousness onto slim-shaped products.

Asset or Liability? The Role of Brand Equity in Times of Crisis

Haiyue (Felix) Xu, Pennsylvania State University, USA
Lianxi Zhou, Brock University, Canada

The present research examines how brand equity affects consumer responses to brand crisis and its contingency on crisis characteristics. Results show that brand equity backfires when a crisis is of high severity or of ethical nature. Confirmatory bias and disconfirmation of expectation are identified to be the underlying processes.

Soap-Opera and Tourism: Rehabilitating the Ottoman Post-colonial

Cagri Yalkin, Brunel University, UK
Georgios Halkias, University of Vienna, Austria

We explore how the tourists from formerly colonized territories in the Ottoman Empire consume the former colonizer through 1. watching Turkish soap operas and 2. visiting Turkey and in doing so how they confront the post-colonial relationship through confronting Turkey as a destination and a nation-brand.

Virtue-Vice or Vice-Virtue: Ingredient Presenting Order
Affects Consumer's Perceived Healthiness and Calorie Estimate

Chun-Ming Yang, Ming Chuan University, Taiwan

Two experiments demonstrate that consumers report a higher (lower) perceived healthiness and lower (higher) calorie estimate when a dish's ingredients are presented in a virtue-vice (vice-virtue) sequence. Perceived healthiness mediates the relationship between ingredient order and calorie estimate. However this effect is weaker for individuals with low appearance self-esteem.

Parenting Mindset Salience and Its Influence on Uniqueness Seeking

Chun-Ming Yang, Ming Chuan University, Taiwan

Two studies demonstrate that parenting mindset salience makes consumer interdependent self-construal more salient but does not do so for independent self-construal. This salient interdependent self-construal leads to a lower preference for unique or cool products. Moreover this effect was stronger for females than for males and mediated by interdependent self-construal.

Fewer When Mixed: When Food Presentation Format
Biases Consumers' Perceptions of Calories and Fat

Ning Ye, Temple University, USA
Maureen Morrin, Temple University, USA
Angelika Dimoka, Temple University, USA
Dipankar Chakravarti, Virginia Tech, USA

Our research aims to investigate whether consumers' calories estimation is biased by the food format: when the ingredients are mixed together versus separate. We found participants underestimated the amount of calories in candies when asked to imagine eating the food in a mixed (versus separate) format.

Embarrassed Customers:
The Dark Side of Receiving Help from Others

Youjae Yi, Seoul National University, South Korea
Seo Young Kim, Seoul National University, Seouth Korea

Receiving support from other customers during service encounters has become common with increased customer-to-customer interactions. However there is a downside of inter-customer relationships. Customers receiving help from other customers during service encounters are more likely to feel embarrassed which would lead to decrease in customer satisfaction.

The Construction of 'Whiteness" in Indonesian Skincare Advertising

Jeaney Yip, University of Sydney, Australia
Susan Ainsworth, University of Melbourne, Australia

This research analyses the discursive construction of beauty through skin care advertisements in Indonesian women's magazines. A country with the largest emerging middle class in Southeast Asia we explore the polysemy of whiteness that promise youthful and fair skin to affluent middle-class consumers and the constant 'upscaling' of lifestyle norms.

How Self-disclosure and Interpersonal Similarity Affect Goal Achievement in Social Media-based Online Communities

Kelly Eunjung Yoon, University of California Irvine, USA
Cornelia Pechmann, University of California Irvine, USA

Our research examines the effects of community members' identity self-disclosure which we posit to be an underlying mechanism in the success of online communities. A mediation analysis supports the notion that identity disclosure in dyads is a significant factor that enables individuals to achieve their goals through strong interpersonal bonds.

Creating the Mood for Humor: A Gender Identity Perspective

Hye Jin Yoon, Southern Methodist University, USA
Yongjun Sung, Korea University, South Korea

Mood effects research in humor advertising with a focus on gender identity is non-existent. Two experimental studies found responses to different arousal and valence mood primes in humor advertising to be contingent on the individual's gender identity. The findings provide implications for theoretical as well as practical contributions.

The Effects of Social Sharing on Consumers' Self-Perceptions of Expertise

Daniel M. Zane, Ohio State University, USA
Rebecca Walker Reczek, Ohio State University, USA

This research explores how sharing preexisting online material (e.g. a news article) can enhance one's self-perceptions of subjective expertise. Sharers believe they are acting as experts by disseminating information to others and conclude from their act of sharing that they must be knowledgeable about the topic of the shared content.

Curiosity under Bright Light: The Influence of Lighting Conditions on Innovative Product Adoption

Yu Zhang, Nankai University, China
Lan Xia, Bentley University, USA
Jiangang Du, Nankai University, China

This paper examines the effect of lighting conditions on evaluation and purchase intention of innovative products. Four studies showed that consumers in a bright environment are more likely to adopt new products than those in the dark environment with curiosity mediating the effect. And the effect is moderated by loneliness.

From Perceived Conceptual Importance to Physical Weight Judgment: A Theme-Fit Analysis

Ke Zhang, The University of Hong Kong, Hong Kong
Echo Wen Wan, The University of Hong Kong, Hong Kong
Sara Kim, The University of Hong Kong, Hong Kong

Prior research shows that the physical weight judgment in a prior context can influence perceived importance of the product but not the other way around. We find evidences in three experiments that the conceptual importance can also influence the physical weight judgment and that this effect occurs in theme-fit conditions.

Warmer but Less Competent: When Co-Branding Helps or Hurts Less-Known Brands

Ke Zhang, The University of Hong Kong, Hong Kong
Sara Kim, The University of Hong Kong, Hong Kong
Echo Wen Wan, The University of Hong Kong, Hong Kong

We show that whether co-branding with a well-known brand will be beneficial or detrimental for a less-known brand depends on consumers' focus on warmth versus competence when evaluating the less-known brand. We show that co-branding with a well-known brand increases perceived warmth but decreases perceived competence of a less-known brand.

Attributions to Individual or Group? A Study on Gender Differences

Chun Zhang, Concordia University, Canada
Michel Laroche, Concordia University, Canada
Marie-Odile Richard, State University of New York Polytechnic Institute, USA

Based on the self-construal literature and the interdependent theory the current work examines the gender difference in attribution behavior. Results show that males are more likely to attribute to individuals while females are more likely to attribute to groups. This difference is also confirmed between relational and collective interdependent self-construal.

Future is "Right" on Your Face:
The Role of Facing Direction of Product on Attitudes toward Product

Yuli Zhang, Drexel University, USA
Hyokjin Kwak, Drexel University, USA
Haeyoung Jeong, Drexel University, USA
Marina Puzakova, Lehigh University, USA

This research demonstrates that the facing direction of product images in advertisements plays a crucial role in consumers' attitudes toward the advertised products. Our two studies reveal that right (vs. left)-facing direction of product is more suitable for products that are intended for future (vs. past) needs.

Neutral Expressions Increase Psychological Distance and Price Estimation of Luxury

Hong Zhu, Nanjing University, China
Xin Wang, Nanjing University, China
Han Gong, Nanjing University, China

Neutral facial expressions of commercial models increase perceived psychological distance between consumers and products which further influence price estimation of goods. The type of products further moderates the effects of facial expressions on price estimation. Psychological distance is the mechanism to explain it.

When Originality Backfires: When and Why Conforming Consumers are
Considered Smarter Than Nonconforming Ones

Ignazio Ziano, University of Ghent, Belgium
Mario Pandelaere, Virginia Tech, USA; University of Ghent, Belgium

Consumers routinely make inferences about products and other consumers based on purchasing behavior. In this paper we study the effect of conforming (or nonconforming) consumer behavior on expected product quality and perceived consumer competence.
