Stefano Puntoni
Rotterdam School of Management, Erasmus University

The 47th Annual Conference of the Association for Consumer Research (ACR) was held at the Maritim Hotel, Berlin, Germany, October 27-30, 2016. This volume reports the presentations made in special sessions, competitive paper sessions, working paper session, roundtables and film festival.

This was a landmark conference. It was the first time that the "North American" conference, the main ACR conference, took place outside of North America. The conference attracted over 1050 participants and an all-time record of 1255 submissions: 75 special session proposals (65.3% accepted), 638 competitive papers (29.9% accepted), 511 working papers (51.7% accepted), 6 roundtables (100% accepted) and 17 films (88.2% accepted).

We thank our generous donors, especially our schools, the Rotterdam School of Management, Erasmus University and the Wisconsin School of Business, University of Wisconsin-Madison. We would also like to thank for their generous support of the ACR Doctoral Colloquium the Journal of Consumer Research, the Eller College of Management, University of Arizona, and the Katz Graduate School of Business, University of Pittsburgh. Also supporting us from industry were Noldus, Now, Sage, and Stukent.

Many wonderful people worked tirelessly to help us. We thank our Program Committee, Competitive Paper Reviewers, Working Paper Reviewers, and Film Reviewers. Special thanks to Francine Petersen and Luk Warlop (Working Paper Chairs), Pierre Chandon, Stijn van Osselaer, and Klaus Wertenbroch (Forums Chairs), Marylouise Caldwell and Paul Henry (Film Festival Chairs), Cait Lamberton and Hope Shau (Doctoral Symposium Chairs), Deborah Small and Debora Thompson (Pre-Tenure Mentorship Program Chairs), and Ana Valenzuela and Joachim Vosgerau (Entertainment Committee). We would like to thank Katja Brunk, Thomas Eichentopf, and Andrea Weihrauch for the excellent ACR Guide to Berlin and the Journal of Consumer Research allowing the use of the journal's formatting for the guide. Many thanks also to our excellent Associate Editors: Eduardo Andrade, Zeynep Arsel, Joseph Goodman, Kelly Haws, JoAndrea Hoegg, Ashlee Humphreys, Hope Schau, Robert Kozinets, Leonard Lee, Tina Lowrey, Mario Pandelaere, Maura Scott, Steven Sweldens, Joachim Vosgerau, and Juliet Zhu.

Special thanks to ACR Executive Director Rajiv Vaidyanathan, Conference Manager Paula Rigling, conference administrative assistant Annette Bartels, website guru Aleksey Cherfas, and ACR Executive Assistant Brenda Monahan.

Our final thank you to colleagues who advised us throughout the year, especially Stijn van Osselaer, to everyone who made our program stellar by submitting their best research, and to Mary Frances Luce, ACR President 2016, for offering us the opportunity to organize the ACR conference and for all the help and support she provided throughout the process.

2016 ACR Presidential Address

It's Time to Think

Mary Frances Luce, Duke University, USA

I would like to start by acknowledging what an historic conference this is for ACR. This is the first time that our major conference, what used to be known as the "North America" conference, takes place outside of North America. As is always the case for ACR, and as was particularly true this year, the most important thing that I did as president was to recruit two excellent volunteers to run the conference. I think we can all agree that Page Moreau and Stefano Puntoni have done an excellent job. There job was harder than most due to the increased uncertainty around pulling off an ACR of this scale outside of North America. I know we all agree that they more-than rose to the occasion, so the organization truly owes them our thanks. This conference is an important step in ensuring that ACR remains the premier global organization for consumer research.

While I believe I did a good job on my main task, that is recruiting Stefano and Page, I was less certain about how to approach a second main task, this talk. It is hard to imagine something worth the time of such a wide and varied audience. In the end, I will make this short and I would like to mainly offer my own reflections on our individual and collective profession.

I start with what I think is a common occurrence for many in our community. We try to explain our profession to someone, explaining our specific job requirements (e.g., a certain number of hours teaching per week or month or year) and similar explicit responsibilities. The perplexed individual asks some version of "but what do you do all day?" More generally, for most of us we have a profession with amazing freedom do fill our days and our thoughts with whatever we find most rewarding. This is an awesome privilege. With this privilege comes, I would argue, the responsibility to be mindful about how we add value to society. I believe that we do so by thinking very deeply, creating new perspectives on important activities of individuals, society, and organizations. I also believe that truly adding value in this way takes time, and not just effort but time for reflection.

The importance, and the value, of time to think has been very clear to me in recent years. I have enjoyed some truly awesome opportunities, for instance to co-edit JCR with Ann McGill and Laura Peracchio and to serve as the dean of the faculty at Duke's Fuqua school. These responsibilities come with their own vexing problems and external deadlines. When I am immersed in these deadlines I, at least, find that I can do some research, but I cannot do research in the same way. Increasing my own level of busy-ness has illustrated to me that there is a stark contrast between producing output, even research output, and really reflecting. I find I have to willfully schedule downtime to really think. It is not something that happens well in spare hours here or there. Not having normal faculty reflection time has, like nothing else, shown me its value. Of course, this is a lesson many learn much earlier in their careers.

It seems to me that production can easily crowd out reflection, particularly in our current professional environments. It is very easy to use tools such as Mturk or google scholar searches to get tasks finished much more quickly than we can reflect on them. These productivity tools are important, and not going anywhere. And they are not bad things. However, today's environment makes it even more important, I believe, for all of us to be mindful of the incentives we set for ourselves and for others. It is easy for counting and other forms of productivity-focus to crowd out thinking and evaluating the quality of ideas. We set incentives as mentors and reviewers. When we do so, its often easy to assess production and harder to assess the novelty or quality of ideas. For example, as a reviewer, it is often easier to check the accuracy of a statistical test than it is to assess if the authors are causing you to think in a new way. As senior faculty making hiring or promotion decisions, it is simply easier to count papers than to read them. However, I believe the vibrancy of our field rests much more on the quality of ideas we collectively produce than on the overall number of experiments, or interviews, or journal pages. I'd like to encourage us all, myself included, to avoid losing sight of our profession as creating truly new ideas and perspectives that have the potential to not only change how each other thinks about consumption, but to ultimately change how business and global society functions. (Overall, then, in speaking of the importance of time to think, I am asking you to do as I say, but not as I do.)

My comments so far raise the question of what we should be thinking about? As members of ACR, we try to understand the role of consumption in people's lives: How they deploy key resources such as time and money, as well as how they promote meaning, enhance community, and steward global resources. Our field has unusual breadth due to the wide swath of human experience we study; we are almost constantly consuming and consumption is incredibly important to our economies, our societies, and our global environment. So, what is the goal of consumer research? I believe that any academic endeavor should ultimately solve problems, that is should ultimately improve the human condition. (Note that this is not the same as saying that research must be motivated by a clear problem. The most basic of research can become the most useful over time, and in unexpected ways.) But whose problems to do we solve? Sometimes we solve the problems of other consumer researchers by suggesting useful theories or methodologies. This is, of course, how science advances. However, if we are to ultimately claim that we have made an impact, we must go beyond solving each other's problems. One source of problems to solve resides in business, and this community has long had an important applied focus. It further seems clear that this organization has always aspired to do more than support business and instead to better society by ultimately making consumers better off with our work. Now, bettering society involves solving complex, messy, multi-determined problems. So, this goal brings me to a conclusion about consumer research that is important to me. Specifically, I think none of us can truly reap the benefits of our own reflection, nor can we truly realize the potential of ACR, unless we attempt to take and interdisciplinary approach to consumer research. Big, societal problems cannot generally be solved by the point of view of one paradigm. The power in ACR comes from our potential for interdisciplinary work integrating across our specific paradigms for robust solutions.

Truly integrative work is much more easily lauded than achieved. My JCR co-editors and I wrestled with this problem in our final editorial. There, we argued that our field is at an inflection point. As a scholarly community, we now have many clear building blocks. It is important to use them to build bridges instead of silos (Peracchio, Luce, McGill 2014). If we take our own field seriously, that is if we take consumption seriously as an important area of inquiry, then it seems that we have to take each other seriously

as well, looking for integrative solutions to truly big problems. It is not an accident that many of ACR's important initiatives, such as the Transformative Consumer Research Initiatives and the Journal of the Association for Consumer Research, are interdisciplinary at their very core.

Thank you very much for your time.

2016 ACR Fellow Address

Brand Attachment: Theory and Practice

C. Whan Park, University of Southern California, USA

Ladies and gentlemen, it is my honor to share with you today my ever-evolving thoughts about the *attachment-based customer-brand relationship*. When we think about human relationships, there is a saying: we should never forget the 3 types of people in our lives: (1) those who helped you in your difficult times, (2) those who left you in your difficult times, and (3) those who put you in difficult times. Surely, we must remember who put, helped, or left us in our difficult times. But perhaps more important is not to forget what caused them to help, leave, or put us in difficult times. Depending on what we have done to other people, they may also either help, leave, or put us in difficult times. Similarly, depending on what a brand does for its customers, the customers may help, leave, or put it in difficult times. This brings up the topic of customer-brand relationship management. The important issue is what type of customer-brand relationship can secure customers who are willing to help the brand not only in its good times but also in its difficult times.

For the next 25 minutes or so, I will address the above issue by proposing that the attachment-based customer-brand relationship is the most effective one in securing loyal customers. In order to deliver this proposition in a time-efficient manner, I introduce the overall model of brand attachment (Figure 1) and address four questions sequentially that relate to the components of the model. Before proceeding with the first question, I want to point out that my talk today reflects our collective view based on many long years of collaborative research with my colleagues. Those who collaborated with me at different stages of the brand-attachment research are Andreas Eisingerich, Sasha Fedorikhin, Dawn Iacobucci, Deborah MacInnis, Jason Park, Joseph Priester, and Matthew Thomson.

QUESTION 1: WHAT SHOULD SERVE AS THE METRIC FOR JUDGING THE STRENGTH OF THE CUSTOMER-BRAND RELATIONSHIP?

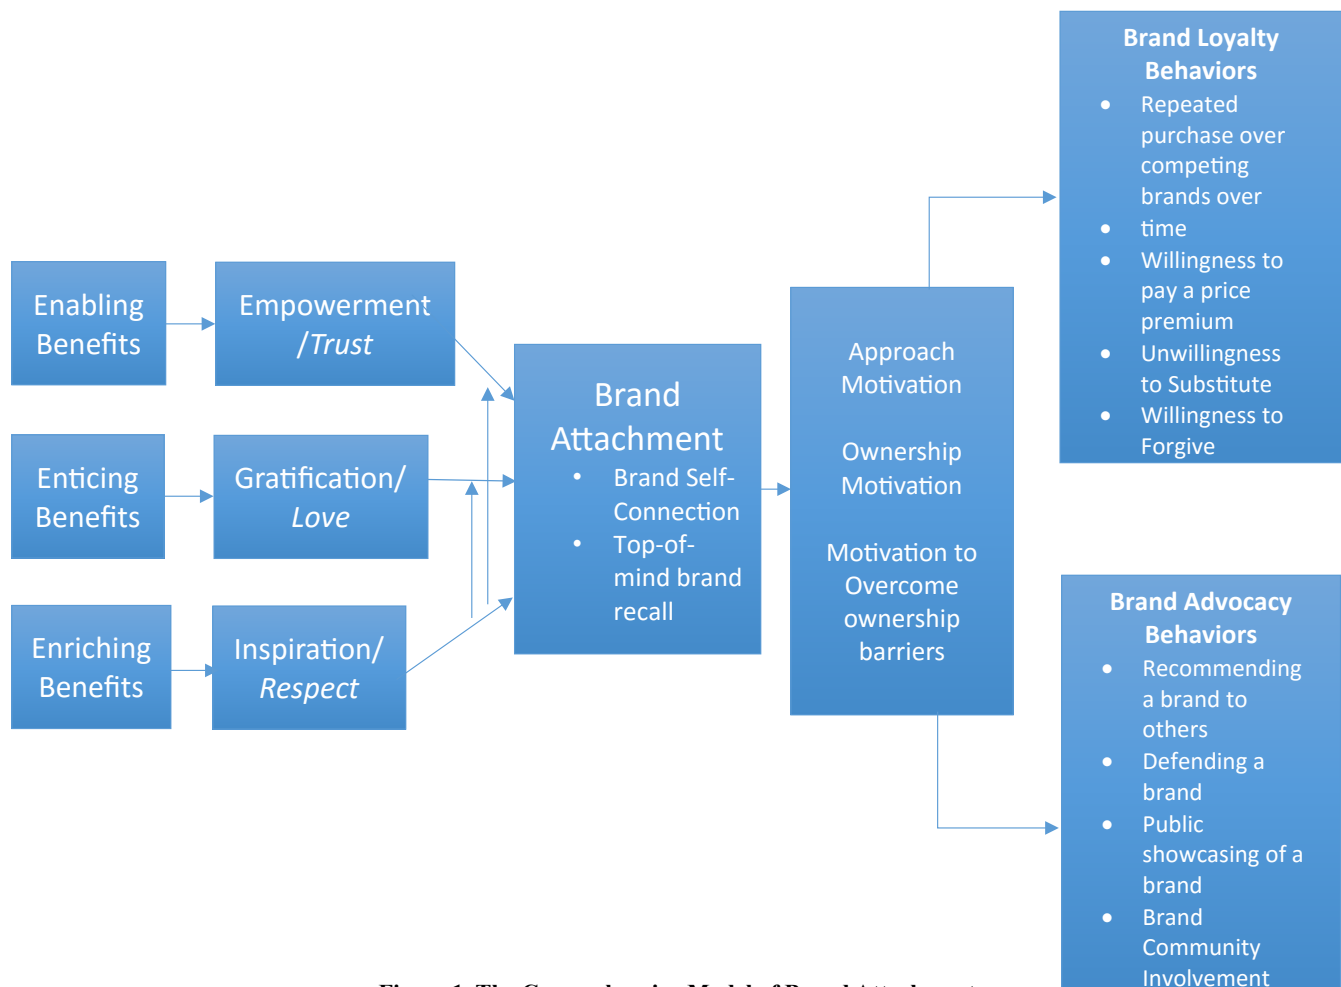
The best way to judge the strength of the customer-brand relationship is to consider how far customers are willing to go to support the brand; what I call pro-brand behaviors. We can think about many pro-brand behaviors that are difficult to enact. What I mean by "difficult" is how much consumers are willing to expend their resources (time, reputation, money, etc.) to support the brand. Examples of difficult-to-perform pro-brand behaviors include the following: (1) Buying Nike shoes, (2) Recommending Nike shoes, (3) Buying Nike


Figure 1. The Comprehensive Model of Brand Attachment

shoes despite their price increase, (4) Defending Nike against negative information, (5) Postponing the purchase and refusing to buy any other competing brands when Nike shoes are not available, and (6) Promoting the Nike brand by participating in Nike community events (spending time and money on behalf of Nike events).

We may assign the above difficult-to-perform pro-brand behaviors into two categories, as noted in Figure 1: (1) brand loyalty behaviors and (2) brand advocacy behaviors. Brand loyalty behaviors refer to repeated brand purchases over time. Brand advocacy behaviors refer to efforts to promote, protect and defend the brand. Engaging in these two types of difficult-to-perform pro-brand behaviors is analogous to helping a brand during difficult times. When customers are willing to engage in these difficult-to-perform behaviors, the relationship between a brand and its customers is like a tree with deep roots. It can resist against strong winds and hard times. A brand in this relationship should be able to secure strong revenues and profit over time.

QUESTION 2: WHAT DRIVES CUSTOMERS TO ENGAGE IN THESE DIFFICULT-TO-PERFORM PRO-BRAND BEHAVIORS?

We propose that *brand attachment* drives customers to engage in difficult-to-perform pro-brand behaviors. It is defined as the psychological state of mind in which customers have a salient, personal connection with the brand. Consumers feel personal connections with a brand and the brand becomes highly prominent in their minds (top-of-mind recall). This brand attachment is, in turn, developed through three key relationship variables: brand trust, brand love and brand respect (see Figure 1). We often use these three words to describe our relationships with others such as "because he is such a trustworthy person, because I love him or because I respect him, I did so and so."

Interestingly, we typically use only one word to describe our relationships with others. We rarely use these three words together to describe our relationships. For example, it is uncommon to say "because I not only trust and love him but also respect him, I did so and so for him." However, when we think about certain special people such as our mothers, our high school teachers, our benevolent bosses, or Mother Theresa, we know that all these three words are needed to describe our relationships with them. Similarly, in the context of a product or service, we typically use one of these three words to describe our feelings toward a brand such as "I love brand X ", "I respect the company X", or "I trust Brand X". It is not common for customers to use all three words to describe their feelings toward a brand. But there are a few brands toward which all three words are needed to describe our feelings. They are the ones that are destined to secure efficient profit and growth over time. Let me explain why these three words together — not one, or two, but all three — need to be present together in order for customers to develop strong brand attachment and to enact their loyalty and advocacy behaviors.

Does only trust alone motivate us to enact difficult-to-perform pro-brand behaviors? Before answering this question, we need to be clear about the meaning of trust. Researchers in the past defined brand trust with three different bases: competence-based, benevolence-based, and integrity-based. I think that this is part of the confusion we have regarding the effects of trust on customer-brand relationships. Because these three bases have different theoretical origins, lumping them all under trust makes it difficult to understand what trust does on customer-brand relationships. We need to separate competence from the other two bases so that we can have a better and sharper understanding of what trust does for us. I will get back to this issue shortly.

I define trust in terms of competence since in the brand context, we tend to understand trust more in terms of how much consumers can rely on the brand to solve their problems. Trust, defined in this way, lacks energy to propel people to engage in difficult-to-perform behaviors. Brand relationships with trust but no love is like a year without summer. It is cold. Brand trust in the absence of love makes consumers too lethargic to enact brand loyalty and advocacy behaviors. Therefore, brand trust without love makes customers highly vulnerable to superior competitive options. Whenever another competing option offers better performance at the same or lower price, they will switch to the competing brand quickly.

What about brand love? Does brand love alone motivate us to enact difficult-to-perform pro-brand behaviors? I doubt it! Let us pause a minute and ask ourselves how we use this term, *love*, in a brand context. For example, when I say I love Godiva chocolates, I do not mean that I am willing to sacrifice my life because of my love for the Godiva brand. I do not really mean the *Romeo and Juliet* or *Tristan and Isolde* type of love. Rather, I use the term "love" more or less in terms of my affective predisposition toward a brand and my positive interest in it. I doubt this type of love alone will cause people to engage in difficult-to-perform pro-brand behaviors. Love needs to be accompanied by trust. Love without trust is like a car with no engine. You can make the car go by pushing it, but it won't get very far.

How about brand respect? Does brand respect alone carry people to difficult-to-perform pro-brand behaviors? I define brand respect as the degree to which consumers look up to and hold a brand in high regard. Respect alone, however, does not trigger strong behavioral motivation. Respect without love involves an arms-length relationship between customers and a brand. Respect is normally accompanied by trust (but not necessarily the other way around). But respect without love makes people only bow at a distance. Without love, a relationship with only respect cannot have a lasting close bond.

Therefore, in order to have a truly meaningful and strong attachment-based customer-brand relationship, a brand must elicit all three attachment-inducing variables: brand trust, love and respect. Using a tree metaphor, trust without love is like a tree without nutrients. It cannot grow well. But a brand relationship based on trust and love can flourish into a tree with lush leaves. That tree might be lovely to look at, and we're OK with just visiting it sometimes — maybe for a picnic. A brand that is based on trust, love, and respect is a different entity altogether. It's not only lovely to look at, it's majestic. It has stature. People notice it, take photos of it, and visit it frequently.

QUESTION 3: WHAT DOES A BRAND HAVE TO DO TO INDUCE BRAND TRUST, LOVE AND RESPECT? ENABLING, ENTICING AND ENRICHING BENEFITS

This is perhaps the most important question to address. My colleagues and I proposed that a brand should offer three different types of benefits shown in Figure 2. They are enabling, enticing and enriching benefits. Enabling benefits offer functional pleasure in two different ways: (1) by solving customers' problems and (2) by conserving their resources like time, money and mental, physical or emotional energy. Enticing benefits offer consumers experiential pleasure, also in two different ways: (1) through any one or a combination of their five senses or cognitive stimulation or (2) by warming their hearts. Enriching benefits offer consumers spiritual pleasure in two ways as well: (1) through internal self-enhancement by reflecting consumers' cherished values or by confirming their self (e.g. their own heritage) and (2) through external self-enhancement by fostering belongingness and distinctiveness.

ENABLING BENEFITS

Solve Customers' Problems/Protect and Keep them Safe

- Enhance performance reliability
- Enhance performance versatility

Conserve Customers' Resources

- Reduce mental energy
- Reduce physical energy
- Save time
- Save money

ENTICING BENEFITS

Please the Senses

- Enhance sensory stimulation
- Enhance cognitive stimulation

Warm the Heart

- Evoke emotion (humor, gratitude, entertainment)
- Evoke empathy
- Evoke nostalgia

ENRICHING BENEFITS

Create Internal Self-Enhancement

- Through values identification
- Through self-confirmation

Create External Self-Enhancement

- Through social acceptance
- Through social signaling

Figure 2. Three Types of Brand Benefits

The functionally effective problem-solving ability of a brand satisfies consumers' psychological need for competence and elicits the emotion of empowerment. As Figure 1 shows, we expect that the empowerment emotion most strongly leads to brand trust. Swiss Army Knives is a great example for the enabling benefits. Remember that we define brand trust in terms of a brand's competence to solve customers' problems or difficulties.

The enticing benefits gratify consumers' psychological need for hedonic well-being. As shown in Figure 1, they elicit an emotion that's best called gratification. As Figure 1 shows, we expect consumers come to love brands that gratify them. In this context, love reflects one's affective predisposition toward a brand. Hello-Kitty is perhaps the best example for these enticing benefits. It is interesting to note that despite its deformed features, it commands so much love from tens of millions of people around the world.

Enriching benefits fulfill consumers' psychological needs for self-affirmation and elicit the emotion of self-esteem. We expect that the self-esteem emotion most strongly leads to brand respect (see Figure 1). Patagonia and Toms Shoes are good examples for the first method (i.e., reflecting consumers' cherished values) of these enrich-

ing benefits because they stand for noble causes like protecting the environment or caring for fellow human beings.

My colleagues and I suggest that brand trust, love, and respect each have a main effect on brand attachment. In addition, we believe that brand respect acts like a multiplier. People do not expect or ask for enriching benefits from a brand. As long as the brand performs satisfactorily and offers experiential gratification, they are content with it. Enriching benefits are not considered. However, strong enriching benefits amplify the contribution of the other two brand attachment drivers: brand trust and love. Enriching benefits *exponentially* increase the positive impact of strong enabling (thus trust) and enticing (thus love) benefits on brand attachment (see the moderating role of the enriching benefits on brand attachment in Figure 1). Perhaps one way to describe the exponential power of enriching benefits is as unanticipated delight or pleasant surprise. Because of its unexpectedness, its impact on brand attachment becomes multiplied.

QUESTION 4: HOW DOES BRAND ATTACHMENT MOTIVATE CUSTOMERS TO ENGAGE IN DIFFICULT-TO-PERFORM BEHAVIORS?

To address this final question, we need to understand how each of the three attachment relationship-inducing variables motivates consumers to enact difficult-to-perform pro-brand behaviors in its own manner.

As Figure 1 shows, we propose that brand love taps into consumers' readiness to positively respond toward a brand. Gratification-based brand love makes consumers ready to move toward and approach the brand. Competence-based brand trust, on the other hand, directly influences consumers' desires to purchase or own a brand. Finally, self-esteem-based brand respect produces strong energy or drive to overcome any barriers that make it difficult for a consumer to buy or own a brand. Brand respect has perhaps the most potent motivational force that bridges the gap between behavioral intention and actual behavior. It generates strong motivation that is necessary for consumers to actually perform difficult-to-perform pro-brand behaviors. Respect only makes people bow at a distance, as I mentioned earlier. It has a limited impact on consumers. However, when respect is accompanied by trust and love, it has an exponential power on them.

FINAL THOUGHT

I must point out that strong brand attachment is a relative term. What I mean is that brand attachment isn't an all-or-none state. Rather, consumers are attached to brands at varying degrees. Even if consumers are strongly attached to a brand, marketers should still look for ways to keep that attachment strong. And just because a brand evokes limited attachment doesn't mean it can't improve. By continuously improving the 3 E's, every marketer should be on a continual quest to enhance the degree to which consumers are attached to their brand. As long as a brand is better than its competitors on at least any one of the 3 E's while being the same on the other two E's, it can still be highly successful. However, the magnitude and the sustainability of the market success of individual brands becomes strongest when a brand offers the 3 E's simultaneously. I particularly think that we need to pay careful attention to the role of the enriching benefits on the strength of the customer-brand relationship. They should deserve more attention and research from marketing scholars.

Think about the time-defying and classic entertainment brands such as *Gone with the Wind*, *Casablanca, Star Wars,* and *To Kill a Mockingbird.* Think about Nike or Apple — despite their relatively short histories, they are very powerful brands. Also, think about time-defying brands like Tiffany, Rolex, and Caterpillar. There is a

common thread that ties all of these brands together: they have benefits that enable, entice and enrich their customers.

When a brand offers the 3 E's together, it should help consumers to emit several chemical transmitters in their brains that are important for feeling happiness, such as oxytocin, endorphin, dopamine, and serotonin. I would thus say that a great brand with all 3 E's together can be a happiness inducer, sustainer and enhancer. This also means that we in the marketing field pursue a science of creating, sustaining and enhancing customers' happiness. Thanks.

2016 ACR Fellow Address

What I have Learned about Variety:
(And are there any lessons here for our polarized US?)

Barbara E. Kahn, University of Pennsylvania, USA

PREFACE

I prepared this talk the month before the November 2016 election and delivered it a week before Donald Trump was elected President. During the campaign season, diversity issues were front and center in much of the nation's conversations. Given my career-long interest in variety-seeking behavior, I wondered if there were any parallels in what I had learned about variety, and what management professors might tell us about how diversity within organizations affects firm outcomes and team performance.

Although I am clearly not an expert in these types of diversity issues, I read some well-cited review papers in the area and perused HBR and other popular business press articles to get a sense of the major findings. I then categorized my variety-seeking research into four major areas. I reviewed the major findings in each of these areas and then looked for parallels in the diversity literature.

1. WHAT IS VARIETY-SEEKING BEHAVIOR?

My interest in variety-seeking behavior began in the early 1980's when I was working on my dissertation at Columbia University under the tutelage of Donald Morrison. Don had discovered an interesting working paper in the library that had been written by Leigh McAlister who was a professor at MIT at the time. In this paper, she introduced the idea of variety-seeking behavior, a somewhat unusual focus for marketers who were naturally more interested in brand loyalty and building market share. We wondered at the time – what exactly is variety-seeking behavior, could we provide parsimonious measures for the behavior, and was this an important idea for marketers to embrace?

As I studied the area more deeply, I learned that others in addition to Leigh (who published her paper in *Journal of Consumer Research* (McAlister 1982) had begun to describe the behavior (e.g., Bass, Jeuland and Wright (1976), Huber and Reibstein (1978), Laurent (1978), Jeuland (1979), Mcalister and Pessemier (1982), Givon (1984), Lattin and McAlister (1985), Lattin (1987), Bawa (1990). Interestingly, many of these papers were dissertations, illustrating how new this idea was at the time.

Together these papers defined variety-seeking behavior as deliberate behavior where consumers derived utility from *change*. Thus by definition, satisfying these types of customer needs would not lead to customer loyalty, which was thought to be the best strategy for profit maximization. Rather satisfying these customers' needs would suggest encouraging customers to switch away from a firm's brand, or provide a portfolio of options, which of course could increase costs. Obviously encouraging variety-seeking behavior then would not be a manager's first-choice strategy, but if the behaviors were naturally occurring, it would be foolhardy to ignore the phenomenon.

At the time, marketing academics had access to panel data that allowed us to observe consumers' actual shopping behavior in grocery stores. This gave me an opportunity to observe just how common variety-seeking behavior was in these types of categories. In my dissertation (which was published as Kahn, Kalwani and Morrison 1986), I proposed a model which could distinguish between variety-seeking, brand loyal and zero order behavior and used this model to describe purchase patterns across four product categories.

Like it or not, consumers were definitely seeking variety in some product categories and the behavior was more prevalent for some brands than for others. I also identified distinct types of variety-seeking behavior: (1) pure variety-seeking, where consumers seek change on every choice occasion, (2) learning or exploring variety-seeking, where consumers seek change early on in a product category, and then move to brand loyal behavior, and (3) satiation behavior, where consumers are reasonably brand loyal for a period of time until they satiate or get bored and then they start seeking variety.

Using the models that I developed in my dissertation, I then studied how variety-seeking affected market share in different types of promotional conditions. Working with various co-authors (Kahn and Raju 1991; Kahn and Louie 1990, Feinberg, Kahn and McAlister 1992), I learned that in general more variety-seeking behavior **hurts high market share brands and helps low market share brands**. In markets where variety-seeking is common, major brands benefit more than minor brands when marketing activities make all the brands seem more similar and when promotional activity is high.

Are there parallels between these findings and what we were observing in the country on attitudes about diversity? I looked at Pew Research Center surveys that had specifically examined voters' attitudes towards diversity prior to the election. Trump supporters at the time were generally thought to be white men, whereas Clinton supporters were thought to skew more towards non-white and female. The survey showed, consistent with what my research had found for high-market share brands, that Trump supporters who would not benefit from diversity initiatives were significantly more likely to say that "compared with 50 years ago, life for people like you in America today is worse (81%), better (11%), same (18%) as compared to Clinton supporters: worse (19%), better (59%), same (6%). Diversity, like variety seeking, helps "lower share brands" or non-majority groups. Consistently, only 40% of Trump supporters agree that an increasing number of people of different races and ethnicities makes the United States a better place to live, whereas 72% of Clinton supports agree with that statement. 16% of Trump supporters thought diversity made the US a worse place to live whereas only 2% of Clinton supporters thought that.

2. WHAT CONSUMER BEHAVIOR FACTORS AFFECT VARIETY-SEEKING BEHAVIOR?

In the 1990's I worked with several co-authors to better understand what consumer-relevant factors increased or decreased variety-seeking (Kahn and Isen 1993, Mitchell, Kahn and Knasko 1995, and Menon and Kahn 1995). Across all the studies, I generally found that positive affect increases variety-seeking behavior for several reasons. First positive feelings cue and facilitate access to positive material in memory. Positive is also more diverse than other material and a happy person has more ready access to a diverse set of cognitive material. Finally, all of this increased awareness of the differences among items make those items more stimulating and thus there is more interchange among brands.

On the other hand, stimulation exhibits an inverted U relationship with variety-seeking behavior. Consumers have an optimal stimulation level, and these differ by individual. This means that If the consumer feels insufficient stimulation, they are likely to seek more variety and if they are over-stimulated they are less likely to seek variety. Stimulation or variety in one context can also affect the amount stimulation or variety the consumer desires in another context, suggesting again that there is some optimal stimulation that consumers crave.

When I looked at the diversity literature there also was a u-shaped connection between stimulation (or creativity) and diversity, but those researchers looked at it from the opposite direction, i.e., not how stimulation affect variety-seeking, but rather how diversity stimulates decision-making. Their findings indicated that diversity (or variety) within a team or group could on one hand could cause too much stimulation resulting in discomfort, rougher interactions, a lack of trust, greater perceived interpersonal conflict, lower communication, lower group cohesiveness, and more concern about disrespect. But diversity or variety in race, ethnicity, gender and sexual orientation could also increase perspectives and thus stimulate creativity and encourage the search for novel information and perspectives that would lead to better decision making and problem solving. Some research indicated that diversity could also improve the bottom line and lead to breakthrough innovations.

My research would add to these findings by suggesting the alternative causility that if there is more stress and conflict in the environment, people would less likely to accept or seek out diversity and variety. This could predict that the stressful pre-election environment made some people less tolerant of differences or diversity among people.

3. ARE PEOPLE CHOOSING TOO MUCH VARIETY?

In 1990, Itamar Simonson wrote a seminal paper that spawned a whole stream of research that asked whether consumers were choosing too much variety. Ironically, by this time, variety-seeking behavior had become so well understood and accepted that people were now questioning whether people should cease seeking variety and stick to their favorites. Simonson (1990) showed that holding consumption constant, the time and patterning of the choice process (e.g., simultaneous vs. sequential) could affect how much variety people chose. Others looked at how preference uncertainty (Kahneman and Snell 1992), choice difficulty (Simonson 1990), flexibility for future (Kahn and Lehmann 1991), choice bracketing (Read and Lowenstein 1995), group choice (Ariely and Levav 2000), and self-monitoring or public image (Ratner and Kahn 2002) affected how much variety people chose.

My most cited paper in this stream was with Danny Kahneman and Rebecca Ranter (Ratner, Kahn and Kahneman 1999). In this paper, we asked participants to listen to sequences of music snippets over time. We varied the sequences to have high or low variety, and by design, the low variety sequences that had more repetition also included more of the participants' favorite songs, while the high variety sequences had less repetition but included less preferred songs. We found that there was a preference for high variety sequences when we asked participants to rate the sequences retrospectively, but when we asked them to rate the sequences in real-time they rated the lower variety sequences with more preferred songs higher. When participants chose their own sequences of songs, they tended to include songs that they did not enjoy as much just for the sake of variety. We concluded that consumers sacrifice utility for variety as a learned response to preferring the variety in memory.

These marketing results suggesting that consumers may be choosing too much variety and sacrificing utility for the favorites does have a direct parallel in the diversity literature. Critics of Affirmative Action initiatives argue that these types of policies in college admissions or in recruiting can yield less optimal candidate choices by prioritizing diversity over raw "intelligence" or "quality" metrics. This is obviously a more controversial discussion in the organizational literature than in marketing.

In defense of Affirmative Action programs, McKinsey (2015) studied the effect of diversity on organizations and found that these policies did have a positive impact on many key aspects of organizational performance. More diversity in an organization was found to help in the war for talent, strengthen customer orientation increase employee satisfaction, improve decision-making and enhance company image. Diversity in organizations also yielded financial returns higher than industry medians, and a BCG study showed that diverse companies could outperform homogenous ones.

Here the organization literature seems to have some implications for marketing in that it suggests that even when consumers choose "too much variety" and thus sacrifice consuming their favorites, there may be value in this variety that is not captured just by looking at utility.

4. ARE MARKETERS PROVIDING TOO MUCH VARIETY?

In 2000, Iyengar and Lepper wrote another seminal paper about variety. Here, they argued that too much choice leads to choice overload and consumers choose not to choose or they delay their choices. This research generated so many studies that there are several review papers and meta-analyses on the topic. My own contribution in this area was in two areas.

First, in Huffman and Kahn (1998) we found similarly to Iygengar and Lepper (2000) that consumers can get overwhelmed by having too much variety, particularly in situations where they were customizing their own products making the assortment seem almost limitless. We found that if we helped consumers learn their preferences through simple techniques the consumers were much more able to appreciate the variety, the perceived complexity was lessened and they were more likely to make choices without delay. I found parallels to these ideas in the diversity literature such that if participants were told to elaborate and think more about the spectrum of information that was offered by diverse teams, the positive effects of diversity increased. Thus in both cases, elaboration helped people appreciate variety.

The other way I have thought about this issue of too much choice is to reframe the discussion into thinking about it as actual variety versus perceived variety. In various studies, I show different ways marketers can arrange the assortment such that the actual variety is held constant but the perceived variety varies – and it is this perceived variety that ultimately affects decision-making.

The first paper I did in this stream was with Brian Wansink (Kahn and Wansink 2004) where we found that increases in perceived variety, holding actual variety constant, increased how much participants consumed. More recently Townsend and Kahn (2014) found that holding everything else constant, that depiction of an assortment visually is found to have more perceived variety than depiction of the same assortment in text. Further, when the assortment is small, people prefer the visual assortment and are more likely to not defer choice compared to the same assortment shown in words. However, when the assortment size gets big, people still prefer visual depiction but this can make the assortment appear too complex and can delay choice as opposed to the same assortment depicted in

text. Most recently in Deng, Kahn, Rao, Unnava and Lee (2016) we showed that holding the actual variety constant but displaying the assortment horizontally (as opposed to vertically) will increase perceived variety and will increase variety-seeking behavior.

Interesting in the diversity literature there have been similar types of investigations comparing actual to perceived impressions. Generally, one of the advantages of diversity in an organization is that different perspectives and different information can come into the discussion and that improves decision making. One study that showed even if the actual information is held constant, mock juries performed better at considering case facts and made fewer errors recalling relevant information and displayed a greater openness to discussing race when the juries were diverse as opposed to all one race. Thus, although the actual diversity of information was held constant, the perceived diversity of information varied and that made people more diligent and open-minded.

CONCLUSIONS

As I reflect back, I feel fortunate that the ideas I explored in my dissertation continued to interest me all of these years later, and that this area could attract other researchers who helped to expand the boundaries of inquiry. Further exploration of variety seeking in marketing seems to have some parallels in other areas that look at variety in different ways.

Summarizing, I found that variety-seeking (or diversity) can threaten the status quo, and the "haves" are hurt, and the "have-nots" are helped. Open-mindedness and positive thinking enhances desire for variety (diversity) and vice versa. However, too much conflict (stimulation) can diminish the desire for variety (diversity). Choosing for the sake of variety can undermine choosing the most preferred options, but is that all bad? Is there such a thing as too much variety? Even if variety is enormous, structure, learning of preferences and elaboration can help. Finally perceived variety (diversity) matters more than actual variety (diversity).

2016 ACR Fellow Address

Reflections: Progress Made and Perspective Shifted

Alice M. Tybout, Northwestern University, USA

Being named an ACR Fellow prompted me to think back to my first ACR conference, which was 44 years ago, almost to the day. As I reflected, I wondered about what has changed and what has stayed the same. What *progress* have we made and how has my *perspective* evolved?

When I attended what was the 3rd Annual Conference in 1972, ACR had 254 members, 20 of whom were students and 19 of whom were from outside North America. The conference was held on the campus of the University of Chicago at the Center for Continuing Education and the program was printed in the Newsletter. JCR was but an idea in the minds of the leadership of the young organization… it would launch two years later. To give younger ACR members a sense of the time, fashion-forward attendees were wearing polyester bell-bottoms, their data analysis was conducted using punch cards, and their paper submissions to the conference were prepared using a typewriter and submitted by U.S. mail. And, I was a first year, first quarter doctoral student at Northwestern attending the conference with my fellow doctoral students and several faculty members.

By last year's conference, ACR membership had grown more than seven-fold to 1973, 628 of whom were students and 714 of whom were from outside North America. Today, we are meeting in Berlin, marking the first time that the main (fall) conference has been held outside North America—this conference has traditionally been called the North American Conference but obviously a new description is needed. JCR is a thriving journal with 3,518 subscribers. Instead of a hard copy program, there's Whova app with the program and much more. You can look around the room for current fashion, data collection is often electronic and uses "M-Turk" to recruit participants, and all conference materials are prepared and submitted online.

Much has changed and I think it is fair to say we have made progress as a field by engaging such a diverse group of scholars who examine a wide range of topics using a variety of methods. The one thing that has stayed the same is my affiliation. I just can't seem to get out of Evanston, IL. And bell-bottom pants are again fashionable, though they've gone in and out of fashion so it's not the same as my unwavering attachment to NU.

In 1972, not only was I attending ACR as a newbie to the field, but thanks to my advisor, Jerry Zaltman, who was in charge of the conference arrangements, I found myself on the program. Let me explain. I was just settling in at Northwestern and stopped by to visit with Jerry, who had been instrumental in my decision to come to Northwestern for my doctoral training. During our conversation, I mentioned that I had conducted a study while at Ohio State, where I did my undergraduate and master's degrees, in which I surveyed women's attitudes toward the feminist movement, a hot topic at the time. The Equal Rights Amendment or ERA as it was called, had been passed by Congress and was being ratified by states across the country, Gloria Steinem and the National Organization of Women were regularly in the news, and women were demonstrating if favor of more equitable treatment in the workplace and at home. Although not active in the feminist movement, I supported equal rights and was interested in the degree to which other women felt the same. However, I was stunned when in response to my mention of the study, Jerry enthused, "That's great, there's a session at the ACR confer-

ence that's coming up where you could present your findings. I'll put you on the program!" Apparently, no long, drawn-out formal review was required to get on the program back then, something I couldn't appreciate at the time! The behavior was pure Jerry. He'd throw you in the deep end of the pool confident you'd figure out how to swim! It made him a great mentor and I'm thankful for the opportunities he gave me.

I was more than a bit intimidated but I set about preparing a presentation based on my study. I'd conducted a telephone survey of 94 women in Columbus, Ohio in which I asked questions regarding their beliefs about equality in the workplace and their knowledge of the Equal Rights Amendment, which was under consideration for ratification by the state of Ohio at the time. My paper was entitled "The Feminist Movement: Attitudes, Behavior, and Potential" and was part of a session on called "Ms. and Consumer Behavior: Some Perspectives" (Beery 1972).

When I re-read my paper in preparing my remarks for today, I couldn't help but wonder about the progress made in terms of women's equality, particularly in light of volatile discussions surrounding the presidential election in the U.S. How might women today respond to the questions I asked in 1972? It didn't seem reasonable to repeat the same telephone survey but I thought it would be interesting to ask some of the same questions to a sample of women and see how different or similar their responses were.

My sample a few weeks ago was 248 women from the Midwest who responded to an online survey. I did not repeat the questions about the Equal Rights Amendment. I suspect most respondents today would either be unfamiliar with the E.R.A. because it was never ratified by the 38 states required for passage, or they would confuse the acronym with ERA the brand, a detergent marketed by P&G.

Differences between the responses in 1972 and 2016 wouldn't be surprising given the myriad of changes in just about everything from the sample and mode of data collection to changes in the workplace. What was interesting to me was the fact that there were both differences *and* similarities. Views toward women working outside of the home when they have young children are now far more liberal; only 6% of the 2016 sample agreed with the statement "Women with young children should not work," versus 47% in 1972. Most likely this reflects the economic necessity of women working either because they are single mothers or because two incomes are often required for a family to earn enough to cover basic expenses. Likewise, agreement with the statement "Because men often have a family to support, they should receive higher pay than women for the same work," had declined from 27.7% in 1972 survey to 3.6% in 2016. Further, women who responded to the recent survey were more likely to believe that their family members support equal employment than was the case in 1972 (57% versus 82%).

However, women were *not* optimistic about work place fairness either then or now. Few agreed with the statement "Women generally receive the same pay as men when they perform the same work (21.3% in 1972, 18.5% in 2016)" and they have good reason to be skeptical. Recent studies report that on average women are paid 20% less than men in comparable positions and this disparity is *greater*, not smaller, for women of color and women with advanced degrees (see Figure 1). This pay gap is not anticipated close before 2052 (see

Figure 2). I won't live to see that the happen and my now 23 year old daughter will be nearing retirement by that time. A significant portion of women in both samples also shared a belief that employers discriminate against women in hiring (36.2% in 1972 and 40.7% in 2016) and felt that women do not have the same opportunity for advancement as men (57.4% in 1972 and 62.1% in 2016).

What do I conclude from comparing the responses to these two surveys? As I look around this conference, it is obvious that women make up a substantial portion of the membership and fill many of the leadership positions in ACR. Moreover, many marketing departments have a number of female faculty at all ranks. My own department and school are led by female faculty. And woman heads the ticket of a major party in this year's presidential race for the first time. These are significant changes and represent considerable progress. But the persistent pay gap, the small number of female CEOs and limited representation of women on corporate boards suggests that there is much still to be done to achieve equality in the workplace. Perhaps the glass is moving toward full but it certainly isn't there yet.

In addition to prompting reflection on the topic of my presentation at the 1972 ACR, looking over the program from that conference reminded me that ACR's founders had a vision bringing together not simply academics from a broad range of disciplines but also practitioners and those who work in government to address issues related to consumers. A number of sessions at the 1972 conference focused on public policy issues and involved speakers from industry and government. Indeed, my dissertation research involved field experiments funded by the Illinois Department of Public Aid in which I examined the effectiveness of various persuasive communication strategies for enrolling Medicaid recipients in an HMO program. Listening to Presidential addresses by Punam Anand Keller and Angela Lee at ACR over the past few years, I sense a resurgence of interest in research that has an impact in addressing real world problems.

Since my dissertation, my own effort to contribute to using my skills as a consumer researcher to address practical problems have taken a more philosophical bent and my thinking in this regard has evolved. A paper entitled "Designing Research for Application," which was coauthored with Bobby Calder and Lynn Phillips and published in JCR in 1981, is my most frequently cited work and it details two alternative paths to research application. Let me briefly recap what motivated us to write the paper and the essence of what we said. In 1977, JCR had a new editor, Robert Ferber, an economist and statistician whose own research relied heavily on surveys. In the tradition of new editors, Ferber wrote an editorial entitled "Research by Convenience," in which he argued strenuously against the heavy reliance on convenience samples of students as participants in consumer research. Ferber's position was grounded in principles of statistical generalization; one must draw a probability sample from the relevant population in order to generalize the finding from the sample to the population.

We did not dispute Ferber's argument about statistical generalization. If generalizing observed effects from a sample to a larger population is the goal, then randomly drawing subjects from that population would support such generalization. However, we viewed Ferber's admonitions about the use of student subjects and the related arguments against laboratory settings as too sweeping and inappropriate when the researcher's goal was not to generalize specific effects but rather to test theory. We argued that, in theory testing research, the goal is to test hypotheses under conditions where the expected effect can be detected if it indeed exists. Homogenous samples of students and controlled settings can strengthen such tests

by minimizing the variance attributable to factors unrelated to the causal relationship under investigation, thereby reducing Type 2 error, the danger of accepting the null hypothesis when the alternative hypothesis is correct. Theories that have been so tested and survived rejection are ones that are appropriate for application to real world problems. The theory, rather than the effects observed to test the theory, is what is generalized and the basis for generalization is the understanding provided by the theoretical explanation not the representativeness of the sample. We also noted that using theory to address a specific real world problems requires translating the theory into a viable intervention, something that involves creativity and the impact of which cannot be known on the basis of the theory. Therefore, when the stakes are high, we argued it may be prudent to stress test the intervention by subjecting it to noisy conditions that characterize the natural setting to assess its impact. Thus, we saw theory as a framework for designing interventions that had a stronger foundation than intuition and avoided problem of induction when generalizing specific effects.

Our paper prompted some debate when it was published and the issue of how to conduct research that is interesting, valid, and applicable continues to engage the ACR community. A recent paper by Lynch and others (Lynch, Alba, Krishna, Morwitz and Gurhan-Canli 2012), distinguishes between two types of research; that which is has the goal of documenting important substantive phenomena and that which is the goal of building and testing theory. The crux of their argument is that both types of research are useful but they should be judged by different criteria. To confuse the two creates unnecessary schisms in the field; the solution is separate but equal. At the same time, questions about reproducibility of effects/phenomena documented in psychology and consumer research have surfaced concerns about the validity of many phenomena and thus their generalizability. The Open Science Collaboration spearheaded by Brian Nosek (2015) documents that many efforts to replicate previous published studies fail. Specific examples can be found in the literature on the attraction effect in choice sets (Huber, Payne and Puto, 1982 vs. Frederick, Lee and Baskin, 2014) and the impact of global versus local norms in encouraging the pro-social behaviors (Goldstein, Cialdini, Griskevicisu 2008 vs. Bohner and Shluter 2014). Recommended solutions to improve reproducibility include greater statistical power and conducting more exact and conceptual replications.

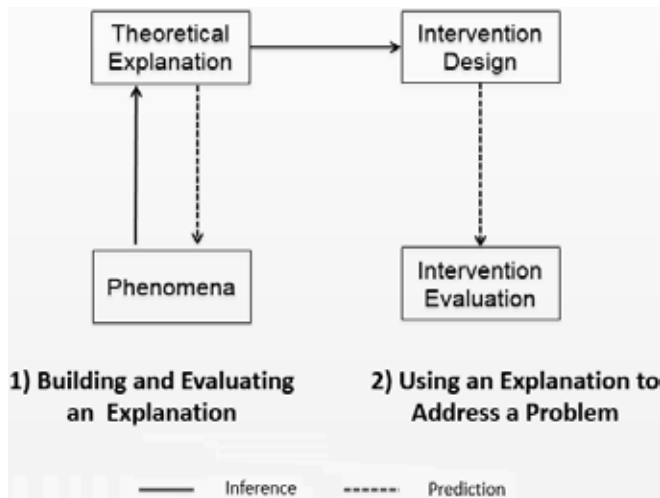
These recent discussions prompted me and my colleagues, Bobby Calder, Miguel Brendl and Brian Sternthal to again consider the relationship between effects, theory and developing solutions to practical problems. Our emerging view is that treating phenomena capture and theory testing as separate enterprises may hamper our progress and ability to address real world problems. Yes, it is important to pin down phenomena to be explained and some researchers may elect to focus on this whereas others may emphasize building and testing theory or using theory to construct interventions. But it is always necessary to move from phenomena to explanation as the basis for application in new settings. Insightful explanations for *when and why* the phenomena occur and careful construction and testing of theory-based interventions will help us address real world problems (see Figure 3).


Figure 3. Integrating Phenomena-Focused and Theory-Focused Research to Design Effective Interventions: A 2-Step Process

And, both steps in the process require imagination, which is the theme of an article that Bobby and I recently published as a commentary on Jerry Zaltman's AMS article titled "Marketing's Coming Age of Imagination"(Calder and Tybout 2016). My current perspective is grounded in my earlier work, but my appreciation for the need to integrate phenomena and explanation and to think abstractly and with imagination about explanations and interventions has increased.

You may have noticed an emphasis on two Ps in my reflections thus far, the *Progress* we've made as a society and field and how my *Perspective* has evolved. One thing that I haven't yet mentioned but that has been a constant in my years on the Northwestern faculty is what I've taught. I started out teaching the core marketing MBA course and 41 years later I still teach the core marketing MBA course. All of you who teach the core know there are four Ps, not two! And indeed, I do have four Ps in mind today. My Progress and my Perspective are attributable to People and Place. I was blessed to have wonderful mentors as a doctoral student (a special thank you Jerry Zaltman and Sid Levy, but my thanks extend to each and every faculty member who taught me at Northwestern and at Ohio State). I also have been blessed with, fabulous colleagues and doctoral students since joining the faculty at Northwestern, and most especially, I am grateful to my numerous, brilliant coauthors. The interdisciplinary nature of the department and the spirit of comradery and mutual respect fueled my personal growth. Which brings me to place. Nearly all of my coauthors share a connection to Northwestern, which has been a very special place for me. In Evanston, we have shared the home called the Jacobs Center. What it lacks in aesthetics (it was built on the heels of campus riots in the 1960s and therefore is more a fortress than a structure designed to foster collaboration and lofty thoughts), it compensates for in the warmth and intellect of the people who work there. In January, Kellogg will move to our new Global Hub. Its open architecture and view of the lake and Chicago skyline promise a place that will fuel even greater imagination and collaboration.

On the people front, I also want to express a special thanks to dear friends who have been by my side on this journey. Carol Scott was there to calm my nerves and support me at that first ACR and we've shared ups and downs in our careers and personal lives ever since. Leigh McAlister joined us a few years into Carol and my journey and her energy, positive attitude and huge commitment to everything she does are a source of inspiration.

In addition, I want to acknowledge my husband Brian, who is also a colleague and coauthor (a trifecta), and our daughter Caroline. The two of you have provided an important work/life balance and brought me great joy. Finally, I want to thank my Dad who is 96 years young, a retired economics professor from OSU and an incredible, ongoing source of inspiration. Dad is still as sharp as ever and spends his time writing to advise President Obama on the correct stance to adopt on issues related to energy and foreign relations, giving humorous speeches at his chapter of Toastmasters, swimming and keeping on top of all family events with cards and calls of celebration and congratulation. My Dad set a standard for mindful engagement in professional and personal life that I may not be able to achieve but I'll keep reaching for.

Today my glass is neither half full nor half empty, it is overflowing with gratitude for this honor.

SESSION OVERVIEW

There is great interest in choice architecture interventions which can change behavior, usually termed nudges (Thaler and Sunstein 2008). To date, this research has focused largely on means (i.e., what is the average impact?) rather than variance (i.e., who is helped and how much? who is harmed and how much?). These papers look at a new generation of choice architecture tools that are customized to meet the differing needs of a heterogeneous population. They ask whether nudges can be both effective *and* selective—can choice architecture interventions have a large impact *and* be customized to individual circumstances?

Many first-generation nudges targeted choices where a single solution approximates most individuals' needs. For example, different individuals should save at different rates, but encouraging everyone to increase savings from near-zero rates benefits most individuals (Thaler and Benartzi 2004). Yet, even with these decisions, there are some people who may need or prefer different options. Further, many important decisions are complex and an intervention which nudges everyone toward the same choice option can hurt some individuals. For example, different individuals have different health needs and encouraging everyone to choose the same insurance plan may help some individuals (e.g., by saving money), but harm other individuals (e.g., by limiting access to specific types of care). This session explores choice architecture interventions designed for a world where individual consumers' circumstances, needs, and preferences may differ.

Our first paper explores whether *preference checklists* help consumers make better decisions that better match their individual needs. Specifically, preference checklists encourage consumers to consider choice-relevant factors that they might otherwise omit; list items are clustered so that reasons supporting one choice option precede reasons supporting other choice options. Appelt and colleagues find that preference checklists significantly influence choice *and* demonstrate selectivity compared to a standard nudge (i.e., a default).

Our second paper investigates whether activating latent goals helps people make choices more in line with their preferences. Specifically, energy-efficient products which cost more upfront but save energy and money in the long run are a better choice for most, but not all, individuals. Hardisty and colleagues find that "10-year energy cost" labels encourage individuals with latent long-term cost minimizations goals to purchase energy-efficient products.

Our third paper asks whether *smart choice sets* can overcome the curse of choice and improve choice outcomes. Specifically, smart choice sets sort choice options based on consumer preferences and partition options into top recommendations and other options (i.e., "the best and the rest"). Dellaert and colleagues find that smart choice sets balance preference-matching and choice costs to help consumers make better decisions.

Our fourth paper explores the interaction between customized choice architecture and the preference for free choice. Specifically, although consumers traditionally prefer free choice, the popularity of services using preference algorithms to provide tailored products suggests that consumers are willing to waive free choice when externally determined choices are based on their own preferences. Cornil and Klesse find higher satisfaction ratings for choices determined by preference algorithm than by personal choice.

Effective, Selective Choice Architecture: Checklists as a More Precise Tool

EXTENDED ABSTRACT

Nudges, or choice architecture interventions which can change behavior (Thaler and Sunstein 2008), have been shown to have large impacts on decisions about such diverse topics as organ donation (Johnson and Goldstein 2003), healthcare (Johnson et al. 2013), and retirement planning (e.g., Knoll, Appelt, Johnson, and Westfall 2015; Brown, Kapteyn, and Mitchell 2011; Liebman and Luttmer 2009; Thaler and Benartzi 2004). However, nudges may act as a blunt tool, affecting people for whom a behavior change would be welfare enhancing *and* those for whom it would be welfare reducing. Better interventions might customize their effects and be selective, depending upon the individual's circumstances and needs.

We introduce a new choice architecture tool, a *preference checklist*, which is a list of choice-relevant factors that consumers might want to consider when making a decision, but often do not due to various factors such as time pressure, lack of information, or output interference. As suggested by query theory (Johnson, Häubl, and Keinan 2007; Weber et al. 2007), checklist items are clustered into factors supporting one choice option or another. Because people tend to construct their preferences for a decision by considering options sequentially, to generate more arguments in favor of the first-

considered option, and thus to choose the first-considered option (Johnson et al. 2007; Weber et al. 2007), the order of the clustered checklist items should have an effect on consumers' choices. Unlike other interventions, such as defaults, checklists do not benefit from disengagement with the decision and instead ask people to more fully consider their options, thinking about which factors are relevant to them. Thus, this type of intervention may be more responsive to individuals' differing needs and have a customized effect.

We report the results of three studies investigating the age at which people prefer to start claiming their Social Security (SS) retirement benefits. The majority of Americans claim benefits early, with roughly half claiming benefits at the earliest possible age (Muldoon and Kopcke 2008; Song and Manchester 2007). For the average consumer, this is a financial mistake (Burtless and Quinn 2002; Coile et al. 2002): It reduces the amount of their monthly check as well as the amount of their overall lifetime benefits. At the same time, the optimal claiming age depends upon many factors, especially expected longevity, current income and retirement savings, and job satisfaction and security. Thus, successful interventions need to act selectively: delaying claiming age for those who should delay, but not delaying claiming for those who should claim early, such as those with a lower life expectancy.

In all three framed field studies, we use web-based samples of older Americans. To ensure the hypothetical benefit claiming decision is relevant to participants, we screen potential participants based on age and benefit eligibility. Participants are invited to continue the study if they are: (1) between the ages of 45 years old and 65 or 70 years old, and (2) either already eligible or expecting to become eligible for SS retirement benefits.

In study 1, we present 309 participants with two checklists constructed from thought listings from prior work (Knoll et al. 2015). The lists contain eight reasons supporting claiming benefits early and eight reasons supporting claiming benefits later. Participants are randomly assigned to see checklist items in one of three orders: the typical order in which people consider the decision (i.e., a checklist of pro-early items followed by a checklist of pro-later items), the reverse order (i.e., a checklist of pro-later items followed by a checklist of pro-early items), or a neutral order (i.e., two checklists of interspersed pro-early and pro-later items). All participants are then asked when they would prefer to claim benefits. Participants who respond to checklists in the reverse order significantly delay preferred claiming age, by 14 months compared to the typical order. The average claiming age in the neutral order is between that of the other two orders, suggesting that salience alone does not account for the effect.

Study 2 (*N* = 344) replicates this result and also examines whether output interference is responsible for the order effect, by examining the time participants spend considering each checklist item. Indeed, the difference in response time completely mediates the effect of checklist order on preferred claiming age: Participants spend more time interacting with the items in the first checklist, and, when this is the pro-later list, this encourages them to delay claiming.

Study 3 (*N* = 451) examines whether the "right" people are affected by the checklists and compares the checklist intervention to a default set at the latest claiming age. Using a standard set of questions, we estimate longevity to, in turn, estimate the optimal claiming age for each individual. We demonstrate again that the reverse-ordered checklist causes a significant delay in claiming relative to control, as does, to a lesser extent, the default. However, the default affects those who should claim early *and* those who should delay, whereas the checklist shows selectivity by reducing the average claiming "error" by 39% relative to control. In other words, the reverse-ordered checklist minimizes the difference between when

participants *should* claim benefits based on their life expectancy and when they *prefer* to claim benefits.

There is growing evidence that choice architecture can substantially improve outcomes for important decisions in a wide range of domains. However, there is also concern that these approaches may ignore individual circumstances and preferences and nudge everyone in the same direction. The current research offers hope that not all choice architecture interventions are blunt tools. Compared to defaults, preference checklists may work as a more selective tool that has the biggest impact on those who would benefit most. Preference checklists can easily be applied to other contexts where consumers struggle to make the right choice, such as saving for retirement, allocating a limited budget, choosing a health insurance plan, et cetera.

Encouraging Energy Efficiency: Product Labels Activate Temporal Tradeoffs

EXTENDED ABSTRACT

Many interventions designed to encourage energy-efficient choices are coercive or blunt. For example, energy inefficient incandescent lightbulbs were outlawed in several U.S. states and Canadian provinces because consumers kept buying them in spite of the large energy savings possible with energy-efficient CFL and LED bulbs. Likewise, defaults are a powerful tool (Dinner et al. 2011) but run the risk that they may nudge consumers in a direction they do not want to go -- more paternalistic than libertarian. Another class of energy efficiency interventions is designed to give consumers more information and thus to improve the quality of their choices without compromising personal freedom. However, these have a mixed record of efficacy (Anderson and Claxton 1982; Abrahamse et al. 2005; Min et al. 2014).

We demonstrate that informational nudges are effective when they tap into a latent consumer goal, such as long-term cost minimization. Normally, when consumers are making purchases, they do not think about long-term costs. However, through a "10-year energy cost" label, we activate this latent goal, thus dramatically increasing the proportion of energy-efficient choices without being coercive. This intervention taps into the latent goals of some consumers but not others (Study 2), and thus serves as a selective nudge (only influencing consumers that care about the attribute) rather than a blunt hammer.

Study 1a shows that 10-year cost labeling substantially increases the proportion of energy-efficient choices. In partnership with a local utility company, BC Hydro, a sample of 147 Vancouver-area residents made hypothetical choices about lightbulbs, TVs, furnaces, and vacuums, in which more energy-efficient products were more expensive upfront. For example, participants chose between two 60-watt incandescent bulbs for $0.97 and two 13-watt CFL bulbs for $17.99. In the "10-year cost" condition, we calculated the average dollar cost of each bulb pack over 10 years (using current electricity prices and average usage rates) and displayed this information directly underneath the upfront cost. Thus, in the "10-year cost" condition (a between-subjects manipulation), participants also saw that the 10-year cost of two 60-watt bulbs was $239, while the 10-year cost of two 13-watt bulbs was $52. Across all four product categories, this manipulation significantly increased the proportion of energy-efficient choices, from 50% to 79% on average.

Study 1b demonstrates the effectiveness of this method in a field study in five drug stores over a period of six weeks, with real purchase decisions made by naïve shoppers. Price labels for light bulbs on store endcaps were changed each week (balanced between stores). Shoppers purchased the energy-efficient bulb 12% of the

time with control labels and 48% of the time with 10-year energy cost labels, $p < .001$.

In Study 2 selective goal activation mediates the effect of "10-year cost" labeling on choice. As 242 MTurk participants considered the product pairs, they indicated their goals when shopping for that type of product. These goals were later coded to indicate whether they concerned long-term costs. Choice results replicated Study 1 results, and also demonstrated that 10-year cost labelling is more effective than 1-year cost or 5-year cost labelling. Furthermore, participants in the control condition rarely mentioned long-term costs, while participants in the 10-year cost condition mentioned long-term costs more frequently and prominently. These long-term cost goals strongly predicted choices and mediated the effect of labelling on choices. In other words, when participants were reminded of long term costs, some of them cared a lot about this, and the nudge had a strong effect on their choices, whereas other participants still did not care about this goal, and the nudge had little effect on their choices. This demonstrates the selectivity of the nudge, as it taps into the existing goals that some consumers have but others do not.

In Study 3, we used an alternative method to activate the long-term cost minimization goal. In addition to the control and "10-year cost" conditions used in earlier studies, we added a "subjective cost estimation" condition. In this condition, 245 MTurk participants saw the same information as in the control condition, and were asked to estimate the 10-year energy cost (in dollars) of each product before making their choice. The choice proportions of participants in this cost estimation condition were identical to those in the 10-year cost condition (and significantly higher than those in the control condition). Furthermore, the average energy costs estimated by participants in the estimation condition were fairly close to the actual energy costs (a "wisdom of the crowds" effect). Thus, it is NOT the case that the 10-year cost labeling simply provides participants with new information. Rather, the 10-year cost label works by activating the latent long-term cost minimization goal, and we demonstrate that alternative means of activating this goal similarly impact choices, even without the provision of new information.

In a sample of 254 MTurkers, Study 4 demonstrates the specificity of the long-term cost minimization goal: although consumers are sensitive to future dollar costs (Min et al. 2014), other frames such as energy savings or dollar savings do not have much effect on choices. Thus, the labelling techniques currently used on energy-efficient products (which emphasize dollar savings or energy savings) may not be very effective. Likewise, this explains why some previous informational interventions in the literature were not effective.

This intervention is more effective than all other known informational interventions, and is less coercive than other tools such as defaults or legal measures. It has broad potential application, because it can be used for all types of energy-using products, including those that have not yet been invented. It should be attractive to retailers because it can be used to nudge consumers towards more efficient, expensive products, and retail firms do not profit from energy costs. This intervention should also be attractive to consumers because it reduces their costs in the long run, and to society because it has the potential to reduce energy usage and environmental harm.

Smart Choice Sets

EXTENDED ABSTRACT

It is no news that consumers and other decision-makers are faced with a massive increase in available options. Increases in the ability of firms to generate more options and the use of online markets to present these options suggest the possibility of choice overload: that by presenting consumers with more choices, they will pick worse options, a phenomenon labeled in the popular media as the Curse of Choice.

Determining how many options to present to a decision-maker might be thought of as balancing two factors (for an excellent review, see Chernev, Böckenholt, and Goodman 2015). The first, which can be thought of as a blessing, it that more options may generate a better match between what the decision-maker wants and what is available. The second, representing the curse, is that adding options increases the cost of evaluating options. Since decision-makers have limited time and cognitive resources, the result may be that they either abandon search too quickly, or adopt a simplified rule or heuristic, leading to suboptimal choice. In this paper, we suggest that well-designed choice architecture (Johnson et al. 2012; Thaler and Sunstein 2008) can be used to deliver the benefits of increasing the number of options while minimizing its costs.

Specifically, in this paper we test one possible way of reducing the costs of search without decreasing the utility of the chosen option. We (1) explore the problem with an analytical model which shows the conditions under which our proposal helps, (2) present two online studies to test the utility of the mechanism, and (3) analyze field data from a large provider of health insurance.

Our model is a new synthesis of existing choice architecture tools: *Smart choice sets* are a non-binding choice architecture which helps overcome consumer information overload in large choice sets. Smart choice sets combine three existing techniques. The first is sorting the list of options. The second is to use a model of the consumer's preferences and to use a prediction of how well each option fits those preferences as the basis of that sort. The third is to partition the set into two components, a primary and a secondary list. This focuses attention on a small set of top recommended options, but provides the possibility of clicking through to the full set of options. We present both theory and empirical evidence that smart choice sets improve the outcomes of choices and reduce effort.

Sorting by a single product attribute, for example price, has a significant effect on what is chosen, but this change is not necessarily an improvement. The typical result is that the sorting attribute is more heavily weighted, a result that may be good or bad (Lynch and Ariely 2000). In contrast, presenting products in order of predicted attractiveness can be an effective way to assist decision making (Dellaert and Häubl 2012; Häubl and Trifts 2000). However, even in sorted lists finding the best product can be daunting for consumers (Johnson et al. 2013). Decision-makers adopt simplification procedures that ignore information. They often eliminate options based on a single attribute, even when the number of options is small, and this can lead to inferior choices. In addition, the use of heuristics, can, paradoxically, cause consumers to search too much in sorted lists, which lowers their decision outcome quality (Diehl 2005).

Therefore smart choice sets provide decision guidance by presenting only the most highly recommended products (which we call the "recommended set"), with the option to click through to see the complete recommendation list with all available products (i.e., the "full set"). Behind smart choice sets is the idea that people can choose how to choose and use decision processes that vary in the quality of decision outcome and in the effort required to use them. Smart choice sets can focus the decision-maker's limited cognitive resources on the best decision strategy and the best subset of alternatives. In this way, partitioning, modeling and sorting are important complements in helping individuals cope with information overload. Partitioning limits the number of options that are considered and encourages the use of better strategies to choose among the consider-

ation set. Sorting on predicted preferences ensures that only the best alternatives are in the partitioned choice set.

We examine the proposed effects in two online survey-based experiments and a field study in the domain of consumer health insurance product choices. In Study 1 (N=858) we find support for the predicted effects of sorting and partitioning. In a 2x2 experiment the quality of the recommendation's sorting and the presence of partitioning were manipulated. We find that both higher quality sorting and partitioning improve consumer choice outcomes. Study 2 (N=1,577) extends Study 1 by also introducing a close to random sorting condition; in addition in this study respondents were asked to choose on behalf of someone else according to a preset decision rule. This allows for objective benchmarking of decision quality. The results replicate the findings of Study 1. In addition, they highlight the important complementarity between sorting and partitioning, in that we find a reversal of the impact of partitioning for the near to random quality sorting condition, where consumers' choice outcomes were worse rather than better when presented with a partitioned list. In the field study (N= 43,632) we analyzed data from a large online health insurance product comparison website in the Netherlands that introduced a new choice architecture that closely mimics smart choice sets. Results from this third study provide external validity and further support for the proposed impact of sorting and partitioning on consumer choice outcomes. After the introduction of the new choice architecture, significantly more consumers chose one of the top recommended alternatives on the website.

We conclude by discussing the drivers of optimal smart choice set size. Partitions that are too large may harm decision outcomes, but partitions that are too small may unduly limit consumer choice. We generalize the insights from our research in terms of optimal smart choice sets size depending on recommendation list quality and consumer decision error.

Choosing Not to Choose: Consumers Are More Satisfied With a Product When It Is Determined by a Prediction Algorithm Than When They Personally Chose It

EXTENDED ABSTRACT

The main criticism lobbed at choice architecture interventions is that, while trying to nudge consumers to make "better choices" (e.g., Johnson et al. 2012; Thaler and Sunstein 2008), they actually restrict consumers' freedom of choice. It has repeatedly been demonstrated that individuals are more satisfied when they can choose themselves compared to situations in which they cannot (e.g., Burger 1989; Cordova and Lepper 1996; Langer 1975). According to past research, there are two main reasons why consumers value their freedom to choose. First, choosing is inherently rewarding (Botti and Iyengar 2004; DeCharms 1968) and, second, consumers feel that only they can choose products that match their personal preferences (Averill 1973; Bem 1967; Collins and Hoyt 1972).

However, recent advances in technology have increased companies' ability to suggest products that match consumers' preferences, without having them choose. For instance, Netflix or Spotify utilize "rating prediction" algorithms that track their users' consumption behavior in order to suggest songs or movies that their customers will like. In this research, we focus on such common business practices and demonstrate that consumers are actually more satisfied with an assigned (not-chosen) song rather than with a self-chosen song, as long as that song matches their preferences.

In doing so, our findings are in contrast with research highlighting the advantage of choice over no-choice for consumer satisfaction. Notably, existing studies have predominately focused on

situations where preferences are constructed on the spot (e.g., Botti and McGill 2011). For instance, individuals were presented with different formats for a photography museum, or a list of ambiguous dishes on a restaurant menu (Botti and McGill 2011). In contrast, our research focuses on situations where consumers have clearly pre-existing preferences (e.g., music). We hypothesize that in such situations, "assigning" a song that matches consumers' pre-existing preferences—through rating prediction algorithms—will yield greater satisfaction than if individuals choose it themselves. We further reason that this occurs because the preferred song was correctly predicted by the algorithm and not because it may have been assigned by chance (e.g., feeling lucky).

To test our hypotheses, we first developed a prediction algorithm. We asked 200 MTurkers to evaluate 21 preselected songs and 61 artists of various genres. We ran a factor analysis of the evaluations of the 61 artists, and identified eight factors each loaded by three artists (24 retained artists in total), with high eigenvalues and item-total correlations. These eight factors corresponded to eight distinct music genres (e.g., eighties-rap, hard-rock, modern-pop, etc.). Then, for each factor, we identified the "best song" (highest positive correlation with the factor), "worst song" (highest negative correlation with the factor), and "average song" (correlation closest to zero with the factor).

We then used our song prediction algorithm in an experimental study with 250 MTurkers. First, all participants evaluated the 24 artists. The survey software automatically calculated each participant's preferred genre. Then, participants were assigned to a 2(choice vs. no choice) x 2(target song: "best song" vs. "average song") between-subject design. In the "no choice" condition, participants received the target song. In the "choice" condition, participants could choose to listen either to the target song or to the "worst song." We selected the "worst song" as the non-target option for two reasons: First, such an easy choice task (a small choice set with a clearly dominant option) increases choice satisfaction (Botti and McGill 2006), allowing a conservative test of our hypotheses. Second, most participants in the choice condition should choose the target song so that the outcome is kept constant for all participants. Finally, participants rated their satisfaction with the assigned/chosen song. A regression analysis of satisfaction revealed a main effect of target song (participants enjoyed the "best" song more than the "average" song), and more importantly, an interaction effect of target song and "choice vs. no choice". As hypothesized, when the target song was the best song, non-choosers were significantly more satisfied than choosers. When the target song was an average song, choosers were directionally more satisfied than non-choosers.

This first study showed that when consumers can listen to a song that matches their preferences, they are more satisfied when it is assigned to them than when they personally choose it. Are they satisfied because their preferences were correctly identified, or because they felt lucky? We answered this question in a second study. 160 MTurkers first completed the artist evaluation survey. Then, they were assigned to one of three conditions. In a "choice" condition, participants could choose the "best" song or the "worst" song. In a "no-choice" condition, participants were assigned to the "best" song, which they were deceptively told was selected randomly. In a second "no-choice" condition, participants were assigned to the "best" song, which they were truthfully told best matched their preferences. Contrast analyses showed that participants were most satisfied when the song was assigned to them, reportedly based on their preferences. Satisfaction was significantly lower in the "choice" condition and marginally lower when the song was allegedly assigned randomly.

In conclusion, by demonstrating that assigned products which match consumers' preferences yield greater satisfaction than self-chosen products, our research challenges the assumption that the freedom to choose always increases satisfaction.

SESSION OVERVIEW

The context in which we make decisions has a huge impact in our decision-making process. For example, consumers sometimes make choices based on extraneous factors, including anchors (e.g., Ariely, Loewenstein, and Prelec, 2003), framing (e.g., Tversky and Kahneman, 1981), or how alternatives are grouped within a choice set (e.g., Huber, Payne, and Puto, 1982; Simonson, 1989). For decades, technological advancements have been constantly reshaping the context in which we make our decisions. Given that technological innovations are an inescapable aspect of our lives, it is important to further understand how they impact consumer behavior. What are the factors that affect how people select and interact with these technological advancements, as well as the possible consequences of these decisions?

Some research has started to examine how the use of technology impacts memory (e.g., Sparrow, Liu, and Wegner, 2011), social interactions (e.g., Ellison, Steinfield, and Lampe, 2007; Kraut et al., 1998), and self-perception (e.g., Wilcox and Stephen, 2013; Chou and Edge, 2012). The four papers in this session build on this work and illustrate how new technological contexts can influence consumer preferences, behavior monitoring, perceptions of others, and information processing.

Electronic and digital options are now the norm within our choice sets; for instance, within 15 years of introduction, sales of high-tech options like digital cameras and smartphones have outpaced their traditional counterparts (Zhang, 2014; Lomas, 2014). The first two papers examine how people interact with technological products. **Atasoy and Morewedge** investigate why consumers often prefer physical products over digital alternatives. They show that for a variety of goods, physical versions are more appealing because they invoke psychological ownership. **Silverman and Barasch** examine how and why people use smartphone apps to track their behaviors. They find that missing the opportunity to log an activity—even when this "miss" is outside the person's control—decreases the user's likelihood of logging the next relevant activity in a tracking app.

Additionally, people often make decisions within technological environments. The final two papers focus on the consequences of consumers' interactions with technology. **Lieberman, Amir, and Schroeder** show that attitudes and perceptions of a communicator and message depend on the method of listening. Specifically, people who listen to messages through headphones, as opposed to speakers, are more immersed in the message and view the communicator more positively, which in turn increases donations in economic games. **Ward and Schwikert** investigate how the ability to easily access information at a later date through technology impacts consumers' processing of information. They find that people remember fewer conceptual details when information is presented in a digital, prerecorded format, compared to a live, unrecorded format.

Together, this session highlights the diverse ways in which technology impacts our daily lives. Given the widespread applicability of the issues discussed, we expect this session to attract researchers interested in experiential purchases, information processing, sequential decision making, memory, product engagement, and consumer identity. Much like "Wanderlust" invokes a sense of exploration, we hope that these varied approaches to technology invoke a lively discussion.

Better to Have a Book in the Hand Than Two in the Cloud: Consumer Preferences for Physical Over Digital Goods

EXTENDED ABSTRACT

New technologies have given rise to digital versions of many goods, including photographs, books, music, and movies, which has eliminated the need to use a physical medium to store this content (Belk, 2013; McCourt, 2005; Odom, Zimmerman, and Forlizzi, 2011; Petrelli and Whittaker, 2010). We examined whether people ascribe greater value to physical or digital goods in self-report and incentive compatible designs. We report five experiments that elucidate the preference between these two formats, and identify greater establishment of psychological ownership for physical goods as the mechanism responsible for their differences in valuation.

We predicted that physical versions of goods would be valued more than digital versions. Our prediction was based on previous research findings that established (1) a connection between physically interacting with objects and perceived ownership for the objects, and (2) a connection between perceived ownership and valuation. Touching (Peck and Shu, 2009) or imagining touching (Peck, Barger, and Webb, 2013) an object, as well as physically interacting with an object for a longer time (Wolf, Arkes, and Muhanna, 2008), increases perceived ownership. As the (perceived) opportunities for physically interacting with physical goods are better than similar opportunities for digital goods, we predicted a stronger perceived ownership for physical goods and consequently a higher valuation, as a long line of research has demonstrated that perceived ownership increases valuation (Kahneman, Knetsch, and Thaler 1990; Thaler 1980; Morewedge et al. 2009; Maddux et al. 2010; Dommer and Swaminathan 2013). Some qualitative evidence also suggests that digital goods may be valued less, as well as less strongly connected to their owners' sense of selves (McCourt, 2005; Giles, Pietrzykowski, and Clark, 2007; Petrelli and Whittaker, 2010; Siddiqui and Turley, 2006), although others disagree with this proposition (Lehdonvirta, 2012).

We found in five experiments that participants ascribed a higher value to physical than digital versions of the same photograph, book, and movie, whether measured in an incentive compatible pay-what-you-want paradigm, willingness to pay, or purchase intention.

Experiment 1 tested our hypothesis in an incentive-compatible field experiment using a pay-what-you-want design (Gneezy, Gneezy, Reiner, and Nelson, 2012). Tourists in Boston were given

as a souvenir either a printed photograph or a digital photograph (of higher quality) of themselves with a costumed historical figure at a historical site. They were then asked to make a donation for the souvenir photo to the organization that preserves the site, by paying whatever they wanted for the picture, including $0. To control for potentially different beliefs regarding the production costs of physical and digital photographs, after collecting donations, participants estimated the average cost of producing their photographs. Participants paid more for printed photograph than digital photographs, even when controlling for the perceived cost of production (F(1,82) = 5.89, p = .02). Note that the photos had no resale value, and thus the effect cannot be explained by a difference in market value.

Experiment 2 found that this difference in valuation generalizes to other product categories including books, music, movies, and magazine subscriptions. Participants indicated a higher likelihood to purchase (F(1, 198) = 13.69, p < .001) and greater willingness to pay (F(1, 192) = 13.48, p < .001) for physical than digital versions of goods across all product categories.

The findings of **Experiment 3** suggest that these findings were not due to differences in perceived consumption utility. Although participants ascribed greater value to physical goods (F(1, 196) = 7.05, p = 0.009), they believed their digital counterparts were more useful on every dimension measured (ps < .001).

Experiment 4 ruled out a social signaling motive. Participants exhibited the same greater preference for physical than digital versions of both high and lowbrow goods. Experiment 4 also found that estimates of the retail prices of digital and physical goods cannot explain this preference.

Experiment 5 identified psychological ownership as a driver of the higher valuation ascribed to physical goods. College students reported their willingness to pay for buying or renting a digital or print copy of a course textbook. The willingness-to-pay gap between physical and digital versions of the textbook disappeared in the rent condition (F(1, 271) = 2.27, p = .13). Whereas students were willing to pay more to buy than rent a physical textbook (F(1, 271) = 13.47, p < .001), they were not willing to pay more to buy than rent the same digital textbook (F(1, 271) = 0.084, p = .77). Similar results were obtained in a replication in which participants considered textbooks that would have no resale value after their use. Renting reduced perceived ownership and thus valuation for the physical version. Renting had a much more limited effect on the valuation of the digital version, as perceived ownership is already low for digital items.

Together, these studies reveal how psychological processes, value, and technology are intricately intertwined.

You are What You Track: The Effect of Failing to Log an Experience on Future Use of Tracking Apps

EXTENDED ABSTRACT

Millions of people keep track of a large range of behaviors through smartphone apps. For example, over 15 million people catalogue their outdoor runs on MapMyRun and over 1 million people record what craft beers they drink on Untappd.

Though some research has investigated how tracking goal progress can affect goal achievement (Soman and Cheema, 2004; Cohran and Tesser, 1996; Etkin, 2016), little work has examined tracking behavior itself. This is especially important to understand since many of these apps assist people in tracking their behavior; the value of Untappd is not in helping people drink more beer, but in simply helping them track the beer they drink. Hence, apps like Untappd find it critical to maintain consistent consumer engagement.

In this work, we investigate how missing the opportunity to log an activity may influence the user's likelihood of logging the next relevant activity. On the one hand, research on licensing and aspirational pursuits suggest that people may try to balance their decisions (e.g., Huber, Goldsmith, and Mogilner, 2008; Dai, Milkman, and Riis, 2014). This would predict that missing a log would make people *more* likely to log their next activity. On the other hand, prior work suggests that people often choose options that reinforce previous decisions (e.g., Dhar and Simonson, 1999; Tykocinski, Pittman, and Tuttle, 1995). This would predict that missing a log would actually lead to consistency, or that people would be *less* likely to log their next activity.

Across four studies in three different contexts, we show that missing the opportunity to log an activity—even when this "miss" is outside the person's control—decreases the user's likelihood of logging the next relevant activity. We also suggest that this effect is due to users' perceptions that their activity log is a personal representation of themselves.

Study 1 (n = 150) tests how being unable to log an activity in a tracking app affects subsequent likelihood to use the app. Participants imagined that they were regular users of an app that allows them to log and rank beers, and that they had just tried several new beers at a festival. Participants were told either that they had logged those beers in their app (*log* condition), that they could not log any of the beers because their phone had died (*miss* condition), or were given no information about whether they logged their beers or not (*control* condition). A one-way ANOVA revealed an effect of condition on likelihood to log a beer consumed the following week (F(2, 147) = 8.47, p < .001). Participants in the *miss* condition were less likely to record their next beer (M = 5.42) than participants in the *log* (M = 6.32; t(95) = 3.67, p < .001) and *control* (M = 6.23; t(101) = 3.45, p < .001) conditions. Participants in the *log* and *control* conditions did not differ in their likelihood to log the next beer (t(98) = .32, p = .75).

Study 2 (n = 180) examines whether this effect also occurs when logging non-hedonic experiences. Students imagined that they regularly used a note-taking app, then were told that for the previous lecture, they either missed logging their notes in the app due to uncontrollable circumstances (*miss* condition) or successfully used the app (*log* condition). In addition, we manipulated whether the previous lecture covered a lot of material (*high impact* condition) or was a review (*low impact* condition). Overall, participants in the *miss* condition were less likely to use the note-taking app in future lectures (M = 8.34) than participants in the *log* condition (M = 9.07; F(1, 176) = 4.56, p = .034). However, there was no effect of impact on likelihood to continue logging (F(1, 176) = 1.83, p = .178), nor was there a significant interaction (F(1, 176) = 0.75, p = .39). These results suggest that this effect occurs even when the app is more utilitarian in nature, and regardless of the importance of the missed activity.

Study 3 (n = 200) replicates this effect with participants who imagined using an app to log their outdoor runs. They were told that they either logged their most recent run or missed logging due to uncontrollable circumstances. Participants who missed logging their last activity were less likely to log their next activity on the app (92.93%) than people who successfully logged their last activity (99.01%; X^2(1) = 4.81, p = .028).

Study 4 (n = 176) explores the mechanism behind this effect. Using the same stimuli as study 3, we also measured the extent to which participants felt like the activity log was a personal representation of themselves (e.g., wanting the running log to be an accurate portrayal of them, wanting the log to reflect a complete account of their runs; α = .825). We again find an effect of previous logging on likelihood to log future runs (F(1, 174) = 5.21, p = .024). We also

find that this effect was mediated by beliefs that the log represents the self (indirect effect = -.399, SE = .192, 95% CI = [-.824, -.068]), such that missing decreased the level of personal representation felt from the app, which in turn decreased likelihood to continue logging.

Overall, we find that when people miss the opportunity to log an experience due to uncontrollable circumstances, they are less likely to continue logging that activity. This research adds to our current knowledge of how and why people track their behaviors and suggests that these app companies may increase customer engagement by instituting ways for people to get back on track after or "make up" for a missing activity.

"Coming Alive" Through Headphones: Listening to Messages via Headphones vs. Speakers Increases Immersion, Presence, and Liking

EXTENDED ABSTRACT

In recent years, individuals increasingly consume media messages, advertising, news, and entertainment through auditory mediums, such as podcasts. In fact, as of early 2013, Apple reported having over one billion podcast subscriptions (Mogg, 2013). Consumers listen to auditory media either via headphones or via speakers, yet little research exists on how these various forms of consumption influence consumer perceptions and subsequent behaviors. Oftentimes, auditory media includes appeals to make purchases or donations, requests that are heavily influenced by feelings of trust and generosity. Relative to speakers, listening to an auditory stimulus via headphones reduces felt social distance (Kallinen and Ravaja, 2007) and evidence demonstrates that decreased social distance leads to increased generosity (Charness and Gneezy, 2008). Recent studies have also shown that hearing an individual's voice makes her seem smarter and more likeable, thus humanizing the communicator (Schroeder and Epley, 2015). We hypothesize that listening to an individual via headphones (versus speakers) will make the communicator seem more present, decreasing felt social distance and increasing trust and generosity.

In an initial experiment, we tested whether individuals anticipated that listening via headphones would result in different assessments of the communicator than listening via speakers. Participants ($n = 102$) imagined listening to a woman talking about a difficult time in her life via headphones (vs. speakers, order counterbalanced). Participants expected that listening to the message through headphones would lead to significantly greater feelings of communicators' presence, ($M_{speakers} = 4.86$ versus $M_{headphones} = 5.18$; $t(201) = 2.09$, $p = .04$), and that they would be significantly more immersed in the story ($M_{speakers} = 4.49$ versus $M_{headphones} = 5.32$; $t(198) = 5.29$, $p <.001$). However, participants did not anticipate that the mode of listening would affect their attitude toward the communicators, ($M_{speakers} = 4.73$ versus $M_{headphones} = 4.82$; $t(198) = .617$, $p =.54$). We next tested whether these perceptions were accurate.

In Experiment 2, stimuli consisted of 3 real messages that were recorded from university students requesting tutoring help in a challenging course. Participants were randomly assigned to one of 6 conditions in a 2 (headphones vs. speakers) x 3 (message requesting tutoring) study design. As participants in Experiment 1 had predicted, Experiment 2 participants who actually listened to a request to help via headphones, relative to speakers, indicated being more immersed ($B = .30$, $t(138) = 2.0$, $p = .05$) in the message. However, contrary to the predictions of Experiment 1 participants, individuals who actually listened to an appeal via headphones judged the communicator significantly more positively ($B = .29$, $t(138) = 2.2$, $p =.03$).

In experiments 3 and 4 we explore two potential behavioral consequences of these effects: increased generosity and persuasiveness. In Experiment 3, participants ($n = 586$) listened to the exact clip described in Experiment 1 via headphones or speakers. Participants who listened to the message via headphones reported feeling significantly greater levels of communicator presence, ($B = .21$, $t(555) = 2.13$, $p = .03$), and were marginally more immersed in the story, ($B = .15$, $t(555) = 1.66$, $p = .09$). Participants again judged the communicator significantly more positively—as both warmer and more competent—when listening to the message through headphones, ($B = .17$, $t(555) = 2.18$, $p = .03$). Further, the effect of mode of listening on communicator perceptions was fully mediated by perceived social distance. Finally, conditional on giving a donation, those who heard the message via headphones were marginally more likely to donate more ($B =.48$, $t(460) = 1.7$, $p = .09$).

Study 4 comprises a dictator game. Participants were placed in individual rooms, assigned the role of dictator and told that they may receive a $10 endowment for participation and may choose to share it with their 'partner,' a participant from a previous session. Participants listened to a prerecorded scripted message from their 'partner,' requesting that the dictator share a portion of their sum. One-half of the participants listened to this message via speakers while the other half listened via headphones. Interestingly, the scripted communicator, who was not a genuine speaker as in the previous studies, was viewed as less warm in the headphones condition ($B = .33$, $t(367) = 2.97$, $p = .003$), an effect that moderated generosity: conditional on having donated any amount, participants who rated the speaker as warmer gave more money when the request was heard through headphones ($B = 0.50$, $t(290) = 2.1$, $p = .03$). These findings suggest an unexpected moderator: authenticity. Listening using headphones may amplify beliefs about a communicator, suggesting that only communicators who are authentic get a boost in likability and persuasiveness when heard via headphones. We are currently exploring this potential moderator in a follow-up study.

These findings make a significant contribution to understanding media consumption and how mode of listening influences consumer experience and behavior. Whether consumers listen via headphones or speakers affects how close they feel to the communicator and how positively they judge the communicator. Our results provide novel insights into auditory media consumption, applicable to communicators and consumers alike.

The Accessibility Liability: Digital Information Undermines Conceptual Understanding

EXTENDED ABSTRACT

The advent of the "Internet Age" has transformed the way consumers acquire, process, remember, and interact with information (e.g., Barr, et al., 2015; Macias, et al., 2015; Ward 2013a, 2013b). In parallel fashion, the rapid rise and proliferation of digital access has transformed the way firms—including educational institutions—*deliver* information. Digital materials such as videotaped lectures, textbooks, and online coursework complement classrooms at every level of education. More strikingly, digitally-delivered information is increasingly used as a replacement for traditional learning environments; over 5 million U.S. college students took courses online in 2013 (Allen and Seaman, 2015), and 35 million individuals enrolled in free massive open online courses (MOOCs) in 2015 (Shah, 2015).

In this research, we explore how the shift toward digital information may undermine the development of conceptual understanding. We propose that consumers' implicit assumptions about the future accessibility of digital information may affect not just infor-

mation *storage* (memory for information), but also information *processing* (understanding of information). These assumptions about the persistent accessibility of digital information, combined with a tendency to offload responsibility for information to future-accessible external sources (e.g., Sparrow, Liu, and Wegner, 2011; Wegner and Ward, 2013), may cause consumers to devote less attention to digital information than to information communicated via traditional mediums. To the extent that encoding of factual information and development of conceptual understanding require different levels of processing, variations in depth-of-processing created by these differences in attention may undermine the development of conceptual understanding for digitally-delivered information, even when consumers are successful at storing this information in internal memory. Ironically, the same principles of accessibility that eliminate barriers to educational access may create barriers for reaping the full rewards of digitally-delivered educational interventions.

Our first experiment examines the effects of presentation format on depth-of-processing in the context of traditional (live) vs. digital lectures. We delivered three 7-minute lectures to 135 undergraduate students under one of four conditions: live, digital with future access (students watched the lectures on YouTube, and were told that they would be able to access the lecture in the future), digital without future access (students were told that they would *not* be able to access the lecture in the future), and digital baseline (students were given no information about future accessibility). Students were told that they would be tested on their "memory and understanding of the lectures," and were prohibited from taking notes of any kind. Immediately following the lectures, participants completed a three-minute cognitive filler task designed to prevent explicit repetition and rehearsal of lecture content. Finally, participants completed a quiz assessing two key types of knowledge: memory for factual information (12 items, $\alpha = .65$) and conceptual understanding (18 items, $\alpha = .77$).

Planned contrasts revealed no differences between any of the three "digital" conditions on either conceptual understanding (all ps > .40) or factual memory (all ps > .22). Subsequent contrasts comparing the "live" condition to all three "digital" conditions revealed differences for conceptual understanding ($F(1,131) = 6.82$, $p = .01$, Cohen's $d = .51$), but not factual memory ($F(1, 131) = 0.24$, $p = .63$). These results were confirmed by a supplementary analysis treating knowledge type (factual memory, conceptual understanding) as a within-subjects factor; a planned interaction contrast comparing within-subjects differences in knowledge type for the "live" condition vs. the three "digital" conditions was significant ($F(1,131) = 9.49$, $p < .01$, Cohen's $d = .54$).

These results indicate that digitally-delivered information is associated with decreased conceptual understanding (relative to traditionally-delivered information), even in the absence of effects on memory for factual information. Whereas prior work has focused primarily on memory deficits associated with reliance on digital resources (e.g., Sparrow, Liu, and Wegner, 2011; Wegner and Ward, 2013), our results suggest that reliance on digital information may have negative consequences for consumer knowledge even when individuals are motivated to commit this information to internal memory (and are successful in doing so). In contrast to traditional learning environments, where students employ enhanced rehearsal strategies when attempting to internally encode information that they believe will be inaccessible in the future (Eskritt and Ma, 2014) and develop high levels of understanding by extracting conceptual themes while taking paper-based notes (Mueller and Oppenheimer, 2014), consumers of digitally-delivered information may fail to develop conceptual understanding because digital sources implicitly promise unlimited future access without requiring consumers to engage in elaborative internal processing.

The results of our first experiment also suggest that implicit assumptions about digital permanence may override explicit information about future accessibility. Although we hesitate to over-interpret null effects, the equivalence of all three "digital" conditions on both outcome measures is consistent with prior research suggesting that implicit beliefs about digital permanence are resistant to explicit claims that information has been deleted (e.g., Sparrow et al., 2011). Pervasive implicit beliefs about the future accessibility of digital information suggest that explicit interventions may be ineffective at counteracting accessibility-related deficits in depth-of-processing for digital information.

We further develop this exploration of the effects of digitally-delivered information on consumer knowledge in a set of follow-up experiments focused on both expanded breadth (e.g., comparing processing of printed pamphlets to equivalent online text) and increased depth (e.g., assessing implicit/explicit beliefs about future accessibility, manipulating attentional resources). For example, we find that imposing high cognitive load during a reading task reduces conceptual understanding of print-based information ($F(1, 111) = 5.87$, $p = .02$, Cohen's $d = .54$), but not digital information ($F(1, 111) = 0.95$, $p = .22$)—a pattern consistent with the idea that consumers devote less attention to digital information, and thus have more cognitive resources to spare.

This research suggests that consumers' implicit assumptions about the future accessibility of digital information may affect not just information *storage* (memory for information), but also information *processing* (understanding of information). This work contributes to the emerging understanding of consumer knowledge in the "Internet Age" by suggesting that inherent features of digital information sources—specifically, ease of access and permanence of storage—may lead to unintended negative consequences.

SESSION OVERVIEW

The rapid consumerization of healthcare calls for detailed exploration of patients' experiences as medical consumers. The papers in this session use multiple methodologies across a range of medical domains to explore the following questions: "How do patients navigate preference-sensitive decisions as medical consumers?" and "How do patients seek decision support during this process?" We define preference-sensitive decisions as contexts in which more than one treatment is medically justified and patients' personal preferences are important (Wennberg 2004). We examine patients' experiences throughout the consumption process, from outside the formal healthcare system (online medical communities and patient education materials) to clinical appointments communication to interactions with the overall medical servicescape. Our findings span over multiple cultures and systems including U.S. private healthcare, U.S. Veterans' Affairs, India, and Finland.

Barakshina, Spanjol, and Malter examine how pregnant women use online health communities to cope with negative emotions, to seek and receive decision support, and cope with negative emotions. Using qualitative analysis of 600 threads on a popular online medical community (Babycenter.com), they find that consumers' behavior is often driven by previously-experienced regret or fear related to a particular alternative. Patients use several coping mechanisms, including repressive coping, derogation of others (including healthcare providers), and transfer of decision responsibilities to others to cope during a high-stakes decision process.

Scherr, Ubel, and Luce examine the effectiveness of two interventions designed to empower patients with early stage prostate cancer. Using a mixed methods approach, they find that increasing

declarative ("what") knowledge about prostate cancer was not enough to increase patient participation in the decision-making process. Rather, they propose that patients may also require procedural ("how") knowledge regarding communication strategies to participate in clinical appointments and become truly empowered consumers.

DuFault et al. compare how parents with children in the Neonatal Intensive Care Unit (NICU) interact with the neonatal servicescape in the US, Finland, and India. Using an ethnographic approach, they find that the degree of technology in the servicescape (high vs. low) impacts how parents "medicalize" their infants, and describe the impact of this medicalization on parents' interactions with their infants and the medical system.

Finally, Zayer, Otnes, and Fischer examine the patient-physician relationship in the context of infertility treatment. They conduct in-depth, semi-structured personal interviews using grand tour questions with 26 informants (patients and their significant others), and propose a previously unidentified type of patient-physician relationship, the "Peripheral Model," in which the physician's role is perceived as rather inconsequential.

In sum, this session features multiple methodologies and collaboration between consumer and medical scholars to examine patients' experiences as medical consumers. This research demonstrates the potential for marketing researchers to provide unique insights, highlighting the need for continued collaboration between marketing and medical professionals.

Coping with Fear and Regret in Online Health Communities

EXTENDED ABSTRACT

According to National Vital Statistics reports, between 3.5 and 3.9 million women give birth in the U.S. annually, and approximately 500,000 of them face a decision to choose between having a Repeat Cesarean (RCS) or Trial of Labor after Cesarean (TOLAC) delivery. Each option offers benefits, but also poses risks to mother and baby. The scope of risks varies greatly: long-term complications, uterine rupture, infections, and maternal and fetal death. Yet, existing medical evidence does not favor one alternative over another (Cox 2014; Capogna 2015), which classifies the choice between RCS and TOLAC as a preference-based decision. In preference-based decisions more than one treatment option is medically justified (Wennberg 2004).

Ideally, physician and patient work as a team to arrive at an optimal solution for the patient. However, patients facing such difficult choices consider many factors that have little or no apparent relevance to clinical practice, such as living conditions, spousal work arrangements, religious beliefs, etc. As a result, medical consumers often seek external support from family, peers and other patients (Pescosolido 1992) who can help navigate the decision process. In this paper, we examine the effect of peer advice, received through on-line health communities, on consumer decision processes and post-decision outcomes for preference-based decisions. Emotional outcomes of decisions often depend on how well patients manage to cope with negative emotions during the decision stage (Luce 2005). On-line communities are studied here as a source of advice to supplement professional medical advice. In effect, we view online com-

munity peers as "non-medical experts" whose expertise comes from having gone through similar experiences.

According to Keeling, Khan, and Newholm (2013), it is not only information exchange that patients look for in online communities, but rather a complex "knowledge negotiation" process, which includes sense-making, information seeking and sharing, and emotional support seeking and provision. Given the importance such communities might hold for consumers facing difficult medical decisions, we focus on understanding how medical consumers (pregnant women) seek and utilize online peer advice. We examine the following questions: Do medical consumers seeking advice and decision support from online peers look for complete information about available options and related experiences, do they engage in confirmation bias (seeking out confirmation for existing preferences), or both? Are medical consumers driven by fear or anticipated regret, and are they turning to online community peers to cope with these feelings? Finally, in view of decision making as coping (Luce, 2005), which strategies for coping with difficult decisions drive consumers to participate in on-line health communities?

Methodology

We chose Babycenter.com (with about 4.6 million unique monthly visitors) as our data source. Consumers use this platform to create communities, or groups, on a variety of subjects, including getting pregnant (currently 2,220 groups), pregnancy (4,876 groups), and baby (4,370 groups). Each group includes a title, brief description and a message from the group owner. Groups are either subject-specific (e.g., breastfeeding support) or associated with a child's birthday or due date (e.g., December 2015 Birth Club).

We employ content analysis of community posts (Spiggle 1994; Neuendorf 2002), focusing on two specific preference-based delivery decisions: (1) RCS versus TOLAC, and (2) delivering with or without epidural pain relief. These decisions were selected as representing different levels of associated medical risks and controversial patient views (Cox 2014; Parajian 2016), hence posing different decision difficulty to the patients. Within a 30-day window, we identified 1,400 threads directly relevant to the two decisions. A stratified random sample of 600 threads was drawn from the posts to form the dataset for analysis.

Using existing research (Zeelenberg and Pieters 2007; Koole 2009) combined with close reading of the excerpts, we identified categories related to our research questions. We coded for the following categories: indication of existing preference, change in preference due to community advice, emotions experienced during the decision-making process (fear, anxiety, regret), and coping strategies used to deal with negative emotions (decision justification, responsibility transfer, avoiding feedback about the forgone alternatives, etc.). A difference in proportions test was used to test for differences in dependent variables (procedure choice, emotions, types of support sought) across two independent variables: level of risk associated with the procedure and prevalence of the procedure in medical practice.

Results

Preliminary results indicate that patients often start a community thread with a planned course of action or a preference towards one option. In many cases, they are looking for both informational and emotional support, to confirm that they've chosen the right path. At times, participants draw on community emotional resources to understand and potentially disagree with a course of action set by a physician. Specifically, we find that consumers who prefer a non-prevalent childbirth choice are more likely to turn to online commu-

nities to seek information and support on how to deal with the formal health care system (medical doctors, hospitals, etc.), compared to consumers who prefer a more prevalent procedure. Thus, consumers tend to post in online health communities in order to gain support for already formed preferences, rather than to initiate a search for information with no clear a priori inclination.

In parallel to the above analysis, we scanned discussion threads to extract longitudinal data, defined as a sequence of multiple posts by a single participant, often over several years. This approach allowed us to track an individual's decision journey from initial considerations, through consideration of decision alternatives, to the decision outcome and beyond (when moms evaluate their decision or offer advice to others). This approach provides an in-depth understanding of how engagement with online communities evolves over time.

Conclusion

Our research contributes to understanding of patient participation in online health communities. We aim to demonstrate which coping strategies, realized through online community participation, help medical consumers feel better prepared and more confident to take an active role in making difficult choices about their healthcare.

Empowering Patients as Decision-Makers in the Context of Early Stage Prostate Cancer

EXTENDED ABSTRACT

Sometimes, the right treatment choice depends on both medical factors and patients' preferences, such as risk aversion and tolerance of ambiguity (Muller-Engelmann et al. 2011). For example, patients with early stage prostate cancer (the context of this study) must choose whether to receive active treatment or active surveillance, each of which is associated with unique risks and benefits. Active treatment can cause erectile dysfunction and may not be good for patients with a high interest in sex, whereas surveillance requires living with untreated cancer and may not be good for patients with high cancer anxiety (Thompson et al. 2007). In these settings, consumer behavior theory can help us better understand how patients evaluate their alternatives, interact with physicians, and choose treatments. Ideally, patients and their physicians work together to determine which treatment alternative best fits patients' preferences (Karni 2009). In this way, patients become empowered medical consumers.

Unfortunately, baseline rates of patient empowerment are relatively low (e.g., Barry and Engman-Levitan 2012). This is partly due to information asymmetry between patients and physicians, such that patients do not feel qualified to participate during appointments (Gafni, Charles, and Whelan 1998). Decision aids (DAs), often in the form of information pamphlets, can educate patients and decrease this asymmetry. Unfortunately, within the context of prostate cancer, DAs fail to consistently improve key outcome variables, such as knowledge and decision confidence (Violette et al. 2015).

In this research, we use consumer behavior theory on information processing, learning, and types of knowledge to develop and test the effectiveness of two unique interventions that aim to empower patients as medical consumers.

Study 1

We conducted a randomized controlled trial to examine the effect of increasing declarative knowledge via an empowering (vs. standard) DA on patient participation in the decision making process. Both DAs provided similar clinical information but differed in three key ways. The empowering DA was written at a lower reading

level; utilized research on choice architecture and framing to better present information; and contained balanced patient testimonials about their decision making experience. In these ways, we followed the guidelines of "ethically responsible choice architecture" (Blumenthal-Barby, Lee, and Volk 2015). We predicted that patients who received the empowering DA would have higher knowledge and increased desire to participate in the decision making process. As a result, physicians' recommendations would be more influenced by patients' values (i.e., prostate cancer related anxiety and interest in sex) in addition to medical factors (i.e., age and cancer severity). We also predicted that the empowering DA would increase the frequency with which patients and physicians discussed sex, information that should inform patients' decisions in this setting.

We recruited patients from four Veterans Affairs Medical Centers and randomly assigned them to an empowering or standard DA condition. Patients (n = 285) completed surveys prior to the appointments in which they learned their diagnoses but after reading their DAs. Clinical appointments were recorded, transcribed, and coded for physicians' recommendations and discussions of sex using deductive content analysis. Treatment choice and medical factors were assessed via chart review. As expected, the empowering DA increased patients' knowledge ($F(1, 248) = 5.41$, p = .021) and desire to participate in the decision making process ($F(1, 247) = 5.91$, p = .016). However, logistic regression revealed that, regardless of condition, physicians' recommendations were heavily influenced by medical factors and not patients' values. In addition, regardless of condition, physicians rarely discussed sex-related topics (13% of appointments).

Our results suggest that increasing patients' knowledge and their desire to participate in decision making via an empowering (vs. standard) DA may not be sufficient to transform patients into truly empowered consumers. In Study 2, we drill down further into the decision process by considering whether adding procedural knowledge (*how* to participate in the decision process) to declarative knowledge (*what* the decision process entails) would more fully empower patients (Brucks 1986).

Study 2

We conducted another randomized controlled trial to examine the effect of increasing both procedural and declarative knowledge (empowering DA plus DVD) versus declarative knowledge alone (empowering DA only) on patient participation in the decision-making process. The DVD was designed to teach patients specific communication skills to interact with their physicians during clinical appointments. We predicted that increasing procedural knowledge would increase patients' ability to actively participate during clinical appointments, and, ultimately, increase the likelihood that their treatment choices reflected their personal preferences.

We recruited participants from one academic medical center and randomized them to the procedural plus declarative knowledge or the declarative knowledge only condition. Patients diagnosed with early stage prostate cancer (n = 208) completed surveys prior to the appointments in which they learned their diagnoses but after reading/watching the DA/DVD. Clinical appointments were recorded and transcribed. Treatment choice and medical factors were assessed via chart review. As predicted, patients in the procedural plus declarative knowledge condition expressed higher confidence that they would participate in their upcoming appointment ($F(1,190) = 7.61$, p = .006). Also as expected, actual knowledge did not differ between conditions ($F(1, 192) = .44$, p = .51), consistent with our conceptualization that the DVD intervention increased implemental (not declarative) knowledge.

We are now conducting qualitative analyses of the recorded clinical appointments to determine if patients in the procedural plus declarative knowledge condition actually had higher participation (e.g., information seeking) during the appointments. Through an iterative process, we have refined the coding system, established reliability and are currently coding the transcripts. We then plan on using a similar approach to Study 1 to examine the impact of the intervention on the likelihood that patients' treatment choices incorporated their preferences, and, if so, will test whether this was mediated by increased participation during clinical appointments.

Conclusion

We designed and tested two interventions (inspired by consumer behavior research) that aimed to transform patients into empowered consumers. We thus bridge the gap between consumer behavior theory and medical practice, providing important insights into how we might empower patients in the context of preference-sensitive medical decisions.

The Neonatal Intensive Care Unit as an Assembled Servicescape: How do Technological Actors Affect Parent/Staff Decision-Making?

EXTENDED ABSTRACT

This study compares neonatal intensive care units (NICU) in three countries to analyze how variations in the presentation of medical technology in the servicescape impact parent/medical staff decision making. We conduct observations of NICUs in the U.S., Finland and India, interviews, in situ conversations, attendance at medical conferences, participation in an international multi-disciplinary NICU research group, and ethnography in process.

NICU and pediatric ICUs have been used as a context in the marketing and consumer behavior literature on difficult decision making at end-of-life (Botti, Orfali, & Iyengar 2009; Orfali and Gordon 2004; Luce, Bettman and Payne 2001). However, the vast majority of babies admitted to the NICU are discharged home to their families (Flacking et al. 2012; March of Dimes 2011). These parental medical consumers have received scant interest from marketing scholars. This is a surprising omission, given that >10% of births result in special care nursery stays in the US and Western Europe (Axelin et al. 2015; March of Dimes 2011). Studies have not explored from a marketing, consumer behavior, or managerial vantage, how these parents become proactively engaged decision makers around the materiality and design of the NICU technology before bringing their babies home.

The NICU staff faces the challenge of providing excellent care without compromising parent-child bonding during extreme care and stress-filled circumstances. All actors in the NICU—human and non-human—are interrelated and fluidly co-produce the servicescape (Bennett 2010; DeLanda 2006; Deleuze and Guattari 1987; Latour 2005; Sassen 2006, Joiner and Lusch 2016). Although medical professionals work in systems coproducing health and healing with their patients, their patients' families, and a number of support circles (Arnould 2007; Joiner and Lusch 2016), and despite the "family-centered care" movement gaining ground since the 1990's (Levin and Chalmers 2014; Chalmers 2002, WHO 2015), many parents in NICUs still feel a loss of personal control and limited understanding of what is occurring. Technology and advanced medical equipment looms large and often feels "scary" and "confusing."

Our research question is: How do highly technical and stress infused servicescapes impact NICU parents' ability to be active decision-makers with the medical team? And more specifically: How

can NICU servicescapes mitigate the impact of the medicalization of the infant to foster better healthcare decision making in the NICU and beyond?

Our data show that in the United States NICU where the medical technology is front-and-center, parents "medicalize" themselves to learn the machines, the medical language, and use the "medical gaze" to interact with their medicalized baby and medical staff (Foucault 2012/1973; 1977). The nurses and doctors often look not to the baby, but to the machines to see how the baby is doing and to make decisions. The parents follow suit. The medicalization process for parents includes assessing their child through the technological assemblage of monitors, alarms, electrodes, IV pump status, and ventilator settings, to name just a few. Upon release from the hospital, in fact, parents feel scared by the lack of equipment and objective ways to assess their baby. Although they can be heavily involved with medical decisions once they can "talk the talk" to be "part of the team," parents have little to no say of when their baby is released, and often end their NICU stay with an ironic trepidation over the lack of technological entanglement.

In contrast, in the Finnish NICU, parents are taught to talk to their babies and not look to the monitors. They can hold their babies for skin-to-skin contact 24-7 if desired, and sleep in the room if there are available beds. Parents are also given an extended period of time to "room in" with their baby in bedrooms at the hospital--without any monitors--before they go home. They actively participate in decision making by telling staff when they feel comfortable going home. They stay on, rooming with their baby without monitors, in the unit, until they do. There is less of a sense of medicalization of parents and baby, and less angst upon discharge.

In contrast to Western NICUs, in India there is minimal focus on medical equipment and bedsides and unobtrusive monitors, which in many cases may be minimal or nonexistent. However, the parents cannot enter the NICU (which may not even be called a NICU) due to the hospital's fear of sepsis (infection). The babies are brought out from inside the NICU to visit the extended family when staff feels the babies are stable enough, generally with minimal technological equipment at that point. The doctors and nurses become surrogate parents, staying highly engaged with the baby physically, preferring to interact with the child directly rather than interact with the technology, providing ritual massage, and holding or carrying the baby when it is fussy. Decisions involving referral and discharge are highly fluid, depending on available NICU capacity, the seriousness of the condition and the financial status of the family.

We find that parents in the US NICU make decisions more confidently when they achieve a Foucauldian medicalized state and could discuss their baby's care with staff using formal medical terminology. Parents in the Finnish NICU made decisions more confidently when they were de-medicalized and taught to look to their babies as a baby, not a patient. Indian parents are never medicalized and have no part in medical decisions, with the occasional exception of termination of care when patients run out of funds.

In conclusion, our initial sample findings of three NICUs in the US, Finland and India reveal that parental decision making can be enhanced in a high-tech environment by assuring parents learn the medical terminology and procedures. However, whether it is beneficial to have parents act as medical staff and see their newborn with Foucault's medical gaze remains to be seen. It also appears that parental decision making can be enhanced by toning down the technological equipment presence and teaching family how to parent a neonatal patient as they would a non-hospitalized baby. Further work is needed to study decision making in more stratified hospitals in each country.

Exploring Patient-Provider Relationships in Preference-Based Health Care Choices

EXTENDED ABSTRACT

Many health care related decisions can be complex because they are not always driven by evidence-based prescriptions from a health care provider, such as a physician, but are preference-based, where the patient often has a range of treatments to chose from. In such instances, the relationship between the physician and patient is even more consequential. Scholarship outside of consumer research has detailed different models of patient-health care provider relationships (e.g., Emanuel and Emanuel 1992; Ballard-Reisch 1990), differentiated patient roles in medical decision-making (Orfali 2004; Thomson et al. 2013), and measured patient autonomy in health care (Stiggelbout et al. 2004), among many other important aspects. For example, Emaunel and Emaunel (1992) identify four different models of patient-physician relationships. The paternalistic model advocates the primacy of the physician irrespective of the patient's preferences while an informative model advocates for the physician to simply present factual information. In an interpretive model, information is presented but care is provided based on eliciting the patient's values. Lastly, in a deliberative model, which the authors identify as "ideal," the physician provides information, assesses patient's values, and persuades the patient through dialogue on the best-perceived course of care. In contrast, Ballard-Reisch (1992) advocates for a model of participative decision making with four relational types with regard to the physician—patient abdication, collaboration, patient autonomy, and relationship termination. While this research from medicine and health communications is useful in shedding light on the different types of patient-physician relationships, they do not capture the full range of relationships that patients may have with providers, nor do they consider the role of the market. Moreover, in the last two decades, discourses regarding medicine, health care, and the role of the "consumer" in society have shifted. Factors such as vast online informational resources as well as online support groups serve to fundamentally change the way patients approach their health care.

Thus, in this research, we ask, what is the patient-provider relationship dynamic as consumers engage in difficult, preference-based choices with regard to their health care? We explore these questions within the context of individuals seeking infertility treatment, a context that often involves extended, emotionally laden, high-risk interactions (Boshoff 2002) that are both costly and often times physically taxing. According to the Centers for Disease Control, infertility is defined as the inability to conceive a baby within one year of trying (www.cdc.gov/ART). Average cost of treatments can start at thousands of dollars (Marchione 2012) and often require multiple tries, entailing a range of treatments that can be pursued by individuals and couples seeking to have a child.

In-depth, semi-structured personal interviews using grand tour questions (McCracken 1988) with 26 informants were conducted, which allowed us to acquire patients' narratives of their experiences with health care providers. Interviews with 26 individuals (mostly women) generated over 450 pages of text. While seeking patterns in the data we reflexively read the relevant literature (i.e. dialectical tacking; Strauss and Corbin 1998). Using data from informants engaged with various types of infertility services, the researchers identified how consumers engage with health care providers as they make difficult choices in their health care.

Findings outline the saliency of many of the models of patient-provider relationships identified in past research (e.g., Emaunel and Emaunel 1992; Ballard-Reisch 1990). In addition, these decisions

are not made in isolation; thus, the research reveals other influencers on the choices consumers make in this context, as well as the tools that aid in making preference-based medical decisions. In addition to interactions with the physicians and key other health providers, close loved ones, information resources, as well as a belief in higher powers, such as God, were critical during the decision-making and coping processes.

However, what this research contributes is that a new type of patient-provider relationship is identified, not previously captured by these past studies. While past research has discussed patient-provider relations whereby the patient acts autonomously, "shopping" for doctors or treatments (Ballard-Reisch 1990) or engages in co creation of value (McColl-Kennedy et al. 2012), we illustrate how some consumers go even further to regard the health care provider as rather inconsequential, or what we label as the Peripheral Model. These patients' relationships with their providers are unique across four distinct dimensions that Emanuel and Emanuel (1992) identify as critical in understanding patient-physician relationships: 1. goals of the patient-physician interaction; 2. physician's obligations; 3. role of the patient's values; and 4. patient autonomy. Some consumers engage in entrepreneurial activities to diagnose, treat and even create consumer choices and marketplace options that did not previously exist for them. That is, if consumers do not attain what they seek from the physician in terms of what they perceive are the best chances for a successful outcome, they seek out other opportunities. The physician's role and obligation are minimized, the patient's agenda takes precedence and they autonomously seek out and/or create alternative options in the marketplace. Another manifestation of the provider in the Peripheral Model is when patients perceive that the physician played a largely limited role in their decision making process. One informant characterizes the role of the physician as, "just there to do the tests and leave." While in these cases, the patient may have hoped for more interaction, they perceive the physician as fulfilling the minimum obligation with little discussion of values, and thus, the patient relies on others (e.g. nurses) for support.

In sum, while patient-provider relationships are key in health care services, particularly in preference-based decisions, traditional models of patient-physician relationships previously identified in research do not always capture the full range of consumers' experiences. Thus, by identifying the Peripheral Model, the current research holds theoretical implications as it examines the saliency of typologies of patient-provider relationships from medicine and health communications while identifying a new model of relationship. Further, understanding the ways in which patients behave outside the traditional models of patient-physician relationships can help to illuminate ways to enhance the patient experience and well being in these contexts.

Eline Y. M. Zwinkels, MediaTest, Netherlands

SESSION OVERVIEW

This session reflects the increasing interest and need for research on language in marketing. Advancing our understanding of the inseparable connection between language and consumer decision-making, the papers address the questions: How does language impact and sometimes *sway* consumption decisions and perceptions? What elements of language are the source of this influence? What conclusions can marketers derive from findings of language research in marketing? Together, the works illustrate how every word, and even every sound, can influence consumer perceptions, decisions, and actions. The four papers are organized by ascending order of language element size, starting with sounds, continuing with words, through phrases, and all the way to texts.

Baxter, Ilicic, Kulczynski and Lowrey will reveal novel discoveries in *sound* symbolism. The authors find that children with lower phonological ability (e.g. identifying word sounds) are less able to infer brand attributes based on the sounds of brand names, but this ability can be instantly improved through in-ad games. This finding is especially relevant today, when children are more involved in family consumption decisions, and when many brand names are meaningless and people infer their meaning based on their sound. Meng, Czellar and Luna focus on *words*. The authors demonstrate that using verbs in marketing communication ("grasp it with ease") leads consumers to take immediate actions, such as clicking a link, whereas nouns ("easy grip") lead to delayed action. The authors explain this link demonstrating that verbs activate an implemental mindset that leads to immediate action. Lee and Kronrod's work takes us to the *phrase* level. This work focuses on the way consensus phrases used by social network participants, such as "everyone likes this movie," change the way strong and weak ties influence our consumption decisions. While people usually rely on opinions of strong ties, when consensus phrases are used, weak ties achieve higher persua-

siveness than strong ties. The authors demonstrate that this is because a consensus expression is interpreted as relating to a larger group when mentioned by a weak tie, compared with a strong tie. Lastly, Willemsen, Verlegh and Zwinkels focus on *texts*. The authors find that, compared with small/no incentives, large incentives change the language consumers use in their product reviews, such as adding aesthetic elements, more emotional and less rational arguments, etc. However, readers deem these reviews less useful than unrewarded reviews, and they elicit lower purchase intentions. The authors make an exciting discovery which bears relevance to today's practice of offering smaller and larger incentives to consumers to leave product reviews.

Together the works in this session highlight the dominant role of language in consumer behavior and propose important insights for marketing theory and practice on all levels of language inquiry. The developing interest in learning about consumers from analyzing textual Big Data promises a wide turnout for this session. As ACR2016 in Berlin reflects an especially multinational and naturally multilingual assembly, this session expects broad discussion among attendants interested in marketing analytics, communication, advertising, branding, and in particular those who got the Wanderlust virus.

Vipiz is Fast, Vopoz is Slow: Phonetic Symbolism is the Way to Go!

EXTENDED ABSTRACT

Marketing research on phonetic symbolism has studied both application (i.e., using sounds in brand names to enhance preferences and signal attributes) and process. Yorkston and Menon (2004) identified phonetic symbolism as an automatic phenomenon for adults. Recent research, however, shows these effects are developmental and rely on the acquisition of language-based skills. Baxter, Kulczynski, and Ilicic (2014) demonstrated that only older children (above 10 years old) possess proficiencies for phonetic-based judgments. This research contributes by examining developmental differences in children's phonological awareness (an ability to recognize sounds in words) on phonetic-based inferences. It is proposed that an awareness of phonemes can be primed, enhancing phonetic symbolism effects in children with lower levels of phonological awareness.

Study 1 demonstrated the moderating effect of phonological awareness on product evaluations. It was expected that effects consistent with phonetic symbolism theory would strengthen as phonological awareness heightens. Participants were 161 Australian children (ages 6-16) in a between-subjects experiment (82 male, 79 female; M_{age} = 9.45). Participants were shown a print advertisement for a fictitious scooter (Vipiz/Vopoz). Participants evaluated the scooter's speed/weight/size (7-point scales), then completed a phoneme-counting task to assess phonological awareness (3 practice words/20 test words, e.g., "*butter* has how many sounds in it?"). A Product Attribute Index (PAI) was created, combining participants' judgments of speed/weight/size. Results (PROCESS, n = 10 000, Model 1) demonstrated that neither product size (β = .253, p = .221) nor phonological awareness (β = .014, p = .102) were significant predictors of product attribute evaluations. However, phonological awareness was a significant moderator of judgments (β = -.070, p = .031, $R^2\Delta$ = .028). Simple effects analysis showed that the 'Vipiz' scooter was perceived as faster/lighter/smaller than the 'Vopoz' scooter; however, this effect was not found in low phonological awareness children.

Study 2 examined whether exposure to a phonological awareness priming task influenced product evaluations. Participants were 184 Australian children (105 male, 79 female; M_{age} = 9.40) in a 2 (task-first vs. task-last) x 2 (front- vs. back-vowel) factorial experiment. Participants in the task-first conditions completed a phoneme-counting task, were then shown a print advertisement for ice-cream (Fipple/Fupple), and asked to evaluate the ice-cream's hardness/smoothness/creaminess (7-point scales; creating a PAI). Participants in the task-last conditions viewed the print advertisement, completed the product evaluations, then completed the phoneme-counting task. It was expected that completing the phoneme-counting task prior to product evaluations would act as a prime, strengthening phonetic symbolism effects for children low in phonological awareness, by heightening their recognition of phonemes. An ANOVA model was estimated with a significant main effect for vowel sound (F(1, 180) = 16.09, p < .001). Consistent with theory, a product paired with a brand name containing a back (front) vowel was perceived as more (less) soft/smooth/creamy (Back Vowel: M_{PAI} = 4.63; Front Vowel: M_{PAI} = 3.88). No other significant main or interaction effects were observed. Next, results (PROCESS, n = 10 000, Model 3) demonstrated that task order (β = -3.96, p = .034) and phonological awareness (β = -.128, p = .046) were significant predictors of phonetic-based judgments. As expected, a significant three-way interaction was observed between product size, task sequence, and phonological awareness (β = -.317, p = .038, $R^2\Delta$ = .022). Results of simple effect analysis demonstrated that the interaction (brand name x task sequence) did not have a significant effect on phonetic-based judgments for participants with higher levels of phonological awareness; however, it was significant at lower levels of phonological awareness.

Study 3 demonstrated the effectiveness of phonological priming in a marketing context, embedding aspects of a phonological awareness task in a game-based print advertisement. Participants were 186 Australian children (106 male, 80 female; M_{age} = 9.51, SD = 2.57) in a 2 (embedded task vs. absent) x 2 (front- vs. back-vowel) factorial experiment. Participants were shown a print advertisement for a ball paired with a brand name (Inik/Onok). A phonological awareness task was absent or embedded in the advertisement. Participants evaluated the ball's hardness/lightness/size (7-point scales; creating a PAI). Participants then completed a phoneme-counting task. ANOVA results revealed a significant main effect for vowel sound (F(1, 186) = 30.72, p < .001). It was posited that the priming effect of an embedded phonological awareness task would be stronger for those who have lower levels of phonological awareness. Consistent with theory, a product paired with a name containing a front (back) vowel was perceived as more (less) small/light/hard (Back Vowel: M_{PAI} = 3.46; Front Vowel: M_{PAI} = 4.10). As anticipated, a significant interaction was found between vowel sound and task presence (F(1, 186) = 5.72, p = .018, η^2 = .030), whereby effects consistent with theory were strengthened for participants exposed to elements of a phonological awareness task (embedded in the advertisement) prior to providing product attribute evaluations. Further, results (PROCESS, n = 10 000, Model 3) revealed that phonological prime (β = .488, p = .048) and product weight (β = .610, p = .026) were significant predictors of product judgments. As expected, a significant three-way interaction was observed between product size, phonological prime, and phonological awareness (β = .044, p = .014, $R^2\Delta$ = .011). Consistent with Study 2, results of simple effects analysis demonstrated that the interaction (product weight and phonological prime) did not have a significant effect on product evaluations at higher phonological awareness levels, but was significant at lower levels.

In conclusion, this research builds on the current understanding of the process underlying sound symbolism effects. Results reveal

that children with lower levels of phonological awareness are unable to formulate phonetic-based judgments consistent with theory, but phonological awareness priming overcomes developmental language-based barriers, supporting phonetic symbolism effects in early developmental groups. Phonological awareness tasks encourage children with low levels of phonological awareness to become aware of sounds in words. For children high in phonological awareness, such priming had no impact on phonetic symbolism effects. These results provide marketers with a method to overcome boundaries of phonetic symbolism effects in branded communications targeted towards children.

From Language to Behavior: Verbs Lead to Consumer Action

EXTENDED ABSTRACT

Consider an online display ad for Aston-Martin with the tagline "Power. Beauty. Soul." Will it lead to more clicks than Jaguar's "Born to perform"? This research provides an answer to that question (verbs lead to higher click through rates than nouns), and explains the psychological process underlying the phenomenon (verbs activate an implemental mindset that leads to immediate action). The growing body of research on the marketing effects of language has devoted little attention to the direct influence of language on consumer actions or choice (for exceptions, see Cheema and Patrick 2008; Kronrod et al., 2012a; Schmitt and Zhang 1998). Our six studies provide empirical evidence that the type of words used by marketers can influence consumer actions. According to neuroscience research, verb processing should result in a pattern of brain activation similar to when individuals actually perform actions. This is because verbs are linked to the frontal lobe of the brain. The frontal lobe includes motor and premotor areas that process actions (Damasio and Tranel 1993; Daniele et al.1994; Warrington and Mc-Carthy 1987). Therefore, verbs, compared to nouns, should have a stronger mental association with actions and an implemental (vs. deliberative) mindset. In related research, Albarracín et al. (2008) describes how priming individuals with action-oriented words (e.g., *go*, *movement*) instead of inaction words (e.g., *stop*, *blockage*) leads to the activation of action goals, which results in a higher likelihood of individuals performing any action that is presented to them. We suggest this is not always the case, and that the lexical category of the action word (verb vs. noun) matters in choice situations because verbs lead consumers to acting now rather than later, even if acting later might include an action of greater magnitude. This is because verbs activate an implemental mindset vs. a deliberative mindset.

Study 1

We designed a study based on the Implicit Association Test (IAT; Greenwald, McGhee, and Schwartz 1998). As predicted, participants responded significantly faster when associating verbs to actions (M=1282.49ms) than when associating nouns to actions (M=1525.34ms, t(133) = -7.00, p < .001). They also responded significantly faster when associating nouns to objects than when associating verbs to objects (d = .345, p < .001).

Study 2

Respondents must choose the best of several mobile phone plans, given a scenario of how they supposedly use the phone. We investigate whether priming respondents with action verbs leads to choosing (a) the fast, easy option of a flat-rate, unlimited mobile plan, or (b) the optimal plan that fits their usage scenario. The latter option would require effort—that is, comparing attributes and analyzing the fit of the plan with the usage scenario. Choosing the unlimited plan

would be consistent with an implemental mindset and choosing the optimal option would be consistent with a deliberative mindset.

Method

Respondents are primed with one of four conditions in a 2 (Lexical category: verbs vs. nouns) x 2 (Goal activation: Action vs. Inaction words). Four mobile phone plans are presented to the respondents simultaneously and they are asked to choose one given a scenario specifying usage.

Results

A significant interaction (χ^2 (1, N = 74) = 3.66; $p < .05$) shows that action verbs priming made people choose the easy/default/no-effort option (62%) more often than the optimal plan (38%). The effect of action goals vs. inaction goals is moderated by lexical category: nouns do not experience an action goal effect. Verbs appear to lead to an implemental mindset. We provide evidence of the moderating role of lexical category on Albarracín et al.'s (2008) findings in a consumer choice context.

Study 3

Here we further investigate whether consumers exposed to a verb-intensive ad are more likely to take immediate action than consumers exposed to a noun-intensive ad. All verbs used are action verbs. We also examine the process underlying the effect. Because verbs represent actions, the activation of verbs will result in an implemental mindset (Gollwitzer and Bayer 1999), which will lead to consumer action.

Method

Participants saw an ad that consisted of an image of an identical pen accompanied by either verb-intensive copy (e.g. writes smoothly; grasp it with ease) or noun-intensive copy (e.g. smooth ink stream; precise grip). After seeing the ad, participants were told that they were about to make a real choice and would receive a pen from the experimenter. They could either (a) get the advertised pen right away by clicking on a button on the screen, or (b) click on another button to go to another screen where they could find information about a larger set of pens they could choose from. Our dependent measure was whether they chose the pen right away or delayed their choice to search for further information on the other pens. Clicking to choose the pen immediately would be consistent with an implemental mindset. Participants then listed the thoughts that came to their minds during the choice task. Next, they performed a lexical decision task (Lemhöfer and Dijkstra 2004), consisting of classifying stimuli on a computer screen as words (including several implemental verbs; e.g., decide and take) or non-words.

Results

In the verb condition, participants were more likely to choose the advertised pen right away compared with participants in the noun condition (Mverb = 44% vs. Mnoun = 29%; χ^2 (1, N = 175) = 4.23; $p < .05$). Also in the verb condition, implemental verbs were more accessible in participants' minds, as shown by the thoughts measure and the results from the lexical decision task.

Studies 4-5 (Field Studies)

Study 4 consisted of placing two versions of a display ad, verb- and noun-intensive, in the Google network. We found that the verb-intensive ad led to a higher click-through rate (Mverb = .51% vs. Mnoun = .44%; χ^2 (1, N = 144,430) = 4.13; $p < .05$). Study 5 found that consumers tended to pick up more often a printed flyer when it included a high incidence of verbs (Mverb = 1.58, *S.D.* = .67 vs. Mnoun = .91, *S.D.* = .94; F(1,21) = 3.96, $p = .06$).

We make the connection between psycholinguistic theory and the behavior of consumers and qualify previous research on the ac-

tivation of general action goals in response to action words. We provide evidence that using verbs in marketing communications leads to immediate (versus delayed) action and product choice, sometimes resulting in suboptimal choices. Such verb-behavior connections predominantly exist when consumers are in low-elaboration purchase situations (e. g., high cognitive load). The effect of verbs on behavior is mediated by the activation of an implemental mindset.

Everyone Likes This Movie! Consensus Language Increases the Influence of Weak Ties over Strong Ties in Product Recommendations

EXTENDED ABSTRACT

When making decisions about products, people often rely on the opinion of close ties (friends, family) more than on weak ties (casual acquaintances) (Alvaro and Crano, 1997; Cialdini and Goldstein, 2004; David and Turner, 2001). But in some cases weak ties may be more influential (Granovetter, 1973; Kim, Zhang, and Li, 2008). We suggest that one such case is when a tie refers to public consensus (e.g. "everybody has seen this movie", Drew, 2003). We predict that in this situation, *weak* ties may be more influential than strong ties, because consensus expressed by a weak tie is perceived to convey the attitudes and behaviors of a larger network of individuals, implying greater consensus about the product. Further, we suggest that referring to consensus is useful in contexts where a person benefits from conforming to the norm. For instance, when recommending products that bear social risk, such as public consumption products (e.g. Fawcett and Miller 1975), weak ties that use consensus expressions may have an especially strong influence. In four studies, we examine the role of weak ties in influencing judgments and decisions on public consumption products (Studies 1 and 2) and public behaviors (Studies 3 and 4).

In **Study 1**, 206 MTurk participants were assigned to one of four conditions in a 2 (tie-strength: weaker/stronger) x 2 (consensus: yes/no) between-subjects design. Consistent with previous conceptualizations of tie-strength in consumer research (Ryu & Feick, 2007; Zhang, Feick, & Mittal, 2014), participants were first told to provide the first name of either their closest friend (stronger-tie) or a casual acquaintance (weaker-tie). Next, participants read a hypothetical tweet from the person about a new film, containing consensus or no-consensus language ("This is the film everybody is (my friends are) talking about"). Participants estimated the general consensus about the film (e.g. the percentage of the population that would eventually see it). A 2-way ANOVA revealed the predicted interaction (F(1,202)=6.96, p<.01): In the consensus language condition, weaker ties generated higher consensus in their statements (M=64.1) than stronger ties (M=52.6; F(1,202)=6.92, p<.01). However in the no-consensus language condition, participants did not differ in their consensus perceptions whether they read the phrase as tweeted by a weaker tie (M=54.8) or a stronger tie (M=60.0; F(1,202)=1.19, p<1).

In **Study 2**, we hypothesized that weaker ties using consensus language would be more influential in the case of public (versus private) consumption. We assigned 340 MTurk participants to one of eight conditions in a 2 (tie-strength: weaker/stronger) x 2 (consensus: yes/no) x 2 (product framing: public vs. private) between-subjects design. Participants read about a hypothetical brand of cellphone cases. In the public condition, the case was described as a "trend setter," and with a "distinct, recognizable pattern;" in the private condition, the case was described as "durable," and with "advanced, protecting materials." As in study 1, participants first wrote the name of a weak/strong tie, and then imagined the person describing the phone case using/not using consensus language. Results revealed a three-way

interaction on behavioral intentions ($F(1,332)=7.59$, p<.01), product attitudes ($F(1,332)=4.95$, p<.05), and consensus ($F(1,332)=9.27$, p<.01). Specifically, participants who read consensus language from a weaker-tie expressed higher intentions to try the cell phone case ($M=5.39$) than participants who read such language from a stronger tie ($M=4.24$; $F(1,332)=14.00$, p<.001). However, this effect disappeared in the non-consensus language condition ($F(1,332)=0.14$, p<1). A similar pattern of results was also found for product attitudes and consensus. Mediated moderation analysis (Hayes, 2013) suggests that perceived consensus mediates the effect of tie strength and language on product attitudes and on behavioral intentions.

In **Study 3**, we extend our previous findings to actual public decision-making. 185 undergraduate students in a lecture classroom participated in a 2 (tie-strength: weaker/stronger) x 2 (decision: public/private) between-subjects design. Participants decided whether to pledge not to drink and drive, and depending on condition, their decision was either made public or remained private. Additionally, we told the students that we ran a preliminary survey on a few members of the classroom, and that a student next to them (stronger tie) or across the room from them (weaker tie) believed that "people are not signing this pledge." Measures on closeness and frequency of interaction confirmed the effectiveness of our tie-strength manipulation. Furthermore, a log-linear analysis revealed a predicted interaction ($\chi^2(1)=4.55$, p<.05). In the public pledge condition, statements from weaker ties influenced the declining of the pledge ($M=16.3\%$) more than statements from strong ties ($M=4.1\%$, $\chi^2(1)=4.01$, p<.05). However, in the private pledge condition, students did not differ whether they read a statement from a weaker tie ($M=32.0\%$) or a stronger tie ($M=40.5\%$, $\chi^2(1)=0.67$, p<1).

Study 4 builds on the results of Study 3 via a Facebook field experiment. 30 student confederates each sent Facebook messages to 10 strong and 10 weak ties, inviting them to click a link to a personality test; thus, messages were sent to 600 Facebook ties. Half of the students made a consensus reference ("everybody is talking about this test") and the other half did not mention consensus. We created four "test" links according to the four conditions and counted the number of clicks on each link. While strong ties' click rates nearly doubled (22.6% vs. 43.3%) when participants used consensus, weak ties' click rates nearly than quintupled with consensus reference (4.7% vs. 22.6%, $Z=-3.77$, p<.001). These results suggest that while weak ties may be less trustworthy in our link-forwarding context, their use of consensus expressions accelerates their social influence relative to similar use by strong ties.

Our findings suggest evidence of "the strength of weak ties" when weak ties use consensus language describing publicly consumed products or publicly-visible decisions. These findings hold across multiple, literature-based, conceptualizations of tie-strength and appear to be driven by the greater perceived scope of the consensus when expressed by weak ties. The moderation of the weak tie effect in public (versus private) contexts reflects the importance of weak tie consensus reference in contexts where impression management concerns may increase interest towards a product or a behavior.

The Hidden Costs of Paying Your Reviewers: How Incentives Affect the Language of Online Reviews and Subsequently their Perceived Helpfulness and their Persuasiveness

EXTENDED ABSTRACT

Online customer reviews (often referred to as eWOM) have a strong impact on product evaluations and sales (e.g., Babic et al., 2016). Such reviews are an important source of information for consumers who are looking for information to assist them in their purchase decisions. Review platforms like Yelp!, Epinions and Tripadvisor, provide value to consumers as an independent sources of product information. To attract customer reviews, review platforms not only make it as easy as possible to provide reviews, but they may also provide incentives to consumers who place reviews on their website. But are such rewarded reviews equally helpful as unrewarded reviews? Recent research on incentives in word of mouth suggests that this is not the case: Verlegh, Ryu, Tuk and Feick (2013) have shown that rewarded referrals have less impact on other consumers than unrewarded referrals. Verlegh and colleagues suggest that this effect is due to a process in which the presence of rewards leads the audience to infer that the word of mouth was motivated by ulterior motives.

Of course, readers may not always be aware of the fact that a reviewer received a reward for placing a review. We argue, however, that this does not mean that rewarded reviews are equally effective as unrewarded ones, in this case. More specifically, we suggest that rewards may affect the language that is used by the reviewing consumers. Building on research on extrinsic versus intrinsic motivation, we expect that reviewers who are rewarded may invest less effort in the process (e.g., Deci & Ryan, 2012).

Several studies have examined the factors that make a review helpful to consumers (e.g., Pan & Zhang, 2011; Willemsen, Neijens, Bronner & de Ridder, 2011). This research has shown that reviews are regarded as more helpful when they are longer and contain more arguments (Pan & Zhang, 2011), and when they contain diverse arguments - similar to two-sidedness in advertising, are more balanced and *less* extreme, and make less use of rhetorical tactics aimed at persuasion (Willemsen et al., 2011).

In our **first Study**, we therefore investigate whether the extrinsic motivation that is induced by rewards may lead to reviews that are less helpful, because they are more extreme, contain less arguments and are shorter than unrewarded reviews. In addition, we will look at some of the textual characteristics that may result from investing less effort in one's writing, such as grammatical errors, and a reduced use of structuring devices such as white spaces and appropriate punctuation. Such characteristics have been shown to reduce the value that readers attach to online comments (Otterbacher, 2011). Study 1 was a content analysis comparing reviews posted on an actual review website (n=700) during: (1) a period during which reviews were rewarded with a small incentive (5-dollar book voucher); (2) a period during which reviews were rewarded with a larger incentive (chance of winning an iPad); and (3) a non-promotional period. To analyze the content of the reviews, we developed a coding scheme based on prior research (Otterbacher, 2011; Willemsen et al., 2011), coding language use and other content characteristics. Two independent coders analyzed the reviews. We found that valence and average ratings were unaffected by incentives, but did find several of the expected differences in language use and paralinguistic features. Specifically, reviews from the large incentive period (vs. small and no-incentive) contained more paralinguistic elements that are commonly used to persuade an audience of a message. These included multiple punctuation (!!!), blank spaces, authority arguments ("I'm an expert"), and emotional arguments ("I love this product"). Also, these reviews were less likely to contain rational arguments ("the 4x-optical zoom gives vivid photos").

Study 2 tested whether consumers are able to differentiate rewarded reviews from unrewarded reviews based on these linguistic characteristics, and furthermore, if these language differences affect review and product attitudes (*n*=114). To address this aim, we conducted a one-factor between-subjects experiment with two cells.

Participants were randomly exposed to a positive review from a restaurant with either (a) language characteristics from a rewarded review, or (b) language characteristics from an unrewarded review. Language characteristics were based on findings in study 1, and varied in the use of multiple punctuation cues (!!!), blank spaces, authority arguments ("*I have eaten in many similar restaurants*"), emotional arguments ("*I felt welcome*"), and rational arguments (i.e., discussing criteria for good food).

Results showed that rewarded reviews were considered less helpful than unrewarded reviews ($M = 4.43$ vs. $M = 5.12$, $F_{(1,113)} = 10.99$, $p < .001$) and raised lower purchase intentions ($M = 4.41$ vs. $M = 5.10$, $F_{(1,113)} = 12.32$, $p < .01$). Furthermore, helpfulness was found to mediate the effect of review type (rewarded/unrewarded) on purchase intention (estimate = -.46, 95% Bca = -.80; -.19), according to bootstrapping analyses (PROCESS, model 4, $n = 5000$).

Together these results suggest that rewarded reviews differ from unrewarded reviews in terms of linguistic and paralinguistic characteristics. These differences rendered rewarded reviews less helpful in the eyes of consumers, which has negative consequences for their intentions to purchase reviewed products.

SESSION OVERVIEW

The concept of consumer sharing is attracting the attention of both researchers and practitioners given the growth of the sharing economy (Botsman and Rogers 2010; Gansky 2010). Sharing was originally defined as compassionate, socially inclusive, unselfish, communal behavior, reflecting our altruistic motives to help and connect with other people, with no expectations of reciprocity (Belk 2010; Benkler 2004). However, recent scholars question the adequacy of existing definitions and are noting a darker side of sharing (Arnould and Rose 2015; Appau, Ozanne, and Klein 2015; Botsman 2013).

This special session asks the question: how are different meanings of sharing socially constructed and when does sharing turning dark? By integrating a macro view of sharing in the context of the sharing economy with a micro view of sharing between individual consumers, and utilizing variety of methodological approaches, this session introduces new forms of sharing, expanding our knowledge about this important consumption phenomenon.

First, Belk explores selfish sharing, which addresses the darker side of sharing that moves away from its original definition of being a caring and inclusionary act. Belk posits that both providers and consumers exhibit utilitarian and selfish motives within many sharing economy services. He focuses on gated communities as a prototype of selfish sharing, showing that members of these communities use sharing within their communities to exclude others from enjoying the shared services.

Second, Yang, Ozanne, and Paladino explore the community of house swapping where strangers allow one another to live temporarily in their homes, arguably one of the most sacred possessions. Through their micro practices of cleaning and hospitality, consumers assert house swapping as altruistically driven exchange that exists outside market logics of commercial lodging services. Nevertheless, subtle practices exclude people who are not like us.

Third, Rose builds on work by Arnould and Rose (2015), Belk (2010; 2016), and Giesler (2008) in an effort to further disambiguate the breadth and depth of the sharing economy and its participants. By focusing on differences in actors (i.e. firms, consumers, workers) and modes of exchange of various contexts, the utility of the mutuality concept in both academic analysis of and business success in the sharing economy is demonstrated.

Finally, Ruvio, Mandel, and Gentina investigate the reciprocal altruistic motives of consumers when they consider with whom they share. In four experiments they demonstrate that sharing is a strategic social decision that leads people to share more with individuals perceived as superior (vs. inferior) to them in a specific domain of social comparison. This behavior is motivated by future expectations for gains, and similar to Belk's paper, questions the perception of sharing as an unselfish, nonreciprocal act.

Each of these papers highlights a different shade of sharing as a consumption phenomenon. Together they expand our understanding of consumer sharing and help push the boundaries of this emerging concept. This session offers potentially fruitful avenues for future research, and will appeal to ACR attendees interested in sharing, sharing economy, altruistic behavior, possessions and self-identity, among others.

Selfish Sharing

EXTENDED ABSTRACT

In the ideal form of "sharing in," inclusionary acts of allowing others to use our possessions as if they were their own are typically generous, caring, and even altruistic acts of kindness intended to help these other people. This is the sort of sharing that is found most often among family members, close kin, and sometimes among friends and neighbors (Belk 2010). At the opposite extreme lies egoistic sharing. While egoistic sharing is not necessarily intended to harm others, it is narrowly or grudgingly inclusionary and is often more concerned with getting "my share" and with excluding others who are not legally entitled to partake of the shared resources. One example is an antagonistic divorce in which each partner is intent on getting as much as they can and with having no further contact with the other party (McAlexander, Schouten, and Roberts 1993; McAlexander and Schouten 1996). This is one extreme of "sharing out."

Egoistic sharing also includes pseudo-sharing (Belk 2014) that involves mercenary short term rental. Such selfish pseudo-sharing uses "sharewashing" rhetoric to cloak the practice of rental in the more socially desirable, but unjustified, mantle of sharing (Belk 2014, forthcoming; Bardhi and Eckhardt 2015). The only differences between car rental companies like Avis and many "car sharing" companies like ZipCar is the length of rental, the places and process of gaining access, and the need for a membership. Both are selling temporary access and *not* the act of voluntarily sharing possessions with others in a caring and generous manner. Quite the opposite is true. Bardhi and Eckhardt (2012) found that ZipCar participants feel no sense of community with other members and fail to make an effort to return possessions prior drivers may have left behind in a vehicle. They instead want to penalize members who return a car later than promised or leave personal items inside.

It is not simply the act of charging a fee that differentiates altruistic sharing from more selfish pseudo-sharing. A small-scale neighborhood car sharing organization like Majorna in Göteborg, Sweden, operates without employees as its 300 members service the organization's 29 cars, run IT, and take care of day-to-day operations (Jonsson 2007). Members want to keep the organization small for fear that they would lose their ability to know all the other members. Similarly, it is not only the no-fee accommodation sharing service of CouchSurfing that provides social benefits to participants, but even

the fee-based service of AirBnB is found to often include sociality as well as a place to stay (Hellwig, Belk, and Morhart forthcoming). Nor, as the millions of participants in both CouchSurfing and AirBnB attest, is it the size of an organization that decouples caring from sharing. Rather, it appears to be the dominance of a utilitarian, egoistic, and selfish orientation among both providers and consumers of sharing services that makes the difference.

In this presentation I focus on a context where selfish sharing is the norm: gated communities. Although they are premised on sharing common resources like roads, swimming pools, landscaping, and guardhouses with fellow residents, gated community members focus more on uncaring exclusionary practices. This is true not only in the sense of excluding neighbors from outside the community like trick-or-treaters and Christmas carolers (National Report 2015), but they may even ban children living within the gated community from these neighborly caring practices (Ramirez 2013). The fears that attract people to buy into gated communities do not seem to abate once inside. Members feel little sense of community, install burglar alarms, and fail to participate in the homeowner associations to which they must belong (Choon-Piew 2007; Dinzey-Flores 2013), Low 2004).

Not only do residents of gated communities tend to engage in only selfish sharing, but developers and municipalities do as well. Because local governments can still collect property taxes without having to provide many services, gated communities are welcomed as cash cows (McKenzie 2006).

Using gated communities as an example, we can see how the growing global divide between rich and poor tends to promote selfish privatization in the name of sharing. Here too the retreat to egoistic "sharing" precludes caring and community. The promise of sharing is found to be inverted from being inclusionary to being another exclusionary neo-liberal practice.

Mutually Assured Explanation: Advancing a Framework for the Sharing Economy

EXTENDED ABSTRACT

As the name of this session, implies, the "sharing economy" has firmly positioned itself within academic discourse. Similarly, a perusal of the *New York Times* will reveal the extent to which the concept has reached a similar vantage point in the mainstream press. Despite this ubiquity, a great deal of the discussion seems to revolve around points of confusion with respect to the phenomenon. The argument presented here is that the theoretical framework of mutuality and possessive individualism introduced to consumer research by Giesler (2008) and elaborated in Arnould and Rose (2015) offers a comprehensive, accessible means of grasping, both analytically (e.g., for academics) and strategically (e.g., for managers), the sharing economy.

Before demonstrating the efficacy of the framework, it bears delving into four issues that seem to be consistently lost in the shuffle when discussions of the sharing economy occur. The first matter is to define what exactly it is that is being discussed, a definition of the subject matter as it were. That is, an economy—a system of resource circulation amongst a collection of actors. This rather elementary point is important because it fixes for us the often-elusive subject of our discussion: a group of people engaged in the activity of exchange. Second, what is being circulated? Money? Access? Obligation? Labor? Services?

The third issue, which follows from the first two, is an explicit recognition of the actors involve in the analysis. Again, this point seems more than a touch elementary, but many of the disputes one encounters in the literature seem to find their source in an ambiguity

about the actors involved in the specific analysis. Are we considering the role of exchange between consumers? Between brands and consumers? Between firms and workers? Between some combination of these?

Fourth, we must recall that economies do not occur in a vacuum. That is, none of these systems of resource circulation take place independently of a cultural context. Delineating the nature of that context sheds additional light on the issue. For instance, exchange of money between citizens of a country in the form of taxes might be viewed as a tyrannical imposition in one context, or in a benevolent cast as fair social redistribution in another.

The framework posits mutuality as a substitute for the nebulous sharing construct and juxtaposes it against another dominant trope, possessive individualism (Giesler 2008). Mutuality, otherwise identified as generalized exchange (Willer et al. 2011), is action that entails the assumption that another party would act toward the first in mutual fashion were their roles reversed. This assumption of mutuality rests on the actors' understanding that they share a common sociality. Thus, mutuality is exchange action that rests on normative sociality, with the expectations attached thereto.

Opposite mutuality, the concept of possessive individualism is the normative underpinning of market exchange. Here, action entails the assumption that the actor maximize his/her own personal benefit. The obligation to receive dominates exchange and actions rest on an ethic of maximization. Possessive individualism lends itself to actions that disregard the shared social context, as its normative imperative is for the individual to control, own, and of course, maximize; it has given rise to conservative and capitalist agendas for these very reasons (Giesler 2008).

In her essay for *The Great Transition Initiative*, Schor beautifully articulates the potential of the theoretical framework, though not in explicit terms: "The key to making sharing economies just is to emphasize an explicit politics of sharing, as well as nurturing collective, public forms of sharing" (2014, p.11). In other words, sharing economies will succeed in their socially promising premise insofar as they are built on and foster mutuality, rather than possessive individualism. To illustrate, consider the following examples.

Lamberton and Rose examine commercial sharing programs, which they define as "marketer-managed systems that provide customers with the opportunity to enjoy product benefits without ownership" (2012, p.109). They find that consumers take a largely utilitarian view of services like Zipcar. Consider the actors: this is a consumer sharing system mediated by a firm. The resources circulating are filtered through an impersonal, private entity. That the possessive individualist norms dominate should thus come as little surprise, as the entire exchange is contextualized as a market transaction without any of the inscribed sociality one would expect from mutuality. Thus, social-like trust and cooperation had limited efficacy. Furthermore, the authors find that increasing familiarity with the sharing concept increases consumers' propensity to participate. One might hazard to guess that this familiarity makes salient the sociality inherent in mutuality and thus shifts perceptions of the exchange.

On the other hand, my own field work in the craft beer industry reveals a network precisely the same: consumers, firms, and consumers. The difference, however, is that these craft brewers provide the social context for relationships develop; their market-mediated exchanges facilitate the grounds for sociality inherent in mutuality. As a result, I found solidarity amongst the consumers and favorable attributions about the brand by consumers, both to one another, to the brand, and to potential consumers. Each of these outcomes is theoretically consistent with the theory of the gift and accounted for by the fostering of mutuality by the firm.

In this manner, I explicate in depth these examples and several others in order to highlight the extent to which the mutuality and possessive individualism framework can help disambiguate the causes and consequences of the variance we see in different contexts of the sharing economy. Clearly identifying the actors and excavating the normative undertones of the exchange allows researchers to use the mutuality and individualism framework analytically as well as strategically.

"People Like Us:" Negotiating Social Boundaries in House Swapping

EXTENDED ABSTRACT

Recent studies find commercial sharing groups do not always produce in-group identity and solidarity (Bardhi and Eckhardt 2012). When the shared good is perceived as scarce, competitive relationships may arise in commercial sharing groups (Lamberton and Rose 2012). We examine the meaning of sharing among individuals who exchange their homes with strangers. Although a sense of solidarity emerges among members who swap homes as a travel lifestyle, subtle exclusionary forces are also at play. We focus on how micro social practices help people negotiate boundaries of inclusion and exclusion.

Home swapping is a well-established online lodging service, which enables members to temporarily stay in each other's home for free. The majority of home swappers are educated couples who are keen travelers seeking authentic cultural experiences (Forno and Garibaldi 2013). This study involved the analysis of online archival data, interviews with 23 home swappers (varying in their level of experience), and home swapping materials (e.g., web profiles and house instructions). We also probed examples of extreme cases, such as best and worst home swaps, to establish the boundaries of our findings (Dion, Sabri, and Guillard 2014).

Many swappers were seeking out people who were like themselves. Jennifer captures this sentiment: "I'm into all sorts of sharing things, but I think it's one of those things where it works best when it's what I describe as PLU, 'people like us.' People with the same standards, same expectations, quite often same education level, not necessarily, but it helps." Early in the home sharing negotiations, swappers even use a dating metaphor as they include and exclude potential swap partners. Sometimes this match making is practical (e.g., families who share similar school holiday dates or retirees who travel for longer period). But significant time is invested in researching potential partners and looking for subtle tells for compatibility (e.g., shared interests, furnishings that reflect similar tastes, or delayed replies suggesting lack of a commitment). Swappers who pass this vetting process often become friends and stay in touch: "It doesn't feel like a business transaction… you feel like a friendship was developed (Ross)."

We find that mundane practices of cleaning are employed by home swappers to substantiate the swap transaction as a form of altruistic sharing. Through the micro-social negotiation of 'clean enough," home swappers achieve a sense of 'we-ness' and differentiate themselves from commercial lodging services. The meaning of cleanliness is expressed and reproduced in everyday cleaning practices (Shove 2003). Cleaning practices symbolize and reproduce social boundaries and a sense of order in our everyday life (Douglas 1984). Through domestic cleaning, people come to realize and negotiate the difference between clean and dirty, inside and outside, and "create a sense of home out of the material house" (Douglas 1984, p. 69).

'Over clean' imposes stress and fear of contamination to swappers and hampers the pleasure of 'being on holiday.' As Michelle described: "They basically spent the whole day cleaning. We got to their house and it's absolutely spotless. And I thought, 'No, this is terrible.'" Excessive cleaning makes swappers more conscious about being in another's home and reinforces the boundary between 'inside' and 'outside,' which in turn positions the swap more like an exchange between strangers. When homes are 'over cleaned,' it violates the shared expectation that swappers are a different group who are relaxed and adaptable. Homes that are too clean highlight the mismatch of expectations between swappers and symbolize characteristics of commodified hotel rooms (Dion et al. 2014).

Among experienced swappers, "clean enough" is the common expectation that marks a person as part of the community. Rather than making their homes "spotless" or "pristine and clean," swappers do basic cleaning of bathrooms and kitchens and provide clean linens, but most leave the home as they normally live. They clear out space in closets but leave the clutter of daily life, which is part of the appeal of living in another person's home. Certain dirt, like breadcrumbs and dirty towels in the hamper, are considered normal and tolerated by swappers (Dion et al. 2014). Thus, 'enough clean' helps swappers navigate potential symbolic pollution and highlights the unpaid nature of home swapping as a form of sharing (Belk 2010).

Finally, the 'under-cleaned' house revealed a sense of local disorder and mismatch of standards. Although some cultural differences are tolerated, swappers who 'under clean' are often considered as an outsider or newbie. Experienced home swappers such as Lucy, attributes the problem of under-cleaning to "the type of people."

There is a downside to home exchange and that can include inconsiderate people who commit to home exchanges and then back out with idiotic explanations (e.g., "I changed my mind"). There are also the slobs and people who do not maintain their homes, leaving you with a myriad of unpleasant problems during the exchange.

Although unusual, another informant left a home horrified at a flat that was "dirty" and "sticky" with bed linens that "looked grubby;" she equated it to living in council flats of the poor and a chaotic life.

These findings extend our knowledge on how and why some symbolic pollution is tolerated while others are not. It also shows that the meaning of cleanliness can be fluid and circumstantial (Dion et al. 2014). In home swapping, the alternative norm of 'clean enough' enables a sense of solidarity and affirms the spirit of altruistic sharing. However, the tolerance of dirt and 'clean enough' is conditional among people like us. This demonstrates that similar to cleaning practices, sharing as a cultural construct is built around distinctions of age, gender, and class (Douglas, 1984).

To summarize, our study shows that the micro social negotiation of exchange and cleanliness can be used by consumers to substantiate the altruistic face of sharing. Underneath its altruistic appearance, sharing implies an in-group practice. More importantly, this study demonstrates how meanings of sharing are actively constructed and reproduced by consumers in everyday practices. This important finding should help us better understand the contemporary sharing economy and consumers' role within it.

Reciprocal Altruism as a Motivation for Sharing: Sharing Up verses Sharing Down

EXTENDED ABSTRACT

The consumer literature on sharing views it as a social phenomenon, and focuses on sharing with close others such as family and friends, portraying it as an altruistic, pro-social behavior with no

expectations of reciprocity (Belk's presentation). However, little is known about what drives people to share important possessions with acquaintances and strangers.

Our research explores the role of social comparison and reciprocity expectations in sharing. Social comparison theory (Festinger 1954) posits that people compare themselves to others who are either superior to them (upward comparison) or inferior to them (downward comparison) on dimensions such as intelligence, appearance, or status. Upward (vs. downward) comparison is often motivated by assimilation needs (Mussweiler 2003).

The extant literature suggests that when considering with whom to share, individuals may have conflicting motivations. On the one hand, individuals may prefer to share up due to reciprocity expectations. While sharing up and sharing down are both strategies that will result in reciprocal altruism, sharing up should be seen as more beneficial, because it has the potential to result in a larger amount of reciprocity. On the other hand, individuals may prefer to share down due to feeling better off, feeling empathy toward the target, or wanting their resources to go a longer way. Under normal conditions (such as when the comparison target is the same as the sharing target), we expect reciprocity concerns to be stronger than altruistic concerns, making people more likely to share up than to share down. However, under conditions in which reciprocity is less likely, we expect altruistic concerns to be stronger than reciprocity concerns, making people more likely to share down than to share up. In four studies, we demonstrate that due to expected reciprocity, individuals are generally more likely to share up than to share down. However, when expected reciprocity is removed from the equation, pure altruism takes over, and individuals become more likely to share down than to share up.

Study 1a investigated the effect of social comparison on the willingness to share, utilizing a 3 (comparison target: upward, downward, neutral) between-subject design with 501 business students. The participants read a scenario about Michael/Michelle, who was a very successful (upward comparison), very unsuccessful (downward comparison) or average (neutral) business student in the same class as the participant (Mussweiler et al. 2004). The gender of the target and the participants were matched to control for the effects of mating motives. Next, the participants read another scenario about the same person approaching them and asking them to share a possession relevant to the academic domain (class notes or a computer) with him or her. Participants indicated their willingness to share the items with Michael/Michelle and their reciprocity expectations (i.e., what they expected to gain) from the act of sharing. Participants were more willing to share-up versus down (M_{upward}=5.01 vs. $M_{downward}$=3.25), with neutral in the middle ($M_{neutral}$=4.25; (F(2,497) = 48.86, p=.00). In addition, they had greater reciprocity expectations from sharing with an upward target than from the other targets (M_{upward}=4.57, vs. $M_{neutral}$=3.90 vs. $M_{downward}$=3.43; F(2,497)= 32.27, p=.00). Furthermore, their reciprocity expectations mediated the relationship between social comparison (b=.20, p=.00) and sharing (b=.77, p=.00). Study 1b replicated these results with a different social comparison scenario (a hypothetical workplace situation) among a sample of mTurk workers. Study 2 replicated these results with another academic scenario, across a variety of different possessions that were either relevant to the domain of comparison (computer and class notes) or non-relevant to the domain of comparison (sandwich and apartment). Participants were again more likely to share up than to share down across these different scenarios and product categories.

In study 3, we varied whether the sharing target (e.g., Jordan) was the same as or different from the comparison target (e.g., Mi-

chael). By doing so, we rendered the sharing decision irrelevant to the comparison act. In other words, Michael's class performance is irrelevant to the decision of whether or not to share with Jordan. We used a 2 (social comparison: upward vs. downward) x 2 (sharing target: same as comparison target vs. different than comparison target) between-subject design with 329 students and the same procedure of the previous experiments. The results showed a main effect of social comparison, with greater intentions to share-up (M_{upward}=4.80 vs. $M_{downward}$=4.13; F(1,325) = 13.21, p=.00), as well as a significant social comparison X sharing target interaction (F(1,325) = 37.99, p=.00). Specifically, when the sharing target was the same as the comparison target, the participants were more likely to share up than down (M_{upward}=5.40 vs. $M_{downward}$=3.64), replicating our previous findings. However, when the sharing target was different from the comparison target, they were more likely to share down than to share up (M_{upward}=4.18 vs. $M_{downward}$=4.63; F(1,325) = 3.13, p=.08).

Finally, Study 4 investigated the moderating effect of the comparison target relevancy, as reflected in the degree of which the comparison target was related to the participants' academic major. We reasoned that a comparison target who has the same college major would be much more likely and capable of reciprocating in the future. We used 2 (social comparison: upward vs. downward) x 3 (comparison target relevancy: high- business major; moderate- biology major taking one business course; low- biology major taking no classes in common with the sharer) between-subjects design with 656 business students. The results revealed a main effect of social comparison, with greater intentions to share up (M_{upward}=5.00 vs. $M_{downward}$=3.83; F(1,653) = 79.74, p=.00). However, this main effect was qualified by a significant social comparison X relevancy interaction (F(2,650) = 8.84, p=.00). In the high and moderate relevancy conditions, participants were more likely to share up vs. down ($M_{high\_relevancy\_upward}$=5.39, SD=1.42 vs. $M_{high\_relevancy\_downward}$=3.60; $M_{moderate\_relevancy\_upward}$=4.89 vs. $M_{moderate\_relevancy\_downward}$=3.59), replicating our previous findings. However, in the low relevancy condition, there were no significant differences between the social comparison conditions (M_{upward}= 4.72 vs. $M_{downward}$=4.29).

Taken together these studies suggest that expected reciprocity motivates people to share up versus down. However, in the absence of such motivations, people's sharing decisions become more altruistic.

SESSION OVERVIEW

The attribution and denial of humanness is a fundamental process of consumer behavior, one whose implications are becoming increasingly important in light of recent technological developments. Attributing humanness to non-human objects is known as anthropomorphism, and has been studied in the context of brands (e.g., Puzakova, Kwak and Rocereto 2013) and products (e.g., Kim and McGill 2011). Denying humanness to human beings is known as dehumanization, and has been studied in the context of ethnicity, race, gender, and more (Haslam 2006; Haslam and Loughnan 2014). In general, anthropomorphizing a product or brand improves consumers' evaluations of those things, whereas dehumanizing a person leads consumers to discriminate against and act antisocially towards that person. These processes can therefore play important roles in many domains of consumer behavior.

The papers in this interdisciplinary session enrich our understanding of the antecedents, interplay, and consequences of consumers' anthropomorphism and dehumanization. The papers approach these issues in the context of consumers' encounters and interactions with both novel consumption stimuli (e.g., smart devices, human enhancement technologies) as well as more common stimuli (e.g., brands and customer service representatives). In addition to shedding new light on the processes of anthropomorphism and dehumanization, each of the three empirical papers also demonstrates novel consequences of those processes for consumer behavior, while the conceptual paper raises several important questions about the future of these phenomena in light of rapid technological progress.

The conceptual paper, by Belk, begins our session by providing a sweeping view of how advances in artificial intelligence and robotics are creating anthropomorphic computers and robots, while simultaneous advances in human enhancement technologies are al-

lowing consumers to become more like machines or robots. The next paper, by Castelo et al., explores the consequences of enhancement technologies for perceived humanness in more depth, showing that currently available products can indeed lead the enhanced consumers to be dehumanized and that dehumanization has important marketing implications. The third paper, by Henkel et al., focuses on dehumanization in a more traditional marketing context, showing that brand positioning can lead to the dehumanization and mistreatment of the brand's employees. Finally, Hoffman et al. return to a theme that Belk introduced – that computers and machines are increasingly anthropomorphized – by studying "smart devices" in the context of the Internet of Things. They show that both features of the devices and characteristics of the consumer determine how such anthropomorphism occurs.

Taken together, the four papers provide multifaceted insights into perceptions of humanness (or lack thereof) of the self, products, other consumers, and employees. Collectively, they address the following questions: (i) which factors are important in shaping consumers' (de-) humanization of the self, others, or products and (ii) what are the consequences of such processes for how consumers see themselves, other people, and products. This session is of interest to a diverse audience as it appeals to those interested in what it means to be human, and how the answers to that fundamental question shape consumer behavior.

Anthropomorphism and Anthropocentrism

EXTENDED ABSTRACT

Justin Leiber (1985) provides the transcript of a meeting of the United Nations Space Administration Commission concerning a Humanico Corporation plan to shut down its space station. Over the period when the station was in operation, human astronauts came and went, but a female chimpanzee named Washoe-Delta remained for years and adapted to weightlessness. The human crew members taught her a portion of American sign language. She came to think of the space station as her kingdom. Also accompanying the astronauts on the space station was a Turing 346 computer that they called "A.I.". It helped solve problems at the station and assist with official projects. It came to recognize astronauts individually and respond to them. The crews came to think of both A.I. and Washoe-Delta as persons and friends. When Humanico announced it would shut down the station and A.I., and let Washoe-Delta die in space (for she could no longer function in earth's gravity), Amnesty International and the International Civil Liberties Union objected before a dubious UNSA Commission. The organizations maintained that both A.I. and Washoe-Delta had the right not to be abandoned in space. Leiber's book is a record of the debates that ensued regarding the question of whether or not the computer and the chimpanzee could be considered to be persons with legal rights according to the UN charter.

Were the members of the space station crew and human rights organizations merely anthropomorphizing A.I. and Washoe-Delta? Or were the skeptical UN Commission members who objected to granting these entities personhood merely being anthropocentric in insisting on an uneven ontology in which only human beings can be persons and possess rights? After all, corporations, nations, and certain organizations are treated as legal persons. And it is clear from the

relatively recent historically momentous granting of full personhood and legal rights to women and slaves that societal views on who can be a person can change and evolve.

Traditionally humans have compared themselves to non-human animals as a way of understanding what it means to be human. During the Industrial Revolution people began comparing themselves to the dumb machines that were replacing them. And in the emerging age of computers and robotics we may be shifting to comparing ourselves to smart machines that are now replacing us. In each case we are coming to appreciate that abilities that we once thought were uniquely human -- strength, cunning, language, memory, emotions, intellect, sentience, forward thinking, and morality -- may not be exclusive to humans (e.g., Brooks 2002; Daston and Mitman 2005; Haraway 1991; 2003; Kurzweil 1999; Mazis 2008; Philo and Wilbert 2000). For example when IBM's Deep Blue beat world chess champion Garry Kasparov in Chess and IBM's Watson beat Jeopardy champions Ken Jennings and Brad Rutter in Jeopardy, these examples of unique human intellectual superiority fell by the wayside. Given such losses to machines, it is perhaps understandable that humans are beginning to adapt through aids and devices such as exoskeletons, distributed online memory through our devices, biological enhancements such as surgical implants and performance boosting drugs, and soon perhaps nanotechnology and genetic engineering of humans.

In this presentation I address the contention that our machines are becoming more human-like and we are becoming more machine-like. In the former case of machines becoming like us, this is aided by our anthropomorphism of human-appearing androids (or the female equivalent, gynoids) and animal-emulating robots. There is a growing literature suggesting that we respond better to such seemingly living creatures. Even sexbots are a part of the emerging robotics market (e.g., Levy 2007). But there is also a hypothesized "uncanny valley," where too great a similarity to humans creates discomfort. Moreover there are fears of "the singularity," or the point where our devices become smarter than us and potentially find us humans unnecessary (e.g., Kurzweil 1999; Moravec 1999). In these cases we are moving from mere anthropomorphism to the point where our smart machines are not only persons but super-beings with whom we can no longer compete. There are several different scenarios through which this could happen (e.g., Kurzweil 2013) as well as many science fiction portrayals of various outcomes. And the field variously labeled robot-, machine-, and computer-ethics is working both to attempt to instill morality in future machines and to consider the rights that such machines might be granted (e.g., Lin, Abney, and Bekey 2012).

Either in an effort to keep up with robots or out of a striving for perfection and even immortality, the human enhancement or human augmentation movement is proceeding apace with the developments in robotics and artificial intelligence (e.g., Chu 2014; More and Vita-More 2013). Whereas the attempt to make humans more like machines can be seen as dehumanizing (Belk 2014b), proponents of transhumanism envision making humans more god-like, with super strength, super intellect, and super longevity. The comparison to religion is often explicit (e.g., Cole-Turner 2011; Mercer and Trothen 2015).

Contemporary consumption may seem distant from these future scenarios, but it may be closer than we think; there is a postulated exponential growth in computer intelligence once our devices possess the equivalence of human intelligence and begin reprogramming themselves. Robots are in our factories and are entering our homes and offices. They can work for us or they can replace us. Envisioning the ethical and moral considerations of human-like machines and machine-like humans is critical now if we hope to shape our future. I offer no solutions, but will layout these issues and attempt to engage consumer researchers in addressing them.

Cyborg Consumers: When Human Enhancement Technologies are Dehumanizing

EXTENDED ABSTRACT

We show that users of human enhancement technologies are dehumanized, even when the enhanced traits are central to humanness. The perceived naturalness of the means and outcome of the enhancement drives this effect. Dehumanization in turn decreases consumers' interest in using the technology themselves, and affects how the enhanced consumer is treated.

In our first study we focused on a technology called transcranial direct current stimulation (tDCS), because it is already available to consumers, and because it is capable of enhancing a range of abilities that are widely considered central to humanness (Cohen Kadosh et al. 2015; Haslam, Bastian and Bissett 2004). It works by passing a mild electrical current through a specific area of the brain to improve that area's functioning. 145 MTurk users read a vignette asking them to imagine that they had an acquaintance who had started using either tDCS or an herbal supplement to enhance their creativity and self-control. Participants then reported how natural and how artificial the enhancement seemed, how human the acquaintance seemed and whether they seemed more or less human than before they started using the enhancement, and finally how much they thought creativity and self-control reflect human nature.

We confirmed that participants considered creativity and self-control to be part of human nature ($M_{creativity}$ = 6.05, $M_{self-control}$ = 5.11, both significantly higher than the scale midpoint of 4, $t(143)$'s > 9, p's < .0001). We then showed that the acquaintance in the vignette was perceived as significantly less human when using tDCS (M = 71.9) compared to an herbal supplement (M = 87.57, $t(143)$ = 3.93, p = .0001). Furthermore, compared to pre-enhancement, the acquaintance seemed *less* human when using tDCS (M = 47.09) but *more* human when using an herbal supplement (M = 52.95, $t(143)$ = 1.96, p = .052), suggesting that enhancement technologies can be dehumanizing. We also showed that perceived naturalness of the enhancement mediated this effect: the bootstrapped indirect effect was -13.5, 95% CI = -23.8 to -7.3. Finally, perceived naturalness and humanness together mediated consumers' interest in using the enhancement themselves (β = -8.12, 95% CI = -16.7 to -3.4).

In our subsequent study, we sought to explore the concept of naturalness and its relationship to dehumanization in more detail. 237 MTurk users read one of four vignettes asking them to imagine a specific acquaintance, John, an ambitious, type-A personality who keeps up with the latest technology trends, and who had recently decided to enhance his mind using a supplement. The vignettes were organized in a 2x2 between-subjects design, in which the naturalness of the means of enhancement and the naturalness of the outcome of enhancement were manipulated independently. Means naturalness was manipulated by describing the natural supplement as made from ingredients extracted from plants and minimally processed, whereas the unnatural supplement was made from ingredients synthesized in a lab and highly processed. Outcome naturalness was manipulated by describing the outcome of enhancement as enabling vs. embellishing the user's true abilities (Williams and Steffel 2014). In the natural outcome condition, the supplement was described as allowing John to perform up to his true intellectual abilities, whereas in the unnatural outcome condition it allowed him to perform beyond his true abilities.

We confirmed that the natural supplement seemed more natural (M = 70.4) than the unnatural supplement (M = 25.6, $t(235)$ = 14.9, $p < .0001$), and the "enabling" outcome seemed more natural (M = 57.9) than the "embellishing" outcome (M = 45.0, $t(237)$ = 3.7, $p = .0002$). These two dimensions of naturalness also impacted dehumanization. An ANOVA using perceived humanness of the acquaintance as the dependent variable revealed main effects for both means ($F(1, 233)$ = 10.8, $p = .001$) and outcome ($F(1, 233)$ = 7.6, $p = .006$), but no interaction ($F < 1$). Specifically, the acquaintance seemed less human when the means were unnatural (M = 70.1) vs. natural (M = 81.0), and when the outcome was embellishing (M = 71.5) vs. enabling (M = 80.6). In both cases, perceived naturalness fully mediated the effect between means/outcome of enhancement and perceived humanness (indirect effect for means: 15.64, 95% CI = 8.37 to 23.96; for outcome: 6.32, 95% CI = 2.73–10.43).

For study 3, 58 undergraduate students came to the lab one at a time and were asked to evaluate an ad that was ostensibly developed for a new product, a tDCS brain-enhancement device. After evaluating the ad, participants met a confederate who was either wearing the enhancement device they just learned about or was not wearing the device. After briefly interacting with the confederate, participants completed a measure of dehumanization of the confederate. Participants also completed a measure of social distance that we thought might mediate any effect of dehumanization on prosocial behavior. Finally, as participants were signing a debriefing form the confederate "accidentally" knocked a jar of 20 pens off of the desk in front of the participant, and then discretely counted how many pens the participant helped him to pick up from the floor. This measure has been used in past research as a measure of prosocial helping behavior (Twenge et al. 2007).

When the confederate was not wearing the enhancement device, participants helped him picked up an average of 7.5 pens, compared to only 4.7 pens when he was wearing the device, $t(57)$ = 2.63, $p = .01$. We identified a two-stage mediation process in which condition (presence vs. absence of device) predicted dehumanization, which in turn predicted how distant participants felt from the confederate. This felt distance measure in turn predicted how many pens they helped to pick up. The indirect effect was .17, 95% CI = .006 to .83. This study therefore provides evidence for the notion that using enhancement technologies can result in negative social consequences for the enhanced consumer.

Ongoing studies generalize these results to include additional forms of enhancement, showing that technologies including Google Glass, Oculus Rift, genetic engineering, prosthetic limbs, and steroids are also dehumanizing, thus demonstrating the broad relevance of technological dehumanization for marketers.

The Undesired Discounting Effect of Budget Brands: How Brand Positioning Affects Perceptions of Customer Service Representatives' Human Qualities

EXTENDED ABSTRACT

We live in a branded world; virtually not a single company operates without a brand name. Employees are crucial in making these brands come alive. In general, interactions with employees can provide rich information about brands to consumers (e.g., Matta and Folkes 2005), and employee–brand alignment might improve brand evaluations (Sirianni et al. 2013). Hitherto, research into brands and employees has focused exclusively on how perceptions of employees and their behavior influence consumers' brand perceptions and evaluations. We argue that the effects also work in the opposite direction: brands shape consumers' perceptions of the human qualities of employees and social interactions between consumers and employees.

While brands may differ on many dimensions, one of the most fundamental positioning distinctions is budget (i.e., low-cost) versus non-budget (i.e., differentiated) (Porter 1980). The positioning of a brand exerts pervasive effects on consumer behavior. Neuroscientific research suggests that budget brands activate different brain regions than up-market brands (Schaefer and Rotte 2007). As budget brands inherently focus on economic aspects related to brand consumption, exposure to a budget (vs. up-market) brand induces consumers to spend less (more) in a subsequent task (Laran, Dalton and Andrade 2011). In line with other work showing that brand primes can lead to unintended outcomes (e.g., Berger and Fitzsimons 2008; Brasel and Gips 2011), we propose that a budget positioning exerts unintended effects on consumer-employee interactions.

Specifically, budget brands lead to a focus on market-pricing principles, which emphasize maximizing personal monetary gains, often at the expense of interpersonal sensitivity. Mere reminders of money may increase social distance and unethical behavior (Vohs 2015). A market-pricing approach to social relations thus may counteract recognizing others as humans and interacting compassionately (e.g., Molinsky, Grant and Margolis 2012). Consequently, we predict that budget brands may attenuate consumers' perception and recognition of employees as fully human relative to employees of non-budget brands and individuals without any brand affiliation. This process is called dehumanization and entails attributing less mind (e.g., Gray, Gray and Wegner 2007; Kozak, Marsh and Wegner 2006) or denying individuals traits that make them human (Haslam 2006). We also examine the consequences of dehumanization for employees. Discounting others' humanness leads to reduced prosociality toward them (Cuddy, Rock and Norton 2007). As interpersonal sensitivity decreases, we predict that consumers are less likely to offer support to employees in need when these work for budget (versus non-budget) brands. In sum, we predict that consumers are more likely to dehumanize employees of budget brands and are less likely to help budget employees in need.

Three studies tested these hypotheses. In study 1, 129 participants completed nine dehumanization items (Bastian et al. 2013). Following Laran, Dalton and Andrade (2011) Walmart and Nordstrom served as budget and non-budget brands, respectively, and participants indicated to which of the two brands the dehumanization items applied more (e.g., "I feel like employees are mechanical and cold, like a robot", "I feel like employees lack self-restraint, like an animal"). As we used a nine-point scale with the brand logos as anchors, participants could attribute equal humanness to the employees of the two brands by choosing the midpoint of the scale. However, participants significantly dehumanized the employees of the budget brand ($p < .001$).

Study 2 (n = 208) tested the underlying mechanism of this effect. Participants were randomly assigned to a budget (Ryanair), non-budget (Lufthansa), or neutral control condition. After reporting their brand associations, participants received printed, photoshopped advertisements displaying the same flight attendant. The neutral condition rated the same person unrelated to a commercial context. Ratings on the stimulus's capacity to think, feel, and plan served as our dependent measure of dehumanization (Kozak, Marsh and Wegner 2006). Consistent with our predictions, participants in the budget condition ascribed less humanness to the employee than those in the non-budget ($p = 0.006$) and the control condition ($p < 0.001$). Moreover, participants in the non-budget condition attributed less humanness to the person than subjects in the control condition ($p = 0.011$). Two independent raters coded whether the associations contained

market-pricing connotations. A mediation analysis with market-pricing focus as a dichotomous mediator (Imai, Keele and Tingley 2010) revealed that the increased market-pricing focus mediates 91.7% of the effect of the low-cost brand (vs. non-budget and neutral control) on dehumanization. A follow-up study (n=180) employing the same paradigm replicated the effect in a supermarket context.

In our final study, 75 participants were randomly assigned to the same two brands as in study 2. Subsequently, they were presented with a manipulated image depicting a budget or non-budget airline cabin. The image featured a stewardess, who had toilet paper stuck to her shoe, walking along the aisle. Our dependent measure of prosocial behavior was participants' intentions to help the stewardess by informing her about the toilet paper. In line with predictions, participants were significantly less likely to help the budget than the non-budget stewardess ($p = .025$).

Taken together, three studies suggest that a budget brand positioning has pervasive, unintended consequences for consumers' perceptions of the humanness of employees associated with such brands. Across different industries and measures, we consistently demonstrate that consumers fail to fully recognize the human qualities of budget employees and are also less likely to offer interpersonal support to these employees when in need. Additional studies are currently in progress, examining further control conditions (e.g., low-status brands), additional outcomes, and potential intervention strategies for budget brand managers.

Anthropomorphism From Self-Extension and Self-Expansion Processes: An Assemblage Theory Approach to Interactions Between Consumers and Smart Devices

EXTENDED ABSTRACT

Hoffman and Novak (2015) have proposed using assemblage theory (DeLanda 2006) to conceptualize consumer experience in the Internet of Things (IoT). Their framework formally identifies consumer experience as emerging from consumer interactions with smart devices in IoT assemblages. Paired capacities exercised in these interactions specify how consumers and smart devices can affect and be affected by each other. This conceptualization links self-extension (Belk 1988) and self-expansion theories (Aron and Aron 1986) in a larger theoretical framework, where anthropomorphism is an outcome of self-extension and self-expansion.

Recently, Connell and Schau (2013) noted there is some confusion in the marketing literature over the distinction between self-expansion and self-extension. Belk's (1988) self-extension theory largely deals with how brands can bring more meaning to consumers' lives through a process where the self is extended into those brands. Through the self-extension process, consumers invest the object with emotions or feelings, so that the object takes on significance beyond a mere possession. In self-expansion theory (Aron et al. 1991), people are motivated to form close relationships with others because it expands their ability to accomplish goals. Self-expansion through close relationships contributes to the formation of our own identities and is achieved by incorporating the resources, perspectives and identities of a close other into one's self (Aron et al. 2004). Connell and Schau (2013) and Belk (2014a) conclude that both self-extension and self-expansion are useful for understanding the relationships that people have with objects.

In our assemblage theory framework, the self-extension process captures the paired capacity of the consumer to affect smart devices and the capacity of smart devices to be affected by the consumer. Self-extension implies that the consumer is in control of the identity they project from themselves into the device. But paired capacities can also operate in the other direction. The self-expansion process captures the paired capacity of the device to affect the consumer and the capacity of the consumer to be affected by the device. With self-expansion, the device is in control of the identity that the consumer absorbs into the self. Thus:

Hypothesis 1: *When the consumer has more control in the interaction, self-extension will be greater than self-expansion; with less control, self-expansion will be greater than self-extension.*

We propose that anthropomorphism is a key mediating emergent experience from the interaction among the paired capacities of the consumer with smart devices. Anthropomorphism is the tendency for people to ascribe human-like characteristics, emotions and behaviors to objects (Epley, Waytz and Cacioppo 2007). Waytz et al. (2010) found that more unpredictable devices were seen as more anthropomorphic. Greater unpredictability corresponds to less control, thus:

Hypothesis 2: *When the consumer has less control in the interaction, anthropomorphism will be greater compared to when the consumer has more control.*

Some research has suggested that anthropomorphism lies on a continuum from a minimal kind of anthropomorphism where you attribute human traits to an object, all the way to seeing the object as human with a "mind of its own" (Aggarwal and McGill 2007). We theorize that such device complexity could moderate whether anthropomorphism occurs through a self-extension or self-expansion processes. In the self-extension process, anthropomorphic experience more likely arises from the consumer's capacity to directly affect simple devices (so-called "long finger" interactions). Consumers might have an easier time extending their essence into the device when it is simple. However, in the self-expansion process, anthropomorphic experience more likely arises from a complex device's capacity to affect the consumer through autonomous, ambient interactions.

Hypothesis 3: *For devices that the consumer has the capacity to effect (self-extension), anthropomorphism will be greater for simple compared to complex devices. For devices that have the capacity to affect the consumer (self-expansion), anthropomorphism will be greater for complex compared to simple devices.*

Study 1 was a manipulation check for the control manipulation based on 101 participants. Across 32 devices (2 new scenarios and 30 of the devices based on Waytz et al. 2010), participants reported significantly less perceptions of control (M=3.26) when devices behaved unpredictably compared to when the participant could program the device (M=5.34; F (1, 99) = 82.176, p <.001).

Studies 2 and 3 tested H1-H3. In study 2, 201 participants evaluated the same 32 devices in a 2 (low vs. high control) x 2 (self-extension vs. self-expansion) design to test H1. For each device, participants indicated either their perceptions of self-extension ("to what degree do you have the capacity to affect [device]?") or self-expansion ("to what degree do you have the capacity to be affected by [device]?"). Results supported H1. Self-expansion (M=4.23) was greater than self-extension (M=3.16) for low control, and self-extension (M=4.61) was greater than self-expansion for high control (M=3.97; F(1,197)=51.243, p <.001).

In study 3, 352 participants evaluated device anthropomorphism in a 2 (self-extension vs. self-expansion) x 2 (low vs. high control) x 2 (simple vs. complex device) design. Results supported H2 and H3. There was less anthropomorphism when control was high (M=1.80) compared to when it was low (M=2.25, (F (1, 344) = 10.13, *p* =.002). In the self-expansion conditions, the complex device (M= 2.29) was more anthropomorphic than that simple device (M=1.89 and in the self-extension conditions, the simple device was more anthropomorphic (M= 2.10) than the complex device (M= 1.87) with the corresponding two-way interaction significant (F (1, 344) = 4.13, *p* = .043).

Our studies support the idea that the self-extension and self-expansion processes can both lead to anthropomorphism. These results, plus an exploratory Study 4 that provides correlational evidence that consumers view interactions with smart devices in terms of paired capacities, lay the groundwork for additional experiments on anthropomorphism arising from paired capacities in different interaction scenarios. Consumers desire for devices to be more "real" than they actually are can satisfy effectance and sociality motivations (Epley et al. 2008). For example, we hypothesize that in the self-expansion process, consumers' need to feel a sense of mastery over the interaction may increase feelings of anthropomorphism for complex devices. Additional studies are in progress to examine these effects.

SESSION OVERVIEW

In essence, the study of consumer behavior is the study of resource exchange. The consumption choices that consumers make are ultimately shaped by how they choose to relate to their resources, be it the income they earn, the spare hours in their day, or their willingness to exert effort.

In order to better understand this relationship, the present session explores the diverse ways in which consumers perceive, monitor, and ultimately, manage their resources. In doing so we seek to answer a number of questions regarding the way in which consumers think about resource accumulation and resource exchange: How do consumers perceive their own resources relative to the resources of others? How do consumers' perceptions of their resources affect their willingness to take a deal? To what extent do consumers feel that resource exchange accurately reflects their true preference for a good? And when do consumers feel it is appropriate or inappropriate to actively manage their resources?

In the first paper, Berman et al. investigate how people evaluate their own resources relative to the resources of others. They find that consumers believe that those who earn more than they do have more financial resources than what those higher earners evaluate for themselves. They explore one consequence of this divergent perspective by examining estimates of how much individuals believe that they and others should donate to charity.

In the second paper, Sharma and Keller examine how perceptions regarding subjective wealth affect consumer preferences for deals—purchases offered at a discount to consumer. They find that financially deprived consumers are less receptive towards discounted purchases as compared to their financially privileged counterparts. These effects are associated with feelings of embarrassment and shame towards deals, and are attenuated when deal adoption does not signal financial inadequacy but rather financial savvy.

Next, Shaddy and Shah examine how different expenditures of resources (such as money, time, and effort) reflect preference strength, or the extent to which consumers desire a given good. They find that resource expenditures are stronger signals of preference strength when (a) those resources are distributed more equally, and (b) when those expenditures are easy to quantify and understand. They further argue that the more that a price of a good reflects preference strength, the more fair that the price is seen.

Finally, Kim, Zhang and Norton investigate how individuals monitor resource exchange in social relationships. They find that individuals who more actively and precisely monitor the exchange of resources in social exchanges are seen as being petty, which is undesirable. This is because petty people are seen treating relationships in a transactional manner, which violates social norms.

Together, these papers offer unique perspectives on how consumers perceive, monitor, and manage their resources. We expect that this session will be of interest to a broad audience, not just those interested in consumer resource management, but will also appeal to those studying judgment and decision making, social cognition, policy making, and prosocial behavior as well.

Passing the Buck to the Wealthier: Egocentric Judgments of Financial Resources Influence Donation Obligations

EXTENDED ABSTRACT

How much do individuals believe that they and others should donate to charity? Diminishing marginal benefits from money suggests that as income rises, the value of a marginal dollar—and the pain felt in sacrificing it—should decrease. Simply put, the more money people make, the easier it should be for them to give. However, consumers must judge for themselves how much their earnings they feel that they ought to sacrifice to help others.

In this paper, we investigate how individuals form judgments of donation obligations across the income spectrum, for themselves and for others. We argue that when evaluating how much a given individual should donate to charity, people base their judgment in part on the amount of spare financial resources they perceive that individual has. However, we find that these judgments about others' spare financial resources depend on an individual's own income. In particular, people believe that others who earn more than they do have more discretionary income, than those wealthier others actually experience for themselves. In other words, people tend to perceive higher earners as more flush than those higher earners themselves feel, which then impacts judgments of appropriate levels of monetary donations.

We begin by examining beliefs about discretionary spending in general. Study 1 (MTurk, N=305) examines whether an individual's income influences how much money they perceive others spend on inessential (discretionary) versus essential (non-discretionary) expenses. Participants evaluated 5 target individuals who differed only in their yearly income ($20k, $40k, $60k, $80k, $100k). For each target individual, they estimated the percentage of the target's spending money that persons uses towards essential expenses versus inessential expenses.

For each target individual, we created a relative income variable by categorizing participants according to whether they make either less than $20k of the target or within $20k of the target individual's

income. We find that the relative income of the participant in relation to the target determined how much the participants believed that the target spends on essential vs inessential expenses, $F(1, 1178) = 15.07$, $p < .001$. Those who earn at least \$20k less than the target believe that the target spends less money on essential expenses and more money on inessential expenses than what those who earn within \$20k of the target estimate. In other words, consumers believe that those who earn more than they do spend less on things they need (essential expenses) and therefore have more money left over to spend on the things they want (inessential expenses) than what those richer others estimate for a similar other. This pattern of results holds across all income levels and is robust to different specifications of relative income.

If consumers expect higher earners to have more money for discretionary spending, then they might expect that those higher earners should be donating a greater proportion of their income to charity. Study 2 examines whether an individual's income affects how much spare money they believe others have and whether perceived donation obligations follow the same pattern. This study was pre-registered (https://osf.io/pm7dn/), and utilized an online panel to recruit a balanced sample of participants who varied in their household income (N = 1,023). Participants again evaluated 5 target individuals, who differed in their yearly income. For each target, participants first evaluated the percentage of household income that they believe that the target should donate to charity. They then estimated how much spare money the target has by indicating the likelihood that each target would be able to make a one-time emergency payment of \$2k on a scale from 1 = "extremely unlikely" to 11 = "extremely likely".

We categorized each target individual by whether their household income was at least \$10k less than or within \$10k of the target individual's income. Results from a mixed model linear analysis show that participants who earn at least \$10k less than the target individual believed that the target would be more likely to make an emergency payment of \$2,000, $F(1, 2,355) = 37.45$, $p < .001$, and also should donate a greater percentage of their income to charity than participants who earn within \$10k of the target individual $F(1, 1,852) = 6.86$, $p < .01$. For instance, on average, those who make less than \$70k/year believe that someone who earns \$80k/year should donate 15.5% of their income to charity. However, those who make \$70k - \$90k/year (i.e. roughly the same amount as the target), believe that the same person should donate only 8.8% of their income to charity $t(728) = 3.91$, $p < .001$. Similarly, those who make those who make less than \$70k/year believe that someone who earns \$80k/year has more spare money (M = 7.58, SD = 2.71) than what those who earn about \$80k a year believe (M = 7.02, SD = 2.62), $t(728) = 2.23$, $p = .03$. These results hold for target individuals across all income levels and are robust to different specifications of the relative income variable.

Together, these studies show that consumers believe that those who have more income than they do have more spare money and discretionary expenses, and should therefore donate more to charity, than those higher earners report when evaluating for themselves. Across all income levels, consumers consistently pass the buck to the wealthier.

Financial Inability or Financial Savvy?
Subjective Financial Well-being Shapes Preferences for Discounted Purchases

EXTENDED ABSTRACT

Within the retail marketing mix, sales promotions have one of the strongest effects on short-term consumption behavior. In par-

ticular, deals that take the form of price markdowns, coupons, and rebates give consumers opportunities to obtain promoted products at reduced prices. These deals may benefit retailers in several ways as well. For example, "two-for-one" offers are often used to trigger impulse purchases (Inman et al., 1990), encourage consumers to switch brands, and may increase long-term sales and loyalty in times of competitor activity (Neslin et al. 1985).

Despite the potential benefits to consumers and retailers, consumer uptake of discounts may fall short. In 2013, on average, every person in the United States was offered \$1,617 in coupon savings; however, consumers only took advantage of \$3.7 billion of these savings or \$11.60 per person (Inmar Trend Reports 2014). Accordingly, the current work investigated one consumer-level factor that may help explain consumer preferences for discounted purchases. Specifically, we investigated effects of consumers' objective and subjective financial standing.

Economically, one would expect the prospect of saving on expenditures to be especially appealing to those who feel pinched financially. However, several real world surveys suggest that wealthier individuals are more likely to price-comparison shop, seek deals, and use mobile coupons (e.g., Bhappu, Garf, and Lawry 2014; Nielsen 2010). The literature on subjective financial well-being and coupon usage is equivocal, with some studies suggesting a positive relationship between income and coupon usage (e.g., Laroche et al. 2003) and others suggesting a negative one (e.g., Mittal 1994).

The current research makes three main contributions. First, we establish that compared to a psychological sense being better off financially, feeling worse off (financially deprived) reduces the attractiveness of deals. Second, we show that feeling poor decreases increases (decreases) feelings of shame (pride) associated with deals. Finally, we then examine contexts that minimize the unpleasant feelings financially deprived individuals have towards discounts and hence enhance their adoption of them.

Study 1 was conducted among 81 participants in a field setting: at either a check-cashing or pay day lender site. Participants imagined purchasing high-end shoes available at a 20% discount and reported their attitudes towards the offer (e.g., the extent to which they felt that paying full price was a waste of money). Participants reported their ability to spend money freely as a proxy for their financial standing. Results supported our predicted negative relationship between financial deprivation and deal receptiveness. The more people felt unable to spend freely, the less they felt that paying full price was a waste of money, $p = .02$.

Study 2 tested the causal relationship between subjective wealth and receptiveness towards discounts. We asked 242 participants on Amazon's Mturk to imagine the purchase of discounted shoes at a second-hand store, and to indicate how purchasing the discounted items would make them feel. Consistent with the results from Study 1, those who felt worse off financially (M = 2.79, SD = 2.23) indicated feeling more ashamed, relative to participants who felt better off financially, (M = 2.24, SD = 1.81), $F(1, 226) = 4.21$, $p = .041$. In addition, those feeling worse off financially (M = 1.71, SD = .88) indicated feeling more distressed while reading about the scenario, as compared to those led to feel better off financially (M = 1.38, SD = .70), $F(1, 226) = 10.02$. Together, Study 1 and 2 suggest a negative relationship between subjective wealth perceptions and the extent to which people are amenable to discounted offers. These effects occur both when the discount is available at "high end" and "thrifty" locations, mitigating the possibility that norms (e.g., appropriateness of spending, desirability of spending) contributed to the effect.

Study 3 investigated deal receptiveness in a different context. After manipulating participants' perceived financial standing, we

asked participants to imagine a buy one, get one (BOGO) offer for a more utilitarian purchase: their preferred shampoo. They indicated their agreement with two statements regarding the offer using a seven-point scale (1 = strongly disagree, 7 = strongly agree): (1) "The offer is a good deal" and (2) "I would accept the offer". These measures were used as a proxy for consumers' receptiveness to the deal (r = .82, p < .001). As expected, evaluations of the deal were lower in the financially deprived (M = 3.93, SD = 1.79) versus privileged condition (M = 4.36, SD = 1.73; F(1, 287) = 4.39, p = .037. Consistent with patterns found in Study 1 and 2, participants in the deprived condition (M = 1.76, SD = .96) reported feeling more ashamed and distressed than did participants in the privileged condition (M = 1.53, SD = .81), F(1, 287) = 4.58, p = .033, and participants in the privileged condition (M = 2.13, SD = 1.03) reported feeling more proud and excited than did participants in the deprived condition (M = 1.87, SD = 1.04), F(1, 287) = 4.43, p = .03.

Study 4 tested one method of boosting preferences for discounted offers. Previous work (Sharma and Keller 2016, unpublished manuscript) has shown that people who feel poorer are more amenable to opportunities to earn rather than save. Accordingly, we aimed to reframe discounted offers as opportunities to "earn / get" money rather than to "save" money. We tested this intervention using a sample of individuals who were led to feel financially deprived and found the anticipated results. Financially deprived individuals rated the discounted offer as more attractive in the "earn / get" condition as compared to the "save" condition, M_{earn} = 4.27, SD = 1.92; M_{save} = 3.66, SD = 2.04; F(1, 232) = 5.38, p = .02.

Results from ongoing follow-up studies provide preliminary evidence of two additional boundary conditions: (1) salience of wealthier peers and (2) attributions associated with the discount. When the context involves non-socially-threatening individuals (e.g., family), or when the use of discounts does not signal one's ability to spend, receptiveness towards discounts increases.

Why Some Prices Are Fairer Than Others

EXTENDED ABSTRACT

When demand for goods and services increases, prices often follow. Airlines and Uber charge more during peak hours, some soda machines raise prices on hot days, and the cost of new prescription drugs can soar with demand. But monetary prices are just one way to ration things that are in short supply. For example, suppose a drought forces a township to regulate water permits. How should it decide who gets the permits? The township can set a monetary price or auction the permits to the highest bidders. It can allocate the permits on a first-come/first-serve basis, which sets a price on time because people must wait in line. It can offer the permits to those with social influence or political connections. It can offer the permits in exchange for labor. And so on.

Previous research has focused on how perceptions of fairness depend on factors related to the firm, such as whether prices change due to increased costs or increased market power (Kahneman, Knetsch, and Thaler 1986). But this overlooks how factors related to the consumer also influence perceptions of whether prices are fair.

Here, we show that consumers believe resources (e.g., time, money, effort) vary in how well they signal preference (i.e., the degree to which someone wants or needs something). For instance, offering a lot of money may not be a clear signal that someone truly wants or needs an item. But offering a lot of time or effort might be. Importantly, perceptions of fairness depend on these preference signals. And pricing and rationing strategies seem fair if they ensure

that the people who want or need something the most are the most likely to get it.

Two factors appear to determine how well resources signal consumer preferences:

(1) Equality. Resources that are equally distributed seem like better signals of preference. (2) Ease-of-use. Resources with scales, magnitudes, and purchasing power that are easy to understand seem like better signals of preference.

We tested this account across three studies.

In Study 1a, participants evaluated how well six resources signaled consumer preferences (money, time, mental energy, physical energy, community support, and social influence). Participants then evaluated how fair it would be to allocate housing according to people's willingness to spend/use these resources. Across resources, the group-level correlation between perceived fairness and perceived preference signaling was strongly positive (r = .97, p < .001), as was the average within-subjects correlation (r = .21, p < .001). To rule out demand effects, in Study 1b we replicated the group-level correlation with a between-subjects design wherein participants rated either the fairness of rationing based on each resource or how well spending each resource signaled preferences (r = .94, p < .001).

In Studies 2a–b, we manipulated preference signaling directly. We presented scenarios in which flu vaccines, high-speed internet, or water during a drought would be offered to those who paid the most money or waited in the line the longest (i.e., spent the most time). We then asked participants to explain, "why the amount of [time/money] someone spends to get something is [not always] a good signal of how much they want or need something." Finally, all participants evaluated the fairness of each policy.

As predicted, participants viewed policies as fairer when they first thought about why spending a resource was a good signal of preferences versus a poor signal of preferences (money: good-signal—M = 2.57, SD = 1.73 vs. money: poor-signal—M = 2.01, SD = 1.36, t(458) = 2.90, p = .004; time: good-signal—M = 3.13, SD = 1.79 vs. time: poor-signal—M = 2.00, SD = 1.40, t(446) = 5.56, p < .001).

Finally, in Studies 3a–b, we tested the two proposed factors that influence preference signaling: equality (i.e., whether the resources are distributed equally) and ease-of-use (i.e., whether the resource's scales, magnitudes, and purchasing power are easy to understand).

Participants read scenarios that described how housing, enrollment for college courses, or leisure events would be auctioned off to the highest bidders. In Study 3a, we manipulated participants' beliefs about whether resources were distributed equally or unequally. In Study 3b, we manipulated ease-of-use (e.g., a currency was volatile or stable, or people did or did not know the rules for using a currency). Participants then rated both the fairness of the auction and whether bids in the auction could be taken as a clear signal of consumer preferences.

In Study 3a, participants perceived the auction to be fairer in the equal condition (M = 4.44, SD = 1.90) than in the unequal condition (M = 2.85, SD = 1.75; F(1, 566) = 107.32, p < .001), and preference signaling mediated the effect of resource equality on fairness (95% C.I. = [–.320, –.075]). In Study 3b, participants perceived the auction to be fairer in the easy condition (M = 4.06, SD = 1.77) than in the difficult condition (M = 3.00, SD = 1.65; F(1, 581) = 55.51, p < .001), and preference signaling mediated the effect of ease-of-use on fairness (95% C.I. = [–.513, –.248]).

This research shows that consumers believe resources vary in how well they actually reveal one's preferences. These beliefs, in turn, influence whether people perceive prices as fair, which has implications for how we consider a range of policies, from surge pric-

ing to the allocation of government assistance. Our findings, therefore, can better inform how marketers and policymakers alike might respond to spikes in demand.

The Negative Consequences of Petty Exchange

EXTENDED ABSTRACT

Informal exchanges of resources—including money and time—are prevalent in our daily lives. We may send gift cards for a favor received, split a bill from dinner, or spend time with a colleague to brainstorm. One factor deemed as important in these situations is the objective value of a resource: in other words, giving "more" improves the quality of interpersonal relationships (e.g., Cotterell, Eisenberger, & Speicher, 1992; Flynn, 2003; Flynn & Adams, 2009). We argue that the quality of interpersonal relationships does not solely depend on giving (and receiving) more; it also depends on how petty—being deliberately attentive over trivial details—the exchange feels.

We first establish a contextual boundary by demonstrating that the negative impact of pettiness is unique to interpersonal relationships. Study 1 recruited participants with Venmo or Paypal accounts, who were assigned to interpersonal or impersonal conditions. Those in the impersonal condition saw Venmo histories of two individuals: one listed petty money transfers to three companies ($9.99, 34.95, 20.05), and another listed round money transfers to the same three companies (10, $35, $20), each summing up to $65. Participants in the interpersonal condition also saw petty and round transfers—but to three individuals. When asked with whom they would rather be friends with, 81% in the interpersonal condition chose the individual with round payments, far more than those in the impersonal condition (50%; p<.001), suggesting that pettiness is unique to interpersonal exchanges.

Studies 2a and 2b further examined the effect of pettiness with money. In Study 2a, participants rated a person who paid $9.99 for $9.99 owed, $10 for $9.99 owed, or $10 for $10 owed when splitting the dinner bill. There was no difference in evaluations between the two $10 conditions; however, the giver who paid $9.99 was disliked more (p<.001), suggesting that people expect others to round up, rather than paying the exact amount owed.

But, could pettiness cause harm even when the amount given is objectively larger than a non-petty amount? Study 2b participants evaluated an individual who gave them a $4.85, $5, or $5.15 gift card in return for a favor. Participants in both $4.85 and $5.15 conditions disliked the giver more than those in the $5 condition (p<.001; p=.03 respectively), despite that $5.15 was higher than $5.

Study 3 examined whether pettiness can manifest through a different type of resource: time. Participants whose relationship status was single participated in an online dating simulation and saw a match. In addition to other information, they also saw what their match had responded to the following scenario—"Your friend is moving to a new home this Saturday and needs some help with moving large pieces of furniture. He/she texts you, asking if you are free to help. What would you text back?"—in one of three different ways: that he/she can help from 1-3pm, 1-2:56pm, or 1-3:04 pm. Those in the 3pm condition were much more likely to accept going on a date (61%) than those in the 2:56pm (35.7%) or in the 3:04pm (43.4%) condition, providing additional evidence that pettiness breeds social avoidance.

Studies thus far operationalized pettiness by manipulating the precision of the amount offered. Here, we operationalize pettiness in two additional ways: an explicit rationale that acknowledges one's act of monitoring (study 4a) and an action that implicitly signals

one's intention to monitor (study 4b). In study 4a, all participants read that they helped their neighbor by driving him to a wedding 3 hours away. They further read that the neighbor offered either to get premium gas for $3.29 to make it the same price as taking a round trip bus ride, or to get regular gas for $3.09. Despite that those in the premium condition received a clearly better option, participants liked the neighbor significantly less than those in the regular condition (p=.01) and found the relationship more transactional (p=.001). Perceived transactionality mediated the relationship between pettiness and liking (95% CI: .14, .60).

In study 4b, participants read about a friend who is spending an hour to help them. Those in the petty condition also read that she had turned a timer on to keep track of time. When asked which 5-minute task they preferred to complete—writing a positive note to the friend or responding to an essay prompt—those in the petty condition were less willing to write a positive note (55.8%) than those in the non-petty condition (69%, p=.01), despite that in each condition, participants received an hour of their friend's time. Those in the petty condition also found the relationship more transactional (p<.01), which mediated the relationship between pettiness and preferred choice (95% CI: -.88, -.24).

Study 5 examined whether removing intentionality can mitigate the negative impact of pettiness. Participants evaluated a person who had given a $10 or $13.50 cafe gift card. They also saw that the café's website listed $13.50 as a default option or did not. If $13.50 were a default option, one would infer that the giver did not intentionally give $13.50. There was a significant interaction (p<.001): among those who did not see $13.50 as a default, participants found the relationship more transactional after receiving $13.50 over $10, which led them to evaluate the giver more negatively (95% CI: .11, .31). However, this pattern reversed when participants knew $13.50 was a default option, and perceived transactionality no longer mediated the relationship (95% CI: -.09, .09).

Six studies, featuring everyday exchanges of goods, money, and time, examined how pettiness can engender negative consequences, even when the petty amount is objectively larger. We also documented the process behind this effect: pettiness makes the relationship feel more transactional, reducing liking and social preference. With the rise of digital tools that facilitate exchanges of resources, we constantly face the question of "how much should we give?". While one may intuit that being attentive to small details signals a more valuable relationship. However, our results indicate otherwise: choosing not to be petty could make your friendships healthier, and may even give you a second date.

Paper #4: Introducing the "Calories per Gram" Label to Promote Healthy Food Choices

Julio Sevilla, University of Georgia, USA
Brian Wansink, Cornell University, USA

SESSION OVERVIEW

The purchase and consumption environment for food choices provides a myriad of environmental cues for consumers to navigate. For example, prior research reveals that consumers miss important health information by allocating their attention toward certain labels and environmental information rather than more important health cues and caloric density (Wansink and Chandon 2006; Wansink 2004). Further, poor estimation of container volume leads consumers toward unhealthy food choices (Chandon and Ordabayeva 2009), and due to financial savings consumers will even sacrifice health goals (Haws and Winterich 2013).

So, how do consumers miss important information or deviate from planned health decisions? The various factors impinging on cognitive resources can severely alter or nullify healthy choices. Ambient music, the weight of a food tray, a higher or lower price than expected, and difficult to understand labels can all influence consumer decisions in regards to healthy choices, and this session seeks to shed light on each of these areas. As a whole, this session tries to answer the following question: How can factors apart from the food itself specifically impact healthy consumption behavior? Further, what can be done to mitigate poor choices when consumers are overwhelmed by environmental information? The papers in this session address these and other gaps in understanding environmental influences on health perceptions and healthy decisions by showing the following: 1) healthy choices increase in the presence of a low volume level of ambient music, 2) an increase in physical burden on consumers during a shopping episode leads to less healthy decisions, 3) consumers utilize pricing information when the healthiness of a product is ambiguous, and 4) presenting nutrition information in a new format (Calories per Gram) can improve food choices.

First, Biswas, Lund, and Szocs show that the ever present ambient music in eateries and stores plays a critical role for healthy decision making. Following, Tal et al. demonstrate the propensity

for physically depleted consumers, even if this depletion is somewhat minimal from such things as carrying bags, to make less healthy food choices. Next, Haws, Reczek, and Sample expose the intuition that healthy food is more expensive, and demonstrate how this belief affects perceptions of the healthiness of food and the importance of associated health claims. Finally, Sevilla and Wansink establish the usefulness of the presentation of nutritional information through a Calories per Gram label as compared to the ubiquitous Nutrition Facts panel. They show that the use of this format helps consumers understand the relationship between calories and serving size and leads to less caloric intake in subsequent consumption opportunities. Together these findings show that there are countless environmental factors that may alter healthy consumer behavior.

This session offers a new appreciation of consumers' health choices with respect to environmental cues. Not only do these papers provide insight into understanding the complexity of food decision making, they also move us further in our ability to market responsibly and protect consumer welfare by understanding how the environment is impacting and being utilized by consumers in relation to healthy food choices.

Ambient Music and Food Choices: Can Music Volume Level Nudge Healthier Choices?

EXTENDED ABSTRACT

We examine how ambient music might influence choices between healthy and unhealthy options. Our choice of a sensory factor, such as ambient music, to nudge healthful consumption is influenced by the fact that sensory cues tend to influence behavior in subliminal manners (Biswas et al. 2014) and hence such cues are non-restrictive in nature and as a result are often more effective than restrictive regulatory policies.

While prior research has examined several interesting factors that can influence choices between healthy and unhealthy options (Romero and Biswas 2016), no study, to the best of our knowledge, has examined how ambient music might influence choices between healthy/unhealthy options. Similarly, while extant research has examined effects of ambient music for a wide range of factors (Garlin and Owen 2006), the effects of ambient music on choices between healthy and unhealthy options have been unexplored.

Focusing on the effects of ambient music on food choices is practically and theoretically relevant, especially since ambient music is ubiquitous at almost all types of restaurant/retail outlets. While there are several dimensions to music, we focus on music volume mainly because from a managerial perspective, it is the easiest to change at very short notice and without much resource commitment. Also, examining cross-modal influences of an auditory-based sensory cue like ambient music loudness on eating behavior can provide interesting conceptual insights.

Loudness of any sound, including ambient music, is the energy associated with the sound. When music is played in the ambience, the sound waves get transduced into neural impulses by the inner ear and the neural information then travels through the brain system to reach the auditory cortex (Zatorre 2005). While it is still not clear as to how music loudness can influence physiological reactions through the neurophysiology system, one plausible explanation put forward is that music influences motor and physiological reactions through

sensory-motor feedback circuits (Zatorre 2005). Hence, loud music tends to make people lively and the loudness level of ambient music tends to have a direct effect on heart rate and arousal, whereby louder ambient music tends to increase overall heart rate and arousal level (Edgeworthy and Waring 2006). In essence, louder music tends to make people more excited and aroused (Witt 2008). In contrast, lower levels of music volume (in the range of around 50 dB) tend to make people relaxed and calm (Nilsson 2009).

Higher levels of excitement (and stress) tend to enhance preference for high energy and high fat foods (Oliver et al. 2000). This is probably because sweet and fatty foods help in reducing high levels of excitement (and stress) levels (Gibson 2006). Moreover, when emotionally charged up or upset, internal restraints and self-control break down, leading to greater eating of unhealthy foods (Baumeister 2002). The opposite pattern of effects occurs when people are in a relaxed state, whereby there is greater self-efficacy for controlled eating under higher levels of relaxation (Manzoni et al, 2009). This implies that lower (vs. higher) volume ambient music will lead to healthier food choices. Accordingly, we hypothesize that low (vs. high) loudness levels of ambient music will enhance choice likelihood of healthy food options. We empirically test this with three studies.

Study 1 was a field experiment conducted at a café in collaboration with the café management. The study had two manipulated conditions – low (55dB) versus high volume (70 dB) of ambient music being played on two random days. The volume levels were determined based on prior research (Witt 2008). The key measure was café patrons' food/beverage purchases from the menu. The items from the menu were a priori coded as healthy, unhealthy, or neutral. We focused only on the "healthy" and "unhealthy" items. A higher percentage of healthy items were sold when the ambient music loudness level was low (vs. high) (42.92% vs. 32.49%; $\chi^2 = 4.79$, $p < .05$). This supports our hypothesis.

Next, study 2 replicated these effects in a lab setting and also compared the outcomes to a control condition. The study had three between-subjects manipulated conditions (ambient music: absent vs. low volume vs. high volume). The choice options involved choosing between a fruit salad and a chocolate cake. The results of a logistic regression show a significant effect of ambient music condition on food choice (Wald $\chi^2 = 6.63$, $p < .01$). Follow-up tests show that consistent with our hypothesis and the findings of study 1, participants chose healthier options to a greater extent with low (vs. high) volume ambient music (86.36% vs. 56.52%; $\chi^2 = 4.87$, $p < .05$). Also interestingly, the choice outcome for the control ("no music") condition was similar to the "high volume" condition (50.0% vs. 56.52%; $\chi^2 = .21$, $p = .65$) and significantly different from the "low volume" condition ($\chi^2 = 7.09$, $p < .01$).

Next, study 3 directly examined the underlying process. If our theorizing holds, then the effects observed in studies 1 and 2 should be weakened when relaxation is induced. Study 3 tested this hypothesis with a 2 (ambient music volume: low vs. high) X 2 (relaxation induced vs. not) between subjects experiment. The first factor was manipulated in the same manner as in study 2. The second factor was manipulated through a relaxation priming task. Fruit salad and chocolate cake were the healthy/unhealthy options.

The results of a logistic regression reveal a significant interaction effect ($\chi^2 = 3.88$, $p < .05$). When relaxation is not induced, consistent with the effects observed in studies 1 and 2, low (vs. high) volume ambient music leads to healthier choices (83.33% vs. 54.17%; $\chi^2 = 4.75$, $p < .05$). In contrast, inducing relaxation attenuates this effect (80.0% vs. 82.76%; $\chi^2 = .06$, $p = .81$).

The results of our experiments show that consumers tend to have higher preference for healthier options when ambient music is of low volume versus when it is high volume or absent. Relaxation induced by music volume seems to be the underlying process for these effects. Our findings have implications for cross-modal influences of auditory cues on food choices.

Heavy Choices: Exertion and Food Choice Healthiness in Field Settings

EXTENDED ABSTRACT

Food choices are determined by a variety of situational factors, with consumers' own physical states playing a central role. A broad range of factors from consumers' hunger (Tal and Wansink 2013; Wansink et al. 2012) to their emotional states (Oliver et al. 2000) alter food choice, and specifically affect healthiness and quantity eaten. In general, many consumer choices in the food domain are not deliberative, and so are prone to a variety of environmental influences (Wansink 2004).

One central factor that interferes with food choices is consumers' cognitive resources. Consumers have limited resources available to monitor and control choices (Baumeister et al. 1998). Resource depletion interferes with consumer choice in general (Baumeister et al. 2008). Generally speaking, reduced resources prevent consumers from exerting self control, and so result in increased impulse purchases (Baumeister et al. 2002; Faber and Vohs 2004).

In the context of food, resource depletion can translate to increased eating or choice of less healthy foods (e.g., Shiv and Fedorikin 1999; Hofmann et al. 2007). Resistance of tempting foods requires regulatory resources, such that even exposure to them can deplete regulatory resources (Muraven et al. 1998). Exposure to tempting foods in choice settings in turn presents consumers with a task that requires them to override the natural pull of the tempting foods by engaging regulatory resources to exert control. Consequently, when depleted, consumers engage in more indulgent eating behavior (Vohs and Heatherton 2000).

A range of activities can rob consumers of their cognitive resources. Suppressing thoughts, feelings, and engaging in cognitively demanding tasks can all deplete resources (Muraven et al. 1998). Even making effortful choices all deplete consumers regulatory resources (Vohs et al.2014), and result in impairments in subsequent decision making.

Notably, most documented evidence demonstrating ego depletion demonstrates depletion following tasks that require cognitive, rather than physical, effort. However, it is now known that regulatory resources correspond to certain physical realities, such as the body's glucose levels (Galliot et al. 2007). From that perspective, anything that saps the body physically should lead to subsequent deterioration in self control. In the context of food, this would translate to increased eating.

In the current work, we explore whether physical depletion, generated by carrying heavy weights in the form of shopping bags (study 1), people's own backpacks (study 2), or serving dishes such as plates (study 3) does indeed lead to increased eating. Studies 1 and 2 provide field demonstrations of the phenomenon, whereby burdened consumers choose more caloric (study 1) and less healthy (study 2) foods. Study 3 explores the phenomenon in a more controlled lab setting.

In our first study, trained observers recorded the number of shopping bags held by shoppers (N = 178) at eight food courts across the US and estimated the calories in their meals. The researchers were blind to the hypotheses of the study, and recorded a series of

other variables to preclude guessing of the hypotheses. Though such estimates cannot be precise, prior to observation, researchers underwent training in calorie estimation. When possible, researchers used objective calorie measures for the foods ordered. Those carrying a greater number of packages ordered foods with a greater number of calories: $F(1, 176) = 5.47$, p = .02. The findings demonstrate that the extent of burden is associated with choice of higher calorie meals.

In study 2, we wished to focus on choice healthiness rather than quantity, and demonstrate that burden influences not merely caloric pursuit but general healthiness of food. Further, we also measured subjective exertion to show its role in influencing food choice, by measuring perceived heaviness of the bags they carried on a scale of 1 (light) to 7 (heavy). We recruited cafeteria attendants (N = 87), and recorded their choices among 7 dishes offered in the cafeteria, coded as healthy or not according to pre-set standards. We found that participants who perceived their bags as heavier chose less healthy foods: p = .029.

To test the results in a more controlled setting, we conducted two lab studies. In a follow up lab study utilizing heavier (1252 grams) and lighter (491 grams) plates, participants carrying heavier plates chose a greater number of unhealthy foods (2.64 vs. 1.81) in a binary choice task, $F(1,51) = 6.63$, $p = .013$.

Burden appears to lead to choose less healthy and serve more food. Engaging in a physically effortful activity such as carrying a heavy backpack or even serving dish reduces regulatory resources, leading to increased food consumption. We demonstrated this across a range of stimuli that are prevalent in consumers natural environments, in both field and a lab setting, and with ecologically valid choices, demonstrating the importance of the phenomenon to actual consumer behavior.

Healthy Diets and Empty Wallets: The Healthy=Expensive Intuition

EXTENDED ABSTRACT

Is this food healthy? Tasty? Affordable? Satisfying? Consumer decision making regarding foods is a belief-laden, complex, and important issue significantly impacting overall health. Prior research examining consumer lay theories with respect to food consumption has shown this, such as the belief that unhealthy products are tastier (Raghunathan et al. 2006). Clearly, underlying beliefs in the relationships among the various factors driving food choices are critical in understanding food decision making.

Health and financial concerns are two factors subject to consumer beliefs that are often in conflict in consumer decision making, for example when offered super-sized pricing, consumers value finances over health by choosing larger sizes with lower unit-prices (Haws and Winterich 2013). Rehm et al. (2011) and Larson et al. (2009) have provided evidence suggesting that a healthier diet may indeed be more expensive, but Carlson and Frazao (2012) have demonstrated that unhealthier diets can be more expensive depending on how it is assessed. Therefore, an understanding of the beliefs behind these factors of health and cost is crucial in understanding food decision making. We examine beliefs about the relationship between the healthiness and expensiveness of food products at the level of the individual consumer in a series of experimental studies, proposing and demonstrating that consumers incorporate a lay theory that healthier products are more expensive, leading to intuition-based inference making, food choice, and more global evaluations of health claims.

In study 1, 108 MTurk participants were provided with information about the health grade of a granola product, with the grade being either an "A-" or a "C". Following this manipulation, partici-

pants were asked to rate how expensive they thought the product would be compared to other similar products on a 7-point scale. As expected, the product rated as healthier was perceived to be more expensive than the less healthy product ($M_{healthy}$ = 5.15 vs. $M_{unhealthy}$ = 4.51, F (1, 106) = 6.29, p<.05).

In study 2, we simultaneously examined how information about product price impacted perceptions of healthiness and how information about healthiness impacted perceptions of product price when the actual food product was consumed. After being provided with information about either the price ($.25 or $2.00) or healthiness level (independent health grade: A- vs. C), participants were asked to indicate the relative healthiness and expensiveness of the product compared to other similar types of products. We examined the contrast of healthiness perceptions based on the cheap versus expensive manipulation and found that the cheaper product led to lower perceptions of healthiness than did the more expensive product ($M_{expensive}$ = 4.77 vs. M_{cheap} = 3.83, t(137) = 2.97, p<.01). Similarly, the less healthy product led to lower perceptions of expensiveness than did the healthier product ($M_{healthy}$ = 4.34 vs. $M_{unhealthy}$ = 3.51, t(137) = 5.64, p<.001). The results of this study suggest that the healthy = expensive intuition operates in both directions, that is, when an item is positioned as more expensive, consumers perceive it to be healthier, and when a product is positioned as healthier, consumers perceive it to be more expensive.

In study 3, we presented 38 participants a scenario in which they were in charge of choosing an entrée that would better meet a goal to be healthier. Following a health goal prime, participants were presented with two different chicken/pasta dishes selected to be similar in terms of healthiness, based upon actual nutrition information. We counterbalanced which option was more expensive, using price points of $15 and $22, and the order of presentation of the options was randomized for each participant. A chi-square test revealed differences in choice selections consistent with the notion that whichever option was more expensive was selected to be more likely satisfy the healthier goal (Chi-square = 5.16, p<.05). Essentially, choice shares between the options reversed such that whichever entrée was listed as the higher price was selected more than twice as often as the other option. Therefore, study 3 provides evidence that beliefs about the link between healthiness and expensiveness impacted choice.

In study 4, the 197 participants were asked to make a series of choices structured as a grocery shopping trip for a family of four. Half of the participants were explicitly told to imagine that they were on a budget. Participants were presented with 26 grocery choices, 13 of which were pairs pretested to differ in healthiness perceptions. An analysis of the number of choices of the less healthy products show that the participants in the budget condition were less likely to choose the healthier products ((M=5.69) than those in the control condition (M=7.17; $F(1,195)$=14.30, p < .001), indicating that when given a goal to conserve money, participants chose less healthy options as a means to do so.

Finally, study 5 examines how beliefs that healthy=expensive impacts broader beliefs about healthiness. Specifically, 115 participants were shown a set of 4 trail mix options in which one mix was labeled as the "Perfect Vision Mix" and said to contain DHA for eye health. Participants either saw a price consistent with the other three options or 20% higher for the focal trail mix. In this case, the dependent measures were perceptions of the importance of DHA and intentions to take actions related to consuming DHA and protecting eye health. All four measures (i.e., "How important is it that a healthy diet include DHA?" 1 = not at all important, 9 = very important) showed that seeing the premium price increased perceptions of the importance of the DHA/eye health claim. For example, those

in the higher price condition thought that DHA was a more important part of their diet than did those in the average price condition (M_{high}=4.93 vs. M_{low}=4.11, $F (1, 114)$=4.89, $p < .05$). .

In summary, we have established a basic link demonstrating a consumer lay theory linking healthiness and expensiveness. This intuition led to lay inferences regarding perceptions of health and price, differences in choice patterns, and more general perceptions of the importance of health claims, suggesting significant implications for food decision making.

Introducing the "Calories per Gram" Label to Promote Healthy Food Choices

EXTENDED ABSTRACT

Past research has shown that consumers tend to make unhealthy food choices even when they attend to caloric information and intend to make healthy decisions (e.g. Balasubramanian and Cole 2002). One factor responsible for such problem is manufacturers' lenient following of the regulations provided by the Nutritional Label and Education Act (NLEA) of 1990, which establishes the portion size that constitutes one food serving. Despite this regulation, manufacturers regularly report smaller serving sizes than established by the NLEA, often with the intention to lead consumers to believe their products have fewer calories and are healthier than they actually are (Mohr, Lichtenstein and Janiszewski 2011). Given eating restrained consumers' (Herman and Polivy 1980) tendency to look for licenses to indulge (e.g. Fitzsimons, Nunes & Williams 2007; Wilcox et al. 2009), it is not surprising that they tend to interpret the ambiguity of such caloric information in a way that allows them to maximize consumption (e.g. Aydinoğlu and Krishna 2011). Furthermore, serving size issue aside, consumers often overvalue the importance of consuming a product containing an absolute lower number of calories (e.g. a small donut vs. a large bagel) to the detriment of attending to other important food attributes such as caloric density (e.g. Wansink 2004), that is, the relationship between the size of a food item and the absolute number of calories it contains. Caloric density has been shown to be an important predictor of caloric consumption (Rolls et al. 2004), as people become more full by the weight of a food than by the amount of calories it contains (Rolls, Bell and Waugh 2000; Rolls et al. 1998; Rolls, Morris and Roe 2002). Thus, this suggests that consuming foods that are high on caloric density often results in an overall higher amount of calories ingested.

These past findings suggest that consumers may benefit from cues or instruments that hint them towards consuming foods that have a lower number of calories per gram or a lower caloric density, even if they contain a larger amount of calories due to their higher volume (e.g. a large bagel vs. a small donut), since these are more satisfying and will likely decrease subsequent consumption. The current work aims to introduce and test the effectiveness of one such tool: the "Calories per gram" label. By introducing this instrument, we aim to teach consumers to make more informed and healthier food choices that may lead them to reduce their total caloric intake. We argue that this metric achieves this objective by allowing consumers to easily compare the caloric density across different options that may vary on their weight and total calories.

In four studies we show that the "Calories per gram" label leads consumers to reverse their choices in favor of healthier options that have a lower caloric density (fewer calories per gram) even when these have an absolute higher number of calories. Study 1 (N=288) showed initial evidence in favor of the effectiveness of the label in a design where participants selected a bagel or a donut. In this study the bagel had a higher number of calories than the donut but

a lower calories per gram ratio. We obtained that when participants only had access to the traditional nutritional information they were more likely to pick the donut (M_{donut}=52.8%) and believed this item was healthier (M_{donut}=53.5%). However, this pattern reversed in the presence of the label, as people were more likely to pick the bagel (M_{bagel}=61.8%; $z = 2.49$, $p = .01$) and believed it was healthier (M_{bagel}=62.5%; $z = 2.72$, $p < .01$). This suggests that using the label nudges consumers towards making healthier choices and helps them realize which item is healthier even if it has an absolute higher number of calories.

Study 2 (N=160) used a similar paradigm and replicated the effect with the use of packaged products: granola bars and chocolates. As expected, we obtained that the healthier item, the granola bar, was more likely to be chosen (M=65.5% vs. M =34.2%; $z = 3.95$, $p < .0001$) and was perceived to be healthier (M=90.5% vs. 68.4%; $z = 3.48$, $p < .001$) when presented with the "Calories per gram" label than when only featured with the traditional nutrition information. Furthermore, we showed that the effect of the label on choice was mediated by healthiness perceptions associated to the products [LLCI: .11 to ULCI: .82].

Study 3 (N=274) showed that merely featuring the label can improve a manufacturer's choice share and healthiness perceptions. Specifically, in this design we compared two potato chips products that had the same nutritional information but that differed on how healthy participants perceived each brand to be: Cape Cod and Kettle. We showed that while Cape Cod was more likely to be chosen and was perceived as healthier when only calories and grams ($M_{Cape-Cod}$ =63.0% vs. M_{Kettle} =37.0%; $z = 3.54$, $p < .005$) or only calories were presented ($M_{Cape-Cod}$ =64.8% vs. M_{Kettle} =35.2%; $p < .05$), this effect was neutralized in the presence of the label, as in these cases Kettle was perceived to be similar to Cape Cod in terms of choice share ($M_{Cape-Cod}$ =52.7% vs. M_{Kettle} =47.3%; $z = .74$, $p = .46$) and perceived healthiness ($M_{Cape-Cod}$ =54.9% vs. M_{Kettle} =45.1%; $z = 1.33$, $p = .18$).

While the initial studies showed the effect in a computer-based setting, study 4 (N=193) did this in a real context in which they chose between a bagel and a donut. Furthermore, this study confirmed our prediction that picking healthier items that have an absolute higher number of calories but a lower "Calories per gram" ratio due to the presence of the "Calories per gram" label leads consumers to ingest fewer calories in subsequent consumption opportunities. Specifically, we demonstrated that those that picked and consumed the bagel against the donut after being exposed to the label ate less granola trail mix when invited to consume such item freely (M_{Bagel} =17.76 vs. M_{Donut} =29.07; $t (103) = 2.78$, $p < .01$).

SESSION OVERVIEW

Since the early days of marketing, next to product- and distribution-related decision, marketing communications and pricing have always been of utmost importance. From a consumer research point of view, it is vital to understand the effects of any such marketing activity on the cognitive and affective information processing as well as on the decision-making of the consumer. Traditional methods of marketing and consumer research can capture those effects only to a certain extent. Consumer neuroscience, as a joint discipline between neuroscience and consumer research, provides an additional approach to add to our current understanding of why and how marketing actually works. Studies within the area of consumer neuroscience may support, help refine or reject established theories. Consumer neuroscience aims at extending our knowledge by adding biological data to complement our understanding of human consumption behavior. Currently, this understanding is predominantly based on behavioral and psychological data. While having started as a niche-phenomenon about two decades ago, today, consumer neuroscience has its fixed place in the consumer researcher's toolbox. In our special session, we want to provide examples of how consumer neuroscience can advance knowledge in regards to selected fundamental concepts of our discipline. In particular, we provide examples on how consu-mer attitudes and preferences as well as consumer decision-making can be explained within a consumer neuroscience context. We discuss neural findings on consumer behavior-related phenomena as a result of cognitive (impact of pricing) and affective (effect of communications) information processing. The main objective of this special session is to broaden our horizon and way of thinking about fundamental concepts which have been relevant to marketing ever since (e.g., price knowledge and effectiveness of advertising). Our four papers presented in the special session will showcase empirical examples which provide a solid basis for a joint discussion on the added value of neural data to better understand fundamental phenomena in marketing and consumer research. We also want to discuss the potential difficulties and challenges that might come with applying neuroscientific methods to resolving questions relevant to consumer behavior. Hence, our four papers raise the following two joint questions for a comprehensive discussion:

What in particular can we learn about selected fundamental concepts of marketing and consumer research by using neuroscientific methods?

How does consumer neuroscience provide added value to our discipline and what can it not provide?

This special session was organized by Monika Koller, WU Vienna. In the following, we present the extended abstracts of the four papers included in our special session.

Emotional Responses to Movie-Trailers Predict Individual Preferences for Movies and Their Population-wide Commercial Success

EXTENDED ABSTRACT

Consumer neuroscience, applying neuroscience methods to marketing, has gained considerable popularity in recent years amongst scholars and practitioners alike (Smidts et al., 2014). As noted by Ariely & Berns (2010), there appear to be good reasons for this enthusiasm. First, because brain data are considered to be less noisy than data obtained through conventional marketing methods, it is thought that data from smaller samples can generate more accurate predictions, making neuroscience methods cheaper and faster than traditional methods. Second, it is believed that neuroimaging methods could provide marketers with information that is not obtainable through conventional marketing methods. This idea is based on the assumption that people cannot fully articulate their preferences when asked to express them explicitly, and that consumers' brains contain hidden information about their true preferences.

Indeed, several decades of research in psychology have shown that many important mental processes occur below the surface of consciousness (Dijksterhuis, 2004), leaving people very limited in their ability to predict their own future behaviour and to accurately identify their internal mental states through verbal or written self-reports (Nisbett and DeCamp Wilson 1977). These issues with self-report data are particularly problematic in the measurement of emotional responses. This is a particularly salient problem because marketing researchers have observed that the emotions evoked by marketing stimuli are important determinants of commercial success and sales. That is, advertisements that manage to evoke the strongest (usually positive) emotions are considered to be the most effective

(Batra & Ray, 1986). However, accurately measuring these emotions is not straightforward due to the limited capacity for introspecting on sub-conscious processes. Moreover, reporting on these processes with a high temporal resolution (for example every second for a video stimulus), might actually alter the ongoing emotional process (Wilson and Schooler 1991).

For the present paper, we set two goals: (1) decode the emotional experience from our participants' brains while they were exposed to marketing stimuli, without relying on self-report, and (2) use this decoded emotional experience to predict individual preferences and choices as well as sales in the population at large.

We had participants perform two tasks, while undergoing fMRI scanning. In the first task, participants passively viewed photographs selected from the IAPS database to represent the four quadrants of affective space (positive and negative valence, and high and low arousal). In the second task, participants viewed cinematic trailers of 18 movies that they had not previously seen. Movie trailers can be seen as advertisements for movies and play a crucial role in the marketing efforts by the movie industry (Gazley, Clark, and Sinha 2011). In addition, we collected both individual stated (willingness to pay) and revealed (choose three DVDs to take home) preference measures, as well as self-reported valence and arousal experienced during trailer-watching. Finally, we obtained US Box Office results of the viewed movies as a measure of population choice/real-world preference.

Our analyses of the data proceeded in several steps. First, we localized the brain areas most strongly associated with processing the emotional content of the IAPS pictures with a support vector machine (SVM) searchlight algorithm. Neural activations from these areas were subsequently used to train two emotion (i.e. valence and arousal) SVM classifiers to predict the emotional content of the IAPS pictures. Then, the trained classifiers were applied to the neural responses during movie-trailer watching to decode the pattern of neural activity at each brain volume into two emotion attributes (i.e. valence and arousal). That is, we classified every brain volume acquired during the viewing of the trailers as either positive or negative in valence, and high or low in arousal. Finally, we took the time course of decoded emotional brain states from every trailer, and tried to predict from this data (1) participants' self-reported emotional state, (2) their preferences and choices with regards to the movies they watched, and (3) the population response to the movies (US Box Office).

The results first showed that the trained SVM classifiers performed well in decoding the emotional content from the brain: using leave-one-out cross-validation, it could predict emotional valence with 57% accuracy (chance = 33%), and arousal with 65% accuracy (chance = 50%). Applying the trained classifiers to the neural data obtained during movie-trailer watching results in two time series (one for valence and one for arousal) of decoded emotional content per trailer and per subject. To test whether these time series actually represent valence and arousal, we tested whether the emotional response decoded from the brain was associated with the self-reported emotional experience. To do this, we aggregated each time series into a single measure of valence and arousal respectively. The results showed that indeed, self-reported experienced arousal could be predicted from our decoded neural arousal measure, while self-reported valence could be predicted from our neural valence measure.

Finally, we tested whether the decoded emotional response was predictive of preference and choice. We found that the neural valence measure was predictive of both stated preference (WTP), as well as revealed preference (the three DVDs they chose to take home). In addition, we found that both the decoded emotional valence, as well

as arousal significantly predicted choice in the population at large (US Box Office). Importantly, while self-reported arousal was also significantly associated with Box Office, self-reported valence was not and the variance in Box Office explained by self-report measures was relatively low (R^2=15%). Adding our neural decoded response measures to this model showed that both decoded valence as well as arousal significantly added to the model and resulted in a significant increase in explained variance (R^2=41%).

Our findings show that, using neuroscience methods, we are able to obtain an implicit measure of the emotional experience evoked by marketing stimuli, and that these measures can be used as a neural marker for commercial success. As such, we provide evidence that neural activations reflecting the emotional experience in response to marketing stimuli are related to real-world outcomes, and that such neural measures significantly add to prediction models of choice behaviour in the population at large.

Neural Prediction of Market-level Crowdfunding Outcomes

EXTENDED ABSTRACT

Although established economic and psychological theories (such as revealed preferences and behaviorism) imply that past choice is the best predictor of future choice (Bernheim, 2008), there may be some fundamental elements of the decision making process that scale more effectively to predict behavior at the market level (Ariely & Berns, 2010). Recent neuroimaging research has demonstrated that neural activity measured in a small laboratory sample can augment behavioral predictors of aggregate behavior (Genevsky & Knutson, 2015). In this work we demonstrate that neural data can predict market-level outcomes in a large consumer marketplace significantly better than traditional behavioral methods.

Crowdfunding refers to the practice of using small financial contributions from a large group of investors to fund new products or ventures. The popularity of crowdfunding on the internet has grown exponentially in recent years, and in 2015 raised over $34.4 billion (Massolution, 2015). Crowdfunding websites offer a unique opportunity for individuals to engage with products as both financial supporters and consumers. However, despite its growing popularity and economic significance, the neural and psychological mechanisms responsible for individual decisions to fund projects have not been explored.

Neural activity has been effectively used to predict individual choices in contexts of consumer purchasing (Knutson, Rick, Wimmer, Prelec, & Loewenstein, 2007)we investigated how people weigh these factors to make purchasing decisions. Consistent with neuroimaging evidence suggesting that distinct circuits anticipate gain and loss, product preference activated the nucleus accumbens (NAcc and financial risk preferences (Kuhnen & Knutson, 2005). Fewer studies, however, have used neural data to predict market-level behavior. For instance, researchers have found neural correlates of aggregate responses to popular music sales (Berns & Moore, 2012), public health message (Falk et al., 2011), and movie box office returns (Boksem & Smidts, 2015). In the present paper, we seek to identify which neural precursors to individual choice best generalize to forecast aggregate behavior. We investigate this question by using neural activity to predict individual and aggregate choices within a crowdfunding context.

To assess the ability of neural activity to predict funding success, thirty subjects (14 female, mean age=23.32) were recruited for a functional magnetic resonance imaging (fMRI) study and asked to make incentive-compatible decisions regarding 36 actual documen-

tary film projects which had been posted online on a crowdfunding website (www.kickstarter.com). We used neural data collected during the task to predict both individual decisions to fund and the real-world funding outcomes of these projects on the internet.

On each trial, participants were first presented with the image from each project page (2 secs), followed by a screen depicting the remainder of the project's brief text description (6 secs). Subjects then indicated whether or not they would like to fund the project using spatially counterbalanced (i.e., left or right) 'Yes' or 'No' prompts by pressing one of two corresponding buttons (4 secs). Finally, subjects fixated on a cross (variable 2-6 secs) until the next trial began. After scanning, subjects rated their liking of each project as well as their predicted likelihood of each project reaching its funding threshold (i.e., perceived project success). Subjects also rated their own affective responses to each of the projects using two scales: one indexing valence (positive–negative) and the other indexing arousal (highly arousing–not arousing).

Neural analysis contrasting whole-brain activity in trials in which subjects decided to fund versus trials in which they did not, indicated significant differences in a defined subset of regions associated with positive affect (i.e., nucleus accumbens or NAcc) and value integration (i.e, medial prefrontal cortex or MPFC). Greater activation in these areas while viewing the projects was associated with eventual decision to fund. This activity occurred before the choice phase of the trial, and thus preceded activity associated with the act of indicating a choice. We next investigated how well laboratory sample behavioral measures and neural activity could forecast market-level outcomes on the internet. A logistic regression model was used to forecast market-level funding outcomes for each of the projects, and included subject's self-report ratings of affect, project liking, and perceived project success, as well as actual funding choices, and neural activity. Of these predictors, only NAcc activity was significantly associated with internet funding outcomes. All other self-report variables and activity in other neural regions of interest were not associated with funding outcomes.

We examined whether affective neural mechanisms could forecast crowdfunding outcomes -- both in individuals, and at the aggregate level of an internet market. While activity in both NAcc and MPFC brain regions predicted individuals' choices to fund in a laboratory sample, only NAcc activity generalized to forecast aggregate funding success. Further, neural forecasts of market-level outcomes outperformed models incorporating self-reported preferences, affect, and even behavior. These results demonstrate in the context of crowdfunding that a subset of the neural mechanisms that predict individual choice can scale to forecast market-level outcomes. The findings also carry the applied implication not only that neural activity might add value to behavioral measures, but may also reveal otherwise hidden information relevant to forecasting aggregate outcomes (Ariely & Berns, 2010). These results highlight a need for marketers and neuroscientists to better understand when, where, and how neural activity can be leveraged to more accurately forecast aggregate choice.

We Are What We Know: Using Consumer Neuroscience to Build a Better Understanding of Price Knowledge

EXTENDED ABSTRACT

Price knowledge (PK) is an important behavioral pricing theme in consumer research (e.g., Kukar-Kinney et al., 2012). However, re-search neglects that PK should not depend solely on product-related or psychological factors, but should also consider neurobiological factors. This neglect is astonishing, given the understanding that PK is stored in consumers' brain memory system (e.g., Monroe and Lee 1999). In addition, there is evidence that PK depends on consumers' individual abilities to remember prices and consists of affective (implicit PK) as well as cognitive (explicit PK) capacities (Kenning & Plassmann 2005). Recent studies in consumer neuroscience show, that the interplay of these processes is at least partially determined by neurobiological processes (e.g., Plassmann & Weber, 2015). As there is at best inconsistent evidence on individual consumer characteristics that determine PK (e.g., Gaston-Breton & Raghubir, 2013), this research tries to answer the following question: Can the integration of neuroscientific methods (i.e., fMRI) lead to a better understanding of PK? The fMRI study was designed to justify the assumptions behind PK and its neural correlates. We propose to find neural activity changes in regions associated with cognitive and affective information processing due the fact that PK has an implicit as well as an explicit component.

In our study, subjects (N=20; 11 female, 9 male healthy, right-handed subjects; M_{age}=41.85 years, SD=3.88) participated in a product-price-decision task (modified task by Knutson et al., 2007) where they had to decide whether or not to buy a certain product for a given price. In order to focus on the processing effect of PK our study has two key aspects: First, we used a fixed product category and only varied decisions with respect to prices. Second, our user sample was pre-screened for consistently using and buying the products. The first parameter used in our study–"price differential"–refers to an explicit and direct integration of the price the consumer saw in the trial before and is defined as the difference of the seen price in t and the price they judged in t-1. The second parameter–"price average"–takes into account that participants develop a more implicit task-dependent PK in the course of the task. This parameter is defined as the average of all prices the participants judged until the current trial. Data analysis was conducted with the SPM8-freeware (Friston et al., 1994) using MatLab as a working base. A General Linear Model (GLM) models events of interest with a parametric modulator for the price phase and decision phase and the two task-dependent PK parameters "price differential" (D_{price_diff}), and "price average" of prices shown before (P_{price_avg}, D_{price_avg})). The parametric modulators were defined as follows: (1) P_{price}/D_{price} = price(t); (2) D_{price_diff} := price(t) – price(t-1); (3) $P_{price\_avg}/D_{price\_avg}$:= mean(price(1:t-1)). We calculated the following first-level single-subject contrasts of interest: 1) decision modulated by D_{price}, 2) decision modulated by D_{price_diff}, and 3) decision modulated by D_{price_avg}. Third, on second-level, for extracting differences of single-subject contrasts between subjects we computed a one sample t-test. Post hoc tests of neural activity changes in regions of interest (ROIs) identified by the second-level group analysis by contrasts of D_{price}, and D_{price_diff} were computed by running three additional GLMs that separated regressors following the procedure in Litt et al. (2011).

To check for behavioral differences in positive judgments between the selected prices, we entered the shares of positive buying intention (pS_{price}) and gender as between subject factor into an one-way ANOVA (with price: [.66;1.24]) corrected for repeated measures using the Greenhouse-Geisser (GG) correction criterion, and found a significant main effect for price; $F(3.011, 54.189) = 26.150$, $p < .001$, but no main effect for gender; $F(1, 18) = 0.243$, $p = .628$, as well as no interaction effect of price*gender; $F(3.011, 54.189) = 0.074$, $p = .425$. For observing a possible integration of task-dependent PK for the given parametric modulators, we checked for inconsistent judgments for a given price level for each participant, which could be confirmed. Additionally, to control for behavioral differ-

ences in inconsistent judgments with regard to the different flavors we entered an interaction term of price shown and $pS_{product}$ to model this possible acceptance bias into an one-way ANOVA (with flavor: [A, J]) and found no significant main effect for flavor; $F (9, 80) = 0.126$, $p = .999$.

Next, we generated statistical parametric maps for the given contrasts of interest (D_{price}, D_{price_diff}, D_{price_avg}) that displayed the t-value of each peak voxel meeting a $p < .001$ (uncorrected) significance level with an extent threshold voxel of $k = 5$. We found neural differences in brain structures associated with integrating background (price) knowledge, decision making and information processing in dependency of the seen product-price combination. In detail, we found that activation in the left medial prefrontal cortex (BA 10), the right and left anterior cingulate cortex (BA 24) and the right parahippocampal gyrus (BA 36) was negatively correlated with the price parameter within the decision phase. Furthermore, we found neural activity changes in brain structures associated with information and knowledge processing according to our task-dependent PK parameters (D_{price_diff}, D_{price_avg}) that differed from the results with regard to the absolute price-level parameter. In detail we found that activation in the insula was positively correlated with increasing price differentials within the decision phase and the parahippocampal gyrus and the caudate were negatively correlated with increasing price averages within the decision phase.

This research helps to provide further understanding of the different aspects of price-dependent decision making in consumers. We demonstrated the complexity of antecedents of price-dependent decision making. The results provide evidence that especially unconscious processes associated with the integration of background (price) knowledge, decision making and information processing influence the brain activation and behavior. First, the integration of explicit and implicit task-dependent PK leads to activity changes in brain regions associated with information processing and decision making and these activity changes differ from the findings with regard to absolute prices. This leads to the conclusion that the integration of PK is a rather complex and dynamic process, depending on various situational factors.

Effectiveness of Print and Digital Media: Insights from Neuroscience

EXTENDED ABSTRACT

Does it matter whether you are reading your favorite novel as a physical book or on a kindle? What are the implications for long-term memory? Given major advances in digital media over the past decade, there has been an emerging interest in comparing print (or physical) versus digital (or electronic) media across various contexts (e.g., Verdi et al., 2002; Terrenghi et al., 2007; Steimle et al., 2010; Kim and Anderson 2008; Millward Brown, 2009; Eden and Eshet-Alkalai 2012). This is a particularly important question in marketing where despite the growing popularity and complexity of managing marketing communications across physical and online media channels (often referred to as cross-media marketing), little is known about the effectiveness of each of these channels and their impact on the consumer buying process.

In this study, we used a novel experimental design involving multiple neurophysiological methodologies (traditional self reports, eye tracking, heart rate, skin conductance and functional neuroimaging, fMRI) to better understand how consumers process print versus digital advertisements. We focused specifically on the differences in cognitive processing across the two formats, both during exposure and retrieval. To overcome the practical difficulties involved with experimental control when participants are interacting with physical stimuli, we conducted the study over two separate experimental sessions with the same set of participants. Both experimental sessions occurred approximately one week apart. A total of 56 participants completed both sessions of the study.

In the first session involving eye-tracking and biometric measures, participants were exposed to a mix of physical and digital ads. A total of 40 ads ranging across CPG products, services and restaurants were used in the study. They were split into two groups of 20 ads each, and randomly assigned to physical or digital condition across participants. Therefore, each participant viewed each ad only once during exposure, in physical or digital format. The digital ads were presented on a Tobii T60XL eye-tracker in the form of emails pre-loaded into offline gmail app. Participants could open the emails in any order and spend as much time as they desired viewing the ads. For the physical ads, they physically placed the ads onto a small platform where the processing could be captured using a combination of camera and eye-tracking system. Processing was measured after they positioned the ads into the platform. The size of the ads was controlled across both formats. At the end of the session, participants were re-exposed to the ads a second time in the same format, while seated in front of a computer. During re-exposure, traditional self-report measures were collected after each ad to measure preferences and attitudes about the ads and their contents. The order was counterbalanced across participants.

We found no significant differences in self-reported preferences and attitudes for the ads between the two formats. Participants spent more time when interacting with physical advertisements ($t = 5.807$, $p < 0.001$). Yet, their eye gazes tended to be more mobile (e.g., greater proportion of time spent on saccades) compared to digital ads ($t = 3.253$, $p = 0.002$). They also had a greater proportion of long fixations (>150ms) when looking at digital ads and spent more time per fixation when processing the ad ($t = -1.834$, $p = 0.072$). Finally, using frequency domain analysis of heart rate variability, we found that digital ads were also associated with greater parasympathetic tone (HF) ($t = 2.552$, $p = 0.015$). Together, these results suggest that digital ads were associated with greater attention and more systematic processing than physical ads (Venkatraman et al., 2014). However, the level of engagement to key components of the ads, such as the products and/or brands featured, showed no differences between the formats. It is possible that the extended exposure time in physical format compensated for lesser attention. We also found converging evidence for greater levels of arousal during exposure to physical ads. The average pupil size was significantly larger when participants viewed ads in the physical format ($t = 9.754$, $p < 0.001$). Similarly, the tonic and phasic skin conductivity were higher at the anticipation of looking at physical ads relative to digital ads ($t = 4.764$, $p < 0.001$).

In order to understand whether the differences in levels of attention and arousal between the two formats were associated with greater depth in processing and improved memory during subsequent purchase decisions, we used functional magnetic resonance imaging (fMRI) in Phase 2 to study memory (item and source) for each of the 40 ads, and purchase intentions (willingness to pay, WTP) for the products and services featured in the ads. We found that participants were more likely to remember an ad and its context if they were previously exposed to it in the physical format. This behavioral difference was corroborated by increased activation in the hippocampus and parahippocampal regions during memory retrieval for physical relative to digital ads. The parahippocampal region has been consistently associated with processing of scenes and places in previous studies (Epstein et al., 1998; Epstein and Ward, 2010).

Therefore, these differences could reflect superior recollection of the context surrounding the ad, when it had been exposed in physical format previously.

Using a BDM auction procedure, participants were asked to provide their WTP for the products and services featured in the ad. There were no differences in the self-reported purchase intentions or willingness to pay for the items featured in the ads based on prior exposure. However, we found increased activation in the ventral striatum when participants were estimating their WTP for items previously exposed in the physical relative to digital format. Based on prior results and the role of this region in reward processing and desirability (Venkatraman et al., 2015), we argue that exposure in physical format could lead to increased desirability for the products and services featured in the ad.

In summary, our findings have tremendous practical implications for marketers and marketing theory. By demonstrating the complementary nature of the two formats using a carefully controlled experimental design, we provide valuable insights for marketers to optimize their media mix.

SESSION OVERVIEW

Technological innovation is transforming many aspects of consumers' lives – how we shop, how we use services and incorporate them into our lives, how we work, how we obtain information, how we pursue our everyday goals (Manyika et al. 2013). Despite these transformational technologies, little consumer research has examined the effects of using and interacting with technology on consumers' lives. The goal of this session is to explore the various and often unexpected ways that interactions with new technologies can affect consumers' information-processing and decision-making. Together the four papers examine various dimensions of this question: the extent to which technology affects consumers' self-concept and becomes a part of their extended self, the extent to which it affects consumers' goal purist, purchasing behavior, and the reactions the technology triggers when it fails.

Specifically, in paper #1, Brasel examines which type of technological feature (i.e., touch versus voice interface) is more internalized into the self as consumers interface with technology-based offerings. In paper #2, Heß and colleagues explore the influence in-store consumer tracking technology can have on consumers' self-concept and downstream purchasing behavior. In paper #3, Mende, Scott, and Nenkov explore consumers' use of self-tracking technology (e.g., FitBits) and its impact on mortality salience and the pursuit of self-relevant goals. In paper #4, Bilstein, Matta, and Hogreve study what happens to consumers when the technology they purchase fails, and the consumer has to continue to interact with the source of technological disappointment to get back on track. Taken together, these papers raise some important questions for discussion during the session, including: (1) Does the influence of technology on consumer behavior vary depending on whether the consumer has selected the technology (papers 3 & 4) or when the use of the technology is imposed on them (papers 1 & 2). (2) How does the use of technology affect self-identity and well-being, and what is the downstream impact on goal pursuit and consumption?

In sum, the papers in this session (all in relatively advanced stages) further our understanding of consumer decision-making in the context of technology interaction and usage - topics that are under-researched and likely to be of substantial interest to the ACR audience.

Touching Versus Talking: Alternative Interfaces and the Extended Self

EXTENDED ABSTRACT

As mobile devices such as tablets and smartphones become the modal form of computer interaction, the primary method of interface has shifted from mouse and keyboard. Touchscreens have come to dominate the mobile computing space, and both Google and Apple have also made strong pushes into voice-control in recent years. But are all interfaces created equal? Prior work suggests that the interfaces used to access content can strongly affect the way that content is experienced, explored, and viewed (Rokeby 1998).

This research explores how touch and voice interfaces can trigger different ownership perceptions and relational paradigms, which in turn color consumer perceptions of the online content accessed through the device. Touch is especially relevant as it remains under-explored in the consumer literature (Peck 2010), and most smartphone and tablet interactions are conducted through a touchscreen. As a more direct metaphor for actually touching online content (in comparison to the more abstract mouse), touch should be a more transparent interface to use, and awareness of the device as a mediator between the user and the content being accessed should decrease. Touch interfaces have also been shown to generate stronger levels of psychological ownership (Brasel & Gips 2014). In addition, prior work suggests that smartphones and tablets may have a more direct association with a consumer's extended self due to this 'transparency' (Hein, O'Donohoe & Ryan 2011), but this has seen little empirical testing.

In contrast, a voice-controlled interface makes the 'command' aspect of the interface highly salient; the consumer voices an instruction, which the device then executes. This positions the device as an assistant or partner, rather than encouraging incorporation of the device into the extended self. This may not only decrease any artificial increase in psychological ownership, it may trigger relational associations such as distributive justice and locus of control. And rather than blur the lines between self and device, it may blur the lines between device and content instead.

Two studies were conducted to explore the role of alternative interfaces in how devices get incorporated into the extended self, and how interfaces can trigger certain relational norms. In Study 1, participants used an Android tablet either through Google voice controls or through traditional touchscreen controls to navigate the process of buying new bath towels from Amazon.com. As voice-control is not yet fully integrated into all shopping apps and programs, primarily being limited to text input rather than menu navigation, the experimenter was also surreptitiously controlling the tablet from behind the participant, using a Bluetooth mouse and to execute participant commands such as "yes" or making selections from a menu. While touchscreen participants exhibited the same self-incorporation as seen in

Study 1, voice-control participants showed little self-incorporation. In contrast, voice-control participants rated the tablet higher on relationship dimensions, thinking of it more as a partner and assistant than did touchscreen participants. This reflects in the responsibility measures; much like Study 1 touchscreen participants gave little credit for a successful transaction to the device. In contrast, voice control participants gave more credit to the device than to the store. Follow-up questions suggest that unlike the self and device becoming blurred as with touch interfaces, voice interfaces instead blur the line between device and the content accessed.

In Study 2, we explored how errors were processed in both interfaces. Using a large touchscreen monitor to control for baseline touchscreen error rates due to smaller phone screens, and a hidden assistant to control the computer in the voice condition, the error rate was experimentally controlled. Participants engaging in a shopping search task either experienced a level of error consistent with current voice interfaces (5-10%), or no errors, regardless whether they were controlling the machine via touch or text. This exposure lasted either one minute or five minutes When using the touch interface, consumers placed the locus of control for errors onto themselves, and did not assign blame to the computer. When using the voice interface, consumers placed the locus of control for errors onto the computer, and perception of the computer as a separate entity increase. When the exposure is increased to five minutes, the results of the voice interface do not change. For the touch interface, however, the increased prevalence of errors beyond the traditional touchscreen baseline experienced in everyday life makes the interface more salient, moving it from the extended self into separate entity status.

In conclusion, the results of two studies suggest that touch and voice interfaces change consumer reactions to online content, but do so in different ways. Compared to traditional mouse-and-keyboard interfaces, touchscreens strongly encourage the consumer to incorporate the device into their extended self, essentially making the device transparent in the online shopping process. In contrast, voice controls establish the device as a partner or assistant, and make the device an active intermediary in the online shopping process. Taken together, these results reinforce that all interfaces are not created equal, and that research must explore the interfaces used to access content to the same degree as content itself.

Personalized Advertising in Public Environments: Perceptions and Consequences

EXTENDED ABSTRACT

Personalized advertising has emerged as a major marketing trend. A steady growth of the collection and usage of personalized information not only characterizes the online world and the private lives of consumers, but increasingly expands into public life areas, such as retail stores or shopping malls, which presents new research questions. Extensive research has examined e-mail marketing, personalized online marketing and personalized postal and telephone marketing (e.g. Alreck & Settle, 2007; Goldfarb & Tucker, 2012; Pavlou & Stewart, 2000; Schumann, v. Wangenheim, & Groene, 2014; Speck & Elliott, 1997), but the results cannot be directly applied to the public context due to specific challenges faced in this field of study: in public, other shoppers are present. Unlike online advertisements where the consumer is the only one who sees the advertisement, personalized content shown in public can also be seen by other shoppers.

Study 1 investigates the interplay between personalization and the presence of others, with a 2(other shoppers present: yes/no) × 2(personalized advertisement: yes/no) between subjects experiment.

Participants read a scenario about shopping in a store that uses new consumer tracking technology (either with other shoppers or alone) and seeing an ad on a monitor in the store, which was personalized to consumers' personal physical metrics or not. Participants then indicated their attitude toward the store and behavioral intentions. ANCOVAs reveal 2-way interactions for attitude (p = .03) and behavioral intentions (p = .008). Contrasts reveal that under personalization, consumers are less favorable when others are present for attitude (M_{others} =3.98 vs. M_{alone} = 4.77, p = .01) and behavioral intentions (M_{others} =4.01 vs. M_{alone} = 4.74, p = .01); these effects are attenuated when the ad is not personalized (ps > .20).

Further, consumers have no influence on the content shown to them on public screens, meaning they cannot control the impression they make on other shoppers as a consequence of the content shown to them. Grounded in theory on self-concept congruity and research on impression management, we examine the perceptions and consequences of personalized advertising in public environments. Specifically, we address the question when and how the presence of other shoppers affects consumers' attitudes and behavioral intentions when exposed to personalized content.

We use a conceptualization of different ad-self-concept congruity states adapted from Sirgy (1982) to analyze the effects of perceived match or mismatch between the image of a personalized ad and the self-concept of targeted individuals in a public environment: *ad-self-concept congruity,* referring to a match between a product-image perception and a self-image belief; *positive self-incongruity* which is the comparison between a positive product-image perception and a negative self-image belief; and n*egative self-incongruity* referring to the comparison between a negative product-image perception and a positive self-image belief. Research reveals impressions individuals try to construct in public depend on their self-concept (Latané, 1981; Leary & Kowalski, 1990). In doing so, individuals attempt to control the way others perceive them and try to leave the best possible impression when in public (Latané, 1981; Leary & Kowalski, 1990). Moreover, consumers are highly sensitive when in the presence of others (Bearden & Etzel, 1982; McFerran, Dahl, Fitzsimons, & Morales, 2010), even when these others don't interact with them (Argo, Dahl, & Manchanda, 2005). We propose, when consumers are exposed to personalized content in presence of other shoppers on a public screen and if others are aware of the fact that it targets a certain consumer, then the consumer can no longer control the way in which the other shoppers perceive him. We expect that presence of other shoppers will potentially impact consumers' attitudes, behavioral intentions and emotional reactions, depending on ad-self-concept congruity state, such that under positive advertising-image perception and a negative self-image belief *(positive ad-self-concept incongruity)* presence of others will negatively influence attitudes, behavioral intentions and emotional reactions, but not under negative ad-self-concept incongruity nor under ad-self-concept congruity.

We test the effects in study 2 which was a 2(other shoppers present: yes/no) × continuous (ad-self-concept congruity) between subjects experiment. Participants read a scenario about shopping in a retail store, which uses consumer-tracking technology. Participants were shown an exercise-clothing ad and were told that the ad was personalized towards them, based on their recorded metrics they provided at the beginning of the survey. We manipulated the presence of other shoppers both in the scenario language and in the visual depiction of the scene. Participants then indicated their attitude toward the store, behavioral intentions, and embarrassment.

ANCOVAs revealed other shoppers × ad-self-concept congruity two-way interaction on attitude (*p* = .03) and on behavioral inten-

tions ($p = .002$); the main effects of other customers and ad-self-concept congruity were non-significant (ps > .41). Spotlight analyses reveal that under *positive ad-self-concept incongruity*, attitude levels were lower with other people present (vs. no others present) (M_{Absent} = 5.22 vs. $M_{Present}$ = 4.58; $B = -.63$, $t = -2.33$, $p = .02$) and behavioral intentions (M_{Absent} = 4.95 vs. $M_{Present}$ = 4.30; $B = -.64$, $t = -2.81$, $p = .005$). Under ad-self-concept congruity and under negative ad-self-concept incongruity, the effect is attenuated (ps > .19).

Moderated mediation (Hayes 2013; model 8) revealed that under *positive ad-self-concept incongruity* embarrassment mediated the negative indirect effect of other peoples' presence on attitude (β = -.46, 95 % CI [-.81, -.17]) and behavioral intentions (β = -.41, 95 % CI [-.71, -.16]). This mediation pattern did not appear for *ad-self-concept congruity* or for *negative ad-self-concept incongruity* states.

Our findings expand research on personalized advertising (e.g. Goldfarb & Tucker, 2012; Pavlou & Stewart, 2000, Alreck & Settle, 2007; Speck & Elliott, 1997; Schumann, v. Wangenheim, & Groene, 2014) by providing evidence that personalization is perceived as negative in a store, especially when others are present. Further, we contribute to distinct types and conceptualizations of congruity (e.g. Sirgy et al., 1991; Sirgy et al., 1997; Kressmann et al., 2006) between self-concept and advertising (e.g. Hong & Zinkan, 1995). Prior empirical research on self-concept congruity did not differentiate between different incongruity states, but our results demonstrate that it is important to examine the direction of the incongruity.

Understanding the Quantified Self: Effects of Self-Tracking on Mortality Salience and Health Motivation

EXTENDED ABSTRACT

Propelled by an explosion of digital technologies, millions of consumers monitor the intricacies of their lives, using wearable devices and other tools to track themselves, a trend often referred to as the "quantified self" movement. Despite the fast-evolving impact that self-tracking has on consumer lives, no marketing research has examined the consumer experience of self-tracking and its psychological facets in detail. This research identifies a potentially unforeseen consequence of self-quantification–increased mortality salience, or accessibility of thoughts related to one's death (Greenberg, Solomon, and Pyszczynski 1997), which could have important implications for consumers' information processing and behavior. A significant amount of research has examined the consequences of increased mortality salience (Burke, Martens, and Faucher 2010; Greenberg et al. 1997), but less research has studied factors that might increase mortality salience in consumers' daily lives. In this research, we examine self-quantification as one such important factor. We propose that exposure to a self-tracking device has the unintended effect of increasing the salience of death-related concerns, which we show has a positive effect on consumers' health motivations, a boost that serves as a defense against the mortality salience threat. Moreover, we explore how a common marketing practice of encouraging consumers to anthropomorphize (i.e., imbue humanlike characteristics onto a non-human entity; Epley, Waytz, and Cacioppo 2007) their self-tracking devices (e.g., Adidas calls its device "My Coach") might interplay with the mortality salience effect we propose. We suggest that anthropomorphization might offer another mortality salience defense, making the health motivation boost we predict unnecessary, resulting in an undesirable backfire effect.

Exposure to a self-monitoring device should increase consumers' awareness of the possibility of their own vulnerability and ultimate death, which will activate proximal defenses to enable one to push the problem of death into the distant future (Greenberg et al.

2000). A common proximal defense used to remove death-related thoughts from focal attention is denying one's vulnerability to disease or premature death (Greenberg et al. 2000). We suggest that people would defend against the threatening awareness of their own mortality triggered by exposure to a monitoring device by increasing their motivation to lead a healthy (and hence long) life; that is, exposure to self-tracking devices should boost consumer health goal motivation.

Study 1. Participants evaluated a self-tracking band or a watch (a non-tracking device of identical design). Next, we measured mortality salience (4-item measure, e.g., "To what extent have you been thinking about death in the past several minutes?"; Van den Bos and Miedema 2000) and health motivation ("In the past several minutes, to what extent have you been thinking about: the importance of living a healthy life; making changes in your lifestyle to increase the likelihood that you will live longer"). Results revealed a main effect of self-monitoring on mortality salience and health motivation. Mediation analysis revealed a significant indirect effect of the self-monitoring on health motivation via mortality salience.

We next examined whether the association between self-tracking and health goal motivation might be influenced by the extent to which consumers anthropomorphize the tracking device. We propose that anthropomorphizing a self-tracking device can mitigate its effects related to mortality salience, as anthropomorphization "comforts people by providing relationships or companionship" (Wan and Aggarwal 2015, p. 122) and may be utilized to increase the predictability and comprehension of what would otherwise be an uncertain world, aiding one in constructing a meaningful and controllable worldview (Epley, Waytz, and Cacioppo 2007). Since construing oneself as a valuable participant in a meaningful universe is a well-established distal mortality salience defense (Greenberg et al. 1997), we propose that anthropomorphization could provide an effective buffer against death anxiety. If anthropomorphism indeed serves as a mortality salience defense, then people might not need to defend against morality salience by boosting their health motivations.

Study 2. Using a 2 (self-tracking: yes/no) × 2 (anthropomorphism: yes/no) design, we asked participants to evaluate either a tracking band or a watch. Procedure was identical to that in Study 1, except that participants in the anthropomorphism conditions were asked to personalize their monitoring band/watch by giving it a name and gender and using one word to describe its personality. We measured mortality salience as in Study 1 and measured health motivation asking participants indicate their motivation to engage in twelve everyday health-promoting behaviors (e.g., eat a well-balanced diet; get enough sleep; Moorman and Matulich 1993).

We found a significant main effect of self-monitoring on mortality salience, but no effect of anthropomorphization and no interaction between the two, showing that self-tracking increases mortality salience whether one anthropomorphizes their tracking device or not.

We then examined the health behaviors motivation index, and results revealed a significant self-tracking × anthropomorphism interaction. In the no anthropomorphism condition participants reported significantly higher health motivation in the self-monitoring condition, replicating prior findings. In the anthropomorphism condition, however, these effects disappeared. These results support our contention that exposure to a self-tracking device (vs. a watch) increases people's health motivation as a defense against the threatening awareness of their own mortality. When participants have the chance to anthropomorphize their self-tracking device, however, these health motivation effects disappear, suggesting that anthropomorphism might be acting as a mortality salience defense, eliminat-

ing the need to deny one's vulnerability to dying by boosting health motivation.

Our studies offer novel theoretical insights, since prior research has not examined the effects of everyday consumer experiences (self-tracking) on morality salience, nor has it established anthropomorphization as a possible mortality salience defense. There is no evidence yet as to whether self-tracking devices might help consumers with the accomplishment of their health goals, as companies frequently claim. This research provides some much needed insight into the possible effects of self-tracking devices on consumers' lives.

Thank You for Your Helping Hand! Ways to Avoid Negative Consequences of Customer Participation in Recovery of Technology Product Failure

EXTENDED ABSTRACT

In this research we develop and test theory on the effect of customer participation in the recovery process on customer satisfaction after recovery for technology based services. By doing so, we extend prior research that has examined customer participation in recovery, most notably, Dong, Evans, and Zou (2008), and Roggeveen, Tsiros, and Grewal (2012). Dong and colleagues investigated customer participation in service recovery in the context of self-service technology (SST) and found that it had a positive effect on satisfaction with recovery, which in turn had a positive effect on customer intention towards future use of the SST. Roggeveen and colleagues expanded on the notion of customer participation by conceptualizing *customer co-creation of the service recovery* where "customers help shape or personalize the content of the service recovery through joint collaboration with the service provider" (p. 772). Those authors found that customer co-creation of service recovery positively impacts customer satisfaction with the recovery process and repurchase intentions.

In extending this stream of research we propose that it is necessary to differentiate between customer participation and customer co-creation in recovery. As co-creation in recovery includes an added value component, e.g., personalization of the recovery outcome, customers in these situations compare a personalized (co-created) outcome to a non-personalized (non co-created) outcome in assessing their satisfaction with the recovery process. In our research we focus on customer participation while holding the outcome of the recovery constant. In technologies based service contexts (e.g., Internet and cable TV service, cell phone service), the recovery process may consist of different options including customer participation or non-participation, whereas the recovery outcome remains the same. The recovery then may not lead to customized recovery outcomes. Even so, customer participation in the recovery process may be a viable option for the company and the customer. Take the example of Fiona, a smart phone customer, who has a problem with her smart phone after downloading an operating system update. To solve the problem, she calls customer service and is guided through several steps to fix the problem including multiple tasks to identify and diagnose the problem. Thus, she spends a significant amount of time and effort in participating in the recovery process. The alternative for Fiona would have been to go a retail outlet of the smart phone provider and get it fixed by the provider. Such instances of customer participation in recovery processes are increasingly common. We believe that it is crucial to examine customer participation in recovery when the recovery outcome is the same regardless of customer participation. For, in such instances of customer participation in recovery, customers evaluate their participation in the recovery process and their satisfaction differently than has been found in prior research (e.g., Dong at al. 2008, Roggeveen et al. 2012) examining situations in which the

recovery outcome shifts due to a customer's increased participation in the recovery process.

In a first study, we explore the prevalence of customer participation in the service recovery process. To understand if, when, and where such customer participation in recovery processes commonly occurs, we asked a representative sample of 300 adult U.S. consumers recruited by a professional market research firm using a consumer panel about their experiences with participation in recovery processes. We found that an impressive 76 % of consumers surveyed reported having participated in a recovery situation at least once. Consumers reported having experienced it most in telecommunications including mobile phones, cable TV and Internet service (38.7 %), computer hardware and software (32 %), restaurants (26 %), travel and hospitality including hotels and airlines (23.7%), and retail (23%). We then used the critical incident research method and asked respondents to recall an instance when they participated in a recovery process after a product or service failure and to describe the situation and what they did in that situation. 206 participants (68.67% of the total number of study respondents) elaborated on a recovery incident in which they participated. The content from these consumer elaborations inspired the construction of our experimental scenarios in the following studies. Our first study showed that customer participation in recovery processes is widespread and a correlation post-hoc analysis unveils that the extent of customer participation in recovery is negatively correlated with satisfaction after recovery.

Based on the additional experimental studies we advance the knowledge on customer participation in recovery in multiple ways. First, we develop and test theory on the negative relationship between customer participation in recovery and satisfaction after recovery (Studies 2 and 3). Second, we identify and test the role of customers' domain-specific expertise as moderator. We find that customers with high domain-specific expertise are more (less) satisfied with low (high) levels of customer participation in recovery, whereas no such difference exists for customers with low domain specific expertise (Study 2). Moreover, we are able to explain the underlying cognitive process by showing that the interaction effect of customer participation and customers' domain-specific expertise on satisfaction after recovery is fully mediated by customers' perceived procedural justice. Study 3 identifies main effects for customer participation and compensation on satisfaction after recovery while their interaction is not significant. This result again indicates lower levels of satisfaction in case of higher customer participation. In Study 4, we vary the framing of the acknowledgement of the customer participation by the provider (i.e., inconvenience, apology, gratitude). In doing so, we introduce the construct of gratitude, first studied in marketing by Palmatier et al. (2009), into the service recovery literature. Specifically, we posit that gratitude expressed by a service firm works better in restoring satisfaction after recovery involving customer participation compared to an apology, and test it empirically (Study 4).

Our studies included a wide range of respondents (N = 860) recruited from consumer panels. Thus, we provide new, meaningful insights on the consequences of customer participation in recovery for a wide range of services, especially for services with a technology component. Finally, our research advances practice by providing guidelines to service firms on how to effectively manage customer participation in the recovery process.

Paper #4: The Two Faces of Innovation Adoption: How Envy Affects Consumers' Evaluation of Innovative Products

Jaeyeon Chung, Columbia University, USA
Leonard Lee, National University of Singapore, Singapore

SESSION OVERVIEW

Most early research on the informational value of emotion focused on its intrapersonal aspects. However, researchers have, of late, been looking more closely at its interpersonal aspects (Andrade and Ho 2009, Keltner and Haidt 1999, Van Kleef 2009). As Van Kleef et al. (2011) pointed out, "…if emotions were only functional at the individual level, why would they show on our faces?" The current symposium proposal highlights the social nature of emotions, and presents four papers that shed light on this important area from different angles. Two papers examine embarrassment and envy, two self-conscious emotions that are inherently social. The other two papers study anger and displayed enjoyment, which are not apparently social but have significant interpersonal implications.

In the first paper, Cavanaugh, Nunes, and Han study identity signals on products (e.g., brand prominence). Although such signals are usually meant to impress others, Cavanaugh et al. find that receiving a compliment related to an identity signal often results in embarrassment, an unforeseen negative consequence. A field study and controlled experiments establish this effect and find that it is mediated by heightened self-awareness.

Just as being complimented may not always be good, being in power may similarly have a counterintuitive downside. In the second paper, Rucker, Duhachek, Kim, and Han find that individuals having high (vs. low) power are more likely to feel angry after a failure experience, probably due to a heightened approach orientation. This effect is amplified in a group (vs. individual) setting, thereby highlighting the social nature of the effect.

Someone who approaches a given activity due to internal drives is usually enjoying that activity. Such displayed enjoyment can signal the approach motivation to observers. In the third paper, Cheng, Mukhopadhyay and Williams find that when people engaging in an activity display large smiles (vs. small smiles or neutral expressions), observers infer that they have greater levels of intrinsic motivation towards the activity. The converse is also true—people given a goal

to signal intrinsic (vs. extrinsic or control) motivation strategically display larger smiles to potential observers.

These informational effects of emotions may at times be highly sensitive to metacognitive effects. In the fourth paper, Chung and Lee study the effects of paying attention to one's feelings, and find that the consequence of even a prominent interpersonal emotion such as envy can be reversed when one pays attention to feelings. They show that envious consumers who are more inclined to attend to their feelings (vs. cognition) exhibit more positive (vs. negative) attitudes toward innovative products, due to stronger self-enhancement motives and lower concern of perceived risk.

This session discusses emotion from a social/interpersonal perspective. Bringing together researchers from five countries, this session proposal raises a lens to the interplay between emotions and their informational effects in social contexts, in domains that are new to emotion research, such as identity signaling, intrinsic motivation, and innovation adoption. We therefore believe that this session has the potential to be well-attended, and to raise interesting questions for debate and discussion.

Please Don't Praise It: How Compliments on Identity Signals Result in Embarrassment

EXTENDED ABSTRACT

As social beings, consumers seek approval from others and therefore frequently make an effort to communicate aspects of their identity, actual or ideal, with the intention of impressing those around them. In consumption, individuals regularly use possessions and brands to signal aspects of their identities (e.g., being athletic, stylish, or sexy) to others (e.g., Escalas 2004; Fournier 1998; Belk 1988; McCracken 1989). Consumers expect observers to make certain inferences about their identities based on which possessions and brands they choose to display and how they display them (Belk, Bahn, and Mayer 1982; Richins 1994a, 1994b). Consumers often anticipate the signal will be seen and understood by others. What consumers are less likely to anticipate is how they themselves might respond to feedback on their signals. In this research, we focus on the *signaler's emotional response* to a positive acknowledgment of an identity signal, i.e. a compliment. By focusing on interactions between individuals and the emotional consequences of compliments, this work links the literature on identity signaling in marketing with the literature on self-conscious emotions (Dahl, Manchanda, Argo 2001; Keltner and Buswell 1996; Parrott and Smith 1991; Tangney et al. 1996; Tracy and Robins 2004).

We show that compliments on identity signals often cause consumer embarrassment owing to heightened public self-awareness. We also show that the extent to which the signaler feels embarrassed by a compliment depends on characteristics of both the signal and the signaler. We observe a similar pattern of effects using a field study (study 1) and controlled experiments examining the effects of the signal and the signaler's self-beliefs using both deception (study 2) and self-identified gaps (studies 3 and 4), using both self-reported (studies 2-4) and observed measures of embarrassment (studies 1 and 2), as well as in studies in which consumers both self-selected (studies 1, 3, and 4) and were randomly assigned (study 2) their identity signal.

Study 1. In a field study, we tested the prediction that a signaler utilizing a self-chosen loud (vs. quiet) signal will experience more embarrassment. Participants carrying handbags were interviewed

and recorded with a digital voice recorder at a local mall under the auspices of a shopping survey. The researcher first asked generic questions and later delivered the same compliment to all participants: "I really like your bag. It is very nice." Finally, the researcher photographed the handbag, which was later rated by independent judges for brand prominence (Han et al. 2010). To measure embarrassment, each participant's voice recording was analyzed using Layered Voice Analysis. We found that consumers carrying louder signals exhibited greater embarrassment in response to the compliment (β = .49, *p* < .01); no such differences were found for any of the other emotions (i.e., happiness, sadness, anger).

Study 2. In a multi-confederate aided lab study, we tested if and how consumers' self-beliefs about an aspect of their identity—sexiness—would impact the level of embarrassment experienced in response to a compliment on a loud vs. quiet signal. Participants (N=53) were recruited under the auspices of a Victoria's Secret event, in which they received an individual consultation concerning first impressions and provided product feedback. After completing questionnaires and tasks, a specialist provided false feedback to manipulate participants' self-beliefs about sexiness. Next, they completed a product evaluation where self-beliefs were measured and actual product trial of Victoria's Secret signature line of "Very Sexy" lotion and perfume occurred. Each participant received a Victoria Secret goodie bag, which was branded quietly or loudly; at this point the event was ostensibly complete. During a final computerized assessment of overall session experience, an attractive male student (another confederate) paid the participant the following compliment: "Wow, I really like your perfume. Is that what you're wearing?" We found a Signal Strength X Self-Belief interaction (p<.06). Those in the loud condition were embarrassed regardless of Self-Belief. In the quiet condition, embarrassment in response to the compliment decreased as sexiness Self-Belief increased (β = -.62, *p* < .01). Additionally, we found a significant indirect effect (β=.6726, 95%CI= .1863, 1.2812), providing evidence of moderated mediation by public self-awareness.

Studies 3 and 4 examined a broader range of self-selected identities displayed in a gender-neutral category (clothing). We held the loud signal strength constant while systematically varying the source of the compliment and type of remark made. In both studies, participants received a list of identities (e.g., athletic, smart, funny, rugged) and rated how important each was to them. They then selected one identity where a gap existed between their ideal and actual perceptions of self-identity at present; this identity was used in the compliment scenario. All participants viewed a navy blue t-shirt with the self-selected identity printed on it followed by a compliment scenario.

In Study 3 (N=228; 44% male), participants were randomly assigned to a 2(Source: friend/stranger) X 3(Remark: compliment/ comment/ unrelated question) design. They imagined wearing the shirt pictured and encountering a person "who looks at you, smiles, and says "I like your shirt. Is it new? [Is your shirt black or blue? / "Do you know if it is still light outside?]." They then completed multi-item emotion and self-awareness measures. We found a main effect for Remark (p<.006); neither the effect of Source or the interaction were significant (F<1). Compliments produced significantly more embarrassment and anxiety than either comments or unrelated questions (all p<.05). We also found evidence that the mediational path predicting embarrassment from a compliment is explained by public self-awareness. Thus, compliments elicit these effects, whereas identical social interactions involving other feedback do not.

In Study 4 (N=153; 51% male), participants received one of four different types of compliments (person/product/ identity-explic-

it product/ control) and completed the same dependent measures. We found that product compliments (implied or explicit) produced significantly more embarrassment, anxiety, and public self-awareness than unrelated questions (all p<.02) and marginally more embarrassment and anxiety than person compliments (i.e., one's haircut; all p<.10). Product compliments also produced significantly less pride and happiness than person compliments (all p<.001). We found additional evidence that public self-awareness mediates the relationship between product-related compliments and embarrassment.

The Effects of Power on Emotional Responses to Self-Failure

EXTENDED ABSTRACT

Previous research suggests that power influences one's expression and experience of emotions (Berdahl and Martorana 2006; Keltner et al.2003; Van Kleef et al. 2006). Specifically, high power results in increased positive emotions whereas, low power leads to elevated negative emotions. However, scant research has examined how power influences the experience of specific negative. To fill this gap, the current research finds a context, in which power actually influences discrete negative emotion with a focus on anger and suggests that high power leads to greater anger when individuals encounter self-failure. The current research focuses on anger because previous literature on anger in the context of self-failure suggests two competing predictions. Thus, the current research aims at resolving these competing predictions. Importantly, this research suggests these emotional differences elicited by different levels of power are contingent on whether the task is done individually versus as a group.

According to cognitive-appraisal theories of emotion (Lerner and Keltner 2001; Smith and Ellsworth 1985), individuals feel angry when they believe that others are responsible for negative outcomes or have high control over negative events (Averill 1983). Given that individuals in high power positions (i.e., leaders) feel more responsible for and control over a task than those in low power positions (i.e., employees, Anderson and Berdahl 2002), one may predict that high power will lead to reduced anger in the face of self-failure. However, given that increased power activates approach-related tendencies due to increased rewards and freedom whereas decreased power activates inhibition-related tendencies due to elevated threat, punishment, and social constraint (Keltner et al.2003) and that anger is associated with an approach orientation (Labroo and Rucker 2010), one may posit that individuals in high power will feel greater anger when encountering self-failure. To resolve these two opposite predictions, the current research empirically examines the effect of power on anger in the self-failure contexts.

Furthermore, since individuals working as a group have a chance to blame other group members whereas individuals working individually do not, anger which is activated when perceiving other's responsibility over the negative outcome (Lerner and Keltner 2001; Smith and Ellsworth 1985) might be amplified. Based on these findings, we posit that in the group task failure context, the impact of power on anger will be strengthened. Across two studies, we demonstrate that individuals in high (vs. low) power are more likely to experience anger in the face of self failure. In addition, we reveal that this effect is exaggerated when individuals fail the task in a group context.

Study 1 examined the effects of power on anger when encountering the individual task failure to resolve the competing hypotheses. We predict that individuals in high (vs. low) power will be more likely to exhibit anger in the context of failure in the individual task. Although low (vs. high) power results in greater negative mood, we

argue that high power may amplify experience of anger when coupled with self-failure. It is because individuals in high power would be motivated to solve the problem of the negative events whereas those in low power would be less motivated (Keltner et al.2003), and anger might help to solve the problem since it facilitates an effort to overcome the violation of what ought to be (Fischer and Roseman 2007). Participants were assigned to either the high or low power condition. We manipulated high (low) power by asking them to imagine to be a boss (employee) at a company. They read about the role and were instructed to vividly imagine that what it would be like to be in this role (Rucker, Dubois, and Galinsky 2011). After then, all participants were asked to solve five insight problems and were informed that their score would be reported to them after completion. After 30 seconds of completion, all participants read that they failed the test. Next, participants indicated the degree to which they felt angry after learning about their test results (frustrated, anger, and irritated; Richins 1997). A one-way ANOVA with power as the independent variable and anger as the dependent variable revealed that participants in the high power condition felt angry to a greater extent than did those in the low power condition ($p < .05$).

Study 2 investigated whether findings from study 1 would be amplified when participants experienced failure in a group task. Participants were randomly assigned to one of four conditions in a 2 (Power: high vs. low) x 2 (Task: group vs. individual) between-participants design. The power manipulation was identical to that in study 1. Next, in the group task condition, participants were assign to a group of three members. Then, they were asked to come up with a fictitious brand's branding ideas for 10 minutes using the paper and pencil. In the individual task condition, participants performed the task individually. Upon completion, a proctor collected the idea sheets and told participants that judges would evaluate the ideas and provide the feedback after five minutes. While participants were asked to complete filler questions, confederates wrote negative comments on all idea sheets. After five minutes, participants received the feedback and indicated the degree to which they felt angry after learning about the result using the same scale used in study 1. A two-way ANOVA as power and task type as the independent variables and anger as the dependent variable revealed significant main effects of power and task type as well as a significant interaction (ps < .05). Simple contrasts revealed that in the high power condition, participants in the group (vs. individual) condition reported anger to a greater extent ($p < .05$). However, in the low power condition, there was no difference across group and individual task conditions ($p > .1$). In both the group and individual task conditions, participants in the high (vs. low) power condition reported greater anger (ps < .05).

Overall, our findings contribute to the consumer literature by providing evidence to understand the relationship between power and consumer's emotional responses to failure in a task as a function of a group size.

Fun Signals Intrinsic Motivation: Observers Infer Motivation from Expressed Emotion

EXTENDED ABSTRACT

Intrinsic motivation means doing something because it is inherently rewarding, whereas extrinsic motivation means doing something to achieve a separable outcome, such as money or fame (Deci, Benware and Landy 1974, Ryan and Deci 2000a). People value intrinsic motivation more because it indicates behavioral commitment or because it is authentic and morally desirable (Kasser 2002). Therefore, the nature of a person's motivation to engage in an activity can be useful information in a social context. However, it is often difficult to tell what a person's motivation is, because a given behavior (e.g., getting married) often looks exactly the same to an observer, regardless of whether the motivation is intrinsic (e.g., for love) or extrinsic (e.g., for the person's wealth). Moreover, verbal claims related to motivation may simply be cheap talk.

Intrinsic motivation arises from basic psychological needs for competence, autonomy and relatedness, which are principal sources of enjoyment and vitality throughout life (Ryan and Deci 2000b). Deci (1975) argues that if an activity is internally rewarding, the end state should be positive affect. Indeed, intrinsic motivation is sometimes defined as doing something for its inherent enjoyment or satisfaction (Ryan and Deci 2000a). Therefore, we suggest that people may use a person's displayed enjoyment as a signal to infer his/her intrinsic motivation. Particularly, we focus on the facial expression of enjoyment because it is readily visible to other people and the "leakage" in facial expressions is often more diagnostic than verbally claimed emotions (Ekman 1993). We hypothesize that observers may infer stronger intrinsic motivation if they see a person who has engaged in an activity displaying a large smile, as opposed to a small smile or neutral expression (H1). Observers may also anticipate better long-term outcomes of an activity if people engaging in the activity display larger smiles, and this effect should be mediated by inferences of stronger intrinsic motivation (H2). Thirdly, smiling should be a diagnostic signal of intrinsic motivation only if the smile is a consequence of engaging in the intrinsically motivated activity. Hence, the proposed effects (i.e., H1 and H2) should be attenuated if the smile is observed before rather than after the focal activity (H3).

Study 1 tested H1 and H3. MTurkers (N=242) read a description of Karate and examined a group photo of a Karate Club. The photo featured 30 club members standing together, dressed in karategi. Participants randomly saw either a fun photo or a neutral photo that differed in the expressed facial emotions, such that the club members were either smiling (fun), or not smiling (neutral). We manipulated the timing of emotion display by saying that this photo was taken either before or after the Karate training. Participants then completed a 23-item scale adapted from the Sport Motivation Scale (Pelletier et al. 1995), which measured their inferences regarding the club members' intrinsic and extrinsic motivations for practicing Karate. The results showed a significant interaction of displayed emotion and timing of emotion, such that if they thought the photo was taken after the training, participants inferred higher intrinsic motivation if the club members displayed smiling rather than neutral expressions. The effect disappeared if the photo was purportedly taken before the training, because the fun is then less likely to be a consequence of practicing Karate.

Study 2 tested H1, H2 and H3 in a different context. College students (N=164) read about a newly married couple – the groom being a successful businessman and the bride a famous columnist – and saw a photo of them embracing, with either big smiles or small smiles. The photo was purportedly taken either on the day before or the day after their wedding day. After viewing the photo, participants answered 14 questions that measured the motivations they ascribed to this couple regarding their marriage, and four questions that measured the anticipated long-term quality of the marriage. When the photo was supposedly taken after the wedding, participants inferred stronger intrinsic motivation, and anticipated the marriage would be more successful, if the couple displayed large (vs. small) smiles. The effect disappeared if the photo was supposedly taken before the wedding. Inferred intrinsic motivation mediated the interactive effect of smile size and timing on anticipated long-term marriage quality.

Having investigated the inferences people make about smiling as communicating intrinsic motivation, we now turn to the question

of whether they proactively use smiling in their own non-verbal communication. As observers, people use smiles to infer intrinsic motivation, and hence as actors may strategically display larger smiles if they want to signal intrinsic motivation to potential observers (H4). We test this hypothesis in study 3.

University students (N=170) imagined that a real estate agent who once helped them find an apartment was soliciting previous clients' photos to promote her business. Participants imagined that they agreed to send a photo to the agent (control condition), and they wanted potential clients who would see their photo to believe that they really wanted to endorse this agent and had no reservation in doing so (intrinsic motivation condition), or felt an obligation to endorse her (extrinsic motivation condition). Participants used the built-in cameras in the lab computers to take headshot pictures. They were free to take as many pictures as they wanted, but could only send one. Two coders who were blind to the hypothesis and conditions coded the facial expressions in the chosen selfies. The results showed that participants proactively displayed bigger smiles when they were given a goal to communicate intrinsic motivation than to communicate extrinsic motivation or no specific goal.

Much past research has shown that affect can be used as information about the self (Schwarz and Clore 1983), and recent research suggests that emotion can be used as social information (Van Kleef 2009). Echoing the social-functional approach to emotion research (Keltner and Haidt 1999), the present research shows that people infer intrinsic motivation from another person's displayed smile that occurs after an activity. We also show that people use this signal strategically and display bigger smiles to communicate intrinsic motivation to potential observers.

The Two Faces of Innovation Adoption: How Envy Affects Consumers' Evaluation of Innovative Products

EXTENDED ABSTRACT

Innovative products can be highly appealing but also aversive to consumers. On the one hand, innovation adoption is associated with a number of positive symbolic qualities that are psychologically rewarding; it signals leadership, a sense of superiority, and a higher group status (Fisher and Price 1992). On the other hand, innovation adoption may also expose consumers to unanticipated risks, such as performance uncertainty, physical perils, and financial risks (Ram 1989).

In this research, we aim to examine which of these two aspects carry more weight in consumers' minds, particularly when consumers experience feelings of envy that arise from social comparison (Cohen-Charash 2008). While envious individuals may focus on the positive aspects of innovation as it allows them to repair their threatened self-image, they might also become more alert toward any risks that can further harm their already threatened self-image.

To understand whether envious individuals are driven by a compensatory self-enhancement motive or a precautionary self-protection motive, we draw upon research on dual-system models (Evans 2003). While people who attend to their feelings tend to process information more holistically and automatically, those who attend to their cognition tend to process information more analytically and deliberatively. Based on these characteristic differences between the affective system and the cognitive system, we predict that envious individuals who attend to their affect are more motivated to repair their negative emotions and are more likely to perceive innovation adoption as an opportunity for compensatory self-enhancement. In contrast, envious individuals who attend to their cognition are driven by a greater self-protection motive; they are thus more likely to recognize the potential risks of innovative products and respond to these products more negatively.

Experiment 1 was designed to test the basic effect that we hypothesized. Participants (N = 143) either described an individual whom they envied (envy condition) or a person whom they knew (control condition) (Cohen-Charash 2009). Following this envy manipulation, in a purportedly unrelated study, all participants saw an advertisement for the "Smart Body Analyzer," a smart multi-function, health-tracking scale. Lastly, participants responded to the Attention-to-Feelings scale (Salovey et al. 1995). The findings suggest that envious (vs. non-envious) consumers who are dispositionally inclined to attend to their feelings respond more favorably to innovative products, whereas envious (vs. non-envious) consumers who are inclined to attend to their cognitive thinking respond less favorably to innovative products ($p = .009$).

Experiment 2 conceptually replicated the findings in experiment 1 by using a different method to manipulate envy: We asked 103 M-Turk participants to complete a Perceptual Ability Test. Participants were told that the goal of the test was to measure how well they processed visual information, and that people who performed within the top 15% would receive a reward of $10. After completing a series of tasks, half of the participants (envy condition) read the following message on the screen: "*Another M-Turk participant just before you won $10 award! Your score is now entered into our database and your percentile is being calculated…*"; the remaining half of the participants (control condition) only read the second half of this message without any mention of another M-Turk worker's performance. Subsequently, participants in both conditions were told that they did not win the $10. (The validity of this manipulation was ascertained in a pretest.) In a purportedly unrelated study, all participants then evaluated an innovative multi-function global adapter and completed the Attention-to-Feelings scale. The results again revealed that envious (vs. non-envious) participants who were dispositionally inclined to attend to their feelings rated the global adaper more positively. In contrast, envious (vs. non-envious) participants who attended to their cognitive thoughts rated the product more negatively ($p =.024$).

Besides further replicating these basic results, the next two experiments provided process evidence for our hypothesized dual-process account. **Experiment 3** employed mediation analysis to show that envious individuals who attend to their cognitive thinking (vs. feelings) are more concerned with the potential risks of innovation adoption, hence resisting against adopting new products. Participants (N = 104) completed the same essay-writing envy-manipulation task from experiment 1 before evaluating an innovative finance-management app, Mint. They also responded to three risk-perception questions (Ram and Sheth 1989), followed by a short filler and the Attention-to-Feelings scale. Analysis revealed that not only were the findings from experiment 1 and 2 replicated ($p = .010$; Attention-to-feelings floodlight region significant above 5.79 and belw 3.80), there was a significant moderated mediation of envy and attention-to-feelings on attitude toward the app through perceived risk (indirect effect $\beta = .18$, 95% CI = .04, .37).

Experiment 4 demonstrated that due to self-enhancement motives, envious individuals who attend to their feelings (vs. cognitive thinking) have a more favorable attitude toward innovative products; by testing a boundary condition where some participants had the chance to self-affirm before the innovative-product evaluation, we showed that these individuals who were self-affirmed of their positive self-image no longer exhibited such a preference for innovative products. Participants (N = 172) were randomly assigned to one of four conditions (Envy: yes/no) × (Affirmation: yes/no). Participants

first engaged in the same essay-writing envy-manipulation task as before. Next, half of the participants (affirmation condition) wrote about their most important life value, while the remaining half of the participants described what a typical AAA battery looked like (no-affirmation condition) (Gao, Wheeler, and Shiv 2009). All participants then evaluated the Smart Body Analyzer (as in Experiment 1) and responded to the Attention-to-Feelings scale. Consistent with our hypothesis, among individuals who were not self-affirmed, we again replicated the crossover interaction from previous experiments ($p = .010$; Attention-to-Feelings floodlight region significant above 5.28 9 and below 4.27). Importantly, envious participants who were self-affirmed prior to the innovation-evaluation task no longer showed such a preference ($p = .999$).

This research contributes to the literature by highlighting the benefits and risks associated with innovative products. More importantly, we add to a limited but growing stream of work that examines how envy influences product consumption by suggesting the latent motives (self-enhancement vs. self-protection) that drive consumers' product attitudes.

Julie L. Ozanne, University of Melbourne, Australia

SESSION OVERVIEW

Food is an integral part of a daily living full of nourishment and joy, comfort and pleasure, and kinship and social connections (Block et al. 2011). Yet, for some consumers, this taken-for-granted part of daily life is fraught with physical, psychological, social, and institutional dangers.

These four presentations are united in their focus on threats to food well-being for at-risk consumers. This session seeks to answer two questions: 1) What can we learn about threats to food well-being across diverse theoretical approaches, including the interplay between biological and psychological theory, perceptual theory, stigma theory, and institutional theory? 2) How can threats to food well-being for different at-risk groups be mitigated in the marketplace? This session explores novel at-risk groups—bariatric patients and consumers with celiac disease, unearths new phenomenon—wishful hearing and inter-individual effects of forms of payment, and employs novel methods—in the moment digital diaries using cell phones.

The first two presentations focus on environmental factors controlled by marketing. In the first paper, the research team compares emergent findings from a study of lean and obese women's sensitivity to marketing actions. They study consumers before and after bariatric surgery hypothesizing the intriguing outcome that overweight consumers will become less sensitive to marketing actions following surgery. These consumer researchers are likely the first to join the recent flurry of research exploring provocative links between intestinal microbial activity and cognitive processing (see www.humanfoodproject.com). Mayor, Block and Ramanathan investigate how auditory processes—specifically the sounds associated with food products and marketing—can threaten food well-being. They draw on extensive data from a series of lab and field studies to show a novel phenomenon of "wishful hearing." Specifically, ambient product sounds can lead to increased consumption of food products that contravene the goals of chronic dieters who are more vulnerable to these forms of auditory marketing.

The next two presentations focus more on interpersonal and institutional influences on well-being. Skinner, Mende, and Scott examine how the choice of payment method in a food retail setting—cash or credit—made by overweight consumers affects the inferences made by, and encounters with, retail employees and customers. Drawing on experimental data, they find that food purchases made by obese customers with credit cards triggered negative connotations, such as poor self-control, and stigmatizing behaviors in retail employees. Carrington, Nyilasy, and Ozanne reveal a range of institutional logics and tactics employed by consumers with celiac disease to also navigate dangerous and stigmatizing food and service encounters in restaurant settings. In doing so, they advance current theorizations of market dynamics to reveal various processes employed by at-risk consumers to maintain, change, or withdraw from the market.

These four presentations span diverse theories and employ a range of methods including lab experiments, field experiments, ethnographic interviews, and mobile digital diaries. This session will be of interest to scholars seeking an in-depth understanding of food well-being spanning diverse methods and theoretical approaches both with a theoretical and practical interest.

Obesity and Sensitivity of Food Perceptions and Preferences to Marketing Actions

EXTENDED ABSTRACT

The environment—and particularly the actions of food marketers—strongly influence the perception of food, which then impacts preferences and eating behavior (Chandon and Wansink 2012). Marketing claims (e.g., "good for you" claims, brand positioning), the size and shape of food packages, their labeling ("medium" or "large") and the range of sizes on the menu all influence food consumption and the perception of food quality ("tasty," "healthy"),quantity.

Research on how food marketing influences food perception and preferences has important limitations. First, almost all existing studies have been conducted with lean, healthy, educated, and young people rather than with the obese people who are most at risk. This is an important concern because research suggests that obese people have become insensitive to internal satiation signals (Bartoshuk, Duffy, Hayes, Moskowitz, and Snyder 2006; Yeomans, Blundell, and Leshem 2004) and to reward signals in the brain (Volkow, Wang, and Baler 2011). The second limitation is the lack of studies examining the effects of the most effective weight-loss remedy for obese people—bariatric surgery—and how it interacts with the effects of the marketing environment. About 200,000 Americans undergo weight-loss surgery (gastric bypass or banding) each year. Yet, only a handful of studies show that weight-loss surgery influences not only food intake, but also food preferences, hunger, and taste acuity (Behary

and Miras 2015; Scruggs, Buffington, and Cowan 1994). More generally, no research has, to date, examined how medical interventions like weight-loss surgery influence people's sensitivity to marketing actions when it comes to food perception and preferences.

The goal of this project is to examine the interplay of biological and psychological factors driving eating behavior before and after weight-loss surgery. Our hypothesis is that the drastic psychological and biological changes (e.g., the composition of the gut microbiota and the levels of metabolic gut hormones) caused by bariatric surgery reduce the impact of marketing factors on food perceptions and preferences.

The study was conducted with the collaboration of the university hospital of Pitié Salpétrière in Paris. A total of 100 female participants were included in the studies. They were divided in two groups (based on BMI): the obese group and the lean group. The obese participants belonged to a clinical study conducted by the Institute of Cardiometabolism And Nutrition (ICAN). Both groups were matched in terms of socio demographic factors (age and employment). However, the obese sample had lower levels of education and income. Because of the slow recruitment of obese patients, the post-surgery data will only be available by the time of the conference in Berlin.

We first measured the effects of food stereotypes. Existing research has shown that people tend to categorize food as "good" or "bad" based on stereotypes, regardless of the actual size of the portion, and that these stereotypes strongly influence food perceptions and preferences (Oakes 2005; Rozin, Ashmore, and Markwith 1996). We selected "surprising" pairs of foods where the stereotypically "good" food actually contains more calories than the stereotypically "bad" food (e.g., a can of Minute Maid pure orange juice, worth 152 calories, vs. a can of regular Coke, worth 140 calories). Overall, we replicated both the "health halo" and the "health horn" effects (Chandon 2013 ; Chandon and Wansink 2007): participants underestimated the calories in the "good" foods by 17% and overestimated the calories in the "bad" foods by 30% (p<0.0001). There was also a main effect of group: Lean participants generally underestimated calories by 8% whereas obese participants overestimated them by 21% (p<0.0001). More importantly, there was a significant interaction (p=0.028): Stereotypes effects were stronger in the obese group (where they led to a 60 percentage point difference in calorie estimations) than in the lean group (34 percentage points).

We also compared inter-temporal preferences for food and money between lean and obese participants. We asked the participants to imagine that they had four euros (or four candies worth one euro each), and asked them whether they would be willing to wait longer in exchange for more money (or more candies). 86% of the obese participants and 100% of the lean participants were willing to wait in exchange for more money. For the candies however, only 33% of the obese participants were willing to wait vs. 67% for the lean participants. This indicates that lean participants are approximately equally impatient when it comes to money or candies, whereas obese participants are more impatient for food than for money.

We also examined the effects of the branding of portion sizes (Aydınoğlu and Krishna 2011) and of the range of portion sizes available (Sharpe, Staelin, and Huber 2008). Here again, obese participants were more influenced by marketing actions than lean participants.

Obviously, the most interesting comparisons will be to compare the responses of the obese participants before and after weight-loss surgery. Finding that weight-loss surgery makes obese people less responsive to marketing actions would provide the first demonstration that weight-loss interventions, such as bariatric surgery, can influence

food perceptions and preferences. It would also suggest that differences in response to marketing actions might be one of the reasons for the higher BMI of the obese group. Alternatively, finding no effect of bariatric surgery would suggest that the higher sensitivity to marketing actions of obese participants is driven by personality or other stable individual differences, and thus that the drastic weight loss typically caused by bariatric surgery is not mediated by sensitivity to marketing actions.

The Effect of Chronic Dieting Goals on Auditory Perceptual Biases

EXTENDED ABSTRACT

The way in which we process sensory stimuli is guided by our underlying goals and motivations. For example, extant research exists exploring the existence of motivated visual perceptual biases, whereby people's internal states shape visual perceptions (Dunning and Balcetis, 2013), and a delicious muffin appeared larger to dieters than non-dieters (van Koningsbruggen, Stroebe and Aarts 2011). In general, the motivated visual perception research finds that desirable objects are perceived as closer to us than non-desirable objects (Balcetis and Dunning, 2009).

The current research extends this prior work by exploring how people's *auditory* perceptual processes are affected by their goals. We propose the existence of "wishful hearing," which establishes that ambient product sounds can be perceived as more spatially proximal when more desirable and thus lead to increased purchase intentions and consumption. In two lab studies, we tested how the goal of chronic dieting, as measured by Herman and Polivy's Restraint (1980) subscale Concern for Dieting, affected auditory perceptual processes, specifically, the spatial distance that exists between a person and a temptation after listening to the associated sound. In our third study, a field experiment, we explore how wishful hearing still exists even when the location of the product is known. To the best of our knowledge, this is the first exploration into how sound threatens food well-being.

In studies 1 and 2, participants were brought into a behavioral lab where they were seated at computer stations with a set of headphones set at the ambiguous volume of "25." Participants were instructed that they would be completing a series of studies. In study 1, seventy-seven participants (70% female, M_{age}=23 years) rated their perceptions of distance from a tempting object (i.e., the ice cream truck) after listening to a 15 second clip of an ice cream truck jingle. To gauge distance perceptions, participants were presented with an image of a stick figure on the left and an image of an ice cream truck on the right with a continuous line with in between. Participants were asked to place an "X" on the line between the stick figure and the ice cream truck demonstrating how close or far they felt to the sound. Participants were then asked on a 7-point Likert scale to gauge how appealing the sound was and if they would like to hear the sound again. Participants were then given a filler task, and finally we measured Concern for Dieting.

A linear regression revealed that chronic dieters placed an "X" on the line that indicated that they felt closer to the sound of the ice cream truck (*b*=.07, *SE*=. 03), *t*(76)=2.40, *p*=.02) than non-chronic dieters. In addition, we also found that spatial proximity mediates how appealing the sound is and the desire to hear the sound again. Specifically, when chronic dieters feel closer to the sound of the ice cream truck, they find the sound to be more appealing (10,000 Bootstraps, 90% CI's: .0005, .0483) and they want to hear the sound again (10,000 Bootstraps, 95% CI's: .0001, .0853).

In study 2, eighty-four participants (49% female, M_{age} =22 years) provided their perceptions of distance after listening to the ice cream truck jingle used in study 1. After providing their distance estimates and rating how appealing the sound was, participants were led into the lab "Ice Cream Shop," where they were allowed to scoop as much ice cream as they wished before returning to a conference room to enjoy their dessert.

Analogous to Study 1, we found that chronic dieters felt closer to the sound of the ice cream truck (b=.08, SE=. 037, t(83)=2.02, p<.05) than non-chronic dieters. In addition, we find serial mediation where chronic dieters feel closer to the sound, which then leads this group to rate the sound as more appealing and subsequently increases willingness to pay (10,000 Bootstraps, 95% CI's: .0002, .0283, see Figure 1) as well as consumption (10,000 Bootstraps, 95% CI's: .0001, .0272, see Figure 2).

In order to identify how consumers would behave in a realistic setting outside of the lab, we designed a field study as our third experiment. Fifty participants (M_{AGE}=41.3 years, 57% male) were recruited for the experiment disguised as a marketing survey for the ice cream shop. In this study, consumers were intercepted after parking across the street from an ice cream shop. In return for their time, participants were awarded a coupon for $1.00. Participants first listened to the same sound used in studies 1 and 2 via headphones connected to a laptop. Following the sound, they responded to questions to gauge their distal perceptions of the ice cream shop. For fear of disrupting business, we used one measured factor that acted as a proxy for chronic dieting. To gauge dieting, on a 7-point Likert scale, we asked: "How interested would you be in trying our Only 8 calorie ice cream?"

A linear regression revealed that customers interested in diet ice cream perceived themselves as closer to the ice cream shop (b=.26, SE=. 09, t(49)=2.02, p=.005). In addition, spatial proximity mediated feelings of attraction towards the ice cream shop (10,000 bootstraps, 95% CI's: .0143, .2656). However, we did not find any significant differences in the amount of ice cream purchased or the amount of money spent, most likely because customers had already made the decision to go and have ice cream.

In conclusion, this research establishes the existence of a novel theoretical phenomenon we have termed "wishful hearing", as well as an underexplored threat to food well-being. In studies 1 and 2 we find that when exposed to a desirable product sound, people wish to hear the sound again and find it more appealing when the sound is perceived as spatially close to them. Study 2 extends our findings to willingness to pay and consumption. In our third study, we provide field evidence that wishful hearing still exists even when you know the exact location of the product in question.

Can Money Tip the Scale? Social Judgment of Overweight Shoppers and the Role of Form of Payment

EXTENDED ABSTRACT

Overweight and obese consumers face the daily challenge of navigating an environment in which food is omnipresent, yet weight-based stigmatization is worsening (Andreyeva, Puhl and Brownell 2008). Many overweight consumers experience an emotionally-charged and difficult relationship with food (e.g., Kidwell, Hardesty, and Childers 2008; Mela 2001). Purchasing food can be a particular stressor to those individuals, and they may be stigmatized by other consumers. Paradoxically, overweight individuals tend to respond to stress with emotional eating, which causes weight gain and begets further stigmatization (Sinha 2015; Tomiyama 2014). In light of this

negative cycle, better understanding weight-stigma in the shopping context is crucial in overcoming potentially harmful consequences.

Overweight/obese status is often attributed to lack of self-control (e.g., over-eating) (Brochu and Esses 2011). The present research investigates whether such consumers can overcome negative judgements by signaling self-control through their form of payment. We theorize that obese people who pay with cash (vs. credit card) when purchasing food may attenuate negative inferences made about them, because the use of cash may suggest greater self-control (e.g., Prelec and Loewenstein 1998; Prelec and Simester 2001). Thus, we examine whether a consumer's form of payment and body weight interact in the formation of social inferences made about them, and how these inferences affect encounters with others. We propose a novel research perspective that focuses on the inter-personal effects of form of payment. Prior work has investigated intra-individual effects of form of payment (e.g., Bijleveld and Aarts 2014; Feinberg 1986; Vohs, Meade, and Goode 2006; Vohs 2015); for instance, studies have shown that consumers spend more when they themselves pay with a credit card or debit card (vs. cash) because cash is the most painful form of payment (e.g., Prelec and Loewenstein 1998; Prelec and Simester 2001).

In contrast, our inter-personal perspective focuses on the social judgments related to how consumers pay. This analytical lens provides new insights into the social perception of overweight consumers, as it reveals that how shoppers pay (i.e., cash vs. credit card) influences how they are perceived by others (consumers and employees) in retail settings. This is the first research to show such inter-individual effects of form of payment, a ubiquitous marketing phenomenon that hitherto has been studied with a strong intra-individual focus.

Our conceptual framework links three literature streams on: spontaneous trait inferences (e.g., McCarthy and Skowronski 2011; 2014), weight-stigma (e.g., Andreyeva, Puhl and Brownell 2008; Friedman and Brownell 1995; 2002), and psychological and behavioral effects of cash and credit cards (e.g., Feinberg 1986; Prelec and Simester 2001; Vohs, Meade, and Goode 2006; Vohs 2015). We theorize that credit card (vs. cash) payments for food trigger less favorable assessments when the target shopper is obese, because obese consumers are thought to lack self-control. The existing literature on form of payment suggests that cash is an indicator of self-control, because it is a relatively painful method of payment.

In a series of six experiments, we examine the effects of form of payment on obesity stigma. We find that obese consumers making a food purchase with a credit card (vs. cash) are assessed less favorably overall (Study 1a) and they are judged to be more gluttonous in consuming indulgent food (study 1b). The effects are robust across different food types (Study 2), and the effects are mediated by judgments about the target shopper's level of self-control (studies 1a, 2, 3, and 4) and moderated by the observer's self-control (study 3, study 4) and financial literacy (study 5). Notably, across all studies, judgments of the normal-BMI shopper were unaffected by form of payment.

Study 1a tested our main hypotheses that the overall assessment of an obese consumer would be less favorable when purchasing food with cash (vs. credit). Participants assessed the obese target more favorably when she paid with cash (vs. credit). There was no difference in the attitude toward the normal weight shopper paying in cash versus credit.

In study 1b, participants attributed less gluttonous consumption (eating less of the food purchased) to the obese consumer paying with cash than with credit; there was no difference in status level for the regular weight consumer.

In study 2, participants assessed their overall impression of the target shopper purchasing either virtue or vice food. A three-way interaction did not emerge. Thus, we collapsed across food conditions and found a consistent pattern: the assessment of the obese consumer was more favorable when paying with cash than with credit; there was no difference in attitude assessment for the regular weight consumer.

Studies 3, 4, and 5 investigate how an observer's own level of self-control and financial literacy moderate the impression formation process. In study 3 and 4, the results show that that individuals with higher (vs. lower) self-control are more judgmental of obese consumers purchasing food. Similarly, in study 5, we find consumers with higher (vs. lower) levels of financial literacy judge obese consumers purchasing food with cash more harshly.

Our results have implications for understanding consumer food well-being. For overweight consumers, who may already experience a difficult relationship with food and for whom purchasing food may trigger emotional responses, feeling stigmatized in a retail setting when purchasing food may further threaten their well-being. Therefore, it is important to understand the mechanisms driving weight-stigmatization, which is often a perceived lack of will-power or self-control. We find that obese consumers making a food purchase may be able to offset these negative inferences by paying with cash because cash signals self-control. It is also important for observers to be aware of possible biases in their judgments of other consumers' payment methods, particularly vulnerable consumers such as those who are overweight.

You're Killing Me!
Exploring How Consumers with Food Intolerances
Navigate Eating Out

EXTENDED ABSTRACT

</div>

Celiac disease (CD) is a genetic autoimmune disease affecting about 3 million Americans with diagnoses increasing globally. Within minutes of ingesting gluten, sufferers experience a range of reactions from no symptoms to abdominal cramping, spontaneous diarrhea, migraines, days of incapacity, and even hospitalization. Long-term consumption damages their small intestine, interferes with the absorption of nutrients, and can have serious complications including infertility, osteoporosis, and anemia (Ludvigsson et al. 2013). The only existing treatment for CD is a gluten-free diet. The 2013 FDA ruling, which set the meaning of "gluten-free" to be less than 20 parts per million of gluten, should have legitimized the needs of celiacs. Restaurants, however, remain a dangerous place. Gluten-free labeling is voluntary, no enforcement exists, opportunities for cross contamination abound, and gluten-free meals come with disclaimers. As Jenny, who has CD, says, "It's so restrictive, you can't go out and enjoy meals with people. You've always got to be thinking that someone's going to get me."

How do consumers with celiac disease engage in service encounters that not only fail to meet their needs but where eating may have severe health consequences? To explore this question, we focused on consumers with CD using four sets of data: in-depth semi-structured interviews, digital diary entries collected 'in the moment' using informants' mobile phones, online postings from a CD support group, and field notes at a gluten-free festival.

Recent consumer research investigates how the micro-practices of consumers can significantly impact the macro-level market dynamics (Geisler 2012; Martin and Schouten 2014). However, few studies consider the struggles of marginalized consumers for market inclusion. Sandikci and Ger (2010) show how Turkish women cre-

ated a parallel fashion market through the destigmatization of veiling practices. In contrast, Scaraboto and Fischer (2013) view stigmatized plus-sized consumers as institutional entrepreneurs seeking greater inclusion within existing mainstream markets. They leverage adjacent institutional logics, such as the logic of human rights and fat acceptance, seeking to expand fashion offerings for large women.

Celiacs similarly struggle with stigmatization and seek greater marketplace inclusion. Yet given the severe health repercussions and limited restaurant offerings that are celiac safe, many withdraw from the marketplace. Celine captures a service failure where she "gets glutened" providing ample justification for why some sufferers prefer cooking basic food ingredients at home:

"I was up half the night with gut wrenching cramps, diarrhea, chills, nausea. The next day I was so tired. Now, I'm super depressed and really just do not want to go on living in a world where someone would take advantage of people like us just to make a buck, and not even get it right. I know I was glutened by this place… I feel sick in my body, my heart and my soul over this." [Celine, Interview]

Still, complete exclusion is difficult, particularly from social dining out events, and our informants draw on a range of tactics and strategies, such as finding one or two safe items on the menu, packing their own contingency food, or patronizing a restaurant that is completely gluten-free. Our informants report that, upon interacting with service providers, sometimes restaurants just do not feel safe. Restaurants and employees have 'tells," including statements servers make (e.g., "we added gf because it is popular" or "we have low gluten pasta"), nonverbals (e.g., long pauses, eye rolling), questions ("how gluten-free are you?"), and disclaimers ("We cannot be held responsible for 'normal' cross contamination that occurs during the preparation of foods in the kitchen."). A common strategy among informants was to go back stage and examine the food prep area and interrogate the chef. Stealth tactics were also employed, such as hiding a sugar packet at the bottom of a salad sent back to see if a new salad was brought or if the old salad was brought back sans croutons.

Communicating the dire importance of their gluten free needs was difficult because of a double invisibility; food service employees neither see the gluten nor its affects since our informants rush home to suffer in privacy if they get glutened. Our informants deftly employ different institutional logics within the service encounter. Drawing on the logic of food safety, they draw analogies to peanut allergies and food poisoning in their communication with restaurant staff: "Most people don't understand autoimmune diseases but they do understand allergies. Whatever it takes to get them to take me seriously (online data)." But they also distance themselves from the logic of customer choice and people who live a gluten-free lifestyle popularized by celebrities like Gwyneth Paltrow: "I am GF not by choice" and "it's a medical necessity." Ironically, recent surveys (Wong 2013) finding that 28% of consumers say they are cutting out or limiting gluten means that our informants have to work even harder to legitimize their claims: "I'm not taken seriously" (Bettina, interview).

In our analysis, we draw on elements of neoinstitutional theory as a useful analytical lens to theorize how marginalized consumers navigate the risk and stigma associated with mainstream markets in which harmful yet invisible food constituents are common and normalized (Dolbec and Fischer 2015). In doing so, we extend current conceptions of market dynamics (e.g., Scarabota and Fischer 2013) to reveal multiple processes through which these at-risk consumers maintain, disrupt, or withdraw from the mainstream market.

SESSION OVERVIEW

Recent developments of neurophysiological measurement techniques and growing interest in their use in marketing research have advanced our understanding of how consumers process information and make decisions. The papers in this session showcase the variety and richness in accessible neurophysiological methods that can inform marketing theory, and provide novel evidence on important drivers of consumer behavior that are inaccessible to a marketing researcher using self-report measures or purely behavioral metrics alone. The current session will exemplify how multimethod approaches such as psychophysiological measurements (fMRI, ECG, respiration), pharmacological interventions, and facial affective encoding can illuminate how consumers process, value and decide among the wide variety of options they encounter in the marketplace.

In the first paper, Couwenberg, Boksem, Dietvorst, Worm, Verbeke and Smidts explore the neural processes evoked by functional and experiential ad appeals in television advertisements, using functional magnetic resonance imaging (fMRI). They demonstrate that functional and experiential ad appeals for the same brand engage different brain regions, and that these activation patterns predict subsequent advertisement effectiveness.

In the second paper, Nave, Nadler, Dubois, Camerer, and Plassmann investigate the causal relationship between testosterone and preference for status goods. Using double-blind placebo controlled exogenous testosterone administration and subsequent hormonal measurements extracted from saliva samples, they reveal that testosterone drives status- but not quality- or power-seeking motivation underlying consumers' product evaluations.

In the third paper, Acikalin and Shiv explore the role of the physiological regulation of emotion in decision making under risk and uncertainty. By quantifying and manipulating vagal tone, a physiological marker of autonomic flexibility and stress vulnerability, they show that increased parasympathetic activity decreases risk aversion.

In the fourth paper, Ling, Shiv, and Plassmann use facial affective encoding in order to investigate the temporal dynamics of affect-as-information effects in consumer judgments. Online measurement of facial responses to incidental rewards during aesthetic evaluations allowed for rapid tracking of when incidental affect was being used as information.

Taken together, these papers provide an overview of how different types of neurophysiological measures can be applied to answer both theoretically and managerially important questions in the field of consumer behavior. In doing so, this session offers novel insights into the neurophysiological processes underlying judgement and choice, raising fundamental questions such as "What can we learn about decisions from consumers' neurophysiological states?". Thereby, not only do we advance the theoretical understanding of the drivers of behavior, but we also generate novel hypotheses for further research. Notably, these papers appeal to a broad audience, as they intersect in their utilization of neurophysiological methods and focus on consumer decision-making, but also tackle central questions in a variety of popular areas in consumer behavior such as advertising efficacy, conspicuous consumption, risky decision-making, and the role of affect in consumer choice.

Neural Responses to Functional and Experiential Ad Appeals: Explaining Ad Effectiveness

EXTENDED ABSTRACT

An advertising appeal - the central idea of a message that highlights specific attributes of the product - can be described in terms of its functional and experiential elements. Ads with a predominant functional appeal typically convey a message that relates to a rational or utilitarian focus on product features, by including references to the product attributes, its use and performance, as well as the benefits and value that come with these features (Abernethy and Franke 1996). In contrast, one of the key ideas of an experiential advertising appeal is that value does not only reside in the advertised good and its utilitarian and functional benefits, but that value also lies in the emotional, sensory and experiential elements associated with the good, and in the (indirect) experience of it (e.g., through advertisements; Holbrook and Hirschman 1982).

Despite the large body of research that has investigated the effect of ad appeals of television advertisements on consumers' internal responses and behavior, our understanding of how different ad appeals are processed remains limited. Neuroimaging methods, such as functional magnetic resonance imaging (fMRI), can serve as a valuable complement to conventional self-report methods, providing more implicit and immediate insights into ongoing mental processes that are typically difficult to access using other approaches.

In the present study, we explore how novel insights from neuro-imaging techniques can advance our understanding of how functional and experiential ad appeals are processed by consumers and how these processes are, in turn, related to advertisement effectiveness.

We compared a unique set of eleven different television commercials for the same brand (i.e., a well-known muscle and joint gel) to investigate the influence of differences in advertisement appeal, in terms of functional and experiential executional elements, on brain responses and subsequent advertisement effectiveness. The selected commercials were of comparable professional quality, equal length (all 20 seconds) and did not differ in terms of lower-level visual features.

In our experimental design, we combine data from three independent samples: (1) an fMRI neural focus group (N = 24), to measure immediate neural responses to the television commercials; (2) a large sample of consumers in the population (N = 1239), to measure ad effectiveness for each commercial; and (3) a sample of advertising experts (N = 9) who assessed each commercial's appeal. We used the expert judgments scale from Zarantonello, Jedidi, and Schmitt (2013), which includes items that pertain to the functional and experiential dimensions of an ad. Advertising effectiveness was measured by the consumer's online information search behavior in direct response to a television commercial (i.e., click-through rate to the product website (CTR)).

To investigate the neural processes evoked by functional and experiential executional elements, and how these processes relate to ad effectiveness, we conducted a series of analyses. First, we assessed to what extent the expert-rated executional elements were related to population-level ad effectiveness. Results of a stepwise linear regression model reveal that ads that demonstrate the functional benefits of the product (i.e., focus on the advantages for the consumer), and appeal to imagination (i.e., thinking in a different, original and innovative way, approaching things from a new angle) were most effective in stimulating click-through behavior (R^2 = .169, $F(1,96)$ = 5.204, $p < .05$).

As a second step, we examined the brain regions engaged by these effective functional and experiential executional elements. While the functional element was particularly associated with responses in the temporal cortex (i.e., inferior temporal gyrus (ITG) and middle temporal gyrus), the experiential element evoked neural responses in the dorsolateral prefrontal cortex (i.e., DLPFC: precentral gyrus, extending into inferior frontal gyrus and middle frontal gyrus). Results exceeded the threshold of $p < .05$ FWE corrected on the cluster-level.

Third, we analyzed whether activity in these specific brain regions in direct response to the commercials was predictive of CTR in an independent sample of consumers. Results of a multi-level linear regression model indicate that the extent to which the brain regions associated with the most effective functional element (i.e., activity in a region-of-interest within the ITG) and experiential element (i.e., activity in a region-of-interest within the DLPFC) were activated while viewing the commercials, predicted the successfulness of the commercials (i.e., DLPFC significantly: b = .014, p = .013; ITG marginally significantly: b = .008, p = .086).

Additionally, we conducted a psychophysiological interaction analysis to assess how functional connectivity between brain regions is altered in response to more effective commercials. Findings revealed interactions between the ITG and the DLPFC, and between the DLPFC and the amygdala, for higher levels of CTR.

Exploring the neural responses to different ad appeals, we dissociated brain regions responding to functional and experiential executional elements in television ads. We found that a functional appeal engaged the temporal cortex. Previous neuroimaging studies demonstrated that the temporal cortex is involved in higher-level perceptual processes, such as object identification, recognition and interpretation (e.g., Bar et al. 2001). The temporal cortex thus plays an important role in identifying '*what*' things are, and constitutes an important hub in the so-called ventral stream, or the '*what pathway*', of visual processing (Goodale and Milder 1992). This potentially indicates that effective processing of information on the product itself, but also of how the product should be used may lead to increased success of the commercial.

Moreover, we found that an experiential appeal engaged the DLPFC. The DLPFC has been related to sustained attention and working memory, processes which are critical for enabling creative thought (Dietrich 2004). Its functional connectivity with the amygdala, a brain structure associated with emotional processing (e.g., Davis and Whalen 2001), may potentially suggest higher emotional engagement for more successful ads.

Furthermore, we show that not only activation in, but also interaction between, the ITG and the DLPFC was related to higher ad effectiveness. Our findings generate hypotheses for a richer understanding of how consumers effectively process functional and experiential ad appeals.

Peacocks, Testosterone and Status Seeking: Single-dose Testosterone Administration Increases Preference for Status Brands and Products

EXTENDED ABSTRACT

Desire for social status is a universal human motive (Maslow, 1943) that is preserved across species, and should therefore have biological signatures (Kenrick et al. 2010). One way in which humans in complex societies obtain, maintain or display their social status is the consumption of status goods (Veblen 1899). Status products represent social markers that elevate humans in the social hierarchy, either through increasing status (respect in the eyes of others) or power (desire for control over valued resources, Magee and Galinsky 2008). Yet, the biological drivers of such (costly) preference for luxury goods remain poorly understood.

The androgenic hormone testosterone (abbreviated 'T') is produced in the male testes and in smaller quantities in female ovaries. T affects physiology, brain development and behavior throughout life. In many non-human species, T levels rise amid breeding season and facilitate behaviors such as intra-male fighting, mating and display of dominance (Eisenegger, Haushofer & Fehr 2011). In humans, T is released into the bloodstream and in the brain in response to external stimuli such as the presence of an attractive mate or in anticipation of a competitive challenge, modulating physiological and cognitive processes in a context-sensitive manner. Correlational studies have further showed that status-related behaviors, such as winning competitions (Booth et al. 1989) or driving Porches (compared to a family Sedan, Saad & Vongas 2009) also increase T levels, making it a prime biological candidate for modulating preferences for status goods.

In the current study, we hypothesized that (1) elevated T levels increase preferences for high status vs. low status goods and (2) that these effects are driven by T-induced status-seeking rather than quality-seeking or power-seeking.

We randomly assigned 243 male students to receive either topical T or placebo (P) gel in a double blind exogenous administration protocol. Participants returned to the lab five hours later, when the T group experienced stable and elevated T levels as compared to the P group (p<0.001, manipulation was checked using saliva samples). Each participant took part in two tasks.

In the first task, subjects were shown five pairs of brands in a randomized, counter-balanced order. Pairs were chosen based on a pretest conducted in a demographically similar population (N=387), such that each pair consisted of pre-tested "high" and "low" social status brands (e.g., Levi's versus Lacoste), where the difference in status association between the two was reliably greater than the difference in quality association. Subjects indicated which of the two brands they preferred, and to what extent, using three 10-point likert rating scale.

In the second task, participants were shown text ads of six different products (e.g., sunglasses, a car), and indicated their attitudes towards the goods. For each product, we composed and pre-tested three different text ads that were identical, except specific phrases, that either emphasized the product's quality, power or status enhancing characteristics. We randomized each product's ads between subjects, such that every subject saw two quality, power and status ads in a counter-balanced fashion. This resulted a 2 (testosterone/placebo, between-subjects) x 3 (quality/ power/ status, between-subjects) x 6 (product, within-subject) design.

We estimated mixed-effect linear models with preference ratings as the dependent variable (such that higher rating implied greater preference for the high, over the low status brand) controlling for subject and brands pair random effects. In line with our main hypothesis, subjects who received T showed greater preference for the high status brands ($\beta=0.45\pm0.24$, p=0.04). Further analysis corroborated the effect's robustness to control for age, mood, treatment expectancy, the 2D:4D digit ratio (a proxy of prenatal T exposure) and the levels of 14 other hormones (measured in saliva) that were not affected by T treatment.

In an analogous manner to task 1, we estimated mixed-effect linear models with products' liking as the dependent variable, controlling for subject and product random effects. We found that the T group subjects liked the products advertised as status-enhancing more than placebo ($\beta=0.63\pm0.25$, p=0.01). On the contrary, there were no reliable differences between the two groups in liking of products advertised as high in quality or power. The effects (and their absence) prevailed when including additional controls for age, mood, treatment expectancy, 2D:4D and 14 other hormones that were unaffected by T treatment.

Our results show that preference for status enhancing brands and products in humans have indeed biological roots: pharmacologically elevated T levels increased consumer's preferences for status vs. non-status brands and goods. Our findings are the first to show a *causal* relationship between T administration and preference for status brands and products, and that T drives status- but not quality- or power-seeking motivation underlying consumer's product evaluations. The latter distinction is an important contribution for two reasons. First, most previous studies do not control for potential higher quality attributes of status products and are thus confounded. Second, as costly signals such as status brand consumption may contribute both to one's power *and* status in the social hierarchy, our results are the first to show that T acts specifically on status- but not power-seeking motivation.

Cardiac Vagal Tone and Risky Decision Making

EXTENDED ABSTRACT

When we make risky decisions, the possibility of undesirable outcomes can elicit negative emotional responses that influence our risk preferences (Loewenstein et al., 2001). For this reason, how we regulate these emotions can determine the how much risk we are willing to take. Emotions are regulated by both higher-level cognitive and lower-level physiological processes. For instance, we can regulate how we feel at the higher-cognitive level by reappraising the source of an emotion or by suppressing it (Ochsner & Gross, 2005). Such regulation strategies have been demonstrated to influence decision-making (Gross, 2013). In addition to these cognitive strategies, which require conscious effort, emotions are also regulated automatically at the physiological level by the autonomic nervous system (ANS). The parasympathetic subdivision of the ANS down-regulates arousal, respiration, heart rate, and attention; aiding emotion-regulation by controlling visceral states (Porges et al., 1994). Unlike cognitive emotion-regulation strategies, the impact of which has been examined in various decision-making contexts, little has been documented about the role of the physiological regulation of emotion in decision-making. The primary goal of this research is to fill this gap in the literature. Specifically, our aim is to delve into the role of emotion-regulation on decision-making from a physiological perspective, focusing on the effects of parasympathetic activity on risk aversion.

In order to understand how the physiological regulation of emotion can influence decision-making, we draw upon the well-documented work on to the vagus nerve, the key component of the parasympathetic nervous system (Critchley & Harrison, 2013). We specifically focus on a non-invasive measure, cardiac vagal tone (VT), measured via respiratory sinus arrhythmia (RSA; Berntson et al., 2007). RSA is a non-invasive proxy for vagal—and thus, parasympathetic—activity and autonomic flexibility (Porges et al., 1994). The regulatory effect of vagal activity on emotional function is ubiquitous in the literature and, thus, VT is widely accepted as an indicator of parasympathetic involvement in the regulation of emotion by physiological means (e.g. Porges, 1996; Gottman & Katz, 2002). Naturally, VT is a strong predictor of stress vulnerability (Porges, 1995). For example, higher resting VT has been shown to protect children from marital conflict (El-Sheikh et al., 2001).

In this research, we examine whether the influence of VT extends to decision-making under risk and uncertainty. Akin to how cognitive reappraisal strategies reduce arousal (Sokol-Hessner et al., 2009) and loss-aversion (Sokol-Hessner et al., 2012) in risky decisions, we posit that increases in VT, indicating improved physiological regulation of emotion, ought to similarly predict reduced risk aversion. In three experiments, where we either measure VT as an individual difference or experimentally manipulate VT using specific breathing techniques, we assess risk preferences in two risky decision-making tasks with built-in incentive compatibility, the Balloon Analog Risk Task (BART; Lejuez et al., 2002) and the Gneezy Risk Task (GRT; Gneezy & Potters, 1997). Together, these experiments document the modulation of risk aversion by vagal activity, as indicated by VT.

In Experiment 1, a correlational study, by measuring VT of free-breathing participants while completing BART, we found that confirming our hypothesis, participants with higher levels of VT showed less risk aversion, indicated by a significant positive relationship between RSA and the adjusted number of pumps (p < 0.0005).

In Experiment 2, we manipulated VT experimentally by regulating the breathing of participants, randomly assigning them to a regular-breathing (control-normal VT) or a deep-breathing (high VT) condition. A manipulation-check confirmed that the breathing manipulations were effective. Participants in the deep-breathing condition had significantly higher RSA levels compared to the control condition (p < 0.0001), which did not differ from the average RSA of the free-breathing participants in Experiment 1 (p > 0.36). The results confirmed our hypothesis, and participants in the deep-breathing condition took significantly more risk than participants in

the regular-breathing condition in both BART (p < 0.021) and GRT (p < 0.027).

In Experiment 3, we investigated whether our breathing manipulations caused any mood effects using the Brief Mood Introspection Scale (BMIS), in addition to addressing whether our main finding in GRT holds controlling for mood measurements. The results replicated our GRT findings in Experiment 2 (p < 0.04). There were no significant differences between groups in the Arousal-Calm dimension (p>0.35), or the Pleasant-Unpleasant dimension (p>0.60) of BMIS. Controlling for mood effects, which had non-significant coefficients (p>0.30 for both), breathing manipulation was still a marginally significant predictor of risk taking in GRT (p<0.09).

These findings are congruent with previously limited and correlational research indicating that VT might predict how individuals deal with stressors in decision-making contexts. For instance, resting VT has previously been found to correlate with the magnitude of stress response to (Dulleck et al., 2011) and the likelihood of rejecting unfair offers in ultimatum games (Sütterlin et al., 2011). Further, this pattern of results is consistent with studies on risky decisions that focus on emotion-regulation from a higher-level cognitive perspective such as cognitive reappraisal modulating the experience of negative emotions and influencing loss aversion (Heilman et al., 2010).

Our experimental manipulation of VT using breathing exercises highlights how immediate the cognitive and behavioral consequences of a change in parasympathetic activity can be. Our participants started eliciting differential behavior in sophisticated decision-making tasks beginning merely a minute after a getting in sync with a deep-breathing rhythm, before they even detected any breathing-driven influences in their emotional states. This can have important implications in a myriad of consequential contexts, such as risky decisions in the medical, political, and business domains.

In sum, we demonstrate that the regulatory effects of VT on emotional function extend to risky decision making contexts. Put simply, how good our bodies are at handling the affective consequences of experiencing uncertainty predicts risk aversion.

Modulation of Judgments by Incidental Affect: the Dynamic Integration of Affect and its Temporal Sustainability

EXTENDED ABSTRACT

Consumer psychology research has suggested that affect plays a central role in consumers' judgments and evaluation processes. A substantial body of studies has found that even incidental affect, i.e. affect unrelated to the decision at hand, can execute a significant impact on judgments and evaluations. This has been known as the "affect-as-information effect" (AIE) (e.g. Pham 1998, 2014; Schwarz and Clore 1983). Specifically in a marketing context, the affect-as-information effect suggests that consumers evaluate products by inspecting their preexisting feelings rather than conducting attribute-based evaluations. For instance, Naylor, Raghunathan and Ramanathan (2006) reported that exposure to promotional stimuli would evoke a positive feeling and subsequently enhanced the evaluation of unrelated products. Since incidental affect is ubiquitously related to consumer evaluations, it is critical for marketing researchers to understand how exactly incidental affect could influence consumers' judgments and evaluations.

Despite decades of research, however, our understanding of the affect-as-information effects is still incomplete. For example, we have limited understanding of the dynamic processes of how incidental affect is integrated while consumers are making judgments or evaluations. It is also unknown whether the integration of affect is purely a psychological process or underlies a neurophysiological foundation. These questions remain unclear because of the methodological limitations in manipulating affect, tracking affect and measuring evaluations in the previous research. Such methodological limitations might have resulted in further confusions in the past research concerning how sustainable the influences of affect on judgments and evaluations are. Some studies suggested that the affective influences fade away after a short period of time (e.g. Dutton and Aron 1974; Gneezy and Imas 2014; Isen, Clark and Schwartz 1976), whereas others suggested that they endure and persistent for hours or even days (e.g. Andrade and Ariely 2009; Ottati and Isbell 1996; Pocheptsova and Novemsky 2010).

In order to address these above questions, we conducted a series of studies to understand the dynamic integration of affect and its temporal sustainability using both neurophysiological and behavioral approaches.

We manipulated affect by delivering or not delivering incidental monetary rewards that was shown previously as an effective way to alter one's affective states (e.g. Eldar and Niv 2015; Isen, Daubman and Nowicki 1987) in each trial, and asked participants to subsequently make aesthetic evaluations of images in a seemingly unrelated task.

In the first study, we employed facial affective encoding using NOLDUS Facereader to track "online" affective alterations, which allowed us to examine the dynamic neurophysiological integration of affect during aesthetic evaluation processes. Behaviorally, the study replicated the affect-as-information effects showing that receiving vs. not receiving an incidental reward increased subsequent aesthetic evaluations of both positive and neutral images (β_{reward}=1.45, p<.001). In addition, our findings revealed that the behavioral AIE were mediated by the online facial happiness responses triggered by winning money (β=.061, 95% CI=[0.016 0.152]). More importantly, analyzing the time courses of the facial happiness response, we further found that the affect integration took place rapidly (i.e. second-basis) and could be amplified and attenuated on a trial-to-trial basis.

In the next study, we examined the sustainability of AIE by introducing two different lengths of temporal delays (i.e. 2-min vs. 5-min) during the aesthetic evaluation task. After receiving money, participants evaluated images before and after an affectively neutral filler task. Both studies replicated AIEs such that participants liked images more after receiving vs. not receiving money (β_{reward_2min}=.342, p<.004; β_{reward_5min}=.438, p<.001). Critically, however, two moderated mediation analyses showed that the AIEs were preserved after a short period of delay ($\beta_{2min-delay}$=.357, 95% CI = [.217 .491]), whereas the AIEs were attenuated after a longer delay ($\beta_{5min-delay}$=.14, 95% CI = [-.161 .296]).

In the third study, we further examined the cause of attenuation of the affect-as-information effects. We reasoned that a long temporal delay did not dilute affect *per se*, but instead, it attenuated the perceived representativeness of affect (i.e. the affective state is less attended than other source of information) to subsequent evaluations. Using the same paradigm as in study 2, we asked participants to report their happiness of winning vs. not winning money either right after disclosure of the lottery outcome or after a 5-min delay. Conceptually, assessing the happiness of the lottery outcomes re-directed participants' awareness to their affective states. We first found that there was no effect of timing on reported happiness of winning or not winning money ($t_{reward(297)}$=1.52, p=.127; $t_{no-reward(276)}$=.5, p=.6). This demonstrated that the induced affect was still preserved after a 5-min delay. We further found that by reminding participants of their affective states after the temporal delay, the perceived representativeness

of affect was reassumed, and the affect-as-information effects were recovered (moderated mediation analysis coefficients: $\beta_{immediate}$=.423, 95% CI=[.273 .587]; $\beta_{5min-delay}$=.461, 95% CI=[.294 .614]).

Taken together, our research has contributed to understand the temporal mechanisms of the affect-as-information effects. Using facial affective encoding, we captured the online facial happiness during the occurrence of AIEs. We provided first evidence that integration of affect into subsequent evaluations is mediated by a fast neurophysiological dynamics on a trial-to-trial basis.

Exploring the temporal sustainability of the AIEs, we found that affective influences could be attenuated after 5min but not 2min interval. We further showed that this was not due to the dissipation of affect but because of the dissipation of the perceived representativeness of affect along the time course. By re-directing participants' awareness to their affective states, we showed that the affect-as-information effects could be recovered even after a long interval.

SESSION OVERVIEW

Consumer research has investigated how various aspects of consumption—anticipation of consumption (Loewenstein 1987), frequency of consumption (e.g., Hamilton, Ratner, and Thompson 2011), and remembering consumption (e.g., Cowley 2007)—impact how the consumed object is evaluated. But what about *non*consumption? How does not consuming something, or deferring usage, shape downstream attitudes and behavior?

This session brings together a variety of perspectives to deepen understanding of nonconsumption. While a few papers have identified motivations for nonconsumption (e.g., Trocchia and Janda 2002; Wansink, Brasel, and Amjad 2000), little is known about how nonconsumption affects downstream attitudes and behavior pertaining to the nonconsumed (Dai and Fishbach 2013; Dai and Fishbach 2014). The papers in this session provide four novel perspectives on how nonconsumption impacts the value of, desire for, and future consumption likelihood of nonconsumed goods across several domains.

The first two papers examine how prolonged nonconsumption affects evaluations of goods we desire. Dai, Kwan, and Fishbach resolve inconsistencies in prior research on intertemporal patience by highlighting two competing goals that result from nonconsumption and are activated differentially across choice contexts: the goal to get the nonconsumed *now*, and the goal to get a *larger quantity* of the nonconsumed. Mead and Patrick explore the impact of nonconsumption specificity, show that unspecific but not specific postponement causes consumers to infer that they desire the temptation less, and are thus less likely to consume it.

The second two papers examine how nonconsumption affects perceptions and consumption of goods consumers already own. Rifkin and Berger demonstrate how deferring usage of everyday goods can spark a specialness spiral by which nonconsumed goods are perceived as more special, and thus are less likely to be used in the future. Finally, Sheehan and Dommer show that while self-relevant goods are more likely to be purchased, they are also more likely to be protected or more slowly consumed.

Taken together, these four papers shed light on how nonconsumption impacts evaluations and future behavior. The papers approach this topic across various domains and methodologies, and ad-dress several questions that remain important to consumer behavior: First, when does nonconsumption increase or decrease desire for and evaluations of goods? Second, when might increased value lead to greater or lower likelihood of future consumption? Finally, what factors drive the inferences that consumers draw from nonconsumption, and how do these inferences impact subsequent consumption?

We believe that this session will have broad appeal to scholars interested in motivation and self-regulation, meaning transfer, identity-relevant consumption, and self-perception more broadly. Given staggering statistics hinting at the massive rate of nonconsumption worldwide—namely, that the average American home contains thousands of goods (MacVean 2014), or that shoppers worldwide spend $1.2 trillion annually on non-essential goods (Whitehouse 2011)—we believe this session brings to light the incredibly relevant, and largely understudied, topic of nonconsumption.

Need and Intertemporal Choice: A Dual Goal Hypothesis

EXTENDED ABSTRACT

Consumer decisions are usually affected by transient changes in people's need states such as hunger, thirst, and sexual desire, as a consequence of non-consumption periods. Findings from existing research (Hoch and Loewenstein 1991; Kim and Zauberman 2013; Li 2008; Loewenstein 1996; Van den Bergh et al 2008) converge to the conclusion that higher need leads to greater impatience.

In this paper we propose and show that need states could *increase* patience under certain situations. Specifically, we distinguish between two types of choice, proximal choice and distal choice. By *proximal choice* we mean a choice between an option that is available immediately or now, and an option that is usually larger and available in the future (e.g., in 10 days). By *distal choice* we mean a choice between options that are both available in the future, and thus could not help satisfy the current need. We propose that need states 1) generally decrease patience in the former, as most existing literature has found (a thorough literature review confirmed that these papers used only proximal choices, and in rare cases, the smaller-sooner option was very close to "now"), and 2) decrease patience in the latter.

We explain such results by a dual-goal hypothesis. We argue that a need state activates two goals: an actualization goal and a quantity goal. The actualization goal concerns the feasibility of getting the need satisfying object. It suggests that a person of high need wants need satisfying target as soon as possible. The quantity goal concerns how much one can get the need satisfying object. A person of high need wants larger quantity of the need satisfying object than a person of low need. Thus, when making proximal choices, those high (vs. low) in need will base their choices on the tradeoffs between the two aforementioned goals. In this case, existing literature found greater preference for the immediate option. This suggests that the actualization goal was more prominent than quantity goal in most situations when the need is high (we take this as a fact and build it to our theorization). Alternatively, when making distal choices, actualization goal is irrelevant as both options are not immediately available (neither option can satisfy this goal anyway). Those high (vs. low) in need thus base their choices on the quantity goal, and show stronger preference for the larger-later option. In line with prior findings that need (e.g., hunger) instigates a general reward seeking tendency, we expect that the effects are similar for need relevant (e.g., food) and irrelevant (e.g., money) targets.

Five studies tested the above propositions. In study 1, participants from Amazon Mechanical Turk made eight decisions on either money or food – four proximal choices and four distal choices. Then all participants reported their hunger level. Consistent with our prediction, when facing distal choices, those who were hungrier were more likely to choose the larger-later options over the smaller-sooner options (i.e., more patient); in contrast, when facing proximal choices, those who were hungrier were directionally more likely to choose the smaller-sooner options (i.e., directionally less patient). Such conclusions were true for both food items and money. Study 2 was a field study in which we approached students who were either walking into (hungry condition) or out of (satiated condition) a university canteen. Participants made six decisions, either on money or food choices, half proximal choices and another half distal choices. As a manipulation check, those walking in the canteen were indeed hungrier than those walking out of it. Replicating the findings in study 1, hungry participants were more patient when making distal choices. For proximal choices, no significant difference in patience was found.

Study 3 directly manipulated hunger. Participants were instructed not to (hungry condition) or to have breakfast (satiated condition) before the study session (in the morning). To strengthen hunger manipulation, those in the hungry condition were given a tiny slice of bread (bite size) to taste and those in the satiated condition were asked to eat two large slices. In a subsequent unrelated study, they made eight food decisions on a computer. Their response time for each action was recorded by the Mouselab program. Results indicated that hungry participants were less patient when making proximal decisions, but more patient when making distal decisions. Hunger significantly decreased patience in this study but not in the previous studies because we had a stronger hunger manipulation (and thus the actualization goal became more prominent). These findings were further corroborated with attention measures from the Mouselab program.

To increase the generalizability of our result, study 4 manipulated sexual arousal instead of hunger. Following Li and Zhang (2014), half participants evaluated pictures of sexy female models (high sexual arousal) and another half evaluated pictures of sexually unattractive females (low sexual arousal). After this task, participants made eight money decisions, with half proximal and half distal choices. Similar to study 1 and 2, sexually aroused participants were more patient when making distal choices, but were not different from the satiated participants in their patience when making proximal choices.

Finally, in study 5 we examined the dual-goal mechanism. Similar to study 1, participants from Amazon Mechanical Turk first made proximal and distal choices of food items and reported hunger levels. Participants also reported the extent to which they would like to get as large piece of food as possible (quantity goal), and as immediately as possible (actualization goal). Results indicated a significant interaction between hunger and decision. Hunger significantly decreased patience for proximal choices but increased patience for distal choices. More importantly, bootstrapping analyses supported the moderated mediation effects of actualization goal and quantity goal. Specifically, both immediacy goal and quantity goal could mediate this effect (in opposite directions) for proximal and distal choices. However, actualization goal was a significantly stronger mediator in proximal choices and the quantity goal was a significantly stronger mediator in distal choices. A meta-analysis of all the studies confirmed that need states decreased patience in proximal choices and increased patience in distal choices.

Postponement Specificity Differentially Affects Desire and Consumption

EXTENDED ABSTRACT

Desires are a hallmark of daily life. Although they can be a source of great pleasure, they can also be a source of pain and torment as they derail people from achieving cherished goals. How can consumers tame unwanted desires?

It is generally accepted that specific goals are superior for facilitating goal completion (e.g., Locke & Bryan, 1969), However, in the present work we suggest that unspecific postponement is more effective for reducing unwanted consumption than specific postponement.

Our hypothesis were based an integration of two separate literatures. First, research suggests that plan specificity changes people's motivation to achieve the set goal, with specific plans strengthening commitment and motivation (e.g., Salancik 1977). Second, recent research suggests that people learn about their desires just as they learn about their attitudes and preferences, by observing and making inferences about their behavior (e.g., Bem 1972; Dai and Fishbach 2014). When taken together, we suggest that when people observe themselves postponing a temptation to an unspecific future time, they interpret their behavior as a signal that they do not strongly value that which they have postponed. In this way, postponement should only weaken valuation for the temptation when people are induced to postpone when postponement is unspecific (not specific).

Experiment 1 (N=108) varied the specificity of postponement and examined desire for the temptation in the heat of the moment by measuring performance on a reading comprehension task in the presence of the tempting cookies (e.g., Masicampo and Baumeister 2011). Before completing the reading comprehension task, participants formed an unspecific postponement intention or a specific postponement intention about the tempting cookies. Specifically, those in the unspecific (specific) postponement condition rewrote an intention to postpone the temptation ("If I have the urge to eat cookies, I will tell myself that I can eat cookies some other time [in exactly one week]!"). Hence, the unspecific and specific postponement intentions were identical except that "some other time" in the unspecific intention was replaced with "in exactly 1 week" in the specific intention. A baseline condition was included in which participants completed the reading comprehension task but were not exposed to the cookies.

Results supported predictions. Unspecific postponement participants reported being less distracted by the cookies and hence performed better on the reading comprehension task as compared to specific postponement participants. Additionally, unspecific postponement participants did not differ from baseline participants suggesting that unspecific postponement enabled participants to perform as though the cookies were not even there.

Experiment 2 (N=186) tested the differential effects of specific and unspecific postponement for liking of a temptation. If unspecific postponement weakens valuation of the temptation, then a change in liking – an affective evaluation – should be reduced by unspecific but not specific postponement. Experiment 2 also tested the hypothesis that individual differences in motivation to forgo the temptation moderate the effect of postponement on consumption. If unspecific postponement weakens liking because it leads people to infer lackluster valuation for the temptation then this should occur most strongly among participants who are motivated to interpret the ambiguous postponement intention as a signal of low valuation of the temptation.

Similar to Experiment 1, participants in the unspecific and specific postponement conditions were exposed to cookies in their cu-

bicles whereas participants in the baseline condition were not. All participants rated their liking for the cookies. Then, participants in the postponement conditions completed the same intention used in Experiment 1. After a distractor task, all participants completed their liking of cookies again. Motivation to forego unhealthy food was measured with the dieting subscale from (Herman and Polivy 1980).

Results supported predictions. An interaction between unspecific postponement (vs. baseline) and eating restraint emerged when predicting change in liking from pre-manipulation to post-manipulation. Dissecting the interaction revealed that unspecific postponement (vs. baseline) reduced liking for the temptation, primarily among participants who were highly motivated to forego tempting but unhealthy food. There was no interaction between specific postponement and eating restraint.

Experiment 3 (N=235) sought to test the differential effects of unspecific and specific postponement for consumption of the postponed temptation. Participants were asked to choose a food temptation and were induced to form an unspecific postponement intention (same as experiment 1), specific postponement intention (identical to experiment 1 except the time frame was "three days"), or no plan (same as experiment 1). Participants received a text message on their smartphone and were asked to click on the link the very next time they consumed the temptation, enabling us a precise measure of consumption delay. Results supported the self-signaling account for the effects of postponement on consumption. An interaction between motivation to forgo consumption and unspecific postponement (vs. no-plan control) but not specific postponement (vs. no-plan control) emerged. Among participants highly motivated to forgo consumption of the temptation, unspecific postponement (vs. no-plan control) delayed consumption. The effect of unspecific postponement (vs. no-plan control) was not significant among those who were not highly motivated to forgo consumption.

In summary, three experiments suggest that when consumers are trying to give up a temptation, unspecific postponement is a more effective strategy than specific postponement. The results imply that people's desires for temptations are partially shaped by the interpretation of their behavior, and that desire modification can be an effective route toward self-control success.

How Everyday Items Become Treasures: Forgoing Usage and the Escalation of Specialness

EXTENDED ABSTRACT

Consumers own many unused items (e.g., Trocchia and Janda 2002; Wansink, Brasel, and Amjad 2003). Some things (e.g., fancy china or tuxedos) go unused because there are rarely occasions nice enough; others (e.g., wine from your wedding) go unused because of sentimental value; and still more things go unused because they are no longer liked (e.g., old clothes) or because usage opportunities rarely arise (e.g., baseball gloves). But are these the only reason items go unused?

A brief glance in one's closet or pantry suggests that some items—such as inexpensive bottles of wine or t-shirts—are continually passed over, even though people like them and have ample opportunities to use them. Further, these "everyday" items didn't come from a special event and don't start with any sentimental value. So why do people continually forgo using them?

We suggest that merely *not* using an everyday item, like a bottle of wine, can lead people to avoid using it in the future. There are many inferences consumers can draw from nonconsumption (Bem 1972) and these inferences shape how non-consumed items are perceived and used (Dai and Fishbach 2013, 2014). In the absence of salient external (i.e., I can't access it) or negative (i.e., I don't like it) attributions, however, we suggest that forgoing usage can lead an item to be perceived as *more* special. If one infers they passed up using something because they are saving it, for example, that suggests the item must be worth saving, and thus must have at least some special quality or aspect to it.

Perceiving an item as more special can in turn decrease subsequent use. Much like the way families restrict using china for special occasions, or wait to open champagne until a big job promotion, people are motivated to protect special items by restricting their use (Belk, Wallendorf, and Sherry, Jr. 1989; Zauberman, Ratner, and Kim 2009). Thus, when everyday items become special due to being passed up, consumers will restrict future usage in two complementary ways: by reducing usage in normal, everyday occasions (e.g., a Tuesday) and by reserving for more extraordinary (i.e., rare or special) occasions (e.g., a birthday).

As non-consumed items are passed up in *subsequent* opportunities, they become even more special, and thus, further restricted from usage. Consequently, forgoing usage may spark a "specialness spiral" whereby items become more and more special, and less and less likely to be used. As a result, everyday items may become treasures: fenced-off gems, only to be used in the most extraordinary of occasions.

Studies 1a-c provide an initial test of this phenomenon. Whether examining tickets to a boat cruise (study 1a; $N = 181$), episodes of a television show (study 1b; $N = 205$), or a bottle of wine (study c; $N = 203$), compared to simply considering such items, forgoing decreased usage likelihood in everyday occasions, and increased likelihood of being reserved for extraordinary occasions (all $ps < .05$). By demonstrating that forgoing usage leads to reserving for more extraordinary occasions, study 1 casts doubt on the alternative explanation that forgoing decreases future use because people infer that they do not like the non-used item.

Study 2 ($N = 320$) tests our proposed mechanism. While people can draw various inferences about why they chose not to use a good (e.g., they don't like it, it's not a good fit for the situation), *saving* inferences should be most likely to enhance that good's specialness. Consequently, if changes in the item's perceived specialness are driving our effect, as we suggest, then encouraging such saving inferences should amplify the effects on future usage. Results confirmed this prediction: People who naturally made saving inferences perceived a non-used item as more special ($r = .56$) and intended to reserve it for a more extraordinary occasion ($r = .64$). Moreover, encouraging such saving inferences led to reserving for more extraordinary occasions ($p = .022$), mediated by increased perceived specialness ($p = .024$; 95% CI [.03, .48]).

Study 3 ($N = 402$) further tests the proposed process by manipulating both saving inferences and whether a subsequent usage occasion is ordinary or extraordinary. Consistent with our notion of everyday items becoming treasures, a predicted two-way Saving Inferences × Usage Occasion interaction ($p = .086$) reveals that passed-up items that have become more special are restricted from everyday occasions (e.g., a normal dinner at home; $p = .001$), but not from extraordinary occasions (e.g., a celebratory dinner at home; $p = .35$).

Does increased specialness always lead to restricted use? Forgoing leads to future usage restriction due to consumers' motivation to protect an items' specialness; accordingly, we suggest that reducing how limited an item seems should attenuate our effect. Thus, study 4 ($N = 227$) manipulated both saving inferences and how limited an item was. As expected, the Saving Inferences × Limited interaction ($p = .05$) revealed that when a non-used item is framed as less limited (and thus, needing less protection), increases in specialness

from forgoing usage did not lead to future restricted use ($p_{limited}$ = .05; $p_{less\ limited}$ = .4).

Finally, study 5 (N = 103) tests the additive nature of "specialness spirals." In a within-subjects design, we find that the more times people pass up using an item, the more special it becomes (all ps < .001), and the less likely they were to use it in subsequent everyday opportunities (all ps < .001).

Across several domains, we demonstrate how everyday items become treasures: A single act of forgoing usage can spark a specialness spiral by which the item seems more special, and is subsequently less likely to be used in the future. This research advances understanding of nonconsumption, first by examining nonconsumption that is neither externally-imposed nor planned in advance, and second, by examining beliefs about *when* non-consumed items should be used; and to the work on meaning transfer, by introducing a non-active process by which goods can be imbued with specialness.

Saving It (and Us) For Later? Consuming and Saving Products that Reflect Our Selves

EXTENDED ABSTRACT

A vast amount of research has demonstrated that consumers prefer products and brands that express their selves and identities (Escalas and Bettman 2005; Fournier 1994; Kleine, Kleine, and Allen 1995; Reed 2004). While clearly consumers like products and brands that symbolize their selves, it is unclear whether/how consumers actually *use* these products. The present research examines whether these products that symbolize one's self are protected (i.e., saved) or are consumed quickly after purchase.

Research in marketing and psychology makes opposing predictions regarding the likelihood of saving versus consuming self-symbolic goods. On one hand, consumers may be more likely to use products that symbolize the self. Research has shown that consumers will cease using products that are identity-inconsistent (Berger and Heath 2008) and often look for products with more identity-consistent characteristics (Ward and Broniarczyk 2011). More recently, research has demonstrated that consuming identity-consistent products, relative to those that are inconsistent, slows down satiation (Chugani, Irwin, and Redden 2015). On the other hand, self-symbolic products may help individuals affirm and protect various self-aspects (Gao, Wheeler, and Shiv 2009; Rucker and Galinsky 2008; Sivanathan and Pettit 2010); saving them for this purpose may prove beneficial in the long run.

We conducted our first study in a lab session to examine the degree to which a self-symbolic product would be consumed. We disguised the experiment as a taste test for a new bottled water offering. All participants were given a bottle of water from a fictitious brand to sample, but half of the participants were given a bottle of water with a custom label that included their name printed on it. All participants were asked to open, taste the water, and to evaluate the water. Participants were then told that the water bottle was theirs to keep, and they could drink the rest of the water whenever they liked. Then, participants completed a series of unrelated studies for the remainder of the 30-minutes lab session. At the end of the lab session, a lab manager measured their water consumption as they were collecting other materials from the participants. Each bottle was measured to determine how much water participants drank from the bottle. We found that participants ended up consuming less of the water when the bottle had their name on it (M_{name} = 14.87% vs. M_{plain} = 35.6%; $F(1, 82)$ = 5.94, p = 0.017), suggesting that they may be more likely to save, rather than consume, self-symbolic goods.

In study 2, we wanted to replicate the conservation of self-symbolic goods while also testing whether and when consumers save such goods for later use. The study utilized a paradigm where participants received a notebook, which was either related to their university identity (i.e., "Notes of [school mascot]") or a control notebook (i.e., "Notes"), as a "thank you" gift for participation. After receiving their notepads, students sat down at a computer station, where two pieces of scrap paper and a writing utensil were placed, to complete a series of computerized studies. Contained in these studies were some difficult problems that would require a pen and paper to solve (e.g., 8384 x 1103 = ?; calculator use was prohibited), and their use of the notebook would be examined. The session concluded by asking participants to rate their notepad on aesthetics and scarcity, as well as measures capturing their level of connection with the university

As predicted, participants given the identity-related notepad were less likely to use the notepad than those given the plain notepad (17.24% vs. 45.45%; χ^2 = 10.51, p = .0012). Importantly, the identity notepad was not rated as significantly better ($M_{identity}$ = 4.38 vs. M_{plain} = 4.25; $F(1, 111)$ = .17, p = .68), or more scarce ($M_{identity}$ = 5.66 vs. M_{plain} = 5.69; $F(1, 111)$ = .02, p = .89) that the plain notepad. Furthermore, a significant interaction term in a logistic regression that also included a participant's notepad condition and connection to the university demonstrates that participants were less likely to use the identity related notepad when they felt more connected to that identity (b = .41, Wald χ^2 = 3.93, p = .047). Moreover, there was a significant (α = .05) Johnson-Neyman point at 4.4180, suggesting that those who reported connection scored greater than 4.4180 (75.22% of participants) were less likely to use the notepad when it was linked to their identity.

As consuming products has been suggested to reaffirm and protect the self (Larrick 1993), study 3 used a similar notepad paradigm, with a participant's personal identity (i.e., "Notes of [participant's first name]"). Those who have a strong desire to protect the self will be likely to use the self-symbolic (i.e., identity) good to serve their protection motives and therefore less likely to save the good for later use. Thus, we expected self-protection motives to moderate our effect such that the conservation of the self-symbolic good (relative to a plain good) will be stronger among those with low self-protection motives.

We found that participants with the named notepads were marginally less likely to use them (54.9% vs. 68.6%; p = .077, one-tailed) and more likely to take their notepads with them at the end of the lab session (78.4% vs. 47.1%; p = .0011). We also found that their self-protection motives interacted with notepad condition to predict the likelihood of using the notepad (Wald χ^2 = 2.99, p = .084); individuals with low self-protection motives demonstrated a lower likelihood of using the named notepad compared the plain notepad, but there was no effect of notepad on usage at high levels of self-protection (Johnson-Neyman point at - .46 SD from the mean; α = .05).

The results from three studies illustrate an interesting paradox. Although consumers prefer products that reflect their identities, they may actually be less likely to use these products. Furthermore, the results demonstrate that this relationship may be more pronounced for individuals who are highly motivated to protect themselves. These findings suggest that the relationship between one's identity and their consumption goes beyond the initial purchase.

SESSION OVERVIEW

Consumer welfare is strongly affected by savings and spending decisions. Consumers must make choices of how much to save for tomorrow, where to invest, and how to spend responsibly. The goal of this session is to investigate some of the external and internal factors driving these important decisions. We address: 1) How and why do external factors, such as the payment medium used and the pain of payment, impact savings and spending decisions? and, 2) Whether internal factors, such as feelings of low control and stress, can impact spending habits?

One of the most interesting aspects in the psychology of money literature is how payment mechanism affects consumer-spending patterns. Prior research has tauted cash as more painful, leading to consumers to curb or avoid their spending altogether. However there are times when parting with money is necessary to save for the future. **Duclos and Khamitov** find that using cash may sometimes backfire in comparison to a less painful method of payment. In three experiments, they suggest that using painful forms of money can lead consumers to save less and/or forego future savings. **Shah, Maglio, and Wilson** dig deeper at why this cash backfiring effect may occur: consumers may be driven by a concrete bias. Cash is a psychologically closer and more concrete form, leading consumers to think of more concrete uses (versus card). This curbs spending both when it is financially prudent (a gamble with negative expected value) and financially irrational (a gamble with positive expected value).

Next we focus on how internal factors, such as perceived loss of control or stress affect subsequent savings decisions and spending habits? **Brannon and Samper** argue that when personal control is threatened, one way consumers may attempt to restore control was through the payment form that they chose to pay with. Across three experiments, they find that individuals who feel a low sense of control prefer making a purchase with a more effortful and tangible form of payment, such as cash, perceiving the payment experience as more empowering than if they used a card. In addition to payment preferences, **Durante and Laran** look at how subsequent saving and spending is affected by low control. They find that consumers under stress strategically use money and make financial decisions in two key ways: consumers will save money because doing so guarantees that these resources will be available when needed; and consumers will spend money on necessities (vs. nonnecessities), which provides a sense of control.

Taken together, these four papers advance our understanding of how external and internal factors can influence consumer spending. Using a diverse set of methodologies these papers have incredible implications for policy and societal well-being, as well as basic scientific understandings of the psychology of money and financial decision-making. This session will appeal to researchers interested in the consumer welfare, judgment and decision-making, financial management, as well as those interested in policy or managerial decision-making. Thus, we expect that a diverse set of scientists, policymakers, and scholars will find value in the session.

Is Cash Almighty? Effects of Hard vs. Soft Money on Saving/Investment Behavior

EXTENDED ABSTRACT

Research on spending behavior suggests that paying in cash is more painful psychologically than paying via dematerialized money (e.g., credit cards). This holds true even after holding expenses constant (Prelec and Loewenstein 1998; Prelec and Simester 2001; Raghubir and Srivastava 2008; Soman 2003; Thomas, Desai, and Seenivasan 2011). A derivative of these important findings is the now-popular "cash diet". To help curb spending, reduce debt, and improve saving rates, TV shows, newspapers, and blogs recommend consumers to operate on a cash basis. Indeed, since cash creates psychological barriers to spending (compared to softer, dematerialized forms of money), using cash makes consumers better savers and budgeters.

We readily agree that paying in cash is effective at curbing expenses. But focusing on saving/investment behavior (rather than *spending* behavior), we show cash may not be almighty. Indeed, extending the "pain of paying" paradigm to saving/investment situations, we find hard money (i.e., cash) may sometimes backfire (compared to soft/dematerialized money) and cause consumers to save less and/or forego lucrative investment opportunities they should seize.

To test our theorizing, experiment 1 recruited participants for a 10-minute study in exchange of $5. Subjects were randomly assigned to one of two conditions (cash vs. card). Participants in the cash condition completed a filler task before receiving their pay, a $5 bill. Counterparts in the card condition completed the same filler task before being offered a $5-credit on their student card (student cards function like debit cards; they can be used to pay at any establishment on and around campus).

Just before processing their payment, however, we offered participants the following deal: (1) collecting their $5 right away, or (2) collecting $7 in a week. In essence, we turned our lab into a financial institution. Leaving money with us for a week guaranteed an incremental gain of $2 (annualized, the rate of return of the $7 option exceeds 2000%), thereby allowing us to assess participants' saving/investment behavior. As expected, participants in the cash condition

(49%) were less likely than counterparts in the card condition (78%; p < .03) to leave their money in the lab's vault for a week.

Experiment 2 sought to extend these findings by examining which consumers are more/less likely to follow this behavioral pattern. To this end, we considered subjects' *prevention* orientation. "Prevention focus" is defined as a mindset or personality dimension that relates to goal pursuit (Higgins 1997; Kruglanski, Pierro, and Higgins 2007; Lee and Aaker 2004). A prevention focus heightens concerns for safety, responsibility, and security. People with a chronic disposition toward prevention approach life with the goal of avoiding losses/negative events (this contrasts from a *promotion* focus whereby people approach life having in mind the pursuit of hopes, accomplishments, and general advancement).

While prevention orientation may be measured as an individual difference, we opted to manipulate it experimentally. Accordingly, experiment 2 followed a 2 (Money format: cash vs. dematerialized) by 2 (Prevention focus: baseline vs. high) between-subjects design. The procedure resembled study 1's with the addition of a writing task to manipulate prevention focus. The DV remained unchanged; participants chose between collecting $5 right away or $7 a week later.

Mirroring the results of study 1, a main effect of money format emerged. On average, participants compensated with cash saved/invested less than counterparts paid with dematerialized money. Importantly, this main effect was moderated by our prevention-focus manipulation (interaction term: p = .031). In the control condition (i.e., when subjects' prevention focus was at baseline), being compensated in cash (dematerialized money) led participants to save/invest less (more; p = .001). In contrast, when prevention focus was heightened, participants exhibited similar saving/investment behavior whether they were paid with cash or dematerialized money (NS). No main effect of prevention focus emerged.

Experiment 3 aimed to test the process underlying our findings. To this end, we adopted study 2's design and procedure but added a series of measures related to the "pain of parting from money". Once again, money format produced a main effect. On average, participants compensated with cash saved/invested less than counterparts paid with dematerialized money. As expected, however, this main effect was moderated by our prevention-focus manipulation (interaction term: p = .047). At baseline levels of prevention focus, being compensated with cash (dematerialized money) led participants to save/invest less (more; p = .003). In contrast, when prevention focus was high, participants' decision to save/invest remained equivalent regardless of money's form (NS). As in study 2, prevention focus had no main effect. Moderated-mediation analyses (Model 7 of the PROCESS macro; Hayes 2013) supported our theorizing. Parting from cash was more painful psychologically than parting from dematerialized money, which in turn caused subjects to save less/forego lucrative investment opportunities.

Theoretical & societal contributions: Theoretically, our findings contribute to the literature in at least two ways. First, unlike prior research, our mechanism based on the "pain of parting from money" (rather than "pain of paying" per se) is able to explain not only (i) why cash helps consumers in spending situations, but also (ii) why it paradoxically hurts them in saving/investment decisions. Second, by documenting the interactive effects of money-format and prevention-focus on saving/investment behavior, our results shed light on a personality dimension with great potential to foster/hinder consumers' financial welfare.

From a societal standpoint, understanding the factors that increase/decrease consumer savings is of great interest to government agencies, policymakers, financial-services firms, and consumers themselves. Our findings could thus offer significant insights for retirement planning, a major issue across the world today. Indeed, with life expectancy ever increasing, citizens will undergo a fierce decrease in quality of life if/when they outlive their savings. This is particularly true for lower-income households who are, in fact, more likely to be paid in cash throughout their working lives (e.g. construction workers, service staff in hotels/restaurants).

Keep Your Money Close: Psychological Distance Influences the Perceived Value of Money

EXTENDED ABSTRACT

Judgments related to money have become as varied as they are ubiquitous. The modern economy presents innumerable options for the storage and exchange of money, and payment options now include cash as well as checks, credit/debit cards, check cards, and gift certificates. Moreover, money is no longer confined to a wallet or a cookie jar. Especially with the advent of the Internet, money can be stored at different locations (local bank branches or offshore holdings) and for different purposes (e-banking accounts, stock portfolios, PayPal). Ultimately, now more than ever, people face the issue of having multiple forms of money stored in a number of different locations. Rational decision models would predict invariance in the appraisal of each store of money, but mounting evidence suggests that this standard is often violated.

For example, recent research has demonstrated systemic psychological and behavioral biases in the way individuals evaluate the value of money based on the payment form (e.g., Raghubir and Srivastava 2008; Soman 2001). Paying with debit card (vs. cash) increases the propensity to evaluate products more favorably and to buy more unhealthy products (e.g., Chatterjee and Rose 2011; Thomas, Desai, and Seenivasan 2011). Research has argued that these differences are due to the amount of pain individuals feel when parting with money. However, could a concrete bias be at play? Could the psychological closeness of money lead to differences in perceived value and purchasing power, subsequently creating differences in spending?

Appraisal and fluctuations in monetary construal begin with the valuation of currency. Perceived valuation – or purchasing power – of a given unit of currency should be insensitive to contextual variations and, as such, evince dynamic consistency. However, a large body of research on this topic has uncovered the tendency of individuals to use heuristics to simplify valuation judgments (Tversky and Kahneman 1974). Building off of construal level theory, we argue that as a target becomes removed from a person's immediate experience, its concrete features become less salient and therefore comes to be represented more abstractly. This abstraction can influence the perceived uses of money—as money becomes more abstract, its perceived fungibility decreases as does its perceived purchasing power. We argue that this is effectively a concrete bias—more psychologically closer representations of money increase its perceived value. Across four studies, we manipulate the psychological closeness of money and investigate its impact on consumer spending behavior.

In Study 1, we develop preliminary evidence for this effect. We inform participants (N=200) that they spend $20 on a pair of headphones, manipulating whether the payment was made via cash or by card. We then ask what else they could have purchased with the money as a measure of perceived fungibility. Participants listed significantly more items with cash than with card, suggesting that individuals believe that more concrete representations of money are more fungible.

According to CLT, concreteness can also be manipulated by physical distance. Thus, in Study 2 we investigated a boundary condition to test our theory. Participants located in New York City were

randomly assigned to condition in a 2 (cash or certificate) x 2 (NYC or LA) factorial design. Participants were asked to imagine that they had transferred all of their assets to an online bank, which stored their assets at the company's central bank either in NYC or Los Angeles, with the latter representing a physically more distant location. Participants were then presented with a list of 8 items, ranging from inexpensive to rather expensive. They were asked to indicate, in dollars and cents, how much of their assets they would be willing to spend on each of the items. Participants were willing to spend marginally less ($p =.10$) using funds stored as cash than they were to spend using cash-equivalent certificates. They were also willing to spend significantly less using funds stored in a near bank than in a far bank. These effects were qualified by a significant interaction between form of currency and location. Participants spent more freely from funds stored in an abstract (non-cash) form and when drawing from geographically far bank accounts.

Study 3 and 4 employed the use of field experiments to determine whether this concrete bias could impact financial decision-making and risk-taking behavior. In Study 3 we gave participants a chance to play as many gambles as they desired out of a set of gambles, using their own money. We varied the form of payment they gambled with (cash or 'plastic' student card). For each of the gambles, we also manipulated the buy-in amount in order to play the gamble ($0.50 or $1), the probability of winning (10%-90%), and the amount earned if the participant won such that the expected value of all gambles was equal to -$0.50, meaning it was more financially prudent not to play. In Study 4, we used the same method except now the expected value of all gambles was equal to +$0.50, meaning it was more financially savvy to play. In Study 3, we found that a more concrete form of money decreased the likelihood of gambling and decreased the number of gambles played. However, when the expected value was positive, people playing with cash were still less likely to gamble, despite it being more financially responsible. Thus, consistent with our hypothesis, individuals exhibited a concrete bias, subsequently affecting financial decision-making and potential earnings.

The present investigation provides support for the hypothesized comparability of abstract form and psychological distance in judgments involving mental construal of money. Psychologically closer representations of money, either through form or distance, lead individuals to perceive more fungibility and purchasing power of money. We also show evidence that this concrete bias can substantially influence spending decisions, regardless of whether spending money is financially prudent or not.

Regaining Control by Ditching the Plastic: Why Abundance Increases Consumers' Aversion to Credit Cards under Conditions of Low Control

EXTENDED ABSTRACT

What drives upper and middle income consumers to end their love affair with plastic in times of trouble? A recent report released by the Federal Reserve revealed a fascinating consumer trend following the 2007 recession. The report showed that, between 2007 and 2009, consumers shed credit cards and decreased debt by 7.8%. Surprisingly, this trend was most pronounced among upper-middle income consumers. Among lower income consumers, the report found no changes in credit card usage. We ask how threats to consumers' control caused by such events influences the way they pay for products and services.

When personal control is threatened, consumers experience discomfort and seek to restore control (Cutright 2012; Kay et al. 2008). One way to restore control is through effortful tasks (Olivola and Shafir 2013). Consistent with this notion, consumers avoid low effort products when they experience low control (Cutright and Samper 2014). In this research, we propose that perceptions of effort associated with the way that consumers pay for products and services also influence preferences under low control. Specifically, we propose that because credit cards are perceived as a painless, low effort way to make a purchase (Prelec and Loewenstein 1998), consumers will have a decreased preference to use them under conditions of low (vs. high) control. Further, we predict that this behavior will only occur among consumers with abundant (vs. scarce) financial resources, as consumers with scarce resources are more debt-averse (Callender and Jackson 2005) and less likely to view credit cards payments as painless or low effort. Finally, we predict that our results will be mediated by feelings of empowerment associated with the payment. Specifically, among consumers with abundant (vs. scarce) resources, low pain of payment associated with using a credit card should decrease feelings of empowerment associated with making a purchase under low control.

Study 1

We conducted a 2 (control: high vs. low, between) × 2 (payment method: cash vs. card, between) x (financial resources, continuous) experiment. We measured financial resources using a 5-item measure from Sharma and Alter (2012). Next, we manipulated control by asking people to write about a time when they felt they had high (vs. low) control over a situation (Kay et al. 2008). We then presented participants with a $50 clothing item from the university bookstore and randomly assigned them to imagine that the vendor only accepted credit card (vs. cash). We next asked them if they would purchase the item (1=yes; 2=no). We found a significant 3-way interaction on purchase intentions (χ^2=6.99, p=.01). Among participants with abundant resources, those who imagined that the vendor accepted credit cards were significantly less likely to purchase the item under conditions of low (vs. high) control (χ^2=5.51, p=.02). However, low (vs. high) control did not affect intentions when the vendor accepted cash only (p=*ns*). Among participants with scarce resources, there was no effect of low (vs. high) control on intentions when paying with credit card (p=*ns*) or cash (p=*ns*).

Study 2

We conducted a 2 (financial resources: scarce vs. abundant, between) × 2 (control: high vs. low, between) × 2 (payment method: cash vs. card, between) analysis on participants' satisfaction with a purchase. We manipulated financial resources by asking participants to describe 3-4 episodes where resources were abundant (vs. scarce) (Roux, Goldsmith, and Bonezzi 2015). We manipulated control by asking people to write about a time when they felt they had high (vs. low) control over a situation (Kay et al. 2008). We then randomly assigned participants to imagine that they were purchasing an identity-related product costing at least $100 with either cash or credit card (Berger and Heath 2007). To measure purchase satisfaction, participants responded to an 8-item subscale of purchase emotions (Richins 1997), which measures feelings of joy, excitement, and contentment associated with making the purchase. We found a significant 3-way interaction (F(1,390)=3.88, p=.05). Among participants with abundant resources, those who imagined paying with credit card reported marginally lower satisfaction under conditions of low (vs. high) control (t(390)=1.79, p=.07). However, low (vs. high) control did not affect satisfaction when participants imagined paying in cash (p=*ns*). Among participants with scarce resources, there was no effect of low (vs. high) control on purchase satisfaction in either the credit card (p=*ns*) or cash (p=*ns*) conditions.

Study 3

We sought to replicate study 2 using another continuous measure of financial resources. We conducted a (financial resources, continuous) × 2 (control: high vs. low, between) × 2 (payment method: cash vs. card, between) analysis on participants' 1) purchase satisfaction 2) spending aversion. We measured financial resources by asking participants to indicate their weekly spending budget (1=$0; 7=$250+). We used the same control and payment method manipulations as in study 2. In addition to measuring purchase satisfaction, we also included a 3-item measure of spending aversion (Soster, Gershoff, and Bearden 2014). Next, participants responded to a 7-item scale indicating how empowered they would feel when making the purchase (Cutright and Samper 2014). We found a significant 3-way interaction on purchase satisfaction (F(1,188)=6.37, p=.01). Similar to study 1, among participants with abundant resources, those who imagined paying with credit card reported significantly lower satisfaction under conditions of low (vs. high) control (t(188)=4.73, p<.001). However, low (vs. high) control did not affect satisfaction when participants imagined paying in cash (p=*ns*). Among participants with scarce resources, there was no effect of low (vs. high) control on satisfaction when paying with credit card (p=*ns*) or cash (p=*ns*). Empowerment mediated this effect (95% CI [.03 to .80]) and contrasts revealed a similar pattern as purchase satisfaction. We found a similar 3-way interaction and mediation by empowerment on our spending aversion measure (F(1,188)=5.49, p=.02).

We find that feelings of low (vs high) control decrease the desire to pay with a credit card among consumers with abundant (vs. scarce) financial resources. This effect is driven by the fact that, among consumers with abundant (vs. scarce) financial resources, low (vs high) control individuals perceived paying with credit card as less empowering.

The Effect of Stress on Consumer Saving and Spending

EXTENDED ABSTRACT

Stress is ubiquitous, yet we know little about the impact of feeling stressed on consumer behavior. Some research suggests that stress decreases consumption (Torres and Nowson 2007). Other findings suggest that stress may also lead to impulsive spending (Burroughs and Rindfleisch 2002).

We propose that certain behaviors are negatively influenced by stress, whereas other behaviors are positively influenced. One characteristic of stress is that it leads people to perceive that they currently lack control over their environment (Cohen 1988). Thus, we predict that consumers may use their monetary resources strategically in order to restore control in situations of stress and do so in two ways: (1) consumers will save money because doing so guarantees that these resources will be available when needed; and (2) consumers will spend money on necessities (vs. nonnecessities), which provides a sense of control.

A pilot investigation asked participants to write about the things that stress them out in life right now, their typical day, or things that make them sad in life right now and were asked about saving money. Participants in the stress condition indicated that they wanted to save more money (*ps* < .05).

Experiment 1 tested the effect of stress on saving, and the role played by control. Half of the participants went through a stressful situation (believing they were going to give a speech). Some participants, however, restored their sense of control after the stress manipulation by writing about something that happened to them because they had control over it. Participants were then asked to imagine that they had $300 and indicated how much they would save vs. spend on products. There was an interaction (*p* = .03). Participants in the high stress condition saved more money (*p* = .01). However, when control was restored, stress did not impact saving (*F*< 1).

Experiment 2 sought to examine the influence of current stress (measured) on willingness to spend on necessities. Participants were asked: "Right now, how important do you feel it is to acquire necessities (i.e., things you need on a day-to-day basis)?" (7pt scale). They also completed an established measures of current stress (Lovibond and Lovibond 1995) and perceived control (Cutright et al. 2013). There was an interaction (*p* =.04). Stressed participants indicated that acquiring necessities was marginally more important when they perceived they currently had low control than when they perceived they currently had high control (*p* = .09). There was no difference at low levels of stress (*p*= .37).

Experiment 3 allowed people to have control (vs. not) over the outcome of the stressful situation. The stress manipulation involved a speech. However, to manipulate low control, half were told they would get extra credit for the speech, but receiving the credit depended on the average performance of all participants. In the high control condition, participants were told that getting an extra credit would depend only on their performance. Participants then indicated how much out of $250 they would save. There was an interaction (*p* = .03). Under low control, participants in the high stress condition were willing to save more (*p* = .05). Under high control, there was no difference (*p* > .26). In the high stress condition, participants saved more in the low control condition (*p* < .01).

Experiment 4 examined whether acquiring necessities is perceived as a way to restore control, and whether this drives the effect of stress on spending on necessities. The stress manipulation was identical to Experiment 3. Participants indicated how much (out of $250) they were willing to spend on necessities and some participants did this for nonnecessities. We also measured the extent to which their spending behavior occurred as a means to restore control. There was an interaction (*p* < .01). Participants in the high stress condition were willing to spend more on necessities (*p* = .04) and less on nonnecessities (*p* = .04). Under high stress, those asked about necessities were willing to spend more than those asked about nonnecessities (*p* < .01). Spending as a means to restore control mediated the effect of stress in the necessities condition (CI: .32 to 12.52).

Experiment 5 sought to demonstrate that the nature of the stressor may shift perceptions of which products represent necessities. We predicted that stress related to starting a new job would lead to increased spending on nice clothing. The study involved people who were or were not starting a new job. Half of the participants wrote about stress related to their new job (vs. current job) and half wrote about a typical day at work. Participants reported how much out of $300 they would spend on nicer, more expensive clothes and reported whether clothing is a necessity. There was an interaction (*p* < .01). We replicated our previous results in the current job condition. In the new job condition, however, participants in the high stress condition indicated that they would spend more money on nicer, expensive clothes (*p* < .01). For people starting a new job, perceptions that clothing is a necessity mediated the effect in the stress condition (CI: 2.16 to 15.57).

Experiment 6 tested whether a reversal of the effect of stress on saving would occur when people believe that attempts to restore control will fail. After writing about a stressor (vs. typical day), half of the participants read an article designed to diminish beliefs that one can restore control. Participants were then asked "Right now, how important do you think it is to save your money vs. spending it on products?" (9pt scale). There was an interaction (*p* < .01). Par-

ticipants in the high stress condition indicated that saving money was marginally more important ($p = .07$). But, when they were led to believe control couldn't be restored, participants in the high stress condition indicated that saving money was less important ($p = .02$).

These findings demonstrate that stress can have a multi-faceted impact on consumer behavior. Stress can lead consumers to prefer to save, but spend strategically on necessities as a means to restore control.

SESSION OVERVIEW

Consumers need to make tradeoffs: Price is weighed against quality, risk against reward, the present against the future. And while previous research has examined many of these specific tradeoffs, in particular, less work has focused on *how* consumers make tradeoffs, more broadly. To that end, the objective of this session is to highlight recent advances in research examining how and when consumers make tradeoffs. Specifically, the papers in this session address the following questions: What factors systematically affect how consumers make tradeoffs? And when are consumers willing to make tradeoffs in the first place?

The first two papers examine *how* consumers make tradeoffs. Specifically, Evangelidis and van Osselaer study how people make tradeoffs in the presence versus absence of non-differentiating attributes (i.e., attributes along which all alternatives perform the same). While different streams of research make competing predictions about the effect of such attributes on choice, Evangelidis and van Osselaer show, across 10 studies, that a non-differentiating attribute can favor a particular alternative because consumers judge performance not based on face value (according to which all alternatives perform the same), but based on the difference between face and expected value.

In the second paper, Zwebner and Schrift examine another important, yet understudied factor that affects how people make tradeoffs: How does being observed impact processes, preferences, and ultimate choice? In a series of seven studies, Zwebner and Schrift demonstrate that consumers have a strong preference to avoid being observed by others during deliberation (especially when deliberations involve tradeoffs). Moreover, once observed, decision-makers distort their preferences and choice in a manner that will enable them to resolve the decision quickly and with as little conflict as possible.

The second two papers examine *when* and the extent to which consumers are willing to make tradeoffs. In particular, Shaddy, Fishbach, and Simonson argue that a number of seemingly distinct phenomena (e.g., variety seeking, licensing/balancing, the compromise effect) fundamentally implicate the degree to which people are willing to make tradeoffs, suggesting a common theoretical de-

nominator. To that end, across nine studies, the authors propose and test variables that affect tradeoff elasticity (i.e., willingness to make tradeoffs), which depends on the fungibility (i.e., exchangeability) of relevant attributes and can potentially account for a wide variety of otherwise unrelated phenomena.

In the fourth paper, Pocheptsova, Kivetz, and Dhar study another factor that affects whether consumers make tradeoffs: the distinction between renting and buying. Although the literature treats these choice processes as interchangeable, the authors, in a series of four studies, demonstrate that consumers actually adopt different mindsets when the decision task involves renting versus buying. These different mindsets, in turn, affect consumers' willingness to consider and make tradeoffs when renting, compared to buying.

Together, these papers describe recent advances in our understanding of how and when consumers make tradeoffs. We expect this session to have broad appeal, given that the theoretical contributions and practical applications of these findings provide significant new insights and speak to a wide range of domains.

Expectation-Based Effects of Common Attributes on Choice

EXTENDED ABSTRACT

Consumers often choose between alternatives that differ with respect to some attributes while performing equally well on others. For instance, consumers may be choosing between two camera brands that differ in price and optical zoom but have the same video capture resolution. Different streams of research make competing predictions about the effect of non-differentiating attributes on choice. First, choice theories such as the elimination by aspects model (Tversky 1972) predict that introducing a non-differentiating attribute should have no effect on choice because such attributes are edited out prior to choice. Second, cognitive psychologists (Nisbett, Zukier, and Lemley 1981) and information integration theorists (Anderson 1971; Troutman and Shanteau 1976) would predict that introducing a non-differentiating attribute should decrease the difference in utility between all alternatives because the impact of the differentiating attributes on choice lessens in the presence of information about a non-differentiating attribute. Third, some decision-making research (Mellers and Biagini 1994) inspires the prediction that introducing a non-differentiating attribute should increase the difference in utility between alternatives because in the presence of information about the non-differentiating attribute, differences in performance on the differentiating attributes are enhanced. Important work in consumer research has found evidence for both increases and decreases in the difference in utility between alternatives by considering attribute importance (Chernev 1997) as a key moderator.

In this paper we argue that earlier research has ignored the role of decision-makers' expectations when examining the effect of non-differentiating attributes on choice. We propose that, before choosing, consumers evaluate an alternative's performance on an attribute not only based on its face value (i.e., stated performance), but also based on the difference between face and expected value. Therefore, we argue that preference for an option can be contingent on one's own expectations about how that alternative should perform on the non-differentiating attribute, and further on the extent to which those expectations are confirmed or disconfirmed. In our studies, we find

that an alternative that was expected to perform worse than the competitor on the non-differentiating attribute is chosen more frequently when information about the non-differentiating attribute is added to the set. Conversely, we find that an alternative that was expected to perform better than the competitor on the non-differentiating attribute is chosen less frequently when information about the non-information attribute is included.

Our empirical section comprises ten studies. All problems are pre-tested to ensure that consumers carry prior expectations that the two alternatives should perform differently on the non-differentiating attribute. Studies 1a-1d document the predicted effects of adding a non-differentiating attribute on choice in the context of various decision problems using actual and hypothetical products. In Studies 1a-1b, we randomly assign participants to one of two experimental conditions (two vs. three attributes). In the two attributes condition participants choose between two options in a tradeoff problem where each option scores higher than the other on one of two dimensions. In the three attributes condition participants solve the same tradeoff problem as their counterparts in the two attributes condition, with the only difference being the addition of information about a third non-differentiating attribute. We find that the option that was expected to perform better than the competitor on the non-differentiating attribute is chosen less frequently when information about the non-information attribute is included. In Study 1c we replicate our finding in a choice problem with a large number of attributes (i.e., choice of a laptop), while in Study 1d we replicate our result when we add a non-differentiating review instead of a non-differentiating attribute.

Studies 2-7 provide evidence for the proposed account. In Study 2, we test whether the observed effect can be explained by an attribute importance account (Chernev 1997) rather than by an expectations account. We test our predictions in the context of a tradeoff problem where one attribute is more important than another. An attribute importance account would predict that in this choice situation, introducing a non-differentiating attribute should lead to further choice share polarization. In contrast, we find that introducing a non-differentiating attribute leads to significant choice share convergence, a result that is in line with our expectation-based account.

In Study 3, we provide direct evidence for the proposed account. When asked "how good" each alternative is on the non-differentiating attribute, we find a difference in perceived performance between the two alternatives even if actual scores are the same. In turn, perceived difference in performance on the non-differentiating attribute drives choice by favoring the alternative that performs better than expected.

In Study 4, we replicate our basic effect using a within- rather than between-participants design and provide additional evidence to our theoretical account by showing that the effect is moderated by the direction of expectancy disconfirmation. When the alternative that is expected to perform better than the other on the additional attribute has the same or worse score on that dimension (i.e., when the expectation is violated), preference for the alternative that is expected to perform better decreases. However, when the alternative that is expected to perform better than the competitor on the additional attribute scores higher on that dimension, preference for the former alternative does not decrease.

Finally, in Studies 5-7 we demonstrate boundary conditions to our effect. In Study 5 we show that the extent to which consumers, as a group, expect a difference in relative performance on the non-differentiating attribute moderates our result. We find that introducing a non-differentiating attribute influences choice only when our participant group holds a clear prior expectation about differences in relative performance between the two alternatives on that dimension.

In Study 6, we find that introducing a non-differentiating attribute influences choice only when the non-differentiating attribute is relatively important. In Study 7, we replicate our effect in joint but not in separate evaluation, presumably, because consumers cannot assess whether one alternative performs better than expected relative to another when they have information about only one of the two options. Our work contributes to work on context-effects, multi-attribute utility theory, and choice architecture.

Scoptophobia in Decision-Making: the Aversion to Being Observed During Decisions and its Impact on Consumers' Tradeoffs and Choice

EXTENDED ABSTRACT

The conflict associated with trading off between different attributes is often a central and important component of many decisions that we make throughout our lives. The current paper explores a straightforward yet important and understudied question: how does being observed by others while making tradeoffs impact consumers' choice processes, preferences, and ultimate choice? First, we find that consumers have a strong preference to avoid being observed by others during the deliberation phase especially when such deliberations involve tradeoffs and conflict. Second, we find that once observed, decision-makers distort their preferences and choice in a manner that will enable them to resolve the decision quickly and with as little conflict as possible.

We argue that this research question is important from both theoretical and applied perspectives. First, contributing to a vast body of literature, this paper explores a relatively understudied aspect of social influence. In particular, when examining social influence (in the context of decision-making) one facet, which had been extensively studied, is how observing others shapes the observer's preferences (see Cialdini and Goldstein 2004 for a review). However, an equally important and understudied question is to understand how being observed by others changes one's preferences and choice.

Second, understanding consumers' reactions to being monitored and observed while making decisions is an increasingly important topic in the marketplace today. Companies nowadays invest growing amount of resources in tracking, monitoring, and analyzing consumers' marketplace activities, which leads to an increase in consumer privacy concerns (Malhotra et al. 2004; Peltier et al. 2009). By better understanding the source for these concerns and how consumers react in the face of being observed, companies and policy makers can address these issues to the benefit of consumers.

In a series of seven studies, we first find that decision-makers are averse to being observed while experiencing conflict in choice. In addition, we find that once observed, decision-makers find ways to avoid having and portraying conflict. In particular, we find that decision-makers reduce the conflict they experience and therefore, the conflict that others may detect, by (i) preferring default options, (ii) constructing more polarized preferences (which decreases tradeoffs in choice), and (iii) by altering their pre-decision activities (such as information search and consideration time). It is important to note that research relating to accountability and justification had examined several aspects relating to the impact of being observed by others. In the current paper we control for such motives, and demonstrate that the aversion to being observed during deliberation as well as consumers' reactions to being observed go beyond the heightened motivation for being accountable.

The goal of Study 1 was to examine whether being observed while making an online decision will lead to uncomfortable feelings and privacy concerns. Further, we examined concerns that may

arise when one's decision-process is being monitored (i.e., observing decision-process but not ultimate choice) and compared these with concerns when one's choice is being monitored (i.e., observing ultimate choice but not decision-process). In a two-cell between-subject design, we found that being monitored during the deliberation phase triggered significantly greater privacy concerns ($p = .001$) and feelings of intrusion ($p = .001$) compared to when only the outcome is being monitored. In several additional studies we replicated this effect across different contexts (Studies 2-4) and found that, indeed, people that were being observed had a strong preference to being observed while announcing a decision as opposed to deliberating it, compared to when observing others (Study 2; $p = .018$). Further, this aversion to being observed during a deliberation phase was found to be more pronounced when one faced a difficult and conflicting decision as opposed to an easy decision (Study 4; $p = .005$).

In Study 5, participants were offered a new online book-commerce portal. We manipulated (between-subjects) the portal's phase of monitoring (decision-process vs. decision-outcome vs. no-monitoring). We measured interest in using the book-commerce portal using six items (Cronbach's alpha = .87). Again, being monitored during the decision-process reduced individuals' interest in the online commerce portal. Participants were significantly less interested when their decision-process was monitored compared to when their decision-outcome was monitored ($p = .008$), or not monitored at all ($p < .001$).

After validating across different domains and contexts that consumers prefer environments in which their decision-processes are not observed or monitored, we turned our attention to examine how consumers actually react to being observed. That is, if consumers indeed dislike being observed while experiencing conflict, one would expect to see them behave in a way that reduces experienced conflict when being observed. In Study 6, participants were engaged in a real lottery for a T-Shirt. They were offered a choice between a "Default-T-shirt" and a "Create-Your-Own-T-shirt." If participants chose to create their own T-shirt, they would have to engage in a deliberation process which included choosing their preferred color, collar type, logo and style. In one condition participants were informed that their decision-process would be observed by a research assistant. In another condition, participants were informed that they would be observed while stating their choice. As expected, participants assigned to the process condition where much more likely to choose the default option compared to those in the outcome condition ($M_{process} = 51\%$, $M_{outcome} = 30\%$, $p = .001$). That is, decision-makers reduced the experience conflict and shortened their deliberation phase by shifting their choice to a default option.

Study 7 examined whether being observed during the deliberation phase changed decision-makers' attribute importance-weights. Consistent with our predictions, we find that decision-makers reduce their experienced conflict by constructing more polarized preferences (which decreases tradeoffs in choice).

To summarize, consumers are often observed or monitored during their consumption activities. In this paper we argue that being observed by others, especially while making tradeoffs, impacts consumers' choice processes, preferences, and ultimate choice. Seven studies validate the impact that being observed has on consumers and demonstrate that consumers prefer to avoid being observed during the deliberation phase, and that once observed, they have predictable ways in which they reduce experienced conflict by distorting preferences and choice.

How Tradeoff Elasticity Affects Consumer Choice

EXTENDED ABSTRACT

Decisions require tradeoffs. Consumers consider price and quality, employees weigh money against free time, dieters balance health and taste, and most everyone faces ethical dilemmas (e.g., honesty vs. self-interest). Various phenomena examining these tradeoffs have been studied. Variety seeking (Simonson 1990), licensing (Monin and Miller 2001), balancing (Fishbach and Dhar 2005), and the compromise effect (Simonson 1989) are several well-known examples.

In this research, we argue that these and other seemingly distinct phenomena fundamentally implicate the degree to which people are willing to make tradeoffs, suggesting a common theoretical denominator. As such, we propose that willingness to make tradeoffs, or *tradeoff elasticity*, can potentially account for many otherwise unrelated phenomena.

We further hypothesize that tradeoff elasticity depends on the fungibility of relevant attributes. For example, price and quality are likely to be more exchangeable than honesty and self-interest. You might be willing buy a smaller television to save a few bucks, but lying to get a discount would be more questionable. In other words, sometimes consumers are willing to make tradeoffs, and sometimes they aren't.

So, when do people make tradeoffs?

We identify two factors that affect the extent to which attributes can be "traded off" and, hence, affect willingness to make tradeoffs:

1. Core values. When attributes are construed as reflecting core values or meaningful principles, prioritization occurs, and willingness to make tradeoffs decreases (i.e., tradeoff elasticity falls).
2. Quantifiability. When attribute levels are quantified, comparisons become easier, and willingness to make tradeoffs increases (i.e., tradeoff elasticity rises).

We tested this account across nine studies, systematically manipulating core values and quantifiability across three phenomena: variety seeking, licensing/balancing, and the compromise effect.

Studies 1a–1c examined the core values moderator. We used a scenario in which participants decided whether to skip work to meet a friend.

Study 1a tested the compromise effect. Participants read that their friend would be in town for a week. In the *baseline* two-option set, participants chose between: "don't skip" or "skip a day." In the *baseline* three-option set, we also included the option to "skip a week." Moreover, in the *core values* conditions, we added meaning to each option: "be honest—don't skip, be carefree—skip a day," or "be crazy—skip a week." The compromise effect (i.e., the increase in choice share of the second option, relative to the first, in the three-option set) was larger in the *baseline* condition (23.9%) than in the *core values* condition (5.4%; $t(181) = 3.67$, $p < .001$).

Study 1b tested licensing/balancing. We manipulated participants' beliefs about whether they had made progress at work. Participants then chose between "don't skip" and "skip a day," and in the *core values* condition, we labeled the options (e.g., "be honest" vs. "be carefree"). We observed more balancing (i.e., choosing to skip work after making progress) in the *baseline* condition (36.2% increase from the no progress to progress condition) than in the *core values* condition (2.8% decrease; $z = 2.46$, $p = .014$).

Finally, study 1c tested variety seeking. We told participants that their friend would be in town twice. Participants made two choices, and we again manipulated core values by labeling the options. Those in the *baseline* condition chose more variety (69.7%

chose one of each option) than those in the *core values* condition (31.3%; $\chi^2 = 9.61$, $p = .002$).

Studies 2–4 examined the quantifiability moderator. Specifically, we provided either the relative position of options on attributes (*baseline* condition) or the relative position of options on attributes *and* added absolute values (*quantities* condition).

Specifically, study 2a tested the compromise effect for choices of a baseball ticket. Those in the *baseline* condition saw relative values (e.g., "lower row number, higher price"), while those in the *quantities* condition saw the same relative values in addition to absolute values (e.g., "row 5, $28"). The compromise effect was larger in the *quantities* condition (15.8%) than in the *baseline* condition (–12.9%; $t(185) = 3.19$, $p = .002$). Study 2b, meanwhile, tested licensing/balancing. We manipulated participants' beliefs about whether they had made progress toward a savings goal before they chose a ticket, and we observed more balancing (i.e., choosing the expensive ticket after making progress) in the *quantities* condition (17.3% increase from the no progress to progress condition) than in the *baseline* condition (15.0% decrease; $z = 2.78$, $p = .005$).

Study 3a tested the compromise effect in a dictator game scenario. Those in the *baseline* condition saw relative values (e.g., "give a below-average amount"), while those in the *quantities* condition also saw absolute values (e.g., "$4"). The compromise effect was larger in the *quantities* condition (34.0%) than in the *baseline* condition (3.6%; $t(191) = 5.59$, $p < .001$). Study 3b, meanwhile, tested variety seeking for two allocation choices, and we observed more variety seeking (i.e., choosing one of each option) in the *quantities* condition (22.9%) than in the *baseline* condition (7.7%; $\chi^2 = 4.54$, $p = .033$).

Finally, study 4a examined licensing/balancing in choice of a grocery store. Those in the *baseline* condition saw relative values (e.g., "below-average environmental rating, below-average prices"), while those in the *quantities* condition also saw absolute values (e.g., "2/5 stars for environmental policies, 4/5 stars for affordability"). We manipulated participants' beliefs about whether they had made progress toward an environmental goal before they chose a store, and we observed more balancing (i.e., choosing the less environmentally friendly store after making progress) in the *quantities* condition (26.6% increase from the no progress to progress condition) than in the *baseline* condition (1.6% decrease; $z = 2.02$, $p = .044$). Study 4b, meanwhile, tested variety seeking for two choices, and we observed more variety seeking (i.e., selecting one of each store) in the *quantities* condition (43.8%) than in the *baseline* condition (32.1%; $\chi^2 = 3.76$, $p = .052$).

In short, we propose that tradeoff elasticity can account for a wide variety of otherwise unrelated phenomena. Thus, these findings not only provide a new theoretical insight regarding how consumers make tradeoffs, but also create significant implications for marketers.

Acquisition Mode Effect on Consumer Product Evaluation and Tradeoff Making

EXTENDED ABSTRACT

In a growing number of product categories, consumers have the opportunity to buy or to rent the same product. This new way of consuming has received substantial attention in the business community and in the popular press. Surprisingly, almost no research to date has examined how consumer decision processes for renting and buying might differ systematically. In fact, most research on consumer decision-making has treated various ways of acquiring a product interchangeably. We propose that consumers adopt different cognitive procedures or mindsets when the decision task is seen as renting in comparison to buying a product. Several related findings in the literature suggest why decision processes for renting and buying may differ systematically. Compared with outcomes of buying decisions, outcomes of renting decisions are perceived by consumers to be less permanent. The relative permanence of a decision heightens anticipated feeling of decision regret (Tsiros and Mittal 2000) because permanent decisions are associated with higher costs if the decision turns out to be suboptimal. For instance, when decision is permanent, consumers forfeit the opportunity to acquire a superior product or a lower priced item in the future. By contrast, when the decision appears to have lower long-term consequences such as a rental decision, consumers experience a lower level of regret (Wood 2001).

Therefore, we expect that consumers facing a buying decision are more motivated to find the best possible alternative during the decision process as compared to consumers who are making a renting decision. As a consequence, we propose that consumers facing a renting as opposed to a buying decision (with regard to the same product offered at the same price) would: (1) inspect fewer alternatives and less information about each alternative, and (2) place lower weight on negative product information. These distinct decision processes should lead to differences in acquisition decisions, such that consumers are more likely to accept the same product for renting but not for buying.

In study 1a, we used a sequential choice paradigm to investigate information acquisition in buying versus renting decisions. Respondents were presented one alternative at a time in a predetermined order and had to decide when to stop inspecting additional alternatives. This design reflects a tradeoff between selecting a current alternative or continuing to search for more alternatives that may become available. We find that the participants in the buying condition reviewed on average two additional alternatives than did participants in the renting condition before making their decision ($M_{rent} = 5.82$ movies vs. $M_{buy} = 7.45$ movies, $t(102) = 2.02$, $p < .05$). In study 1b, adapting a process-tracing technique (Payne et al. 1988), we allowed participants to examine additional information about each choice alternative (a movie) by clicking on a link to a webpage with reviews and trailers. We measured the total time participants spent on this webpage. We find that participants in the buying condition spent, on average, almost 15 seconds examining information about each of the five movie titles ($M_{total\ time} = 74.23$ seconds). In contrast, participants in the renting condition spent on average about only 9 seconds per movie title ($M_{total\ time} = 45.81$ seconds; $F(1, 264) = 4.95$, $p = .03$).

Study 2 examines differences between renting and buying decisions in evaluation of alternatives, namely the extent to which consumers weigh negative attributes of the choice options. To test the hypothesis that consumers assign relatively more weight to negative product features in buying than in renting decisions, we presented consumers with two options and varied the extent to which one of the product attributes (focal attribute) was negative. We measured the relative weight assigned to the focal attribute. A 2x2 ANOVA revealed the predicted interaction between acquisition decision and valence of attribute information ($F(1,340) = 6.80$, $p = .01$). When the focal attribute was negative, participants in the buying condition assigned significantly more weight to this attribute ($M = 15.89$) than did participants in the renting condition ($M = 10.62$; $F(1,340) = 9.38$, $p = .002$). In contrast, when the focal attribute was positive, there was no significant difference between participants assigned to the renting and buying conditions in the weight they allocated to this attribute ($M_{buy} = 12.40$ vs. $M_{rent} = 13.18$; $F < 1$). These results demonstrate how

acquisition mode can affect tradeoffs between product attributes in the decision process.

Study 3 tests our hypothesis that consumers would be more likely to acquire the same product for rental than for purchase. Participants were asked to express their interest in participating in a deal of paying one dollar for a movie regularly listed at \$4.99 for purchase or for rental. 41% of participants in the rent condition accepted the deal, whereas only 26% of participants in the buying condition accepted the deal ($c^2 = 4.32$, $p < .05$). Study 4 introduces an experimental condition in which a buying decision is seen as more transient and thus more similar to a renting decision by drawing attention to the retailer's free return policy. A one-way ANOVA revealed a significant effect of condition ($F(2, 502) = 5.71$, $p = .004$). Planned contrasts demonstrated that participants were more likely to acquire the mini-fridge in the renting condition ($M_{rent} = 5.04$) than in the buying condition without a return policy ($M_{buy\ without\ returns} = 4.66$; $t(500) = 1.92$, $p = .056$). Further, participants in the buying condition with an explicit return policy were significantly more likely to acquire the mini-fridge than were participants in the buying condition without the return policy ($M_{buy\ with\ returns} = 5.32$; $t(500) = 3.36$, $p = .001$).

A series of studies demonstrate that consumers adopt different mindsets when the decision task involved renting as opposed to buying; this finding held even when the price of acquisition and the length of consumption were the same for the renting and buying conditions. Considering growing consumer demand for temporary ownership options (e.g., renting, leasing, and sharing options), both marketing practitioners and researchers will benefit from a better understanding of how consumers make such choices.

SESSION OVERVIEW

It is difficult, if not impossible, to imagine a time in history not permeated by stories (Van Laer et al. 2014a). As we move into the digital era, stories are more prevalent than ever. Narratives are traditionally defined as an account of an event or a sequence of events leading to a transition from an initial state to a later or end state, which a storyteller conveys to a story-receiver (Bennett and Royle 2004). Social media presents challenges this definition, as the demand for content rises and the modality of consumption changes. All four of the papers in this session explore the interaction of narrative communication in the digital era. In the first paper, the authors explore how the use of digital devices fundamentally affects how consumers navigate TV narratives. Two key dimensions emerge in how consumers navigate serial narratives: time and depth, both of which enable consumers to engage in either condensation or augmentation practices. The second paper looks at online consumer reviews: the narrative structure of experience reviews enhances positive feedback from consumers reading them, which is supported through the refinement of text analysis techniques and an automated text analysis of over 190,000 reviews on TripAdvisor.

Additionally, consumer research in this arena has focused primarily on two stages of: (1) 'storytelling' (i.e., the communicational provision of a story from the storyteller to the story-receiver, Escalas 1998) and (2) 'story-receiving' (i.e., the interpretation of a story by its audience and the transformative effects exerted on that audience, Green and Brock 2000). Thus, consumer research misses the 'story-making' stage, that is, the design of a story preceding storytelling and story-receiving. The two remaining papers in this session help

to further fill this gap. In the third paper, the authors use a structural approach to narratology to develop a better understanding of story-making, putting forward a set of comprehensive guidelines to help consumer researchers understand how stories work and how they are conceived. Finally, the fourth paper provides an integrative framework to guide story construction for Social Impact Organizations (SIOs), focused around an SIO's metanarrative, an overarching mission-focused story about the SIO and why it exists.

Two questions that each paper in the session answers are:

RQ1: How is the consumption or creation of stories affected by changes due to digital devices and social media?

RQ2: How is digital storytelling conducted by those cast in the role of story-maker, that is, the stage prior to storytelling and story-receiving?

Navigating Narratives and Altering Time: Consumption Practices in the Digital Age

EXTENDED ABSTRACT

The digital era is fundamentally affecting how consumers watch TV. While for decades families would gather to watch TV in the living room, the TV set is now irrelevant in the eyes of many. Changing viewing habits mean that at least 63% of US consumers use digital devices more than once a week to stream videos or watch on-demand features (Crosett 2013). Consumers have always been able to control narrative pace when reading, a self-paced medium. Consumer control is now spreading to a wider range of media, including TV programming, movies, but also radio podcasts that, traditionally, were externally paced. Today's digital environment affords consumers navigational tools that open narrative possibilities for the receiver at all levels (Drucker 2008). A topical question is: How does greater ability to navigate narratives affect the temporal unfolding of the story receiver's experience?

Navigational devices affect the temporal unfolding of the narrative and thus alter how consumers experience it. From Genette's (1980) foundational work to Barthes' (1975) structural analysis of narratives, narratologists concur that basic structural elements of narratives affect how they are read or viewed. Genette's notion of narrative duration is particularly useful to understand the interplay between time and narrative consumption: Genette (1980) defines narrative speed as the "relationship between the duration of the story and its length" within a narrative and distinguishes between *narrative* time, i.e. the amount of time devoted to the representation of a scene and *narrated* time, i.e. the amount of time that passes within the diegetic scene. From the reader/viewer perspective, perceptions of time vary according to the narrative's inherent structure or speed: when a story unfolds slowly, narrative time expands in relation to narrated time and this extending of time due to "empty spaces" may create boredom (Tucker 2007). In contrast, when an interesting event happens, narrative time contracts (Tucker 2007).

Prior work has identified that storytellers and readers can control narrative pace at three levels: story, discourse, and narration (Baetens and Hume 2006). When consumers have control over the calibration, as is the case with digital devices to view TV narratives, they can alter the temporality between the real world and the narrated world. In this research, we explore how navigational practices affect narrative and narrated time and how the pace of delivery alters the

narrative experience, taking note of the inherent characteristics of narratives as containing 1) the temporal unfolding of events, 2) the structural and material fact of texts, images, etc. and 3) the narrativizing, the action taken by the story receiver (Drucker 2008). Prior work in the cyber-literature borrowed the term noema developed by Husserl (1962) to distinguish between noematic and extranoematic efforts (Aarseth 1997). While noematic efforts allow the reader to participate in the unfolding of the story but not modify how it develops, extranoematic efforts reflect when the viewer is able to alter the narrative rather than simply being guided by it.

Method

In line with recommendations about using contexts to extend theory (Arnould, Price, and Moisio 2006), we use TV series viewing as an empirical context. We conducted 36 interviews with TV series watchers using a mix of grand tour questions and floating prompts (McCracken 1988) to yield first-person accounts of participants' viewing practices and experiences of serial narratives. An initial identification of themes was developed, and theoretical categories were elaborated on during open and axial coding procedures. We then began a process of dialectical tacking, moving back and forth between our findings and the literature to deepen our understanding of the practices associated with TV series consumption.

Results

We find that consumers navigate the temporal unfolding of the narrative by engaging either in noematic practices, i.e. actively choosing not to transform the narrative, or extranoematic practices i.e. altering the narrative. We categorise extranoematic practices into two categories: 1) condensation and 2) augmentation practices. For instance, one informant reports using extranoematic augmentation practices by piling up episodes of his favorite series to watch several episodes in a row, in order to create a more immersive viewing experience, which would be hindered by having to wait one week in between episodes. Contrarily, other extranoematic practices condense time. For example, an informant reports saving time by reading online summaries of the second season of Homeland before watching selected scenes only, as well as skipping all scenes featuring a specific character from the series 24, because it is perceived as unrelated to the main storyline. Interestingly, these two strategies lead to opposite outcomes: While the first strategy triggers a reduced pleasure from viewing the series and an inability to evaluate its quality, the second strategy is a gratifying experience, as skipping the side story of a character he reports hating enables the informant to devote himself to the main storyline. Therefore, while Genette (1980)'s semiotic work studies narratives as linguistic objects, detached from production and reception, we intend to examine how consumers navigate and transform the narrative, and to disentangle the outcomes derived from such actions. After delineating the narrative navigational practices viewers engage in when watching TV series, we identify the impact on emotional outcomes, along with boundary conditions including the social viewing context.

Implications

We also discuss the implications of our work for our understanding of narrative consumption in the digital age, and develop recommendations for the construction and release of serial narratives. In particular, our analysis suggests that TV writers targeting digital natives should be wary of using a slow narrative pace, as young viewers are likely to fast forward through slow scenes which may lower their enjoyment. Moreover, we find that releasing a full season on-demand enables viewers to monitor their viewing pace.

If the channel broadcasts the episodes weekly, many viewers wait until several episodes are available to watch them in a row to avoid the frustration of having to wait one week in between each episode. Broadcasters could avoid this by releasing all episodes in one go.

Reviewing the Review: A Text Analysis of Why Experience Reviews Receive Positive Feedback

EXTENDED ABSTRACT

Seventy percent of consumers indicate that they base purchase decisions on consumer online reviews, thus marking these reviews as the highly influential form of word of mouth (WOM) (Nielsen 2013). Most hosting sites offer consumers the option to submit a second-order review, which evaluates the focal review. This positive feedback raises a review's ranking and visibility on the site, thus increasing its influence on consumers' purchase decisions (Moore 2015). In this article, we propose and find support for an overlooked feature of reviews that helps generate positive feedback from consumers.

Prior research provides a valid description of positive feedback on reviews of (hedonic and utilitarian) material purchases. "Material purchases are those made with the primary intention of acquiring a material good" (Van Boven and Gilovich 2003). In contrast, "experiential purchases are those made with the primary intention of acquiring a life experience" (Van Boven and Gilovich 2003).

In contrast with reviews of material purchases, we define positive feedback on reviews of experiential purchases as a vote for reviews that are narratively structured, which describes the experience consumed and recounted by the reviewer. Not all reviewers are equally capable of narratively structuring their reviews, and this inequality is likely to contribute to additional variance in positive feedback. Organizing an experience review around a narrative structure is likely to increase positive feedback. By investigating the content of experience reviews, this research aims to contribute to the narratology and WOM language literature streams by fulfilling three objectives: (1) organizing the relationships among words in experience reviews, which are manifold and indeterminate, in a narrative structure; (2) empirically demonstrating novel links between narrative structure elements and positive feedback; and (3) providing an instrument for determining the development of emotions over sentences and examining whether there are intertextual differences in this shape.

Method

We highlight seven narrative structure elements: (1) landscape of affective consciousness, (2) landscape of cognitive consciousness, and (3) canonicity, (4) temporal embedding, (5) spatial embedding, and (6) drama, and (7) genre. In social psychology, Gergen and Gergen (1988)Change</label><urls></urls></record></Cite></EndNote> develop a genre taxonomy that allows for the elaboration of a specific, testable hypothesis on story genre. Their genre taxonomy's five basic types are progressive, regressive, stable, comedy, and tragedy.

The corpus stemmed from TripAdvisor. Our procedure mined 190,461 reviews of 989 experiences consumed in Las Vegas. The reviews averaged 89 words (SD = 89.74; ranging from 3 to 2,335 words), seven sentences (SD = 4.56; ranging from 1 to 148 sentences), and .77 positive feedback (SD = 2.01; ranging from 0 to 103 votes).

In support of our automated text analysis, we relied on the Linguistic Inquiry and Word Count (LIWC) software program. LIWC measures the intensities with which word categories, classified in

dictionary entries, are used in a given text. We used validated LIWC dictionary entries as a starting point from which to operationalize our narrative structure elements, except for drama for which we developed a dictionary from scratch.

Results

To account for the excess number of zero positive feedback (Vuong's $Z = 41.45$, $p < .001$), we conducted zero-inflated Poisson regression analysis. The first model consists of control variables, which explain 14.20% of the variance in positive feedback (Wald's $\chi^2_{(24)} = 20694.75$, $p < .001$). In the second, third, and fourth model, we entered the landscapes and canonicity (Model 2: Wald's $\chi^2_{\text{Change (2)}} = 3137.17$, $p < .001$), temporal and spatial embedding, and drama (Model 3: Wald's $\chi^2_{\text{Change (2)}} = 2595.16$, $p < .001$), and genre (Model 4: Wald's $\chi^2_{\text{Change (2)}} = 93.94$, $p < .001$). These explain additional significant proportions of variance in positive feedback (14.82%, 15.32%, and 15.37%, respectively).

For the narrative structure elements, we find that landscape of affective consciousness ($\beta = .15$, SE $= .02$, $p < .01$, IRR $= 1.17$), landscape of cognitive consciousness ($\beta = .11$, SE $= .02$, $p < .01$, IRR $= 1.12$), canonicity ($\beta = .09$, SE $= .01$, $p < .01$, IRR $= 1.10$), temporal embedding ($\beta = .31$, SE $= .01$, $p < .01$, IRR $= 1.36$), and spatial embedding ($\beta = .04$, SE $= .01$, $p < .01$, IRR $= 1.04$) have significant, positive effects on positive feedback. Furthermore, reviews coded as comedies ($\beta = .07$, SE $= .02$, $p < .01$, IRR $= 1.07$) or tragedies ($\beta = .09$, SE $= .03$, $p < .01$, IRR $= 1.10$) receive more positive feedback than reviews with a progressive ($\beta = .01$, SE $= .06$, $p = .950$), regressive ($\beta = -.06$, SE $= .03$, $p = .068$), or stable shape; thus, we find support for hypothesis 3. However, a significant, negative effect emerges for drama ($\beta = -.02$, SE $= .01$, $p < .05$, IRR $= .98$).

Implications

Our newly developed instrument helps extend current knowledge of how to analyze corpora of big data. When the World Wide Web was made available to the general public, it was heralded as "the Great Equalizer" (Dugan 1996) because it democratized communication: Everyone could share information and tell stories. Today, making sense of the millions of words posted in review form 24/7 (http://www.internetlivestats.com/) is critical to understanding the effect of narratives on consumers. For any (collection of) digital text(s), our tool can construct between-sentence emotional change to determine the development of emotions over sentences and examine whether there are intertextual differences in this shape.

Brand Story-making and Digital Conversations

EXTENDED ABSTRACT

Recently, Intel and Toshiba (2012) developed "The Beauty Inside", a film about a man who wakes up every day with a new body and a new face. Its distribution on social media gave audience members the opportunity to film themselves and play the main character throughout the narrative, which resulted in many storytellers producing the narrative. Google is another company that has overcome the idea of simply being an information provider to claim its ability to deliver stories in a digital world. While remaining true to their business, many more brands have turned their communication from analytical (Petty and Cacioppo 1986) to narrative persuasive messages (Van Laer et al. 2014a).

Built on extensive literature review and the authors' former research, this conceptual paper aims at fostering scant academic works providing guidance about does, don'ts, and risks of brand story-making in digital conversations. Since the definition of narrative trans-

portation (Gerrig 1993), rich academic works, mostly grounded in cognitive psychology, have investigated the profound mechanisms of story reception. Such works help understand the need behind story consumption (Van Laer, Visconti, and Feiereisen 2014b), how an audience receives a story (Escalas 2004), what variables are likely to transport it (Van Laer et al. 2014a), and the engrossing effects of transportation (Green and Brock 2000; Phillips and McQuarrie 2010). Yet, these contributions are often too theoretical to be directly applicable to digital brand conversations, which remain mostly grounded on a 'trial and error' approach. As an illustration, though consumers check their smartphones dozens of times per day, a lot of brand content online remains unobserved due to a lack of storytelling (Vigneaux 2015).

Conceptual Development

To date, academic works have been mostly focused on two stages of brand digital conversations: (1) 'storytelling' (i.e. the communicational provision of a story from the storyteller to the story receiver, Escalas 1998) and (2) 'story-receiving' (i.e. the interpretation of a story by its audience and the transformative effects exerted on that audience, Gerrig 1993; Levy 2006). However, research on the 'story-making' stage—the design of a story preceding storytelling and story-receiving—is scant. Through story-making, story providers decide strategically and practically on issues as varied as: which audience is likely to be persuaded through a story; what are the key structural components of a story to design; how should these components be designed to prove effective; and what principles can guide these decisions? This paper aims to advance current understanding of the story-making stage and provide comprehensive answers to similar questions. These answers will contribute to our understanding of the function of digital marketing more broadly.

Implications

Four questions lead to corresponding contributions. First, in line with Barthes' (1975) structural approach to stories, we question the structural components for successful digital brand stories and discover four: (1) identifiable characters (i.e. characters whose thoughts, feelings, and behavioral motivations are clearly understandable, Van Laer et al. 2014a)feelings`, and behavioral motivations are clearly understandable`, </Prefix><DisplayText>(i.e. characters whose thoughts, feelings, and behavioral motivations are clearly understandable, Van Laer et al. 2014a; (2) imaginable plot (i.e. a spatially embedded sequence of events thematically and symbolically interconnected, Thompson 1997); (3) climax (i.e. an emotional and narrative construction leading to a key turning point, which may result from rhetorical deployment of different story genres, Stern 1995); and, (4) outcome (i.e. a clear learning favoring appraisal of a brand's contract and memorization, Stein and Albro 2010). Second, we question the guiding principles for strategic story-making in a digital world and discuss four of them: (1) historical fit with ongoing acute social contradictions (Holt 2004); (2) connectivity between the online story text and offline texts (intertextuality, Kristeva 1986); (3) gestaltic storytelling (Diamond et al. 2009) derived from a concerted use of multiple storytellers through social media; and (4) usefulness versus entertainment as the two main content types that online consumers are likely to consider (Vigneaux 2015). Third, by observing how brands successfully engage online customers, we unveil the different inspirational sources brands exploit for their story-making: (1) brand heritage; (2) brand's charismatic leader; (3) existing myths and famous stories; (4) consumers' narratives; (5) brand characters; and (6) distinctive product ingredients. Fourth, we inspect limits and risks of adopting brand stories in the digital world. In particular, we

identify three pitfalls of brand stories online: (1) content strategies; (2) temporary campaigns by the latest hotshot; and (3) influencer marketing programs. We comment on possible drifts that stories are susceptible to take online whenever brand managers lose control of story-making and/or contradict an established brand contract. Finally, we identify ethical risks related to story-making and -telling.

Acknowledged as art within the precincts of literature and philosophy, story-making is not requested to stand as art within the precincts of the digital world. Yet, it demands way more than current 'bricolage'. This paper is meant to improve theoretical understanding of how stories work and how they should be conceived, particularly for an online audience.

Transformative Digital Storytelling: A Framework for Crafting Stories for Social Impact Organizations

EXTENDED ABSTRACT

Building from the rich interdisciplinary literature on narrative processing, we provide a framework to guide authentic communication for Social Impact Organizations (SIOs) including non-profit organizations, public policy entities, and enterprises engaged in solving important social problems such as poverty, hunger, homelessness, sustainability, and racism. For SIOs to alleviate these complex and multi-layered social problems, it is crucial for them to engage their many audiences including clients, donors, volunteers, and the community. Storytelling is a powerful and creative tool SIOs can use in their efforts to address pressing social problems. Additionally, recent advances in social media offer a growing opportunity for SIOs to tell and share stories, creating pressure to ensure the stories they propagate are engaging, memorable, and strategically consistent with their mission and objectives.

Conceptual Development

A story must contain three essential elements: Characters, Chronology, and Causality (Bruner 1990; Stern 1995). Stories contain characters that interact with each other and serve as agents of cause and effect (Zwaan, Langston, and Graesser 1995). Chronology or time is configured in stories as episodes, each with a beginning, middle, and end, providing a temporal sequence for events (Schank 1995). Finally, causality refers to the relationships among story elements that allow for inference making; i.e., the characters' goals lead to actions that result in outcomes (Pennington and Hastie 1986). Given the important, often emotional, issues faced by SIOs, their stories may be powerful and emotionally charged. But, for a SIO's stories to be compelling and effective, they must also communicate strategic content about the SIO and its mission.

We propose that SIOs can best leverage the power of individual stories when these stories are linked to a broader, overarching mission-focused story about the SIO and why it exists. We term this overarching story the organization's *metanarrative*. Stephens and McCallum (1998) define a metanarrative to be a story about a story, encompassing, explaining, and uniting other "little stories" into an integrated whole. An SIO's metanarrative serves as a guide for the construction of each story the organization uses in its outward facing communications program, which are intentionally crafted with a specific audience in mind and designed to yield a specific behavioral outcome, for example, an increase in program attendance.

A mission-focused metanarrative is itself a story and thus must possess character, chronology, and causality. The main character, the protagonist, of the metanarrative is the organization itself. In a metanarrative, the organization is treated as a protagonist that has a history, undertakes actions, and hopes to achieve future goals. A metanarrative also has chronology, conveying the organization's past, present, and future. The organization's past may encompass its history, founder's story, or the societal issues that the organization addresses. The organization's present consists of the SIO's mission, values, programs, and strategic objectives: what the organization does and why. Finally, the metanarrative includes the organization's long-term vision for the future, the road map of how the SIO hopes to achieve its organizational objectives and goals. The third component of a compelling metanarrative is causality, or plot. A metanarrative should present characters with goals who follow a course of action to achieve those goals, resulting in a final outcome. The mission-focused metanarrative should highlight the most important challenges facing the organization, including a few critically important past failures and successes.

We recommend that SIOs develop a rich metanarrative in order to anchor and guide the stories they construct to reach the multiple audiences they serve and hope to rally into action. Our conceptual framework also provides detailed advice for crafting these stories, because stories vary in the extent to which they are engaging, compelling, and memorable. Certain features of stories contribute to capturing the audience's attention, engaging them in the story, and calling an audience to action (Green and Brock 2000; Van Laer et al. 2014a). Specifically, we explore several important story features: a hook, character development, a climactic plot, a mission motivated message, and crafting the story.

Implications

Our framework offers a strategic structure for the practice of SIO storytelling, beginning with the crafting of a mission-focused metanarrative. The metanarrative becomes the point of connection for each individual story crafted by the SIO, which must also be cognizant of the key features of a good story including a hook, character development, and a climactic plot.

One challenge SIOs may face in implementing this storytelling framework is deciding which stories to tell. While it may seem wise to craft stories that illustrate an SIO's success, stories that lead directly from a problem to a solution may not paint an authentic portrayal of many SIOs' history and experiences. Further, if only success stories are told, it may undermine the SIO's ability to portray challenges in a way that is relatable to others who struggle or demonstrate an ongoing need for support.

A second practical consideration in crafting a story for SIOs is selecting the appropriate length. Due to consuming information on digital technologies, consumers' attention span for longer stories appears to be waning. Thus, many stories crafted by an SIO will need to be relatively short. However, consumers have shown a renewed interest in longer form drama, but on their own terms, such as binge watching streaming content. Thus, storytellers need to assess the audience's attention span as well as the best media for communicating an engaging story.

In sum, our transformative story framework is a tool that bridges academic research on narrative construction to enrich SIO practice. Although not the focus of this research, other entities, such as government agencies, that might also benefit from our framework, which promotes authentic communication of pressing social problems and seeks to move people to action— such as volunteering and engaging in desired behavioral outcomes. We will end our presentation with directions for collaborative research by consumer researchers and SIOs to refine storytelling best practices, so that we may develop a broader set of tools to guide SIOs as they unlock the transformative power of storytelling.

SESSION OVERVIEW

Money is central to almost all aspects of consumers' life: people seek to acquire it through their participation in the workforce, use it to manage their image and their social relationships, spend it to acquire valuable goods and services, and save it or invest it in the hope of a better future. Because of its numerous uses, money is extremely complex, and a significant source of influence on consumer behavior by inducing feelings as diverse as fear, hope, envy, competence or alienation (Furnham and Argyle 1998). It is as much the cornerstone of all market transactions as a social and cultural item (Nelms and Maurer 2014), and as such it is best understood through a multidisciplinary perspective which incorporates social, cultural, and economic aspects (Aarts and Bijleveld 2014).

In the proposed special session, we present four research projects which explore the interplay between the psychological and economic aspects of money. In the first paper, **Fennis, Chaplin, Tierean and Vohs** explore circumstances under which the poor are more generous than the rich. Reconciling conflicting findings in the literature, they show that charity appeals focusing on others make the poor more generous, while those focusing on the self make the rich more generous. In the second paper, **White and Sussman** develop behavioral interventions to help consumers manage their investment more responsibly, and show the impact of such nudges on consumer financial decision making in a series of lab and field studies. In the third paper, **Andre, Carmon and Wertenbroch** shows that consumers who are more satisfied with their jobs attach greater intrinsic value to the money they earn, and as a consequence have a harder time letting it go. Finally, **Yoon, Yang and Morewedge** show that educating consumers about the return that they get on education can backfire by making them pick less advantageous loans.

Collectively, the four papers of the session present recent contributions from leading scholars in the field of money and financial

decision making, and paint a compelling picture of consumers' relationship to money, from the moment it is earned to the moment it is used. The session covers important aspects of consumers' life (job satisfaction, college choice…), and offers promising behavioral interventions to improve consumers' management of their money. Because the session considers both the economic dimension of money and its psychological and sociological aspects, it would appeal to a large audience, and bring researchers with diverse trainings and research interests together to further our understanding of money.

A Sense of Wealth or Poverty Can Help or Hurt Charitable Giving

EXTENDED ABSTRACT

Are the rich more generous, or the poor? Myriad perspectives on this question have been offered – with supportive findings on both sides. Such disparate findings suggest that both a sense of wealth and poverty can promote generosity, albeit under different circumstances. Therefore, a key objective of the present research was to identify the conditions under which wealth and poverty produce generosity (as measured by charitable giving), and to validate these findings in controlled and naturalistic settings. To that end, we measured willingness to donate time to a fictitious cause, and solicited monetary donations to an existing charity. Finally, we examined whether our findings are limited to the adult population, or extend to children as well, which gave us insights into the universal nature of the phenomenon described.

The literature on how social status and material well-being affect charitable giving is fraught with conflicting findings. On the one hand, there are grounds to infer a positive association between having money and donation behavior. First, charitable donations typically flow from the more fortunate to the less fortunate rather than the opposite (Hong and Bohnet 2007). Extensive research on the behavior of consumers in the top income brackets (households with tens to hundreds of millions of dollars) spanning 20 to 50 years indicates that as wealth levels increase, so does charitable giving (Schervish and Havens 2002).

On the other hand, some findings have found generosity to decrease in the level of income. For example, a survey that tracks philanthropic behavior reported that households earning more than $100,000 donate a smaller fraction of their income to than households earning less than $25,000 (Gardyn 2003). In addition, reminding people of money has been shown to reduce generosity, both in the form of charitable donation and helping behavior (Vohs, Mead, and Goode 2008).

Previous research therefore suggests that having money might sometimes promote and sometimes hinder generosity. Complicating matters still, the same results has been found with regard to lacking money, which can sometimes reduce prosocial behavior (Gasiorowska, Zaleskiewicz, and Wygrab 2012; Vohs, Mead, and Goode 2006) or conversely promote it (Cialdini 2001)

We propose a reconciliation of these seemingly conflicting findings. We predicted that the relationship between possession of monetary resources and displays of generosity might depend on whether the person is self-oriented (versus other-oriented) when faced with charitable opportunities. Indeed, previous research has identified

that the behavior of those with money appears to largely be driven by self-focused considerations, whereas those without money are guided by the choices and behaviors of others (Kraus et al. 2012). By implication, we argue that in order to favor charitable behavior, the charitable appeal should be in line with the orientation of the potential benefactor. For people reminded of money, self-focused appeals will produce increased levels of generosity, and other-focused appeals will decrease it. For people primed with lacking money, the reverse will be true. In three experiments conducted in the lab and on the field, we provide support for this hypothesis, and show that the effect holds both for young children and adults.

Study 1 used a 2 (mindset: having versus lacking money) x 2 (focus: own versus others' behavior) between-subjects design in which participants read an essay and imagined themselves as the main character. The story described either a relatively wealthy individual who led an affluent life (having money condition) or someone with few financial means who lived a modest life (lacking money condition; 6). Next, participants were either asked to describe an event in which they behaved generously toward someone or an organization requesting help (own behavior condition) or in which someone else behaved generously toward someone or an organization (other's behavior condition). Finally, participants were asked to indicate the amount to hours they would be willing to volunteer towards the University Student Fund, and their answer served as a measure of generosity.

Results showed that when participants had been reminded of how they personally acted generously in the past, people in the mindset of having money signed up to donate more of their time than those in the lacking money condition. Among participants reminded of the generosity of others, the pattern reversed — as expected.

Study 2 extended these findings by including a control condition to assess the directionality of the effects found, and focusing on generosity with money instead of time. Participants in this study were first primed with having money, lacking money or a neutral state using a sentence unscrambling paradigm. Next, the experimenter indicated that she was soliciting monetary donations for the World Wildlife Fund (WWF). When the focus was on the self, she asked participants whether they agreed that the WWF is an important enterprise for a green and sustainable planet (all participants agreed). When the focus was on the choices of others, she mentioned that many participants had already donated money to the cause. Results showed that, compared to the control condition, participants in the mindset of having money only donated more when the charitable appeal was focused on participants' opinion about the charity. The reverse pattern was found for participants in the mindset of lacking money, who were only susceptible to the appeal to others' behavior.

The last study, involving children aged 8-11 used the same design and procedure of Experiment 1 and found similar results thus showing that, even among young children—who might not yet have extensive experience with and a full understanding of the meaning of money— a sense of financial wealth or poverty can help or hurt charitable giving depending on whether the behavior of the self or of others is made salient.

Invoking the Responsible Self and Enhancing Subjective Competence: Nudges to Increase Financial Engagement

EXTENDED ABSTRACT

With millions of senior citizens living below the poverty line in the US (Short 2014), researchers, policymakers, and practitioners have sought ways to improve savings and investing decisions earlier in life. In addition to saving more, individuals can also improve their long-term financial prospects by making wiser financial decisions using the money they have already saved. However, far from focusing on improving their financial decisions, many individuals disengage from decisions about their financial futures. For example, people tend to stick with their company's default retirement plan (which may not have an ideal contribution rate or distribution of funds), fail to rebalance their portfolios over time, and use naïve diversification strategies (e.g., 1/n heuristic) rather than making thoughtful choices about their portfolios (Benartzi and Thaler 1995, 2007; Samuelson and Zeckhauser 1988). Each of these tendencies can be costly to consumers in the long run, significantly impacting their wellbeing during retirement.

One potential method for helping individuals become better financial decision makers is to provide financial literacy training, which has been linked to participation in the stock market and better planning for retirement (Lusardi 2008). However, financial literacy programs have had mixed results (Boshara et al. 2010; Fernandes, Lynch Jr, and Netemeyer 2014). Perhaps more concerning, some research even suggests that some components of financial literacy training may highlight gaps in knowledge, unpleasantly underscoring individuals' ignorance and leading to a decrease in willingness to participate in the market (Hadar, Sood, and Fox 2013). Although there are many potential reasons for low levels of financial literacy and engagement, one potential factor is that individuals avoid seeking information about topics which they find unpleasant to think about, especially if they do not feel competent or on track to meet their goals and learning more would make those shortcomings salient (Golman, Hagmann, and Loewenstein 2015; Sweeny et al. 2010; Townsend and Liu 2012).

Thus, our research aims to design nudges that increase individuals' engagement with their finances (i.e., increasing willingness to learn more or become proactive decision makers with respect to finances) by increasing perceptions of financial competence and personal responsibility for the financial outcomes. Our research draws from earlier work which suggests that invoking a sense of identity can motivate behavior (Bryan et al. 2011; Bryan, Adams, and Monin 2013; Bryan and Hershfield 2012) and that self-affirmation exercises can lead to improvements in program participation (Hall, Zhao, and Shafir 2014). We propose and test interventions to increase financial engagement across 3 online studies and one large field study, using a variety of metrics to measure financial engagement. Studies 1 and 4 aim to evoke a sense of financial responsibility to oneself or others, while studies 2, 3, and 4 aim to boost perceptions of financial competence in an investing domain. Because women have lower levels of financial literacy and stock market participation (Lusardi and Mitchell 2008), as well as traditionally different social roles, we anticipated gender differences in the effectiveness of different interventions.

Study 1 (N=525) aimed to invoke identities that instilled a sense of financial responsibility to oneself or others. Subjects randomly viewed control instructions or one of three "responsible self" instructions, which read as following: "As Chief Financial Officer of [your life/ your future life/ your family], you're responsible for making wise financial decisions." Relative to control, subjects in the "future self" condition spent more time on a page where they could learn about investment options before proceeding to a hypothetical allocation decision (p=.004 for log-transformed measure with outliers dropped).

Studies 2 and 3 tested the effect of boosting self-efficacy in a financial domain. In study 2 (N=493), subjects completed a self-affirmation exercise, either writing about a wise purchase decision, a wise saving decision, a wise investment decision, or their daily eating routine (control). All self-affirmation conditions boosted self-

assessed ability to make wise financial decisions (p<.05), and subjects who wrote about a wise investment decision were significantly more likely to express interest in learning more about finances and investment options (p<.05). In study 3 (N=510), subjects took a fabricated financial personality quiz and were told either that they already had the skills to be good investors or that they would need to invest significant time in learning about investing in order to become good investors. The confidence-boosting manipulation significantly increased a within-subject measure of confidence (p<.0001), and women (but not men) in the high confidence condition spent significantly more time on a page where they could learn about investment options before making a hypothetical investment decision (p=.028 for log-transformed measure with outliers dropped).

Study 4 (N=45,196) aimed to test the effect of similar marketing messages in a large field study conducted on existing customers of a large financial advisory firm. The firm sent emails encouraging customers to stay on top of their long-term financial goals and click on a retirement planning tool. Our test included four conditions: control ("learn more"), responsibility to family ("CFO of your family"), responsibility to self ("CFO of your own life"), and confidence ("You're a better investor than you think"). We used click rate minus unsubscription rate as a measure of financial engagement. The responsibility to family manipulation was effective on women (family vs. control: women only, p<.01; men only, ns), while the responsibility to self manipulation was effective on men (self vs. control: men only, p<.1; women only, ns). The confidence boost manipulation was directionally less effective than control. We suspect this is due more to ineffective phrasing than to a lack of connection between confidence and engagement, which is an area to explore in future studies.

These studies suggest that well targeted messages invoking individuals' financially responsible selves, as well as interventions inducing subjects to feel more competent specifically in investing-related domains, can impact individuals' engagement with their finances and investments. That inducing a sense of competence can increase interest in learning more about investments may be counter-intuitive to investment or financial education professionals. Future research can explore whether confidence-boosting messages can improve uptake of such services in a real-world settings.

Meaning Transforms Money: How Job Satisfaction Affects Consumers' Perception and Use of Their Earnings

EXTENDED ABSTRACT

Past research has highlighted important differences in the management of financial resources across consumers. Notably, while some consumers exhibit patterns of overspending (Shah, Mullainathan, and Shafir 2012), others oversave (Carroll 1998). Similarly, important differences have been highlighted with regard to risk-taking and gambling (Holt and Laury 2002). In the present research, we propose that such differences can in part be attributed to the circumstances in which consumers earn money. In particular, we hypothesized that when consumers derive greater pleasure and satisfaction from their job, they view the money that they earn from this job not only as a medium which allows them to acquire valuable resources, but also as a symbol of their achievements and success. In turn, this greater intrinsic value attached to their earnings makes these less fungible, which in turn makes consumers more conservative in their use of money. In contrast, when consumers work dissatisfying jobs, they do not attach such symbolic value to their paycheck: the money

has no intrinsic value and is more fungible, which makes consumers less conservative in using their earnings.

Past research has suggested that that money can both function as a medium or as a good (Lea and Webley 2014). The first aspect, money as a medium, corresponds to the way microeconomic theory describes money: it is viewed as a quasi-universal and fungible medium of exchange, which does not possess intrinsic worth but derives its value from its ability to acquire valuable goods and resources (Jevons 1875). The second aspect, money as a good, speaks to the fact that money is at the heart of numerous social and cultural practices, through which it can acquire intrinsic value. According to this second perspective, not all "monies" are the same, and consumers can attach special value to money as a function of the context in which it was acquired (Carruthers 2010; Zelizer 1989). In the present research, we hypothesized that when money is acquired in a job which reflects favorably on people's self, the money would be more likely to be treated as a good than when the money does not reflect such favorable associations.

In the first study, we sought basic support for the effect of job satisfaction on the perception of money: a survey administered to MechanicalTurk respondents showed that people who are satisfied with their jobs are also more likely to report "a sense of personal connection with their paycheck", are more likely to agree that "they view their paycheck as special", and are less likely to agree that "they would not distinguish between their paycheck and money earned from other sources".

In the second study, we established a causal validation of our correlational results. We recruited currently employed respondents on MechanicalTurk and gave them a list of changes to their job that would increase (vs. decrease) their job satisfaction before asking them to imagine working in that environment. Our manipulation successfully replicated the results of the first study: participants who had been asked to imagine a more (vs. less) satisfying job reported that they would feel a greater (vs. smaller) sense of personal connection with their earnings, would treat the money as more (vs. less) special, and would view the money as more (vs. less) fungible.

In the third study, we aimed at replicating the results, provide support for our hypothesized mediator, and rule out an alternative explanation. We hypothesize that the change in the perception of the money stems from a sense of competence that the earnings have become associated with. However, an alternative explanation could be that lower job satisfaction triggers a sense of disgust with the money (Di Muro and Noseworthy 2013). Job satisfaction was first manipulated by asking participants to generate changes which would improve or degrade their work environment, and imagine that such changes would be implemented. This manipulation replicated our results on the participants' perception of money. We then measured participants' disgust by asking them to imagine touching, rubbing and handling close to their face the money from their paycheck, and to report how attractive (vs. repulsive) doing so would be. There was no difference in disgust between conditions, which does not support disgust as a mediator for our effect. Finally, we asked participants whether they would feel competent in the job that they had imagined, and whether they felt that their paycheck would reflect this sense of competence. The projected sense of competence significantly mediated people's attitude toward the money, which supports the hypothesized psychological process.

In the fourth study, we investigated the behavioral consequences of treating the money as a good (as opposed to a medium). We recruited participants to work on a task purportedly meant to measure their creativity, and asked them draw an alien. Twenty-four hours after completing the task, participants were contacted by email, and

told that we had decided to reward them with a $1 bonus. The reason for the bonus was manipulated between subject: participants were either told that the bonus was because we had an extra budget available for the study (control condition), because the average quality of the drawings exceeded our expectations (small competence condition) or because the quality of their drawing exceeded our expectations (strong competence boost condition). Participants were given the opportunity to get the bonus as is, or to gamble the money in a double-or-nothing bet. As expected, participants were more conservative when the bonus was framed as strongly linked to their competence than when it was weakly linked to their competence or framed as a gift. Further laboratory studies are currently being run, investigating other downstream consequences of job satisfaction on saving, spending and investing behavior.

Tuition Aversion: Impatience Impaired Financial Decision Making for Higher Education

EXTENDED ABSTRACT

Student loans are one of the largest sources of consumer debt in America, second only to home mortgages. In response to the mounting cost of college, government, for-profit, and non-profit agencies including the Department of Education, Payscale, and Money magazine, have attempted to aid students and parents with the financial planning of their higher education. These efforts attempt to steer consumers to consider their choice of higher education, in part, as an investment decision. In other words, in addition to other factors such as school rank, location, and recreational opportunities, students should consider the costs and long-term financial ramifications of attending each of the colleges they consider.

The assumption of these agencies is that students do not consider higher education as an investment decision because they lack information about the true costs and returns of attending different colleges. Consequently, decision aids in this domain typically provide information about prospective colleges such as their average annual cost (tuition and expenses), graduation rate, and starting salary post-graduation. These efforts assume that students will reduce their debt load and increase their lifetime earnings if they are simply provided with all of the relevant information.

We suggest that the primary complicating factor is the temporal structure of when consumers will incur the costs of higher education (i.e., immediately or in the near future) and when they will reap its rewards (i.e., in the more distant future). This disjunction between the payment of the investment and start of its return makes the choice of higher education a choice over time—an intertemporal tradeoff. In this case, the problem impairing the consideration of college as an investment decision may lie within the decision maker (her impulsivity) rather than in the manner in which information regarding the decision is presented.

In five experiments, we examined how providing financial information affected financial decision making in the context of college choice. Specifically, for pairs of colleges, we provided student and convenience samples of participants with various mixtures of information including: the total cost of tuition, expected annual salary, and 30-YR return for pairs of real colleges taken from a recommended aid, College Scorecard. We then examined whether this information would lead participants to make more financially savvy choices when faced with a choice between a low cost but low return school (School L, hereafter) and a high cost but high return school (School H, hereafter). In our experiments, School L was always cheaper to attend than School H, but a less prudent choice, as its to-

tal return would be substantially smaller over the course of 30 years (even when accounting for its higher tuition).

We first tested whether simple decision aids, and trust in the information they contained, would increase consideration of both the financial costs and benefits of higher in Studies 1 and 2. In Study 1, we compared students' college choices when provided with information about the costs, returns, or both the costs and returns of higher education in various formats to see whether simply providing students with better information would be sufficient to improve their financial decision making. In Study 2, we examined whether students who did chose the low return school simply did so because they did not trust return information. If these students did not trust they would earn the projected returns, their choice might rationally be based then on the more certain cost of tuition and expenses.

In Studies 3-5, we tested our proposed and alternative psychological explanations underlying the tendency to underweight the long-term financial consequences of higher education decisions. Our assumption is that temporal discounting is a root cause of the preference to minimize immediate expenses rather than maximize total earnings. We tested our discounting hypothesis against a simple heuristic to choose the cheapest option in Study 3. We tested our discounting hypothesis against the possibility that participants were instead considering return on investment (ROI) in Study 4. In Study 5, we examined where individual participants' discount rates predicted their overall preference to minimize tuition rather than maximize total returns.

In all studies, we found strong evidence of a "tuition aversion." Participants exhibited strong tendency to prefer low return schools (School L) when compared to high return schools (School H), which was present in virtually all cases in which tuition costs were provided (whether alone, and alongside expected annual salary information, and/or alongside 30-YR aggregated expected income information). Several process studies found that tuition aversion was not explained by uncertainty or mistrust of the financial information provided. Even people who preferred School L believed that they would earn more money over their lifetime if they attended School H instead (Study 2). It was also not explained by the different ratios of tuition costs and total returns or percentage ROI for the two schools (Study 4).

Instead, the results point to temporal discounting underlying preferences for the dominated option (School L), suggesting that different perceptions of immediate costs (i.e., tuition) and long-term returns (i.e., income) play a substantive role in college choice. This hypothesis was tested directly in Study 5, which found that more impatient participants were more likely to prefer School L's, implying that high impulsivity inflates the perceived immediate cost bigger and undervalues the long term benefit of preferring School H's. Our findings demonstrate a new anomaly in a consequential financial decision faced by millions of students, and provide evidence for the process resulting in these suboptimal decisions.

SESSION OVERVIEW

Consumers invest both time and money in experiences, from the ordinary (e.g., watching a movie), to the special (e.g., vacations), to the extraordinary (e.g., skydiving; Bhattacharjee and Mogilner 2014; Celsi, Rose, and Leigh 1993). In fact, spending on experiences is often encouraged (e.g., Dunn and Norton 2013) as a growing body of literature has demonstrated that experiences, compared to material purchases, increase satisfaction with the purchase and overall happiness (e.g., Van Boven and Gilovich 2003).

Much of the work examining these benefits has done so by identifying different characteristics of experiences that contribute to increased happiness, such as reduced hedonic adaptation (Nicolao, Irwin, and Goodman, 2009) or fewer unpleasant social comparisons (Carter and Gilovich 2010). However, given that experiences are so important to consumers, there is much more to learn about the ways consumers interact with experiences, particularly beyond consuming those experiences in the present. ***What factors are active both before and after an experience that affect how consumers anticipate and reflect on those experiences?*** In this session, four papers explore these factors, revealing how enjoyment of experiences can be extended over time and into other important downstream consequences.

In the first paper, **Franssens and Botti** examine the role of receiving information prior to the experience. They show that such information may not enhance, and may even reduce, anticipated satisfaction when an individual derives a sense of control from imagining upcoming experiences. In the second paper, **Kumar, Walker, and Gilovich** demonstrate downstream consequences that emerge from the gratitude that experiences foster. They find that thinking back to experiences can trigger greater pro-social behavior towards strangers down the road.

Moreover, enjoyment from experiences can also be extended over time, as people derive utility from their memories of those experiences. In the third paper, **Goodman, Malkoc, and Stephenson** investigate how the enjoyment of special milestones (e.g., college graduation) can be amplified in the future. They find that tangible,

as opposed to experiential, purchases activate more meaning and greater enjoyment in the long run, an effect that is not anticipated by consumers. Finally, **Barasch, Diehl, Zauberman, and Zhang** examine situations where people create tangible memory cues during the experience by taking photos of their surroundings and the people they shared the experience with. They show that people mis-predict which kinds of photos allow them to best relive the experience.

As a whole this session provides novel and important insights in the area of experiences which should be of interest to a wide range of consumer researchers, from those interested in experiential consumption, to those interested in materialism and even memory processes. All projects are in advanced stages with multiple studies conducted and represent a range of methodologies from text analysis, to field studies and economic games.

Consumers' Reliance on Imagination Moderates the Effect of Information on Anticipated Satisfaction

EXTENDED ABSTRACT

Research has shown that having information (vs. not) about upcoming experiences enhances people's expected satisfaction because it gives them a sense of personal control (Averill, 1973; Schulz, 1976) as well as accelerated physical decline--are at least in part attributable to loss of control. A field experiment in which institutionalized aged were randomly assigned to one of four conditions was carried out to assess the effects of increased control and predictability upon the physical and psychological well-being of the aged. Individuals in three of the four conditions were visited by college undergraduates under varying contingencies, while persons in the fourth condition were not visited and served as a baseline comparison group. Subjects in the control condition could determine both the frequency and duration of visits they recieved. A second group of subjects (predict. We predict that this positive effect of information on anticipated liking of experiences decreases, and may even reverse, for consumers in an imaginative (vs. non-imaginative) mind-set (Thompson & Hamilton, 2006). Based on research linking positive fantasies to an inflated sense of attainability (Oettingen & Mayer, 2002), we propose that the process of imagining desirable experiences enhances consumers' sense of self-determination. This heightened sense of self-determination reduces the need for information as a source of control. Consequently, providing information (vs. not) will have a smaller effect on anticipated satisfaction for consumers in an imaginative (vs. non-imaginative) mind-set. Information about future experiences may even negatively affect anticipated satisfaction when this information constrains consumers' ability to imagine and lowers their perceived self-determination. Three experiments test this hypothesis with different manipulations of imagination and information.

Experiment 1

Procedure

601 female U.S. citizens were recruited from Mturk.com. The introduction informed participants that they would be asked a few questions about a gift voucher for a spa. We expected that participants would be more likely to rely on their imagination while evaluating the ad when their visit to the spa was hedonic ("to relax and pamper themselves") vs. utilitarian ("to get treatment for their physical ailments"), because hedonic consumption is more conducive to fantasizing than utilitarian consumption (Holbrook & Hirschman, 1982).

The voucher included a picture of a massage room and stayed on the screen for thirty seconds. Participants were then asked to imagine that they would use the voucher for the "Revitalizing therapy". Some participants were told which specific treatments would be included in the therapy whereas others were not. Participants then responded to four questions measuring how satisfied they would be with the spa (1-5 scale).

Results

The four measures were averaged into one measure of satisfaction (α=.92). The interaction between motivation and information was significant ($F(1,597)$=7.05, p=.008). In the utilitarian condition, information had a positive effect on satisfaction (4.13 vs. 4.5, $t(308)$=4.22, p<.001, d=0.48), but, as expected, in the hedonic condition, information had no effect on satisfaction (4.2 vs. 4.24, $t(289)$=0.4, p=0.69, d=0.05). This provides initial evidence for our hypothesis that the value of information is diminished for consumers in an imaginative mind-set.

Experiment 2

Procedure

142 citizens from the UK, the US, and Canada (71 men, M_{age}=29.6) were recruited from prolificacademic.co.uk. Participants were told they would be asked a few questions about a real estate ad that would remain on their screen for 30s. All participants saw a picture of the same house. Participants were then instructed to rely on their imagination (vs. not) while evaluating the house. Participants in the *imagery* condition were asked to visualize, imagine, and dream about making the house their own, whereas participants in the *no imagery* condition were asked to "take a closer look at this place" (based on Petrova & Cialdini, 2005). The presence of information was manipulated by showing the house either furnished or unfurnished. Then, participants indicated how much they liked the house and how much they would want to live there (1-9 scale).

Results

The two dependent variables were averaged into one composite score of satisfaction (r=.87). One participant scored three standard deviations below the mean of her experimental group and is not included in the following analysis. The interaction between furniture and imagery was marginally significant ($F(1,137)$=3.73, p=.055). Participants who were not asked to use their imagination, were more satisfied with the furnished house than with the unfurnished house (5.61 vs. 7.01, $t(73)$=3.82, p<.001, d=0.89). Participants who were asked to use their imagination, however, were not significantly more satisfied with the furnished house than with the unfurnished house (6.24 vs. 6.79, $t(65)$=1.42, p=0.16, d=0.35). Again, this provides evidence for our hypothesis that the positive effect of information decreases when people are in an imaginative mind-set.

Experiment 3

Procedure

134 English speakers from various countries (70 men; M_{age}=26.1) were recruited from prolificacademic.co.uk. The introduction informed participants that they would be asked a few questions about a vacation ad that would remain on their screen for 30s. The ad displayed the same picture of an island for all participants. Some participants were instructed to use their imagination (vs. not) while viewing the ad. The instructions to imagine were similar to those of Experiment 2. Then, participants in the *information* condition read two sentences about the island that mentioned the view from the most visited spot on the island and which other activities

visitors could engage in during their stay. Participants in the *no information* condition did not read anything about the island. Participants indicated how much they liked the island and how much they would want to spend their vacation there (1-9 scale).

Results

Two participants scored three standard deviations below the mean of their experimental group on the satisfaction measure (average of two dependent variables, r=.80) and are not included in the following analysis. The interaction between imagery and information was significant ($F(1,128)$=6.58, p=.01). In the no-imagery condition, results are directionally consistent with the first two studies in that satisfaction was greater when information was present than when it was absent (6.09 vs. 6.63, $t(65)$=1.47, p=0.14, d=0.36). In the imagery condition, however, information had a negative effect when participants imagined their stay on the island (7.17 vs. 6.38, $t(63)$=2.15, p=0.033, d=0.54).

Three experiments show that having more information does not always have a positive effect on consumers' anticipated satisfaction, and may even have a negative effect, when consumers are in an imaginative mind-set. Further research will focus on demonstrating the proposed process that imagination heightens people's sense of self-determination and therefore fulfils a need for control. Further research will also investigate why, in the imagination conditions, information had no effect in Experiments 1 & 2 and a negative effect in Experiment 3. We speculate that the information in Experiment 3 was too constraining such that participants' sense of self-determination was undermined.

Cultivating Gratitude and Giving Through Experiential Consumption

EXTENDED ABSTRACT

Research on material consumption—buying for the sake of *having*—and experiential consumption—buying for the sake of *doing*—has predominantly focused on differences in the satisfaction consumers derive from each. A growing body of evidence argues that consumers tend to get more satisfaction, and more enduring satisfaction, from the money they spend on experiences than the money they spend on material possessions (for a review, see Gilovich and Kumar, 2015). Here, we focus on another downstream consequence of buying experiences, in addition to the more enduring satisfaction that results from doing so: facilitating a grateful emotional state. Gratitude promotes well-being and prompts pro-social behavior (Bartlett and DeSteno, 2006; Emmons and McCullough, 2003). In the present research, we examine a novel way to cultivate this beneficial emotion. We demonstrate that these two different types of consumption differentially foster gratitude and giving. In six studies we show that reflecting on experiential purchases (travel, meals out, tickets to events) inspires more gratitude than reflecting on material purchases (clothing, jewelry, furniture), and that thinking about experiences leads to more subsequent altruistic behavior than thinking about possessions.

In Studies 1-2b, we empirically test our main hypothesis: that people are more grateful for what they've done than what they have. In Study 1, we employed a counterbalanced within-subjects forced-choice paradigm to examine whether participants reported that their recent experiential purchases prompted greater feelings of gratitude than their recent material purchases. Indeed they did, $X^2(1, N = 95)$ = 6.06, $p = 0.01$. To rule out demand effects, we replicated this finding using more conservative between-subjects experiments (Studies 2a-2b; N's = 75 and 100). In these studies, participants rated their experiential purchases as having fostered more gratitude than their

material purchases when responding on continuous scales, t's > 2.8, p's < 0.01. These studies address the possibility that participants in Study 1 felt they were *supposed* to say that their experiences prompt more gratitude than their material goods, or that saying so might cast them in a more favorable light. The between-subjects design used prevents direct comparisons between experiential and material consumption in the minds of participants. The methods used in Studies 1-2b also allowed us to rule out other artifactual concerns about the differences we found; our results could not be explained by factors like the price of the purchases in question or the amount of time that had passed since the purchase had been made.

Study 3 finds evidence for this effect in a real world-setting: online customer reviews (N = 1,200). Consumers are more likely to spontaneously mention feeling grateful for experiences they have bought than for material goods they have bought, $F(1,1192) = 52.17$, $p < 0.0001$. We investigated this by utilizing a large data set of reviews posted on materially-oriented websites (i.e., *CNet*, *Amazon*) and on experientially-oriented websites (i.e., *TripAdvisor*, *Yelp*). After randomly sampling 1,200 distinct comments from these sites, reviews were then coded for expressions of gratitude by two independent raters who were blind to our hypothesis. Far removed from the laboratory, and even in the context of consumer reviews where mentions of grateful feelings are uncommon, people tend to be more inspired to comment on their feelings of gratitude when they reflect on the trips they took, the venues they visited, or the meals they ate than when they reflect on the gadgets, furniture, or clothes they bought.

Might the gratitude elicited by experiential purchases extend their benefits outward to other people as well? In our final two studies, we explore a significant behavioral consequence that stems from the greater gratitude people tend to feel as a result of their experiential purchases by showing that experiential consumption also makes consumers more likely to be generous to others. In these experiments (N's = 48 and 60), participants who contemplated a significant experiential purchase behaved more generously toward anonymous others in an economic game (when assigned the role of allocator in the standard "dictator game;" see Camerer, 2003) than those who contemplated a significant material purchase, p's < 0.05. These results indicate the benefits of experiential consumption extend beyond the purchase itself and even beyond the experiencer: they flow outward to others as well. It is particularly noteworthy that participants who were prompted to think about an experience they had bought were more generous to anonymous strangers, recipients they knew they would never meet or interact with, and who would never know they had acted generously. Buying experiences instead of "things" not only cultivates gratitude, it also facilitates one of gratitude's most beneficial effects: pro-social behavior. It thus appears that shifting spending towards experiential consumption can improve people's everyday lives as well as the lives of those around them.

Gratitude may not be the first thing that comes to mind when thinking of "consumerism." But what we have shown here is that a certain type of consumption—experiential consumption—is more likely to foster feelings of gratitude than the consumption of material items. And by prompting feelings of gratitude, it also leads to more pro-social behavior. It is especially notable that these results were obtained using a variety of different types of studies, thereby providing convergent evidence for our central claim. Together, this research demonstrates that shifting some personal consumption toward "doing" rather than "having" may increase feelings of gratitude and, in so doing, leads people to act more virtuously by being more generous to others.

Celebrate or Commemorate? A Material Purchase Advantage when Honoring Special Life Events

EXTENDED ABSTRACT

Moments that mark a special life events are rich in meaning and often inspire people to spend money to signify their importance. In doing so, consumers can either *celebrate*—making a purchase with the primary intention of creating an experience (such as a wedding reception, graduation party, or a trip to Europe)—or they can *commemorate*—making a purchase with the primary intention of acquiring a material object (such as a wedding or class ring, watch, or framed picture). Though little is known about how these two purchase types might better achieve this goal of honoring a special life event, consumers seem to favor celebrations over commemorations. For instance, the average amount spent on graduation celebrations in 2015 was $985 (www.graduationparty.com) compared to $230 on class rings (http://staugustine.com). Weddings are the same: wedding receptions cost $15,000 on average and engagement rings $6,000. Further, in terms of maximizing happiness, research supporting an *experiential advantage* agrees: Celebrate because experiences lead to more happiness than comparable material goods (e.g., Nicolao et al. 2009; Pham 2015; Van Boven and Gilovich 2003).

Yet, honoring a special life event is often not about maximizing happiness with a purchase; instead, it increases meaning in life by connecting an important event in the past with the future. Whereas happiness is a present-oriented feeling signaling satisfaction with one's current needs and goals, meaningfulness comes from feeling connected with one's past accomplishments and significant moments, like weddings, graduations, births, or promotions (Baumeister et al. 2013; Belk 1988; Deci and Ryan 2008; MacKenzie and Baumeister 2014; Wildschut et al. 2006). As such, an important role of purchases that mark special life events is to facilitate the connection between the past special event and one's future self.

We propose that when consumers are marking special life events, material purchases reveal an advantage over experiential purchases as time passes. Further, we propose that consumers do not predict this material advantage because they fail to appropriately consider the permanent nature of material goods. Across seven studies we (1) provide evidence for a material (i.e., commemorative) advantage over experiences (i.e., celebrations) when marking a special life event, (2) demonstrate that consumers do not accurately forecast such an advantage (and thus choose experiences), and (3) provide an explanation for this misprediction by demonstrating a way to mitigate the preference for experiential purchase (i.e., when permanence is salient).

In study 1 we asked married participants to describe either their wedding reception (celebratory experience) or their wedding ring (commemorative material good). They rated their connections between the purchase and this special occasion and how long they had been married. We found a significant purchase type by time since marriage (logged) interaction on connection to the special event (b=.25, $t(127)$=2.88, p<.01). Participants who focused on their reception reported a declining connection to the past event (b=-.41, $t(127)$=-3.03, p<.01); however, those who focused on their ring had a non-significant positive slope (b=.1, $t(128)$<1).

Study 2 extended our findings to positive affect and graduations. We asked participants to think back to their most important graduation, and then asked them to either recall how they commemorated or celebrated. They then responded to seven positive affect measures, indicated the connective value of the purchase, amount spent, and years since graduation. We found the same significant purchase type by time interaction on connective value (b=.33, $t(144)$=2.31, p<.05).

A test of mediation showed a significant indirect effect of connection to the event on positive affect (95% CI=.0083,.1300), suggesting that over time material purchases provided stronger connections to past special events, which enhanced the feelings experienced when consumers thought back to their event.

Studies 3A-3C, 4, and 5 explored whether and why consumers (mis)predict advantages for material goods. Study 3a asked participants to imagine they received a $1000 gift card to either a jewelry store or a vacation website (between subjects) as a way to honor graduation. We then asked how well they expected to feel seven positive emotions in 1 or 20 years. Participants believed that their emotions would fade over time, (*p*'s<.05); however, they did not expect the advantage to commemorating over celebrating (*F*<1) that we found in previous studies. We found the same effects for expected memory (study 3b) and in a choice task participants chose more experiences than material goods (study 3c).

Studies 4 and 5 tested our proposed mechanism: Whether these mispredictions are due to consumers failing to consider the permanence of material purchases. In a 2(Purchase Type: Experiential vs. Material) x 2(Permanence: More vs. Less) between subjects design, study 4 asked participants to write about a purchase that would either last in their possession for a long (more permanence) or short (less permanence) time. They then were asked to imagine spending a $1000 gift card to either a jewelry store or a vacation website to honor a graduation and to rate their happiness. Participants expected to be happier with an experience (M=5.98) compared to a material item (M=4.33, F(1,197)=84.50, *p*<.001), and it was moderated by permanence (F(1,197)=6.85, *p*=.01): The difference in predicted happiness was smaller in more (M=1.18) than less (M=2.13) permanence. Study 5 was a similar design but used an open-ended dependent measure and a subtler permanence manipulation: Participants viewed advertisements that either highlighted a permanent or a nonpermanent aspect of the advertised product (e.g., "a diamond is forever" vs. "a diamond is sincere"). The permanence condition chose gifts that were rated as a more material than experiential (M=3.53) compared to control (M=4.09, F(1,141)=3.98, *p*<.05). In sum, when permanence was salient, consumers better appreciated the long-term advantages of material items, diminishing their mispredictions.

The results suggest a potential exception to the widely accepted experiential advantage, while providing important implications for how purchases contribute to meaningfulness in life. Though consumers tend not to appreciate the long-term advantages of material items when choosing to celebrate or commemorate. the results suggest that people can increase their long-term happiness by giving themselves permanent reminders of special life events—which are often the very experiences that have been shown to increase happiness.

Expected and Actual Reliving of Experiences Through Different Types of Photos

EXTENDED ABSTRACT

Recalling memories of one's experiences increases positive affect and meaning in one's life (e.g. Wildschut et al. 2006; Holbrook 1993). While memories can be a source of enjoyment, people are aware that memory fades and that they may forget aspects of an experience (Flavell and Wellman 1975). Consequently, people try to counteract memory loss either by recording significant parts of the experience (e.g., filming videos, writing diaries) or by investing in specific memory cues that they believe will allow them to relive the experience later (e.g., souvenirs, Zauberman, Ratner, and Kim 2009).

Because experiences are fleeting, one must decide *which* memory cues to invest in for the future. Yet, even though these decisions are made strategically, they may not maximize enjoyment as intended. People are poor predictors of what will optimize their future feelings (Gilbert et al. 2002) and mispredict which experiences they will enjoy revisiting (Zhang et al. 2014). People also sometimes choose memory cues that in the long term create regret, rather than enjoyment (Abendroth and Diehl 2006).

While prior literature has examined the efficacy of different *externally provided* memory cues for *accurate recall* (e.g., Herz 1998), the literature has mostly neglected how the *choice or creation* of such cues affects the *ability to relive* the experience. We assess people's *expectations* about which memory cues will be useful for reliving and hence which cues they invest in at the time of the experience. Then, we examine which cues *actually* help people to best relive an experience.

We explore this question in the context of photos as memory cues, in particular we examine whether people capture photos of people or scenery. We propose that at the time of the experience people will capture more photos of the surroundings, since those are the aspects of the experience that seem distinct and unique in the moment. However, at the time of revisiting, people will enjoy photos that include people in them more than scenery photos. This is consistent with work showing that people are drawn to and pay particular attention to social content in photos (Birmingham, Bischof, and Kingstone 2008) and that they are better at correctly recognizing photos of people as opposed to objects (Isola et al. 2011).

In two studies, we examine people's photo-taking behavior and expectations about these photos shortly after an experience and their actual reliving enjoyment when looking at these photos after one or four months.

Study 1 examines the types of photos people take on a field trip to an arboretum, and which photos they actually enjoyed looking back at either one or four months later. Visitors (*N* = 94) took more photos that include scenery (61% of all photos; *M* = 12.82, *SD* = 17.81), than photos of people (39% of all photos; *M* = 34.17, *SD* = 54.09), *F*(1, 93) = 13.37, *p* < .001.

After the trip, participants uploaded four photos of each scenery and people. One month and four months later, participants (*N* = 38) saw one randomly selected photo from each category (scenery and people) in random order. A repeated-measures ANOVA with enjoyment of the photo as the dependent measure and photo contents (scenery vs. people) and time (1-month vs. 4-months) as within-subject factors revealed a main effect of photo contents. Individuals enjoyed viewing photos of people more (*M* = 75.71) than photos of scenery (*M* = 69.29), *F*(1,37) = 6.53, *p*= .02. The same analysis with the extent to which the photo helped participants relive the moment as the dependent measure, also revealed a main effect of photo contents, such that photos with people helped individuals relive the experience better (*M* = 74.78) than photos of scenery (*M* = 67.37), *F*(1,37) = 6.86, *p* = .01.

Interestingly, in the moment, visitors took many more photos of the surroundings than of people, however, those photos were not the ones that best allowed them to relive the experience. One may argue that in an arboretum the surroundings are particularly focal and salient which could have contributed to these findings. Hence in Study 2 we examine the creation of memory cues in a different, less nature-focused context: during Christmas celebration.

In **Study 2,** participants (*N* = 172) uploaded one photo of just scenery and one photo that included people (as well as other "distractor" photos) that they had taken during Christmas. They also reported how much they expected to enjoy looking at each photo in the future. Four months later, participants were shown the two focal

photos and rated how much they enjoyed looking at each photo and how much it allowed them to relive the experience.

A repeated-measures ANOVA with enjoyment of the photo as the dependent measure and photo content (scenery vs. people) and timing (predicted vs. actual) as within-subject factors revealed a main effect of photo content ($M_{Scenery} = 76.60$, $M_{People} = 80.66$), $F(1,171) = 12.36$, $p = .001$, and a main effect of time ($M_{Predicted} = 82.94$, $M_{Actual} = 74.32$), $F(1,171) = 40.72$, $p < .001$. More importantly, however, we find a significant interaction, $F(1,171) = 11.08$, $p = .001$. Participants expected to enjoy scenery and people photos similarly when they took the pictures, $F(1,171) = .13$, $p = .72$. However, four months later they enjoyed looking at the people photo more ($M_{Scenery} = 70.48$, $M_{People} = 78.17$), $F(1,171) = 16.68$, $p < .001$.

Since we did not want to reveal the purpose of the study to participants, we directly measured reliving only at Time 2. Paralleling the findings for photo enjoyment, people felt that the people photo they had taken ($M = 76.70$) allowed them to relive the experience to a greater extent than the scenery photo ($M = 66.78$), $F(1, 171) = 37.16$, $p < .001$.

In sum, although individuals expect to like scenery and people photos equally well in the future, and oftentimes take more photos of scenery, photos with people are enjoyed more and allow the photographer to better relive the experience.

SESSION OVERVIEW

Understanding interactions between customers and firm has received growing attention from both marketing scholars and marketing practitioners. This special session aims to examine the interpersonal aspects of consumer experience by focusing on consumers' relationship with producers or brands. In this session, four papers address the important question of how to create a sense of connectedness between consumers and the companies that produce the products they buy.

The first two papers in this session study consumers' alienation from producers and ways to reduce this alienation. In the first paper, Fuchs and colleagues examine the effect of providing personal information about producers. Six studies demonstrate that "personizing" producers increases consumers' preferences for products by inducing feelings of closeness with the producers. In the second paper, Lim and colleagues investigate how providing personal information about consumers to producers can affect consumers' preferences. They show that consumers expect that identifying them by their names would lead producers to treat them in a less objectifying manner, which in turn leads to a greater preference for a product. Together, these two papers shed light on how personal identification, of either producers or consumers, create a meaningful connection between the two entities.

The next two papers focus on the specific relationships that form between consumers and brands/firms. Bonezzi, Lisjak, and Neslin explore how conditional versus unconditional rewards can have a different impact on consumer-brand connectedness. Across two lab experiments and a field study, they demonstrate that unconditional rewards (vs. conditional rewards) are more effective to strengthen consumer-

brand connection, but only when these rewards signal communal relationship norms. Finally, Dong and Aggarwal examine the role of hierarchy in consumer-brand relationships by examining the effect of positioning the brand as a servant versus a partner. They find that people expect servant brands to be high on competence, and partner brands to be high on warmth. In addition, they show that the brands are evaluated more extremely – more negatively and more positively – when these expectations of competence for servant brands and warmth for partner brands are respectively violated or upheld.

In summary, this session provides a window into consumer behavior by illuminating research that investigates consumers' relationships with producers/brands. By bringing together the papers that examine the issue of consumer relationships from diverse perspectives, this session will enrich and sharpen our understanding of psychological mechanisms that affect perceptions of connectedness between consumers and firms.

Reducing Consumer Alienation: The Effect of Making Product Producers Personal

EXTENDED ABSTRACT

Since the time of the industrial revolution, technology has improved the well-being of both producers, whose incomes could rise through greater productivity, and consumers, who benefit from greater availability and lower prices of consumer goods. This, however, has come at the cost of separation and alienation between consumers and producers. Accordingly, in an era of mass production, consumers rarely know anything about the persons who have created the products they use on a daily basis. New developments in the marketplace have led some firms – deliberately or not – to reduce the separation between consumers and producers of products. In particular, firms have started to introduce the persons behind their products to their customers. Information about producers is now featured on firms' websites, or even included on or with the products. Commercial platforms such as Etsy even enable consumers to directly get in touch with a product's producer.

This study is a first attempt to shed light on this emerging phenomenon by examining the psychological consequences of providing consumers with personal information about product producers – a practice that we refer to as "personizing". Drawing on analogies from Karl Marx's theory of alienation of the worker (1844), we introduce a theory of alienation of the consumer and posit that consumers feel less alienated from the producer if they see the person behind the product. We thus theorize that providing personal information about the producer – personizing the producer – should facilitate the creation of a psychological connection between consumers and the producer. This feeling of connection to the producer should have positive effects on consumer wellbeing and on the way consumers perceive both the producers and their products. A series of six studies documents the existence of this personizing effect on product preference, provides process evidence, and rules out alternative accounts.

Study 1A provides initial experimental evidence that making product creators personal has positive effects on product preference. The study deployed a choice-based experiment in which information on the product producer was manipulated (personal information on the producer present vs. not present). We find that consumers have a significantly higher preference for the same product if non-diagnostic personal information about the product producer is provided

(i.e., the information describes the producers as a person, without giving direct indications of expertise or product quality). Study 1B replicates the personification effect and rules out the possibility that the effect is caused by demand artifacts or is caused by perceived similarity to the described person. The study (and a pilot study) also rules out the alternative explanation that participants expect higher quality because the personified producer can be held more accountable for her products.

Study 2 shows that consumers have a higher preference for the same products if the producer described is the actual producer of their product but not if the producer described did not produce the consumer's actual product. This finding suggests that the effect is not simply caused by providing positive information nor by merely providing more (versus less) information. In addition, this study casts doubt on the common practice of giving examples of a brand's producers without certifying that this specific producer produced a customer's product (for example, describing a farmer who supplies a brand without any indication that a specific consumer actually receives the product from that specific farmer). Study 3 uses a free association task to test our predicted process account. Consistent with our theoretical account, we document that the increased preference for products of firms that personize their producers is mediated by feelings of closeness to the product creators. Study 4 shows that the personizing effect materializes only if information on the producer (but not on a customer) is provided. The observed moderation is mediated by feelings of closeness with the product producers.

Study 5 shows that the personizing effect is largely unaffected by the neediness of the focal producer. The personification effect remains highly significant if the producer is additionally described as being well off (and thus not in financial need). Thus, we rule out the possibility that the effect is driven by an attempt to "help out" a specific person in need (similar to an 'identified victim' effect account; Jenni and Loewenstein 1997). Importantly, the study also provides empirical evidence for the full process chain: providing consumers with personal information about the producer facilitates feelings of closeness to the producer, which increases trust in the producer and makes the product appear less of a commodity. These two positive perceptions pertaining to the producer (trust) and to the product itself (de-commoditization) drive the preference for products of firms that feature personal information about their producers.

Study 6 takes our work outside the lab and to a different product category (cookies), a different dependent variable (a taste test of cookies) and to different settings (private vs. commercial). The study shows that consumers perceive the same cookies to be more tasty when the baker was personized (versus not). This effect is observed in both a commercial and a private setting. Also in this setting, it is shown that the increase in taste can be explained by increased trust in the producer and by the perception that the product is not a commodity.

Taken together, this set of studies provides a first step towards understanding the consequences of personizing product producers. It also advances our understanding of the alienation concept in a consumer context. The work has implications for theory and practice, and might stimulate further research on this timely topic.

Made for You: The Effect of Consumer Identification on Consumer Preference

EXTENDED ABSTRACT

How can we make consumers' experiences more personal and meaningful? This research suggests that one effective way to do this is to allow consumers to give their name to product producers, that is, by making producers know who they are making their products for.

Previous research has documented that identifying a person causes others to perceive that person more as a tangible and relatable being and to readily feel emotional and social connectedness toward him or her. For instance, people tend to donate more money for an identified victim than for a non-identified one (Jenni and Loewenstein 1997; Small and Loewenstein 2003). Similarly, allocators in a dictator game were likely to split the money more generously when their partner's name was provided to them (Charness and Gneezy 2008). Together, these results suggest that identifying a person induces positive responses from others.

This research examines the effect of identifying consumers' names to producers on consumers' evaluation of products by introducing the concept of consumer objectification. Building on Nussbaum's conceptualization of objectification (1995), we define *consumer objectification* as consumers' perception of being treated by a producer or seller as an interchangeable object rather than an individual person. We argue that consumers would believe that identifying their names leads producers to perceive them in a less objectifying way, which in turn would increase preference for those producers' products.

Study 1 tested whether consumers evaluate a product more positively when the product producer knows their names. Two hundred undergraduate students read descriptions of two similar coffee shops, differing in whether a barista saw customers' names or order numbers on their coffee cups. We counterbalanced which coffee shop was described as identifying consumers across participants. Results showed a "Starbucks effect", that is, participants significantly preferred to go to the coffee shop where customers were identified to the barista ($t(198) = 9.23$, $p < .01$, Cohen's d = 1.30).

Study 2 was designed to achieve two objectives. The first objective was to replicate the effect of consumer identification across various products. The second objective was to provide evidence on the underlying mechanism of de-objectification. Five hundred and forty-six Mturkers were randomly assigned to one of eight conditions in a 2 (counterbalancing of which producer identifies its customer by name) x 4 (product replicate: cake, desk, fountain pen, dress shoes) between-subjects design. The procedure of this study was identical to that of Study 1, except for the fact that sense of objectification and perceived product quality were measured in addition to the preference measure. Consistent with Study 1, participants indicated a greater preference for the company when the producer was given the customers' names ($F(1, 538) = 50.14$, $p < .01$, $\eta_p^2 = .09$). This effect was significantly mediated by perceived objectification [5,000 samples; 95% CI: 0.87, 1.42] even after controlling for perceived product quality.

Study 3 sought to examine whether more identification induces a greater impact on consumer preference by manipulating the amount of personalizing information given to a producer. Three hundred and fifty-six Mturkers were randomly assigned to one of four conditions in a 2 (counterbalancing of identification) x 2 (amount of identifying information: low vs. high) between-subjects design. Similar to studies 1 and 2, participants read descriptions of two patisseries. In the low identification condition, one of the patisseries was described as identifying customers' names to the baker, whereas in the high identification condition it was described as identifying consumers' name and additional personalizing information that customers wanted the baker to know. Again, we found that participants exhibited a greater preference for the product when the producer was given their name ($F(1, 352) = 4.08$, $p < .05$, $\eta_p^2 = .01$). This effect, however, did not become stronger with additional personalizing information ($F < 1$). Further analyses revealed that the additional information leads participants to feel not only a lower sense of objectification but also a greater risk of privacy violation, resulting in the null effect of iden-

tification level. Together, these results suggest that adding more personalizing information beyond a first name would not always be better and it can cause greater concerns for privacy violation.

In conclusion, this research demonstrates that identifying consumers to producers increases product preferences by making consumers feel less objectified (i.e., more like a person). By doing so, this research suggests a novel way to make consumers' experiences more meaningful.

A Relationship Account of Marketing Rewards: The Effect of Conditional vs. Unconditional Rewards on Self-Brand Connection

EXTENDED ABSTRACT

Developing and nurturing a connection between a brand and consumers is one of the most important goals bestowed upon marketing managers. Indeed, a strong consumer-brand connection ultimately translates into increased profitability for the company (Kalwani and Narayandas 1995; Pine II et al. 1995; Price and Arnould 1999). As a result, marketers employ various tactics to develop strong connections with consumers. In particular, a commonly used tactic involves awarding customers with rewards for engaging with the brand. To illustrate, consumers might be promised a reward after a certain number of purchases. Importantly, these rewards are typically given conditional on consumers engaging in behaviors that meet terms and conditions specified by brands, and thus are referred to as *conditional rewards*.

In this research we argue that the widely adopted practice of using conditional rewards may be unsuited to foster consumer-brand connections. Instead, we propose that *unconditional rewards* may be more effective at fostering consumer-brand connection. We use the term unconditional rewards to refer to rewards that are perceived not to be contingent on consumers performing certain behaviors that meet terms and conditions specified by a brand, but given out of the company's benevolence.

We postulate that conditional and unconditional rewards might be differentially effective in fostering brand-self connection, because they signal different relationship norms (Clark and Mills 1979, 1993; Aggarwal 2004; Aggarwal and Law 2005). In particular, we suggest that unconditional rewards heighten the salience of communal norms, compared to conditional rewards. Importantly, the salience of communal norms influences how psychologically connected consumers will feel towards the brand (Aron et al. 1991; Liu and Gal 2011). Three studies support this hypothesis and provide evidence for the proposed theorizing.

Study 1 demonstrates that unconditional rewards are more effective than conditional rewards at fostering brand-self connection. Participants were given the opportunity to complete a survey for the chocolate brand Milka. In the conditional reward condition, participants were told that if they chose to fill out the survey, they would receive a Milka chocolate bar for their input. In the unconditional reward condition, participants were not told anything, but still received a Milka chocolate bar upon completing the survey. Furthermore, to compare how receiving a conditional or unconditional reward affects self-brand connection relative to receiving no reward, we asked a third group of participants to simply report brand-self connection towards Milka. Consistent with our predictions, the results revealed that participants who received an unconditional reward felt more connected to Milka compared to participants who received a conditional reward ($t(154) = 1.96$, $p = .05$), and to participants in the baseline condition ($t(154) = 2.29$, $p = .02$). Furthermore, brand-self connection did not differ significantly between the conditional reward and baseline conditions ($t(154) = .34$, $p = .73$).

Study 2 served two main goals. First, we wanted to rule out the possibility that the effect observed in study 1 was merely driven by unconditional rewards eliciting higher levels of surprise relative to conditional rewards. To do that, we kept surprise constant across conditions, by inducing all participants to expect to receive a reward. Second, we wanted to test whether the effect observed in study 1 operates via salience of communal relationship norms, as per our proposed theoretical account. To do that, participants were randomly assigned to conditions in a 2 (reward: conditional vs. unconditional) × 2 (persuasion knowledge: salient vs. not salient) between-subjects experimental design. We reasoned that, to signal communal relationship norms, an unconditional reward needs to be attributed to the benevolence of the company, rather than to self-interest. Thus, by making persuasion knowledge accessible, the attribution of the unconditional reward to the company's benevolence should be undermined, and as a consequence an unconditional reward should lose its effectiveness as a signal of communal norms. The results revealed a significant reward type × persuasion knowledge ($F(1, 162) = 6.1$, $p = .03$). Participants for whom persuasion knowledge was not salient felt more connected to the brand when the reward was unconditional than when it was conditional ($t(162) = 3.42$, $p = .001$). However, for participants for whom persuasion knowledge was salient there was no difference between receiving an unconditional and conditional reward ($t(162) = .28$, $p = .78$). A moderated mediation analysis further revealed that communal norms mediated the effect of type of reward on behavioral intentions, only when persuasion knowledge was not salient.

Study 3 aimed to probe the external validity of our findings, by showing the effect of conditional vs. unconditional rewards in a consequential setting. This study was a field experiment, conducted in a grocery store. Shoppers were approached by a research assistant who posed as a Coca Cola representative and asked shoppers to participate in a short survey. In the conditional reward condition participants were told that they would receive a free can of Coca Cola for their input. In the unconditional reward condition participants were not informed they would be receiving a reward for their input. After participants completed the survey, they were rewarded with a can of Coca Cola. Participants then continued with their grocery shopping. At the cash register, we collected each participant's shopping receipt. The results revealed a significant main effect of reward type on purchase behavior ($\chi^2(1) = 23.39$, $p < .001$), such that 61% of participants who received an unconditional reward subsequently bought Coca Cola, compared to only 21% of participants who received a conditional reward.

In sum, this research provides a first systematic examination of the effects of rewards on self-brand connection. Across three studies we show that rewards might indeed foster brand-self connection, but the way they are awarded influences their effectiveness at doing so. In particular, we compared and contrasted conditional to unconditional rewards and found that unconditional rewards are more effective than conditional rewards at fostering brand-self connection, because they increase the salience of communal relationship norms. These findings contribute to the literature on relationship management and self-brand connection and provide practical suggestions for how to design rewards that are effective at nurturing a connection between a brand and its customers.

Partner or Servant? When Relationship Type Affects Trait Expectations and Evaluations of the Brand

EXTENDED ABSTRACT

Marketers often position their brands around distinct social roles (Aaker, Fournier, and Brasel 2004; Aggarwal 2004; Fournier 1998). For instance, Allianz (one of the world's leading financial or-

ganizations) emphasizes its core mission of being a trusted *partner* to its customers whereas Scrubbing Bubbles stresses its role of being a dependable *servant*, as reflected in its advertising taglines "We work hard so you don't have to".

Essentially, these two positioning strategies emphasize equality ("brand-as-partner") and hierarchy ("brand-as-servant") respectively – two distinct and fundamental social relationships (Fiske 1992) and moral motives (Rai and Fiske 2011). Despite the practical prevalence of these two brand positioning strategies, there is little empirical research investigating the theoretical underpinnings of pursuing these relationship types, and if they might result in different responses from consumers facing positive and negative outcomes. The only prior research that we are aware of that looked at the distinction between partner and servant brands used it as a moderator to test an unrelated hypothesis (Aggarwal and McGill 2012). Drawing on the stereotype content model (Fiske et al. 2002), we posit that much like human relationships, brands' social roles – partner versus servant – may lead to differential expectations toward the perceived warmth and competence of the brand, which would impact consumers' brand evaluations.

Research in social relationships suggests that people expect their partners to be warm and caring and be "someone who were always 'there for you' when you needed a favor" (Walker 1995). Thus, much like the warmth traits they expect from their close relationship partners in a social context, consumers may expect similarly higher warmth traits from their partner brands relative to servant brands. In contrast, as hierarchies emphasize rank in social groups and consist of roles that imply division of labor, people higher up in the hierarchy expect those below them to follow directions and complete assigned jobs competently (Yukl and Fu 1999). Analogously, in consumer-brand relationships too, we argue that servant brands would be expected to do the job proficiently and hence exhibit more competence than partner brands.

Based on the reasoning above, we propose that relative to servant brands, partner brands are expected to be higher on warmth compared to competence. Drawing on the role congruity theory which suggests that the (mis)fit between the perceived target's performance and the presumed beliefs or expectations about the social role to which the target belongs could lead to (un)favorable inferences (Eagly and Diekman 2005), we further propose that consumers would express more favorable attitude for partner (servant) brands that exhibit high level of warmth (competence) – the domain in which the brand is expected to excel. Moreover, they would also express more unfavorable attitude for partner (servant) brands that perform poorly on warmth (competence) traits. Five studies were conducted to test these propositions and underlying mechanisms.

Before commencing a full test of our hypotheses, a pilot study (N=200) was conducted with 20 real brands. The results confirmed a significant relationship between brand role and trait expectations such that consumers tend to associate warmth traits more with partner brands ($r_{partner-warmth}$=.41 vs. $r_{servant-warmth}$=.28; Z=9.08, p<.001), but associate competent traits more with servant brands ($r_{partner-competence}$=.33 vs. $r_{servant-competence}$=.38; Z=3.50, p<.05).

In Experiment 1 (N=96), participants rated a fictitious brand ascribed a partner role as possessing more warm traits ($M_{partner}$= 6.96, SD = 1.42; $M_{servant}$=6.29, SD=1.62; F(1, 94)=4.68, p<.05), while they rated the same brand ascribed a servant role as more competent ($M_{partner}$=6.55, SD=1.42; $M_{servant}$=7.10, SD=1.25; F(1, 94)=4.01, p<.05). Together with the pilot study, results from Experiment 1 suggest that warmth and competence are respectively associated with a partner and servant role that is assigned to brands.

Having demonstrated the association between brand trait and brand role, Experiment 2A (N=210) tested whether consumers polar-

ized their evaluation for partner brand in *warmth* judgment domain while Experiment 2B (N=176) examined the polarizing effect for servant brands in *competence* domain. In Experiment 2A, we first presented an advertisement of a fictitious fitness club ascribing either a partner or a servant role. Subsequently, participants read a scenario describing either positive or negative staff service (rated as the most typical warmth feature through a pre-test) encountered at the fitness center. Finally, participants reported their evaluations of the fitness club. As expected, when the brand warmth was high, participants evaluated the brand more positively if it was positioned as a partner compared to a servant brand ($M_{partner}$=5.88, SD=1.55; $M_{servant}$=5.27, SD=1.59; F(1, 204)=4.30, p<.05). However, when the brand warmth was low, participants evaluated the brand more negatively when it was positioned as a partner than as a servant brand ($M_{partner}$=3.76, SD=1.12; $M_{servant}$=4.34, SD=1.67; F(1, 204)=3.93, p<.05). Together, this suggests that consumers' evaluation toward the partner (vs. servant) brand was more extreme both when exhibiting high and when exhibiting low warmth.

In Experiment 2B we first described a laptop brand as either a partner or a servant to the consumer. Participants then manipulated high and low competence by describing the laptop's positive or negative functional performance, which resulted in them completing an onerous assignment much faster or slower than expected. As predicted, when the brand competence was high, participants evaluated the brand more favorably if it was positioned as a servant than as a partner ($M_{partner}$=7.30, SD=1.60; $M_{servant}$=8.13, SD=1.63; F(1, 172)=4.29, p<.05). However, the reverse was true when the brand competence was low ($M_{partner}$= 6.07, SD=2.08; $M_{servant}$=5.29, SD=2.07; F(1, 172)=3.89, p=.05).

Finally, Experiment 3 (N=299) replicated the findings of Experiments 2A and 2B within the same 2(brand role: partner vs. servant) × 2(brand trait: warmth vs. competence) × 2(brand performance: positive vs. negative) between-subjects study in a different context (i.e., hotel service evaluation). Furthermore, expectancy violations in "perceived warmth" [95% CI: 1404, .5679] and "perceived competence" [95% CI:-.4931, -.0200] mediated the outcome × trait interaction effect on evaluation for partner and servant brands respectively.

Taken together, this research reveals the theoretically meaningful role of consumers' expectation from partner versus servant brands in shaping their brand evaluations, and offers new insights for marketers to manage their brands and its relationship role more effectively.

SESSION OVERVIEW

Among different aspects of wellbeing, financial wellbeing tends to be one of the most problematic (Brown and Sharpe, 2014). For this reason, there has been an increasing interest among consumer behavior researchers in examining how financial decision making can improve consumer welfare and life satisfaction (e.g. Dunn, Gilbert, and Wilson, 2011; Fernandes, Lynch, and Netemeyer, 2014; Hershfield, 2011; Sussman and Alter, 2012).

This session examines a particular component of the consumer financial decision making process: The consideration of one's current and (potential) future state of wealth. The four papers demonstrate that considerations of states of wealth have important psychological consequences that go beyond their monetary utility and that can influence choices in the financial domain.

The session examines both psychological antecedents and consequences arising from different ways in which consumers think and feel about their current and future states of wealth. The antecedents include factors that motivate consumers to monitor their money. The consequences include consumers' intentions to take out loans, their likelihood to base present spending on future income expectations, and the propensity to accept risky gambles.

The paper by Garbinsky, Klesse, and Huang examines the effect of a psychological sense of power on money monitoring. They show that power can increase the extent to which consumers monitor their money due to enhanced perceived instrumentality of money.

The paper by Greenberg and Hershfield investigates how the trajectory of anticipated pain associated with taking out a loan affects consumers' likelihood to do so. They find that consumers who expect the psychological pain to increase over time are less likely to take out a loan than those who expect pain to decrease over time.

The paper by Schanbacher, Faro, and Botti examines how consumers' expectations of future income affect present discretionary spending. They find that consumers are less likely to spend at present when expecting an income decrease but are not more likely to spend when expecting an income increase. However, consumers expecting an income increase are more likely to spend when the sense of psychological connectedness to the future self is enhanced.

Finally, the paper by Jung, Critcher, Wong, and Nelson examines how the consideration of different sets of potential gains and losses shapes the subjective valuation of a particular gain or loss. They demonstrate that the range of gain and loss values in recently considered gambles impacts subjective valuation, and thus loss aversion.

This group of papers includes hypothetical studies as well as experiments with consequential behaviors. Questions raised for discussion include: How can the extent to which consumers track their money be increased? When do emotional responses to expected wealth help and when do they hinder consumer wellbeing? And related to that, how can consumers be encouraged to think about potential or expected future states of wealth in a way that fosters welfare enhancing choices? Interest in such questions is expected to connect researchers from diverse areas such as consumer financial decision-making, consumer welfare, affect, and behavioral economics.

The Power to Know What You Have: Feeling Powerful Increases Money Monitoring

EXTENDED ABSTRACT

How much money do you have? According to a recent survey, only half of all Americans would be able to correctly answer this question (Rossman, 2011). Knowledge of how much money one has is needed to avoid overspending. It is surprising that individuals fail to monitor their money considering that simple actions such as checking monthly bank statements, logging into online bank accounts, or counting the money in one's wallet could easily accomplish this task. With numerous vehicles available to help individuals monitor their finances, why are most people failing to do so?

While existing research has predominantly focused on dispositional factors and demographics (Bertrand, Mullainthan, & Shafir, 2006; Chen, 2013; Cole, Paulson, & Shastry, 2014; Vohs & Faber, 2007), we move beyond these stable factors to propose and test a psychological factor that contributes to money monitoring – the feeling of power. The advantage of examining a psychological factor, such as power, is that it is more malleable in nature and thus lends itself more easily to potential intervention strategies.

On the surface, it might appear that power, which leads to increased optimism and greater risk taking (Anderson & Galinsky, 2006), will be associated with decreased money monitoring. We, however, provide empirical evidence that power actually increases money monitoring because it increases the perceived instrumentality of the money one owns. To test our hypotheses, we conducted fifteen studies in total, ten of which yielded significant results consistent with our predictions. Below, we report five studies that best tested the proposed theory, and conclude with a meta-analysis of all studies.

S1: Power and Money Monitoring. The objective of Study 1 was to test whether manipulating how powerful one feels affects money monitoring tendencies. Participants were placed in the *high*

power, *low power*, or *control* condition, and expressed money monitoring intentions by indicating their likelihood of engaging in money monitoring behaviors (e.g., organize the money in their wallet). Participants differed in money monitoring tendencies, $F(2, 116) = 3.53$, $p = .033$; those in the high power condition ($M = 5.85$) monitored more than those in the low power ($M = 5.16$), $t(116) = 2.48$, $p = .015$, and control condition ($M = 5.35$), $t(116) = 1.95$, $p = .053$.

S2: Actual Money Monitoring and Financial Accuracy. The primary objective of Study 2 was to explore whether the effect of power on money monitoring intentions that was observed in Study 1 translates to actual money monitoring behavior. The second objective was to demonstrate the importance of engaging in money monitoring behaviors by showing its downstream effects on financial accuracy. Participants were placed in the *high power* or *low power* condition before playing Monopoly. When ready to play, we took a picture of their Monopoly money set-up, and assessed financial accuracy (i.e., "indicate how much money you had"). Those feeling powerful ($M = 6.26$) monitored their money more than those feeling powerless ($M = 5.30$), $t(101) = 2.45$, $p = .016$, as assessed by coders that rated pictures of their money set-ups. This increased monitoring enhanced financial accuracy, $t(102) = 2.251$, $p = .026$.

S3: The Mediating Role of Money Instrumentality. The objective of Study 3 was to shed light on the underlying mechanism of money instrumentality. Participants were placed in the *high power* or *low power* condition before playing Monopoly, and expressed money monitoring intentions (e.g., I would check how many bills I have of each kind). To assess perceived instrumentality, they indicated how many properties, houses, and hotels they thought they could buy. Those feeling powerful thought their money was more instrumental (i.e., they could buy more) than those feeling powerless, $t(99) = 3.431$, $p = .001$. This increase in instrumentality mediated the effect of power on monitoring (95% CI: .1211, .6026).

S4: Unpacking Money Instrumentality. The primary objective of Study 4 was to shed further light on the mechanism of money instrumentality by measuring this variable directly. The second objective was to rule out feelings of responsibility and subjective wealth as alternative explanations. Participants were placed in the *high power* or *low power* condition, and expressed money monitoring intentions. To more realistically assess instrumentality, participants expressed how much they could buy with their own money (e.g., "I can buy a lot with my money.") We also measured responsibility and subjective wealth as alternative explanations. As predicted, instrumentality (CI = .0359, .4170), rather than responsibility (CI = -.1163, .3048) or subjective wealth (CI = -.3210, .0589), mediated the relationship between power and monitoring.

S5: Manipulating Money Instrumentality. The objective of Study 5 was to provide further evidence for the mechanism by directly manipulating it via a moderation-of-process approach (Spencer, Zang, & Fong, 2005). Focusing only on those feeling powerful, we directly manipulated instrumentality by varying financial feedback that participants received. Those in the *high instrumentality condition* saw a list of six products (product A, product B, etc.) and were told they could afford product A or product B, etc. Those in the *low instrumentality condition* randomly saw one of these six products. Those in the *no feedback condition* did not receive any feedback. Participants differed in money monitoring tendencies, $F(2, 147) = 4.247$, $p = .016$; those in the high instrumentality condition ($M = 5.91$) monitored more than those in the low instrumentality condition ($M = 5.14$), $t(147) = 2.89$, $p = .004$, and those in the no feedback condition ($M = 5.63$) monitored (marginally) more than those in the low instrumentality condition, $t(147) = 1.87$, $p = .064$.

In addition to these studies, a meta-analysis of the fourteen studies that tested the main effect utilizing META XL software (Study 5 was not included because it does not examine the effect of power on money monitoring) confirmed that feeling powerful increased money monitoring relative to feeling powerless, with $d = .35$. Theoretically, our findings add to research on power and financial decision making (e.g., Garbinsky, Klesse, & Aaker, 2014). In addition, our research provides valuable insights for financial institutions: Financial advisors should create an environment that makes customers feel "at power."

Debt Aversion and the Trajectories of Psychological Pain

EXTENDED ABSTRACT

Although research has supported the claim that consumers are averse to taking on debt (Prelec and Loewenstein 1998), little attention has been given to understanding the reasons why they might do so. When considering taking on debt, people must consider the ways their financial well-being will change (or not) as a result, and these considerations can ultimately influence the choice to take out or avoid debt. The aim of the current investigation is to understand what consumers think about when making this decision. In particular, we explore how projecting psychological pain from taking out a loan or holding on to a loan impacts the tendency to take on debt. Theoretically, if consumers anticipate an especially high level of pain in the near term (i.e., at the time a loan is taken out), they may be deterred from taking out the loan. However, we find that expecting a higher level of pain in the long term (i.e., after holding on to a loan for some time) generates a greater aversion to debt. In some cases, this pattern of projecting future pain could cause consumers to make decisions that fail to serve their long-term financial interests.

Consumers might predict that the pain from a loan is worst at the beginning. Many prefer to delay pain for as long as possible (e.g., Frederick, Loewenstein, & O'Donoghue, 2002), and thus might avoid experiences that they expect will cause them pain sooner rather than later, even if they will adapt it over time (Frederick & Loewenstein, 1999). People might perceive taking out a loan as a painful action since it typically involves immediately realizing a large debt. Findings on future anhedonia suggest that when considering a loan, consumers might expect the pain they will experience will be more salient when taking out the loan (Kassam et al., 2008).

Alternatively, consumers might project that psychological pain grows over a loan's lifecycle. An affective-forecasting account suggests that when projecting the psychological pain a loan will cause, consumers might overweight future negative emotions they will experience (Wilson & Gilbert, 2003, 2005). In addition, if consumers are pessimistic, they might set low expectations to cope with inherent anxiety about the future (Norem & Cantor, 1986), causing them to believe they will have more negative feelings as time goes on so that the pain does not become debilitating.

As an initial examination (Study 1), we asked a sample of adults to graphically plot "pain" levels over different parts of the lifecycle of a multi-year loan. The two main points in time participants identified as most painful were the latest point in time--one year after the loan was taken out--and the exact time the loan was taken out. Importantly, participants in the former group projected a rising trajectory of pain while those in the latter group projected a declining trajectory.

Study 2 documented that these perceived trajectories of pain have important implications for the decision to take on debt. In Study 2a, participants were shown two graphs depicting the perceived trajectories of pain found in Study 1--one in which pain peaked at the

time the loan was taken out (immediate pain trajectory) and another in which pain reached its peak a year in to the loan (growing pain trajectory). After indicating which graph represented their own perceived trajectory of pain, they were asked to indicate how likely they would be to take out the loan. Participants who chose the growing pain trajectory were more loan averse than those who chose the immediate pain trajectory. Study 2b replicated these findings using a different scale. Study 3 showed that the growing pain trajectory does, in fact, cause loan aversion.

In Study 4, using a task in which participants had to list the first five thoughts that came to mind after focusing on either the immediate pain trajectory or the growing pain trajectory, we found that participants who focused on the immediate pain trajectory had more thoughts related to consumption than those who focused on one year in to a loan and fewer thoughts related to repayment than those who focused on the growing pain trajectory.

Study 5 demonstrated that these these thoughts have important relevance to consequential behavior. Compared to those who had not considered a personal loan in the past, those who had thought less about the pain of repayment and more about the consumption the loans could afford them. These findings suggest that perceiving a growing pain trajectory heightens the anticipated pain of repaying the loan (Prelec & Loewenstein, 1998; Rick, Cryder, & Loewenstein, 2008; Soman, 2001).

Across six studies, we showed that consumers view the psychological pain resulting from a loan as following an immediate pain trajectory or a growing pain trajectory. Importantly, the view that the pain follows a growing pain trajectory causes loan aversion, in part because thinking about such a trajectory causes people to focus on the pain of repayment as opposed to the pleasures of consumption. These results provide an account for one way that debt aversion might arise, and suggest that perceived pain trajectories are important determinants of financial decision-making.

How Does Future Income Affect Present Discretionary Spending? The Role of Future Self-Continuity

EXTENDED ABSTRACT

How does future income affect present consumption? Economic theory (Friedman, 1957) posits that consumers maximize utility by anticipating lifetime earnings and spreading them evenly across the lifespan. Consequently, a person who expects her income to increase in the future should increase present consumption and someone who expects income to decrease in the future should reduce it, relative to no income change. However, empirical evidence of such consumption smoothing is inconsistent (e.g. Wilcox, 1989). Explanations for observed lack of consumption smoothing have focused on economic factors, such as liquidity constraints (Wilcox, 1989).

Taking a psychological approach, we propose that future income is more likely to influence present spending on discretionary purchases, such as specialty coffee or a better laptop model, when consumers perceive high future self-continuity – i.e., when they feel that their future self is at core the same person as their present self (Bartels and Urminsky, 2011; Hershfield, 2011; James, 1890). We argue that people tend to perceive higher future self-continuity when expecting an income decrease (vs. increase). This is based on the argument that future self-continuity is enhanced by mental future simulation (Prebble et al., 2013; Tierney et al., 2014), and people are more likely to simulate negative than positive changes (Bilgin, 2012; Dhar and Wertenbroch, 2000). Thus, consumers should reduce spending when expecting an income decrease, but be less likely to boost spending when expecting an income increase. Enhancing the sense of future self-continuity should attenuate this asymmetry by boosting discretionary spending among consumers expecting an income increase.

Study 1a tested the prediction that discretionary spending is more likely to be affected by future income decreases than by increases. We varied current and future income in a scenario and examined the effect of future income on desire to make discretionary purchases at present. Specifically, participants imagined being a student who either lives on a low income, or receives generous financial support and lives on a high income. Participants further imagined that graduates from their course of study typically earned a high or low income. We found that among participants with high present income, the expectation of a decrease reduced the desire to buy, compared to no change. However, among participants with low present income, desire to buy did not differ between those expecting no change and those expecting an increase.

Study 1b tested the impact of real income increases and decreases in the lab. Ostensibly before the actual study, participants were informed that payment for study participation would be increased, decreased, or remain unchanged in the new budgeting period. Participants then had the option to spend some of their present payment on specialty chocolates. Results show that they were less likely to buy chocolates after learning that payment would decrease in the future than when expecting no change, but were not more likely to buy when expecting payment to increase.

Study 2 tested the proposed process. Starting from their actual current income, participants imagined an increase or decrease in three years, or unchanged income. Participants either read a brief description of their future financial situation (control) or were additionally encouraged to mentally simulate their future with the help of images (simulation). Simulation was intended to increase future self-continuity. Participants then rated their likelihood of making discretionary purchases at present. The control condition replicated the results from Study 1: Compared to no change, consumers were less likely to buy when expecting an income decrease but equally likely to buy when expecting an increase. In the simulation condition, however, expectation of an income decrease lowered, and importantly, expectation of an increase heightened the likelihood of buying.

Study 3 used an identity continuity prime to manipulate self-continuity. Participants completed a task requiring them to focus on either stability or change in identities of brands. This was intended to prime high vs. low self-continuity, as brands are commonly perceived to have human qualities (Aaker, 1997; Van Rekom et al., 2006). In an ostensibly unrelated survey, subjects were then presented with income scenarios and buying opportunities as in Study 1. The low-continuity condition replicated the results from Study 1: among participants with high current income, those expecting a decrease reported lower likelihood of buying than those expecting no change; among participants with low current income, those expecting an increase were equally likely to buy as those expecting no change. In the high-continuity condition, participants with high current income who expected a decrease were again less likely to buy than those expecting no change. Importantly, in support of our predictions, here a future income increase (compared to no change) raised the likelihood of buying when current income was low.

Study 4 manipulated self-continuity directly, and examined natural variation in future income and real choice. Student participants read a passage stating either that individuals' core identity changes (low self-continuity condition) or that it is stable (high self-continuity condition) around university graduation (adapted from Bartels and Urminsky, 2011). Next, participants completed measures of current income and expected income after graduation. Participants then

made hypothetical choices between basic and pricier purchasing options (e.g. basic vs. gourmet meal). In addition, participants were informed that they would be entered into a lottery for a voucher and indicated their preference for a massage (discretionary item) or groceries voucher (necessity). On the hypothetical and the behavioral measure, future income was positively related to the likelihood of choosing the discretionary options in the high, but not in the low self-continuity condition.

Previous research has linked increased future self-continuity to reduced present spending. This research examined direct trade-offs between the present and future (Bartels and Urminsky, 2011; Hershfield, 2011). We provide evidence that future self-continuity moderates the impact of future income on present spending. We show that increased future self-continuity can boost present spending in the case of future income increases.

Excessive restriction of indulgent behaviors can have detrimental effects on consumer wellbeing (Kivetz and Keinan, 2006). Our findings suggest that people expecting significant future income increases may excessively restrict present discretionary spending based on low future self-continuity.

Examination of the Sampling Origin and the Range Hypothesis of Loss Aversion in 50-50 Gamble Settings

EXTENDED ABSTRACT

Walasek and Stewart (2015) showed that people were more sensitive to losses over gains when they made choices with a wider range of gains and a narrow range of losses. In particular, typical loss aversion experiments test preference for gambles formed by combining a wide range of gains (widely spaced apart, $12, $16, $20…$40) with a narrow range of losses (narrow spaced, $6, $8 ,…$20) to produce lotteries. Consistent with decision-by-sampling, people are sensitive to the rank of the values given a set sampled from their memory. However, there still remains much ambiguity about how and when these values of varying ranges and increments in people's memory operate to influence the sensitivity to losses over gains. In three studies, adopting the original and modified experimental designs used in Walasek and Stewart (2015), we examined how and when decision-by-sampling operated to influence the sensitivity to losses over gains.

It is possible that the asymmetric spacing of losses and gains in the studies in Walasek and Stewart (2015) led people to be more sensitive to shifts in losses, which looks like loss aversion. In Study 1 we replicated the original findings of Walasek and Stewart (2015) and tested whether the increments of values differentially influenced decisions from the range variation. We used a 2(Big Range: gains or losses) X 2(Interval Equivalence: yes or no) factorial design. The Big Range factor indicates whether gains or losses ranged from $12 to $40 (big range). The other outcome always has a small range ($6 to $20). The Interval Equivalence factor indicates whether we made the interval between adjacent payoffs equivalent (at $2) or not equivalent ($4). Only the main effect of Big Range was significant such that the loss aversion coefficient was greater when gains were shown over a big range, suggesting that the range variation moderated loss aversion regardless of the interval equivalence.

In Study 2 we examined whether it is the mere exposure to the range of values that participants make decisions about or it is the context in which they consider the values that are part of their choices influenced their sensitivity to losses over gains. We varied the gain range from $6 to $20 or $6 to $32 on number lines, but in one condition with the large range, the values over $20 were selected to be considered to accept or reject, whereas in another condition with the

same large range, the values over $20 were never selected but merely presented. Participants were significantly more loss averse when they saw a larger range of gain values *and* those values were selected to be considered than when the values were merely presented on the number line, suggesting that loss aversion was not driven purely by the mere presence of high gain values.

In Study 3 we examined how much people have to "engage with" gain values in order to show a greater relative sensitivity to losses over gains. Participants engaged with higher gain values three different ways: 1) they actively thought about the values—more than just seeing them on a number line—by typing in the selected values. 2) they considered the subjective value of the lottery by indicating how attractive each gamble is. 3) they considered the full question of whether one will accept or reject those lotteries. Participants who indicated the attractiveness of the gambles were more loss averse than those who typed the high gain values. Furthermore, participants were more loss averse when they actually considered accepting or rejecting lotteries than engaging with higher gain values by typing the value or by indicating the attractiveness of the gambles.

SESSION OVERVIEW

Charitable giving and socially responsible initiatives are pervasive across consumer contexts. Research in these areas has explored the affective influences on individual giving decisions (Aknin, Dunn, & Norton, 2012; Genevsky, Vastfjall, Slovic, & Knutson, 2013; Small & Verrochi, 2009), as well as the effects of socially responsible initiatives by firms on consumer responses (Bodur, Gao, & Grohmann, 2014; Torelli, Monga, & Kaikati, 2012). Despite this work, the field is lacking a cohesive framework that connects the affective and contextual factors in prosocial behavior across different levels of analysis.

The four papers in this session incorporate a complimentary set of research questions and methodologies to explore charitable giving at the individual level, as well as with regards to customer engagement with firms. This session will advance our understating of the roles of affect and context in charitable giving behavior. Specifically, this set of presentations explores questions about charitable behavior that span the consumer-firm relationship. How do features of donation requests interact to influence charitable giving decisions? How do features of the organization affect giving behavior? How can communication of motives and charitable initiatives be optimized to increase giving and improve customer engagement?

The first presentation by Alexander Genevsky, Brian Knutson, and Carolyn Yoon addresses a core question in the study of prosocial behavior: are affective influences on giving absolute, or are they moderated by contextual features? Across six studies they demonstrate that request framing moderates the influence of affective facial expressions on charitable giving. Further, they demonstrate that experienced positive affect of potential donors is the psychological mechanism that underlies this effect. These finding have important implications for the effective crafting of donation requests.

The second presentation by Elizabeth Keenan and Ayelet Gneezy uses a combination of laboratory and field experiments to examine how aversion to overhead costs of charitable organizations affects donations. They find that overhead costs diminish donations, but the effect disappeared when donors are not responsible for these fees. In a field study, they find that informing donors of a seed grant covering organizational overhead increased subsequent donations. Their findings contribute to our understanding of decision making in the prosocial sector and make practical suggestions for improved solicitation practices.

The third presentation by Grant Donnelly, Duncan Simester, and Michael Norton presents a unique perspective on the effectiveness of firm's social responsibility initiatives. By asking customers for input regarding the recipient of the firm's donations, rather than simply informing them, they find significant increases in both purchasing behavior and membership renewals. These findings highlight the economic benefits of empowering customer roles in firm's socially responsible initiatives.

The final presentation by Alixandra Barasch, Emma Levine, David Rand, Jonathan Berman, and Deborah Small explores the roles of emotion and reasoning in cooperation. Across a series of studies they demonstrate that emotional decisions are correlated with cooperation, and that players are able to accurately identify emotion as associated with cooperative actions. Intriguingly however, they find that emotion is not strategically used to communicate cooperative intent.

All presentation are unpublished work. Presentations 1 and 3 have completed data collection and analysis, and are preparing drafts of working papers. Presentation 2 is a working paper. Presentation 4 has completed data collection and analysis.

Request Framing Moderates Affective Preferences in Charitable Giving

EXTENDED ABSTRACT

Objective

Affective features of requests for charity can influence donor behavior (Genevsky et al., 2013). Affective features are not presented in isolation, however, since they necessarily occur within the context of other features of solicitations. Thus, request framing may moderate the influence of affective features on donor behavior. While some research has investigated the influence of affective features of aid requests (Genevsky et al., 2013; Small & Verrochi, 2009) and message framing (Chang & Lee, 2009) on charitable giving, no work has fully explored the interaction between these factors, or the psychological mechanisms responsible for these relationships.

Studies of predictors of prosocial behavior suggest that emotions might influence giving, but they have now begun to examine the limits of these influences. This research has generated a number of compelling but competing hypotheses. On one hand, some findings suggest that appeals evoking negative emotions (e.g., guilt or distress) may promote charitable behavior (Carlson & Miller, 1987; R B Cialdini et al., 1987; Robert B. Cialdini, Darby, & Vincent, 1973; Small & Verrochi, 2009)negative-state relief, attentional focus, and responsibility/objective self-awareness, are examined in an expanded analysis of published research. For this purpose, judges assessed for each of 85 negative affect conditions the contextual levels of the variables relevant to each theory by reading relevant material that was excerpted from the method section of each article. Higher

order partial correlations were then calculated between each variable and the 85 helpfulness effect sizes. The results are consistent with the attentional focus and the responsibility/objective self-awareness models. Both increased perceptions of responsibility for causing the negative event and attentional focus on another (as opposed to oneself. Alternatively, other evidence indicates that inducing positive affect (e.g., joy or warmth) can promote charitable behavior (Aknin et al., 2012; Andreoni, 1990; Carlson, Charlin, & Miller, 1988; Genevsky et al., 2013).

Drawing from a rich literature on message framing grounded in prospect theory (Kahneman & Tversky, 1979) indicating that framing can influence individual decisions (Chen, Monroe, & Lou, 1998; Heath, Chatterjee, & France, 1995; Levin, 2013; Puto, 1987; Sinha & Smith, 2000), we hypothesize that the framing of donation message may moderate the impact of affective features on charitable giving. In a series of studies utilizing online and in-laboratory samples, and hypothetical as well as incentive compatible paradigms, we investigate whether message request framing moderates the influence of affective facial expressions on charitable giving.

Methods

In six studies, we explored the role of positive and negative affective features, request framing, and their interaction on charitable giving behavior. In all studies, affect was manipulated with respect to the facial expressions of potential donation recipients depicted in images accompanying the aid requests. In study 1, we directly assessed the influence of positive and negative facial expressions on charitable giving as well as the potentially moderating effect of request framing as an opportunity or threat. In studies 2 and 3, we tested the limits of these effects by exploring multiple novel aid scenarios (study 2) and directly manipulating the framing of a single aid scenario (study 3). In study 4, we expanded on the previous binary preference design with a willingness-to-pay assessment of charitable giving. In study 5, we recruited community members to the laboratory and replicated the findings with an incentive-compatible donation task. Finally, in study 6, we directly assessed affective responses in potential donors. We then conducted mediated moderation analyses to assess the ability of experienced affect to account for the influence of affective facial expressions of potential recipients as well as request framing on charitable giving.

Results

In study 1, participants donated more to individuals with happy expressions than sad and neutral expressions. This preference was significantly moderated by the context framing of aid scenarios. Specifically, direct comparison of happy and sad expressions indicated that participants gave more when expressed affect and request framing were congruent. Studies 2 and 3 replicated these findings with a series of threat and opportunity scenarios, as well as by reframing a single aid scenario. These replications suggest that the observed framing moderation generalizes to different scenarios of opportunity versus threat.

Study 4, extended the binary choice designs utilized in studies 1, 2, and 3 to a willingness to donate assessment. Request framing again moderated the influence of affective stimuli on charitable giving. Study 5 utilized an incentive compatible donation paradigm and recruited participants to the laboratory to verify further generalizability of these findings. Study 6 included affect ratings, to assess the role of experienced affect as a potential mediator of these effects. Analyses indicated fully mediated moderation, such that the level of positive aroused affect elicited in potential donors across request framing conditions explained the moderating role of message content on affective stimuli.

Conclusions

In six studies utilizing online and in-laboratory samples, and hypothetical as well as incentive-compatible procedures, we investigated the influence of affective facial expressions of potential recipients and request framing on charitable giving. Across studies, we found reliable interactions of affect and framing, such that framing of requests moderated the influence of affective features on charitable giving. Utilizing a mediated moderation framework, we further identified experienced affect as the psychological mechanism driving the influence of emotional expression and framing on charitable giving. These findings extend previous efforts to understand the factors that influence prosocial behavior by linking affective features and request framing. The findings thus have significant implications for enhancing charitable giving and informing best practices in crafting persuasive messages.

Understanding and Overcoming Overhead Aversion In Charity

EXTENDED ABSTRACT

In this research we explore individuals' aversion to overhead spending and its effect on charitable giving. While concerns about charity overhead spending receive ample media attention, only a handful of studies have looked at the extent to which individuals' behavior is influenced by overhead spending information, and no research has investigated the factors underlying this relationship.

Individuals are averse to overhead such that donations decrease as overhead increases, though only when donors' personal contributions are used (in part) to cover overhead (Gneezy, Keenan, and Gneezy, 2014). Gneezy et al. (2014) suggest that donors are motivated to give based on the impact they feel when they know they are helping the cause directly, rather than when their contribution is used to cover overhead costs. As a result, informing donors that initial large donations have been used to cover overhead costs, making their potential donation "overhead-free", significantly increases giving compared to traditional fundraising techniques (2014). While effective, the "overhead-free" approach simply bypasses individuals' reluctance to donate due to overhead-related concerns rather than targeting the aversion itself. As noted by the authors, "this method could lead to a growing unpopularity of overhead costs among donors, causing a race to the bottom among nonprofit organizations soliciting gifts to cover overhead costs." Charities already struggle to communicate to donors the importance of overhead costs and the overhead-free approach may undermine ongoing communication efforts. Moreover, the approach may not be practical for charities without access to large gifts to cover overhead costs.

The current research aims to gain insight into the mechanisms underlying the relationship between overhead and giving, and to explore ways to overcome overhead aversion more directly. We focus on two fundamental factors that have been previously identified as drivers of giving—to do good and to feel good. Given the aversion donors have for overhead, we propose that if a portion of a donor's gift is used to cover overhead it will interfere with her sense of doing good and feeling good. In particular, individuals may be more likely to feel they have made a positive impact when they know they have helped the cause directly rather than contributed to the salary of a charity's staff member. This reasoning is consistent with the theory of impact philanthropy, which proposes that some donors—the impact philanthropists—are motivated by the opportunity to personally

make a difference (Duncan, 2004). According to this model, the impact philanthropist would prefer to target a specific charitable cause rather than overhead because she perceives that the former is more impactful. Moreover, if her donation is used to cover overhead, not only will she feel less impactful, she may also feel less happy about her donation (Cryder, Loewenstein, & Seltman, 2013). Ultimately, the negative effect of overhead on donors' perceived impact and happiness could lead to a decrease in donations. This suggests that increasing potential donors' sense of impact and resulting happiness, even when part of their donation is allocated to overhead, may mitigate the negative effect of overhead on donations.

In Experiment 1 we explore whether the relationship between overhead and donations is mediated by the perceived impact of one's own donation and the positive emotions associated with giving. Participants (N=602) read one of five descriptions of a hypothetical charity in which the overhead level varied: low (5%), moderate (25%), high (55%), plus two control conditions. Participants were then asked: (1) how much they would like to donate to the charity (from $0 to $25), (2) "To what extent do you believe your donation will make a positive difference?", and (3) "How happy do you feel about your donation?" (2 and 3 were answered on a 7-pt scale).

As expected, donations decreased as overhead increased. Participants in the 5% overhead condition donated significantly more (M_5=10.61) than participants in both the 25% (M_{25}=8.63; p=.04) and 55% (M_{55}=7.15; p<.01) overhead conditions. Similar to the donation results, there was a negative effect of increasing overhead level on participants' reported sense of impact and happiness. We evaluated perceived impact and happiness sequentially as mediators and found that they mediate the relationship between overhead level and donation amount (indirect effect = -.01, SE = .0028; 95% CI [-0.0151, -0.0039]) such that the higher the overhead level, the lower the perceived impact and happiness one experiences, which negatively impacts donations.

In an effort to mitigate the effect of overhead, in Experiment 2 we provided potential donors with additional information that highlights the importance of overhead with emphasis on the ways that overhead is meaningful and significant (i.e., impactful). In a 2x2 between-subjects design, participants (N=601) were randomly assigned to read a description of a hypothetical charity that had low (5%) or high (55%) overhead and did or did not include the following statement: "Most donors prefer for their donations to be used directly on programming costs. What these individuals do not understand, however, is that in order for a charity to successfully fulfill its mission it must also incur administrative and fundraising costs, making donations spent on overhead also meaningful and significant." Two controls conditions were also used in which the overhead level was not specified. Participants were then asked how much they would like to donate to the charity (from $0 to $25).

As in Experiment 1, donations decreased as overhead increased. Participants in the 55% overhead condition donated significantly less (M_{55}=7.36) than participants in both the 5% (M_5=9.90; p=.01) and 5% with impact statement ($M_{5Impact}$=9.94; p<.01) conditions. Yet, when the impact statement was included in the 55% overhead condition, the differences were not significant ($M_{55Impact}$=8.48 vs. $M_{5Impact}$=9.94 and $M_{5Impact}$=9.94, ns). This distinction between conditions suggests that reading a statement about the impact of overhead increased donations despite high overhead and provides some preliminary evidence that highlighting the meaning and significance of overhead can help donors overcome overhead aversion.

Additional lab and field studies are currently underway to build on the above findings and identify effective methods for overcoming

donors' overhead aversion and, ultimately, to increase donations in real world contexts.

Voting for Charity: The Benefits for Firms of Direct Consumer Involvement in Charitable Campaigns

EXTENDED ABSTRACT

Recently, a new form of corporate social responsibility has emerged, which invites the customer to select the cause they wish to support through the purchasing of a specific item (Robinson, Irmak & Jayachandran, 2012). While research has evaluated consumer impressions to voting empowerment in corporate social responsibility activities (Robinson, Irmak & Jayachandran, 2012), we evaluate such empowerment in 'pure' donations and the resulting financial decisions of voting and non-voting consumers. Across two field studies at multiple store locations of a large grocery retailer, we give some consumers the opportunity to vote for the cause that the firm will support, while others are merely informed of the firm's charitable actions. Consumers given the opportunity to "vote for charity" upon entering a retailer exhibited increased purchasing and membership renewals during in-store visits.

Study 1 was designed to investigate whether inviting customers to participate in a firm's corporate giving program affects the customer's subsequent purchasing behavior. The study was conducted with the cooperation of a large retailer similar to Costco. This first field experiment was conducted over 10 weekdays at one of this retailer's New England stores. Two research assistants were positioned at the front entrance of the store and intercepted customers as they entered the store. They implemented two experimental conditions. In the "voting" condition, the assistants gave the customers a 1-page description of three local charitable organizations, stating that this store planned to give a total of $4,500 that month to these charities. Customers were asked to help the retailer decide which charity should receive the largest grant. The charity that received the most customer votes would receive a $2,500 grant, while the other two charities would receive a $1,000 grant.

In the second treatment, the "information" condition, the assistants gave the customers the same 1-page description. However, they did not ask them to vote on which charity should receive the grants. The information condition was designed to serve as a control condition. It controls for the possibility that merely providing information about the retailer's charitable giving could influence customer behavior.

The days were divided into two day-parts: mornings (9am – 1pm) and afternoons (2pm – 6pm) and the experimental treatments were rotated between these day parts across the 10 test days. We received transaction data that included a time stamp and we used this time stamp to match the transactions to the treatments. In particular, for the morning day-part we used transactions between 9am (the retailer opened at 9am each morning) and 1:15pm. For the afternoon day-part, we used transactions between 2:30pm and 6:15pm.

Across the 10 days we observed 5,010 baskets in the information condition and 5,048 baskets in the voting condition. In our initial analysis we measured basket size using dollar revenue, with a log transformation to control for outliers. The average log revenue in the voting condition is 4.02, compared to 3.98 in the information condition. The difference between these averages is significant ($p < 0.05$, $t = 1.99$). The use of the log transformation means that the exponent of the difference between the two conditions reveals the % difference in the basket sizes. Giving customers a choice about which charity would receive the next grant increased their average basket sizes by

4.2%. The median basket size is $248, and so this translates to a $10.41 increase in the average basket size.

In our next analysis we investigate whether the voting treatment had a stronger impact on purchases of items associated with pro-social behaviors. To identify these items a research assistant visited one of the retailer's stores and identified products with 15 different packaging labels. The findings reveal that items with pro-social labels on their packaging contributed a significantly higher proportion of units in the voting condition (than in the information condition). Allowing customers to vote on the next recipient of a charitable gift increased their purchases of pro-social items. The effect was strongest for the "Charitable or Ecological" and "Organic" pro-social labels.

We conducted a second study to evaluate the impact of voting on membership decisions. This field experiment was conducted over three weekends in four New England stores of the same retailer that participated in Study 1. At the time of the study the retailer was conducting a promotional campaign encouraging new members to visit the store for a 2-month trial membership. When a prospective customer visits the store to enact a trial membership, the customer service representative asks the customer if they would like to upgrade to a full membership. The focus of this study is investigating whether prospective members are more likely to upgrade in the voting condition than in the information condition.

All membership enquiries are processed at a membership service desk at the front of the store. The treatments were implemented by positioning an assistant near this desk. The assistants intercepted customers as they approached the line. They then implemented the same voting and information treatments that were used in the first study. The three charitable organizations were different at each store and were local to each store. The total donation in this study was $5,000 for each store, distributed as $3,000 to the charity receiving the most votes, and $1,000 to each of the other two charities.

In this second study, the treatments were rotated between successive customers. To match the treatments with the outcomes, the customers took their survey and voting forms (for those that voted) to the membership desk. After completing the transaction, the membership service representative then marked the form to indicate why the customer visited and the outcome of the transaction.

The voting condition had a positive impact on the proportion of new members that chose upgraded memberships. In the information condition, 30.6% of the new members chose the regular or rewards membership. In the voting condition, 55.0% converted to the regular or rewards membership. This difference in the conversion rate (55.0% versus 30.6%) is statistically significant p<0.01. Increasing the conversion rate by even a small percentage has the potential to create tremendous economic benefits for this retailer.

Signaling Emotion and Reason in Human Cooperation

EXTENDED ABSTRACT

Consumers are often faced with decisions to cooperate or to act selfishly. While cooperation is essential to social life, it can be threatened by beliefs about whether others will cooperate or pursue their own self-interest. Therefore, it is important to understand why people choose to cooperate and how they infer that others are cooperative. One important factor for both decision-making and signaling cooperation is whether a person relies on emotion or reason when making decisions.

Past theoretical and empirical scholarship provides mixed evidence about whether reason or emotion promotes social good. On one hand, utilitarian philosophy argues that relying on reason produces the greatest social good (Baron 1993; Bentham 1843/1948; Singer 2009). However, recent empirical evidence suggests the opposite: deliberation leads to lower rates of cooperation in economic games (Rand, Green, and Nowak 2012) and calculative mindsets increase selfishness (Wang, Zhong, and Murnighan 2014).

Emotion has also been characterized as both generous and selfish. Feelings of sympathy and empathy inspire prosocial deeds (Batson 1990; Loewenstein and Small 2007) and yet, it is often argued that feelings represent impure altruism. For example, individuals often feel good as a result of helping others, leading scholars to question whether individuals are motivated by their selfish desire to feel happy (Andreoni 1990).

Recent research on the lay theories behind this association finds that emotion is seen as a positive signal of moral character (Barasch et al., 2014). Individuals who experience emotion towards a cause, or who feel happy as a result of supporting a cause, are seen as more moral than individuals who lack emotion. This is because emotion is perceived to be an untainted signal of individuals' pure intentions to help others.

We build on these findings and explore whether emotion can signal cooperation and, in turn, promote cooperative decisions from others. We contrast emotion- and reason-based decisions and explore four fundamental questions. First, we examine the actual association between decision modes (relying on emotion versus reason) and cooperation (RQ1). Second, we examine lay theories regarding this relationship – whether people have correct or incorrect beliefs about the frequency of cooperation among emotional and rational actors (RQ2). Third, we examine how individuals respond to others who signal emotion and reason in cooperative contexts (RQ3). Fourth, we test whether people will strategically signal their decision mode in these contexts (RQ4). We examine these questions in a series of sequential dyadic prisoners' dilemma (PD) games in which players can send and receive signals about whether emotion or reason guided their decisions.

In **Study 1** ($N = 498$), Player A in the PD made a decision (cooperate or defect), and then reported whether they made their decision using emotion or reason. Player As who made a decision using emotion were more likely to cooperate (64%) than those who made a decision using reason (27%; $\chi^2 = 21.00$, $p < .01$; RQ1).

Player B subsequently learned whether his partner made his decision using emotion or reason , though Player Bs never learned their partner's actual decision (cooperate or defect). Player Bs who learned that their partner made a PD decision using emotion were more likely to predict that their partner cooperated (62% vs. 25%; $\chi^2 = 28.40$, $p < .01$; RQ2) and were more likely to respond with cooperation (36% vs. 19%; $\chi^2 = 7.46$, $p < .01$; RQ3). This suggests that participants use their partner's emotional cue not just in understanding how they make their decision, but also in deciding how they will respond to their partner.

The findings above are robust across different measures of emotion and reason. For example, we found the same pattern of results when we used a continuous measure to depict the degree to which Player A relied on emotion versus reason. We also found that there is no additional effect of decision mode once cooperative behavior is known.

In **Study 2** ($N = 477$), we sought to explore the discrete emotions that players feel and that observers perceive in cooperative contexts. We found that both players and observers associate emotional decision-making with more positive, other-focused emotions (e.g., empathy, sympathy; $F(1,473) = 60.78$, $p < .01$) *and* more negative, self-focused emotions (e.g., fear, guilt; $F(1,473) = 23.45$, $p < .01$) than reason-based decision-making. Nonetheless, observers still be-

lieved that players who made decisions based on emotion were more likely to cooperate than those who made decisions based on reason (64% vs. 24%; $\chi^2 = 35.25$, $p < .01$; RQ2). As in Study 1, this belief was correct: players who made their decision using emotion were more likely to cooperate (65% vs. 23%; $\chi^2 = 30.41$, $p < .001$; RQ1).

In our final three studies, we explored whether or not decision-makers strategically signal emotion in cooperative contexts in order to induce their partners to cooperate and thus maximize their own payoffs (RQ4). Across all three studies, we replicated the result that emotional decision-makers are more likely to cooperate. However, we found no evidence that individuals strategically signal emotion to their partners. Individuals were no more likely to report that they made their decision emotionally when they were told their decision mode will be shared with their partner (**Study 3**, $N = 470$; 24% vs. 22% reported emotion as their decision mode; $\chi^2 = .10$, $p = .75$) or when they could choose whether to share it with their partner (**Study 4**, $N = 186$; 48% vs. 52% reported emotion as their decision mode; $\chi^2 = .06$, $p = .81$). Additionally, emotional decision-makers did not disproportionately choose to send this information to their partners (**Study 5**, $N = 590$; B = .32, SE = .48, p = .51).

Taken together, we demonstrate that emotion *is* and *is perceived to be* a signal of cooperation, but that decision-makers are not strategic about signaling emotion. This research provides basic insight into the nature of human cooperation and ultimately identifies ways that individuals can improve joint decision-making in cooperative contexts.

SESSION OVERVIEW

The goal of this session is to motivate consumer researchers to incorporate more studies with children into some of their work to develop a fuller understanding of the phenomenon they are studying. Why? When most consumer researchers conclude something about "consumers," what they really mean, is "adult consumers" (and not much, if anything, can be said about the 2.4 billion consumers in the world who are under the age of 18 (U.S. Census Bureau 2014).

We need more research with children for a number of reasons: 1) The consumption landscape has changed dramatically in the last decade, with social media penetrating every aspect of children's lives, from how they shop to how they interact with others. 2) Children lack the social-cognitive sophistication, as well as the experience with products, brands, and spending that adults have, which may (or may not) lead them to behave similarly to adults. 3) Studying children would allow researchers to understand how early certain consumer phenomena emerge and any age-related changes in the phenomena.

This session includes four papers, each offering either a novel approach to a research question or surprising findings. In **Paper #1**, Gentina brings old school, forgotten "offline" friendships back into the socialization discussion to better understand the trend of developing "online" friendships. In **Paper #2**, Friedman and Pesowski report results of four experiments with 3-5 year-olds that show that ownership is central in even young children's reasoning about material goods. In **Paper #3**, Kappes shows that surprisingly similar to adults, four year-olds—who lack knowledge of and experience with money (Webley 2005)—perceive spending as a signal of wealth. Finally, in **Paper #4**, Chaplin et al. report results of six studies with 3-17 year-olds and identify an exception to the accumulating body of evidence that "experiences are preferred over material objects."

Altogether, this session will report findings from twelve studies (correlational, experimental, longitudinal) with children ages 3-17. The four papers use a variety of methodological approaches, and present often surprising results (especially when compared to results based on adults-only research). The topic, overall, should be of interest to those doing research with children, as well as to scholars who study materialism and experiential consumption. Together, the papers contribute to consumer behavior, in that most challenge "common-sense" beliefs about consumption and findings based on adult participants. The papers offer a very cohesive and synergistic view of how children's developmental stages impact their consumption behaviors, but each paper offers novel insights. For all of the papers, data collection is complete, and analysis is ongoing, but preliminary results for each paper already contribute significantly to the field. We expect the session to generate intense discussions (possibly debates) as well as raise at least two questions for future research: 1. When will children's lack of social-cognitive sophistication, and experience with products, brands, and money lead them to behave similarly to (differently from) adults? 2. In general, how can testing children help consumer researchers develop a fuller understanding of consumer phenomena?

Offline Friendships Affect Facebook Activity and Teens' Theory of Mind

EXTENDED ABSTRACT

Facebook has revolutionized day-to-day social interactions (Subrahmanyam and Lin 2007), making it an integral part of adolescents' lives. It is estimated that 92% of adolescent social media users have a Facebook profile and go online daily (Pew 2015). With many adolescents active on Facebook, we investigated how quality versus quantity of offline (non-computer-mediated) friendships might impact the degree to which adolescents are active on Facebook, and, how degree of Facebook activity affects adolescents' theory of mind (ToM), the ability to understand others' mental states and predict their behavior (Begeer et al. 2010).

Some researchers suggest that the use of Facebook increases relationship closeness and connectedness with friends (Ellison et al. 2007). Others have found that Facebook deteriorates the quality of social bonds (Hei-Man 2008). We look to offline friendships to shed more light on Facebook friendships. Specifically, we examined how quantity vs. quality of adolescents' offline friendships affects their activity level on Facebook, and how this in turn, affects their interpersonal social skills, namely ToM.

We tested an integrative model with two independent variables – 1) offline friendship quality (measured using self-reports of peer support and loneliness), 2) offline friendship quantity (measured using peer-and-self-reports of adolescents' social integration within a classroom setting). Friendship quality refers to the degree to which relationships are meaningful within a social network (degree centrality) regardless of quantity (number of offline friends). Quantity of friendships refers to the size of participants' offline social network regardless of the quality—the larger the network the more direct connections to others. Our model also included frequency of Facebook activity (making connections, posting selfies, and posting comments). and ToM.

    Hypotheses   *How do offline friendships affect the frequency with which adolescents use Facebook? The answer is unclear. Having fewer offline friendships may lead adolescents to use Facebook more to fill*

a void in their offline social networks. However, offline friendships can be effective in cultivating quality relationships. Keller and Fay (2012) have shown that individuals prefer face-to-face interactions (offline frienships) over Facebook to keep in touch with others. We predicted:

Hypothesis 1   *Offline friendship <u>quantity</u> is <u>positively</u> related to the frequency of Facebook activity*

Hypothesis 2   *Offline friendship <u>quality</u> is <u>negatively</u> related to the frequency of Facebook activity.*

How do offline and online friendships influence ToM development? Little is known about the relationship between ToM, exposure to media, and information sharing among adolescents. Nathanson et al. (2013) emphasized that exposure to media such as television is not enough to affect ToM. Instead, for ToM to develop, children must experience an "exchange and negotiation of thoughts and ideas" (Nathanson et al. 2013, p. 1102). Because Facebook provides a place for these conversations and exchanges of content to take place, we predicted:

Hypothesis 3   *Frequency of Facebook activity is positively related to adolescents' ToM.*

Adolescents with quality relationships may prefer offline friendships over Facebook to communicate with friends (Keller and Fay 2012), and maintain networks of strong and meaningful relationships (regardless of the quantity) that provide them social support and a sense of belonging (Podolny and Baron 1997), resulting in low levels of loneliness (Baumeister and Leary 1995). Thus, we hypothesize:

Hypothesis 4   *Online friendship quantity is positively related to the frequency of Facebook activity, which in turn is positively related to ToM.*

Hypothesis 5   *Offline friendship quality is negatively related to the frequency of Facebook activity, which in turn is positively related to ToM.*

Method

The survey was administered in the classroom, a suitable environment to identify adolescents' social positions (Gentina and Bonsu 2013). A questionnaire was distributed to 647 adolescents across 28 classrooms. This sample was then randomly divided into two sub-samples. The first sample ($N_1 = 238$) served to validate the measurement scales. The second sample ($N_2 = 409$) was used to test the proposed model. It encompassed 17 classrooms (public and private schools), and consisted of 419 students: 65 thirteen-fourteen years-olds, 200 fifteen-sixteen year-olds, and 144 seventeen-eighteen year-olds.

To measure offline friendship quantity, we measured adolescent's social integration within the social network using peer and self reports. To measure offline friendship quality, we used Chaplin and John's (2010) peer support scale and Peplau and Cutrona's (1980) revised UCLA Loneliness scale.

Frequency of Facebook activity (making connections, posting comments and posting selfies) was measured using a frequency scale

(1 = never, 5 = always). ToM was measured using the general ToM scale (Dietvorst et al. 2009), a false belief task (Birch and Bloom 2007) and the eye-test (Baron-Cohen et al. 2001).

Results

Confirmatory factor analyses on the first sample (N_1=238) showed good fit statistics (χ^2 = 216.242, RMSEA = 0.055, GFI = 0.907, CFI = 0.900, adjusted c^2 = 1.716). The composite reliability coefficients were acceptable (Jöreskog rhô > .704); convergent and discriminant validity tests were also conducted and results were acceptable.

Structural equation modeling (SEM) based on maximum likelihood estimation was used to estimate the conceptual model (n_2 = 409). The fit of the full model was good (RMSEA = .017; X^2/df = 1.117; GFI = .985; CFI = .990, and square SRMR = .041).

Results indicated that offline friendship quantity (quality) is positively (negatively) associated with how active adolescents are on Facebook. Additionally, the frequency of Facebook activity mediated the relationship between offline friendship quantity and ToM, as well as the relationship between offline friendship quality and ToM. Findings from this research underscore both the importance of offline friendships and the benefits of online social networks in the development of adolescents' ToM.

Ownership Shapes Children's Judgments about Material Goods

EXTENDED ABSTRACT

Ownership is a major influence on how people think and feel about material goods, and how they use them. For instance, people value and prefer their own goods over non-owned goods (Beggan 1992; Kahneman, Knetsch, and Thaler 1991; Morewedge, Shu, Gilbert, and Wilson 2009); ownership impacts people's memory for objects (e.g., Coventry, Griffiths, and Hamilton 2014; Cunningham, Turk, Macdonald, and Macrae 2008; DeScioli, Rosa, and Gutchess 2015); and ownership even influences how people physically handle objects (e.g., Constable, Kritikos, and Bayliss 2011).

An increasingly influential view of ownership draws a distinction between "psychological" and "legal" aspects of ownership (e.g., Pierce, Kostova, and Dirks 2001, 2003; Peck and Shu 2009). For instance, people can feel ownership over material goods that are not actually theirs, and can also feel little or no ownership over goods that do belong to them. That is, feelings of ownership (i.e., "psychological" ownership) are not always aligned with ownership status (i.e., "legal" ownership).

However, there are reasons to think that "legal" aspects of ownership are not strictly legal, and are themselves psychological. One reason to believe this is that people regularly make a variety of judgments about the ownership status of material resources, even though they have no legal training, and even though their judgments do not always align with legal rulings and precedent (e.g., DeScioli and Karpoff 2015; Friedman 2010). In fact, such judgments and effects of ownership status are already evident in toddlers and preschool-aged children. Young children's judgments not only lack familiarity with the law, but their judgments about the ownership of material goods may sometimes be at odds with adult input or intuitions (e.g., Kanngiesser, Gjersoe, and Hood 2010; Neary and Friedman 2014; Ross 1996). For instance, young children often uphold ownership rights in instances where adults' give priority to other principles entitling people to use material goods. As such, young children's sensitivity to the ownership status of material goods suggests that ownership status is itself psychological (rather than legal), and like-

wise that there is more to psychological ownership than feelings of ownership over goods.

Present Experiments

We review four experiments showing that ownership status shapes young children's judgments about particular material goods. We show that ownership affects these judgments even when owned goods are physically identical with other available goods (also see Gelman, Manczak and Noles 2012; Gelman, Manczak, Was, and Noles 2016; Gelman, Noles, and Stilwell 2014), or when they are inferior to other available goods. We also show that ownership affects judgments that are fundamental to children's social functioning: The first two experiments examine children's judgments regarding how people *should* behave, and the second two examine children's predictions about how they *will* behave.

First, we will present two experiments showing that ownership status affects children's judgments about how people should behave in relation to physically identical material goods. For instance, in one study, children were shown vignettes in which a girl and boy had identical balloons. The boy took the girl's balloon, and then one of the balloons happened to pop. When children were asked whether the girl could take the remaining balloon, their answers depended on whose it was. When the boy's balloon popped, and the one belonging to the girl remained, children said she could take it back. However, when the girl's balloon popped, children said the girl should not take the boy's balloon. In other words, they upheld his ownership rights, even though the two balloons were identical, and even though the boy's actions essentially deprived the girl of her property. These findings show that ownership status is a powerful factor in children's reasoning about how people ought to behave, and also that pre-schoolers view owned objects as non-fungible.

The next two experiments show that children, aged three to five years, also use ownership status to predict people's behavior. In these experiments, children were shown vignettes in which a character stood between two objects. Children were then told about the ownership status of the objects, and asked which object the person would use or take. For instance, in one vignette, a girl was shown standing between two wagons, one of which was more attractive than the other. Children were told that the less attractive wagon belonged to the girl, and that the more attractive one belonged to someone else. Children were then either asked to predict which wagon the girl would take home, or to judge which one she liked more. We found that children indicated the wagon belonging to the girl more when predicting which one she would take than when asked about liking, and that this difference increased with age. These findings are noteworthy because they show that ownership influences children's judgments even when consideration of material goods should lead to opposite judgments—we normally expect people to use superior material goods.

Summary

In sum, we show that from early in development, ownership status plays an important role in assessments and predictions of others' behavior. The "legal" aspect of ownership is crucial for basic psychological judgments from early childhood.

Signaling Versus Accumulating Wealth: For Children, Refraining from Spending Implies Poverty

EXTENDED ABSTRACT

Consumer economists (e.g., Lea, Webley, and Young 1992) point out that "savings = income – spending." Holding income constant, lowering spending increases savings, and thereby builds wealth. In fact, wealth accumulation often relies on refraining from spending (Stanley and Danko 1996). Although individuals who refrain from spending may be wealthier than their counterparts who spend money in similar situations, these individuals may not be perceived that way. Indeed, the vast literature on signaling status via consumption indicates that spending money often succeeds in conveying impressions of wealth. Thus, refraining from spending may be interpreted as a signal of relative poverty rather than wealth. This research examines whether children (who lack knowledge and experience with money), also use spending as signal of perceived wealth.

Even young children (ages 3-10) associate groups of people with different levels of wealth (Olson, Shutts, Kinzler, and Weisman 2012), and are able to tell based on appearance whether someone is poor (Ramsey 1991). Marketers use status-based appeals to attract children, and children are sensitive to status symbols (Schor 2004). However, it is unclear how refraining from spending affects perceived wealth for children, and whether the effects of spending versus refraining on perceived wealth might vary across ages. The present research investigates these questions.

Method

To test how children perceive refraining from spending, participants ages 4-12 (N = 75) were presented with a short scenario describing a target child, "Casey," visiting a store with her (his) friends. Casey's gender was matched to the participant's gender.

Design

The scenarios were varied in a between-subjects experimental design such that children read about Casey visiting a candy store or a bookstore, and either buying something or refraining from buying.

Measures

As a manipulation check, participants were asked whether Casey had bought anything at the store; those who answered incorrectly (N = 21, 14.6%) were excluded from the analyses below. Thereafter, children were asked to judge Casey's wealth on 7-point scales, with the questions "Do you think Casey has a lot of money?" (reversed) and "How poor do you think Casey is?" These items were combined into an index of perceived wealth. Children answered an open-ended question about why they thought Casey bought/did not buy candy/a book.

Results and Discussion

Wealth

Children who learned that Casey refrained from buying candy or a book judged Casey to be less wealthy (M = 4.50) than children who learned that Casey bought something (M = 3.86), $F(1, 54) = 5.33$, $p = .025$, $\eta^2_{partial} = .09$.

In response to the open-ended question about why Casey bought/did not buy candy/a book, more than half of the explanations for why Casey refrained from buying (58%) spontaneously referred to money, whereas none of those for why Casey bought something did so, $\chi^2(1) = 22.73$, $p < .001$. Children who spontaneously referred to money in their explanation for why Casey refrained from buying were older than those who did not refer to money, $t(29) = 2.92$, $p = .007$ (8.39 years versus 6.15 years old).

Moreover, tests of interaction effects between participant age and target behavior (spend versus refrain from spending) on the target's perceived wealth suggested that older children were less likely to take refraining from spending as an indicator of poverty.

Summary

This research finds that children as young as four years-old perceive spending as a signal of wealth. As children age— and acquire more experience with and knowledge about money (Webley 2005)— they may come to understand that refraining from spending is a way to acquire wealth rather than an indicator of less wealth.

How Do Children Derive Happiness from Past Experiences? Developmental, Experimental, and Longitudinal Evidence

EXTENDED ABSTRACT

People evaluate experiential purchases more favorably and are happier after recalling an experiential purchase compared to material purchases (Van Boven 2005; Van Boven and Gilovich 2003). Many experiences are inherently social (Caprariello and Reis 2013), which may make experiences more likely than objects to foster strong social relationships, which are crucial to happiness and well-being (Diener and Seligman 2004; Howell and Hill 2009).

To enjoy past experiences, people must be able to recall them, which relies on memory processes. Enjoyment of past experiences might also rely on an understanding their social significance. To understand experiences' role in terms of social relationships, people can make use of others' feelings and perspectives, which relies on theory of mind. Although memory and theory of mind skills often are taken for granted in adults, children are deficient in these cognitive skills and develop them as they grow older. Memory development helps children recall details of experiences (which otherwise can be difficult given their intangible nature), and theory of mind development helps children make sense of their social world and the actors in it. Both skills should help children enjoy experiences.

If these cognitive capabilities are necessary for the full enjoyment of experiences, then it is likely that children may not derive that much happiness from past experiences, especially at young ages. However, as children age and become more cognitively advanced, they may become able to derive happiness from past experiences, and eventually, should eventually surpass objects in the happiness they give.

Present Research

Across six studies with over 400 children and adolescents ages 3-17, we show that children ages 3-12 derive more happiness from objects than from experiences. As children age, the happiness they derive from experiences increases, to the point that older adolescents derive more happiness from experiences than from objects.

Study 1 (N=242) used a longitudinal design spanning a two-year interval to achieve two aims. The central aim was to test the development of happiness from past experiences. The second aim was to test whether memory improvements boost theory of mind, which in turn boosts retrospective happiness from experiences. To measure happiness with experiences, we used a collage methodology because it is able to capture the variables of interest and was suitable for our participants' wide age range of 3 to 17 years old (Chaplin and John 2005, Chaplin and Lowrey 2010). Children created a collage using images of experiences and objects in order to answer the question, "What makes you happy?" We measured memory (recall and recognition) and theory of mind (false beliefs) using standard tasks.

Study 1 revealed that over the course of 2 years, children's memory improved as well as their theory of mind. Memory scores positively predicted theory of mind scores at both T1 and T2. Not only did theory of mind scores positively predict the proportion of happiness collages that were made up of experiences at both times,

but the effect also significantly increased as children mature. Finally, over the course of 2 years, the proportion of happiness collages that were made up of experiences also increased (see Appendix B).

Study 2 starts off a chain of experiments with 3-5 year-olds to enhance the happiness that experiences can provide. Studies 2 (N=40) and 3 (N=35) used two different memory interventions to assess whether it improved happiness from experiences. If being able to remember an experience is a key component of being able to derive happiness from experiences that have long since passed, then experimentally boosting memory should increase happiness from a past experience. We tested this proposition by experimentally manipulating memory for an experience in 3-5 year old children and measuring their happiness from that experience two weeks later. The experience was an initial interview with the experimenter. Studies 2 and 3 demonstrated that increasing children's memory for an experience increased their retrospective evaluation of the experience. These results replicated that of Study 1's longitudinal findings.

Study 4 (N= 38) moved to testing theory of mind. Study 4 made use of a manipulation aimed at improving understanding of people's inner mental worlds among children ages 3-5. The intervention took place over two weeks, and manipulation checks confirmed that it worked as intended. The children who were randomly assigned to receive a theory of mind intervention (training to understand the mental states of others) were subsequently more skilled at theory of mind tasks than a neutral condition that received numerical training.

Results showed that children in the theory of mind condition reported being happier than children in the neutral condition when recalling the initial study experience. Additionally, from a within-subjects perspective, children in the theory of mind condition were happier at time 2 than they were at time 1, whereas no change in happiness occurred among children in the numerical-boost condition. These results showed that theory of mind is needed to derive happiness from experiences, with this experiment showing its causal role.

Study 5 (N= 68) replicated and extended findings from Studies 1-4 by using an experiment to confirm the mediating role of theory of mind on the relationship between memory and happiness derived from experiences. These results show that being able to remember experiences is a key reason why experiences bring pleasure. However, having a good memory is not sufficient. Children must also develop good theory of mind, and remember the social aspects of experiences, to fully appreciate them.

This study further demonstrated that giving children a salient reminder of an experience can increase the pleasure they derive from that experience. What kind of salient reminders result in the greatest pleasure? Reminders about the social aspects of the experience result in more happiness than reminders of non-social aspects or no salient reminders at all. These results provide causal evidence of the link between memory, theory of mind, and happiness derived from experiences.

Deriving more happiness from experiences than from objects is a developmental process that unfolds overtime. Having good memory and a mature theory of mind set the stage for children to fully appreciate the benefits of experiences.

Jonathan Levav, Stanford University, USA

SESSION OVERVIEW

Today, consumers multitask more than ever. Technological advances such as mobile devices allow consumers to simultaneously consume multiple media at home or while on the move. For example, while watching TV, US consumers simultaneously use a second device 77% of the time (Google 2012). While multitasking may have substantial implications for consumer behavior and decision-making, research on consumer multitasking is scarce. In this session, we explore the impact of consumer multitasking across a variety of behaviors and contexts by focusing on two questions: (1) what are the drivers of consumer multitasking and (2) what are the consequences of consumer multitasking.

The first paper investigates a unique driver of multitasking and its impact on decision-making and consumer well-being. In three experiments, **Han and Broniarczyk** examine how incidental feelings of low control boost consumers' propensity to multitask. The authors also observe that this multitasking subsequently results in impaired decision-making and lower well-being.

However, multitasking may not always negatively impact consumer judgments. **Zane, Smith and Reczek** find that the impact of distracting background advertisements on product judgments depends on metacognitive inferences about distraction. Across three studies, the authors show that consumers' metacognitive inferences about distraction can lead to increased or decreased interest in products.

The next project investigates how multitasking influences consumers' ability to learn brand associations, and it challenges previous work which has shown that multitasking tends to have a negative impact on consumer learning. In two experiments, **du Plessis, Sweldens and van Osselaer** show that performing tasks simultaneously facilitates predictive learning of brand associations by motivating consumers to allocate more attention to the outcome that is the focus of prediction in the primary learning task.

The increased prevalence of consumer multitasking is due in part to consumers now being able to complete certain tasks without having to interrupt their daily routines. For example, instead of having to set aside time to go shopping exclusively, consumers can now shop on their mobile devices while completing their daily routines. Thus, consumers often perform a given action across multiple contexts (e.g., initiating product search on a smartphone while out of the house and finalizing the transaction on a laptop once home). The final paper in this session explores the consequences of such context shifts for self-control performance in sequential tasks. In four experiments, **Mead and Levav** find support for the theory that changes in mental and physical contexts reset self-control.

Overall, this session advances our understanding of consumer multitasking by shedding light on the antecedents and consequences of multitasking. The session should appeal to a broad audience of researchers and practitioners because (1) it investigates an emerging phenomenon that has profound implications for the "modern" consumer, (2) speaks to several established literatures in consumer research, including decision-making, power, learning and self-control, and (3) and illustrates how technological advances can reshape fundamental psychological processes and influence consumer well-being.

Juggling When Low in Control: The Effects of Control on Choice to Multitask

EXTENDED ABSTRACT

The development of portable devices has resulted in an environment where consumers are constantly multitasking, which refers to "rapidly switching from one task to another or juggling multiple tasks at the same time" (Ie et al. 2012). Multitasking is related to the distraction and cognitive load literature in that it involves a dispersion of attention or decrease in the amount of cognitive resources available for a task. However, multitasking is distinct in that it is a volitional behavioral mode in which consumers choose to engage in simultaneous task performance even though they have the opportunity to complete tasks sequentially. Despite the widespread nature, there is a lack of investigation into the antecedents and consequences of multitasking in a consumer context. We examine the effect of an important consumer variable, perceived control, on multitasking tendencies. Interestingly, we find that those experiencing low control are more likely to multitask, but that this has deleterious effects as multitasking leads to lower task performance and well-being.

Past work has shown the negative effects of multitasking on attention and subsequent memory recall. For example, chronic multitaskers were more susceptible to interference from irrelevant environmental stimuli and representations in memory (Ophir, Nass, and Wagner 2009). Although such work is shedding light on the effects of multitasking, little work has looked into the triggers of multitasking behavior. Work that has looked into the cause of multitasking has been limited to correlational research methods (e.g. Wang and Tchernev 2012).

Past research has argued that people feeling low control become motivated to restore control (Fiske, Morling, and Stevens 1996). Bardhi, Rohm, and Sultan (2010) report that people believe multitasking provides higher control as it entails increased decision and choice making. Similar to this view, Duff et al. (2014) reported a correlation between high chronic multitasking and feelings of low control. Thus, we predicted that people feeling low control would be more likely to choose to multitask on subsequent tasks, compared to those feeling

high control. Moreover, we expected that such multitasking would lead to a decrease in subsequent task performance and increase in negative affect.

In **study 1**, participants first completed a control manipulation, where they recalled a time when they either had high or low control (Whitson and Galinsky 2008). Then, participants were instructed to complete two tasks: a vocabulary task and a video task. For the vocabulary task, participants were given 4 minutes to memorize a list of German vocabulary words. For the video task, participants watched a 4-minute-long video documentary about twins. Participants were asked whether they wanted to complete the tasks sequentially or simultaneously (i.e. multitask). Participants who selected the sequential option completed each task independently. Participants who selected the multitasking option saw a screen split in half where half of the screen displayed the vocabulary list, whereas the other half displayed the video. Task performance was measured via five vocabulary quizzes and 4 video comprehension questions. As expected, people feeling low incidental control were more likely to multitask on subsequent tasks compared to those feeling high control (χ^2 (1) = 3.4, $p < .06$). Also, as predicted, those who multitasked performed worse in both the German vocabulary test (F (1, 186) = 15.37, $p < .0001$) and the video task (F (1, 186) = 41.04, $p < .0001$).

Study 2 aimed to replicate the effect of control on multitasking while testing the effect of multitasking on consumer decision making. Specifically, we tested the effect of multitasking on people's consideration of irrelevant attributes (Hutchinson and Alba 1991) multiattribute information about stereo speakers was presented to subjects in a training phase. However, only one attribute was diagnostic. Analytic processing (i.e., the ability to isolate the diagnostic attribute in a subsequent test of product knowledge when making purchase decisions. The procedure of study 2 was similar to study 1 except that participants completed a consumer task instead of the vocabulary task. In the consumer task, participants read a description of a friend's product preference and were asked to choose between two products. One of the products had fewer attributes but was more in line with the preference of the friend, whereas the other product had more attributes but was less in line with the friend's preference. We also measured participants' preference for multitasking. The results again showed that people feeling low control were more likely to multitask on subsequent tasks (χ^2 (1) = 9.51, $p < .002$). Also, as in study 1, multitaskers performed worse in the two tasks than those who worked sequentially (F (1, 100) = 6.06, $p < .01$). Moreover, perceived control also had a significant effect on task performance (F (1, 100) = 5.87, $p < .02$), and this effect was mediated through people's preference to multitask (95% CI: [.0014, .1762]; Preacher and Hayes 2004)formal significance tests of indirect effects are rarely conducted. After a brief overview of mediation, we argue the importance of directly testing the significance of indirect effects and provide SPSS and SAS macros that facilitate estimation of the indirect effect with a normal theory approach and a bootstrap approach to obtaining confidence intervals, as well as the traditional approach advocated by Baron and Kenny (1986.

Study 3 sought to further explore the consequences of multitasking on consumer well-being. We also measured people's performance expectations in order to rule out alternative explanations. The procedure was similar to study 2, except that we asked participants how well they expected to perform after they made their choice to multitask or not and measured their stress and negative affect after completing the tasks. As before, participants feeling lower control were more likely to choose to multitask compared to those feeling high control (χ^2 (1) = 3.76, $p < .05$). Also, those who multitasked performed worse on both the product choice task (F(1, 139) = 9.82,

$p < .002$) and the video task (F(1, 139) = 88.62, $p < .0001$). More relevant to our goals, we found that those who chose to multitask experienced higher levels of stress (F (1, 139) = 8.96, $p < .01$) and negative affect ($F = 11.69$, $p < .001$). Mediation analyses also confirmed that feeling low control resulted in higher stress and negative affect, and that these effects were mediated through choice to multitask (Baron and Kenny 1986). Finally, the data also showed that pre-task expected performance was not affected by the control manipulation or the choice to multitask, ruling out an alternative explanation based on biased expectations.

The current research advances our understanding regarding the antecedents of consumer multitasking behavior and documents the detrimental effect of multitasking on subsequent task performance and well-being.

Drawing Conclusions while Multitasking: Distracting Background Ads Cue Consumers to Infer Product Interest through Metacognitive Inferences

EXTENDED ABSTRACT

Consumers multitask more than ever (e.g., 84% of Americans use a second device while watching television; Nielsen 2010). These tendencies toward multitasking often relegate marketing messages to the background while consumers focus on other tasks. This research explores whether consumers draw metacognitive inferences based on how distracting they find a background ad relative to expectations, and what they conclude from this distraction.

Consumers tend to believe that they are able to effectively multitask (Sanbonmatsu et al. 2013). However, consumers are prone to often being distracted away from a focal task by a background stimulus (Finley, Benjamin, and McCarley 2014). Thus, when consumers find their attention moving away from a focal task towards a background stimulus, they experience distraction, which is often unexpected given consumers' beliefs that they can successfully multitask. We theorize that when consumers find themselves more distracted than expected by a background advertisement, they draw on an underlying lay theory that distraction implies interest in the contents of the distracter to make the metacognitive inference that they are interested in the advertised product. We also identify important boundary conditions for this effect, including accessibility and diagnosticity of the lay theory.

In **study 1**, 110 undergraduates participated in a three cell between-subjects experiment. All participants colored a drawing while simultaneously listening to a long-form car advertisement. Participants in the "high perceived distraction" condition first read that students are good at tuning out advertisements while focusing on creative tasks. Participants in this condition should believe any experienced distraction is more than expected and should infer greater interest in the advertised product. Participants in the "low perceived distraction" condition read that students are *not* good at tuning out advertisements while focusing on creative tasks. Distraction in this condition should align with expectations and should not serve as a signal of interest. Additionally, we included a control condition in which we did not manipulate participants' expectations of distraction. Because consumers generally believe they are able to effectively multitask (Sanbonmatsu et al. 2013), any experienced distraction by participants in this condition should also seem unexpected. After coloring and listening to the ad, participants indicated their interest in the advertised brand.

To analyze the between-subject conditions, we created orthogonal contrasts comparing (1) the high perceived distraction and control conditions to the low perceived distraction condition and (2) the

high perceived distraction condition to the control condition. Regression revealed a main effect of the first contrast ($F(1,107) = 8.86$, $p < .01$), such that mean brand interest in the high perceived level of distraction and control conditions ($M = 5.25$) was significantly greater than mean brand interest in the low perceived level of distraction condition ($M = 4.64$). There was no significant main effect of the second contrast ($F(1, 107) = 1.16$, *ns*); mean brand interest was the same in the high perceived level of distraction condition ($M = 5.11$) and the control condition ($M = 5.37$). Study 1 establishes initial evidence that consumers infer their level of interest in an advertised product from their perceived level of distraction towards a background ad.

In **study 2**, we demonstrate that when the diagnosticity of the "distraction=interest" lay theory is questioned, consumers who are more distracted than expected no longer infer greater interest in the advertised product (Feldman and Lynch 1988; Schwarz et al. 1991). In this study, 207 undergraduates participated in a 2 (Perceived Distraction: high, low) X 2 (Diagnosticity of Distraction: high, low) between-subjects experiment. They all completed the same tasks as in study 1. Participants' perceived level of distraction was manipulated as in study 1. We also manipulated whether the "distraction=interest" lay theory appears diagnostic. Participants in the "low diagnosticity of distraction" condition read that students are [are not] good at tuning out advertisements, "regardless of whether they are interested in the product being advertised," thus challenging the diagnosticity of the lay theory. Those in the "high diagnosticity of distraction" condition did not read any additional material and hence diagnosticity of the lay theory was not challenged. Once the advertisement ended, participants indicated their interest in the brand. The interaction of these two factors was significant ($F(1, 203) = 3.64$, $p = .057$). When distraction was diagnostic, participants in the high perceived distraction condition reported significantly greater interest in the brand ($M = 5.35$) than those in the low perceived distraction condition ($M = 4.90$; $F(1, 203) = 3.99$, $p = .05$). There was no difference in interest across perceived distraction conditions in the conditions where the diagnosticity of the "distraction=interest" lay theory was challenged ($M = 5.01$ vs. 5.17; $F(1, 203) = 0.48$, *ns*).

Study 3 explores whether priming consumers to access a competing lay theory (i.e., that "distraction=annoyance"; Deval et al. 2014; Schwarz 2015) results in opposing metacognitive inferences about their interest in the advertised product. This study used a 2 (Perceived Distraction: high, low) x 2 (Lay Theory Prime: "distraction= interest," "distraction=annoyance") between-subjects design. Participants first read an article that primed one of the lay theories by arguing that marketers use interesting [annoying] ads to grab attention. They then colored while listening to a cruise ship advertisement. Before coloring, participants' perceived level of distraction was manipulated as in study 1. Afterwards, participants indicated their interest in the brand. A significant interaction emerged ($F(1,217)=6.48$, $p=.01$). Among participants primed with the "distraction=interest" theory, those in the high perceived distraction condition were more interested in the product ($M=4.64$) than those in the low perceived distraction condition ($M=4.22$; $F(1,217)=2.78$, $p=.10$). Among participants primed with the "distraction=annoyance" theory, those in the high perceived distraction condition were less interested in the product ($M=4.11$) than those in the low perceived distraction condition ($M=4.61$; $F(1,217)=3.72$, $p=.05$). These results demonstrate that when an opposing lay theory is accessible when consumers experience distraction, the resulting metacognitive inferences lead to opposite evaluations of the advertised product.

Together, this research extends metacognitive theorizing into the domains of distraction during multitasking and yields useful theoretical and practical implications.

How Multitasking Influences Consumer Learning of Brand Associations

EXTENDED ABSTRACT

This research explores how multitasking influences consumer learning of brand associations. Brand associations are learnt either through predictive (van Osselaer and Alba 2000) or incidental (Anderson and Bower 1973) learning processes. In predictive learning, the degree to which a cue is associated with an outcome depends on how diagnostic the cue is of a change (e.g., increase) in the outcome. For example, imagine a consumer learning about wine who first tries a wine from a particular region and finds it has good quality. Next she tries another wine from the same region which carries the brand of a particular estate, and finds it to be of the same good quality. Whereas the first experience will have led her to associate the region cue with 'good quality,' the same will not occur for the estate cue she encountered in the second learning trial. The reason is that the region cue already perfectly predicted the 'good quality' outcome. This type of 'blocking' effect is a staple finding in predictive learning where cues interact and compete for associative strength with outcomes. Other known examples are 'conditioned inhibition' and 'unblocking' (Kamin 1969).

Such cue interaction effects do not occur in incidental learning. Here, the degree to which a cue is associated with an outcome depends on the frequency with which they co-occur. Predictive and incidental learning can occur simultaneously; consumers engage in predictive learning of outcomes they are trying to predict, but incidental learning of outcomes they are *not* trying to predict (van Osselaer and Janiszewski 2001). Hence, the consumer in the previous example might have acquired an association between the estate cue and 'good quality' via incidental learning instead, but only if she wasn't primarily focused on learning about quality (but rather on, say, the aging potential of the wine).

In this research we investigate how multitasking, operationalized by a cognitively demanding secondary task, influences these learning processes. Theoretically, countervailing predictions can be made. From a resource dependence viewpoint, predictive learning should suffer from cognitive capacity constraints because prediction is effortful (van Osselaer, Janiszewski and Cunha 2004). In contrast, incidental learning has been found to occur when people expend less effort on learning (De Houwer, Hendrickx, and Baeyens 1997).

In contrast, attention management theories allow for the possibility that multitasking could *facilitate* predictive learning. Because additional cognitive load arising from the secondary task increases task difficulty, consumers need to invest more effort into predictive learning. Based on prior research showing that attention narrows and becomes more directed when tasks require more effort (Kahneman 1973) or when motivation increases (Gable and Harmon-Jones 2010), one could predict that consumers will allocate more attention to the outcome that is the focus of prediction when they are multitasking. We test these countervailing accounts in two experiments.

Study 1 (n=249) provides an initial test of the hypotheses. Participants were assigned to conditions in a 2(focus: bouquet quality, aging potential) x 3(cognitive load: low, moderate, high) x 2(product attribute that uniquely predicts target benefit: attribute 1, attribute 2) mixed design. The first two factors were manipulated between-subjects. Participants were instructed to learn to predict either the bouquet quality or aging potential of wines. Before starting the learning trials, subjects memorized a pattern. Here we manipulated cognitive load using a dot probe task (Bethell-Fox and Shepard 1988). Next, all participants were exposed to six learning trials. The key depen-

dent variable was the difference in predicted bouquet quality when a wine was made with attribute 1 versus attribute 2.

It was predicted that, because subjects told to focus on bouquet quality will engage in predictive learning of bouquet quality, and predictive learning is characterized by cue-interaction effects, the difference in predicted bouquet quality should be positive (attribute 1 > attribute 2) due to unblocking of attribute 1, and blocking of attribute 2. In contrast, subjects told to focus on aging potential should engage in incidental learning of bouquet quality, as evidenced by a negative bouquet quality rating (attribute 2 > attribute 1). This will occur because attribute 2 was paired twice with a high bouquet quality whereas attribute 1 was paired once with this outcome. In line with the predictions from attention management theory, a significant positive trend was observed among participants told to focus on bouquet quality (b=.55, t=3.77, p< .001). The difference in bouquet quality was higher among those under high (M=.53, SD=.80) than moderate (M=.10, SD =.71) and low (M=-.14, SD=.65) cognitive load. Further, the linear trend was not significant among participants told to focus on predicting aging potential (b=.32, t=.32, p=.75). These results indicate that cognitive load intensified predictive learning, and had no effect on incidental learning.

Because study 1 used unblocking and blocking as cue interaction effects, study 2 (n=320) sought to replicate these findings for a different type of cue interaction; conditioned inhibition. Participants were assigned to the same conditions as study 1, except that there were only two load conditions (low vs. high) and that the cue interaction effects characterizing predictive learning were unblocking of attribute 1 and conditioned inhibition of attribute 2.

As in study 1, we found that predictive learning improved under high cognitive load. Indeed, a contrast showed no difference in predicted bouquet quality based on attribute 1 versus attribute 2, among participants under low load (F(1,83)=2.19, p=.14) who focused on predicting bouquet quality. However, among participants under high load who focused on predicting bouquet quality, the contrast became significant (F(1,77)=4.62, p=.03).

In addition, cognitive load again did not impact incidental learning. Among participants told to focus on aging potential, attribute 2 was predicted to lead to higher bouquet quality than attribute 1 under low (F(1,81)=13.46, p <.001) and high load (F(1,75)=7.63, p=.003).

This research finds that multitasking can facilitate predictive learning without affecting incidental learning of brand associations. Thus, it contributes by showing that attention management, and not resource dependence theories, best describe how learning occurs when consumers are handling multiple cognitive operations simultaneously.

A Change is as Good as a Rest: Changing Contexts Restores Self-Control

EXTENDED ABSTRACT

Due to the increasing sophistication of mobile devices, consumers are increasingly making purchasing decisions while changing contexts. This enables them to initiate product search in one context, and finalize the transaction in another context. Indeed, it has been estimated that 67% of American consumers start shopping on one device but move to another screen to complete the shopping session (Google 2012). The present research examined how context changes influence consumer self-control.

According to the strength model (e.g., Baumeister et al. 1998), self-control works similar to a muscle: after initial exertion, it becomes fatigued and needs to be rested before it can become operable again. Recent theorizing suggests, however, that self-control

failure after initial self-control exertion may stem from an unwillingness rather than inability to continue exerting self-control (Inzlicht and Schmeichel 2012). Building on this, we hypothesized that self-control may be contextually bound. More specifically, in the same context, people may become increasingly reluctant to engage in self-control because they are drawing from the same self-control account. However, a change in context may signal a new self-control account and hence may restore people's willingness to exert self-control. Given that self-control governs impulse buying (Vohs and Faber 2007), a shift in shopping context may have implications for purchasing decisions.

Four experiments tested the context hypothesis by assigning participants to complete a relatively more or less depleting task (task 1) and then randomly assigning them to complete a subsequent self-control task (task 2) in the same or different room. To establish the robustness of the effect, experiments 1-3 tested the basic hypothesis using diverse depletion manipulations and measures. To rule out the possibility that a context change improved self-control because of mere physical movement (which can induce arousal) or disruption, experiment 4 held constant physical movement and disruption while varying whether task 2 was completed in the same context as task 1. Rest replenishes self-control (e.g., Tyler and Burns 2008), so the amount of time that elapsed between the two tasks was held constant across all conditions in all reported experiments.

Study 1 examined performance on the Stroop task (Stroop 1935) as a function of prior self-control exertion (vs. no exertion) and context change (vs. no context change). To manipulate depletion, participants were or were not required to regulate their emotions while reading a neutral, boring passage (Vohs and Schmeichel 2003). For the second task, participants stayed in the same room or moved to a different room down the hall in the same laboratory. The key dependent measure was the time difference between completion of incongruent and congruent trials on the Stroop task. As predicted, an interaction between depletion and context emerged, $F(1,184)=6.033$, $p=.015$, $\eta^2=.032$. Among participants who completed both tasks in the same room, participants in the depletion condition performed worse on the Stroop task ($M=2.72s$, SD=2.14) than their no-depletion counterparts ($M=1.71s$, SD=2.05; $F(1,184)=6.730$, $p=.010$), conceptually replicating previous ego-depletion effects. More important, depleted participants who switched rooms performed better on the Stroop task ($M=1.72s$, SD=1.55) than their non-depleted counterparts who stayed in the same room ($F(1,184)=6.50$, $p=.012$). Additionally, among participants who switched rooms, there was no effect of the depletion manipulation ($F<1$).

Study 2 examined consumption of a tasty but unhealthy snack. Participants randomly assigned to the depletion condition were asked not to think about a white bear during a thought-listing task, whereas participants assigned to the no-depletion condition were allowed to think about anything they liked, including thoughts of a white bear (Wegner et al. 1987). Participants then stayed in the same room or they were moved to a different room for task 2. The dependent measure was grams of potato chips consumed. Conceptually replicating study 1, there was a depletionXcontext interaction, $F(1, 144) = 4.751$, $p = .031$, $\eta^2 = .032$. Among those who completed both tasks in the same room, participants in the depletion condition ate more chips ($M=40.657g$, SD=23.90) than participants in the no-depletion condition ($M=31.359g$, SD=20.46; $F(1,144)=2.71$, $p=.056$) although that effect was only marginally significant. More important, participants in the depletion condition who changed contexts consumed fewer chips ($M=28.671g$, SD=14.99) than their depleted counterparts who did not change rooms, $F(1,144)=6.16$, $p=.014$.

Study 3 examined cheating, which is governed by self-control (Mead et al. 2009). The depletion manipulation concerned writing an essay that required participants to override the impulse to use words that contained common (vs. not common) letters. Participants in the depletion condition wrote an essay without using words that contained the letters 'A' and 'N' whereas those assigned to the no-depletion condition left out words containing the letters 'X' and 'Z' (Schmeichel 2007). The room manipulation was identical to that used in experiments 1 and 2. The measure of self-control was unethical behavior – specifically, the amount of unearned money taken by participants. Conceptually replicating studies 1 and 2, participants in the depletion condition cheated more (M=.37, SD=.69) than participants in the no-depletion condition (M=.11, SD=.42), but only when they completed both tasks in the same room, $F(1,116)$=5.19, p=.025. As predicted, participants in the depletion condition who switched rooms were less unethical (M=.06, SD=.25) than their depleted counterparts who stayed in the same room, $F(1,116)$=7.18, p=.008.

Study 4 aimed to provide support for the context theory while ruling out the possibility that restoration of self-control in studies 1 to 3 was merely due to disruption or physical movement. To achieve this goal, study 4 included a comparison condition in which participants completed both tasks in the same room but in between the two tasks they were led outside of the room (vs. no change or change). The depletion manipulation was the same as that used in study 3 (essay task) and the dependent measure was performance on the incongruent trials of the Stroop task. Study 4 conceptually replicated the results of studies 1 to 3: changing rooms restored self-control (p=.047) However, that restoration was specific to a context change. Mere physical movement/disruption was not sufficient to restore self-control (p=.227).

In summary, four experiments suggest that consumers' self-control may be contextually bound. Alternative explanations such as a boost in mood, physical movement, and mere disruption were ruled out and cannot account for obtained effects. The studies have practical implications for how self-control functions in daily life and theoretical implications for the strength model of self-control.

SESSION OVERVIEW

Guiding questions:

1. How do marketers use market-based processes, practices and discourses to facilitate destigmatization?
2. How do stigmatized consumers use marketplace strategies to cope with or attenuate stigma?

The objective of this session is to explore and theorize the power of the marketplace to both stigmatize and destigmatize conditions, consumers and contexts. In his seminal work, Goffman (1963, p. 15) defined stigma as an "attribute that is deeply discrediting," reducing the person who possesses it "from a whole and usual person to a tainted, discounted one." Stigma is a significant social phenomenon, one which leads to vulnerability, marginalization, and exclusion, and reduces opportunity for economic and social advancement.

Extant research on stigma emphasizes the perspective of the stigmatized, with some scholars exploring how social institutions shape stigma within particular cultures. Yet the ways stakeholders within sociocommercial spheres create, perpetuate, resist or attenuate stigma remains largely overlooked (for an exception, see Mirabito et al 2017). In this session, we explore how marketplace stakeholders (consumers, companies, employees, and institutions) contribute to destigmatization through market-based discourses, practices and tactics.

Strong theoretical links draw the papers together –inclusion, exclusion, stereotyping, power and vulnerability run through the work. While the papers cover a range of stigmatized states to illuminate the complex relationship between market agents and stigma, at their core they are united by a sense of social justice. Marketers and the marketplace unquestionably fuel social stigma but interestingly, they may also play a part in destigmatisation processes. Recounting and illuminating these processes has the potential to bring valuable, ameliorative, insight, fostering both conceptual clarity and consumer well-being.

In "More Homely than Home: Stigma, Liminality and Pilgrimage Consumption," Higgins and Hamilton reveal how marketization and detraditionalization have silenced public religious expression,

creating feelings of stigmatization and existential liminality for Catholic consumers in everyday life. They re-conceptualize liminality and find the pilgrimage marketplace to become the *balm* that enables consumers to temporarily shed their stigma and existential liminal state.

In "How Do Brands' Destigmatizing Messages Travel Through Social Media? 'Like a Girl,'" Mirabito, Crosby, and McManus examine the way brands tap social media to destigmatize race, gender, and medical conditions. In particular, they compare the Twitter network of a brand-driven destigmatizing initiative (#LikeAGirl) with a grassroots destigmatizing initiative (#BlackLivesMatter). The #BLM network is dense, with tightly connected groups and strong connections between groups, suggesting an ongoing conversation about the topic. In contrast, the brand-driven initiative yields small clusters engaged in conversation and many unconnected individuals who appropriate the message to further related agendas.

In "Delusion or Deception: Examining Racialized Stigma and Colorblind Politics in the Marketplace" Thomas, Morris and Matias explore marketers' attempts to assuage the racialized stigma of marketplace discrimination by implementing colorblind policies and conclude the experience of racialized stigma does not appear to be lessening. They deconstruct this apparent paradox by investigating how colorblindness is practiced by marketers and experienced by consumers.

Spiteri Cornish, Cronin and Dunnett's "Divesting Identities: Counterbalancing and Demythologizing the Stigmatized Identity" contributes to the theorization of unwanted consumer identities by uncovering the practices and discourses employed by fat consumers to divest stigmatized identities. They outline tactics for divesting identities, such as counterbalancing and demythologizing fatness through consumption narratives. The authors conclude that market-based practices can play a role in destigmatisation but the price for the individual is increased social labor.

More Homely Than Home: Stigma, Liminality and Pilgrimage Consumption

EXTENDED ABSTRACT

The relationship between religion and consumerism remains contentious, yet it is undeniable that the rise of a consumption ideology has coincided with the decline of traditional forms of religion in many westernized countries (Gauthier, Woodland and Martikainen, 2013). Religion is no longer a taken-for-granted institutional pillar in identity projects in consumption-oriented cultures (McAlexander et al. 2014). However, it is poorly understood how these trends of marketization and detraditionalization are associated with religious consumers' experiences of marketplace stigma. This paper aims to provide a deeper understanding of how the sociocultural environment impacts on the stigma experienced by Catholic consumers and, in doing so, we shed new theoretical light on the relationship between stigma and liminality.

There is little agreement on how religious consumers experience marketplace stigma. Sandikci and Ger (2010) found particular religious orientated consumption choices to be "virtuous" as religious consumers seek the stigma attached with the consumption choice in order to differentiate themselves from others within the predominant societal worldview. Similarly, others view the sacrifice and stigma

felt by religious followers as generally not costs but rather deliberate choices pursued to create "tension with the dominant culture" as a means of creating a "distinctive identity" (Kurtz, 2012, 18; Ianna-conne, 1988). Alternatively, other research reveals that consumers may mask their religious identity in an effort to minimize differences with others and avoid potential stigmatization (Weinberger, 2015). This study advances our understanding of what happens when consumers unwantedly experience stigma in light of their association and practice of a specific religion.

The paper is based on a three-year ethnographic study on the consumption of the religious pilgrimage experience to Lourdes in France. The Lourdes pilgrimage was ignited in 1858 by a series of apparitions between fourteen-year-old Bernadette Soubirous and a woman, who was authenticated by the Catholic Church in 1862 as the Mother of Jesus Christ. A consumption experience that continues to grow after 150 years, with over six million pilgrims journeying there annually in search of physical, spiritual and personal renewal. In keeping with standard ethnographic practice, multiple methods of data collection were employed. Fieldwork was based on participant observation, which at times incorporated volunteering with teams. Fieldwork data resulted in over 200 pages of double spaced field-notes, approximately 3000 visuals (photographs and videos), and many informal and serendipitous interviews with pilgrims on site at Lourdes, which were audio-recorded when possible. Depth interviews were conducted with twenty-three respondents lasting from thirty minutes to four hours in length enabling the understanding of personal life histories. All interviews were transcribed verbatim, tallying over 1000 double spaced pages of transcription.

Findings reveal that religious conversation and expression is becoming less tolerated and as such is silenced or "backgrounded" (Weinberger, 2015) within respondents' home environments. Respondents agree that practicing Catholicism results in them being labelled and stereotyped as part of "The God Squad" or as "Crazy Catholics". We find such existential silencing to be detrimental to Catholic consumers, creating feelings of stigmatization and causing many to feel continuously liminal in everyday life. Turner (1969, p. 103) suggests that submissiveness and silence are characteristics associated with liminal entities. The liminal state has been viewed as a "negative, ambiguous phase" during which liminars suffer a "suspension of their identity" and experience a "vague or blurred" sense of self (Cody and Lawlor, 2011, 211). However, rather than overtly or publically transgressing against normative society, respondents turn to the marketplace. By consuming the Lourdes experience, such religious repression is temporarily freed and consumers are able to temporarily shed their existential liminal state.

The Lourdes pilgrimage consumption experience encapsulates a familiarity that is expressed as being a "home away from home," that is "comfortable", "homely", and "welcoming". Consequently, many align their pilgrimage consumption experience to being encapsulated within what is colloquially termed the "Lourdes Bubble" with the Lourdes pilgrimage affording them a time and place where they feel "safe", "secure", and "protected", more so than they do at home:

"On the way home everyone is tired, but happy. I can hardly wait to get home, but by this I mean that I can hardly wait to go home to Lourdes next year because that is how I feel about going to Lourdes every year – I am going home!"(Patricia, 93).

Therefore, while emically respondents speak of Lourdes as a home away from home, etically our findings reveal that Lourdes can in fact be more homely than home because of the perceived safety, security and religious freedom that is missing from daily life.

Previous consumer research has found that consumers embrace the stigma associated with their religious fervour (Sandikci and

Ger, 2010). In contrast, we find that the religious setting is not consumed to signify religious virtue but rather to temporarily escape "stigmatic boundaries" and provide a "form of sanctuary and acceptance" (Kozinets, 2001, 72) where consumers are free to express and practice their religiosity. Thus while consumers may suffer a tearing of the self (Jafari and Goulding, 2008) in their everyday lives, the Lourdes marketplace offers a repair; a *balm* that enables consumers to temporarily shed their existential liminal state and experience a temporal cohesive, accepted, holistic sense of self. Van Gennep (1909/ 1960, 46) distinguished between the *physical* return versus *the social* return from rites of passage, a distinction that has yet to be incorporated into consumer research. This study demonstrates that whilst consumption experiences may be *physically* located within a peripheral, liminal landscape, the *social* experience can provide consumers with a holistic sense of self, unachievable in their mundane, everyday lives. The peripheral *physical* location of the Sanctuary of Lourdes, in the Pyrenees region of France, denotes liminality. However, the *social* experiences of Lourdes consumers signals not a "betwixt and between" but rather a stable, holistic state. Thus, through Van Gennep's distinctions, we advance Schouten's (1991, 421-422) understanding of "prolonged" and "continued" liminality demonstrating that consumers can be simultaneously *physically* liminal and *socially* whole.

How Do Brands' Destigmatizing Messages Travel Through Social Media? 'Like a Girl!'

EXTENDED ABSTRACT

Stigma's presence in the marketplace has been uncovered in product stigmatization (Ellen and Bone 2008), the experience of stigmatized groups in customer service encounters (Adkins and Ozanne 2005; Crockett, Grier, and Williams 2003), coping through consumption (Ho and O'Donohoe 2014; Nguyen, Chen, and Mukherjee 2014), and the effects of stereotyping on consumer behavior (Campbell and Mohr 2011; Matta and Folkes 2005; Yeh, Jewell, and Hu 2013). Yet little research has explored ways brands destigmatize (for an exception, see Mirabito et al 2016). This is surprising in light of the influence brands can have on individual's identity formation and values.

Several brands have begun destigmatization initiatives. Dove's campaign for real beauty seeks to normalize ordinary features, Dorito's Rainbow promotion sought to normalize sexual orientation, and Always' Like a Girl campaign aims to destigmatize gender roles. Gender stigmas begin to appear at early ages. Children as young as two categorize clothing, colors, toys, activities, and occupations by gender (Levy, Sadovsky, and Troseth 2000; Liben, Bigler, and Krogh 2001) Metheny's (1965) studies of gender stereotypes found that sports considered to be female sports were aesthetically pleasing and lacked face-to-face competition or overt aggression, while male sports tended to be more aggressive and competitive, with high levels of bodily contact. According to Riemer and Visio (2003), sports such as gymnastics and aerobics are considered to be feminine, while football and wrestling tend to be viewed as masculine. In in-depth interviews with children ages 8-10, Schmalz and Kerstetter (2006) found most children followed the gender sports stereotypes, but did not have solid answers as to why. Always' Like a Girl campaign challenges gender stereotypes by exploring the meaning of running "like a girl."

Social movement organizations (SMOs) also spread destigmatizing messages. Social movements are created as individuals band together for a common cause. Social media, including Twitter conversations, have been embraced by firms and grassroots organizations as a way of recruiting allies and spreading messages. How do

stigma-challenging messages created by brands differ from social change efforts wrought by SMOs? Extant research in social movement formation prior to the advent of social media (cf., Passy and Giugni 2001) concludes that movements are built on dense networks; friends recruit friends. This research explores whether brands' social media networks have a similar shape and structure as those of SMOs.

Methods

Social media networks are created organically as Twitter users share information and viewpoints. Users tweet original messages, reply-to, and mention one another's posts. Popular topics attract the interest of a large number of users who connect in a network structure. Twitter data can be analyzed to uncover the shape of these network, summarize the content and valence of their discussion, and identify the people playing central roles in extending the messages.

We used NodeXL Pro (Social Media Research Foundation 2016) to download and analyze publicly available Twitter messages incorporating the phrase #LikeAGirl. We captured from the Twitter Search service usernames, hyperlinks and hashtags, and information about each writer's connection to other Twitter users. We created visual maps of the social networks, evaluated network characteristics including group density and clustering and identified central players who transmitted messages to other groups of friends. To gain insight into the ways brand-supported destigmatizing campaigns compare with grassroots destigmatizing campaigns, we compare the structure of the #LikeAGirl network with that of #BlackLivesMatter, a grassroots social movement aimed at destigmatizing race. We downloaded both networks in February 2016; following Smith et al (2015) practice in comparing different sized campaigns, we analyzed a similar numbers of messages from each network (approximately 2400).

Preliminary Findings

We observe several differences between the two networks. First, the #BLM network is substantially denser. Density is calculated as the ratio of the total edges to the maximum number of possible edges; the #LAG network is just 60% as dense as the #BLN. The implication is that the #BLN tweeters are conversing with each other, whereas the #LGA tweeters broadcast their message to friends who do not necessarily reply on that topic. Second, and relatedly, the #LAG features relatively more tweets and fewer replies/mentions than #BLM, with 32% of #LAG's activity in tweets to 11% of #BLM. #LAG consists of several small groups, loosely connected, whereas #BLM has more connections between groups. Third, the largest #LAG group, includes just 5% of #LAG users. The group, marked with dark blue disks in the upper left of the map, is anchored by @gridironbeautie, a women's gridiron football enthusiast, who uses #LAG as an endorsement for women's athletics with posts such as "Say Hello to spring football #likeagirl @WFAfootball @IWFL @WWCFL @MWFLfootball @MyLFL @SSFLfootball https://t.co/tBkPWg7asH." In contrast, 49% of #BLM tweeters are connected to a news commentator, @blackvoices. An illustrative tweet, "Trayvon Martin was killed on this day four years ago. His death forever changed America. #BlackLivesMatter https://t.co/8iFqomMLQA."

More broadly, the #LAG group resembles the Twitter network associated with a brand, breaking news, or big event (Smith et al. 2015). Many users are likely to mention the topic without having connections to one another. Even the brand itself, @Always is connected to just 3% of users. In contrast, #BLM represents a clustered community featuring many hubs, each with a separate crowd of friends. Within #BLM, the hub and spoke nature of the large group anchored by @blackvoices is typical for media outlets or celebrity networks.

Discussion

While brands have added their voices to efforts to eradicate social stigmas, little is known about how brands' social messages are transmitted. Do the brands become central figures in their campaigns, broadcasting their message and build a tight network of adherents to the cause? This exploratory study suggests not. Instead, the #LGA network includes some small clusters of conversationalists; but most #LGA tweeters appear to use the message to further separate agendas. In contrast, #BLM network is dense, with tightly connected groups and with strong connections between groups, suggesting an ongoing conversation about the topic.

Delusion or Deception: Examining Racialized Stigma and Colorblind Politics in the Marketplace

EXTENDED ABSTRACT

Introduction

A peculiar phenomenon is afoot in the marketplace. As marketers make an exerted effort to assuage race-based marketplace discrimination and the racialized stigma that accompanies it by implementing race-neutral/colorblind policies and practices, the experience of racialized stigma does not appear to be lessening for non-white consumers. For instance, enacting nondiscriminatory policies on the basis of race is a customary practice in the marketplace which is typically further supported by federal mandate, yet previous research has demonstrated that the way in which a consumer is racialized bears significantly on the quality of service provided (Ainsworth and Motley, 2000), the assortment of available goods and services (D'Rozario and Williams, 2005), and the pricing of offered products (Talukdar, 2008). In each instance, researchers have found that non-white consumers are adversely impacted, receiving poorer quality service, fewer product options, and higher pricing than consumers from other racial groups. Why does race-based stigmatization continue to exist under the politics of colorblindness, which professes to destigmatize by providing equal treatment and opportunity to all regardless of racial background?

The purpose of this study is to deconstruct this peculiarity by investigating how colorblindness is practiced by marketers and experienced by consumers. We begin with an investigation of race from a socio-historical perspective. This is followed by an exploration of the tenets of colorblindness and the process by which race is reconceptualized through the politics of colorblindness. Utilizing a multifaceted methodological approach that includes a critical discourse analysis of historical and present-day marketing communications and depth interviews with 20 consumers in the U.S., we propose a framework for a colorblind/post-racial aesthetic used by marketers that underpins and potentially exacerbates race-based stigmatizing practices.

Race Historicized

From a socio-historical perspective the concept of race as it is currently experienced can be understood as a configuration of discourse and materiality supported by an historical context (Hall, 1997; Mills, 2014; Smedley, 1998). As a discursive construct race acts as a floating signifier, its meaning shifting with context and ideology (Hall, 1997). Race also serves as a historical construct. Race is a relatively new invention in the history of humanity. Its development coincided with the vast expansion of colonial and imperial projects by European powers. Race served to justify these projects. The construction of race enabled colonial/imperial subjects to be positioned as inferior bodies that required the stewardship of superior beings -- in essence, race was

developed to uphold/secure white supremacy (Smedley, 1998). Lastly, the language (i.e. discourse) of race combined with its historical context create material outcomes closely associated with racial categories (Mills 2014). For instance, with respect to the wealth gap in the United States, the median net worth of white households is 13 times greater than that of black households (Kochhar and Fry, 2014). That is to say, discursive practices combined with systemic and institutionalized policies that have historically favored whites has resulted in the materialization of dire wealth disparities.

Colorblind Politics | Post-racial Society

Many individuals who affirm colorblind politics believe the U.S. is now a post-racial society. The construct of a post-racial society assumes a social environment where racial preference, prejudice, and discrimination are obsolete (Squires, et al., 2010). Impressions of a post-racial America have in part been shaped by the election of Barack Obama as President, increased acceptance of interracial marriage, and shifts in advertising practices (Walker, 2003; Haq, 2010; Squires, et al., 2010). The primary arguments attached to colorblind/post-racial attitudes suggest that a person's racial classification no longer impacts their lived experiences. The politics of colorblindness are heavily rooted in meritocracy, or the belief that the hardest working and most qualified individuals will always succeed, regardless of their race. Equal opportunity, the belief that everyone is afforded the same possibility to achieve success, and personal responsibility -- The belief that people control their fates regardless of social position, and that individual behaviors and choices determine material outcomes (Bonilla-Silva, 2003). Together, these colorblind principles form a post-race ideology-- a set of philosophies individuals use to understand and assign meaning to society. Under post-race ideology the sociohistorical significance of race is obfuscated, and when issues of racial inequality are raised, they are rebuffed as "excuses", or a failure to assume responsibility for individual actions (Bonilla-Silva, 2006). The reconstruction of race in this way reinforces racial stigmas, as adverse material outcome related to race are attributed to an alleged innate substandard ability of these groups—arguments that frequently mirrors historical racial stereotypes (Bonilla-Silva, 2006). In essence, the politics of colorblindness appear to transform race from a dynamic hierarchal system of discursive and institutionalized power into an ahistorical construct that is no longer an outcome of materiality, but rather materiality becomes an outcome of race.

Preliminary Findings

Our preliminary data collection and analysis, which includes a critical discourse analysis of a randomly selected sample of print advertisements from the United States from the present dating back to the early 1900s supports our conceptualization of race, both from a socio-historical and post-race ideological perspective. From a socio-historical perspective the meaning of race in marketing communications has shifted over time. In the early 1900s, marketing communication often utilized race to normalize a hierarchical social system (e.g. Auntie Jemima and Uncle Ben), while during the civil rights movement advertisements explicitly visualized forms of black empowerment. Present-day advertisements often practice racial tokenism, wherein racial diversity and harmony are simulated through the limited and generally tangential inclusion of non-white models into an advertisement dominated by white bodies. Depth interviews with 20 American consumers (10 white; 10 black) are currently being analyzed to more deeply understand how consumers interpret and experience post-race ideology in the marketplace.

Divesting Identities: Counterbalancing and Demythologizing the Stigmatized Identity

EXTENDED ABSTRACT

Within consumer research, much has been written about the development, construction, restoration, and even rejuvenation of identities (Üstüner and Holt, 2007; Schau, Gilly, and Wolfinbarger, 2009; Moisio, Arnould, and Gentry, 2013; Thompson and Üstüner, 2015; Barnhart and Penaloza, 2013), but surprisingly much less attention has been given to the *divestment* of stigmatised identities. The relative absence of work focussing on less desired identity positions, leaves a conceptual vacuum in our understanding of today's reflexive, self-managing and personally edifying subject (Cronin, McCarthy and Delaney, 2015). We argue that outlining the tactics used to manage stigmatised identities could generate important insights for those seeking to improve consumers' quality of life and their existential security in a marketplace that places ever more pressure to reach for "perfection" (Mick et al., 2012).

In his seminal work, Goffman (1963, p.15) defined stigma as an "attribute that is deeply discrediting", reducing the person who possesses it "from a whole and usual person to a tainted, discounted one". We draw on the context of "overweight" women, to theorize how stigmatized consumers counterbalance (Toyoki and Brown, 2014) and demythologise an undesired, imposed identity (Arsel and Thompson, 2011). In order to do so we examine two powerful forces of stigmatisation – the medicalisation of fatness as obesity and the characterisation of fatness in popular culture. Our framing takes both inspiration and departs from that of Scaraboto and Fischer (2013) whose informants reappropriate the label "fat" to legitimise a new cultural identity of "fatshionistas" through which they challenge their exclusion from the fashion marketplace. Scaraboto and Fischer concentrate their analysis on consumer activism and market creation, we are, however, more interested in the cultural and medical discourses which underpin the mundane, everyday negotiations in familial and micro-social interactions.

Medicalisation is an overlooked phenomenon in consumer research but one which has far-reaching implications for consumer wellbeing. We characterise it as a clinical, dispassionate process of modernity in which consumption practices, bodily conditions and mental states that were previously considered to belong to normal human life are defined and treated as medical problems that can be solved through medical and scientific intervention. The medicalisation of fatness as obesity creates its own discourses, understandings and indeed, markets. As obesity is "constructed at the intersection of scientific knowledge and a complex of culturally-based beliefs, values, and ideals" (Gard and Wright, 2005, p.168), the identity trajectories and coping processes of fat consumers is an important context for study.

In order to achieve the research objectives outlined above, 28 in-depth, semi-structured interviews were conducted with "overweight" women (operationalized as UK size 18 and over), from a variety of socio-economic backgrounds. Studies have shown that women experience weight bias, stigmatisation and discrimination more than men, in part because women are more vulnerable to the Western 'thin ideal' and to contemporary fashions relating to beauty and sexual desirability (Puhl & Heuer, 2009; Roehling et al., 2007). This research therefore focuses exclusively on female participants. Interviews focussed on the informant's sense of self, her life world, her life course and her likes and dislikes about herself. Part-to-whole analysis (Thompson, Locander, and Pollio 1989) revealed informants had a hyper-awareness of their "overweight" status, and the negative stereotypes surrounding fatness - both the medicalised "obese" self and the caricatured "lazy", "greedy" person.

Informants thus spoke about feeling that their sovereignty was 'flanked on two sides'; firstly, through the medical gaze of doctors, marketers and science; and secondly, through the negative stereotypes of popular culture representation. The undesired and imposed medical identity of obese is concretised in a market of scientised, legitimised weight-control products and abstracted in the caricatures of television programs like *"Too Fat to Fly"*. Specifically we unpack the tactical processes by which these consumers manage others' perceptions of them, how they reconsider and reformulate the meanings of consumption for themselves and ultimately how they fashion identities in contra-distinction to pervasive stereotypes.

Informants' sought avenues of liberation through discursive tactics. These women warded off stigma through counter-balancing and demythologising discourses, 1.) by being vocal and defensive about their bodies, 2.) by avoiding scenarios that might instigate social judgement e.g. public consumption of unhealthy foods; and 3.) by discursively recasting what it means to fat e.g. discussing fitness activities. Further, the latter tactic of discursively recasting obese was materialised through the personas and narratives tethered to adjectives like "bubbly", "larger than life"; "funny", "warm", "good listener". Such identity work has the objective of changing negative perceptions about weight, enabling these women to divest themselves, at least in part, of the stigmatised identities forced upon them (Rice, 2007). We label this cohort the "New Fat" consumers, where fatness becomes a social construct preferable to the medicalised language of the bio-medical model and "medicalized marketplace" (Thompson, 2003).

This study makes several contributions to consumer research. Firstly, we enhance current understandings of the ambivalent infrastructure which makes up consumers' overall identity projects by illuminating the previously overlooked dimensions of divestment of stigmatised identities. Secondly, the development of alternative descriptors to counter-balance and ultimately replace the biomedical model imposed on them results in new characterisations of 'fatness' worthy of further investigation. In particular, our analysis demonstrates how these women manage the toxicities of social denigration in an era of dehumanising medicalisation to authorize and legitimate ostensibly authentic versions of themselves. Drawing from Oyserman's (2007) identity-based motivation model, it is possible to argue that our interviewees' positive characterisations of fatness – such as holding the comedic role, being a good listener, or being "bubbly" enable them to disarm stigmatising discourses arising from culture and/ or medicalisation. However this destigmatisation is not without its cost as informants describe the "extra" burden of this social labour.

SESSION OVERVIEW

Whether consumers relate to brands similarly to the way they relate to people has been a focus of consumer researchers and managers alike. For example, a substantial body of research has suggested that consumers' responses to brands are cognitively, emotionally, and behaviorally similar to their responses to people (Aggarwal 2004; Dunn and Hoegg 2014; Fournier 1998; Khamitov et al. 2016; Park et al. 2010; Sayin and Gürhan-Canli 2015; Thomson et al. 2005). However, other work has shown that the findings in the interpersonal domain do not frequently apply in the branding context (Whelan and Dawar 2014; Yoon et al. 2006). Similarly, marketing practitioners seem to exhibit a diversity of views – some document a consumer tendency to enliven brands and form emotional relationships with them (Cary 2000), while others doubt the existence of such relationships (Earls 2002). Thus, research that investigates conditions under which consumers' interactions with brands are either similar to or different from their interactions with people would enhance our understanding of the nature of consumers' connections with brands (Alvarez and Fournier 2016; Swaminathan and Dommer 2012). The aim of this session is to examine such consumer-brand connection processes. Specifically, the four papers in this session address the following questions: 1) under what conditions can brand and interpersonal relationships operate in parallel, and 2) how do these brand relationships impact and how are they impacted by interpersonal processes? Session attendees will learn about factors contributing to the similarities and differences between brand and interpersonal relationships and how these factors influence consumers' judgments and behaviors.

The first two papers focus on when and how consumers' interaction with brands are similar to interactions with people. Huang and Dou examine the effect of a brand's self-disclosure (intimate vs. superficial) on brand perceptions as a function of anthropomorphism that activates interpersonal processes in brand relationships.

They show that intimate brand disclosure increases brand closeness under high brand anthropomorphism, but does not increase desire for monetary exchange. Connors, Khamitov, Rotman, Thomson, and Perkins investigate how congruency between a brand's psychological distance to the self and a construal mindset enhances brand evaluations, documenting the results analogous to the findings in the interpersonal domain.

The last two papers examine the social factors that change perceptions and evaluations of brand relationships. Kim, Moore, and Murray show that socially excluded consumers turn to warm brands as relationship partners, and beyond transient consumption, these brand relationships can alleviate the relative deprivation of and the subsequent need for human connections. Lastly, Danienta and White investigate the effect of self-threat coming from social comparisons on the self and the brand relationship, finding that following negative feedback, consumers evaluate a highly self-connected brand more negatively.

Taken together, this session provides multifaceted insights into when and how consumers' responses to brands correspond to interactions between people. Exploring brands through potential extensions and limitations of interpersonal relationship theory can enrich our brand relationship theories. We expect this session to be of interest to researchers in the areas of brands, consumer-brand relationships and interpersonal relationships.

Brand Communication on Social Media: Effects of Non-Persuasive Self-Disclosure on Consumer Perceptions

EXTENDED ABSTRACT

Since relationship closeness promises sales (Sela, Wheeler and Sarial-Abi 2012), increasingly, brands directly communicate with consumers via social media to forge intimate relationships (Neff 2014). They may share information not directly related to products (e.g., inspiring quotes, hobbies, anecdotes). For example, Planters claims that "I like to work out and take leisurely lunches in the park." (Dahl 2014). While prior research emphasizes persuasive brand communications (e.g., Laran, Dalton, and Andrade 2011), non-persuasive tactics (i.e., self-disclosure) is less understood. In response to Brown (2010)'s call for more theoretical guidelines on social media communication, we explore how non-persuasive self-disclosure influences consumer perceptions.

Self-disclosure refers to the act of revealing personal information to initiate a more intimate relationship with the audiences (Collins and Miller 1994). In brand communication, this tactic may induce a priming effect as consumers behave in a manner implied by self-disclosure (Berger and Fitzsimons 2008). For example, the Wal-Mart brand primes thriftiness in shoppers (Chartrand et al. 2008). Altman and Taylor (1973) state that intimate disclosures (e.g., hopes and fears) generate more intimate feelings than superficial disclosures (e.g., general interest). Further, people who share more intimate information are liked more (Collins and Miller 1994). Therefore, a brand disclosing personal information should be more effective in close relationship building than those acting "formal."

However, we suggest that brand's self-disclosure may cause a reverse priming effect.

Laran et al. (2011) show that seeing the Walmart slogan "Save Money, Live Better" increases subsequent spending because of the

automatic correction to the persuasive tactics. The contents delivered by a brand may activate persuasive knowledge for correction (Oza, Srivastava, and Koukova 2010) such that consumers may infer the persuasive intent and act in a contrary manner. We propose that brand anthropomorphism can impact consumers' reactance to brand's self-disclosure.

Anthropomorphism, a tendency to attribute humanlike characteristics to nonhuman objects, can delude defensive mechanisms (Epley et al. 2007). People regard anthropomorphized objects more moral (Gray, Gray, and Wegner 2007). Anthropomorphized brands trigger consumers' goals for social interactions and cause behavioral assimilation to the liked brand (Aggarwal and McGill 2012). Thus, people perceive self-disclosure by a highly anthropomorphized brand with less persuasive intents and thus decrease resistance. However, self-disclosure by a lowly anthropomorphized brand may arouse persuasive inferences and trigger reactance. We have tested this prediction in three studies.

In study 1, an apparel brand's followers (N=269) on the Chinese biggest micro-blogging site participated in a 3 self-disclosures (intimate vs. superficial vs. baseline) x anthropomorphism tendency measured design field experiment. This experiment contained three phases. This brand had not been using a self-disclosure tactic previously. So, the most recent eight days persuasive contents were screenshot as the baseline stimuli for phase 1. Then intimate disclosures (personal emotions & secrets) were posted for eight days in phase 2. Five days later, superficial disclosures (weather & food) were posted for eight days in phase 3. Participants completed a survey at the end of each phase and answered questions on their feeling closeness to the brand (Edwards, Lee and Ferle 2009), Inclusion-of-Other-in-the-Self (IOS) (Aron et al. 1992), and the anthropomorphism tendency (AT) (Waytz et al. 2010) based on the snapshots of each disclosure condition. This process involved a between-subject design with every participant taking the survey only once.

Regression analysis revealed significant interactions of intimate*AT (B = .22, t(263) = 3.96, p < .001) and superficial*AT (B = .13, t(263) = 1.88, p < .07) on closeness. The slope was positive in the intimate (B = .26, t(263) = 9.99, p < .001), superficial (B = .17, t(263) = 3.40, p < .01), and insignificant in the baseline condition (p > .44). Spotlight analysis (Fitzsimons 2008) indicated higher closeness in intimate than in superficial disclosure (B = –2.22, t(263) = –4.84, p < .001) or baseline (B = .99, t(263) = 6.18, p < .001) at AT(+1SD). No differences were at AT (-1SD). Similar results occurred on IOS, providing an initial support for a priming effect when anthropomorphism was high.

Study 2 measured the actual brand anthropomorphism of a hypothetical watch brand in the lab. 97 undergraduates in Hong Kong joined a 2 disclosures (intimate vs. superficial) x brand anthropomorphism measured study. They read the snapshots of the brand's Twitter either sharing intimate or superficial information. Then they reported feeling closeness, interaction likelihood, and brand anthropomorphism (α = .91; Aggarwal and Mcgill 2007). Regression analysis revealed a main effect of disclosure ((B = .79, t(94) = 4.74, p < .001), brand anthropomorphism(B = .47, t(94) = 7.49, p < .001), and their interaction (B = .26, t(93) = 2.11, p < .04). Higher closeness was observed in intimate than superficial condition at brand anthropomorphism (+1SD) (B = 1.14, t(93) = 4.90, p < .001) but the pattern reversed at brand anthropomorphism (-1SD) (B = .44, t(93) = 1.90, p < .07). Same patterns occurred on interaction likelihood. These results replicated study 1 and documented a reverse priming effect when brand anthropomorphism was low.

Study 3 manipulated thinking style evaluating a skin care brand Twitter. 148 American

undergraduates engaged in a 2 thinking (anthropomorphism vs. object) × 2 self-disclosures (intimate vs. superficial) between-subject study. We manipulated thinking style by asking the subjects to evaluate the brand by human personalities vs. object attributes (Chandler and Schwarz 2010). Then we tested the closeness, brand evaluation and willingness to pay. An ANOVA revealed a main effect of the disclosure (F(1,112) = 7.76, p < .01), the thinking style(F(1,112) = 32.6, p < .001), and their interaction (F(1,112) = 9.21, p < .01) on closeness. Closeness was higher in the intimate as compared to superficial disclosure under the anthropomorphic thinking while the reverse was true under the object thinking. Interestingly, while the brand evaluation replicated closeness patterns, WTP showed the opposite results. The results imply that intimate disclosure by anthropomorphized brand may enhance brand evaluation but decrease monetary exchange desires.

This research contributes to an understanding of the non-persuasive marketing communication effects and has important implications for brand's marketing communication in the digital world.

Fostering and Leveraging Consumer-Brand Relationships: A Psychological Distance Perspective

EXTENDED ABSTRACT

A substantial body of research has focused on understanding the various types of relationships that consumers form with brands (Fournier 1998; Miller, Fournier, and Allen 2012). However, less emphasis has been placed on identifying how managers can differentially leverage these brand relationships in order to facilitate more positive outcomes. To address this, the current research examines how the nature of brand relationships influence perceptions of a brand's closeness to the self and, when matched with the appropriate construal level, can result in mindset congruency effects that positively impact consumers' brand evaluations.

Extant research demonstrates that consumers' brand relationships may parallel their interactions with other people (Fournier 1998; Aggarwal 2004). Drawing from the construal level theory of psychological distance (CLT: Trope and Liberman 2010), a key feature of interpersonal relationships is their ability to influence perceptions of the relationship partners' closeness to the self. For example, one's relationship with their sister is more psychologically proximal, whereas one's relationship with a server at a restaurant is more distal. Similarly, extant branding literature shows that consumers can form strong connections between the brand and the self (Escalas and Bettman 2003; 2005), and that individual-level differences exist in the tendency to form such connections (Sprott et al. 2009). Synthesizing these literatures, we posit that brand relationships should impact perceptions of the brand's closeness to the self, shedding light on important opportunities for marketers to better foster brand relationships and better leverage their value.

If brand relationships impact consumers' perceptions of psychological distance, this subjective difference in closeness to the self should be directly related to one's construal level when processing information pertaining to the brand. CLT states that objects that are psychologically distant to the individual are represented by high-level construal, whereas objects that are near to the individual are represented by low-level construal. As such, we posit that the nature of a brand relationship affects consumers' perceptions of the brand's closeness to the self resulting in congruency effects when matched with the appropriate construal level. Specifically, we show that when psychologically close (distant) brands are matched with a low-level (high-level) construal mindset, it results in a mindset congruency effect which facilitates more positive brand evaluations and influ-

ences actual consumer spending. Importantly, we demonstrate that this congruency effect is mediated by increased processing fluency (Lee and Labroo 2004).

Study 1 manipulates brand relationship type (committed, secret affair) and construal level (high, low) to test the mindset congruency effect. Participants first nominated a brand that they felt matched the description of the target relationship type (Miller, Fournier, and Allen 2012). Construal level was manipulated by instructing participants to elaborate on either *how* (low-level) or *why* (high-level) they use the brand. Results support the hypothesized mindset congruency effect. Across three dependent variables (attitudes, trust, and relationship satisfaction) responses were more favorable when participants in the psychologically proximal 'committed' relationship condition were in a low-level construal mindset. In contrast, participants in the psychologically distal 'secret affair' condition displayed more favorable responses in a high-level construal mindset (p's <.05).

Study 2 provides a conceptual replication of the mindset congruency effect using a direct manipulation of brand closeness, a subtler concreteness-based manipulation of construal level, and measures of behavioral intentions. The study was conducted under the guise that researchers were interested in testing a new online product quality rating system, *International Standard*, which compiles information from online sources (e.g. consumer reports, online product reviews, etc.) to evaluate the overall quality of a brand. Adapting the Inclusion of Other in Self scale (Aron, Aron, and Smollan 1992) to manipulate brand closeness, participants provided the name of a brand that either had 'very large' self-overlap or was 'separate' from the self and were then instructed to wait while the system calculated a quality score for their brand. After a delay, the system informed participants that their brand had received a score of 9.2/10. Construal level was manipulated by providing participants with a list of the "top five factors that contributed to the *International Standard* score that the brand received" that varied based on *how* (concrete) or *why* (abstract) the brand received the score that it did. Results again provide evidence to support the pattern of the brand closeness ´ concreteness interaction across all three brand evaluation variables in addition to purchase intentions and word of mouth (p's <.05).

Study 3 provides a conceptual replication of the effect and undertakes an empirical examination of the proposed fluency mediator. To manipulate closeness, participants nominated a brand that represented either a 'committed' (close) or 'secret affair' (distant) brand relationship. Participants' brands were then used in the same *International Standard* manipulation of concreteness followed by measures of the fluency mediator and dependent variables. Significant and contrasting conditional indirect effects (Model 8; Hayes 2013) support the hypothesized mindset congruency effect being mediated by increased processing fluency across all three dependent variables used in study 1 (95% confidence intervals did not contain zero). Matching the psychological distance associated with a given brand relationship type with the appropriate construal level increases processing fluency leading to more favorable brand evaluations.

Study 4 embeds a concreteness manipulation within a co-branded charity appeal advertisement to demonstrate that the construal mindset congruency effect that arises when closeness is matched with an appropriate construal level carries over to impact the amount of money donated to a charity affiliated with the target brand. Results show that at higher (lower) levels of brand closeness, participants donated more when the charity advertisement appeal used concrete (abstract) language.

This research contributes to the branding literature by demonstrating that consumers view brands more favorably when they receive information that matches the construal level associated with the psychological closeness of the brand. This mindset congruency effect results in the information being processed more fluently, which facilitates more positive brand evaluations and intentions. Based on these findings, marketers are advised to match the concreteness of their marketing communications with the closeness associated with the types of relationships that the target market experiences with their brand.

Warm Brands as Relationship Partners: The Dynamics of Social Exclusion, Brands, and Interpersonal Connection

EXTENDED ABSTRACT

People have a fundamental need to form positive and lasting relationships (Baumeister and Leary 1995). When people are socially excluded—that is, when they are isolated or excluded by groups or individuals (Williams 2007)—this disrupted social connectedness brings negative downstream consequences such as anxiety and depression (DeWall and Bushman 2011). Thus, excluded individuals engage in coping behaviors to alleviate this adverse state. Recent work has examined consumption as a coping behavior following social exclusion, such as engagement in strategic consumption for the purpose of social inclusion (Mead et al. 2011), conspicuous consumption (Lee and Shrum 2012) or nostalgic product consumption (Loveland, Smeesters, and Mandel 2010). However, little is known about the implications of social exclusion for consumer-brand relationships and for the subsequent dynamics between brands and interpersonal relationships. Thus, this research investigates (1) whether consumption following social exclusion is transitory, that is, fades away once consumption is complete, or it can trigger brand attachment, leading to meaningful consumer-brand relationships and (2) how these brand relationships formed under social exclusion influence the subsequent need for social connections.

Warmth and competence are important dimensions that characterize consumers' interactions with brands (Aaker, Garbinsky, and Vohs 2012; Kervyn, Fiske, and Malone 2012). Warmth reflects consumers' perceptions of brands' intentions as positive or negative; brands perceived as friendly and sincere are seen as warm. Competence concerns brands' abilities to carry out its intentions; brands that possess a skill set to execute functions successfully are perceived as competent (Bennett and Hill 2012). Existing research has presented competence as a main driver of consumers' purchase intention (Aaker et al. 2010). However, in the context of social exclusion, we argue that the deprivation of social connection should lead consumers to attend to brands' warmth, the image of which is akin to social closeness, more than brands' competence. Such social closeness imbued in warm brands may have a powerful impact on consumers' psychological attachment to warm brands similarly to the way sharing adversity with those present during a difficult time creates strong attachment to others (Sarnoff and Zimbardo 1961). Thus, we predict that when people are socially excluded, it will trigger emotional attachment to warm brands, thereby leading to continuous brand consumption. In addition, Foa (1993) argues that people deprived of the most needed resource tend to choose the resource similar to the deficient one. Along the line, we predict that in the context of social exclusion, warm brands will function as social resource, which is close to social warmth, creating relative abundance and thereby alleviating the deprivation of and the need for the social connectedness.

Prior to testing our predictions, we created and pre-tested two hypothetical brands: "Sammy (heart) Danny" as a warm brand and "Smith & Dent" as a competent brand. The results showed that the "Sammy (heart) Danny" brand was perceived as a warm but less

competent brand, while "Smith & Dent" as perceived as a competent but less warm brand (all $p < .005$; N = 42, M_{age} = 31.9).

In Study 1 we tested the effects of social exclusion on emotional brand attachment and brand short-term and long-term consumption. MTurk participants (N = 121, M_{age} = 33.7) completed a writing task in which they were randomly assigned to one of two conditions: (1) social exclusion and (2) no exclusion (Lee and Shrum 2012). Next, participants viewed both two laptop bags presented as either warm or competent (as pre-tested above) and indicated their purchase and repurchase intentions for the brand (1 = not at all, 7 = very much). They also rated the extent to which they felt passionate, connected, and affectionate toward each brand (emotional brand attachment; Thomson et al. 2005). The repeated measure analysis revealed that when people were socially excluded, they were significantly more likely to purchase the warm than the competent brand ($F(1, 118)$ = 5.23, $p = .024$; = 5.31 vs. = 4.37). Socially excluded participants were also marginally more willing to repurchase the warm than the competent brand ($F(1, 118)$ = 3.05, $p = .08$; = 5.39 vs. = 4.41). Bootstrapping analyses (Hayes 2013) showed that emotional brand attachment significantly mediated the effects of social exclusion on warm brand purchase and repurchase intentions (95% CI [0.0228, 1.1314] and 95% CI [0.005, 0.888] respectively).

Study 2 tested how social exclusion interacts with brand types to affect the state of deprivation and the need for social connection. Similar to Study 1, all MTurk participants (N = 111, M_{age} = 40.35) were asked to write about their social exclusion experience, and were randomly assigned to view (1) a warm brand, (2) a competent brand, or (3) no brand; in the no brand condition, participants did not see any brand and reported their deprivation of and need for social connection. The regression analysis showed that socially excluded participants were more emotionally attached to the warm brand ($t(72)$ = 4.54, $p < .001$) and more likely to purchase ($t(72)$ = 2.36, $p < .05$) and repurchase the warm brand ($t = 2.95, p < .01$), as compared to the competent brand. Importantly, participants in the warm brand condition were feeling less deprived of social connection ($t(108)$ = -2.04, $p < .05$) and indicated a lower need for connection with people (than those in the competent brand condition ($t(108)$ = -2.04, $p < .05$), while the differences between the competent and no brand conditions were not significant (all $p > .40$).

In conclusion, our findings contribute to an understanding of the relations between social adversity, brands, and human relationships: Not only do socially excluded consumers turn to warm brands, but, as a result, they feel less deprived of and less in need of human connections. By showing how brands can fill the social roles in thwarted social relationships, we hope that our work will interest researchers in the areas of social adversity, interpersonal and consumer-brand relationships.

Seeing Brands Through "Me" Colored Glasses: Effects of Self-Threat and Brand Attachment on Brand Evaluations

EXTENDED ABSTRACT

It is well documented that consumers use brands to shape and reflect who they are and want to be (e.g., Belk, 1988; Fournier 1998; Escalas and Bettman 2003). An important type of brand attachment can be referred to as a self-brand connection (SBC). A key premise of recent research on SBC is that, if it is possible that the brand concept (i.e., the way consumers think about the brand) can *reflect* consumers' self-concept, then it is also possible that the brand concept can *affect* consumers' self-concept. If so, consumers' sense of self-worth may be adversely influenced by exposure to negative brand information. Indeed, research by Cheng, White and Chaplin (2012)

confirms this possibility. Their research demonstrates that consumers with high SBC respond to negative brand information as they do to personal failure – they experience a threat to their positive self view. These findings highlight important, yet unintended *outcomes* of consumer brand attachments.

In this research, we further explore consequences of SBC. Specifically, we examine the notion that if the brand concept can affect the self-concept of high SBC consumers, then the opposite might also be true. Is it possible that consumers' beliefs about themselves influence their beliefs about the brands to which they feel connected? Is it possible that the experience of self-threat, which can make consumers feel worse about themselves, can also make them feel worse about their high SBC brands? We examine these questions in the context of brand evaluations. In three experiments, we demonstrate that self-threat decreases high (vs. low) SBC consumers' brand trust judgments. Moreover, these effects extend to perceptions of brand competence and attractiveness.

Literature and Hypotheses

Self-affirmation theory posits that people are motivated maintain a positive self-concept (Steele 1988). Yet, individuals often experience incidents that threaten this belief. For example, consumers sometimes feel shame about their appearance when they view attractive models (Gulas and McKeage 2000), or feel incompetent when they realize they paid more than others for an identical item (Argo, White, and Dahl 2006). In response to these incidents, individuals are often motivated to reduce self-threat and restore a positive self-view by derogating others (Campbell and Sedikides 1999) or by choosing products that bolster the threatened aspect of the self (Gao, Wheeler, and Shiv 2009).

Consistent with prior research, we argue that, when consumers' self concept is threatened, they experience a "shake" - a temporary decrement - to their self-confidence (Gao et al. 2009). However, we explore an important, yet largely unexplored, consequence of this "shake," namely a marked decrease in consumers' judgments of their own trustworthiness. Self-trust reflects a positive sense of one's own motivations and values (Govier 1993). Lack of self-trust stems from a decreased confidence in one's ability to meet expectations (Gambetta 2000). We argue that self-threats, particularly those resulting from negative feedback, decrease consumers' self-trust and, therefore, their trust in highly connected brands.

Method and Results

Prior to Studies 1 and 2, SBC perceptions were measures for several brands using the scale developed by Escalas and Bettman (2003). Based on the results of the pretests, we selected exemplars of high and low SBC brands. For the sake of brevity, we only report findings from S2 and S3 below.

In S1, respondents were randomly assigned to either a high (Apple) or low (Blackberry) SBC condition. After reading an article about the correlation between IQ and success, participants completed a Remote Associates Task (RAT) (Mednick et al. 1964) and were randomly assigned to receive either negative performance feedback (i.e., scores in 23rd percentile on the RAT) or no feedback. Next, in an ostensibly unrelated task, respondents rated trusting beliefs about either Apple or Blackberry using measures by Schlosser, White, and Lloyd (2006).

The procedure in S2 is similar to S1 except we used Nike and Reebok as exemplars of high versus low SBC brands, respectively. In addition to trust beliefs, we also measured respondents' ratings of how smart they believe the brand to be. If receiving negative performance feedback adversely affects performance self-esteem

(Shrauger and Rosenberg 1970), respondents should feel less smart following negative feedback and, consistent with our predictions, report lower smartness ratings for high SBC brands.

A two-way ANOVA revealed a significant main effect for SBC ($F (1, 84) = 11.46$; $p < .001$) that was qualified by an SBC X Feedback interaction ($F (1, 84) = 4.626$; $p < .05$) for brand smartness ratings. As predicted, whereas feedback had no effect on perceived smartness for those in the low SBC conditions ($M_{control} = 4.68$; $M_{negative} = 4.95$; $F (1, 84) = ns$), smartness ratings were significantly lower following negative feedback for those in the high SBC conditions ($M_{control} = 6.19$; $M_{negative} = 5.29$; $F (1, 84) = 19.790$; $p < .001$). Similarly, planned contrast analyses of a marginally significant SBC X Feedback interaction ($F (1, 84) = 2.960$; $p < .09$) for trust ratings reavealed that, although trust ratings did not depend upon feedback for those in the low SBC condition ($M_{control} = 4.09$; $M_{negative} = 4.36$; $F (1, 84)$, ns), brand trust was significantly lower following negative feedback for high SBC respondents ($M_{control} = 5.34$; $M_{negative} = 4.35$; $F (1, 84) = 9.143$; $p < .05$).

In study 3, we measured SBC for the focal brand, Gap. We also manipulated appearance threat (Park and Maner 2009). Finally, in addition to brand trust, we measured brand attractiveness. We regressed attractiveness ratings and trust judgments on SBC, appearance threat, and their interaction. As predicted, for attractiveness ratings, a significant SBC main effect was qualified by a significant SBC X Appearance Threat interaction ($B = -.339$; $p < .05$). Similarly, trust judgments were significantly affected by SBC as well as the SBC X Appearance Threat interaction ($B = -.306$; $p < .05$). For both DVs, high (but not low) SBC respondents' ratings were significantly lower following negative appearance feedback.

Paper #4: Evaluating Anthropomorphized Products Less Positively: "Shame on Me!"

Ping Dong, University of Toronto, Canada
Pankaj Aggarwal, University of Toronto, Canada

SESSION OVERVIEW

Anthropomorphism refers to the tendency to imbue nonhuman agents with humanlike characteristics, motivations, intentions, or emotions (Epley, Waytz, and Cacioppo 2007). As a common phenomenon in consumption environments, anthropomorphism has drawn wide attentions from both social psychology and consumer researchers (Aggarwal and McGill 2012). Previous consumer research has largely focused on how imbuing products with *general* humanlike features affects liking of products (e.g., Aggarwal and McGill 2007). However, relatively fewer studies have attempted to identify the *specific* humanlike features that drive the effects. The four papers in this session identify important cognitive and emotional processes associated with such specific humanlike features, and explore new implications for consumer behaviors.

In particular, the first two papers in the session focus on consumers' perceptions of anthropomorphized products. The paper by Jia et al. explores the effect of "bodily consideration" activated by anthropomorphic product presentations on preferences for complementary accessories. Huang, Wong and Wan's research suggests that consumers tend to treat an anthropomorphized product as an integrated entity, and explores the implications for comparative judgment strategies. The remaining two papers link anthropomorphism research with feelings or emotions. The paper by Wang, Zhou, and Kim introduces the role of perceived warmth of anthropomorphized money in a charitable giving context. Dong and Aggarwal demonstrate shame as a novel emotional antecedent on consumers' evaluation of anthropomorphized products.

The first paper shows in four studies that anthropomorphic presentations of a base product (e.g., making a *Canon* printer "talk" in a video advertisement) increase consumers' choice share of complementary accessories from the same brand that provides the base product (e.g., *Canon* ink cartridges) over accessories from a different brand (e.g., *Staples* ink cartridges). This effect occurs because anthropomorphism activates a "bodily consideration" and consumers are biologically averse to foreign body-related substances.

In the second paper, five experiments show that anthropomorphism of product alternatives increases the chance that consumers use an absolute judgment strategy (vs. dimension-by-dimension strategy) in comparative judgment. This effect is mediated by consumers' perception of each anthropomorphized alternative as an integrated entity (vs. a bundle of attributes).

The third paper explores what happens when people think of money as a human. This research systematically examines in six studies the effect of money anthropomorphism on charitable giving, and finds that money anthropomorphism leads people to consider money to be warmer and thus makes people more inclined to donate.

Finally in the fourth paper, four studies demonstrate that experiencing shame (vs. fear, sadness, or neutral emotion) decreases consumers' preference for anthropomorphized products. The effect is driven by a heightened desire to avoid social contact, and is stronger for consumers with interdependent (vs. independent) self-construal and for products consumed in private (vs. public).

Taken together, these papers present new insights and directions in anthropomorphism research. Given the growing impact of anthropomorphism in consumer research and its marketing implications, we expect this session to generate high interest among ACR attendees and spark future research, as well as engage the audience to discuss the interpretation of many consequences of anthropomorphism. I Need My Own Substance! Effects of Anthropomorphic Product Presentations on Brand Choice of Complementary Accessories

EXTENDED ABSTRACT

Many firms across various industries adopt a "razor-and-blade" business model, in which these firms attract consumers by offering a base product (e.g., a razor) at a low price and then earn their real profit from consumers' repeated purchases of complementary accessories (e.g., replaceable blades) for the base product (Teece 2010). Oftentimes, this business model faces threats from competing generic brands that offer cheaper alternative accessories to consumers.

In this research, we examine whether marketers can subtly vary the way they present a base product to change consumers' subjective perception of the product, as a solution for protecting their market share in the accessory market. Specifically, we focus on anthropomorphic product presentations, that is, making a base product look, move, or talk as a human being in ads, product appearances, or consumer-product interfaces (Aggarwal and McGill 2007; Kim and McGill 2011).

We propose that anthropomorphic presentations of a base product (e.g., a *Canon* printer) will increase consumers' choice share of

complementary accessories provided by the same brand that offers the base product (e.g., *Canon* ink cartridges) over accessories from a different brand (e.g., *Staples* ink cartridges). This is because there is a "whole-part" relationship between a base product and its complementary accessories, so that anthropomorphic presentations of the base product will activate a "bodily consideration" — consumers are biologically averse to foreign body-related substances (Tybur, Lieberman, and Griskevicius 2009), and they also project such an aversion onto accessories from a different brand, which represent "foreign body substances" to the anthropomorphized base product.

In Study 1, we assigned 156 undergraduates to two conditions. In the anthropomorphic condition, participants watched a video in which a Canon printer appeared to introduce itself from a first-person perspective (it also moved its "lips" when "talking"); in the non-anthropomorphic condition, the same Canon printer was introduced from a third-person perspective (see Puzakova, Kwak, and Rocereto 2013 for similar manipulations). Then, participants made a choice between a Canon ink cartridge and a low-cost alternative provided by Staples. We found that participants were more likely to choose the Canon ink cartridge for the Canon printer in the anthropomorphic condition (50.0%) than in the non-anthropomorphic condition (34.2%; *Wald* = 3.94, *p* < .05).

In Study 2, we presented a Samsung laptop computer to participants with a video manipulation similar to that used in Study 1. After participants (*N* = 201) watched the video, they were instructed to imagine that they had just purchased the Samsung laptop computer, and to further choose between a Samsung hard drive and a Toshiba hard drive for their Samsung laptop computer. Then, participants rated the perceived compatibility between the Samsung laptop computer and the Toshiba hard drive ("be compatible with/work well with," α = .97). Replicating the results of Study 1, we found that participants were more likely to choose the Samsung hard drive for their Samsung laptop computer in the anthropomorphic condition than in the non-anthropomorphic condition (79.0% vs. 62.4%; *Wald* = 6.55, *p* < .01). Furthermore, anthropomorphic product presentation decreased the perceived compatibility between the Samsung laptop computer and the Toshiba hard drive (5.01 vs. 5.62; *F*(1, 199) = 7.29, *p* < .01), and such a decrease in the perceived compatibility mediated the effect of anthropomorphic product presentation on brand choice (95%CI: .15, .89).

In Study 3, we again used the Samsung laptop videos to manipulate anthropomorphism and added a second between-subjects factor to the experimental design. A half of participants made a decision on hard drives for their Samsung laptop computer as those did in Study 2, and the other half made a decision on what tablet computer (Samsung vs. Toshiba) to buy together with their Samsung laptop computer. There was an interaction between anthropomorphic presentation and decision target (*N* = 201; *b* = -1.12, *z* = -1.88, *p* = .06). In the hard drive condition, we replicated our results, such that the anthropomorphic presentation of the Samsung laptop computer increased the choice share of the Samsung hard drive over the Toshiba hard drive (74.5% vs. 54.7%; *b* = .83, *z* = 1.95, *p* = .05). In contrast, this effect disappeared when the decision target was tablet computer (*b* = -.29, *z* = -.70, *p* > .48). These results demonstrated that anthropomorphic product presentations only influence consumers' brand choice of accessories for the base product, but not their brand choice of other products that can work independently of the base product. Such findings are consistent with the "bodily consideration" account — a "whole-part" relationship does not exist between a laptop computer and a tablet computer, and thus a "bodily consideration" should not be activated, consequently inhibiting consumers' projection of their own aversion to foreign body-related substances onto this context.

In Study 4, we manipulated product anthropomorphism using print ads. In the anthropomorphic condition, a Philips electric toothbrush was described from a first-person perspective, while the same electric toothbrush was presented from a third-person perspective in the non-anthropomorphic condition. After imagining having decided to buy the Philips electric toothbrush, participants (*N* = 102) chose between a Philips replacement brush head and a low-cost alternative provided by Up & Up (a store brand owned by Target) for their Philips electric toothbrush. Replicating the previous results, we found that participants were more likely to choose the Philips replacement brush head for their Philips electric toothbrush in the anthropomorphic condition (52.8%) than in the non-anthropomorphic condition (30.6%; *Wald* = 5.05, *p* < .03). In addition, at the end of the survey, we measured participants' chronic aversion to foreign body-related substances (e.g., "having a blood transfusion) with a four-item scale (α = .81). We found that the effect of anthropomorphic presentation on brand choice of accessories increased with participants' chronic aversion to foreign body-related substances (*b* = .55, *z* = 2.05, *p* < .04), further supporting the "bodily consideration" account.

In sum, our research contributes to the literature on product anthropomorphism by demonstrating that anthropomorphism can activate a "bodily consideration" in the context of accessory decision. The findings also enrich our understanding of consumers' brand choice of complementary goods. (1000 words)

The Influence of Product Anthropomorphism on Comparative Judgment Strategy

EXTENDED ABSTRACT

Previous research has shown that anthropomorphism can influence evaluation of a product when considered in *isolation* or in comparison with *non-humanized* product (e.g., Aggarwal and McGill 2007; Chandler and Schwarz 2010; Kim and McGill 2011). However, little is known about the influence of anthropomorphism on comparisons among several anthropomorphized alternatives presented simultaneously. Intuitively, the effect of anthropomorphism may be cancelled out in such a context, if the effect of anthropomorphism is considered for each product alternative individually. The present research, however, suggests that anthropomorphism influences the comparative strategy to process the product information, and eventually affects consumers' preference.

Consumers who have to make a decision between different choice alternatives may compute a preference in at least two ways. On one hand, they may perform a *dimension-by-dimension comparison* and choose the alternative that is superior with the greatest number of dimensions (Shafir, Simonson, and Tversky 1993). Alternatively, consumers may first estimate the overall attractiveness of each alternative by integrating the values along the dimensions and then choose the alternative with the greatest overall attractiveness (*absolute judgment process*; Parducci 1965). The final decision can be quite different, depending on which strategy is adopted (Park and Kim 2005). That is, the alternative scoring higher on overall attractiveness may be inferior along more dimensions than the other alternative(s).

When product alternatives are presented in a humanized manner, consumers tend to treat each alternative as an organic whole with a soul rather than a loose combination of instrumental attributes—similar to the way we treat people (McGill 1998). Just like each person is distinctive, each humanized product as an integrated entity is perceived as structurally distinct from other humanized products, and should not be broken down to pieces and compared by individual dimensions mechanically (Chandler and Schwarz 2010; Fiske and

Neuberg 1990). We propose that when confronting a consideration set in which all alternatives are anthropomorphized (vs. non-anthropomorphized), consumers are more likely to perceive each alternative as an integrated entity and thus, increase their chance to use an absolute judgment strategy.

Experiment 1 tested the effect using a choice task with a one-factor, two-level design (anthropomorphism vs. non-anthropomorphism). Specifically, each participant was presented with two laptops to choose. One laptop (i.e., absolute-dominant laptop) was designed to be preferred if participants use an absolute judgment comparative strategy (i.e., with an overall higher performance), while the other laptop (i.e., dimension-dominant laptop) was designed to be preferred if a dimension-by-dimension strategy is used (i.e., with a greater number of superior dimensions). Anthropomorphism was manipulated by describing the laptops in a human-like tone and by asking participants to concentrate on thinking of each laptop as a person. As expected, anthropomorphism increased participants' choice of and preference for absolute-dominant alternative.

Experiment 2 tested the underlying mechanism using a moderation-of-process design. We expected that the effect of anthropomorphism on comparative judgment strategy should not hold when participants are led to believe that even human attributes are autonomous and can be detached from each other. The experiment had a 2 (belief of human attributes: autonomous vs. integral) × 2 (anthropomorphism of products: anthropomorphism vs. non-anthropomorphism). Participants first read a paragraph containing arguments that human attributes are either "autonomous and contribute individually" or "integral and embedded to each other" (general trait manipulation approach; Chiu, Hong, and Dweck 1997). Then, similar to experiment 1, participants were presented with a pair of either anthropomorphized or non-anthropomorphized smart phones for evaluation. When participants were led to believe that human attributes are integral, the results replicated those in experiment 1. However, the effect diminished when they were led to believe that even human attributes can be detached and evaluated individually.

To provide direct process evidence of the judgment strategies elicited by anthropomorphism, process-tracing software Mouselab was used in experiment 3. Participants were asked to evaluate two alternatives of restaurants, both described in either a human-like tone or a non-human-like tone. Information of the restaurants was presented on the computer screen in the form of a 2 (alternative) × 3 (attribute) matrix. The information in the matrix was hidden behind masked boxes, and the participants had to open one box at a time by moving a mouse-controlled cursor to the box. Mouselab recorded which boxes the participants opened, and in what sequences. The amount of alternative-based cursor movements relative to attribute-based movements was calculated in a way suggested by Payne, Bettman and Johnson (1988), and this value was significantly higher in anthropomorphism condition than in non-anthropomorphism condition.

Experiment 4 tested the effect using eye-tracking technique with real information of products. Participants were presented with two alternative digital cameras to choose—described either in a human-like manner or not. Participants' eyeballs movements were recorded by an eye-tracking machine and analyzed using the method similar to the MouseLab study. The results replicated those from experiment 3.

Experiment 5 further tested the effect in a real choice context. Participants were told that they can get a bag of corn snack for free, and were asked to make a choice between two corn snack alternatives based on the package pictures and descriptions, which were displayed in a way similar to online shopping. Anthropomorphism of snack alternatives was manipulated using human-like or non-human-like packages. Consistent with expectation, participants were more likely to choose the absolute-dominant snack in the anthropomorphism condition than in the non-anthropomorphism condition. Importantly, participants' perception of each product as an integrated entity or a bundle of attributes was directly measured, and was found to mediate the effect of anthropomorphism on the choice they made.

To summarize, in five experiments involving comparative judgments of products in various categories, we show that anthropomorphism leads to perceptions of each product alternative as an integrated entity (vs. a bundle of attributes), and thus increases consumers' chance to use an absolute judgment strategy. While previous anthropomorphism literature rarely compares multiple anthropomorphized products presented simultaneously—a context that is pervasive in everyday consumption—this research fills this gap. Additionally, this research contributes to comparative judgment literature by identifying anthropomorphism as a new antecedent of judgment strategy. (1000 words)

Money Helps When Money Feels: Money Anthropomorphism Increases Charitable Giving

EXTENDED ABSTRACT

Throughout history, philosophers and psychologists have considered money as a negative force that weakens social bonds and reduces people's tendency to help others (Marx 1844, 1964; Vohs, Mead, and Goode 2006, 2008). However, is it possible that thoughts of money can actually promote helping and charitable giving to others? What happens when people think of money as a person? Will money anthropomorphism increase charitable giving? In the present research, we propose that money anthropomorphism, imbuing money with humanlike characteristics, leads people to consider money to be warmer and in turn makes people more inclined to donate. Across seven studies including one pilot study, we tested our hypothesis.

In the pilot study, we examined consumers' dispositional tendency to anthropomorphize money and its correlation with their donation intention. We also measured a general tendency to anthropomorphize any entities to show our effect is specific to money anthropomorphism. A correlation analysis revealed that a consumers' dispositional tendency to anthropomorphize money was positively correlated with their donation intention, whereas the general tendency to anthropomorphize any entities was not. The findings provided preliminary evidence to support our argument that money anthropomorphism can enhance charitable giving. In the main studies, we manipulated money anthropomorphism to examine the casual effect of money anthropomorphism on charity donations.

In Study 1, we used a previously validated anthropomorphism manipulation (Aggarwal and McGill 2007), and show participants in the anthropomorphism condition displayed a higher donation intention ($M = 4.42$, $SD = 1.98$) than those in the object condition ($M = 3.69$, $SD = 2.03$).

Study 2 replicated findings in Study 1 by using a different method to manipulate money anthropomorphism (adapted from Chandler and Schwarz 2010). In the anthropomorphism condition, participants thought of money with personality traits, whereas in the object condition, participants thought about money in terms of its physical features. Consistent with Study 1, money anthropomorphism significantly increased participants' donation intention. In addition, we also tested the underlying mechanism of the effect of money anthropomorphism on charitable giving. A mediation analysis showed that the effect of money anthropomorphism on donation intention was mediated by the enhanced warmth perception of money (Indirect effect: b

= .17, SE = .12, 95% CI[.01, .53]). However, we did not find strong evidence to suggest that the enhanced competence perception mediated the effect (Indirect effect: B = .15, SE = .12, 95% CI [-.01, .50]).

Study 3 further examined the underlying process of the money anthropomorphism effect by examining a boundary condition. Our logic was that if perceived warmth, not perceived competence, mediated the money anthropomorphism effect on charity donation, the effect should be attenuated if participants were explicitly guided to think of money as a competent, agentic person (agentic human condition). We predicted we would replicate the findings in the previous studies when participants were asked to think of money as a warm, empathetic person (communal human condition). Supporting our prediction, results showed that participants in the communal human condition ($M = 4.50$, $SD = 1.94$) had a higher donation intention than those in the object condition ($M = 3.84$, $SD = 2.12$, $F (2, 259) = 4.90$, $p = .02$) and those in the agentic human condition ($M = 3.73$, $SD = 1.86$, $F (2, 259) = 6.66$, $p = .01$). There was no significant difference between the agentic human and object conditions ($F (2, 259) = .13$, $p = .72$). A mediation analysis further confirmed that perceived warmth, not perceived competence, served as the mediator for the money anthropomorphism effect.

Study 4 focused on ruling out an alternative explanation that charitable donations might have benefited from a humanization itself rather than money anthropomorphism per se (humanization halo effect). That is, anthropomorphizing anything might enhance charitable giving. However, our results showed that the effect was specific to money anthropomorphism ($M_{anthropomorphism} = 4.33$, $SD_{anthropomorphism} = 1.67$, $M_{control} = 3.40$, $SD_{control} = 1.86$, $F (1, 363) = 9.68$, $p = .002$). We did not observe the same effect when participants were asked to anthropomorphize the charity, any object they can easily anthropomorphize, or any familiar product they can think of (all $ps > .17$). These findings suggest that anthropomorphism itself is not sufficient to induce a heightened intention to donate. Although the charity organization is also involved in the charitable process, charity anthropomorphism did not lead to an increase in donation amount compared with money anthropomorphism.

Study 5 examined whether money anthropomorphism would lead participants to donate real money. Results showed that money anthropomorphism increased not only the probability of donation ($P_{Human} = 72.09\%$, $P_{Object} = 46.80\%$, $\chi^2 = 5.93$, $p = .02$) but also the amount of donation ($M_{Human} = 2.98$, $SD = 3.52$; $M_{Object} = 1.36$, $SD = 2.52$, $t (75) = 2.49$, $p = .02$).

In Study 6, we used a different method to manipulate money anthropomorphism that can enhance the external validity and provide meaningful managerial implications. For example, in the anthropomorphism condition participants were asked to contribute one "George Washington," whereas those in the control condition were asked to donate $1 dollar. Moreover, we ruled out an alternative explanation that the effect might have been driven by the reduced pain of parting with money.

Our research provides new insight into the potential positive effects of the cue of money on consumer behavior. The findings also contribute to the emergent theorization about underlying psychological mechanisms for the effect of anthropomorphism on consumer behavior. (893 words)

Evaluating Anthropomorphized Products Less Positively: "Shame on Me!"

EXTENDED ABSTRACT

Shame is an aversive affective reaction that occurs following the failure to meet internalized social standards (Tangney 1999; Tracy and Robins 2004). Hence, shame has been characterized as both a "self-conscious" (Tangney 1999) and a "social" emotion (Fischer and Tangney 1995), and has been linked with low self-worth (Tracy, Robins, and Tangney 2007), dysfunctional interpersonal behaviors (Tangney, Stuewig, and Mashek 2007), and a motivation for escape or concealment (Tangney et al. 2007). These findings suggest that shame-laden individuals tend to cope by avoiding public exposure.

Although the strategies that people use to cope with feelings of shame in social relationships are well documented, the impact of these feelings on non-social, consumption behavior has not received much attention. Building on the premise that shame-laden individuals have a strong desire to avoid public exposure, the current research explores the possibility that shame may lead to lowered evaluation of anthropomorphized products. Prior research suggests that when people anthropomorphize a product, they imbue it with humanlike characteristics, motivations, intentions, or emotions (Aggarwal and McGill 2007; Epley, Waytz, and Cacioppo 2007). As a result, people may interact with anthropomorphized products in a way similar to their interactions with other persons. Consequently, even the mere presence of anthropomorphized products might create a psychological feeling of being in a public environment and being under the watchful eyes of others, regardless of actual anonymity (Bateson, Nettle, and Roberts 2006). Thus, we expect that shame-laden consumers would evaluate the anthropomorphized (vs. non-anthropomorphized) products less favorably, and that this effect will be driven by a general desire to avoid social contact with others.

Moreover, we argue that the effect of incidental shame on reduced evaluation of anthropomorphized products will be (a) stronger for consumers with interdependent (vs. independent) construal, as they are generally more susceptible to others' evaluations (Oyserman and Lee 2008); and (b) weaker for products consumed publicly (vs. privately), as we do not expect the presence of an anthropomorphized product to exert any additional effect on consumers' desire to avoid social contact above and beyond what they already experience in a public consumption context.

Further, the effect will be specific to shame and would not generalize to other negatively valenced emotions such as fear or sadness, which are characterized by different cognitive appraisals and social motivations. While shame elicits a greater desire to avoid social interaction with others (Tracy and Robins 2004), people tend to cope with fear and sadness through greater affiliation with others. For instance, Dunn and Hoegg (2014) showed that fearful consumers tend to seek affiliation with an available brand when the opportunity to build affiliations with others is not immediately available. Similarly, sadness may evoke the motivation to seek help and accompaniment from others driven by a sense of loss and helplessness (Gary and Lerner 2013). Thus, to get further evidence for the process by which shame reduces consumers' evaluation of anthropomorphized products and to rule out a generalized negative valence of the emotion as an alternative explanation, we compared the effect of shame with fear and sadness. Four experiments were conducted to test the proposed hypotheses.

Experiment 1 employed a 3 (emotion: shame vs. fear vs. neutral) × 2 (product type: anthropomorphized vs. non-anthropomorphized) between-subjects design. Participants first recalled a past experience that gave rise to feelings of shame, fear or neutral emotion (a typical day experience). Afterwards, participants proceeded to an ostensibly unrelated task, in which they provided evaluations of either an anthropomorphized or non-anthropomorphized smoothie-maker Puzakova et al. 2013). As expected, participants who recalled a shameful (vs. fearful or neutral) experience provided less favorable evaluation of an anthropomorphized smoothie-maker, but not

a non-anthropomorphized smoothie-maker. Moreover, as expected, fear (vs. neutral emotion) increased consumers' evaluation of the anthropomorphized product.

Experiment 2 replicated the results of Experiment 1 and further tested the underlying mechanism of the effect. We followed the same procedure as in Experiment 1 except that we used sadness (rather than fear) as the comparison negative emotion and a different product category (i.e., digital camera). The results mirrored those of Experiment 1. A moderated mediation analysis revealed that participants' desire to avoid social contact with others mediated the emotion × product type interaction effect on evaluation.

Experiment 3 tested the moderating role of self-construal through a 2 (emotion: shame vs. neutral) × 2 (self-construal: independent vs. interdependent) × 2 (product type: anthropomorphized vs. non-anthropomorphized) between-subjects design. Participants were randomly assigned to an independent or interdependent self-construal condition (Schlosser 2015), and then one of two emotion induction conditions (shame vs. neutral) using the same recall task. As predicted, the negative effect of shame on evaluation of anthropomorphized products occurred for participants primed with interdependent self-construal, but not independent self-construal.

Experiment 4 further tested the moderating role of private (vs. public) consumption context using a 2 (emotion: shame vs. neutral) × 2 (product type: anthropomorphized vs. non-anthropomorphized product) × 2 (consumption context: public vs. private) between-subjects design. After recalling either a shameful or neutral event, participants were asked to imagine that they had just bought a tablet and would like to buy a case for it. To manipulate consumption context, participants were instructed that the tablet was mainly used at home (private context) or at school (public context). Then participants provided evaluations of a tablet case that was either anthropomorphized or not. As further support for our underlying mechanism, we found that when the product was used publicly (i.e., when social contact was already high), the negative effect of shame on anthropomorphized product disappeared, in keeping with our hypothesis. However, when the product was used privately, the social presence of anthropomorphized product resulted in a less favorable evaluation.

Taken together, this research documents a novel emotional antecedent – incidental shame – on consumer's evaluation of anthropomorphized products. Although anthropomorphizing a products have been shown to lead to positive outcomes (Chandler and Schwarz 2010; Delbaere et al. 2011), our research suggests that marketers may need to re-consider the effectiveness of this strategy if their products elicit feelings of shame (e.g., counterfeit products). SESSION OVERVIEW

Most theories of self-control in consumption characterize self-control as an effortful process requiring cognitive resources or willpower (e.g., Baumeister et al. 1998; Shiv and Fedorikhin 1999, Bazerman et al.1998, Hoch and Loewenstein 1991). According to these theories, consumers in general want to exert self-control but often lack the necessary resources to do so, as epitomized in the Biblical saying "The spirit is willing but the flesh is weak." The proposed session explores factors beyond the traditional three factors lack of cognitive resources, willpower, and volition, in affecting the antecedents and consequences of exerting self-control.

The first paper by Koley, Warren, and Ramanathan looks at how experienced emotions influence consumers' propensity to exert self-control. The authors argue that anxiety activates the goal to seek security (Raghunathan, Pham, and Corfman 2006). As a consequence, experiencing anxiety facilitates exertion of self-control when doing so promotes a security goal. Anger, in contrast, activates a goal to seek dominance (Peterson and Harmon-Jones 2012), and facilitates self-control when doing so promotes that goal.

The second paper by Mochon, Schwartz, and Ariely investigates the strategies that people use to constrain unhealthy consumption. In a longitudinal field experiment, grocery shoppers voluntarily committed to a 6-month contract that led to increase in the share of virtues and decreases in the share of vices. This strategy emerged over time, and persisted for 6-months after the intervention ended. Furthermore, there were no signs of negative spillovers on exercising or customer loyalty as a result of giving up (some) vices.

In the third paper by Kim and Kim, the consequences of exerting or not exerting self-control on wasting is explored. Specifically, the authors argue that¾like the consumption of vices¾the wasting of vices introduces guilt. For virtues, however, only the wasting but not their consumption engenders guilt. As a consequence, people are more likely to waste leftover vices than leftover virtues.

Finally, the fourth (theoretical) paper by Vosgerau, Scopelliti, and Huh argues that the prevalent conceptualization of vices as hedonic and virtues as utilitarian implies an unrealistic prediction, namely that all hedonic consumption must be thwarted by feelings of guilt and regret. The authors propose to recognize excessive consumption¾rather than hedonics¾as the defining characteristic of vices, and that self-control should be measured as amount consumed, not as choice share of vices.

Together, the four papers extend the popular theorizing of self-control as a lack of cognitive resources or willpower. The findings presented suggest that emotions and self-image consistency can drive self-control. Furthermore, not exerting self-control can lead to wasting. Lastly, the very definition and measure of self-control as choice share of vices may have to be revised. The papers encourage session attendees to critically examine current theories of self-control, and to explore the implications for public policy aimed at helping consumers to exert self-control.

Effect of Anger and Anxiety on Choice in Self-Control Dilemmas

EXTENDED ABSTRACT

Research suggests that negative emotions generally harm self-control. For example, distressed consumers eat more junk food (Gark, Wansink, & Inman 2007), and save less money (Cryder, Lerner, Gross, & Dahl 2008). In contrast, we show that negative emotions can either facilitate or impair self-control depending on the match between the goals activated by the emotion and the benefits associated with the virtuous and gratifying options in the choice set.

A self-control dilemma involves a choice between virtuous options that facilitate long-term goals (e.g., saving money) and gratifying options that facilitates immediate desires (e.g., buying something fun; Tice & Baumeister, 1997). Importantly, these virtuous and gratifying options can be chosen for different benefits (i.e., to attain different goals). For example, consumers may choose to save money in order to accumulate wealth and power (a dominance goal), or to achieve a secure retirement (a security goal). Similarly, gratifying by buying an unnecessary pair of sunglasses, may achieve different immediate benefits, such as eye protection (a security goal) or signaling one's status (a dominance goal).

Furthermore, just as self-control options are associated with different goals, negative emotions too activate different goals. Negative emotions, which occur in response to threats or obstacles in the environment, activate goals that enable individuals to cope with the threat or the obstacle (Lench, Flore, and Bench 2011). For example, anxiety signals a risk of facing punishing consequences in the future, and therefore activates the goal to seek security (Raghunathan, Pham, and Corfman 2006). In contrast, anger signals that something or someone is obstructing the active pursuit of a reward, and thus activates the goal to seek dominance (Peterson and Harmon-Jones 2012).

These goals activated by emotions in-turn increase choice for options that are consistent with the activated goal (van Osselaer & Janiszewski, 2012), even in unrelated contexts (Lerner & Keltner, 2000). Thus, the effect of any negative emotion on self-control should depend on the match between the goal activated by the emotion and the goals linked to the gratifying and virtuous options in the choice set. Specifically, we predict that anger would impair self-control when the virtuous-option moves the consumer towards a security goal rather than a dominance goal (e.g., saving for a rainy day rather than saving for status). Conversely, anxiety would impair self-control when the virtuous-option facilitates a dominance rather

than a security goal (e.g., saving for status rather than saving for a rainy day).

We test these predictions across four experiments. In study 1 we looked at the effect of anger and anxiety on self-control while manipulating the benefit associated with either the virtuous-option or the gratifying-option in the choice set. The study used a 3 (emotion: anxiety, anger, control) x 2 (benefit provided by: gratifying-option, virtuous-option) x 2 (benefit: dominance, security) between-subject design. Participants (N =352) first viewed a pre-tested video that induced anger, anxiety, or no emotion (control). As part of an ostensibly separate study, they were subsequently asked to choose between a relatively virtuous gift-card to a supermarket and a more gratifying gift-card for a pair of Ray-Ban sunglasses. The effect of the emotion manipulation on self-control depended on which gift-card was associated with an additional benefit as well as whether that benefit promised dominance or security (three-way interaction: $p <$ .01). Angry (anxious) participants were more (less) likely to gratify when the sunglasses were described as "having a reputation as the most prestigious brand" than when they were described as "having a reputation for offering the best protection from damaging UV-rays" ($ps <$ .10) Conversely, angry (anxious) participants were less (more) likely to gratify when the virtuous-option was described as "making individuals appear more confident and powerful" than when it was described as "making individuals more secure" ($ps <$ .10)

Study 2 replicated study 1 using a different choice task and emotion manipulation. The study used a 3 (emotion: anxiety, anger, control) x 3 (benefit: dominance, security, neutral) between-subject design. Participants wrote about events that make them feel angry, anxious, or that occurred recently (control condition). As an ostensibly separate study, they next chose between looking at entertaining cartoons (gratifying-option) and reading an article to prepare for job-interviews (virtuous option). Again, the effect of the emotion manipulation depended on whether the virtuous job-interview article was associated with dominance benefits (e.g., it will help you find a prestigious job) or security benefits (e.g., it will help you find a secure job; interaction: $p <$ .01). As predicted, angry (anxious) participants were more likely to choose the job-interview article over the entertaining article when the article was associated with dominance (security) rather than security (dominance) benefits ($ps <$ .05).

Studies 3a and 3b use the causal chain approach (Spencer, Zanna, & Fang, 2005) to provide process evidence. Study 3a used a lexical decision task (Fishbach, Friedman, and Kruglanski 2003) to demonstrate that anger activates the goal of dominance, whereas anxiety activates the goal of security. After completing the emotion manipulation described in study 2, participants judged whether a series of letter-strings were words or non-words as quickly as they could. Consistent with our prediction, angry participants were quicker at identifying words related to dominance (e.g., authority, prestige) than security (e.g., protect, insurance), whereas anxious participants were quicker at identifying words related to security than dominance (interaction: $p <$ .05).

Study 3b used a goal priming procedure to examine the second step in the causal chain: that individuals with an active dominance (security) goal would exert greater self-control when virtuous behavior benefits a consistent rather than inconsistent goal. Participants unscrambled words to create valid sentences (Bargh and Chartrand 2000). Depending on the goal prime condition, some of the words were either related to dominance (e.g., prestige, authority) or security (e.g., protect, insurance). Participants were subsequently presented with the same choice as in study 2. As predicted, participants primed with a dominance (security) goal were more likely to choose the job-interview article over the entertaining article when the article

was associated with dominance (security) rather than security (dominance) benefits (interaction: $p <$ .05).

Bringing Ulysses to Scale: A Tale of Persistence, Spillovers and Customer Loyalty

EXTENDED ABSTRACT

Financial incentive programs are an increasingly attractive way to improve health. While research from the behavioral sciences shows that many such interventions effectively improve a specific health behavior while in place, less is known about the underlying strategies people use to achieve their goals and their extended effects on behavior. These effects are essential to understand when bringing behavioral science insights to scale. If an intervention has positive effects on a targeted behavior, but leads to negative consequences once the program ends, or shows negative spillover effects in other domains, it may not be sustainable.

We address this question by examining the behavioral strategies and extended effects of a penalty-based behavioral health intervention: a voluntary 6-month commitment contract that significantly improved the health of grocery purchases (Schwartz et al. 2014). Member households, who were already receiving a 25% discount on healthy (virtuous) food grocery purchases, put their discount on the line by precommitting to a 5-percentage-point increase above their household healthy food baseline. Those who met the goal kept their discount; those who did not forfeited it. Participants were free to choose any strategy to meet this goal. For example, they could increase the purchase of virtuous items like fruit and vegetables, decrease the purchase of vice items or some combination of both. The results showed that over time, households were best able to meet their and maintain their goal with a strategy that balanced virtue and vice.

Since this precommitment field experiment was run within a comprehensive health rewards program, we could examine the commitment device's strategic impact beyond the specific time period and targeted behavior (nutrition). Specifically, we examined the penalty effect's persistence once it was removed, whether it lead to negative spillover effects while in place (i.e., healthier nutrition = less exercise) and, finally, the impact of the penalty on customer loyalty and engagement.

Persistence: Consistent with the persistence prediction, the committed group continued to make healthier grocery purchases during each of the 6-months in the post-intervention period ($\beta =$ 2.84, SE = .95, $p <$ .01). Persistence was strongest for the most loyal customers, as well as those who had the biggest discount on the line, thus demonstrating that penalty-based incentives can be catalysts to promoting long-term healthy change.

Spillovers: We see no evidence of negative spillover effects, especially as households had to give up some vices in order to meet their goal. Committed households exercised slightly more (though not significantly) than control households ($\beta =$ 07, SE=.05, *n.s.*). Interestingly, there was a significant positive effect on exercise when examining participants who had put the most money on the line during the commitment period, ($\beta =$.23, SE=.07, $p <$.01). Our results reinforce the value of incentives as a tool for improving health, by suggesting that they do not lead to negative consequences in other domains, and may even lead to positive spillovers for some.

Loyalty effects: While penalty-only commitment contracts may improve targeted health behaviors, this may come at the cost of customer loyalty—a trade-off many firms are unwilling to make. We test the effect of the intervention on customer loyalty by examining involvement with the health rewards program during the year after the

commitment contract ended. Committed households showed a positive (though non-significant) change in loyalty status (our measure of involvement) during the year after the intervention ended (β=.07, SE=.12,*n.s.*). This is an important finding, because most committed households forfeited their discount at least once, which could have resulted in backlash. Consistent with this finding, the results of a follow-up survey further suggested that committed households did not blame the firm for failures. Indeed, 68% assigned more blame to themselves than to the firm for failing (only 15% assigned more blame to the firm). This suggests that consumers took responsibility for their own actions, and consequently for their own failures, which mitigated any negative feelings towards the firm.

Taken together, these results highlight the potential for insights from the behavioral sciences to be implemented on a large scale basis, and that some concerns over negative spillovers and consumer backlash may be overstated.

Waste Aversion for Virtue versus Vice

EXTENDED ABSTRACT

Consumers are averse to wasting, and like to maximize the use of what they pay for (Arkes 1996; Bolton and Alba 2012). Yet, waste of goods still abounds. Nearly one-third of food produced for human consumption is wasted globally, which amounts to the economic loss of $750 billion per year (FAO 2015). The question of why people waste, despite their inclination to be averse to wasting, is an important problem which has not been explored much (Porpino 2016). In this research, we answer this question of why consumers waste by exploring how they respond to wasting of virtues and vices differently in the context of food waste.

We propose that consumers relax their tendency to be averse to wasting when consuming makes them feel as guilty as does wasting. When does that happen? Past research has shown that there is a difference in how much guilt is elicited when consuming virtues versus vices. The distinction between virtues and vices is characterized by the intertemporal conflict consumers face in choosing between tempting immediate pleasures (e.g., tasty but unhealthy food) and long-term future benefits (e.g., less tasty but healthy food). In general, choosing virtues is viewed as normatively good (Rook 1987), whereas choosing vices induces guilt (Lascu 1991; Ramanathan and Williams 2007).

Importantly, the guilt induced by consuming a vice pulls one's consumption decision in the direction towards wasting the vice. We propose that relative strength of waste-guilt compared to consumption-guilt determines one's decision to waste or not. Specifically, we predict that for virtues, consumers would feel guilty when wasting as compared to consuming, and thus, they would be more likely to save food from being wasted (i.e., demonstrating the expected pattern of waste aversion). On the other hand, we predict that for vices, consumers would not feel guiltier when wasting as compared to consuming, and thus, they would be less likely to save food from being wasted (i.e., no pattern of waste aversion). Across three studies, we test this hypothesis and demonstrate that one of the reasons why people waste may be because consuming feels as guilty as wasting.

A pilot study (*N*=87) we conducted confirmed our argument related to guilt; for virtues, consuming felt less guilty than wasting (F(1,83)=4.60, *p*=.03) whereas for vices, consuming felt as guilty as wasting.

In the first study, participants (*N*=119) were randomly assigned to one of the two conditions (virtue vs. vice), and asked to imagine that they were at a chocolate-tasting event. They read a description of a chocolate that either framed the chocolate as healthy (virtue)

or tasty (vice; Mishra and Mishra 2011). Participants were told that they are last people at the event and the organizer of the event asked them to take some left-over chocolates with them, otherwise, left-overs will be thrown away and wasted. Participants indicated how guilty they would feel if they leave chocolates (therefore wasted) and how likely they are to take some chocolates with them (to prevent from being wasted) on a 7-point scale. As predicted, wasting virtue-framed chocolates (*M*=5.93) felt guiltier than wasting vice-framed chocolates (*M*=5.28; *F*(1,117)=4.77, *p*=.031), and participants were more likely to save virtue-framed chocolate (*M*=6.35) than vice-framed chocolates (M=5.95; *F*(1,117)=4.16, *p*=.044) from being wasted. A bootstrap analysis revealed a significant mediation by guilt ($CI_{lower-bound}$=.04, $CI_{upper-bound}$=.40).

In study 2, we included a control condition wherein the food is not wasted in order to demonstrate that waste aversion is observed for virtues, but not for vices. The study was a 2 x 2 (waste: waste vs. waste-not x framing: virtue vs. vice) between-subjects design and the same chocolate-tasting scenario from the first study was used. Importantly, participants (*N*=277) were told that left-over chocolates would be either thrown away and wasted (waste condition) or given away to other people at the event (waste-not condition). Participants were asked to indicate how likely they are to take some chocolates with them on a 7-point scale. Consistent with our predictions, for virtue-framed chocolates, participants were more likely to take some chocolates with them when they were to be wasted (*M*=6.28) than not (*M*=5.53; *F*(1,273)=8.39, *p*=.004), showing the expected pattern of waste aversion. However, there was no difference in how likely participants were to take some vice-framed chocolates when chocolates were to be wasted versus not (*p*>.97).

In study 3, we replicate our findings from study 2 by employing a real measure of waste aversion. Participants (*N*=198) were randomly assigned to one of the four conditions (waste: waste vs. waste-not x framing: virtue vs. vice), and read a description of lemon drops that were framed as either vitamin-c supplements (virtue) or candies (vice). A cup holding 80 lemon drops was placed in front of participants. To be consistent with the cover story of evaluating lemon drops, participants answered two questions on color and shape of the lemon drops. Afterward, an experimenter came in and told them that they were last people for the study, and they can take some lemon drops with them if they want to, otherwise lemon drops will be thrown away and wasted (waste condition) or given away to other people in the lab (waste-not condition). Then the experimenter left the room to get an exit sign-up sheet to give some time for participants to take lemon drops. The number of lemon drops taken served as our main dependent variable. Consistent with the results from study 2, participants took more virtue-framed lemon drops when they were to be wasted (*M*=5.53) than not (*M*=1.17; *F*(1,194)=7.36, *p*=.007). However, participants did not take more vice-framed lemon drops when they were to be wasted versus not (*p*>.2).

Across three studies, we demonstrate that consumers show waste aversion for virtues but not for vices because wasting virtues makes them feel guiltier than consuming them, a pattern that does not hold for vices.

Pleasure, Guilt and Regret in Consumption: Revisiting the Vice-Virtue Categorization in Theories of Self-Control

EXTENDED ABSTRACT

Self-control problems are often characterized as intertemporally inconsistent preferences (Ainslie 1975; Loewenstein and Prelec 1992), where a consumer prefers the immediate consumption

of a good to its consumption in the future, but as time passes by she regrets having consumed the good in the past. Based on intertemporally inconsistent preferences, Wertenbroch (1998) introduced a formal definition of vice and virtues: A product X is a vice relative to product Y, and Y is a virtue relative to X, if X is preferred now rather than later, and Y is preferred later rather than now.

We argue that Wertenbroch's (1998) definition¾in combination with the corollary that vices are hedonic and virtues are utilitarian¾has led to the development of theories of self-control that postulate that enjoyment derived from consumption is always accompanied by feelings of guilt and regret. We show this by reviewing the self-control literature, and propose a change to the definition of vice-consumption that recognizes excessive consumption¾rather than hedonics¾as its defining characteristic.

Wertenbroch's definition was highly influential, the vice-virtue distinction has been adopted in the literature on self-control in social psychology and consumer behavior (a comprehensive review of self-control papers published in JEP:G, JPSP, Psych Science, OBHDP, JCR, JM, JMR, Marketing Science, and Marketing Letters from 1995 to 2016 shows that over 70% use the vice-virtue distinction). In the typical self-control experiment (e.g., Baumeister et al. 1998; Shiv and Fedorikhin 1999), participants are given a choice between a vice (e.g., a piece of chocolate cake) and a virtue food (e.g., a fruit salad). Choice shares serve as the dependent variable, where higher shares of the vice are interpreted as a relative lack of self-control. In fewer instances (e.g., Coelho do Vale et al. 2008; Campbell and Mohr 2011), self-control is measured by the absolute amount of vices chosen or consumed.

Khan, Dhar and Wertenbroch (2005, p. 20) postulated: "…by Wertenbroch's (1998) formal definition, hedonic goods could be characterized as vices and utilitarian goods as virtues in a direct comparison with each other." (cf. also Alba and Williams 2013; Milkman et al. 2008, 2010; O'Curry and Strahilevitz 2001; Read et al. 1999). According to this corollary, vice products are tempting, elicit more affective responses, and provide for more experiential consumption, fun, pleasure, and excitement than virtue products do. Virtues, in contrast, are primarily instrumental and mainly purchased and consumed on the basis of their functional aspects, that is they promote health and¾in case of durables¾efficiency. The idea that self-control conflicts can be characterized as choosing between hedonic and utilitarian consumption opportunities is also present in other theories of self-control, such as the conflict of want versus should selves (Bazerman et al.1998), desire versus willpower (Hoch and Loewenstein 1991), heart versus mind (Shiv and Fedorikhin 1999), and enjoyment versus control (Stroebe et al. 2012).

If vices = hedonic and virtues = utilitarian, pleasure derived from hedonic consumption must be accompanied by feelings of regret because¾by definition¾vices are preferred now rather than later, and virtues are preferred later rather than now. Consequently, the consumption of vices will necessarily be regretted at a later stage (Baumeister 2002; Read et al. 1999) and induce feelings of guilt (Kivetz and Simonson 2002). Enjoyment from immediate consumption will be tainted by feelings of guilt and anticipated regret, and post-consumption enjoyment (e.g., memories) will be thwarted by experienced regret. The more enjoyment is derived from hedonic consumption, the more guilt and regret will be anticipated and experienced. So, according to current theories of self-control, the self-disciplined consumer lives a healthy life devoid of enjoyment.

Clearly, this is an incorrect depiction of hedonic consumption. Many people seem to enjoy consuming products without being plagued by feelings of guilt and regret. The consumption of any product, whether hedonic or utilitarian, may be harmless in modera-tion. In excess, however, consumption becomes problematic and perilous. Pizza for example¾typically considered a vice¾is per se not bad for one's health. Millions of Italians eat it several times a week, and they belong to the slimmest people in Europe. Even for addictive and strictly toxic substances such as cigarettes, consumption amount linearly determines health damages (Bjartveit and Tverdal 2005), so a cigarette a day is much less damaging than a pack a day. Likewise the consumption of so-called virtues can be harmful when consumed in excess. Fruitarianism, for example, a diet consisting exclusively of eating fruits, is dangerous and may cause nutritional deficiencies in protein, calcium, vitamins D and B. The deficiency of some of these nutrients can cause severe and irreversible damage, especially to the brain and nervous system (https://en.wikipedia.org/wiki/Fruitarianism). Our argument also holds for vices and virtues other than foods. Spending time with friends and family can be a virtue unless done in excess. Working is a virtue unless done in excess. Praying, running, eating, sleeping, having sex,…. , any activity is harmless or even beneficial in moderation but perilous in excess.

Realizing that excessive consumption¾not hedonics¾is the defining characteristic of vices leads to a number of straightforward but fundamental implications. First, the definition of vices needs to include consumption amount as its defining characteristic. Second, tests of self-control theories should use consumption amount¾rather than choice share of vices¾as dependent variable. Third, moral licensing effects (justifying future consumption of vices by past consumption of virtues) rely to a large extent on the binary classification of virtue- versus vice-consumption. When consumption amount¾a continuous variable¾is the defining characteristic, however, moral licensing is much harder to accomplish as it is difficult to define the cutoff of consumption amount at which licensing is psychologically feasible. Finally, the most important implication concerns consumer welfare. Consumers can enjoy hedonic consumption without being plagued by feelings of guilt and regret as long as they consume with moderation. Indulgence is not a matter of too much enjoyment but of too much consumption. Consequently, consumers can exert self-control without depriving themselves of enjoyment derived from consumption (cf., Cornil and Chandon 2015).

SESSION OVERVIEW

Money is the most influential tool for enabling mutually-beneficial interactions with outgroup members and strangers. Money thus connects people to others outside their small, intimate sphere, making it conducive to a style of sociality best for dealings in the large group (Baumeister and Sommer 1997). Large-group sociality differs qualitatively from behaviors that suit relationships with intimate others and kin (Baumeister and Sommer 1997), suggesting that money should be helpful for outcomes pertaining to large-group endeavors, such as being an employee or consumer, and harmful for outcomes that have features of small-group relating. The four talks in this session show both patterns.

Being a consumer is a primary form of large-group sociality. Ksendzova, Donnelly, and Trudel tested how the salience of money influences consumers' prosocial glow in exchange transactions. Field and experimental studies revealed that cash payments (versus credit and debit cards, which are less symbolic of money) increase customers' perception of having helped the businesses and employees.

Being an employee is another key role in large-group relating. Shah and Holden used incentive-compatible experiments to show that rewards that make money more salient (e.g., cash instead of direct deposits) foster greater motivation to persist in a task. Speaking to the large-group theory, getting paid in cash (vs. direct deposits) builds organizational connection and trust.

Two papers demonstrate the harms that money can bring to small-group sociality. Vohs and Bianchi used two large nationally representative samples (N=116,000) to study how people spend their non-working time. They found that the more people earn, the less time they spend with family and neighbors. Furthermore, as income rises, the limited time people do devote to socializing is spent with friends. Insofar as family and neighbors are prime sources of small-group relationships, whereas friends connect people to the wider social network, this paper shows both that money orients people to larger spheres as well as creates small sphere divisions.

Given that companies are representations of large-group collectives, how do consumers react when firms act in a manner befitting small-group sociality? Lee, Bolton, and Winterich measured the support consumers give organizations that are for-profit versus non-profit and that aim to benefit society. Prosociality is a feature of small groups, whereas profit-making benefits the large group. This conflict leads people to be averse to supporting — through donation or product purchase — prosocially-oriented for-profit organizations.

Studies ranging from large-scale surveys to field investigations involving customers and donors suggest that money is a vehicle for participating in nominal relationships and group endeavors (e.g., businesses), and thus brings people beyond the close, intimate sphere of relating. Money connects people in a manner that enables larger groups, such as societies and cultures, to flourish — but is incongruent and thus disruptive to interactions among close, intimate ties.

The Prosocial Glow of Cash: How Payment Method Affects Customers' Perceptions of Helpfulness

EXTENDED ABSTRACT

Over the last decade, many have researched the motivational and interpersonal consequences of having money on the mind. When money becomes a salient topic for people in words, images, or actual currency (compared to neutral concepts and stimuli), it has potential to fray social ties by decreasing generosity, cooperation, and social interaction (see Vohs 2015 for review). Money primes an "exchange mindset," including a focus on costs (e.g., Chatterjee and Rose 2012). Social ties become unnecessary baggage – a barrier in the pursuit of personal reward. Yet, the exchange of money between people is an ever-present component of their daily lives, from infrequent large purchases to daily morning coffees, that is done for mutual benefit. Consequently, it is important to better understand the psychology of money and, specifically, how it affects people's social experiences in an exchange setting.

The salience of money depends, in part, on how people pay. Cash most clearly embodies the general construct of money, compared to the less-symbolic payment types (Prelec and Lowenstein 1998). Not surprisingly, cash possesses a social dark side. For example, participants who counted $1 bills (compared to days on a paper calendar) were more likely cheat in a task by lying to the researcher (Gino and Mogilner 2014). However, an emerging line of research points to the bright side of cash, which best signals costs people endure when they pay. The psychological "pain of paying" with cash (compared to less symbolic methods) brings a gain of greater postpurchase satisfaction (Shah, Eisenkraft, Bettman and Chartrand, 2016). Building on these findings, we examine the role of money salience in how buyers feel about their exchange with the sellers. If cash (compared to debit or credit cards, for example) best represents costs to the self, can it also pleasantly remind people of the contributions they make to others?

In Study 1, we investigated people's perceived helpfulness to the seller based on salience of money in the payment (cash or card) and characteristics of the seller (small or large business). We surveyed customers (N = 222), exiting either a small or multinational-chain coffee store. Customers reported their payment method and its perceived helpfulness to the business. Neither store encouraged cash

payments or required a minimum purchase amount for electronic payments. We observed a main effect of cash payments on perceived helpfulness (with and without controlling for total amount spent). Moreover, post-hoc tests revealed that consumers judged cash to be more helpful than cards at the small business, rather than the large business.

In Study 2, we aimed to a) control for people's self-selection into buying at small versus large businesses, b) conceptually replicate Study 1, and c) extend our understanding of why customers judge cash payments as helpful. We randomly assigned Amazon Mechanical Turk participants (N = 404) to answer questions regarding a hypothetical purchase of an umbrella in a 2 (cash vs. credit card) x 2 (small vs. large business) between-subjects design. We replicated our results from the field study in that cash payments were perceived as more helpful than card payments, especially to small businesses. Moreover, regardless of business size, people who imagined paying with cash (compared to credit cards) imagined lesser overhead costs to the business, a more direct exchange between themselves and the business, greater closeness to the business, and stronger empathizing with its employees. In a moderated dual-mediation model, we found that people felt helpful paying cash because they recognized that cash helps businesses avoid overhead costs (e.g., "to benefit from my entire payment"). Further, in the case of small businesses, empathizing with employees (e.g., "think of the business as a group of people") also explained the relationship between cash payments and perceived helpfulness.

Then, in Study 3 (N = 608 mTurk participants), we examined whether empathizing with relatable employees of a large business can elicit stronger perceptions of helpfulness from paying with cash. We compared judgments of helpfulness between payment method, business size, and three variations of additional business descriptions: control (none), a description prompting consideration of employees (i.e., a description of employees who believe their identity is intertwined with the business identity), and a description prompting a more specific consideration of relatable employees (i.e., a description of employees being similar to the participant). Only in the "relatable employees" condition there was no difference in consumers' perceived helpfulness of cash between small and large businesses. In a post-test, another group of mTurk participants read one of three business descriptions, paired with mention of either small or large business size (N=50 per cell). In response, they selected one out of seven circles, one circle representing "self" and the other "employees," with varying degrees of overlap (per Aaron, Aaron, and Smollan, 1992). As expected, judges evaluating the relatable-employees scenario indicated a greater self-employees overlap than judges evaluating the consideration-of-employees or control scenarios, regardless of whether the business in question was small or large. Thus, large-business customers can also feel helpful when paying with cash, rather than by card, to the extent they can empathize with the employees.

Examining the downstream consequences of perceived helpfulness, we then surveyed customers of a food truck plaza (N = 460) about their purchases in Study 4. Each customer was asked to recall how much they had paid, payment method, perceived helpfulness to the business, and purchase satisfaction. People who paid with cash judged their payment to be more helpful than people who paid with debit or credit cards, and they were also happier with their purchase. Perceived helpfulness mediated the relationship between payment type and purchase satisfaction.

These findings illustrate a bright side for the psychology of money in the context of large-group sociality. Money is meant to maximize mutual benefit in exchanges of resources, and methods of payment that make money salient have potential to further enhance the value of such exchanges for both buyers and recipients. Consequently, businesses may benefit from encouraging cash payments while serving happier and more connected customers.

Can The Way Individuals Are Rewarded Affect Motivation And Engagement?

EXTENDED ABSTRACT

The individuals at the head of Houston-based oil company Hilcorp decided to give out $100,000 bonuses to each of the company's 1,381 employees for the 2015 holiday season after reaching their goal to double the size of their company within a five-year period. One reporter commented, "with the way Hilcorp treats their employees, it might be worth sticking around for a few more years." (Grainger 2015). The reporter taps into an important topic in consumer behavior. Bonuses, as incentives or anticipated rewards, are important drivers of motivation and engagement with the organization (Gagné and Deci 2005). And while the Hilcorp example is on the extreme end, it is quite common for rewards to be given out, whether for the accomplishment of individual goals or milestones. However, not all bonuses are distributed in the same form within organizations; bonus types can range from cash (as at Hilcorp) to check to gift cards to direct deposit. Thus, a natural question emerges: can these different forms have differential effects on an individual's behavior, influencing their motivation and connection to their organization? Finally, what happens when individuals anticipate this bonus but fall just short? Do different forms of a bonus payment affect subsequent motivation, engagement, and connection with the organization after the bonus has been lost?

Recent research has demonstrated systemic psychological and behavioral biases in the way individuals evaluate the value of money based on the payment form (e.g., Raghubir and Srivastava 2008; Soman 2001). More salient forms of money (i.e., paying with cash vs. a debit or credit card; paying with a debit card vs. direct deposit) influence the amount of pain individuals feel when paying with the money. Paying with a less painful form of money increases the propensity to evaluate products more favorably and to feel more psychologically connected to the product, brand or organization (Chatterjee and Rose, 2011; Shah et al. 2016). However, most research on the influence of payment form on behavior and relationships has focused on when individuals *pay* money. Yet, there are so many instances where individuals *receive* money. We propose and find that individuals feel more connected to the organization and are more motivated, increasing their persistence on a task, when the bonus payment form is more salient (i.e., cash or gift card versus direct deposit). However, this effect reverses when individuals finish just short (i.e., second place), subsequently feeling less connected and decreasing motivation in comparison to those who were told that they lost a less salient bonus.

In study 1 (N=200), we investigated whether the form of the $50 incentive (gift card or direct deposit) influenced perceived motivation and organizational commitment. Individuals reported feeling significantly more, organizational connection, organizational trust, rewarded for their efforts, and more motivated to work harder in a task when the reward was a more tangible and salient reward (i.e., gift card). While we establish initial support for our hypothesis, what happens when individual *do not* win the bonus? Do more salient forms of payment continue to keep motivation and organizational connection high or is there a backlash effect? In study 2 (N=204) we attempted to get a better sense whether payment form could affect subsequent motivation and connection post-loss. We once again

varied the form of the incentive ($100 cash, $100 direct deposit) and asked individuals questions regarding their perceived motivation and organizational connection. After finishing this questionnaire, individuals were informed that they finished second in the task and would not be receiving the bonus. We asked how motivated they would be in a future task and their organizational connection. We replicated the results in Study 1: cash participants had significantly higher organizational commitment, trust, and motivation prior to finding out whether they won the bonus or not. However, after finding out they finished second, cash participants now reported feeling more disappointed and feeling less connected to their organization than direct deposit participants.

In study 3, we sought to measure actual behavior and engagement, as well as look at the mechanism behind these effects. We invited participants to the lab (N=164) for a two-period task. In the first period, participants that they would be engaging in a copyediting task and that they would be scored on how well they performed in the task. If they finish within the top 5% they would win either a $150 cash prize (a more salient form of money) or a less salient form—$150 directly debited to their student card (which is accepted everywhere on campus and on many locations commonly frequented off campus). Individuals who were told that they would be winning $150 cash if they finished in the top 5% spent more time on the copyediting task, caught more errors, reported putting in more effort, and reported greater feelings of organizational connection and trust than those who were told that they would be winning $150 directly deposited into their account. These results were mediated by anticipatory reward, whereby cash bonus participants felt more anticipatory reward driving motivation, and organizational commitment. Following the first period, we manipulated whether participants lost the task by finishing in the top 6% (i.e., just missing the prize) or merely being told that they lost the task generally. We gave them a subsequent copyediting task, where they would get a $150 cash (or $150 direct deposit) bonus for finishing in the top 5%. Similar to study 2, individuals who just missed the cash bonus in the first round were now significantly less motivated, spent less time on the subsequent copyediting task, and reported feeling less organizational commitment than those who lost the direct deposit bonus. However, this was not the case when individuals were told they lost the prize more generally.

These studies identify an important new aspect of consumer behavior—different forms of payment can influence feelings of reward and subsequently influence motivation and organizational connection. This work has important implications for consumer behavior, motivation, and organizational relationships in understanding how to foster a better workplace.

Social Class And Social Worlds: Income Affects The Frequency And Nature of Social Contact

EXTENDED ABSTRACT

Does access to money predict social behavior? Past work has shown that money fosters self-reliance and reduces interest in others, both in form of short-term exposure to cash (Vohs, Mead, and Goode 2006) and stable states of wealth (Kraus and Keltner, 2009). Logistically, money allows people to meet their needs with lesser reliance on others for help (see Kraus, Piff, and Keltner 2011; Vohs and Baumeister 2011). Psychologically, this work suggests, presence of money puts people into an agentic mindset, one in which people are motivated to pursue their own goals with their own means (Mogilner 2010). These findings suggest that greater wealth should decrease reliance on those likely to help based on geographical affiliation or communal ties. In contrast, the goal-oriented motivation of money may lead people to more deliberately craft their social networks. Building on these implications, we examined whether income predicts the frequency and type of social interactions.

In Study 1, we used a nationally representative sample of American adults (N = 29, 399) who had filled out twenty three annual surveys about their lives as part of the General Social Survey (GSS; Smith, Hout, and Marsden 2012). These participants reported on how frequently they had spent social evenings with relatives, people from their neighborhoods, or friends outside of their neighborhoods in the previous year. Moreover, participants reported income (which was adjusted for inflation) and hours worked per week, among other demographic variables.

Beyond effects of age, marital status, or time spent working, people with higher household incomes (compared to those with lower incomes) reported spending fewer evenings per year socializing with others. Particularly, they reported spending less time with relatives and neighbors; however, higher incomes predicted more frequent socializing with friends outside one's neighborhood. Predicted values indicated that people with higher incomes (+1 SD) spent 5.8 fewer evenings with family and 10.3 fewer evenings with neighbors each year, compared to people in households with lower incomes (-1SD). Conversely, people with highest incomes spent an additional 6.5 evenings a year with friends compared to people with the lowest incomes

Next, we addressed the potentially meaningful roles of living with relatives out of economic necessity and having moved away from one's home state (a life event more common for people with wealthier backgrounds). To do so, we tested the relationship between income and social time in sub-samples of a) people living alone and b) those who had moved away from their home states, respectively, and observed similar patterns: income negatively predicted total time spent with others and, more specifically, greater income predicted less time spent with family and neighbors but more time with friends. This pattern of time use suggests that people with great wealth more voluntarily configure their social worlds.

In Study 2, we sought to examine the influence of people's income on how and with whom they spend their time in a different nationally representative sample (N = 86,627) and with different metrics used to gauge social activity. As part of the American Time Use Survey (ATUS; 2002 – 2011), participants were asked to reconstruct the previous day by estimating minutes spent on each activity. Social activities included spending time with immediate and extended family members, friends, and by oneself (outside of work). Moreover, participants reported demographic and other relevant information, such as time spent at work and childcare.

People with high (+1 SD), compared to low (-1 SD), household incomes spent an additional 10 minutes alone, 22 minutes with friends, and 26 fewer minutes with family each day. Controlling for marital status, age, time spent working, and childcare activities, we again observed that people's incomes positively predicted leisure time spent alone and with friends and negativvely predicted time spent with close and extended relatives.

This research sheds light on how wealth shapes people's social relationships and helps qualify previous findings that generally depict money as a social barrier. People with higher incomes reported spending fewer evenings socializing (Study 1) and a smaller fraction of their day in the company of others (Study 2). Moreover, income predicted how people allocated their social time. People with higher incomes spent less time socializing with family and neighbors and more time socializing with friends. Further, the results speak to a broader trend of Americans being more disengaged from community

life than in the past (Putnam 2000), despite the ever-improving quality of economic life that allows greater flexibility in their leisure time. These patterns imply that money, more specifically, may act as a barrier in social relationships that also serve an instrumental function.

To Profit or Not to Profit? Consumer Support For the Social Venture Question

EXTENDED ABSTRACT

Social ventures—organizations serving an explicit social purpose through transactions in the marketplace—can achieve their social missions through either nonprofit or for-profit orientation (i.e., for-profit social ventures, hereafter FPSVs). Although social ventures have traditionally been nonprofits, increasing number of social entrepreneurs today choose a for-profit status to gain flexibility in generating revenues and greater operational efficiency (Dees and Anderson 2003; Easterly and Mieasing 2007). Is a for-profit status really more beneficial to the social ventures? To help address the social entrepreneur's quandary of 'to profit or not to profit', we investigate consumer reactions to social ventures that vary as a function of profit orientation.

This research proposes consumer support will be lower for FPSVs (vs. nonprofits) due to inferences of greed arising from the FPSV's profit orientation (Aakeret al. 2010; Gregoire, et al. 2010), which in turn reduce consumers' anticipated warm glow (i.e., emotional utility consumers get from being benevolent; Andreoni 1990). In addition to exploring this focal proposition, we subsequently identify theoretically and pragmatically relevant boundary conditions that alter the perceptions of greed and warm glow, and in turn, support for social ventures.

Study 1A-1C tested our fundamental proposition by exploring participants' actual monetary donations, financial and material donation intentions, and product purchase intentions toward a target organization described as either FPSV or nonprofits. Study 1A found that participants donated less money and reported lower intentions to donate both in-kind goods and money when the organization was described as a FPSV (vs. nonprofits). This aversion to FPSV (vs. nonprofits) was robust for consumer support in the form of product purchase (Study 1B), regardless of the quality of the product (Study 1C). The effect of profit orientation on consumer support occurred due to higher greed perceptions associated with the FPSV, which deterred anticipated warm glow (greed perceptions and warm glow were found as serial mediators in these and all subsequent studies).

Study 2-4 examined boundary conditions that may turn on/off the greed perceptions. Specifically, Study 2 explored the interplay of profits, operational efficiency, and revenue source. We expected that if a FPSV discloses minimal level of profits, it would reduce perceptions of greed associated with profit. Also, given that consumers exhibit 'overhead aversion' (Gneezy et al. 2014), justifying profits through greater operational efficiency would reduce greed perceptions. Importantly, the mitigating role of an efficiency justification for the effect of profit would occur, especially when the FPSV's primary revenue source is from product sales rather than donations. A significant three-way interaction of profits, operational efficiency and revenue source on consumer support for FPSV (vs. nonprofit) indicated that when the revenue source of FPSV was product sales, the negative effect of profit was significant in the absence of the justification but profit had no effect in the presence of the justification. When donation was the revenue source, profit undermined support for the FPSV regardless of whether a justification was provided or not,

Study 2 found increased support for FPSVs (vs. nonprofits) based on minimal profits or operational efficiency when revenue source was product sales but only to the point of indifference between FPSVs and nonprofits. Building on this finding, Study 3 sought to find how to overcome this aversion more effectively. We expected that a superior level of cause support in addition to minimal profits would lead consumers to prefer FPSVs over nonprofits. Additionally, we expected individuals' communal orientation (Clark et al. 1987) would moderate this effect: communal individuals would be more sensitive to organizational greed and cause support information. An interaction of cause support level and communal orientation indicated that consumers tended to support the nonprofit when cause support was unknown or equal for FPSV with minimal profits but switched to supporting the FPSV with minimal profits (vs. nonprofit) when cause support was higher for it. This effect was stronger for those with communal orientation.

Recognizing only about 24-31% of participants in Studies 1A-1C were aware of FPSVs prior to the studies, Study 4 explores whether disclosure of the organization's profit orientation is critical for consumer aversion to FPSVs (vs. nonprofits) to arise. To enhance practical and public policy implications, Study 4 examined reactions of *actual donors* to a social venture (FPSV vs. nonprofit) as a function of disclosure of the organization's profit orientation and consumers' communal orientation. We expected communal individuals would be more sensitive to disclosure of profit orientation given their sensitivity to greed. Participants were recruited based on prior donation experience (to Goodwill or USAgain) and were either informed of the organization's profit orientation (i.e., describing its nonprofit/for-profit status) or not. As expected, a three-way interaction of organization type, disclosure of profit orientation, and communal orientation emerged on repeat donation intentions. In the disclosure condition, participants were less likely to re-donate to FPSV (vs. nonprofit), with this effect stronger for those with higher communal orientation. In the no-disclosure condition, participants were equally likely to re-donate to both organizations and communal orientation uniformly predicted donations to both organizations. These findings suggest actual donors to FPSVs are largely unaware of the organization's profit orientation and, when so informed, their support declines.

Together, these studies demonstrate a strong aversion among consumers to FPSVs versus nonprofits due to higher greed perceptions and lower anticipated warm glow. This aversion is attenuated by minimizing profits or by justifying profits through operational efficiency and generating revenues through product sales. However, to be preferred to a nonprofit, a FPSV should provide superior cause support *and* take only minimal profits. Importantly, actual supporters of for-profit social ventures indicate reduced support when the organization's profit orientation is disclosed. Consumers with higher communal orientation are especially sensitive to disclosure of profit orientation, as well as the level of organization's cause support. By addressing new and important questions regarding the role of profit orientation in social ventures, we broaden the literature on consumer support for social causes, advance literature on organizational greed and warm glow, and provide important insights for social ventures and public policy.

SESSION OVERVIEW

Although extant research has made great strides in illuminating how consumer food choices are shaped by environmental and contextual factors, many questions remain ripe for exploration. This session explores two broad questions regarding consumer beliefs, preferences, and choices regarding healthy vs. unhealthy foods and portion sizes: (1) How does context affect the preferences and choices consumers make around healthy eating and portion size? (2) What are the implications and downstream consequences of perceiving healthy vs. unhealthy foods? With a multi-methods approach, this session explores the questions above from four complementary perspectives.

First, Liu, Dallas, Harding & Fitzsimons explore the implications of increasing the visual salience of various items in shopping displays. The authors detail an extensive field study at twelve convenience stores. Their results speak to the key managerial decision of which types of foods to feature (i.e. healthy vs. unhealthy vs. mix of both). For example, the authors show that featuring healthy foods increases sales of healthy foods; however, featuring both healthy and unhealthy foods leads only to an increase in sales of unhealthy foods.

While visual salience is unquestionably important, the following two papers explore other ways in which the context surrounding food consumption affects preferences.

Sussman, Alter & Paley directly examine the situation in which foods are consumed. When the same foods are eaten in more exceptional scenarios (e.g. a snack consumed in an airplane rather than in a car), consumers underestimate the caloric impact of their meal. In turn, this leads to preferences for larger portion sizes and an increase in actual consumption.

Next, Hagen, Krishna & McFerran suggest another contextual influence that guides preferences around consumption experiences: whether consumers wish to serve themselves or be served by others. When faced with unhealthy foods, consumers prefer to absolve themselves from responsibility for indulgent decisions. Correspondingly,

for unhealthy (but not healthy) foods, consumers display a marked preference for being served by others rather than serving themselves.

Lastly, Andre, Chandon & Haws provide a nuanced view of various types of health-related messaging. The authors identify two key dimensions characterizing health-related claims — positivity (vs. negativity) and naturalness (vs. scientific-alteration). Importantly, these dimensions have implications on perceptions and preferences regarding the healthiness, taste, satiation, and quality of the foods. These perceptions differ between French and American consumers.

In sum, addressing the first question raised earlier, this session provides three novel contextual factors shaping decisions around healthy vs. unhealthy foods and portion sizes: (1) the types of foods featured in displays (Liu et al.), (2) perceptions of consumption experiences as ordinary versus exceptional (Sussman et al.) and (3) preferences for being served by others vs. serving oneself (Hagen et al.). Regarding the consequences of perceiving healthy and unhealthy foods, this session identifies and explores important nuances surrounding health claims (Andre et al.), and details the consequences of perceiving healthy versus unhealthy foods on sales (Liu et al.) and serving-style preferences (Hagen et al.). Overall, this session offers key insights into real-world issues and carries implications for both managers and consumers.

Better for Both the Waistline and the Bottom Line: A Field Study on the Sales Impact of Featuring Healthy Foods, Unhealthy Foods, or a Mix of Both

EXTENDED ABSTRACT

Many stores offer both unhealthy foods and healthy ("better-for-you") foods (Gebauer and Laska 2011). Yet although healthy options are increasingly available, consumers often do not select them. One of the most common reasons is lack of salience (Chandon and Wansink 2002). Thus, policy makers have called for featuring healthy foods as a way to increase healthy food sales (Cohen and Babey 2012). Indeed, considerable research suggests that featured products are more likely to be chosen (e.g., Just and Wansink 2009).

However, we know little about the real-world impact of featuring either healthy or unhealthy foods on sales of the non-featured food type and thus on overall sales. We also know little about the impact of jointly featuring both food types. From a managerial perspective, both questions are important because they have implications for whether it is a more effective sales strategy to feature healthy foods, unhealthy foods, or a combination of both. Additionally, there are theoretical reasons why we might expect featuring one food type (healthy or unhealthy) to have a particular impact on sales of the non-featured food type and why we might expect a certain impact of jointly featuring both food types. For instance, the concept of licensing suggests that featuring healthy foods might increase both healthy and unhealthy food sales if consumers choose healthy foods and then feel licensed to indulge (Khan and Dhar 2006). As another example, the concept of vicarious goal fulfillment, whereby exposure to a healthy food can vicariously fulfill health goals (Wilcox et al. 2009), suggests that featuring both healthy and unhealthy foods will primarily lead to an increase in unhealthy sales.

Importantly, however, these various theoretical concepts have been identified through laboratory studies, primarily of hypothetical

choices, and few field tests exist. Given that some research suggests similarities in findings between hypothetical-choice lab studies and field tests (Shah et al. 2014), whereas other research suggests dissimilarities (Kiszko et al. 2014; Mochon et al. 2016), field tests are important when the findings have implications for real-world managerial decisions. Such field tests may also indicate which theoretical forces are strong enough to overcome the noisiness of the field.

Accordingly, we conducted a field study in twelve convenience stores over eight weeks, using an efficient Latin-Square research design enabling comparison of the impact of three treatment conditions (vs. a control) while controlling for differences between stores and time periods. Specifically, we identified 18 target products (9 unhealthy, 9 healthy) and compared the sales impact of featuring unhealthy foods, healthy foods, or a mix of both (vs. a control display not featuring any target products identified for this study) on sales of the 18 target products. The convenience stores provided basket-level sales data.

First, we found that featuring either only healthy foods or only unhealthy foods successfully increased sales of the featured foods. Second, we found that relative to the control condition, featuring only healthy foods did not decrease sales of unhealthy foods. In contrast, featuring only unhealthy foods resulted in a decrease in sales of healthy foods. In other words, featuring healthy (vs. unhealthy) foods had different effects on sales of the non-featured food type. Third, we found that featuring a mix of both healthy and unhealthy foods only significantly increased sales of unhealthy foods. The first finding is consistent with research showing that increasing the salience of products increases their sales (e.g., Just and Wansink 2009). The second and third findings offer unique contributions by representing field tests of effects predicted by various theoretical accounts from lab research. The second finding does not follow straightforwardly from any single theoretical account identified in prior research, showing that lab findings and field tests do not always converge cleanly. The third finding could be consistent with a vicarious goal fulfillment account whereby the presence of the healthy foods addresses a health goal for some consumers (Wilcox et al. 2009).

Interesting results were also found at the basket-level, shedding light on potential explanations for the sales results. The basket-level data for when only unhealthy foods were featured mirrored the sales data—unhealthy items per basket increased (vs. control), and healthy items per basket decreased. However, the basket-level data for when only healthy foods were featured and when a combination was featured did not mirror the sales data. Specifically, when healthy foods were featured alone, healthy items per basket increased (consistent with the sales results), while unhealthy items per basket decreased (differing from the sales results, which showed total unit sales of unhealthy items were not affected). We conjecture that this difference between unhealthy items per basket and unit sales of unhealthy items might have occurred because the healthy display may violate expectations for a convenience store (Gebauer and Laska 2011) and thus draw attention (Bettman 1979; Helgeson and Beatty 1987), leading some to make an unplanned healthy purchase; further, people who entered the store planning to buy an unhealthy item likely still purchased it (i.e., increasing the number of baskets purchasing any test items but not affecting sales of the unhealthy items). Similarly, when both healthy and unhealthy foods were featured, unhealthy items per basket increased (consistent with the sales results), whereas healthy items per basket decreased (differing from the sales results, which showed that total unit sales of healthy items were not affected). Again, we conjecture that this difference between healthy items per basket and unit sales of healthy items occurred because the healthy items drew people's attention to the display, increasing the number

of baskets purchasing a test item. Yet although some customers purchased healthy test products, most consumers still purchased the unhealthy test products, perhaps because of vicarious goal fulfillment processes (Wilcox et al. 2009). Thus, total unit sales of healthy foods directionally increased in this condition, but the number of such products per basket significantly decreased.

In sum, these findings mitigate potential concerns about featuring healthy foods. Rather, featuring healthy foods alone may be better from both firm and consumer welfare standpoints than either featuring unhealthy foods alone or featuring both food types.

Mental Accounting for Food in Exceptional Contexts

EXTENDED ABSTRACT

What seems like a bigger setback to one's diet: A small bag of peanuts consumed on a typical car ride or that same bag of peanuts consumed on a flight across the ocean? While the food is the same, the consumption context differs. This research suggests that the difference in context has broad consequences: the extent to which a consumption occasion is considered more ordinary or more exceptional guides eating behavior. Specifically, we demonstrate that people do not appropriately account for calories consumed during exceptional circumstances. This occurs in part because people have greater difficulty tracking these foods, and are less likely to recall eating them. In turn, this leads to a preference for larger portions and an increase in consumption.

Prior research has examined the distinction between ordinary and exceptional items in a financial context. Sussman and Alter (2012) demonstrate that people underestimate spending on exceptional purchases and overspend on such items. This occurs because of errors in budgeting. In the domain of charity donations, more exceptional framing of causes can increase donations (Sussman, Sharma, & Alter, 2015).

Across five lab studies, we investigate whether a similar distinction between ordinary and exceptional contexts influences choices we make for our diets. Examining both real and hypothetical consumption, we explore mental accounting processes around tracking caloric consumption. We provide evidence that people have greater difficulty tracking and recalling their consumption when foods are considered more exceptional.

In study 1, we prompted participants to consider a target food (chocolate) as more ordinary or more exceptional through a broad vs. narrow categorization task. Some participants were asked to list prior instances of junk food consumption, making chocolate seem more ordinary. Other participants were asked to list prior instances of chocolate consumption, making chocolate seem more exceptional. Then, participants had the opportunity to eat chocolate or other healthy snacks. We find that participants who view chocolate as more exceptional consume more of the target food (chocolate); however, they do not consume more of the control foods ($F_{int}(1, 144) = 6.21, p = .014$).

To better understand this behavior, in studies 2a and 2b, we showed participants a list of 10 foods consumed in exceptional contexts and 10 similar foods consumed in ordinary contexts (20 items per subject, counterbalanced between subjects). Participants indicated the extent to which each food was a setback to their diet. Participants considered the foods consumed in exceptional contexts to be less of a setback to their diets when compared to the same foods consumed in ordinary contexts (study 2a; t(152) = 2.71, p = .008). Further, participants believed that those same foods required less exercise to work off when consumed in exceptional (vs. ordinary) contexts (study 2b; t(149) = 2.42, p = .017).

In study 3, we explored a consequence of these beliefs. With the same list of foods used in studies 2a and 2b, we demonstrate a preference for larger portion sizes when a particular food is consumed in an exceptional (vs. ordinary) context (t(247) = 4.27, p < .001). The relative difference in preferred portion size between exceptional and ordinary contexts was mediated by the difference in the perceived setback to one's diet between foods consumed in each of the two settings (b = .33, (t(246) = 8.26, p < .001; Judd, Kenny, and McClelland, 2001).

In study 4, we apply a mental accounting framework to investigate how the calorie tracking process may vary as a function of perceived exceptionality. After seeing a list of 30 exceptional and ordinary items, participants were asked to recall the items shown. Participants had worse recall for exceptional items, suggesting errors in booking (t(64) = 3.94, p< .001). Participants were also asked to categorize recalled foods in seven categories (breakfast, morning snack, lunch, afternoon snack, dinner, evening snack, and other). For exceptional (vs. ordinary) items, participants were more likely to place them in the miscellaneous category, suggesting errors in posting (t(58) = 2.27, p = .027). This study points to the notion that people may be less likely to take note of exceptional consumption instances and less likely to post them to meaningful budget categories.

In five studies, we show a preference for higher levels of consumption (studies 1 and 3) when an identical food is considered exceptional rather than ordinary. We provide evidence that this discrepancy stems from errors in both booking and posting: episodes of exceptional consumption are less likely to be either remembered or meaningfully noted. People may fail to record the full value of their caloric intake when foods are consumed during exceptional circumstances (study 2a 2b, and 4), leading to higher levels of consumption.

Individual overindulgences can accumulate with little awareness. The conceptual distinction between caloric consumption in exceptional versus ordinary contexts is important for understanding biases that prevent people from leading healthier lives.

Outsourcing Responsibility for Indulgences

EXTENDED ABSTRACT

For many consumers, food consumption contexts are ridden with conflict. On the one hand, unhealthy food options are enticing—consumers perceive them as tastier (Raghunathan, Naylor, and Hoyer 2006) and more satisfying (Finkelstein and Fishbach 2010), and overall they elicit strong positive affective reactions (Shiv and Fedorikhin 1999). On the other hand, unhealthy eating is generally considered a "vice" (Chernev and Gal 2010; Thomas, Desai, and Seenivasan 2011), the consumption of which leaves many consumers feeling guilty (Ramanathan and Williams 2007; Wansink and Chandon 2006). Some research has found that consumers attempt to resolve this uncomfortable conflict with the help of motivated reasoning strategies so that they can "have their cake and eat it, too." For instance, they may fabricate licenses for their indulgence by minimizing their remembered prior consumption (May and Irmak 2014) or exaggerating foregone consumption (Effron, Monin, and Miller 2013). In this paper, we predict and find that a different path to remorse-free indulgence that consumers take is having someone else serve them.

Recent work suggests that consumers become more likely to make unhealthy choices when they are served by someone else, because being served allows them to reject responsibility and thus feel less bad for their unhealthy eating (Hagen, Krishna, and McFerran 2015). Based on these finding we hypothesize that consumers may strategically and proactively outsource responsibility for unhealthy eating. Specifically, we propose that consumers have a lay theory that being served by someone else will allow them to absolve themselves of (some) responsibility. If that is indeed the case, they should (i) strategically choose being served (versus serving themselves) for unhealthy (but not healthy) foods, and (ii) this preference for being served (versus serving themselves) should be driven by a motivation to reject responsibility. Two field studies and one controlled laboratory experiment support this idea.

Studies 1A and 1B tested consumers' preference for being served (versus serving themselves) unhealthy and healthy foods in field settings. Both studies featured contexts where who serves (self or other) is chosen by the consumer, that is, both serving oneself and taking a pre-served portion are available side by side.

In study 1A, we provided beverages in different groups of an undergraduate extra-curricular program. Students were told they could feel free to take a cup or pour themselves one if they wanted. In all classrooms, we provided the beverage containers and empty 8oz cups as well as half-filled 8oz cups. Thus people could either serve themselves the drink or take a pre-served cup. We manipulated the beverages' healthiness (healthy almond milk/blueberry juice versus unhealthy chocolate milk/pumpkin eggnog; pre-tested to be seen as differentially healthy but equally well-liked) and measured the respective proportions of students that chose the pre-served cups versus the empty cups to serve themselves.

Healthiness and server choice had a significant relationship, χ^2 (1, N=88)=30.34, p < .01. Specifically, for the unhealthy beverages, people who elected to have a drink were disproportionally more likely to choose the pre-served cups (50 out of 52) than to serve themselves (2 out of 52; χ^2 (1, N=52)=44.31, p<.01). For the healthy beverages, however, people were equally likely to take the pre-served drink (16 out of 36) as they were to serve themselves (20 out of 36, χ^2 (1, N=36)=44, p>.5).

Study 1B replicated the pattern from study 1A using snack foods in international student orientations. Together, the two field studies showed that, as predicted, for unhealthy (but not for healthy) foods consumers prefer being served instead of serving themselves. This is consistent with the hypothesis that consumers seek to avoid serving themselves in the case of unhealthy food, because they strategically seek to push off responsibility for unhealthy food. Yet, these data are aggregate, and process can only be inferred. Study 2 examined the hypothesized process directly in the laboratory and tested whether consumers' stronger preference for being served by someone else (versus serving themselves) when the food is unhealthy (versus healthy), is due to a greater motivation to reject responsibility for unhealthy (versus healthy) food.

In study 2, participants imagined a dinner reception where dessert was offered. We manipulated the dessert's healthiness (healthy fruit versus unhealthy cake) and measured participants' preference regarding who should serve the food as well as their motivation to reject responsibility. Serving preference was measured on a slider scale ranging from "*I prefer serving myself*" (0) to "*I prefer another person serving me*" (100). Motivation to reject responsibility was measured via agreement with "*For chocolate cake [fruit salad], I would probably look for 'excuses' allowing me to eat this food*" and "*For chocolate cake [fruit salad] it's nice if I can ascribe 'responsibility' for having it to other circumstances,*" measured on a slider scale from "*Strongly disagree*" (0) to "*Strongly agree*" (100). These two items were combined into an index for "motivation to reject responsibility" (α=.63).

People's preference for being served by someone else was higher for the unhealthy dessert than for the healthy dessert, F(1, 118)=11.80, p<.01. They were also more motivated to reject responsibility for the unhealthy dessert than for the healthy food, F(1, 118)=11.03, p<.01. Finally, motivation to reject responsibility medi-

ated the effects of food's healthiness (healthy versus unhealthy) on the preference for who should serve it (95% CI= -10.15 – -.21).

These results align with our motivated reasoning account: People's preference for being served (versus serving themselves) is enhanced for unhealthy food compared to healthy food, and the driving process behind this effect is the motivation to reject responsibility for consumption. Interestingly, we found that this process seems to occur even when people themselves chose to have a certain food.

These findings suggest that when offering indulgent foods (e.g., frozen desserts) providing full service may more easily attract consumers than requiring self-service. Studies directly testing this managerial implication are underway.

You Call This Healthy? Refining "Healthy Food" Claims and Their Impact on Choice and Healthiness Associations

EXTENDED ABSTRACT

Although it is well-known that consumers are poor at understanding food claims (see Marioti et al. 2010; Nocella and Kennedy 2012 for a recent review), it may come as a surprise that practitioners, food researchers, and consumers still have limited conceptual tools to navigate the diversity and complexity of the plethora of food claims present in the marketplace. Indeed, although past research has investigated people's responses to specific food claims (e.g., "low fat"), we do not know whether these reactions 1) can be generalized to other claims, 2) differ based on health goals, or 3) vary across different cultures (Rozin et al. 1999).

In this research, we first identified two dimensions of high theoretical and practical relevance in the context of food evaluations. First, positivity (focusing on the positive or negative aspects of the food), has been shown to lead to different responses in the context of food benefits (Malaviya and Brendl 2014), and this distinction between positive and negative nutrients is commonly used by business practitioners (e.g. "Smart Choice" or "NuVal" labeling systems). The second dimension, naturalness, reflects the natural or scientific derivation of the food claim. Indeed, concerns for the naturalness of food are widespread (Rozin et al. 2012), and marketers often highlight the natural qualities of their food products or extol the scientific benefits of their production process.

Next, we identified a set of 37 common and familiar food claims using an Amazon MTurk sample (N=432). These 37 claims were then used in Study 1, in which 401 MTurk participants each evaluated 8 food claims randomly chosen from the 37. The assessments included measures of naturalness, positivity, as well as inferences about the healthiness, taste and satiating power of the food, as well as demographic information.

Results revealed that consumers' perceptions of food claims are appropriately described by a four cluster solution, corresponding to a 2 (nature vs. science based) x 2 (positive vs. negative focus) perceptual space. We propose labels for the four types of claims we identify from this framework as follows: "Removing" claims (which are science-based and negative-focused, e.g., "gluten free"), "Adding" claims (science-based and positive-focused, e.g., "added vitamins"), "Not Removing" claims (nature-based and positive-focused, e.g., "organic"), and "Not Adding" claims (nature-based and negative-focused, e.g., "no artificial flavor"). Further analysis revealed that each type of claim was associated with different taste, health, and satiation expectations. For example, positive-focus claims were seen as healthier than negative-focus (M=5.49 vs. M=5.05, $F(1,33)$=19.67, p<.001), and similar differences were observed for the predicted satiation from the food (M=4.35 vs. M=3.70, $F(1,33)$=22.32, p<.001). The differences were even stronger for predicted taste: "Not Remov-ing" claims were seen as tastier than both "Not Adding" and "Adding", which were in turn seen as tastier than "Removing".

In study 2, we examined how our framework can predict choice. We focused on two specific products, corn flakes cereals and milk, and tested the impact of the four types of claims identified in study 1 across different eating goals. A U.S. marketing research firm provided us with a panel of 600 participants, who were primed with one of three goals, two of which were health-related (losing weight goal vs. being healthier goal), and a "taste good" control condition. Consumers were then asked to pick one cereal among a set of five different realistic cereal boxes, four of them bearing a health claim for each of the four types (e.g., "no artificial flavors" for negative-natural claims and "low in sugar" for negative-scientific claims) and the fifth being a control option bearing no claim. Analysis revealed that preferences for food claim types shifted across goals. For example, consumers primed with a weight loss goal favored science-based claims, while those primed with a healthy eating goal chose nature-based claims. This pattern was particularly true for negative, but not positive claims. Similar findings emerged based on subsequent choice of milk to accompany the cereals, using different exemplar claims from our health-claim framework.

In study 3, we sought to conceptually replicate the results obtained in study 2, but also investigate similarity and differences between cultures in responses to the health claims. To do so, we collected samples from both U.S. MTurkers as well as a demographically matched sample of French participants (Total N=1367). We selected 16 food claims from our previous list of 37 (4 from each cluster), and each participant was randomly assigned to view four food claims. For each claim, the participants were asked to imagine a cereal box bearing the claim, and to evaluate the predicted benefit of consuming the product in terms of health, taste, satiation, quality, and dieting. For overall evaluation of the cereal, the French preferred those with the nature-based claims over those with the science-based claims, whereas the Americans liked both nature and science-based claims equally. Health claims focusing on positive elements led to better inferences in general (about healthiness, taste, and quality) than health claims focusing on negative elements across both cultures. However, while Americans viewed science-based claims as healthier than nature-based claims, the opposite was true amongst the French participants. Science-based and negative "Removing" claims were perceived to be better for dieting in both countries. Finally, nature-based claims were linked to better taste and food quality than science-based claims across cultures.

In conclusion, our results provide both food researchers and marketers with a better understanding of the way consumers perceive healthy food claims based on the underlying dimensions of positivity and naturalness, and the extent that food claims impact choice based on various health goals, and the different expectations in terms of taste, healthiness, and other characteristics. Further, our cross cultural study documented both some similarities, but also striking differences in how health claims were perceived by American and French participants, suggesting that the cultural context is critical in determining which type of claims most effectively communicate a product's healthiness.

Stephan Meier, Columbia University, USA
Olivier Toubia, Columbia University, USA

SESSION OVERVIEW

The financial decisions consumers make are increasingly complex and important for their financial welfare. For instance, consumers now decide whether to finance a purchase on any of several credit cards that vary along interest rates, reward structures, grace periods, and potential fees. Consumers decide which investments fit their risk tolerance, despite widespread misunderstanding of how financial risk works (Reinhold, Fernbach, and de Langhe 2016). Consumers also make decisions about mortgage refinancing not only in light of the complexities of the loans, but also in light of predatory lending practices (Bond, Musto, and Yilmaz 2009). Financial decisions like these present challenges to decision-makers; they usually involve a time component, trading off current desires for future necessities, and reasoning about complex, nonlinear relations (e.g., compounding: Mckenzie and Liersch 2011; stock-flow problems: Cronin, Gonzalez, and Sterman 2009). To deal with such complexity, consumers mentally simplify the decisions. The papers in this session describe several ways consumers simplify, and show cases where the result is beneficial or detrimental to consumer welfare.

First, Long, Fernbach and de Langhe find having a high understanding of what a company does leads people to perceive the company's stock as being less risky. They also find understanding is unrelated to the true risk of a stock, indicating the bias leads to consumers making investments that do not match their risk preferences. Second, Walters and colleagues investigate a novel individual difference – debt aversion. They find debt aversion is associated with several biases, such as negative discount rates for losses. However, in real-world decisions debt aversion can lead to an especially positive outcome – better credit scores. Third, spiller, Reinhold, and Maglio find consumers tend to form opinions based on the direction of a trend regardless of whether the same information is presented as a stock (e.g. asset price over time) or a flow (e.g. rate of return over

time). For instance, if an asset's price is increasing at a diminishing rate, when presented as a stock the direction is positive, and people tend to think the price will keep increasing. When presented as a flow, the direction is negative, and people tend to think the rate of change will continue, and the stock's price will soon decrease. Finally, Johnson, Meier, and Toubia find consumers overwhelmingly do not accept beneficial mortgage refinance offers. Consumers' high suspicions about financial institutions' motives lead to decreased offer acceptance.

These papers seek to answer not only how consumers simplify the complex decisions they face, but also how these heuristics affect the quality of decisions. The session will be a great opportunity for students interested in the burgeoning field of consumer financial decision-making to get a good sense of the topics and methods researchers are tackling. The papers present a variety of methodologies from laboratory experiments to secondary-data analysis to field experiments, and they deal with a range of substantively important topics like debt accumulation, investing, and mortgage refinancing. They also cover a broad theoretical range from basic psychological processes to actual consumer behavior in the marketplace.

Better Understood Companies Seem Like Safer Investments

EXTENDED ABSTRACT

Investment experts often advise people to invest in companies that they understand. This can be a beneficial strategy, because a consumer may have local knowledge other investors do not have, allowing the consumer to make a better valuation of the company (Hayek 1945). However, this rationale means that understanding is merely a starting point – the first step in determining a company's value. Unfortunately, consumers often misinterpret the experts' advice, thinking companies they understand are safer to invest in.

Prior research has found that sense of understanding influences preference formation (Hadar and Sood 2014; Fernbach, Sloman, St. Louis, and Schube 2013; Hadar, Sood, and Fox 2013). Our research shows that a person's sense of understanding influences preferences by impacting risk perceptions. When people feel they understand what a company does, investing in that company feels safer. While sense of understanding may be a valid indicator of risk in some domains, it is not in the financial domain. Thus relying on sense of understanding to guide investment decisions leads to suboptimal choices.

Study 1a

We presented 248 participants with ten company descriptions, sampled randomly from the S&P 500. Each participant read the company's profile from Yahoo! Finance, and rated how risky investing in the company was, how well they understood what the company does, and how familiar they were with the company. Participants completed the epistemic and aleatory risk scale (Ears; Fox, Tannenbaum, and Ulkumen 2016). Ears measures the degree to which a person believes an event's outcome is knowable in advance, given enough information (epistemic) versus completely random (aleatory). Finally, we computed each stock's capital asset pricing model (CAPM) beta statistic, which is an objective measure of a stock's risk.

As predicted, companies rated as higher in understanding received lower risk ratings ($r = -0.31$, $p < .001$). However, understand-

ing did not correlate with objective risk (r = -0.06, *p* > .23). Regression analyses indicate that the relationship between understanding and risk is robust (β = -0.12, t(475) = -2.74, *p* < .007) after controlling for differences in familiarity, objective risk, or aleatory/epistemic risk judgments.

Study 1b

We presented 335 participants with four company profiles, sampled randomly from the S&P 500. Instead of rating risk on a seven-point scale, participants completed a distribution builder task in which they constructed a histogram by assigning 100 balls to 11 bins that represent possible rates of return for the stock. From the participant's distribution, we calculate several statistics including the mean rate of return and standard deviation. Participants also rated other covariates as in s1a and we calculated objective risk statistics.

We used the standard deviation as a proxy for perceived risk due to its long history of representing risk in mean-variance models of investing (Markowitz 1952). Again, we found that higher understanding is related to lower risk perceptions (r = -0.19, *p* < .001) and that this relationship remains significant when controlling for other measured variables (β = -0.23, t(446) = -4.26, *p* < .001). We also analyzed participants' mean expectations for stock returns. Participants estimated higher average returns for higher understanding companies (r = 0.16, *p* < .001), and the result remained significant when controlling for the other variables (β = 0.26, t(446) = -2.99, *p* < .003). The effects of understanding on perceived standard deviation and mean of the outcome distribution is consistent with previous research connecting risk perception both to uncertainty and to the likelihood of bad outcomes (Slovic 1987).

Study 2

Studies 1a and 1b established across a broad range of companies that people perceive less risk in companies that they understand better. In study 2, we manipulate understanding by providing participants with structured versus unstructured information about companies. In the structured condition, participants examined a table containing divisions of the company in one column and what that division produces or sells in the second column. In the unstructured condition, participants received the same information, except the table was split in two, such that participants could not directly match a division with what it produced or sold. Pretests indicated that the structured condition had higher ratings of understanding for companies that were rated as easy to understand in studies 1a and 1b, but had the opposite effect for companies rated as hard to understand in studies 1a and 1b (f(1, 198) = 16.42, *p* < .001). In the main study, we measured ratings of risk on the same 7-point scale as study 1a, and found that for companies that were rated as easier to understand in studies 1a and 1b, structure caused lower risk ratings (t(199) = -3.67, *p* < .001). For companies that were rated as harder to understand in studies 1a and 1b, structure caused higher risk ratings (t(199) = 3.13, *p* < .001).

Study 3

In study 3, we investigate how sense of understanding impacts portfolio composition. Participants were asked to allocate $10,000 to stocks to create a portfolio for a hypothetical client. Participants were randomly assigned either a client described as having a high risk-tolerance or a low risk-tolerance. Participants were shown three company profiles rated as easy to understand in previous studies and three rated as difficult to understand. If sense of understanding is negatively correlated to risk in people's minds, participants in the low risk-tolerance condition should allocate more money to well-un-

derstood companies and participants in the high risk-tolerance condition should allocate more money to poorly understood companies. In line with these predictions, participants allocated a higher percentage of money to high understanding companies in the low risk-tolerance condition than high risk-tolerance condition (m_l = 61%, m_h = 44%, t(149) = 6.36, *p* < .001).

Across several studies we show that risk perceptions are driven by consumers' sense of understanding about what a company does. However, sense of understanding is unrelated to the true riskiness of a stock. Reliance on sense of understanding as a cue for risk can thus lead people to select investments whose true level of risk mismatches their risk preference.

Debt Aversion: Anomalous in Theory, Advantageous in Practice

EXTENDED ABSTRACT

Casual observation suggests that people display varying attitudes towards debt. However, the traditional view of time preference is that people are prone to taking on debt, paying a premium to make payments later rather than sooner. In this paper we assert that debt seeking may not be as universal as standard discounting models assume. Even if people take on debt in practice due to liquidity constraints, they may treat debt as inherently unappealing. For instance, many people who pay off their balances in full each month prefer to make purchases by debit rather than credit card, even though using a credit card under these conditions is tantamount to an interest free loan (Zinman 2009).

In this paper we introduce a novel scale to measure general attitudes towards debt: the debt attitude scale (DAS), a 4-item measure of aversion to debt that we show can predict three anomalous intertemporal preferences in the lab: individuals higher in debt aversion are more likely to exhibit negative discount rates for losses, greater patience for losses compared to gains (the gain-loss asymmetry), and greater patience for borrowing compared to saving (the borrowing-saving asymmetry). Despite the fact that debt aversion predicts anomalous patterns of preference in the lab, in a field study we find that individuals who report higher levels of debt aversion actually have better credit scores.

The first anomaly, negative discount rates for losses, is the observation that many people prefer incurring a loss sooner rather than later and therefore require a premium to postpone making payments (Scholten et al. 2016; Yates and Watts 1975) so that measured discount rates are sometimes negative (Hardisty, Appelt, and Weber 2013). This finding, which contradicts standard economic analysis, might also be interpreted as an expression of debt aversion. Thus, we predict that explicit ratings of aversion to debt on our rating scale will be associated with a higher frequency of negative discount rates for losses in a generic intertemporal choice task.

The second anomaly, the gain-loss asymmetry (Loewenstein and Prelec, 1992), is the finding that people tend to be more patient when making decisions concerning future losses than future gains. For example, a person who is indifferent between gaining $100 today and gaining $120 one year from today will generally prefer losing $100 today to losing $120 one year from today. Our interpretation is that delayed losses or payments tend to be construed as debts, since they are obligations to pay money in the future, and that people who are debt averse will prefer to incur the loss as soon as possible. Thus, we predict that people who express more debt averse attitudes on the DAS will exhibit greater patience in a generic intertemporal choice task when assessing losses relative to gains (i.e., show greater gain-loss asymmetry in discounting).

A third, related anomaly, which we call the borrowing-saving asymmetry, is the observation that people's discount rates are typically lower for borrowing than saving (Prelec and Loewenstein 1998; Meissner 2015). We predict that because people with more debt averse attitudes discount future losses less than gains, they will generally have lower discount rates for borrowing (i.e., gaining money today in exchange for losing money in the future) than saving (i.e., losing money today in exchange for gaining money in the future).

Although debt aversion may be associated with "anomalous" behavior, in that it violates standard economic accounts of intertemporal discounting, it may nevertheless provide some advantage or protection to people making every day financial decisions. It is well known that people tend to be impatient, and seek to favor immediate over deferred gratification, which is often funded by unsustainable debt (e.g., running up credit card balances). An instinctive aversion to debt may serve as a restraint on such behavior and thus moderate any tendency to over-borrow.

In study 1 we find that debt aversion is associated with negative discounting for losses. Participants (n = 520) first completed the debt attitude scale (DAS). Participants then completed a titration of discount rates for losses using a standard discount-delay task and a measure of loss aversion. We find that the majority of participants expressed debt aversion (i.e., responses above the midpoint of the scale). Participants reporting greater debt aversion on the DAS were more likely to express negative discount rates for losses, even after controlling for other factors such as loss aversion ($p < .001$).

In study 2 we extended this result to show that debt aversion is associated with greater asymmetry in gain-loss discounting. Participants (n = 168) completed the DAS and a titration of discount rates for both losses and gains. Participants higher in debt aversion tended to express lower discount rates for losses-vs-gains whereas participants low in debt aversion showed no difference across elicitations (interaction $p < .05$).

In study 3 we find that debt aversion is associated with greater asymmetries in discount rate for borrowing versus saving. Participants (n = 313) completed the DAS, a borrowing schedule titration, and a saving schedule titration. Once again, participants reporting greater debt aversion on the DAS tended to be more patient for borrowing (trading off an immediate gain against a larger looming loss), but not for saving (trading off an immediate loss for a larger looming gain), interaction $p < .05$.

Although debt aversion is associated with anomalous behaviors in the laboratory, we expected that it might confer some advantage in practice. In study 4 participants (n = 152) completed the DAS, other individual difference measures, and gave consent to obtain their credit scores. We find that higher scores on the DAS are related to better credit scores, after controlling for demographic variables ($p < .01$). Further, we find the DAS is a stronger predictor of credit scores than previously proposed attitude scales.

In sum, we develop a new, easy to administer attitudinal measure of debt aversion. We find debt aversion to be common. Further, debt aversion appears to serve as a useful heuristic for better financial decision making in the field, but leads to anomalous behavior in the lab.

Judgments Based on Stocks and Flows: Different Presentations of the Same Data Can Lead to Opposing Inferences

EXTENDED ABSTRACT

Prudent financial decision-making requires understanding how quantities change over time and how they might change in the future. Good investors should understand macroeconomic trends such as sales and job growth when deciding whether to enter a market. Families should understand their financial assets and liabilities before committing to expenditures or debt. Quantities that change over time can be presented in different ways. Here, we focus on two ways to present the same information: as a stock (e.g., wealth over time) or as a flow (e.g., income less expenditures over time). Although each format presents the same information, even well-educated adults have substantial difficulty translating between stocks and flows (Cronin, Gonzalez, and Sterman 2009; Sweeney and Sterman 2000; Sterman 2010). We find that presentation format (stock vs. flow) influences the judgments consumer make.

When making judgments, people heavily weight information that is made the most salient (Kahneman 2015; Slovic 1972; Tversky and Kahneman 1981; in graphical displays: Cleveland and McGill 1984; Lurie and Mason 2007). As a result, trends that are explicit influence judgments more than trends that must be deduced. Consider a $1,000 bank account balance that increases to $1,700, to $2,100 and finally to $2,200 with an implied flow of +$700, +$400, +$100. One might judge the balance based on the stock trend (increasing) or the flow trend (decreasing). One common mistake is to conflate the two, inferring that stocks and flows track each other's patterns (Sweeney and Sterman 2000). Our results indicate that presentation format – and the apparent trend that varies by format – shapes consumer judgments.

Study 1

100 participants were randomly assigned to view us employment data (2007-2013) as either a stock (number of private-sector jobs per month) or flow (number of private-sector jobs gained or lost per month). The most rapid job loss occurred around January 2009 when Barack Obama was inaugurated. The rate of job loss accelerated in the previous year and slowed (but did not reverse) in the year following his inauguration. Although they show the same data, the apparent stock trend during Obama's first year was negative and the apparent flow trend was positive.

When asked "in your view, what effect did Barack Obama have on the American economy during his first year in office?" (1 = "made it much worse," 7 = "made it much better"), flow participants reported that Obama had a positive effect ($m = 4.84$, $sd = 1.36$), whereas stock participants reported that Obama had a negative effect ($m = 3.32$, $sd = 1.61$; $t(98) = 5.10$, $p < .001$); each of these values significantly differed from the midpoint (4 = "made no difference," ps < .01). We do not claim whether one depiction better represents the economy, but rather that they lead to very different judgments.

Study 2

402 participants were randomly assigned to make forecasts from each of 9 stock graphs or 9 flow graphs. These nine graphs came from a 3 (stock trend: negative, zero, positive) x 3 (flow trend: negative, zero, positive) design; domains and magnitudes were randomized across patterns. Consider the sequence (32, 41, 47, 50, 50) with the associated flow (+9, +6, +3, +0). This sequence has a positive stock trend (32 to 50) and a negative flow trend (+9 to +0). Par-

ticipants saw four years of monthly data and the ending quantity and made a forecast of what the quantity would be one year later.

Across the 9 patterns, the modal response reflected a linear extrapolation from the ending trend. In 5 cases, this trend had the same sign for stocks and flows, with the dominant response receiving 79% to 100% of responses. In the other 4 cases, forecasts followed the observed ending trend, which varied for stocks and flows. For example, for a positive stock / negative flow trend, the modal forecast in the stock condition was no change (41%) and the modal forecast in the flow condition was negative (94%). In each of these 4 cases, the distribution of signed changes varied by condition ($p < .001$).

Study 3

Are these differences due to an inability to comprehend the graphs? We selected the four cases with different ending trends from study 2, but calibrated the trends differently (e.g., the positive stock / negative flow trends were patterned (20, 32, 41, 47, 50) and (+12, +9, +6, +3), respectively). 605 participants were assigned to one of six conditions in a 3 (graph: stock, flow, stock+flow) x 2 (order: forecast then describe; describe then forecast) design. Participants in the stock+flow condition saw both graphs; their responses fell between the stock and flow participants and we do not discuss them further. The forecast task was like the study 2 task. The describe task asked participants to read and compute quantities from the graph rather than make a forecast of the future.

Aggregate results replicated study 2. Among the observations on which participants described the graphs correctly (42%; cf. Cronin et al. 2009), the differences persisted when flows trended upwards or downwards. For example, for a positive stock / negative flow trend, the modal forecast in the stock condition was positive (97%) but the modal forecast in the flow condition was negative (41%; $p < .001$).

Study 4

Study 4 tested whether the effect persists when data are displayed as a table. 401 participants were randomly assigned to one condition in a 2 (data: stock, flow) x 2 (display: graph, table) design. Each described and then made a forecast based on a positive stock / negative flow. Results replicated study 3. Even among participants faced with a table, the effect persisted among the 81% who read the table correctly. The modal forecast in the stock condition was positive (87%) but the modal forecast in the flow condition was negative (50%; $p < .001$).

The decision to present data as stocks or flows, despite being formally equivalent, is not a neutral choice. Stark differences in judgment valence result from such differences, even among those who demonstrate a priori that they can accurately describe such graphs.

Leaving Money on the Kitchen Table: Exploring Sluggish Mortgage Refinancing using Administrative Data, Surveys, and Field Experiments

EXTENDED ABSTRACT

Refinancing is one of the most important financial decisions of households. Getting this decision wrong can be very costly for homeowners. Previous research does suggest that borrowers do not optimally refinance (see, e.g., Stanton 1995; Campbell 2006; Agarwal et al. 2012). The many borrowers who do not refinance when they should or do so sluggishly (referred in industry circles as "Woodheads") potentially leave a lot of money on the table. Keys et al. (2014) estimate based on loan-level data that the median present-discounted cost of failing to refinance is about $11,500. In this paper, we take advantage of the home affordable refinance program (HARP), a setting that has multiple features that allow us to address these issues. First, we have detailed information about the offers sent to about 800,000 borrowers and then observe whether they refinanced through this program. Second, all those offers have no upfront costs – all prepayment penalties and appraisal costs are waived and provide substantial savings, suggesting that refinancing should be frequent. We ask 1) how much money do borrowers leave on the table by not accepting the refinance offers, and 2) whether heterogeneity in borrower's preferences, attitudes, and/or financial sophistication can explain part of the refinance patterns. Finally, HARP refinancing is very lucrative for same-servicer refinancing as these loans are sold at a premium (see, p. 35 in Fuster et al. 2013). This allows the offerer to conduct several different (behaviorally informed) interventions to attempt to increase refinancing rates. Thus HARP provides us with a relatively unique setting in which many empirical problems are minimized.

The results show that only 16.23 % of the borrowers applied to the first refinance offer sent by the bank. While we observe refinance offers, we do not have information about other offers from competitors. However, we do know whether borrowers paid off their mortgage – which can be either through another refinance offer from our fi, by refinancing with a competitor or paying off the loan in full. Overall, 60.16% did not refinance. This is stunningly high given the fact that there are no monetary costs and that the pre-approved offers are attractive: on average, the interest rate drops by 1.8 percentage points (median: 1.75). Such a rate decrease would lead to a monthly savings of $204 on average (median: $122). If non-applicants had picked up the offer from the fi, they would have saved several thousand dollars over the life time of the mortgage. Our results show that many households leave substantial amounts of money on the table by not applying to the refinance offer. However, this does not mean that borrowers do not pay any attention to the offer because, on average, borrower react to the attractiveness of the offer in an expected way: the more attractive the offer (the greater decrease in interest rate) the more likely borrowers are to refinance. However, application rates increase only up to a certain point after which the application probability almost returns to the baseline level. Because borrowers react to the attractiveness of the offer, it appears that they at least looked at it.

We next investigated potential reasons for not refinancing by conducting a large-scale survey with a subset of borrowers. We match the answers to the survey to the administrative data. The responses suggest that part of the problem of sluggish refinancing is suspicion by borrowers of the motives of financial institutions. Apparently, refinance offers under the HARP program seem too good to be true for many borrowers. Households expect there to be hidden fees and cumbersome processes that are not compensated by the attractiveness of the offer. The evidence from the survey matched to the administrative data suggests that higher suspicion about the motives of financial institutions is robustly associated with lower application rates. In addition, we find that typical time preference parameters such as present bias and discount rates are significantly related to the refinancing decision. Present bias and discount rates (following Laibson (1997)) predict how sensitive borrowers are to the attractiveness of the offer (i.e., the interest rate decrease). At the same time, other psychological factors, like numerical ability, conscientiousness, and others seem less important in determining refinance decisions.

Our resulting set of field experiments demonstrates that barriers to refinancing are extremely difficult to overcome. For example, the literature suggests that financial incentives may nudge present-biased individuals into applying (see, e.g. Charness and Gneezy 2009;

Gneezy et al., 2011). Based on this logic, in one field experiment the fi offered an immediate benefit, i.e. gift cards of up to $100, for applying. In another field experiment, the bank relied on a third-party (in our case, Fannie Mae and Freddy Mac) to increase the credibility of the program. Finally, in a third field experiment the bank committed to paying $500 to the borrower if the process took more than 30 days. However, when borrowers are suspicious, they are likely to discount such interventions. If anything, these interventions might backfire, and borrowers become even more suspicious. Evidence from three large-scale field experiments (with more than 100,000 borrowers per experiment) indicates that these interventions have no effect on application rates. Offering gift cards, for example, has—if anything—a slight negative effect on application rates. In other words, interventions that try to tackle psychological barriers like present-biased preferences may not be effective when customers are suspicious.

This result sheds light on the question of how sustainable it is to exploit consumers' decision-making biases. If the suspicion of our borrowers was really shaped by the past behavior of the financial industry, then the resulting loss of trust has delayed costs in that it restricts the fis ability to sell its products. As such exploiting behavioral bias in the short-run, might then have long-term costs in terms of increased suspicion. Indeed, the importance of trust (and the lack thereof) in guiding customer behavior has been well documented in marketing (Berry 1996; tax et al. 1998; Garbarino and Johnson 1999; Sirdeshmukh et al. 2002; Harris and Goode 2004), but neglected in finance.

SESSION OVERVIEW

To say that affect and cognition both shape decision-making is in no way new. However, most of the research to date has studied the affective and cognitive drivers of judgment and decision-making in isolation from each other. In this special session, we present four papers that consider the interplay of affect and cognition and collectively answer the following questions:

How do incidental, anticipated, and actual emotions shape the building blocks of cognitive activities (e.g., reference point formation, information processing, and intertemporal discounting)?

Does recognizing these emotional influences allow us to better explain or change effects observed when decision-making is viewed from a purely cognitive perspective?

Though sharing a fairly tight focus on the above-two questions, the papers in the session approach affect differently enough to offer a range of perspectives. While some examine the influence of incidental affect on otherwise cognitively-driven decisions (Mormann, Nowlan, and Johnson), others focus on integral affect (Hardisty, Frederick, and Weber; Nikolova and Lamberton; Sokolova and Krishna).

The session starts with a paper by Moormann, Nowlan, and Johnson who examine how *incidental emotions* affect reference point formation in stocks evaluation decisions using eye-tracking. The authors suggest that incidental emotions determine how investors allocate attention to different pieces of financial information when evaluating a stock (initial, current, high, low prices), which, in turn, impacts their reference point for the stock.

The session continues with illuminating our understanding of the interplay between cognition and *integral affect*. Hardisty, Frederick, and Weber demonstrate that asymmetries in anticipatory affect explain why losses are discounted less than gains (the "sign effect"). Results show that waiting for gains is a mixed emotional experience (pleasurable due to savoring and painful due to impatience), whereas waiting for losses is a unidimensional painful experience. These differences in anticipatory affect mediate the "sign effect" in discounting.

Nikolova and Lamberton examine the role of anticipatory integral affect in self-regulation. The authors demonstrate that individual differences in affective forecasting accuracy predict indulgence/restraint in emotion-driven domains (food and time management) better than does trait self-control. Further, they find that mispredictions of hedonic (but not self-conscious) affect, drive indulgence, and suggest simple debiasing strategies.

Finally, Sokolova and Krishna take a broader perspective and examine how task type (choice, rejection) alters the impact of the affective, heuristic-based System 1 and deliberative System 2 on decision-making. Using robust judgment and decision-making phenomena (e.g., framing effects), the authors show that task type shifts decision-making from the affective, heuristic-based System-1 processing (in choice) to the deliberative System-2 processing (in rejection).

In sum, the papers in this session (comprising 19 studies and one eye-tracking experiment) advance our theoretical understanding of the affective and cognitive influences on judgment and decision-making from four intriguing perspectives in a variety of disciplines (marketing, psychology, economics, and finance), using different methodologies (lab studies, eye-tracking experiment, and quantitative modeling), and considering a variety of important decisions. We expect the session to be of great interest to a broad audience of researchers working in the areas of judgment and decision-making, affect, cognition, and self-regulation.

(Emotional) Reference Point Formation

EXTENDED ABSTRACT

Reference points influence investor behavior because financial outcomes are coded as gains or losses relative to the reference point. The behavioral finance literature mentions multiple reference points, such as the purchase price or historic highs. However, it is not clear exactly how reference points are formed or "how multiple reference points compete and combine" (Kahneman 1992), and whether transient emotional states influence the combination of multiple reference points.

Here, we use eye-tracking to examine how people form their reference points. In addition, we investigate how incidental emotions affect reference point formation. Recent work has shown that emotions influence financial decisions at the market level (e.g., Edmans, Garcia, and Norli 2007) as well as the individual level (e.g. Lee and Andrade 2011). This area of research emphasizes the underlying role of social inferences in explaining the effect of emotions on decision making. Here, we focus on another mechanism through which emotions should drive decision making; namely, perception and attention.

We suggest that incidental emotions guide investors' attention when evaluating financial assets, which, as a result, influences their subjective valuation, or reference point, for those assets. Relative to negative emotions, positive emotions have been shown to increase the breadth of attentional processes and guide attention to peripheral stimuli in basic visual tasks (Fredrickson 2001; Wadlinger and Isaacowitz 2006). Building on this research, we designed an experiment in which participants observe stock charts conveying temporally local information (i.e. the current price) and peripheral information (i.e.

historic highs, lows, and the purchase price). We explore whether the relationship between emotion and attentional breadth can predict: a) which prices investors look at, and b) their subsequent valuations of each stock they observe.

The experiment consisted of two tasks. First, incidental emotion was induced by showing either a joyful, fearful, or emotionally neutral control video. Second, after watching the video, twenty-two subjects viewed stock charts and were asked to determine their "neutral selling price", i.e., reference point, for each stock across multiple trials (Baucells, Weber, and Welfens 2011). Eye-tracking was used to examine the amount of time people fixated on, i.e., considered, the initial, current, high, and low trading prices on the stock chart as they formed their reference points.

Our eye-tracking data shows that, as individuals form their reference points, the initial and current price receive the most attention, followed by highs, while lows receive very little attention. We find that incidental emotions significantly influence formation of the reference point ($F(2, 232) = 7.13$, $p < .01$): joyful investors form the highest reference points, followed by neutral investors, and finally fearful investors.

Our eye-tracking data reveals that incidental emotions influence how investors allocate their attention to stock charts: attention to the current price is greatest among those in the fear condition ($F(2, 241) = 10.77$, $p < .01$), while attention to the initial and high prices is greatest among those in the joy condition ($F(2, 241) = 10.16$, $p < .01$; $F(2, 231) = 8.59$, $p < .01$, respectively).

Finally, we develop a quantitative model of the underlying process and show that emotions affect how investors allocate their attention and that, in turn, attention affects reference point formation. The model demonstrates that for a given stock graph, attention to the low price decreases the reference point while attention to the high price increases the reference point. For stocks in which the current price was relatively high (i.e., when the stock trend is up), we find that attention to the current price increases the reference point, but we find the reverse when the current price was relatively low (i.e., when the stock trend is down). Follow-up analyses demonstrate that looking times at the current price region mediate the negative effect of fear on reference point when the stock trend is down (indirect effect = -.046; 95% CI: -.108 to -.004), and suppress the negative effect of fear when the stock trend is up (indirect effect = .035; 95% CI: .002 to .110). These findings implicate attention as one of the processes through which incidental emotions influence the reference point.

This research makes important contributions to the decision making literature by highlighting a key situational factor that influences reference point formation; namely, incidental emotions. Further, we build on findings in the attention and perception literature by demonstrating that the effects of emotion on attentional scope translate to relatively complex information search and judgment contexts. These findings carry implications for household financial decision-making and can help us better understand various market level phenomena, such as the disposition effect.

The Bright Side of Dread: Anticipation Asymmetries Explain Why Losses Are Discounted Less Than Gains

EXTENDED ABSTRACT

The desire to have good things immediately is much stronger than the desire to postpone negative outcomes (Thaler 1981; Hardisty and Weber 2009). Though this "sign effect" is a robust result, the reasons for it are not well understood. We hypothesize that the desire to postpone losses is weaker than the desire to accelerate gains because aversive anticipation of bad things is stronger than the pleasur-

able anticipation of good ones, even after controlling for loss aversion. Anticipation utility predicts lower discount rates for losses, but has little effect on gains, producing the sign effect. This anticipation asymmetry happens because waiting for a gain is a mixed emotional experience that is both pleasurable and painful, whereas waiting for a loss is a more unidimensional painful experience.

Loewenstein (1987) famously found that people were willing to pay more for a kiss from a movie star in three days than for an immediate kiss, and inferred that the increased value of the delayed kiss was driven by savoring. However, we ran several replication studies (Pilot Studies 1-3) and were not able to replicate this finding. This suggests that savoring may be less robust than previously thought. In contrast, several papers have documented the importance of dread in intertemporal choice. For example, Berns and colleagues (2006) assessed dread for electric shocks using both self-report and fMRI of brain activation during the period preceding them. People who reported greater "anticipatory anxiety" exhibited more activity in posterior elements of the cortical pain matrix, and had a stronger preference for immediate shocks. Such results demonstrate the efficacy of self-report measures of dread. The relative strength of anticipation for positive versus negative events, however, has rarely been examined, and is our focus.

In Study 1 (n = 193), participants chose between $49 today OR $60 in 89 days. These amounts referenced gains or losses depending on the condition to which respondents had been randomly assigned. Participants were then told to "Imagine expecting to receive [pay] $60 in 89 days." and were asked "How psychologically pleasurable or displeasurable would the anticipation be? In other words, how would you feel while waiting for it?" They responded on a 201 point bipolar scale ranging from -100 "strongly dislike the feeling of waiting" on the left to +100 "strongly like the feeling of waiting" on the right, with 0 labeled "neutral." Participants then answered 26 other choices between smaller smaller sooner and larger later rewards [penalties] (all from Kirby, Petry, and Bickel 1999) and some demographic questions.

Participants' desire for immediate gains was stronger than their desire to postpone losses, replicating the sign effect. SS rewards were preferred 57% of the time in the gain conditions compared to just 26% preference for LL losses, $t(191) = 10.7$, $p < .001$. This implies annualized discount rates of 332% for gains and 34% for losses.

Anticipating a future loss was rated as -36 ($SD = 46$), whereas anticipating a future gain was rated as -5 ($SD = 55$), $t(191) = 5.6$, $p < .001$, $d = 0.8$, supporting our hypothesis. Moreover, these expected anticipatory emotions mediated the sign effect, $p < .001$. The valence of the event in question affects judgments of the associated anticipatory emotions, which in turn predicts time preferences.

In Study 1b (n = 100), we show this same pattern of results in a consumer choice setting with a choice between two air conditioning units. One option had a cheaper upfront cost but was energy inefficient, wasting money in the long run. We framed the future energy usage of both models as gains or losses, between subjects. In the positive frame, 59% of participants chose the "impatient" model, compared with 29% in the negative frame, $t(92) = 3.0$, $p < .01$. Furthermore, this result was mediated by asymmetries in anticipation ratings, replicating Study 1a.

In Study 2 (n = 169), we demonstrate the robustness of this anticipation asymmetry across twenty different events (10 gain and 10 loss), including classics from the literature such as the electric shock and kiss from a movie star. We also demonstrate the assymetry across different time horizons, from 3 days to 5 years.

In Studies 1 and 2, we made no attempt to equate the *subjective* magnitude of positive and negative events. Thus, our suggestion

that that dread is stronger than savoring may simply reflect the fact that the set of negative events were more psychologically significant than the set of positive events (i.e., loss aversion). We addressed this in Study 3 (*n*=106) by presenting each participant with pairs of positive and a negative event and dynamically adjusting the magnitudes until each participant was indifferent between accepting or rejecting the pair, indicating that the positive and negative event had been subjectively equated. Notably, the median participant was indifferent between a $25 loss and a $49 gain for the financial items, replicating the 2:1 ratio typically found for loss aversion (Kahneman and Tversky 1979). Participants then gave their time preferences and anticipation ratings for these tailor matched events. The results replicated previous studies, including the sign effect in choices, the asymmetry in anticipation, and the ability of anticipation to predict choices.

If not loss aversion, then what drives this asymmetry in the anticipation? In Study 4 (*n*=69), we demonstrate that anticipation of gains is a mixed emotional experience, while thinking about losses is a relatively unidimensional experience. Participants rated both the positive *and* negative anticipation of each event on separate questions. We found that when thinking about receiving a future gain, people look forward to the event and experience some pleasure while imagining it ("savoring"), but also feel some deprivation that they don't have it yet ("impatience"), and this makes the anticipation somewhat aversive as well. Overall, then, anticipation of gains is neutral or weakly positive. In contrast, when thinking about paying $60 in the future, people dislike thinking about the future loss ("dread"), but derive little positive enjoyment from the fact that they don't have to pay yet ("enjoying the moment"). The net result is strong disutility when anticipating future losses.

Do You Know How Much You'll Hate the Fruit Salad? Affective Forecasting Ability and Self-Regulatory Success

EXTENDED ABSTRACT

Readers of the self-control literature could infer that self-control represents a battle of the mind and the heart, with the mind prompting restraint and the heart prompting indulgence (Shiv and Fedorikhin 1999). When trait self-control operates, cognitive processes effortfully exert control over impulsive tendencies (Muraven and Baumeister 2000). Then, when cognition is impeded, emotions drive consumption, generally leading to greater indulgence (Shiv and Fedorikhin 1999).

In the present paper, we argue that cognition and emotion cannot be so neatly divided with regard to their impact on self-control. Rather, we suggest that individuals' *affective forecasting ability* (AFA) – a cognitive skill that determines the accuracy of one's predictions about the emotional outcomes of an experience - explains self-regulatory behavior above and beyond trait self-control. This insight is important for two reasons. First, consumers' affective forecasting accuracy is a skill, not a limited resource such as trait self-control (Muraven and Baumeister 2000). Thus, affective forecasting errors can explain self-control failures even in cases where depletion is unlikely. Second, as it is a cognitive skill, affective forecasting can be improved through simple debiasing interventions, thereby improving restraint without attempting to alter a stable internal trait.

To substantiate these arguments, we first developed a six-item affective forecasting accuracy measure (AFA, sample item: "I usually know how my decisions will make me feel in the future;" a = .94). The scale was validated in Study 1A using a standard predictor-experiencer paradigm: Seahawks/Patriots fans who scored higher on the AFA had lower forecasting errors in predicting how they would feel after their team lost/won the 2015 Super Bowl (b = -.21, *t*(117)
= -3.04, *p* = .003). The scale also showed acceptable levels of test-retest reliability (ICC = .71) and theoretically appropriate levels of convergent and discriminant validity (Studies 1B and 1C).

Studies 2A and 2B both establish nomological validity of the AFA scale and distinguish it from the trait self-control scale (Tangney et al. 2004). A pretest revealed that consumers' self-control decisions are more affect-driven in the food and time management domains and more cognitive-driven in the money domain. As such, we anticipated that AFA will have a stronger predictive power in the former two domains, while trait self-control will be a more powerful predictor of financial self-control decisions. In line with these predictions, Study 2A (n = 161; 45% male) revealed that trait self-control predicted the amount of money allocated to indulgences in a money budgeting task (b = -2.89, *p* = .003), but AFA was not a significant predictor (*p* = .17). In contrast, AFA predicted the time allocated to having fun in a time budgeting task (b = -2.48, *p* = .04) and the amount of calories and fat in a food selection task (b = -27.50, *p* = .05 and b = -3.10, *p* = .005). Conversely, trait self-control did not emerge as a significant predictor of self-control decisions in the time management and food domains (*p*'s > .40).

Study 2B (n = 52, 51% male) replicated the food domain findings using a real self-control decision (i.e., a choice between an apple and a cupcake). Results showed that the higher participants' AFA was, the less likely they were to select the indulgent snack (b = -.81, *p* = .03). Importantly, even after controlling for trait self-control (b = -.20, *p* = .70), AFA still predicted participants' snack choice (b = -.72, *p* = .07).

Study 3 examines the types of mispredictions that undermine the self-control of low AFA individuals. Participants (n = 72, 35% male) first completed the AFA scale. After a filler task, participants were asked to imagine a self-control scenario in which they had to decide between going to a birthday party (vice) and studying for an exam (virtue; Hung and Mukhopadhyay 2012). Participants then forecast the self-conscious (guilt/pride) and hedonic emotions (pleasure/ deprivation) they would experience if they make each decision. Finally, participants indicated their decision (1="definitely study" and 7="definitely go to the party.")

The higher participants' AFA was, the less likely they were to go to the party (b = -.44, *p* < .001). Furthermore, as AFA rose, individuals forecasted lower levels of negative hedonic emotions (deprivation) from studying for the exam (b = -.26, *p* = .06). AFA was also a marginally significant predictor of positive self-conscious emotions (pride) associated with the virtuous decision (b = .18, *p* = .08). However, AFA did not predict forecasted negative self-conscious emotions (guilt) or positive hedonic emotions (pleasure) associated with the vice decision (*p*'s > .12). Most importantly, mediation analysis revealed that *only* the predicted negative hedonic emotions associated with the virtuous decision mediated the relationship between participants' AFA and their preference to attend the party (95% CI: -.12, -.009).

Using this insight, Study 4 tests an intervention designed to improve the accuracy of forecasting negative hedonic emotions associated with virtue consumption. We use surrogation, or using other people's affective reactions, as a debiasing strategy (Gilbert et al. 2009). Study 4 (n = 255; 58% male) used a 2 cell (control/debiasing intervention) between-subjects design with AFA as a second continuously measured factor. Participants were notified that they would participate in a tasting test and asked to choose between a milk chocolate (vice) and a dark chocolate (virtue). Before making their choice, participants in the debiasing condition were given product reviews from prior participants which included information about the level of negative hedonic emotions (e.g., deprivation, missing

out) experienced from consuming the virtuous product; respondents in the control condition read neutral reviews that lacked any affective information. Results revealed a significant interaction of participants' AFA and intervention condition (b = -.49, p = .05). Low AFA participants (-1SD) who received the debiasing reviews were more likely to select the dark chocolate than those who received the control reviews (b = .86, p = .01). However, for high AFA participants (+1SD), there was no significant difference between the debiasing and control reviews conditions (p = .79). These results were unchanged when we controlled for participants' trait self-control (p = .95).

In sum, the current research suggests that affective forecasting accuracy is an important component of successful self-regulation, such that a better ability to correctly predict one's emotional reactions facilitates restraint in affectively-laden self-control domains. In highlighting this path to restraint, we offer a new hope for individuals who want to avoid indulgence or firms who want to prompt consumers toward restraint – simple interventions that reduce consumers' need to rely on their own, possibly faulty affective forecasting abilities can reduce impulsive decisions and prompt greater long-term well-being.

Is It More Rational to Say "No"?: How Choosing Versus Rejecting Alternatives Affects Information Processing

EXTENDED ABSTRACT

Consumers make their decisions in different ways. In some situations, they choose alternatives from a set of available options to form their consideration sets; however, in other situations, they reject (filter out) the less-attractive alternatives from a list of available options. While the two decision strategies (choosing vs. rejecting) should normatively lead to the same outcomes, research in consumer psychology and behavioral economics has shown that oftentimes they produce different decisions (e.g., Laran and Wilcox 2011; Shafir 1993). In this paper we add to the previous line of work on choice versus rejection by showing that these decision strategies can affect consumer evaluations *by shifting the decision-making from the automatic and heuristic-based System-1 processing (in choice), to the deliberative System-2 processing (in rejection)*.

To develop this prediction we build on research in consumer behavior and cognitive psychology. Rejection is a potential source of "action," or commission errors: making the wrong rejection decision implies elimination of the best option. In contrast, choice is a source of "inaction," or omission errors: making the wrong choice decision implies *not* selecting the right alternative. Because individuals hold themselves more responsible for the negative consequences of commissions, than for those of omissions (Ritov and Baron 1992), they should be more motivated to reduce their potential regret and to deliberate on their decisions in rejection as opposed to choice.

Further, studies looking at the differences between negation and acceptance, two decisions that mirror rejection and choice, suggest that rejection may be less automatic and more deliberative than choice. "Nay-sayers," who tend to reply "no" to "yes/no" questions and to disagree with Likert-scale items, are more reflective than people who demonstrate an overall agreement tendency (Couch and Keniston 1960). Finally, several studies imply that rejection draws upon cognitive resources and, thus, involves System-2 processing more than does choice (Krishnamurthy and Anish 2008; Laran and Wilcox 2011). For example, Krishnamurthy and Anish found that resource depletion affected decisions in rejection, but not in choice. In sum, prior research indicates that rejection decisions are less automatic, more deliberative, and rely to a greater extent on cognitive

resources, all of which imply greater involvement of System-2 processing in rejection tasks.

We tested our prediction across seven studies. To demonstrate that rejection relies more on the deliberative System-2 processing than does choice, in the first three studies we utilized the robust finding that the gains versus losses frames affect choice under System-1 processing, but not under System-2 processing (e.g. De Martino et al. 2006; Simon et al. 2004). In Study 1A, we used the Asian disease problem, wherein people had to consider two programs of combatting an unusual disease (Tversky and Kahneman 1981): a riskless program A, and a risky program B. Driven by System-1 processing, people change their preferences across different problem frames: they favor the riskless option in the domain of gains and avoid this option in the domain of losses. Greater involvement of deliberative System-2 processing has been shown to mitigate the effects of problem framing and to produce more consistent preferences across gains and losses frames (De Martino et al. 2006). In line with our predictions regarding greater involvement of System-2 processing in rejection, decision-makers expressed more consistent preferences across the gains and the losses frames when they had to indicate "which plan <they would> reject" (Π_{gains}=48% vs. Π_{losses}=43%, p = .66), than when they had to indicate "which plan <they would> choose" (Π_{gains}=76% vs. Π_{losses}=42%, p = .001). Study 1B and an incentive-compatible Study 1C replicated the moderating effect of task type on framing effects: when asked about monetary gains (vs. losses) people exhibited more consistent preferences in a rejection task (1B: Π_{gains}=54% vs. Π_{losses}=38%, p = .12; 1C: Π_{gains}=41% vs. Π_{losses}=50%, p = .43), compared to a choice task (1B: Π_{gains}=96% vs. Π_{losses}=29%, p = .001; 1C: Π_{gains}=79% vs. Π_{losses}=42%, p = .001).

Study 2 demonstrated the effect of task type on information processing in the context of online reviews. Participants had to remove hotels from (save them to) their list after looking at their aggregate numerical ratings (i.e. aggregate information) and at two of their randomly selected reviews (i.e. anecdotal evidence). People have been shown to discount aggregate information in the face of anecdotal evidence under System-1 processing, but not under System-2 processing (Alter et al. 2007; Kahneman and Tversky 1973). We expected that participants would put more weight on aggregate information in System-2 laden rejection, than in System-1 laden choice. Indeed, rejection reduced the share of hotels with bad ratings and good individual reviews ($\Pi_{rejection}$=28% vs. Π_{choice}=39%, p = .028), and increased the share of hotels with good aggregate ratings but bad individual reviews in participants' consideration sets ($\Pi_{rejection}$=31% vs. Π_{choice}=22%, p = .098). Next, Study 3 showed that under rejection instructions people were less likely to opt for the objectively more expensive but seemingly cheap cell phone plan favored under System-1 processing ($\Pi_{rejection}$=51% vs. Π_{choice}=70%, p = .045).

Study 4 examined the impact of cognitive depletion hindering System-2 processing on rejection and choice decisions regarding monetary gains (we earlier observed that rejection reduces the System-1 driven preference for riskless gains). We replicated the effect of task type on the preference for the sure gain in the control condition ($\Pi_{rejection}$=54% vs. Π_{choice}=81%, p = .009). However, when participants were cognitively depleted, the share of the riskless option in the rejection task increased (p = .04), and the task-type effect was eliminated ($\Pi_{rejection}$=75% vs. Π_{choice}=83%, p = .36). Study 5 examined the effect of feeling-based processing – consistent with System-1 – on choice versus rejection decisions regarding monetary gains. We replicated the effect of task type in the control condition ($\Pi_{rejection}$=52% vs. Π_{choice}=95%, p < .001). However, when the instructions induced a feeling-based evaluation, the share of the riskless option in the rejection task increased (p = .02), and the difference

between the rejection and choice tasks was reduced ($\Pi_{rejection}$=73% vs. Π_{choice}=89%, p = .027).

This research shows that choosing versus rejecting alternatives determines how the information about the attributes is processed. In addition, this research introduces task type as a novel moderator of the framing effects, documented both in behavioral economics and consumer psychology.

SESSION OVERVIEW

Making financial decisions is a fundamental aspect of being a consumer. However, the typical consumer lacks basic financial literacy (Fernandes, Lynch, and Netemeyer 2014) and borrows and spends significantly more than they should. As the private sector shifts away from pension plans (Novy-Marx and Rauh 2011), the onus on the consumer to better manage their finances is paramount. While much of past research has focused on identifying ways in which consumers engage in financial behavior and how these behaviors can be improved (Thaler & Sunstein 2009), we contribute to the dialogue by exploring the dark side of financial behaviors—the causes and consequences of poor financial decisions.

Specifically, in this session we explore false beliefs and biases that cause poor financial decision making, and examine their downstream consequences in four major domains of financial behaviors: spending, planning and forecasting, borrowing, and investing.

First, Morris and Huang examine the impact of feeling ownership over the decision to spend. They find that low perceived ownership over the incurrence of an expense can lead to less pain of payment and consequently a higher likelihood of over spending—especially among consumers who tend to be less financially responsible and thus more likely to use the lack of ownership as justification for spending. In the second paper, Howard, Hardisty, Sussman, and Knoll examine the expense prediction bias and find that over a broad American sample, consumers predict lower expenses for the future than they recall for the past. Through five studies, they find that this effect is due to perceiving past expenses as more unusual than future expenses, and that it is predictive of high interest payday loan usage. In the third paper, Tully and Sharma identify a key variable that determines a consumer's willingness to borrow—whether the target item is an experience or a material good. They argue through seven studies that despite being more ephemeral, consumers have a higher willingness to borrow for experiences because of a heightened importance of purchase timing. Finally, in the last paper, Reinholtz, Fernbach, and de Langhe show that individuals—both high and low in financial literacy—do not understand diversification and falsely believe that it increases the expected return and volatility of a portfolio. Consequently, these biases lead investors to construct risky portfolios that mismatch their risk preferences.

Together, the four papers in this session enhance our understanding of how and why poor financial decisions occur. The studies incorporate paradigms and methods that extend from histogram building tools, large-scale archival data, to multiple experiments involving actual financial decisions with real implications. Collectively, these papers draw from a wide spectrum of literature including agency, categorization, time, and risk perceptions, and provide insight into poor financial behaviors such as spending, inadequate planning and forecasting, borrowing, and improper investing. We believe that this session will attract a broad audience, and facilitate interesting discussions and collaborations that can generate valuable insights for researchers, marketers, and policy makers who aim to help consumers make better financial decisions.

When Your Hands Are Tied: The Effect of Expense Ownership on Financial Decisions

EXTENDED ABSTRACT

Consumers experience varying degrees of ownership over the incurrence of an expense. For example, the decision to purchase a new iPhone to replace an old one with a shattered screen could be perceived as highly dictated by a consumer's own will (e.g., the phone seems functional but the consumer decides to incur the expense anyways), or as relatively low in decision ownership (e.g., the phone does not seem to be fully functioning and thus the situation mostly dictates the incurrence of the expense). While in either case the consumer makes the ultimate decision to incur the expense of a new iPhone, we posit that different levels of perceived ownership will affect the consumer's spending experience and the specific choice for the expense (e.g. whether they choose a pricier new model or a cheaper old model).

The act of choosing is closely linked to perceptions of personal causality (deCharms, 1968), and such causal attributions have been shown to affect emotional responses to an outcome (Botti et al., 2009). Although consumers prefer making choices for themselves (Langer 1975; Langer & Rodin 1976), when facing a set of unattractive options, choosing could lead to lower satisfaction (Botti & Iyengar, 2004). Similarly, in the domain of financial decisions, while choosing to incur an expense can be greatly enjoyable because of the hedonic or functional utility one receives from the purchase itself (Csikszentmihalyi, 2000), such decisions can also be perceived as aversive due to the pain of payment one experiences from spending money (Prelec & Loewenstein, 1998; Knutson et al., 2007). While previous research has focused on the consequences of having autonomy in making a choice among various options, we explore the impact of perceived expense ownership—the extent to which a choice agent feels that the incurrence of the expense is dictated mostly by their own will or the situation—on the spending experience and the ultimate spending decision.

Specifically, we hypothesize that when consumers decide to incur an expense, a lower perceived level of expense ownership makes the expense easier to justify in their minds, leading to less pain of payment. This lower pain of payment has important consequences on financial decisions, such as increasing consumers' willingness to select a more expensive option for fulfilling that expense.

We conducted four studies to capture the impact of expense ownership on financial decisions as well as its underlying processes. In Study 1, 150 participants read two versions of a scenario where their old TV was having mechanical issues and they had decided to purchase a new TV. In the high ownership scenario, their old TV was having mild issues; in the low ownership scenario, their old TV was having the same mild issues in addition to more severe issues. Significantly more participants anticipated feeling less pain of payment (85%) and a higher likelihood of choosing a more expensive new TV (83%) in the low ownership scenario. Additionally, given that they were to buy a new TV, significantly more participants would prefer to be in the low ownership scenario (65%) even though in this scenario their old TV would be less usable and have lower resale value.

In Study 2, iPhone owners were led to imagine incurring the expense of a new iPhone because the screen of their current phone was shattered; however, the old phone was either still highly functional (high expense ownership) or had lost major functionality (low expense ownership). Participants then chose a specific new iPhone to purchase (varying in price and model), rated their anticipated pain of payment, and judged how easy it was to justify purchasing a new phone. We found a significant two-step mediation from expense ownership → ease of justifying purchasing a new phone → pain of payment → phone choice (95% CI: [.13, 9.09]). When participants experienced lower ownership in incurring the expense (i.e., they felt that the expense was mostly dictated by the situation), it was easier to justify the expense and they anticipated less pain of payment. Consequently, they chose more expensive phone options for fulfilling the expense.

Study 3 used the same design as in Study 2, and we varied whether participants imagined themselves or a friend as the decision agent in the scenario. While we replicated the two-step mediation when the decision agent was the self (95% CI: [.65, 14.05]), the effect was not significant when the decision agent was a friend. The results suggest that low expense ownership is effective in alleviating pain of payment only when it is self-serving.

In Study 4, participants earned real money from an initial filler task that included a scale of financial responsibility and were then presented with the opportunity to either pay to rent a short film or perform a boring task at no cost. Participants who stated their preference for renting a short film were then led to believe that they had either chosen the short film task (high expense ownership) or were assigned to it randomly based on a number they selected earlier (low expense ownership). Participants then chose between three short films that varied in price ($0.25-$0.75) and quality. We found a significant interaction of ownership condition and financial responsibility on film choice ($b = -1.27$, $t = -2.96$, $p = .003$), where participants who were low in financial responsibility (1 SD below the mean) chose a significantly more expensive movie when they were in the low ownership condition (vs. the high ownership condition), $b = 1.45$, $t = 2.44$, $p = .015$. Conversely, participants who were high in financial responsibility (1 SD above the mean) showed the opposite effect, $b = -1.10$, $t = -1.93$, $p = .054$. While financially irresponsible consumers took advantage of low expense ownership to alleviate the pain of payment in order to spend more, financially responsible consumers seemed to have experienced reactance and spent less. Additional work to further explore the moderating role of financial responsibility is currently underway.

Understanding the Expense Prediction Bias

EXTENDED ABSTRACT

Previous research on expense misprediction has shown that people predict lower expenses for the future than they recall for the past (e.g., Peetz & Buehler 2009, 2013), a phenomenon we've labeled *expense prediction bias* (EPB). Gaining a deeper understanding of this bias is important because of the high frequency with which people make spending predictions (Peetz et al., 2016), and because expense misprediction may have serious real world financial consequences, especially for low-income consumers. With these considerations serving as motivation, the present research makes several notable contributions. First, we hypothesize that EPB occurs because people tend to think of their past expenses as somewhat unusual, and yet predict that future expenses will be more ordinary. In support of this theory we find evidence that *perceived unusualness* of future expenses acts as a moderator capable of reversing the bias. Furthermore, we provide novel evidence that EPB is associated with serious financial consequences, highlighting the importance of identifying an effective intervention. We also provide evidence that: (A) there is no corresponding income bias, (B) EPB gets stronger (rather than weaker) with careful prompting and thought by participants, (C) EPB is associated with underestimating the *number* of unique future expenses but not the *amount* of each one, and (D) EPB is *not* associated with numeracy, consideration of future consequences, propensity to plan, risk preferences, temporal discounting choices, income, or education. (These null results are not discussed in detail below due to space constraints). Finally, we augment research in this area—generally conducted with small samples of undergraduates—by replicating the bias across 5 studies conducted with 2,762 adult Americans from diverse economic backgrounds.

In Study 1, participants recalled and predicted the dollar amount of their required, optional, and unexpected expenses for the past and next week in counterbalanced order (no order effect was observed), and we calculated an EPB score by subtracting aggregate predicted from aggregate recalled expenses. Consistent with prior research on expense misprediction, participants under-predicted future expenses relative to past expenses, leading to a mean EPB score of $63.58 (different from 0, p=.03), or 13.0% of recalled expenses. In Study 1 participants were also asked to recall and predict their income. Consistent with prior research on expense vs. income-neglect (Berman et al., 2015), a corresponding income prediction bias was not observed. This null result was replicated in Studies 2-4 and is not discussed further.

Study 2 extended the EPB measure utilized in Study 1 by employing a time 1/time 2 design. This allowed us to examine a conceptually similar pattern, but calculate an alternative bias measure by subtracting time 1 predicted expenses from time 2 recalled expenses. The mean EPB score was $60.61 (different from 0, p=.05), replicating the bias in a time 1/time 2 design.

In Study 3 participants were asked to recall and predict regular and irregular expenses. They were subsequently provided with a list of common expenses to consider (e.g., rent, car repairs, home improvements), and given the option to revise their initial estimates. Initially, participants recalled $480 worth of expenses, and predicted $381 (Mean difference=$99, p<.001). After completing the detailed expense prompts, participants recalled $584 worth of expenses, and predicted $419 (Mean difference=$165, p<.01). Thus, the detailed expense prompts actually led to *higher* EPB scores, because participants revised their recalled expenses upward to a significantly greater extent than their predicted expenses (p=.01). Study 3 also asked participants to report their experience with payday loans, allowing

us to compare EPB between payday loan users and non-users. The mean difference in initial EPB between payday loan users and non-users was $74 ($p$=.07), and this difference grew to $233 ($p$=.01) after participants were given the opportunity to revise their estimates. This result provides suggestive evidence of a link between EPB and high interest debt burdens.

Study 4 replicated the bias once again and also included an expense listing task that asked participants to estimate the dollar amount of unique expenses that they had during the last week and believed they would not have during the next week, as well as for unique expenses that they anticipated having next week but did not have during the last week. These measures showed that participants underestimated the *number* but not the *amount* of unique future expenses vs. unique past expenses (Mean difference for number=0.66, p<.001; Mean difference for amount=$19.48, p=.34), and that underestimating the number of unique future expenses is correlated with EPB (r=.15, p<.01).

Study 5 sought to reverse the bias. Building off of our results from Study 4, as well as work by Sussman & Alter (2012) showing that individuals underpredict total exceptional (but not ordinary) expenses, we manipulated *perceived unusualness* of future expenses by randomly assigning participants to either a control condition that asked participants to recall and predict their expenses, a "different" condition that asked participants to list three reasons why their expenses for the next week might be different from any other week (before they predicted their expenses for next week), or a "similar" condition that mirrored the design of the different condition. As predicted, the bias was replicated in the control condition (M=$37.31), reversed in the different condition (M=-$75.33), and not meaningfully affected in the similar condition (M=$20.41), F(2, 446)=14.01, p<.001.

The present research makes several important contributions to the literature on expense misprediction. Most notably we show that EPB is prevalent in large samples of adult Americans, that EPB is associated with payday loan use, and that EPB can be reversed by manipulating perceived unusualness of future expenses. In sum, these results advanced our theoretical understanding of EPB by integrating cognitive accounts of expense misprediction, and they have the potential to meaningfully impact policy that can tangibly improve consumer financial well-being. The present research also suggests several exciting directions for future research. Examples include investigating whether or not underestimating the number of unique future expenses (vs. the amount of each expense) mediates the bias, and establishing a causal link between EPB and downstream consequences such as payday loan use.

Discretionary Debt Decisions: Consumer Willingness to Borrow for Experiences and Material Goods

EXTENDED ABSTRACT

Previous research suggests that people prefer borrowing for longer-lasting purchases because they continue receiving benefits from the purchase while they pay for it (e.g., Hirst et. al 1994). One fundamental categorization of purchases that is inherently tied to longevity is that of experiences and material goods (Van Boven and Gilovich 2003). Since experiences are ephemeral, the previous research suggests that people should prefer borrowing for material goods (vs. experiences). In contrast, the current work argues that, on average, people are more willing to borrow for experiences despite their greater ephemerality.

People typically consider borrowing when current funds cannot be used. Given the implicit tradeoff between borrowing and fore-

going a purchase in the present, we suggest that the importance of purchase timing is a stronger driver of willingness to borrow (WTB) than physical longevity. Further, we propose that purchase timing importance is generally greater for experiences than for material goods. In contrast to material goods which are typically used repeatedly over time, experiences exist for a finite time period. As such, experiences may be more likely to be conceptualized as a function of the time-specific properties when the experience is expected to occur. Thus, delaying an experience may seem like a more fundamental change to the purchase. Consequently, we suggest that WTB is greater for experiences (vs. material goods). An analysis of archival data and seven lab studies provide support for our hypotheses.

Using archival expenditure data from The Bureau of Labor Statistics, we calculated relative spending on discretionary experiences as a function of total spending (Tully et al. 2015). As predicted, greater spending on discretionary experiences predicted higher credit card balances (β=0.03, t(30240)=5.35, p<.001), as well as more financing interest paid in the last month (β=0.03, t(30240)=4.68, p<.001).

Study 1 demonstrated the basic effect in a lab setting. Participants considered either a material good or an experience they intended to purchase and indicated their WTB for the purchase. WTB was significantly greater for experiences, F(1, 335)=5.80, p=.017, and was mediated by differences in purchase timing importance (95% CI: .17, .63).

Study 2 orthogonally manipulated purchase type and physical longevity to rule out the possibility that short-lived purchases incite a sense of urgency. Participants imagined visiting a local art store that was offering either art classes or a high-end painting kit and were further told that the purchase was expected to last them either 4 weeks or 12 weeks. WTB was greater for the experience, F(1, 297) = 6.33, p = .012, and was unaffected by physical longevity, F<1.

Studies 3 and 4 provide greater evidence of mechanism by examining boundary conditions. In Study 3, participants imagined being on vacation and wanting to buy either an experience (a city tour) or a material good (a painting from a local artist). However, we varied the purchase timing importance of the material good by varying whether the good was available for purchase online after the vacation was over. As predicted, WTB was greater for the experience when the material good was available online, F(1, 208) = 17.24, p<.001. However, there was no difference in WTB for the experience and the material good that was only available during the vacation, F(1, 208) < 1, NS.

Study 4 examined attenuation by reductions in purchase timing importance for experiences. To do so, we examined the strength of the link between an experience and a specific period of time. In Study 4a, participants wrote about either an experience or material good they intended to purchase and indicated whether they had chosen a date (to have the experience or acquire the material good). When a date had been chosen (and the experience could be conceptualized as a function of time-specific features), purchase timing importance was greater for experiences, F(1, 135) = 21.36, p < .001. However, without having chosen a date, purchase timing importance was no different for experiences and material goods, F<1. Building from this, Study 4B asked participants to consider buying an experience (day at local theme park) or a material good (smartwatch). They were either told that a date had been planned or that they were considering one date in addition to others. WTB was greater for the experience when the date was set, F(1, 329) = 10.47, p < .001, but otherwise did not differ, F<1.

To reconcile our results with previous research, Study 5a varied whether the context was an acquisition decision (whether to borrow or to forego the purchase in the present) or a source-of-funding

decision (whether to use cash or borrowed funds to make the purchase). Since timing is unaffected in source-of-funding decisions, we expected that in these contexts, people would prefer to borrow for longer-lasting purchases in line with previous research. Thus, some participants imagined one purchase (either a stereo or music festival tickets) that would need to be financed, whereas other people imagined making both purchases, where *one* would need to be financed and the other could be acquired with cash. As expected, WTB was greater for experiences when the decision was framed as an acquisition decision, $F(1, 503)=7.35$, $p=.007$. However, WTB was greater for the material good when framed as a source-of-funding decision, $t(244)=12.07$, $p<.001$.

We have suggested that the reversal found in Study 5a was due to the relevance of purchase timing importance. However, two alternative possibilities are that when material goods and experiences can be directly compared (1) physical longevity becomes more evaluable (e.g., Hsee 1996) or (2) people feel like they *ought* to borrow for the material good (Bazerman et al. 1998). To isolate our proposed explanation, Study 5b was identical to Study 5a but for the addition of two new conditions in which we provided participants with a reference purchase to contrast the focal purchase against. Again, WTB was greater for the material good when framed as a source-of-funding decision, $t(238)=10.60$, $p<.001$). However, regardless of whether a reference purchase was provided, WTB was greater for the experience when framed as an acquisition decision (no reference: $F(1, 975)=3.26$, $p=.071$; with reference: $F(1, 975)=15.85$, $p<.001$).

Do People Understand the Benefit of Diversification?

EXTENDED ABSTRACT

Diversification—investing in many imperfectly correlated assets—reduces exposure to risk without sacrificing expected returns. Some assets in a diversified portfolio will perform better than expected and others will perform worse, but the value of the portfolio will be less volatile as these unpredictable deviations will tend to offset. Despite this benefit, many people are undiversified (Campbell, 2006; Goetzmann & Kumar, 2008). For example, a typical individual investor holds a portfolio with only four stocks (Barber & Odean, 2001).

While several explanations have been proposed to account for improper diversification, we explore a more fundamental question: Do investors understand the benefit provided by diversification?

Understanding how diversification affects portfolio performance requires understanding the distributional properties of a sum of random variables. This may be easy for statisticians, but most people have poor statistical intuitions (Lipkus, Samsa, & Rimer, 2001). Moreover, people may lack the financial literacy required to apply this knowledge correctly (Lusardi & Mitchell, 2007).

We demonstrate two pervasive errors in people's beliefs about diversification. First, many people believe that diversification increases, rather than decreases, the volatility of a portfolio. This error is particularly common among people low in financial literacy, and appears to result from a judgment of representativeness: Because diversification involves investing in many unpredictable assets (vs. only a few), it feels like it should increase the aggregate unpredictability of the portfolio. This is analogous to conflating the properties of an outcome distribution with the properties of the generating mechanism (Kahneman & Tversky, 1972, 1973).

Second, many people incorrectly believe that diversification increases the mean performance of a portfolio. This error is most common among those high in financial literacy and seems to result from a misunderstanding of financial advice: People may know that diversification is a good investment strategy but associate this with an increase in the mean, rather than a decrease in volatility. This is consistent with previous work suggesting the central tendency of a distribution is more salient than the degree of dispersion (Obrecht, Chapman, & Gelman, 2007).

In Studies 1A–1F, we had people make forecasts for diversified and undiversified portfolios using a graphical, histogram building tool (Goldstein & Rothschild, 2014). In effect, this tool yields a subjective probability distribution of each participant's beliefs about the future value of each stock portfolio. We found that many people, but especially those low in financial literacy, expected greater variance in possible stock prices (i.e., more risk/volatility) from the diversified portfolio. Further, most people, but especially those high in financial literacy, expected a greater mean stock price (i.e., better returns) from the diversified portfolio. These biases are inconsistent with inferences about portfolio construction, as they occurred even when stocks in the portfolios were "randomly selected" or explicitly known.

In Studies 2A and 2B we explored possible downstream consequences of these biases using a portfolio construction task. We found people tended to create portfolios that mismatched the risk preferences of investors in ways consistent with the false beliefs documented in Studies 1A–1F. Specifically, those low in financial literacy tended to give a less diversified portfolio to an older, risk-averse investor than they gave to a younger, risk-seeking investor.

Finally, in Study 3 we explored possible explanations for these biases by manipulating what people thought about before forecasting the performance of a portfolio. Participants who first thought about how the individual stocks in the portfolio might perform expected greater unpredictability from the portfolio, while those who instead thought about the value of diversification expected greater returns from the portfolio.

SESSION OVERVIEW

Much of our identity is rooted in how we belong to different social entities such as our families, ethnicities, nationalities, political and religious affiliations, and professional classes. All of these contribute to who we are and what we do. In his seminal work on human motivation, Maslow (1943) positions belongingness needs immediately after physiological and safety needs. Baumeister and Leary (1995) compile a preponderance of evidence to support a construct they identify as the "need to belong" (NTB), one they argue is universal. Empirical evidence affirms the NTB as one of the most fundamental human needs, suggesting it developed to increase chances of survival (Baumeister and Leary 1995; Buss 1990).

Disciplines such as sociology, social psychology, anthropology, and education express interest in how people develop their desires to belong (Yuval-Davis 2006; Hurtado and Carter 1997; Baumeister and Leary 1995). Yet despite the centrality of social connections and consumption to daily life, links between belonging and consumption receive little empirical attention in consumer behavior (Mead et al. 2011). Moreover, most consumer research in belonging examines how consumers react to belongingness threats (e.g., social exclusion). This research stream primarily develops from the state-based construct of the Need to Belong (NTB) (Baumeister and Leary 1995), which they define as a "need to form and maintain at least a minimum quantity of interpersonal relationships, [and] is innately… human" (p. 499). Though this theoretical framework offers clear value, there are facets of belongingness in consumer behavior that remain unexplained and require alternative theoretical perspectives. For example, the NTB definition (1) does not account for cases outside of the interpersonal context such as belonging to larger imagined communities (e.g., nations, religions, political parties) or physical environments, (2) is not conducive to studying the processual nature of building a sense of belonging, and (3) is not helpful when to examining consumers' conscious efforts to belong within various entities.

This special session places the study of belonging front and center, investigating the complex relationships among belonging, exclusion, identity, and consumption from diverse approaches. James Mourey, Jennifer Olson, and Carolyn Yoon study how adverse effects from belongingness threats may be mitigated via interactions with anthropomorphized products. Robert Arias examines how belonging is studied across disciplines, leverages empirical data, and develops a theoretical construct to better understand how individuals *proactively* consume to pursue processual belongingness goals. Meredith Thomas and Dr. Thomas O' Guinn investigates how physical design and urban planning strategies impact feelings of belonging within a community. Drs. Benedetta Cappellini and Vicki Harman examine how middle-class British mothers display their social class belonging through the everyday mundane practice of making lunchboxes for their children. Collectively, we provide a multifaceted approach to how belonging research may be advanced in the consumption domain. In addition to including a more traditional approach to consumer belonging (i.e., by examining social exclusion), we promote an alternative perspective that acknowledges consumers' conscious efforts to pursue belonging. This session is likely to appeal to scholars interested in identity, brand/consumption communities, experiential consumption, among other domains.

Toward a Conceptual Understanding of Belonging in Consumer Research

EXTENDED ABSTRACT

Much of our identity is rooted in how we belong to different memberships. In fact, a preponderance of evidence suggests belongingness is an innate human need (Baumeister and Leary 1995). The notion that humans possess an inherent need to belong is not new by any means, however (Maslow 1943).

Belonging, however, remains to be fully explored and utilized in consumer research, despite social connections and consumption being central facets of daily life (Mead et. al 2011). Though research streams such as those relating to identity and brand communities employ forms of the term "belonging," in fact these constructs are often peripheral and remain unexamined or even undefined (Muniz and O'Guinn 2001; McAlexander et al. 2002). The minimal consumer research relevant to belonging mostly examines how consumers react to belongingness threats to the state-based construct, the Need to Belong (NTB) (Baumeister and Leary 1995).

Consequently, the objective of the current presentation is to critically evaluate the current status of the belonging construct(s) in consumer behavior research, illuminate valuable research opportunities, and leverage extant research and empirical data to develop a consumer-conducive definition of the "sense of belonging" construct. Through this strategic review, I contribute to our conceptual understanding of belonging by uncovering a novel approach to investigate consumption/belonging linkages. Given the nature of the contribution, this analysis may be classified as a theoretical advancement via identification (MacInnis 2011), revealing dimensions of the consumption/belonging research domain that are previously unexamined.

To understand the current status of belonging in consumption research, one must be familiar with the theoretical construct of NTB (Baumeister and Leary 1995). Baumeister and Leary (1995) were the first to compile evidence to empirically demonstrate that NTB exists. They define the NTB as a "need to form and maintain at least a minimum quantity of interpersonal relationships, [and] is innately prepared among human beings" (p. 499). To manipulate NTB, researchers employ a variety of manipulations such as instructing confederates not to talk to a participant in a group setting (Snoek 1962)

and providing false feedback, informing the subject his or her test results revealed a future with fading social relationships (Twenge et al. 2001).

The few studies in consumer research that integrate belonging in its research design often adopt Baumeister and Leary's (1995) theoretical framework, using social exclusion as an implicit proxy for a temporarily-heightened NTB. For example, recent findings demonstrate that after social exclusion, consumers are more likely to express an increased desire for specific consumer goods valorized by aspirational social groups (Dommer et al. 2013), to sacrifice "personal and financial well-being for the sake of social well-being" (Mead et al. 2011, p. 902), and to desire nostalgic products (Loveland et al. 2010).

Though the NTB construct (Baumeister and Leary 1995) effectively allows consumer researchers to study aspects of belonging, it possesses limitations. Importantly, I allocate my focus on the *sense of belonging* construct, one considered to be processual and fluid (Yuval-Davis 2006). Importantly, I do not use the term "feelings" of belonging (Easterbrook and Vignoles 2013) because our empirical findings and extant research reveal the SB involves more than emotions for consumers (Hagerty et al. 1992). Though it has been inconsistently defined (Mahar et al. 2014), core commonalities exist among the "sense of belonging" definitions. I integrate key elements from various conceptualizations in an effort to delineate the construct and develop its conduciveness for consumer research. I employ the term "sense of belonging" to refer to the subjective, context-mediated experience that derives from a personal relationship with an external referent, evolving in response to the degree to which individuals (1) believe the relationship to be reciprocal, (2) feel accepted, (3) perceive their traits and values are shared or complement the referent, (4) believe the relationships to be secure and temporally stable (Hagerty et al. 1992; Levett-Jones et al. 2009; Mahar et al. 2014). In addition to utilizing extant literature, I show evidence for each of the definition's four components using empirical data.

Unlike the NTB construct, this definition of "sense of belonging" acknowledges belongingness experiences beyond the interpersonal context such as belonging to collective identities, imagined communities, or even physical spaces. Because the definition is inclusive, it may act as a springboard to allow researchers to investigate belonging/consumption links beyond reactions to belongingness threats, such as how individuals *proactively* consume to pursue a sense of belonging. Though, prior research contends that the sense of belonging as a theoretical construct has not been well studied and is inconsistently defined, I delineate the construct to facilitate future explicit study of belonging (Meeuwisse et al. 2010). Overall, this close examination of the belonging literature across domains demonstrates that belonging can (and should be) investigated beyond social exclusion.

Products as Pals: Engaging With Anthropomorphic Products Mitigates Effects of Social Exclusion

EXTENDED ABSTRACT

From Apple's Siri to Amazon's Alexa, iRobot's Roomba to Google's self-driving vehicle, there is no question that anthropomorphized consumer products exist in an increasing number of industries. As products feature more characteristics typically associated with "being alive," whether through design, interaction, intelligence, responsiveness, and/or personality, an important question to consider is how these "living" products might influence basic human needs for affiliation. As such, the present research explores whether anthropomorphized products can mitigate well-established effects of social exclusion (i.e., threats to affiliation) and, if so, whether boundary conditions exist with respect to an anthropomorphized product's ability to fulfill needs typically fulfilled via social interaction.

Prior research indicates that anthropomorphism affects moral care and concern for non-human targets, such as the environment or animals, and even trust placed in non-human technological agents like autonomous vehicles (e.g., Waytz, Cacioppo, and Epley 2010). Linking exclusion and anthropomorphism, prior research also showsthat people who feel more chronically disconnected from others attribute anthropomorphized qualities to a variety of objects and entities (e.g., religious agents, pets, imaginary creatures) more than those who are more connected (Epley et al. 2008). This suggests anthropomorphized products could potentially affect measures of social connectedness in ways that have, to date, remain untested. Waytz and Epley (2012) find that the more socially connected one is (to real people), the more s/he dehumanizes others, suggesting that once social connections are fulfilled, one may have a *weaker* need for social reassurance from others. The present work extends into a nonhuman, consumer product domain to examine whether interacting with an anthropomorphized product could also result in a mitigated need for social assurance from human others. We test this hypothesis in a series of six experiments that feature a broad range of consumer products varying in their anthropomorphism.

Experiment 1A builds upon prior research (Maner et al. 2007) demonstrating that socially excluded individuals satisfy their desire to reconnect by rating neutral faces as being "more sociable." Participants were randomly assigned to either a social exclusion condition in which they wrote about a time they were socially excluded (Epley et al. 2008) or a control essay condition in which they wrote about their prior day. Following the essay manipulation, participants completed a trivia game and were asked to use either Siri (anthropomorphized aid) or Google (non- anthropomorphized aid) for assistance. They then rated a series of neutral faces on personality factors per Maner et al. (2007). The results reveal that introducing an anthropomorphized product dampens the tendency among socially excluded consumers to view others as more sociable.

One limitation of this initial experiment is that it is unclear how interacting with Google and Siri compares to genuine interpersonal interaction, as there was no human interaction condition. Experiment 1B explores this idea by randomly assigning socially excluded and control essay participants to work with an anthropomorphized calculator, a non-anthropomorphized calculator, or a human partner to solve math problems. Prior research reveals dampened mood effects following exclusion (e.g., Baumeister et al. 2005; Twenge et al. 2001), which can be improved via human interaction. Our results not only replicate this prior research, but demonstrates that engaging with an anthropomorphized calculator has mood restorative effects comparable to those of engaging with a real human being.

Experiments 2A and 2B explore the extent to which individuals compensate for social exclusion. Following the essay manipulation, participants were asked to consider questions regarding their cellular phone (placed in their hand as part of the study). The control group's questions were worded neutrally (e.g., "What is the design of your phone like?") whereas the experimental group's questions had the same meaning but were phrased in an anthropomorphized way (e.g., "What is the body of your phone like?"). The results reveal that socially excluded participants estimate that they have more Facebook friends (experiment 2A) and will send more text messages in the upcoming month (experiment 2B) compared to control essay participants, unless they engage with an anthropomorphized phone.

Experiment 3 tested our prediction with respect to previous findings, suggesting socially excluded individuals engage in prosocial behavior as a means of reestablishing social bonds (Lee and Shrum

2012). Participants completed the essay task and phone tasks from the previous two experiments, but also completed the Need for Social Assurance scale (Lee and Robbins 1995) and indicated their willingness to complete additional surveys without compensation, a measure of prosocial behavior (Mortensen and Cialdini 2009). As predicted, socially excluded participants in the anthropomorphized vs. non-anthropomorphized phone condition report a lower need for social assurance, which, in turn, reduces their willingness to engage in prosocial behavior, suggesting their need to forge bonds had been satisfied.

If anthropomorphized products subtly fulfill needs for social assurance, then drawing explicit attention to the fact that an anthropomorphized product is *not*, in fact, actually alive should eliminate the effects. Our final experiment tests this prediction. Following the essay condition manipulation, participants were randomly assigned to view one of three Roomba vacuums: Roomba turned to look like a face (anthropomorphized), Roomba turned 90-degrees (control), or a Roomba turned to look like a face with an explicit reminder that it was "…just a machine, not a real person." As predicted, socially excluded individuals reported a significantly higher need for social assurance in both the control Roomba condition *and* the misattribution condition, but not in the anthropomorphized condition, supporting the misattribution story.

Taken together, our results indicate that engaging with anthropomorphized consumer products can mitigate well-established effects of social exclusion. As more consumer products blur the line between product and person, be it avatars, smart cars, or responsive technology, and people feel increasingly less connected to "real" others, understanding anthropomorphized products and how they affect consumer psychology and behavior is more critical than ever before. We hope the current research inspires future studies further exploring how consumer products and people fulfill innate social needs, sometimes at the expense of one another.

The Perfect Lunchbox: Social Class Identity and Everyday Mothering

EXTENDED ABSTRACT

This paper contributes to this special session on belonging by investigating how middle-class British mothers display their social class belonging through the everyday mundane practice of making lunchboxes for their children. As an example of home food being eaten in the school setting without parents being present, lunchboxes present an interesting case for understanding how consumers display their social identities.

Social identity theories highlight how individual identity is framed by membership to social categories including social class, gender and family roles. These categories provide individuals with a set of norms and tools enabling consumers to define their own selves (Schouten 1991). Consumption plays a key part in displaying individual belonging to certain categories, as mothers, for example, use objects to materialize their sense of fitting into a particular way of mothering and their disregard of other forms of mothering (Thomsen and Sorensen, 2006). The marketing literature has highlighted how identities are not static as individuals move between different memberships during their lives (Ulver and Ostberg, 2014) and thus individual identity can contain contradictions. Consumption can provide a solution of such contradictions but can also aggravate anxieties and insecurities (Shankar at al. 2009). For example, the current way of doing middle class mothering, also defined as intensive mothering (Hays 1996), is characterized by intensified consumption practices prioritizing children's desires. This intensified consumption causes identity uncertainties and anxieties in mothers (Voice Group 2010).

From the aforementioned literature, we understand consumers are the ones who move from one sense of belonging to another. Without denying the importance of seeing consumers' sense of belonging as an ongoing process, this study takes a slightly different perspective, showing it is not only consumers' identities that are on the move. Rather, norms and conventions change over time and thus they are also mobile and fluid. Historical research on mothering, for example, shows us that what were considered good mothering practices in the past are now perceived as unconceivable way of parenting (Lee et al. 2014). This is indeed the case of feeding children, an aspect of mothering which is subject to rapid changes in norms and conventions (Schor and Ford 2007). Given that norms on how to feed children are subject to such changes, how do mothers maintain the narrative of the self as a 'good mother'? How are mothers' consumer strategies, as revealed through the example of the lunchbox, influenced by their social class identity?

We answer these questions by looking at the everyday experience of 30 middle class and working class British mothers making lunchboxes for their children. Semi-structured interviews and focus group discussions were used to understand the individual and collective identity of being a mother, and the everyday practices associated with such a sense of belonging. Findings from our thematic analysis reveal that middle-class mothers tend to possess a clear set of ideas and ideals of what constitutes good mothering. Their ideals replicated the aforementioned intensive mothering (Hays, 1996), understood by participants as an intensified and financially demanding labor aimed at prioritizing the children's desires ahead of their own. If mothers were able to describe these classed ideals of good mothering and their aspiration to belong to such a category, identifying the set of practical rules and conventions was indeed more challenging.

The impossibility of listing the set of norms and conventions of doing good mothering through feeding the children was attributed to the rapid changes in the marketplace. For example, mothers highlight the rapidity in which food and indeed brands can be classified as "good" or "bad." Given that bad food is often framed as mass-produced items associated with working class mothering, participants carefully avoid consuming food that could lead to display a 'wrong' identity. Also, they describe the constant introduction of new items, products and rules in the marketplace, making the work of feeding the children 'properly' a very challenging one. Government initiatives, celebrity chefs, supermarkets and also schools and other parents are listed as actors constantly redefining conventions and rules around the practices of feeding the children. Giving these perceived continuous changes, mothers feel anxious as they need to constantly display an up-to-date good mothering, showing they are aware of the new marketplace conventions of feeding children. As one mother eloquently says "I need to check if I am not losing the plot." In order to not to lose the plot, mothers activate a set of consumer strategies including learning about new products (e.g. thermos flasks for keeping food hot) and brands via celebrities and experts, but also activating mechanisms of surveilling other mothers.

To conclude, this research shows how the marketplace is one of the main forces modifying norms and conventions in relation to certain social categories, such as what it is to be a 'good mother' and how to display a middle class disposition in relation to children's food. If the previous marketing literature highlights how consumers might have identities on the move, this study shows how social categories can also change over time. This study has shown how the category of 'good mother' is fluid but with a clear social class positioning. Given such a fluidity, good mothering is a never fully-achieved target, and as such, women's sense of belonging to this category is surrounded by a sense of uncertainty and anxiety. An intensified but

highly discerning type of consumption requiring the constant learning of the market's new options and distinguishing oneself from the 'wrong type' of consumers is seen by middle class mothers as a way of coping with the constant changes in the market.

The Joneses Don't Live Here: Conspicuous Consumption in a New Urban Neighborhood

EXTENDED ABSTRACT

The demise of traditional community has been the subject of social science research for well over a century (Marx 1848; Tonnies 1887; Durkheim 1893 Veblen 1899; Simmel 1900; Weber 1922). Sociologists have often pointed to the rise in consumer culture as a main driver in the breakdown of relationship-focused society. Certainly, with the rise of the automobile, suburbanization, television, dual career households, and the Internet, people interact less in person (Putnam 2000). But, in this study, we have found that the desire for that connection is very much alive.

In consumer literature, scholars have passed over traditional, face-to-face community in favor of studying community centered around brands and past-times (Muniz and Schau 2005; Cova and Cova 2001; Muniz and O'Guinn 2001), and more imagined (Anderson 1991) or technologically mediated forms of community (Jayanti and Singh 2010; Kozinets, De Valck, Wojnicki, and Wilner, 2010; Cayla and Eckhardt 2008; Mathwick, Wiertz and de Ruyter 2008; Thompson and Coskuner-Balli 2007).

This research investigates a neighborhood planning strategy that is built, marketed and sold with the promise that by living there, one can experience belonging in a traditional community. This trend is called New Urbanism and is spreading quickly in popularity across the United States and around the world (Katz 1994; Dreier, Mollenkopf & Swanstrom 2004). It takes very old concepts of urban planning, and builds them into new neighborhoods, which are thought to facilitate social interaction, trust, sharing, and a communal spirit (Zukin 2009). In this study, by community, we mean "a (physical) place, shared ideals, social network, collective framework, neighborly interaction, including "structural, cultural and sentimental supports and an altruistic outreach of affection and empathy (Keller 2003)."

This work explores how traditional community exists in contemporary consumer culture. We also ask, "How does the market try to (re)create community through a residential product?" We explore the role of consumption in these neighborhoods, and its role in creating a sense of belonging to a traditional community.

To date, the first author has conducted 28 semi-structured depth interviews with 37 residents of a New Urban neighborhood. Additionally, we have used extensive field notes, photographs, and secondary data sources to understand how traditional community exists.

The site of our study, Pleasant Valley, USA, features New Urban residential design, with modest homes on small plots of land, ample shared space, but relatively minimal personal property. In Pleasant Valley, belonging to a traditional community constitutes the brand platform and consumer promise. It is also a place where a way of life, is marketed, sold and in turn, consumed. In this study, we ask whether this neighborhood product delivers on its promise, and if so, how.

A second line of questioning focuses on an issue that has been studied since Veblen's 1899 work on the Leisure Class. Conspicuous consumption is thought to be a way of expressing one' self through possessions, in place of personal interaction. We ask whether the role of conspicuous consumption is different in this place where personal interactions are the focus and goal.

The adage "keeping up with the Joneses" is widely recognized to be a suburban phenomenon in which neighbors express themselves and especially their economic worth by trying to consume the biggest and best on their neighborhood block. The New Urban ideal promotes a carefully controlled, common aesthetic in which neighbors are encouraged to contribute to the overall image of the neighborhood, both behaviorally and materially (Zukin 2009). Therefore, our research explores the ways in which residents in New Urban neighborhoods use consumption to signal individual meaning and how that establishes the parameters for in-group belonging, reinforcing the communal focus.

Our results show that a desire for community is the most popular reason for purchasing a home in Pleasant Valley. However, the most powerful ways informants recount a sense of belonging in the community involve adhering to the proper consumption script. One common topic is the "anti-consumerist" community ethic, and the importance of deliberately and visibly living beneath one's means. The culture of the community is perceived as more socially and environmentally conscious, less materialistic.

Instead of common portrayals of conspicuous consumption in which extravagant consumption replaces social connection (Veblen 1899), in this case consumption is driven by the desire to convey an ideology, politic or philosophy of moral responsibility.

Informants expressed a sense of obligation to make moderate, controlled decisions about consumption, and expect others to do the same. This results in the accumulation of field-dependent cultural capital within the neighborhood (Bourdieu 1986).

Using underconsumption to express one's belief in the neighborhood ideology seems to solidify community in Pleasant Valley. However, there was one common theme among informants that was seen to cause a breakdown in community. Residents who presented ostentatious displays of wealth are thought to weaken community by disregarding the community culture of underconsumption. Informants who described this often made character judgments about those offending residents, even though they had never met. After discussing the "infidels" or "outsiders," informants described themselves to be more like the majority of residents in the neighborhood who also consume responsibly. This represents an ideological conflict, one that has been central in American culture: libertarian free market versus communitarian (Putnam 2000), and social expression as taste.

To conclude, in much of the social science literature, community has been placed at odds with consumer culture. However, in this case it is through consumption activity that residents feel a sense of common ground and belonging to the neighborhood and its members. Also, they practice a form of conspicuous consumption that is not intended to be used for comparison purposes, but rather to be less remarkable, and to signal an understanding of the shared moral responsibility. This is in contrast to popular theories on conspicuous consumption. Also, this research offers new findings related to Bourdieu's theories of capital by presenting a case in which the visible results of high levels of economic capital diminish cultural and social capital. We also hope to provide insights into New Urbanism's effectiveness in recapturing a traditional sense of community.

SESSION OVERVIEW

Markets are replete with social interactions. Many of these interactions require impression management, either for the purposes of ingratiating service providers to clients, managers to employees, or consumers with one another. Some interactions regulate markets, and require a coordination of needs between the regulators and the regulated, and still others require coordination among consumers to achieve maximum utility. Given the differing goals and perspectives of consumers in the marketplace, there arises the possibility for asymmetry in how an action is intended and how it is perceived and reacted to. The papers in this session each take a critical look at actor-observer asymmetries in the consumer setting, and provide a cautionary tale for those who would attempt to influence others, as well as a strategy for overcoming these asymmetries and maximizing benefit for all parties.

The first two papers together demonstrate failures of two distinct impression management strategies. O'Donnell, Jung, and Critcher show that, although humor is a widely used tactic to engender liking, the use of self-deprecating humor has unintended negative consequences for the self-deprecator. Indeed, the reliable message is that self-deprecation is taken seriously, and is understood to be a diagnostic statement of one's belief about one's own ability, as well as a negative signal of self-esteem. Likewise, Sezer, Wood Brooks, and Norton investigate a similar failure of impression management through the use of backhanded compliments. Although flatterers who use backhanded compliments intend to simultaneously garner liking while also maintaining status distance, their compliments are viewed as insulting and draw social penalties from the ostensibly flattered. Importantly, those who use backhanded compliments as a means of being both liked and respected are often rewarded with neither.

The third paper demonstrates the complex interplay between would-be-regulators and the regulated in the marketplace. Schroeder, Waytz, and Epley show that regulators prefer to impose paternalistic policies on others (e.g., banning fatty foods) they themselves prefer to be less actively regulated. These asymmetries arise because the regulators underestimate the self-control and mental capacity of those being regulated. However, hinting at a possible reconciliation between each of the asymmetries detailed so far, when the regulators are reminded of their own shortcomings, their preferences for paternalistic policies increases.

Finally, the fourth paper shows how the costs of informational and motivational asymmetries can be mitigated. Williams, Amir, and Lieberman demonstrate that by reminding consumers to consider the choices of others, cooperation increases and positive outcomes are maximized. By focusing on the behavior of others, consumers coordinate over scarce resources and arrive at better outcomes. Indeed, the conclusions of this paper suggest that the breakdown between the intentions of actors and the reception of their actions detailed in each of the papers could be mitigated by inducing the actors to consider more carefully how others will act and respond.

Taken together, attendees at our session will leave with a strong understanding of how informational asymmetries can have unintended consequences in the marketplace, but also learn how to avoid undesirable outcomes and maximize benefit in marketplace interactions.

The Potential Benefits and Pitfalls of Poking Fun at Yourself: Self-Deprecating Humor as Impression Management

EXTENDED ABSTRACT

Imagine a meeting between a contractor and a client. Just as the meeting is wrapping up and negotiations are finalized, the contractor makes a self-effacing remark, "Fortunately, every project I've ever done has been on time and under budget, if you double the estimates!" Even if the contractor is obviously joking, she has likely already formed a negative impression in the mind of the client. Impression management is the process by which people or organizations attempt to influence how others view them (Leary & Kowalski, 2012), and is under-studied in marketing. Grove & Fisk (2013) point out that impression management can be of great importance to firms and particularly service providers, where the individual is the firm.

Humor is a common tactic for impression management, as it reduces social distance (Ziv, 1984). However, there is no single definition of humor, and we propose that one type of humor, self-deprecation, can be especially fraught as a means of managing impressions. Self-deprecating humor is a favorite of standup comedians, but the limited literature on self-deprecation suggests that it is primarily a component of negative self-esteem (Owens, 1993). While self-deprecators might believe they are signaling confidence, Kruger et al. (2005) found that communicators often misperceive how observers will understand their meaning. Thus, within the context of self-deprecating humor, we investigate its impact as a signal for self-esteem, as well as its use as a buffer against others' development of negative perceptions of the self.

In Study 1, we investigate how observers perceive self-deprecation. Four hundred thirty-eight participants took part in a study with a 2X2X2 design. We varied the attractiveness of the self-deprecator, using normed pictures from the Chicago Face database and we var-

ied intelligence by providing cues about the speaker's intelligence (a surgeon/trash collector-in-training). Finally, we varied whether the speaker made a self-deprecating remark about his intelligence or attractiveness, with the following joke: "I'm so [ugly/stupid], a monkey looked at me and decided it's proof that evolution sometimes works in reverse!" We find that participants consistently take self-deprecators' remarks at face value: observers think that the target believes himself to be less intelligent when joking about his intellect and he believes himself to be less attractive when joking about his appearance. While the self-deprecating joke is framed as a light-hearted remark among a group of friends, self-deprecating humor is seen as reflecting poor self-esteem, regardless of the target's actual intelligence or attractiveness. This is likely not what a self-deprecator intends to achieve by making a self-deprecating remark.

In Study 1, the target always makes a self-deprecating remark. This approach allowed us to keep constant the effect of self-deprecation, while investigating its effects across multiple domains. Study 2 builds on Study 1 by varying whether or not the target self-deprecates, allowing us to test for the effect of self-deprecating humor itself. Five hundred fifty-two participants took part in a study with 2X2X2 design in which we varied whether the participant learns about either the target's attractiveness or intelligence, whether the target is either high or low status on that dimension, and whether the target either does or does not self-deprecate on that dimension. Once again, we find a main effect of self-deprecation, such that self-deprecating targets are universally regarded as having lower self-esteem. Moreover, self-deprecators are seen as viewing themselves as less positively on the dimension about which they self-deprecate. Study 2 provides converging evidence that self-deprecators may be inadvertently conveying negative views about themselves when they make self-deprecating remarks.

Study 3 investigates the impact of self-deprecating humor on a novel dimension. Seven hundred fifty-seven participants took part in a study with a 2X2X2 design in which they read about somebody taking an art class at a local community center. We varied the target's status (high or low ability), whether or not there was an image of his art, and whether or not he made a self-deprecating joke about his art ("I think my art is pretty bad, but I actually already have a buyer lined up…the local zoo want to line their birdcage with it!"). We again find that self-deprecation is taken at face value, such that when the target self-deprecates, he is assumed to have lower self-esteem and view himself as a worse artist. However, here we find evidence that self-deprecation can be effective in managing impressions, as evidenced by a self-deprecation by status interaction. When the target is a bad artist, self-deprecation is associated with higher self-esteem ratings, but this effect is reversed when the target is a good artist. Study 3 suggests that self-deprecation might be effective for certain domains.

Study 4 integrates the findings of Studies 1-3 to provide more insight into the circumstances under which self-deprecation can be useful and when it is not. Seven hundred sixty participants took part in a study with a 2X2X2 design. We varied the dimension (artistic ability or intelligence), the target's status on the dimension, and whether or note the target self-deprecates ("Intelligence/Artistic ability may grow over time, but in my case, you can't grow something from nothing!"). We again find that self-deprecators are seen as having lower self-esteem than those who do not self-deprecate. However, we do find a significant three-way interaction, such that for artistic ability, self-deprecation blunts the impact to self-esteem of being a bad artist, but for intelligence, self-deprecation is always associated with reduced ratings of self-esteem.

The results of four studies show that self-deprecation is taken at face value – self-deprecators transmit an unintended message in addition to the their intended humor. Indeed, even when self-deprecation mitigates the impact of being a bad artist on one's self-esteem, observers think the target believes he is a bad artist. However, self-deprecation about one's intelligence or appearance is always negative. Continuing work is underway to investigate whether the centrality of the dimension to a person's self-esteem can explain the differing results for artistic ability and intelligence or appearance. Regardless, the results suggest caution for professionals– the self-deprecating contractor should know that her joking putdowns are taken at face value.

Backhanded Compliments: Implicit Social Comparison Undermines Flattery

EXTENDED ABSTRACT

Consider how you would feel at the end of a meeting – after you'd given a lengthy presentation – if a colleague turned to you and said: "Your ideas were good." Now, consider your emotional reaction if your colleague tacked on just a few more words: "Your ideas were good… for an intern." We explore the psychology of such backhanded compliments. Given their ubiquity in the workplace (*You speak well… for a woman*) in everyday life (*Those clothes make you look thin*), and in academia (*This seems pretty rigorous for a social psychologist*) we suspected that actors may believe that backhanded compliments are effective – but that targets might feel otherwise.

Giving compliments—communicating positive things about another person—is an important part of social and organizational life (Gordon, 1996, Zivnuska, Kacmar, Witt, Carlson, & Bratton, 2004). Several streams of research suggest that using flattery in social and professional interactions leads to positive outcomes, from likeability to evaluations of job performance to career success (Bolino, Varela, Bande, & Turnley, 2006; Wayne & Liden, 1995). Because flattery is egocentrically validating, people view those who compliment them in a favorable light (Gordon, 1996; Jones, Stires, Shaver, & Harris, 1968).

At the same time, however, flattery may come with costs. In particular, flattering someone may imply that the flatter is of lower status than the recipient – as with the phrase, "sucking *up* to the boss." We suggest that one means by which flatterers seek to gain positive evaluations yet maintain their status is by deploying backhanded compliments: e.g. "You are smarter than I thought." Backhanded compliments are a distinct, common, yet understudied type of praise. We examine whether flatterers believe that backhanded compliments are effective strategy for gaining liking and status – and also assess whether recipients actually grant that liking and status to flatterers.

Drawing from research on social comparison, we suggest that people perceive backhanded compliments as less flattering than straightforward compliments. An extensive body of research has shown that social comparison has affective and cognitive consequences (Buunk & Gibbons 2007; Dunn, Ruedy, & Schweitzer, 2011). In particular, while downward comparisons enhance one's self-image, upward social comparisons are aversive (Achee, Tesser, & Pilkington, 1994), and evoke feelings of threat, envy, and anger (Cohen-Charash & Mueller, 2007). We suggest that targets perceive backhanded compliments as offensive because they induce an implicit social comparison between the target and another standard, reducing feelings of positive affect compared to straightforward compliments.

Building on psychology and management literatures on impression-management, we suggest that individuals use backhanded compliments to signal their status while simultaneously expressing praise for the target. The desire to gain and signal status is a fundamental and powerful driver of human behavior in social and organizational life (Argyle, 1994; Berger, Rosenholtz, & Zelditch, 1980). Individuals are motivated to acquire and signal status by attaining respect and admiration from others (Berger, Cohen, & Zelditch, 1972; Magee & Galinsky, 2008), because people with high status receive countless material and social rewards (Berger et al., 1980; Fennis, 2008). Based on the need to signal status, we suggest that people use backhanded compliments to signal their status while eliciting liking. Although people choose to give backhanded compliments when motivated to make a favorable impression by conveying status, we suggest that it backfires. We hypothesize that individuals who offer backhanded compliments will be perceived to have lower status than those who give straightforward compliments.

We tested our account in four studies. In Study 1, we participants to recall a backhanded compliment or compliment they had received and rated the extent to which they felt they were being compared to another person or a group on a 7-point scale. As expected, ratings of implicit social comparison was higher for backhanded compliments than straightforward compliments, $t(154) = 7.71$, $p < .001$.

In Study 2 we assessed recipients' evaluations of backhanded compliments compared to straightforward compliments. Participants were randomly assigned to one of the seven conditions to receive different types of compliments and backhanded compliments: *"Your ideas were good."* (compliment) or *"Your ideas were good for a [your gender]."* (backhanded compliment). Participants' ratings of offensiveness ($F(6, 708) = 62.10$, $p < .001$, $\eta^2 = .35$), and experience of positive emotions ($F(6, 708) = 49.38$, $p < .001$, $\eta^2 = .30$) varied across conditions. Participants perceived backhanded compliments as more offensive – and experienced lower positive emotions when receiving them – compared to compliments.

In Study 3, we asked participants to choose which of two self-presentation strategies – giving a compliment or giving a backhanded compliment – would best elicit liking, convey status, or achieve both goals. In both conditions in which status was a goal, participants favored the backhanded compliment ($\chi^2(2, N = 300 = 71.64$, $p < .001$), reflecting their belief that backhanded compliments would signal status.

In Study 4, we tested the efficacy of giving straightforward compliments, backhanded compliments, and straightforward insults in garnering status. As predicted, an ANOVA revealed a significant effect on perceived status, conditions $F(2, 233) = 124.61$, $p < .001$, $\eta^2 = .52$. Most importantly, ratings of perceived status were lower in the backhanded compliment condition than in the compliment condition, $t(153) = -8.57$., $p < .001$, $d = 1.37$.

Finally in Study 5, we tested whether perceived self-presentational concern mediates the relationship between backhanded compliments and perceived lower status. As in Study 4, participants who received a backhanded compliment perceived their coworker to have lower status than those received a compliment, $t(247) = 14.68$, $p < .001$, because targets who offer backhanded compliments are perceived to be more concerned about self-presentation.

By investigating backhanded compliments, we contribute to the impression management literature by identifying and examining a distinct self-presentation strategy that people use to signal status. Second, our work contributes to management and organizational behavior research by investigating boundary conditions of flattery. Finally, we extend research on status by highlighting the often-neglected conflict between signaling status and eliciting liking: would-be flatterers believe that backhanded compliments will garner them both liking and status, whereas the recipients of their efforts grant them neither.

Endorsing Help For Others That You Oppose For Yourself: Mind Perception Guides Support for Paternalism

EXTENDED ABSTRACT

As members of a highly interdependent species, people not only try to improve their own well-being, they also try to improve others' well-being. People can choose to help themselves and others in more or less paternalistic ways. For example, providing or banning specific goods is more paternalistic because it restricts the recipient's choice compared to giving cash or information. We propose that support for paternalistic aid depends in part on people's subtle inferences about the mental capacities—self-control and rationality—of those being helped.

Our proposal provides an explanation for why paternalistic aid is popular when giving to others but unpopular among those they are targeted to help (e.g., Conly, 2013; Hill, 2006; Mill, 1869). People tend to believe that others have weaker mental capacities than the self, at least in part because they experience their own minds directly but observe others' minds indirectly (Epley & Waytz, 2010; Haslam et al., 2005; Pronin, 2009; Waytz, Schroeder, & Epley, 2014). We propose that this difference in how people judge their own versus others' minds accounts for self-other differences in support for paternalism. Although other factors may also influence support for paternalism (e.g., ideology, need for autonomy; Costa & Kahn, 2013; Jung, Mellers, & Baron, 2015; Tannenbaum & Ditto, 2015), these do not predict a self-other difference in support for paternalism.

We tested our hypothesis in Experiment 1 by asking participants to choose the most effective policies either for themselves or for an "average citizen." Participants made five sets of choices (avoiding unhealthy foods, avoiding credit card debt, not misusing a gun, saving for retirement, and avoiding mortgage debt) each with two options: a more or less paternalistic policy. For example, participants could either select a policy that banned unhealthy foods (more paternalistic) or provided information on calorie counts (less paternalistic). They also reported how capable they (and the average citizen) were of achieving each goal. As expected, participants were more likely to select paternalistic policies for the average citizen than for themselves, and this was fully mediated by perceived capacity to exert self-control.

Experiments 2-4 next tested how beliefs about the mental capacities of others in need affected paternalistic aid. In Experiment 2, the greater mental capacity that participants believed recipients of charity aid had, the more likely they were to donate their own earnings to a less paternalistic charity (GiveDirectly, which gives direct cash donations to recipients) compared to a more paternalistic charity (Red Cross) or no charity. In Experiments 3 and 4 we manipulated mental capacity beliefs about different groups of people (e.g., Kenyans), and again measured subsequent donations to more or less paternalistic charities. Donors who read information framed to make recipients seem less (vs. more) mentally capable were more likely to donate to the more paternalistic charity. Although beliefs about recipients' mental capacities predicted to *which* charity they gave, only beliefs about recipients' magnitude of need predicted how *much* they gave.

Finally, we tested whether making people aware of their own mental shortcomings will increase support for paternalistic approaches to help themselves (Experiment 5). We asked participants

to evaluate the effectiveness of four policies for reducing obesity either just before or just after a major cultural temptation for overeating: Thanksgiving dinner. Two of these policies were relatively paternalistic, and two were relatively agentic. Consistent with our hypothesis, participants thought that paternalistic approaches to obesity are more effective just after their Thanksgiving dinner then just before it, because they recognized more weakness in their own self-control after (vs. before) Thanksgiving.

Across five experiments examining beliefs about one' own and others' mental capacities, participants consistently preferred to provide paternalistic aid to those who seemed to have less mental capacity: other people (Experiments 1-2), those described as having diminished mental capacities (Experiments 2-4), or oneself after experiencing a moment of mental weakness (Experiment 5). Our findings have important theoretical and practical implications.

Theoretically, these results highlight how subtle inferences about others' mental capacities can affect social life. In particular, our research suggests that the subtle tendency to dehumanize others (Haslam & Loughnan, 2014)—to think of their mental capacities as relatively diminished compared to one's own (Pronin, 2009; Waytz et al., 2014)—matters because it can affect how people attempt to help each other. Thinking of others as being somewhat mentally incapable, perhaps more like children than like adults, can lead people to treat others as relatively childlike as well, preferring a more paternalistic approach to helping others rather than a more agentic approach that enables others to help themselves.

Practically, these results are important for policy makers, charitable organizations, and any others who are trying to improve people's lives through different sources of aid. Decisions about how to help others *should* be guided by empirical evidence about the actual effectiveness of particular interventions. Our experiments, however, demonstrate that these decisions in the absence of evidence may actually be guided by a less useful source: potentially mistaken inferences about the minds of those being helped. Those who design policy, offer aid, or try to help those in need would be wise to remember that good intentions may be guided by mistaken assumptions about the very people whose lives they are trying to improve.

Encouraging Consumers to Consider Others' Perspectives Helps Them Optimize Decisions about Scarce Resources

EXTENDED ABSTRACT

Consumers often converge on scarce resources, like money, time, space, and attention. If consumers better anticipated the behavior of others and slightly shifted their choices to coordinate with them, it would improve general welfare. Sometimes people can coordinate by basing choices on the same focal point (e.g., Camerer 2003), or by making choices sequentially rather than simultaneously (Rapoport 1997) or with one-sided communication (Cooper et al. 1989). But these approaches are not always possible. We address a particular understudied class of coordination problems, in which decision-makers must anticipate others' actions while being unable to communicate with them, and avoid rather than match their behavior. We suspect that these coordination problems are challenging because people typically underweight or even fail to consider other people's behavior, even though accounting for that behavior is inherently part of the coordination task. Across five studies we show that encouraging decision-makers to consider what others are likely to do can ameliorate these coordination problems by shifting consumers' choices.

In an initial field experiment, individuals entered a lottery to participate in a study with a monetary incentive. Timeslots were limited; participants could enter the lottery for only one timeslot and one person was drawn per slot. Participants receiving a reminder to consider why others might select particular timeslots chose less popular timeslots, increasing their competitive advantage, and were thus more likely to be invited to participate (47.0%) than control participants who received no reminder (28.6%; $\beta = .18$, $t = 2.81$, $p = .006$). In study 2 we demonstrate this effect in a different domain. Participants imagined participating in a costume contest in which the goal was to stand out from the crowd and were given six potential costumes from which to choose, including two trendy costumes, two classic costumes, and two unusual costumes. Participants who were reminded to consider what others might wear to the contest were more likely to choose one of the unusual costumes (39.3%) than participants in the control condition who received no such reminder (25.7%; $\chi^2 (1, N = 298) = 6.33$, $p = .01$, $\phi = .15$).

Studies 3 and 4 suggest that these shifted choices do stem from an increased likelihood of considering others' probable behavior. In study 3, participants imagined a trip to the bank on a busy day and chose when to go between four 15-minute timeslots: at the beginning of the workday, during lunch, in the midafternoon, or at the end of the workday. Participants were asked to choose a time that was most likely to allow them to complete the errand on time, and provided a reason for their choice. After they provided their reason, they self-rated how focused that reason was on their own time constraints and on other people's behavior. Participants receiving a perspective-taking reminder were more likely to choose the less-busy midafternoon timeslot (55.8%) than control participants (30.8%; $\chi^2 (1, N = 419) = 26.60$, $p < .001$, $\phi = .25$). Perspective-taking participants also indicated that they were more focused on other people's behavior ($M = 6.17$, $SD = 1.38$) than control participants $M = 5.39$, $SD = 1.96$; $t(370.82) = -4.68$, $p < .001$, $d = .47$) and that they were less focused on their own constraints ($M = 4.66$, $SD = 1.96$) than control participants ($M = 5.34$, $SD = 1.72$; $t(405.47) = 3.73$, $p < .001$, $d = .37$). Study 4 demonstrates that people who are naturally inclined to consider others' perspectives are more likely to optimize their social media use to get a large audience with less competition for users' attention. Participants indicated how likely they would be to post on Twitter at seven different times (12:00am, 4:30am, 9:00am, 2:22pm, 5:00pm, 7:00pm, and 1:30am). They then completed versions of the Fantasy and Perspective-Taking subscales of the Interpersonal Reactivity Index (Davis 1981). Participants who scored higher on the perspective taking scale demonstrated increased variance in their posting times ($\beta = .03$, $t(266) = 2.88$, $p = .004$), suggesting that they are more responsive to when people are likely to be on Twitter and are therefore more discerning when they post.

Finally, in study 5, we demonstrate a boundary condition as well as provide further support for the idea that reminders facilitate coordination because people do not naturally consider others' actions enough, by showing an exception for situations where those actions are inherently obvious. Specifically, when participants are asked to plan an outing to the beach that would avoid crowds during a busy holiday 3-day weekend, they were equally likely to go to the beach on the Friday of that weekend whether they were reminded to consider others (7.8%) or not (6.7%; $\chi^2 (1, N = 207) = .08$, $p = .77$, $\phi = .02$). However, participants deciding when to go to the beach on a weekend where they had a personal 3-day weekend were more likely to choose Friday for the beach day when they were asked to consider when other people would go to the beach (35.3%) than when they did not receive the perspective taking reminder (19.8%; $\chi^2 (1, N = 203) = 6.10$, $p = .01$, $\phi = .17$). The interaction between conditions is significant ($\chi^2 (1, N = 410) = 23.14$, $p < .001$, $\phi = .24$).

Employing both laboratory and consequential field situations, we demonstrate that consumers underutilize their ability to perspective-take, even though perspective-taking is intrinsically part of coordinating with other people. Encouragement to consider what others will do and why enhances coordination and improves outcomes. This insight offers potential solutions to consumers, marketers, and policy makers who aim to improve customer experience, satisfaction, and welfare.

SESSION OVERVIEW

Health problems caused by excessive food intake are increasing. Millions of people across the world are suffering from being overweight or obese (Ng et al. 2014; WHO 2014). Overwhelming food choice enviroments like supermarkets and fast-food restaurants increase the relevance for research about how consumers make healthier food choices and, more importantly, how consumers can be motivated to do so (Chandon and Wansink 2012). The purpose of this session is to report and discuss new insights from different perspectives on healthier food choices and to expand the body of knowledge: first, the various findings from the four papers contribute to consumer research by showing new behavioral mechanisms and dynamics, but also potential implementation strategies, which are relevant for healthier food choices. Hence, consumer researchers will gain insights into how to achieve win-win situations for both consumers and food suppliers. The four papers apply different methodologies to answer novel research questions and will, therefore, provide a promising foundation for a vivid discussion. The papers are summarized as follows:

In Paper #1, Oh, Huh, and Mukhopadhyay present a field experiment, manipulating availability of nutrition information, and reveal that consumers set day-level mental budgets for calories. They found that consumers who set budgets adjust dinnertime consumption in response to information about past calorific consumption. The authors demonstrate that such mental calorie budgets interact with calorie information provision and can influence subsequent decisions. Hence, their results provide evidence about transmitting effects of calorie information, and emphasize the importance of considering these insights when evaluating nutrition disclosure effectiveness.

In Paper #2, van der Heide, van Ittersum, and van Doorn report how the healthiness of a series of sequential purchases evolves throughout a shopping trip. Their research combines results from an online study and a lab experiment and, their findings show healthy-shopping dynamics: overweight consumers purchase healthier options in the first half of the shopping trip, while making unhealthier choices during the second half. Normal weight consumers did not show any choice patterns during the shopping trip. These results highlight how focusing on single purchases and end-of-trip baskets can fail to capture individual differences regarding healthy-shopping decisions.

In Paper #3, Elshiewy, Jahn, Doering, and Boztug combine results from supermarket purchase and experimental survey data to investigate how consumers respond to voluntary front-of-pack nutrition labels. Experimental results reveal an overall increase in brand trust, while product attitude increases (decreases) for healthy (unhealthy) products. Interestingly, results show that nutrition labels only affect sales and purchase intention for products with potentially misleading nutrition claims (i.e., 'low fat' products with high sugar content).

In Paper #4, Reimann and Lane show how healthier food choices can be motivated in fast-food restaurants. Their findings reveal that including an inexpensive non-food item (toy) with a smaller-sized meal incentivizes children to choose the smaller-sized "Happy Meal" instead of the regular-sized version without non-food item. This effect even holds among children with overweight and obesity. Their findings matter for both food marketers and public policy makers, who aim to stimulate healthier food choices.

The Mental Budgeting of Calories: How Nutrition Information Influences Food Consumption Day by Day, Not Meal by Meal

EXTENDED ABSTRACT

Does the presence of calorie information influence food consumption? Over the last decade or so, calorie labels have been mandated across several jurisdictions worldwide, in the hope that they will help curb the obesity epidemic. However, the emerging evidence reveals that these measures have had a disconcertingly weak effect, if at all (Downs et al. 2013). We suggest that these observed null effects may, in part, be attributable to the paradigm that has been used. Almost all research on nutrition labeling has studied how the provision of nutrition information about a given food item affects consumers' choices of that specific item. However, given that most consumers make multiple food decisions a day (Cutler, Glaeser, and Shapiro 2003) and decisions may not be independent of preceding decisions (Khare and Inman 2009), examining the effect of nutrition information within a narrowly defined choice context may not adequately capture how consumers use such information.

We propose instead that, consistent with public health messaging, consumers have day-level calorie consumption limits (i.e., mental budgets of calorie consumption), which affect their food decisions more broadly. Much research has shown that consumers use mental accounts to keep track of financial expenses (e.g., Thaler 1985, 1999; Heath and Soll 1996; Cheema and Soman 2006). They set budgets for a certain period of time (e.g., weekly food and entertainment budgets) and regularly monitor the balance to avoid overspending (Read,

Loewenstein, and Rabin 1999). We propose that, like these monetary budgets, consumers have a budget for calorie consumption, which is set daily. Since the calorie content of any single food item is usually much lower than a daily budget, the provision of calorie information will not have a major influence on one-off decisions unless the information reveals an unusually high calorie count. However, this information may well have an observable effect across consumption situations at a day level. If so, a consumer's decision regarding dinner may well be influenced by the nutrition information processed at lunch.

Who is likely to have a mental budget for calories? Restrained eaters (Herman and Polivy 1980) care about and pay attention to food-relevant information. Therefore, restrained (vs. unrestrained) eaters should (a) be more likely to have such mental budgets, which (b) are generally smaller. Consequently, we predict that the effect of calorie information disclosure should be apparent at a day level, for consumers who are restrained eaters.

Study 1 tested for the existence of mental calorie budgets. 3,150 respondents participated from Australia, Hong Kong, India, South Africa, UK, and USA (minimum 500 respondents from each country). Participants were asked to indicate the acceptable calorie range for them to eat for a normal day by typing the minimum and the maximum calories, in an open response format with an option to indicate if they did not normally watch the number of calories they ate. 47% of respondents reported having daily consumption budgets. Broken down by country, the US reported the highest proportion, 63%, followed by UK, 59%, Hong Kong, 48%, India, 40%, Australia, 40%, and South Africa, 32%. On average, consistent with public health messaging, daily calorie budgets ranged from 1,425 calories to 2,683 calories.

Study 2 tested whether the size of the mental budget varies depending on dietary restraint. MTurkers (N=200) first indicated their acceptable range of daily calorie consumption with an option to express that they did not have limits on food consumption. Then, we measured dietary restraint (Herman and Polivy 1980). As predicted, more restrained eaters were more likely to have daily budgets ($p <$ .001), and have smaller budgets ($p <$ .05).

Based on the evidence of existence of daily calorie budgets especially for restrained eaters, Study 3 tested how these budgets interact with the provision of calorie information at a day level. Calorie information provided for meals on the same day (e.g., breakfast and lunch) enables restrained eaters to track how much of their budget has been used and how much budget is left for dinner. Therefore, when calorie information is provided for the prior intake, restrained eaters should "balance" the remaining budget at dinner (i.e., eat less [more] when the remaining budget is tight [ample]). Study 3 was a field experiment that tested these predictions.

Participants (N=190 undergraduate students) recorded their food diaries for an entire day. In the late afternoon, half the participants received accurate and itemized feedback about how many calories they had consumed till then. The other half, control, got no feedback. As predicted, there was an interaction such that restrained eaters who had consumed relatively high calories prior to feedback (one SD above the mean of average pre-feedback calorie intake) decreased calorie consumption at dinner (vs. control; $p =$ .06). Conversely, restrained eaters who had consumed relatively less calories (one SD below the mean of average pre-feedback calorie intake) during the day subsequently increased their dinnertime calorie consumption (vs. control; $p <$ .01). Providing feedback did not influence the dinnertime consumption for unrestrained eaters (ns).

In summary, we provide evidence for daily mental budgets for calorie consumption. The likelihood of having calorie budgets and

the sizes of the budgets vary depending on dietary restraint. We demonstrate that such mental calorie budgets interact with calorie information provision to influence subsequent decisions. Hence, the null effects of calorie information provision observed in past research may be due to the fact that researchers have been looking with too narrow a lens.

Healthy-Shopping Dynamics: The Relative Healthiness of Food Purchases Throughout Shopping Trips

EXTENDED ABSTRACT

Globally, nearly 30% of the world population is now considered overweight or obese (Ng et al. 2014). This obesity epidemic is largely driven by the overconsumption of unhealthy (i.e., energy-dense and nutrient-poor) foods (Asfaw 2011). Surprisingly, while supermarkets account for more than 50% of public food expenditures (Glanz, Bader, and Iyer 2012), we know little about the "healthiness" of people's shopping baskets. Research to date typically focuses on healthiness of single purchases or end-of-trip baskets, investigating for instance the impact of health labels and "fat taxes" (Khan, Misra, and Singh 2016; Wansink and Chandon 2006). However, a growing body of research suggests that the grocery purchase process is more than a series of independent decisions—it is dynamic and evolves in response to earlier purchase decisions (Gilbride, Inman, and Stilley 2015).

Taking these dynamics into account is highly relevant, since the positive immediate effects of health interventions might in fact backfire due to dynamic responses. For instance, while price reductions effectively stimulate healthy food purchases, they may increase the total number of calories purchased in the end-of-trip shopping basket (Waterlander et al. 2012). Therefore, the goal of this research is to examine healthy-shopping dynamics throughout major shopping trips. Do shoppers consistently purchase relatively (un)healthy foods, or do they interchangeably purchase relatively unhealthy and healthy foods?

Existing theories offer support for both accounts: a dynamic interchange of healthy and unhealthy purchases (Khan and Dhar 2006) and the consistent purchase of (un)healthy foods (Williams and DeSteno 2008). These varying dynamics seem to originate from an interplay of licensing effects, "what-the-hell" effects and feelings of pride and/or guilt. First, a healthy food choice may license the purchase of a self-indulgent, unhealthy product (Hui, Bradlow, and Fader 2009; Khan and Dhar 2006). Second, when consumers purchase an unhealthy product, their failure to adhere to health goals may cause a "what-the-hell" response, leading to further unhealthy purchases (Cochran and Tesser 1996). Third, consumers may experience pride after a healthy food purchase (Mukhopadhyay and Johar 2007), facilitating further pursuit of (health) goals (Williams and DeSteno 2008). Fourth, consumers may experience guilt after purchasing an unhealthy product, which may motivate healthier future choices (Chen and Sengupta 2014).

Concluding, existing literature suggests multiple dynamic forces that affect (un)healthy food purchases. Moreover, these dynamics could differ across weight categories. Among others, overweight consumers differ from their normal-weight counterparts in terms of the guilt they experience regarding their eating behavior (Wansink and Chandon 2006). We empirically investigate these notions in two initial studies.

In Study 1, we first conducted an online study on healthy-shopping dynamics involving 160 MTurk participants (M_{age} = 31.6; 46% female). Participants made 11 within-category product choices (e.g., diet coke within the coke category). We assessed the relative healthi-

ness of these choices in terms of calories—the number of calories relative to the average number of calories of all presented options. Each product decision involved four options (presented with a picture, price and caloric information) and a no-purchase option. Furthermore, participants were randomly assigned to different real-time caloric feedback conditions (no feedback vs. % GDP feedback vs. total calories feedback).

After classifying participants as normal-weight (BMI < 25) or overweight (BMI ≥ 25), we conducted a repeated measures analysis with polynomial contrast analysis on relative healthiness. The within-subjects effect of relative healthiness was highly significant ($F(10, 1540) = 6.80$; $p < .01$), supporting the existence of healthy-shopping dynamics. The between-subjects effects of participants' weight ($F(1, 154) = 1.69$; $p = .20$) and feedback condition ($F(2, 154) = 0.37$; $p = .69$) were not significant. However, contrast analysis suggests a significant cubic interaction between relative healthiness and weight ($F(1, 154) = 13.65$; $p < .01$), indicating that healthiness dynamics differ between normal-weight and overweight shoppers. Among overweight participants, cubic contrasts are significant ($F(1, 69) = 43.57$; $p < .01$). They purchase relative healthy options in the first half of the shopping trip, while making relatively unhealthy choices during the second half of the trip. Among normal-weight participants, cubic contrasts were also significant ($F(1, 85) = 5.25$; $p = .02$), although less pronounced. No significant contrasts or interactions were found for the caloric feedback conditions ($p > .10$).

This study supports the presence of healthy-shopping dynamics, particularly among overweight shoppers. To address some of the study's limitations, Study 2 was conducted.

We next conducted Study 2 as a lab study involving 320 undergraduates ($M_{age} = 20.7$; 49% female). Participants made 25 (virtual) product choices in randomized order. Product decisions involved three product options (without a no-choice option). Furthermore, to stimulate realistic choices, one of the participants could win a $75 prize package containing the selected products and cash. No caloric feedback was provided in this study. The rest of the design and procedure were identical to Study 1.

Repeated measures analysis again yielded a significant within-subjects effect for relative healthiness ($F(24,7632) = 1.51$; $p = .05$). Again, the between-subjects effect of participants' weight was not significant ($F(1,318) = 1.43$; $p = .23$). Contrast analysis suggests a significant quadratic interaction between relative healthiness and weight, further indicating that dynamics differ across weight categories ($F(1, 318) = 3.92$; $p = .05$). A marginally significant quadratic evolution was found for overweight participants ($F(1, 33) = 3.63$; $p = .07$)—they select more low-calorie options (i.e., healthier options) at the start and the end of the shopping trip than half-way through the trip. For normal-weight participants, quadratic, cubic and linear contrasts remained insignificant ($p > .10$).

This study further supports the existence of healthy-shopping dynamics throughout a major shopping trip and confirms differences across weight categories. Since normal-weight and overweight shoppers did not differ in terms of overall relative healthiness, these results highlight how the currently prevalent focus on single purchases and end-of-trip baskets would fail to capture important individual differences regarding healthy-shopping decisions. Planned follow-up studies will also consider other individual differences and test potential underlying processes.

'Low Fat' but High in Sugar: Consumer Response to Misleading Nutrition Claims

EXTENDED ABSTRACT

Package-based claims and labels have become popular tools to influence consumers' perceived healthiness of food products (Andrews et al. 2014, Chandon 2013). In particular, marketers make use of nutrition claims (e.g., 'low fat') and voluntary nutrition labels (e.g., GDA) posted on the front of the package to emphasize the nutritional advantage of their products (Elshiewy, Jahn, and Boztug 2016; Newman, Howlett, and Burton 2014). Nutrition claims increase the perceived healthiness of food (Andrews, Netemeyer, and Burton 1998; Belei et al. 2012; Geyskens et al. 2007; Wansink and Chandon 2006) and can have a positive impact on sales in supermarkets (Balasubramanian and Cole 2002; Levy et al. 1985; Teisl, Bockstael, and Levy 2001). The downside of these findings is that misleading nutrition claims can be responsible for overeating and obesity (Belei et al. 2012; Wansink and Chandon 2006). The so-called health-halo effect implies a simultaneous overestimation of the food's healthiness and an underestimation of its energy content, which can result in increased consumption (Chandon and Wansink 2007). For nutrition claims such as 'low fat,' consumers may overgeneralize the information from the claim and rate the product as being healthy on other nutrients not mentioned in the claim (Andrews, Netemeyer, and Burton 1998; Roe, Levy, and Derby 1999). The perceived healthiness will be biased if the food product features, for example, a 'low fat' claim but is high in sugar content. Such biased perception is not unlikely as food manufacturers sometimes increase the amount of sugar to compensate for the fat reduction in order to keep the food's tastiness (Brennan and Tudorica 2008).

Our research seeks to explore how consumers react to food products featuring a nutrition claim after the introduction of a front-of-pack (FOP) nutrition label. We do not expect a generally healthier choice behavior, but contend that it depends on the combination of claim content with the amount of other nutrients disclosed on the FOP nutrition label. We argue that FOP nutrition labels alter the perception of food products only when expectations are disconfirmed (Burton et al. 2015, Burton, Howlett, and Tangari 2009). If consumers overestimated the healthiness of a product before nutrition label introduction due to a nutrition claim, we predict aversion behaviors toward this product. That is, nutrition label introduction should lead to decreased consumption of food that claims to be, for example, 'low fat' but is high in sugar.

We combine results from supermarket purchase data and an experimental survey to investigate how consumers respond to such potentially misleading nutrition claims. Our purchase data analysis uses supermarket scanner data for 24 yogurt products covering a two-year period, one year before and one year after a voluntary FOP nutrition label introduction. The label displays the amount of calories (in kcal) as well as sugar, fat, saturated fat and salt (in g) per serving together with the percentage of recommended daily amount. After label introduction, sales volume did not decrease for unhealthier products in general. Sales volume did decrease, however, for yogurts with low fat content (and the corresponding 'low fat' claim), but only when they also contained high amounts of sugar.

To investigate the underlying mechanism, we conducted an experimental survey as a follow-up analysis. We used a 2 ('low fat' claim absence vs. presence) x 2 (low vs. high sugar content) design with repeated-measures (before and after nutrition content disclosure). Four different yogurts were constructed as stimuli, two of which fulfilled FDA requirements to feature a 'low fat' claim (less than 3 g fat per 100 g). We averaged the fat and sugar content of

yogurts typically available at supermarkets to create four distinct conditions: a *'low fat' claim/ low sugar* natural yogurt (.6 g fat/5.8 g sugar), a *no claim/low sugar* Greek yogurt (10.8 g fat/ 6.7 g sugar), *no claim/ high sugar* fruit yogurt (4.5 g fat/13.8 g sugar) and a *'low fat' claim/ high sugar* fruit yogurt (1.5 g fat/13.8 g sugar).

For our online experiment we recruited 405 respondents using MTurk. First, participants answered questions about their dietary concerns and nutrition proficiency, and were then randomly assigned to one of the four conditions. They were presented an image of a fictitiously branded yogurt product; in two of the conditions the product featured a 'low fat' claim. Importantly, other information about the nutrition content was not revealed. Respondents were asked about their product attitude, brand trust, and purchase intention. Following these evaluations, participants were presented the same yogurt again, but this time with additional FOP nutrition information (calories, sugar, fat, saturated fat and salt per 100 g and the percentage of recommended daily amount). As before, we asked about product attitude, brand trust, and purchase intention.

Results from ANOVA and mediated moderation analysis provide strong support for the proposed mechanism. Product attitude and purchase intention increased for a low-sugar yogurt featuring a 'low fat' claim after FOP nutrition label provision. Interestingly, product attitude for yogurts without the claim decreased significantly, while the purchase intention was not affected by the FOP nutrition information. In line with our prediction and the results from the purchase data analysis, purchase intention significantly decreased for the *'low fat'/high sugar* yogurt after FOP nutrition label exposure. Product attitude worsened as well. We used dietary concerns and nutrition proficiency as control variables in our models. Taken together, results suggest that FOP nutrition labels can correct for biased healthiness perceptions, but do not promote healthier choices per se. With respect to misleading nutrition claims, comprehensive nutrition information appears to mitigate the health halo and reduce choice. Importantly, label introduction had a positive effect on brand trust across all four conditions. It appears that voluntary FOP nutrition disclosure still works as a brand-perception improving food marketing strategy.

In summary, our research reveals aversion behavior towards food products with potentially misleading nutrition claims. The combination of results from supermarket purchase data and an experimental survey greatly enhances external and internal validity of our findings. Our results, therefore, contribute to the growing literature in healthier food choice, with relevance to consumer research, food marketing and public policy.

Can Children Still be Happy If 160 Calories Are Cut Out of The Happy Meal? Reinforcing Effects of Toys on Portion Choices

EXTENDED ABSTRACT

As childhood overweight and obesity have risen, researchers have started investigating food marketing tactics that may have contributed to the pandemic. For example, toy premiums in children's meals (e.g., McDonald's Happy Meals) effectively motivate children to visit fast food restaurants (Bernhardt et al. 2013). At the same time, children's meal bundles have undergone scrutiny for high energy density (Powell, Harris, and Fox 2013; O'Donnell et al. 2008). Relatedly, two recent systematic reviews found character endorsers (e.g., McDonald's Ronald McDonald) considerably increase children's liking and preference (Smits et al. 2015; Kraak and Story 2015) for energy-dense foods (Kraak and Story 2015). These tactics' popularity among food marketers and meal bundle's link to over-weight and obesity have generated suspicions that toy premiums have incentivized over-consumption, even encouraging legal action (Otten et al. 2014). The effects of food marketing tactics on children are especially worrisome because they likely establish and reinforce long-lasting food choice patterns (Connell, Brucks, and Nielsen 2014).

In the present research, we asked whether toy giveaways (henceforth referred to as toy premiums) could be used to incentivize children to choose a smaller-sized meal. Specifically, we tested whether including a toy with a smaller-sized (420 calories), but not with a regular-sized (580 calories), Happy Meal would predict smaller-sized meal choice. On first sight, cutting 160 calories out of a meal may not be an effective strategy, considering smaller-sized food portions are less attention-grabbing (Fisher and Birch 1999) and less desirable (Jansen, Mulkens, and Jansen 2007) than larger-sized ones and are, therefore, often rejected by children (Wansink and Hanks 2014).

We argue that toys can be used as effective substitutes for food. One might expect that substitutes need to satisfy common physiological needs (e.g. both water and juice satisfy thirst) (Green and Freed 1993). Yet, we build on extant research in arguing that even highly different stimuli such as food and toys share a common physiological basis, hence allowing their behavioral substitution. Humans have learned to associate solid and liquid foods with appetitive and survival values, which makes food a vegetative reward (Schultz 2006; Rollins et al. 2014). Because children can be reinforced for the receipt of toys (Bijou and Sturges 1959), toys can represent artificial rewards. Hence, we argue that the reinforcing prowess of the toy can counterbalance the lower reinforcement value of a smaller-sized (compared to a regular-sized) meal. The translation of both food and toy into a common reinforcement value should facilitate choice substitution of food with toy. Indirect evidence for the notion of a common physiological basis of vegetative and artificial rewards comes, for example, from a recent adult study that observed automatic responses (e.g., salivation) for attractive material goods (Gal 2012) similar to those expected for delicious food. Following this novel notion of choice substitution, we argue that toys can be used as positive reinforcers, strengthening children's choice behavior for the smaller-sized meal.

At present, there is no experimental evidence evaluating the potential reinforcing value of toys in smaller-sized Happy Meal choice. The goal of the present work was to test the effectiveness of toys in lowering food portion choice and consumption. The research was conducted in the field with actual Happy Meals, across time (i.e., across two repeated trials) and in regard to BMI. Recent research showed that food cues are more attention-grabbing in individuals with obesity (Castellanos et al. 2009; Davids et al. 2010) and that overweight individuals are more susceptible to larger portion sizes (Burger, Fisher, and Johnson 2011), implying BMI could moderate or even nullify the effect of toy on smaller-sized meal choice. Conversely, other research reports overeating in response to larger portion sizes to occur regardless of BMI (Livingstone and Pourshahidi 2014). We attempt to reconcile these findings by determining if BMI will moderate children's portion choice.

In the present research, inclusion of a toy with a smaller-sized meal, but not with the regular-sized version, predicted smaller-sized meal choice ($B = 2.84$, $SE = .77$, $z = 3.67$, $p < .001$, 95% CI [1.33; 4.36]), suggesting that children can be incentivized to choose less food when such is paired with a toy. BMI neither moderated nor nullified the effect of toy on smaller-sized meal choice ($p = .125$), suggesting that children with overweight and obesity can also be in-

centivized to choose less. Further, neither age, sex, nor hunger level affected choice.

In conclusion, the findings from this study suggest fast-food restaurant chains should include toys to motivate children to choose less food. Children offered a smaller meal with a toy (vs. regular meal without one) are more likely to choose the smaller meal compared to children that are offered a regular meal with a toy (vs. a smaller meal without one).

SESSION OVERVIEW

Food labeling is a powerful marketing tool to create associations between food products and desirable attributes (Chandon and Wansink 2011). Prior research has demonstrated that labeling influences perceptions such as taste and healthiness, which in turn affect food choice, sensory experiences, and enjoyment (Levin and Gaeth 1988; Belei et al. 2012; Shah et al. 2014). In this session we offer novel sensory and social perspectives on how food labeling influences consumption decisions for the self and others. Specifically, we have compiled four exciting papers examining how food labels change consumers' expectation for sensory experiences (Ordabayeva and Srinivasan), enhance hedonic pleasure (Dallas, Liu, and Fitzsimons), and influence consumption decisions in the social sphere for the self (Oh and Huh) and for others (Boegershausen, Cornil, and Howard).

The first paper by Ordabayeva and Srinivasan examines the influence of sound salience in labels on consumption experiences. When labels make the sound of food salient (vs. not salient), consumers' expectations are drawn to experience of sound, which increases consumption enjoyment as well as consumption, even for healthy foods. However, this positive effect is reversed when competing sounds are present or when consumption monitoring is activated by the food or the social environment.

In the second paper, Dallas, Liu, and Fitzsimons demonstrate the existence of a "local halo" effect: Labeling foods as "local" leads consumers to perceive foods as healthier and tastier simultaneously, thus overcoming the "healthy = not tasty" lay belief. This local halo effect even holds for low-fat foods that are conventionally perceived as less tasty than their regular counterparts, boosting choice of low-fat foods.

The third paper by Oh and Huh further extends the role of food labels to interpersonal contexts based on the impression manage-

ment literature. Lab experiments and a field experiment show that when consumers are motivated to convey their competence to others, consumers are more likely to choose low-calorie labeled (vs. non-labeled) food. Further, this is due to the belief that choosing low-calorie foods reflects one's competence.

Finally, Boegershausen, Cornil, and Howard examine how the recommendations by waiters in restaurants are influenced by food labels, and by the external characteristics of patrons. In line with stereotyping theory, they demonstrate that participants assuming the role of a waiter are more likely to discourage female (vs. male) customers from choosing unhealthy but tasty food when customers are heavy (but not thin). This pattern of paternalistic recommendations (imposed self-control) is a novel form of subtle, insidious discrimination against heavy female consumers.

Collectively, the four papers (all in advanced stages) shed novel insights on the role of food labeling. Taken together, the papers address the following questions: (i) which food labels can moderate or even reverse well-established labeling effects and (ii) how do labels affect choices in more interpersonal settings. A full appreciation of the far-reaching effects of food labels can enrich our theories about food consumption. This session is of interest to a diverse audience as it appeals to researchers interested in food consumption, labeling, expectancy effects, sensory perception, and social influence.

Does Salience of the Sound of Food Increase or Decrease Consumption?

EXTENDED ABSTRACT

The sound that a food makes when it is eaten is central in our experiences of food (Vickers 1981), and it is an attribute that marketers often highlight to boost the appeal of products (Mermelstein 2013). Yet, the marketing literature has overlooked the effect of the sound salience of food on consumption experiences. Existing marketing studies on audition have reported the effects of sounds invoked by brand names (e.g., "Frosh" vs. "Frish" ice-cream) and of ambient sounds in the environment on perceptions of food products (Lowrey and Shrum 2007; Milliman 1986). In the meantime, the use of sound in labels, advertising slogans, and packaging is pervasive. In our analysis of new snack foods introduced in the US in 2013-14 (data provided by Innova Marketing Insights), we found that 70% of new snacks made the sound of food salient. It is therefore important to understand how the salience of the sound of food, controlling for the food's actual sound, influences consumption experiences, and to delineate conditions in which sound salience increases or decreases consumption. This is the focus of our research.

We build on studies in food science that correlated the food's actual loudness with expectations of the food's sound and freshness (Vickers 1983; Zampini and Spence 2004). We integrate these findings with marketing insights about the effects of expectations created by food labels on product experiences (Levin and Gaeth 1988; McCabe and Nowlis 2003). We posit that making the sound of food salient will enhance consumers' expectations of the food's sound. In turn, when consumers' heightened expectations of the food's sound are confirmed, the salience of the food's sound will increase food enjoyment and consumption. However, when expectations of the food's sound are disconfirmed (when auditory attention is diverted to a competing sound) or when the salience of the sound of food

triggers consumption metering (when consumption monitoring is active), the salience of the sound of food will reduce consumption. We test our predictions in five studies.

First, we ran a pre-test to verify our proposition that the salience of the sound of food enhances sound expectations. Participants saw an advertisement of chocolate candies with a crunchy exterior and a creamy interior. The ad slogan of the candies manipulated the salience of the candies' sound by describing the candies as "delicious and crunchy" in the sound-salient condition or "delicious and creamy" in the sound non-salient condition, while keeping the actual candies and their actual sound constant across conditions. Participants indicated that they expected the sound of the candies to be more pronounced (loud, audible, salient, attention-grabbing) when the ad made the sound salient vs. non-salient.

Study 1 tested the effect of sound salience on consumption enjoyment and purchase intentions. Participants sampled three chocolate candies from the pre-test, and they saw the same ads of the candies (describing candies as "delicious and crunchy" in the sound-salient condition vs. "delicious and creamy" in the sound non-salient condition). After sampling the candies, participants rated their enjoyment of the candies (enjoyment, taste, and deliciousness) and their intentions to purchase the candies. The results revealed higher purchase intentions when the sound of the candies was salient (vs. non-salient), and this effect was mediated by consumption enjoyment.

Study 2 tested the role auditory attention in moderating the effect of sound salience. Participants watched a movie clip while snacking on potato chips. The ad slogan of the chips made their sound salient ("crunchy and tasty") or non-salient ("tasty"). We also manipulated auditory attention by using an auditory instruction, and we measured actual consumption. In the control condition, we provided no auditory instruction and expected to replicate the positive effect of sound salience on consumption. In the competing sound condition, we instructed participants to pay attention to a competing sound (the movie) and expected to reverse the effect of chips' sound salience due to disconfirmed expectations of the chips' sound. The results supported our predictions.

Studies 3 and 4 tested the role of consumption monitoring in moderating the effect of sound salience. In Study 3, participants watched a movie clip while snacking on potato chips. The ad of the chips made their sound salient ("crunchy and tasty") or non-salient ("tasty"), as in Study 2. Furthermore, the chips were served in a transparent pack that activated consumption monitoring (Deng and Srinivasan 2013) or an opaque pack that did not. The results revealed that sound salience increased consumption from an opaque pack that did not activate consumption monitoring, but decreased consumption from a transparent pack that activated consumption monitoring. Consumption enjoyment mediated this interactive effect of sound salience with consumption monitoring. Study 4 replicated the moderating effect of consumption monitoring with an alternate description of the chips' sound ("loud") and a contextual manipulation of consumption monitoring (public consumption setting: consumption monitoring active vs. private setting: consumption monitoring not active).

Study 5 tested whether the sound salience of healthy foods can increase healthy food consumption among adults in a weight-loss program. Participants read a book excerpt while sampling carrots. The carrots were described as having been chosen for the study because of their sound (sound-salient condition) vs. popularity (sound non-salient condition). Participants indicated the quantity of carrots that they desired to eat and completed the behavioral activation scale (Carver and White 1994) that captured their inherent tendency to seek enjoyable sensory experiences. The results indicated that sound salience increased desired consumption among individuals with a high tendency to seek enjoyable sensory experiences, which reinforced the importance of sensory enjoyment in driving the effect of sound salience.

In sum, our findings demonstrate that the mere salience of the sound of food, controlling for the food's actual sound, can significantly impact consumption experiences and decisions. However, this effect may be positive or negative, depending on the attention that consumers are able to pay to the sound of food and the degree of consumption monitoring that is triggered by the food or the environment. The findings shed light on the benefits as well as the potential costs of sensory labels.

The Local Halo: Local Foods are Perceived as Both Healthy and Tasty

EXTENDED ABSTRACT

Consumers often have multiple goals when making food choices (Finkelstein and Fishbach 2010; Liu et al. 2015). For example, consumers generally want their food to be both tasty and healthy. However, addressing both of these goals simultaneously can be difficult because many consumers believe that there is an inverse relationship between tastiness and healthiness (Liu et al. 2015; Raghunathan, Naylor, and Hoyer 2006). Indeed, consumers believe that healthy foods are generally less tasty than unhealthy foods (Liu et al. 2015) and that the same food will taste worse when it is labeled as healthy rather than unhealthy (Raghunathan et al. 2006). Because of this perceived conflict between a health goal and a taste goal, consumers often feel that they must pick one goal to pursue with a given food choice. Problematic from a health perspective, many consumers prioritize taste goals over health goals (Glanz et al. 1998; Stewart, Blisard, and Jolliffe 2006), such that consumers' health goals affect their food choices only if they are convinced that their taste goals will also be addressed. This combination of consumers' belief that healthy foods are not tasty, and the priority that they place on taste over health, may contribute towards excess weight gain, with negative health consequences (Flegal et al. 2010). Thus, it is critical to find a way to overcome consumers' unhealthy = tasty (and healthy = not tasty) intuitions. The current research proposes that labeling a food with a "local" label can overcome these intuitions, such that local foods are perceived to be both tasty and healthy.

Recently, there has been a movement within the United States to "buy local" products (Lyon 2014). In fact, between 2008 and 2012, local and regional food sales increased from $4.8 billion to $6.1 billion (Wright 2015). Indeed, local products—particularly foods—are increasingly seen positively (Klavinski 2013). We suggest that this positivity creates a "local halo," such that local foods are perceived to be both tasty and healthy. Halo effects occur when "an initial favorable impression promotes subsequent favorable evaluations on unrelated dimensions" (Schuldt, Muller, and Schwarz 2012, p. 581) and were originally examined in person-perception contexts (Asch 1946; Kelley 1950). In terms of past research on "halo" effects in the food context, consumers have been shown to generalize the associations they have with a particular label (i.e., a restaurant name or the organic or fair trade label) to the product's healthiness. For example, Chandon and Wansink (2007) found that people believe restaurants that are positioned as healthy serve lower calorie foods than restaurants that are not positioned as healthy even when that is not the case. Relatedly, Schuldt and Schwarz (2010) identified an "organic halo," such that consumers infer that organic foods are lower in calories than non-organic foods, and Schuldt, Muller, and Schwarz (2012) identified a similar halo for "fair trade" products. However, whereas this past research has identified a label's halo effect on a single at-

tribute of healthiness, we instead test whether a local label's halo extends beyond a single attribute of healthiness to include tastiness. Examining whether the local halo can increase both healthiness and tastiness perceptions is particularly interesting because these two attributes are typically viewed as being inversely related (Liu et al. 2015; Raghunathan et al. 2006). In sum, we predict that the positivity that consumers feel towards local foods will lead them to infer that such foods are "positive" on both taste and health (i.e., are both tasty and healthy), overcoming the healthy = not tasty intuition.

Three studies tested these hypotheses. Study 1 randomly assigned participants to consider either a yogurt parfait labeled as made with ingredients from local farms, a yogurt parfait labeled as made with ingredients from distant farms, or a yogurt parfait with no label. Participants were then asked how healthy and tasty they thought the parfaits would be. Participants who rated the parfait with the local label believed it would be significantly healthier than the control parfait ($p = .029$) and directionally healthier than the distant label parfait ($p = .149$), and significantly tastier than the control parfait ($p = .015$) and the distant label parfait as well ($p = .005$).

Study 2 tested whether the local halo can overcome the healthy = not tasty intuition. All participants were presented with cheddar cheese crackers. Based on random assignment, participants were either told that the crackers were low-fat, made with local ingredients, both low-fat and made with local ingredients, or were not provided any additional information. Participants were then asked how healthy and tasty they thought the crackers would be. There was a significant effect of condition on both healthiness ($p < .001$) and tastiness ($p < .001$). Participants rated the local crackers directionally tastier than the control crackers ($p = .135$) and significantly healthier than the control crackers ($p < .001$). In addition, participants rated the crackers that were both low-fat and made with local ingredients as significantly tastier ($p < .001$) and healthier ($p < .001$) than the crackers that were just low-fat.

Study 3 tested the effect of the local label on choice. Participants were randomly assigned to make a choice between either regular cheddar cheese crackers and low-fat cheddar cheese crackers or between regular cheddar cheese crackers and low-fat cheddar cheese crackers made with local ingredients. There was a significant effect of condition on choice ($X^2(1) = 29.31$, $p < .001$), such that participants were significantly more likely to select the regular crackers when the other alternative was low-fat crackers (81.36%) as opposed to when the alternative was low-fat crackers made with local ingredients (47.37%). Accordingly, adding the local label eliminated the preference for regular crackers over low-fat crackers.

In sum, the present research demonstrates a local halo. Local products are perceived as healthier and tastier than their non-local counterparts, and are even able to overcome the healthy = not tasty intuition. Additional studies are currently in progress, testing the impact of the local label on actual taste perceptions and on consumer choices in a field setting.

Judge Me for What I Eat: Consumers Choose Low-Calorie Labeled Food to Signal Competence

EXTENDED ABSTRACT

Consumption decisions reflect not only one's preference but also one's identity to others (Belk 1988). Knowing this signaling power of possessions and brands, consumers strategically make purchase decisions to convey a desirable impression to others (Schlenker et al. 1996). As many of social interactions involve food and eating, it is also important to understand how consumers use food decisions for impression management (Herman, Roth, and Polivy 2003). The current research examines how food labels are used as a means to convey a desired image to others. We suggest that consumers strategically choose low-calorie labeled food when they are motivated to impress others.

Despite popularity of research on food labels, a potential signaling power of food labels has been largely overlooked (see Chandon 2013 for a review). Exceptionally, it has been found that some food labels discourage consumers' choice in public when labels connote undesirable implications to decision maker such that men are less likely to choose femininity-laden food (e.g., ladies cut steak) in public versus private (White and Dahl 2006). As with possessions and brands, consumers may use positive and/or negative associations with food in decisions to signal a desired image to others.

Because low-calorie food is perceived as less tasty but healthy (Raghunathan et al. 2006), choosing low-calorie food would require self-control. Hence, choosing low-calorie food would be associated with chooser's endurance and pursuit of virtue in sacrificing pleasure. Such restraint and self-control is related to capabilities to achieve goals (Barrick and Mount 1991). Therefore, when consumers are motivated to convey their high self-control and competence to others such as in job interview, they will be more likely to choose a low-calorie labeled option (vs. when the same option is not labeled).

Studies 1A and 1B examined whether consumers are more likely to choose low-calorie labeled foods when they are motivated to convey a desirable image to others, but not when the decision is made in private. Study 1A employed a 2 (visibility of choice: not vs. visible to other) x 2 (label to target options: no label vs. low-calorie labeled) between-subjects design. Participants imagined they were consultants and had a meeting with an important client. During the break time, they went out to have a snack and chose from five pastry options. Low-calorie labels were attached to two target options only in the label condition. Half of participants made a choice with the client, while the other half made a choice alone. As we predicted, low-calorie label increased choice of target options in public condition (choice$_{no\_label}$ = 11.7%; choice$_{low-calorie\_labeled}$ = 30.5%; $p = .01$) but not in private condition ($p > .6$). In study 1B, we replicated the findings in a different context (i.e., job interview) with different set of stimuli (i.e., beverage). Low-calorie labels increased choice of target beverages when participants made a choice with the interviewer (choice$_{no\_label}$ = 25.6%; choice$_{low-calorie\_labeled}$ = 44.8%; $p < .05$), but not in private ($p > .3$).

In study 2, participants made an actual chocolate choice that would be consequential. Participants in the public condition made a choice that would be evaluated by other student in the same lab whereas participants in the private condition made a choice that would be kept confidential. Consistent with studies 1A and 1B, choice of labeled options was increased in the public condition (choice$_{no\_label}$ = 35.8%; choice$_{low-calorie\_labeled}$ = 50.9%; $p < .05$), not in private ($p > .7$).

Study 3 examined consumers' belief that choosing low-calorie foods would reflect one's competence. Undergraduate participants saw a beverage choice of other student and evaluated how competent they think the student would be for their group projects. As predicted, participants judged the student as more competent when her choice was (vs. not) labeled with low-calorie ($p = .01$).

Study 4 investigated the boundary condition. Although choosing low-calorie labeled option is helpful to convey competence to others, it may not signal all other positive traits. Impression formation literature has suggested that competence and sociability are two fundamental dimensions for social judgments (Cuddy et al. 2008) but they are not positively related (Judd et al. 2005). Thus, consumers would not necessarily choose a low-calorie labeled option when

they are motivated to signal their sociability. The study employed a 2 (social goal: competent vs. sociable) x 2 (label: control vs. low-calorie) between-subjects design. Participants in the competence condition imagined that as a consultant they went out for a snack with an important client as in Study 1A. Participants in the sociability goal condition imagined that they as a party planner went out with an important client and it was important to be seen as a social person. The low-calorie label increased choice share of the target pastry (choiceno_label = 15.7%; choicelow-calorie_label = 28.9%; $p < .01$) but no difference was found in the sociability goal condition ($p > .9$). The findings suggest that the low-calorie labels are not used to deliver all positive impression, but specifically related to competence personality.

Study 5 was a field study to test how low-calorie labels are used for the impression management. The study was conducted during actual interviews for recruiting research assistants. The job description specified that the research assistants should be conscientious, well-organized, and highly motivated. At the end of each individual interview, an interviewer offered a cookie as a small gift for coming for the interview. Interviewees chose between two different brands of cookies, one of which had a 'low-calorie' label next to the brand name in the half of interviews. Replicating the findings from previous studies, we found that when the cookie was labeled (vs. not labeled) as low-calorie, job candidates were more likely to choose the target cookie (choiceno_label = 29.4%; choicelow-calorie_label = 64.7%; $p < .05$).

In summary, the current research examined how low-calorie labels are used for impression management. Across six studies, we found that consumers strategically choose low-calorie labeled food when they are motivated to impress others. We provide evidence suggesting that this is due to the belief that choosing low-calorie foods reflects one's competence.

No Fries for You! Waiters Externally Impose Self-Control to Restaurant Customers Depending on Their Weight and Gender

EXTENDED ABSTRACT

Overweight people now constitute the majority of the US population (Ogden et al. 2014), still they are stigmatized and suffer from discrimination in their access to health care, in the workplace, but also in shopping environments where they receive mediocre service (e.g., Carr and Friedman 2005; King et al. 2006; Rudolph et al. 2009; Vanhove and Gordon 2014). In addition, weight discrimination tends to be associated with gender discrimination; it is less socially acceptable for women than for men to be overweight (Judge and Cable 2011; Owen and Laurel-Seller 2000; Ricciardelli and McCabe 2001). Weight discrimination often relies on the belief that heavy people lack self-control especially in relation to food (Crandall, Nierman, and Hebl 2009), and this stereotype is also associated with women (Else-Quest et al. 2012).

Our research further investigates the interaction between weight and gender in shaping discrimination, in consumer contexts that are associated with eating self-control – restaurants. Discrimination is defined as any form of specific treatment based on an individual's presumed traits. We examine a novel, subtle form of discrimination: the content of recommendations provided by waiters to restaurant patrons. Because of information asymmetries (e.g., better knowledge of menu items), waiters can influence the decisions of customers by selectively adapting how they present the menu to customers. For instance, waiters may vary the amount of information about dishes or offer explicit recommendations for certain items. Recommending

dishes lower in calories – and lower in taste – to specific patrons can be interpreted as paternalistic "advice" designed to externally impose self-control, i.e., a form of prejudicial treatment (Dana and Cain 2015). We predict that waiters' dish recommendations can vary as a function of patrons' weight and gender, such that waiters recommend healthier options to heavy females, but not to heavy men.

In order to test how customer size and gender influence waiters' recommendations we developed a paradigm, which mimics customer-waiter interactions. Participants are asked to endorse the role of waiters and are shown a restaurant menu featuring three courses (two dishes per course). All dishes are designed and pretested such that one dish per course is healthier but less tasty than the other dish. Participants are given a 'cheat sheet' with additional information about the dishes, not available to patrons, such as ingredients or preparation style. Next, participants are randomly assigned to one of four pictures displaying a hypothetical customer varying in gender (male/female) and size (thin/heavy). We carefully pretested these images to ensure that perceptions of weight status, attractiveness, and healthiness varied only across weight status but not across gender. To test how customer gender and size interact to shape waiters' recommendations we used two different dependent measures in study 1 and 2.

In study 1 (n = 201; MTurk), participants selected the dish information that they wished to present to customers in a drag-and-drop task. Participants could select only 50% of the total available information. Our cover story was that there was limited time to pitch the menu, therefore participants had to select the most relevant information about the dishes. A 2 (gender) x 2 (size) ANOVA on the percentage of tasty-unhealthy pieces information produced only a significant gender x size interaction ($p = .004$). Gender did not significantly impact the dish recommendations when patrons were thin ($M_{thin\ female}$ = 54%, $M_{thin\ male}$ = 50%, n.s.), but had a significant influence when patrons were heavy: waiter-participants were less likely to mention tasty-unhealthy options to heavy female than to heavy male customers (($M_{heavy\ female}$ = 47%, $M_{heavy\ male}$ = 53%, $p = .019$).

Study 2 relied on a more implicit measurement of dish recommendations. Participants in study 2 (n = 230; undergraduate students) were told to endorse the role of waiters at the university restaurant, and were asked to present the menu (the same as in Study 1) to the customer they saw on the screen. Their pitch was recorded on video. They were free to present any information, but had a limited time to do so. Subsequently, two independent coders, who were blind to the conditions, watched and evaluated the videos in order to create an index of the content of waiters' recommendations (-3 = only healthy options recommended, 0 = neutral, 3 = only unhealthy options recommended), which served as a dependent measure. Inter-rater reliability was high (Krippendorff's $\alpha = .81$) and disputes were resolved via a third coder and discussions. A 2 (gender) x 2 (size) ANOVA on the overall recommendation index produced a significant effect of customer gender ($p = .001$) and a marginally significant interaction between gender and size ($p = .078$). Consistent with study 1, gender had no significant impact on dish recommendations when patrons were thin ($M_{thin\ female}$ = -.36, $M_{thin\ male}$ = -.02, n.s.), but had a significant influence when patrons were heavy: waiter-participants were less likely to recommend unhealthy options to heavy female than to heavy male patrons ($M_{heavy\ female}$ = -.58, $M_{heavy\ male}$ = .51, $p < .001$).

Our work uncovers a novel, insidious form of weight-gender discrimination involving paternalistic advice and externally imposed self-control. Two studies show that waiters use weight cues differently depending on whether the customer is male or female. Unlike heavy male customers, heavy female customers are particularly likely to receive paternalistic recommendations prioritizing health concerns over pleasure.

Paper #4: The Need to Feel Better

Charlene Y. Chen, Nanyang Business School, Singapore
Michel T. Pham, Columbia Business School, USA

SESSION OVERVIEW

It is well accepted that affect and emotion are among the principal drivers of consumer behavior. Within the body of work that examines these effects, more insight is needed on the impact of affect. Our symposium addresses this need by bringing authors from three continents together to articulate the gap in knowledge around affect and fill this gap with an enriched understanding of fear, envy and affect regulation.

In the first paper, Puccinelli and colleagues present a comprehensive qualitative and quantitative review of the effects of affect, focusing on when affect leads to affect congruent effects and when affect leads to affect incongruent effects. White and colleagues examine fear and find that fear increases choice and reduces deferral. Next, Huang and Sengupta show that benign envy improves self-control compared to malicious envy, because of heightened self-awareness in the former. Finally, Chen and Pham advance a new need to feel better construct with four distinct dimensions and demonstrate its predictive validity with respect to affect regulation.

Together these papers emphasize the important contribution of affect research to our understanding of consumer behavior. Collectively, they underscore the role of relevance in affective experience (Puccinelli et al.). The importance of fear to a situation leads to immediate as opposed to deferred action (White et al.). The relevance of self-awareness on the effects of envy (Huang and Sengupta). And the role of individual differences in the need to feel better (Chen and Pham).

This session includes qualitative and quantitative review and experimental methodologies to examine the impact of affect. The session also considers the influence of affect from several perspectives: Congruence and incongruence (Puccinelli et al.), choice deferral (White et al.), self-control (Huang and Sengupta) and affect regulation (Chen and Pham). As such it is likely to engage audiences both within and beyond the domain of affect and emotion. Each of the pieces of research included represent completed papers consisting of several studies and extensive analyses. Importantly, the session represents a unique opportunity to consider the effects of affect in concert to draw important generalizations about affective phenomena.

As a group all of these papers examine when affect leads to positive and negative effects, exploring in particular how these effects are shaped by attribution and goals.

Two Roads to Affect Effects

EXTENDED ABSTRACT

Imagine a customer walking into a bank. He finds the branch is playing his favorite song and offering free cookies both of which put him in a good mood. However, when a salesperson approaches offering to help him open an account, he is even more critical of the bank's offerings. His goal to assess the account options accurately and not to be influenced by his good mood makes him more critical of the options. This scenario highlights the complex and consequential nature of consumer affect. Given the ubiquity of affect (i.e., mood and emotion) and its tremendous impact on customer behavior, it is critical to understand when positive affect will be advantageous and when it could be detrimental to a favorable consumer response.

The substantial role that affective feelings play in people's judgments and decisions has been the focus of behavioral and marketing research for the past few decades (Bechara et al. 1997; Epstein 1994; Novak and Hoffman 2009; Pham 1998; Pham et al. 2001; Schwarz and Clore 1996). During that period, it has examined the effects of different feelings states and responses (e.g., positive vs. negative moods, pleasant vs. unpleasant feelings) on a variety of judgment related variables (Edell and Burke 1987; Gardner 1985; Kahn and Isen 1993; Luce 1998; Morales and Fitzsimons 2007; Winterich and Haws 2011), it has examined the conditions that promote a greater influence of feelings on judgement (Greifeneder, Bless, and Pham 2011), such as accessibility, diagnosticity (Feldman and Lynch 1988), representativeness and relevancy (Gorn, Goldberg, and Basu 1993; Kim, Park, and Schwarz 2010; Raghunathan, Pham, and Corfman 2006; Siemer and Reisenzein 1998), and it has examined the influence of feelings under different processing abilities, such as distraction (Albarracin and Kumkale 2003; Albarracin and Wyer 2001), time pressure (Pham et al. 2001; Siemer and Reisenzein 1998), or cognitive load (Shiv and Fedorikhin 1999).

Affect And Consumer Response

Given the ubiquity of affect (i.e., mood and emotion) and its tremendous impact on customer behavior (Averill 1983), it is critical to understand when positive affect will be advantageous and when it could be detrimental to a favorable consumer response. Research on the affect-congruence effect suggests that consumers in a positive affective state should evaluate offerings more positively and those in a negative affective state should evaluate offerings more negatively (Forgas 1995; Pham 2009). Several mechanisms have been identified as underlying this effect. At an unconscious level, it is suggested that a priming effect leads affect to bring more affect-related content to mind (Forgas 1995), for example, feelings have been found to be more influential when people are instructed to pay attention to them, which presumably increases their relative accessibility compared to other inputs (Siemer and Reisenzein 1998; White and McFarland 2009). In this case, the influence of feelings is done relatively auto-

matically and without much deliberation, or filtering. As such, consumers just transfer their affective reactions to whatever object is in front of them, similar to the classic halo effect. At a more conscious level, however, it is the perceived diagnosticity of the feelings that is the basis for judgment. The affect-as-information (AAI) effect suggests that individuals use affect as an informative cue and base their favorability or unfavorability of an option on how it makes them feel at the time of judgment (Pham et al. 2001, Schwarz and Clore 1983). However, if consumers find their feelings to not be representative of the target or irrelevant to the judgment at hand (such as in the case of upbeat music in a bank), they might overcorrect for their reactions that in turn will result in a less favorable attitude toward the product – affect incongruence.

Regardless of this vast amount of research on affective feelings, the direct effect of positive or negative affect on consumer behavior is still unclear. Some research suggests that the valence of the feelings will lead to the same valence of the response, hence, positive affect leads to a favorable consumer response, while negative affect leads to an unfavorable response, an effect also known as the affect congruence effect (Brown, Homer, and Inman 1998; Forgas 1995; Greifeneder et al. 2011; Pham 1998; Schwarz and Clore 1983, 1988). Other research, on the other hand, finds that this effect can disappear or even be reversed, also known as the affect incongruence effect (Cavanaugh, Bettman, and Luce 2015; Erber, Wegner, and Therriault 1996; Goldsmith, Cho, and Dhar 2012; Labroo and Mukhopadhyay 2009; Lasaleta, Sedikides, and Vohs 2014; Puccinelli 2006; Puccinelli, Wilcox, and Grewal 2015; Salerno, Laran, and Janiszewski 2014). Hence, hypothetically, a clothing store can play upbeat or somber music, a bank could give away cookies or not, and an advertiser could feature smiling or serious models, without fully being aware of the impact these affective features might have on consumers' attitude and purchase behavior. In other words, how does affect (Griskevicius et al. 2009; Morales, Wu, and Fitzsimons 2012; Pham 1998; Pham, Lee, and Stephen 2012) influence consumers' evaluation and behavior? When can managers expect positive affect to lead to favorable consumer evaluation and behavior? When might this effect be attenuated?

Present Research

Managers launch ad campaigns and develop retail strategies designed to make consumers feel good, where the hope or lay belief is that feeling good will carry over to the brand, products, and store, and lead consumers to evaluate the brand more favorably, buy more product and remain in the store longer. However, in reality, that is not always the case. Our research identifies situations where managers can utilize positive effects of feel-good strategies and situations where there are pitfalls that can lead such a strategy to backfire. In our research, then, there are two possible types of effect: affect congruence and affect incongruence. This paper will qualitatively and quantitatively review the research on affect to identify the principal factors driving affect congruence versus affect incongruence effects.

In addition to the contribution of this paper to the role of affect theory directly, the impact of affect in practical terms is quite substantial since understanding the role of affect has very real implications for managers. Managers can significantly increase the favorability of consumer evaluations toward their brand and purchase intentions toward their products by using informed elicitation of positive affect. The papers that follow will offer a more nuanced understanding of how the specific emotions of fear (White et al.) and envy (Huang and Sengupta) impact behavior.

Apocalypse Now: The Effect of Fear and Time Orientation on Choice Deferral

EXTENDED ABSTRACT

Although researchers have examined how a range of psychological processes can influence consumer choice among sets of alternatives, less is known about the factors that shape choice deferral. Because the decision to choose or defer underlies every consumer decision, the psychology of choice deferral is integral to understanding consumer behavior. In the current investigation, we consider the role of incidental fear in deferral. In doing so, we focus on the functional relationship between fear, time orientation, and situational vigilance. Following on the previous paper (Puccinelli et al.) the current paper exemplifies the counterintuitive notion that a negative affective state (i.e., fear) increases favorable behavior (i.e., choice).

Past research has highlighted the usefulness of considering the functionality of specific emotions—in particular, how emotions help people navigate recurring sets of threats and opportunities (e.g., Griskevicius, Shiota, and Nowlis 2010). As part of a broader self-protection system (Daly and Wilson 2005), fear may uniquely affect choice deferral. Once activated, this system increases vigilance to the current environment, enhances present-focus, and fosters perceptions that the future is risky (Angie, et al.2011; Davis et al. 2011). When it comes to choice, increasing focus on the present is likely to reduce deferral—a person facing a threat may not be around long enough to choose in the future. Supporting this, people are less likely to defer choice when facing time pressure (Dhar and Nowlis 1999). More generally, because fear enhances vigilance and attention to details of the current situation, people experiencing fear may increasingly value non-threatening aspects of their environment. Thus, fear may lead people to value products that they encounter in their present environment more—regardless of whether they choose them or not.

In five experiments, we examine the impact of fear on choice deferral. In study 1, participants were randomly assigned to read a story designed to elicit fear, disgust, or no emotion. Afterwards, participants made a series of decisions in which they could select among several products in a choice set or "wait to get more information." Participants made eight such decisions among choice sets that represented a variety of products. In line with the functional perspective, participants in the fear condition were significantly less likely to defer choice than participants in the other conditions (ps <.03).

Much previous research has distinguished emotions based upon their underlying appraisal tendencies (Smith and Ellsworth 1985). In study 2 we compared fear to a range of other emotions selected to represent variation along several appraisal dimensions (disgust, sadness, hope, and pride). Participants were exposed to pictures designed to elicit one of these emotions. Then, they completed the same dependent measure from study 1. Participants in the fear condition were less likely to defer choice than participants in any of the other emotion conditions (p = .002); none of the other emotion conditions were significantly different from one another (ps > .3). Together, studies 1 and 2 support our initial contention that fear reduces choice deferral, and that this tendency is unique to fear, exclusive from other emotions with similar appraisal tendencies.

In study 3, we tested whether the relationship between fear and deferral is mediated by an increased focus on the present. Participants were randomly assigned to view a series of pictures that either elicited fear or no emotion. Next, they completed the dependent variable from the previous studies and a measure of time orientation that assessed present- versus future-focus (Strathman et al. 1994). Participants in the fear condition deferred less than those in the con-

trol condition ($p < .05$) and also became more present-focused ($p < .01$). Importantly, the increased present-focus mediated the relationship between the fear manipulation and deferral (95% CI: .0045, .0343).

In addition to reducing deferral, the functional perspective also would predict that people concerned with fear may value products that they encounter in their present environment more, regardless of whether they choose them. In study 4, we tested this prediction. Rather than giving participants the option to "wait to get more information," participants in study 4 could opt to defer choice by selecting "none" of the products. If fear is increasing participants' valuation of products, people primed with fear should elect to choose a product—even when they don't have to make a choice because they perceive options in the present choice set more favorably than any unknown or future options. Participants were randomly assigned to read one of the three stories from study 1 and completed the modified dependent variable. As predicted, participants in the fear condition were less likely to defer choice than participants in the other conditions (ps < .05).

Study 5 used the same independent and dependent variables from study 4. However, after deciding whether to select a product or defer choice, participants also rated how much they liked each product. As in previous studies, participants in the fear condition were less likely to defer (ps < .05). Moreover, relative to the other conditions and consistent with the proposed underlying process, participants in the fear condition also rated all of the products that they were presented with more favorably (ps < .03)—even those that they did not choose.

Taken together, these findings highlight the role of incidental fear in choice deferral. Specifically, we documented that: (1) fear increases choice and reduces deferral, (2) the link between fear and choice is mediated by (a) negative perceptions of unknown products and (b) positive evaluations of known products, and (4) other discrete emotions do not similarly affect the tendency to defer choice. This work stands in contrast to past research (Luce 1998), which suggested that general negativity could increase deferral. In so doing, we highlight the unique aspects of fear that prompt action in the current situation, compared to a more general view of negative emotions. These results show how a fleeting situational factor, such as briefly activating the emotion of fear, can help marketers increase the likelihood that consumers make a choice and thereby "close the sale."

The next paper (Huang and Sengupta) will build on this investigation by examining how different types of envy shape self-control.

The Different Effects of Benign versus Malicious Envy on Self-Control

EXTENDED ABSTRACT

Although it is an emotion that is both ubiquitous to consumer settings and a prime motivator of purchase behavior (van de Ven, Zeelenberg, and Pieters 2011; Crusius and Mussweiler 2012), envy – the negative feeling induced by wanting something that another person has (Smith and Kim 2007) – has been surprisingly understudied in our field. Of late, however, consumer scholars have sought to understand this emotion, with one focus being on the distinction between benign envy (which occurs when the envied possession/achievement is deemed to be deserved, e.g., a job promotion based on hard work) and malicious envy (which occurs when the envied possession/achievement is deemed to be undeserved, e.g., a job promotion based on being the boss's relative; van de Ven, Zeelenberg, and Pieters 2009; Chan and Sengupta 2013). Expanding on the pre-vious paper (White et al.) the current paper explores how the underlying attribution process for envy shapes its effects on self-control.

This paper extends current understanding on the distinction between benign and malicious envy by examining their impact on consumer decision-making. We propose that benign envy, as compared to malicious envy, heightens people's self-awareness and therefore benefits subsequent self-control. Benign envy is characterized by greater causal attribution to the self and a motivation to improve oneself, both of which induce a focus on the self and its role in creating and changing the current situation – hallmarks of self-awareness (Duval and Wicklund 1972). In contrast, malicious envy is characterized by a motivation to undermine the envied target, which focuses attention outward on the target and the unfair situation. Further, past work finds that heightened self-awareness promotes a correspondence between people's behaviors and normative standards (Gibbons 1990; Wicklund and Duval 1972). Assuming that self-control represents a normative ideal for most people, we argue that benign envy (vs. malicious envy) enhances self-control. We tested this and related hypotheses in a series of studies.

Experiment 1a tested our basic premise by having student participants read a neutral scenario, or one that either elicited benign or malicious envy by describing a fellow student in a course as having received an A+ either deservedly or undeservedly. Self-control was then measured by observing their preference between chocolate cake and fruit salad; a preference for the latter indicates greater self-control (Shiv and Fedorikhin 1999). As predicted, envy type influenced self-control ($F(2, 99) = 3.20$, $p = .045$), such that participants in the benign envy condition reported greater relative preference for the salad (vs. cake; $M = 5.52$) than those in the malicious envy ($M = 4.18$; $t(99) = 2.07$, $p = .041$) and control conditions ($M = 4.03$; $t(99) = 2.13$, $p = .023$); higher numbers indicate salad preference.

Experiment 1b used a similar procedure but also included a standard measure of self-awareness (Govern and Marsch 2001). Benign envy produced both greater self-awareness ($M = 4.76$) and greater preference for the salad ($M = 6.57$) than malicious envy (Self-awareness: $M = 4.25$; $F(1, 59) = 4.22$, $p = .044$; Preference: $M = 5.13$; $F(1,59) = 4.26$, $p = .044$). Importantly, the effect of envy type on self-control was mediated by self-awareness (95% CI: .03 -1.08). Although overall mood was more positive for benign (vs. malicious) envy, controlling for mood did not affect self-control results in any of our studies.

Experiment 2 further examined the role of self-awareness in driving the effect of envy on self-control. We manipulated both envy type (via a job promotion scenario similar to the opening vignette) and self-awareness (via a priming task). If the self-control improvement for benign (vs. malicious) envy is based on improved self-awareness, priming the latter should increase self-control for those experiencing malicious envy, but not for benignly envious people, who are already experiencing high self-awareness. Envy type and self-awareness indeed exerted an interactive effect on self-control ($F(1, 118) = 4.57$, $p = .035$). Further, preference for salad under malicious envy was greater when self-awareness was primed ($M_{prime} = 5.31$, $M_{no-prime} = 3.88$; $t(118) = 1.95$, $p = .05$). No such effect was obtained in the benign envy condition ($M_{prime} = 4.63$, $M_{no-prime} = 5.45$; $t(118) = 1.08$, $p = .28$). That priming actually seemed to (non-significantly) decrease self-control in this condition might be a manifestation of a contrast effect (Herr, Sherman and Fazio 1983).

Not only does the self-awareness distinction between benign and malicious envy enable a prediction of immediate choice, it also contains implications for sequential decisions (e.g., Mukhopadhyay, Sengupta and Ramanathan 2008). Our final study first presented benignly vs. maliciously envious participants with a scenario

in which they and a friend jointly ordered either an indulgent dessert or a healthy one. We then presented them with the cake-salad choice. We predicted that benignly envious participants would exhibit choice consistency (greater likelihood of choosing salad in the second choice when the first scenario indicated a preference for the healthy dessert than the indulgent one). The rationale was that benign envy increases private self-awareness; it should therefore increase the likelihood that participants attribute the first choice to themselves (vs. the friend; Duval and Wicklund 1972). Further, self-aware participants are likely to infer their own preferences from the choice they just made (Bem 1972); consequently, the next choice is likely to be consistent with the earlier one (Mukhopadhyay et al. 2008). No particular prediction about choice consistency was made for malicious envy. As predicted, the thought of having chosen a healthy (vs. indulgent) dessert earlier led to greater relative preference for salad (vs. cake; $M = 4.45$ vs. $M = 3.13$; $t(142) = 1.94$, $p = .054$) in the benign envy case. In the malicious envy condition, relative preference was not influenced by prior choice ($M_{healthy} = 3.46$, $M_{indulgent} = 4.11$; $t(142) = .89$, $p = .37$; 2-way interaction $F(1, 142) = 3.91$, $p = .050$).

Collectively, these results, and others from parallel studies in our lab not described here, contribute to both the envy literature (highlighting hitherto-unexamined effects of feeling benignly versus maliciously envious) and also the self-awareness literature by identifying a new antecedent of increased self-awareness, benign envy. More broadly, this research provides insights into consumer decision-making by showing how envy – a widely-prevalent consumer emotion – can influence decisions in seemingly-unrelated contexts.

The paper that follows moves on from the previous ones in the session by considering individual differences in the goals elicited by an affective state.

The Need to Feel Better

EXTENDED ABSTRACT

In modern societies, consumption in one form or another is often regarded as a major affect-regulatory device (Luomala and Laaksonen, 1999). In advertising campaigns, products and services are often marketed as ways to make consumers "feel better" if they are in a bad mood (e.g., flowers, spas, movies, alcohol, etc.). This phenomenon is widely based on the popular lay-belief that negative mood is unpleasant, and therefore people necessarily strive to repair their negative mood. The previous papers illustrate how a negative affective state does not always lead to affect regulation. Moreover, one can think of instances where people dwell on their negative mood and do nothing to improve it (Andrade and Cohen 2007). For instance, people may seek out melancholic music when they feel sad, or choose to remain miserable when something frustrates them. Our research proposes that people vary considerably in the degree to which they need to feel better when they experience negative feelings. Specifically, it advances current understanding of why certain individuals choose to remain in their negative mood, or even bring on unpleasant emotions, rather than to improve their mood. To this end, we have developed a construct called the "Need to Feel Better" (NFB) which encompasses four distinct facets: 1) behavioral tendency to repair bad moods, 2) aversion to negative feelings, 3) pleasure derived from negative feelings, and 4) tendency to reflect on negative feelings.

Differentiating individuals on their NFB allows us to predict when people are likely to engage in mood repair. Hence, we have developed a scale that includes 16 items which tap into the four different facets of NFB. The scale possesses good internal consistency

($\alpha = .85$), test-retest reliability at two weeks ($r = .68$), and construct validity. Our data shows that females tend to have higher NFB than males ($M_{female} = 4.52$ vs. $M_{male} = 4.29$; $t(518) = 4.17$, $p < .001$), and that NFB is positively associated with age ($r = .09$, $p < .05$). NFB is also correlated with the Big Five personality traits (John, Donahue, & Kentle, 1991): it is positively correlated with extraversion ($r = .21$, $p < .01$), agreeableness ($r = .31$, $p < .001$), and conscientiousness ($r = .22$, $p < .01$) but negatively correlated with neuroticism ($r = -.17$, $p < .05$). Furthermore, NFB is associated with more frequent engagement in common mood repair activities such as leisure shopping ($r = .24$, $p < .005$) and exercise ($r = .19$, $p < .05$). Finally, people with NFB report greater life satisfaction ($r = .19$, $p < .05$) and happiness ($r = .26$, $p < .005$).

We conducted three experiments to test the predictive validity of the NFB construct. The first two experiments tested whether high-NFB individuals would be more likely than low-NFB individuals to regulate their affect by choosing positive stimuli when they experience negative (vs. neutral) affect. Both experiments comprised two-parts that were separated by a week. In part 1, participants filled out the NFB scale. In part 2, participants in the negative-affect condition watched a sad video whereas those in the neutral-affect condition watched a documentary on computers. After watching the video, participants answered some questions about the video and their mood. Following that, they were told that they would be evaluating different media items (e.g., recorded music, newspaper articles) and that due to time constraints they could choose which items to review. In Experiment 1, student participants made a choice between two neutral pieces of music (a distractor question), followed by a choice between a happy ("Laughs and Swings") and a sad ("A Rainy Day") song (key dependent variable; Cohen and Andrade 2004). High-NFB participants were more likely to choose the happy song when they experienced negative (vs. neutral) affect ($\beta = -.69$, Wald = 4.95, $p = .026$); this difference was non-significant among low-NFB participants ($\beta = .21$, Wald = .65, $p = .419$). In Experiment 2, Mechanical Turk participants were presented with six different pair-wise choices of news article headlines: three were distractor choices, and the other three included a positive and a negative option. The key dependent variable was the number of positive options participants chose among these three choices. High-NFB participants chose more positive options to repair their negative affect ($\beta = -.35$, $t(156) = -3.28$, $p = .001$); this difference was non-significant among low-NFB participants ($\beta = .02$, $t(156) = .14$, $p = .885$).

To provide further evidence for the predictive validity of our construct, we investigated whether high-NFB (vs. low-NFB) individuals would display more favorable attitudes towards products with mood-lifting benefits independent of their existing affect. We measured Mechanical Turk participants' NFB scores in part 1. After a week, in part 2, we showed them an advertisement for a vitamin C health supplement that either highlighted its mood-lifting benefits or not. After viewing the ad, participants were asked to indicate their interest in buying the product. Results showed that high-NFB participants indicated greater interest when the mood-lifting appeal was present versus absent ($\beta = .55$, $t(146) = 2.86$, $p = .005$), but the same difference was non-significant among low-NFB participants ($\beta = .11$, $t(146) = .55$, $p = .582$). These results suggest that NFB predicts how attracted people are towards mood-lifting appeals in marketing.

Our research proposes a new construct called the "Need to Feel Better," and provides evidence of individual differences on this motivational construct. It challenges the assumption that people have a universal tendency to want to feel better, and that people necessarily engage in affect-regulation when they feel bad. It enhances our understanding of why certain individuals choose not to regulate their

negative affect and also allows us to decipher when people would behave in a mood-congruent versus mood-incongruent way (Cohen and Andrade 2004). Our research has implications for the marketing of "feel-good" products (e.g., aromatherapy and vacation packages) and the use of mood repair appeals (e.g., *Volkswagen*'s "Get Happy" campaign). Marketing strategies that incorporate such appeals should be targeted at consumer segments that tend to have higher NFB. Finally, our research also has implications for consumer satisfaction with product consumption, and more broadly, consumer welfare. Finally this paper offers a conclusion to the session as it moves beyond the impact of affect to the ways in which goals may or may not shape the influence of affect on behavior.

SESSION OVERVIEW

Research has demonstrated the fundamental role haptics play in shaping consumer outcomes (Holbrook 1983, Peck and Childers 2003). For example, studies have documented the influence of "mere touch" on product evaluations (Peck and Shu 2009) and the effect of haptic sensations on taste perceptions (Krishna and Morrin 2008). As a consequence, tactile considerations are becoming increasingly important in product design (Vanhemert 2015). However, haptic sensations vary in their characteristics and can be delivered through various different mediums. This suggests that the consequences of haptic engagement are by no means obvious in nature, and there are many complex mechanisms through which touch might exert its effects on consumer responses.

Our session advances research on haptics and consumer behavior by providing a nuanced understanding of how, when and why haptic cues might impact consumer responses. Across four papers, we document surprising responses to haptic cues in a wide range of behavioral contexts: in-store shopping, online browsing, and interpersonal communications. The papers examine various features of tactile cues, including texture (e.g. soft vs. rough), shape (e.g. round vs angular) and vibrotactile feedback (delivered electronically); and demonstrate that these haptic sensations can influence appraisals of the touched stimulus itself (in papers 1 and 4), but also impact incidental judgements (in papers 2 and 3). Accordingly, while each paper individually documents the importance of touch in a different consumer context, collectively the session demonstrates that the antecedents, behavioral outcomes and situational applications of haptic engagement can vary greatly.

In the first paper, Ruan, Peck, Tanner and Wang demonstrate that because rough (vs. smooth) objects are easier to grip, haptic roughness increases feelings of control, and accordingly leads to greater psychological ownership and prolonged interactions. In the second paper, Hadi and Valenzuela find that vibrotactile sensations (delivered through mobile phones and wearables) can represent technologically-mediated social touch, and ultimately influence both performance and certain incidental judgments (e.g. sender attributions). Streicher and Estes explore how haptic exposure to an object can facilitate visual processing and choice of other seen products. Finally, Chung, Chakravarti, and Zwick examine how online product research via different interfaces (e.g. desktops vs. tablets) can subsequently influence haptic judgements offline. All of these papers are in advanced stages of completion, with multiple studies run.

Importantly, these papers highlight that there are many different processes through which haptic cues might impact consumer responses. We accordingly draw upon various theoretical frameworks to explain the behavioral outcomes: psychological ownership (Ruan, et al.), mediated social touch (Hadi and Valenzuela), crossmodal fluency (Streicher and Estes), and contrast-priming (Chung et al.). By focusing on the underlying processes, we address calls to more critically examine the mechanisms through which sensory cues exert their effects (Krishna 2012). The progressive approaches and novel results are sure to induce a lively discussion, and are likely to appeal not only to haptic/sensory researchers but to a broader audience interested in product design, multi-channel retail, and consumer-technology interaction.

Grip not to Slip: How Haptic Roughness Leads to Psychological Ownership

EXTENDED ABSTRACT

In a series of studies, we found that haptic roughness leads to a greater perception of psychological ownership, and longer interactions, compared to smoothness. We conjecture that this is because rougher objects are easier to grip leading to more control, an antecedent of psychological ownership.

As one of the most important sensations, touch is prevalent in consumers' interactions with products. We touch a mouse when using computers; we touch its cover and screen when using a cell phone; we touch money or credit cards when consuming. It has also been well established by previous research that haptic sensation plays an important role in consumers' decisions and evaluations of products (e.g., Holbrook 1983; Peck and Childers 2003). However, in the domain of marketing and consumer behavior, most prior research on touch focuses on the individual aspect (e.g., Citrin et al. 2003; Martin 2012; Webb and Peck 2015), the comparison between the presence and absence of touch (e.g., Grohmann, Spangenberg and Sprott 2007; Peck and Shu 2009) and the valence of touch (e.g., Peck and Wiggins 2006). Limited research has explored the effect of different tactile attributes of products and the influence they may have on consumers.

In this research, we investigate the effect of haptic roughness on psychological ownership. We hypothesize that haptic roughness, compared to smoothness, would increase people's physical control over the product being touched, which would, in turn, lead to greater psychological ownership (Furby 1980; Pierce, Kostova and Dirks 2003). We next report three studies in which we find empirical evidence supporting our hypothesis.

In Study 1, we selected two sports bottles as stimuli, one of which has a textured surface and the other of which has a smooth surface, with all other attributes being the same. Participants were

randomly given one of the two sports bottles and were told that they had three minutes to evaluate the bottle, after which they filled out a questionnaire asking their evaluations of the bottle including the measure of psychological ownership. Three items measuring psychological ownership—"I feel like this is my bottle," "I feel a very high degree of personal ownership of the bottle," and "I feel like I own this bottle"— each on a 7-point scale ranging from 1 (strongly disagree) to 7 (strongly agree) (α = .83), were embedded in the questionnaire. We also included the valence of touch, the weight of the bottle, the appearance of the bottle, and how easy it was to hold. The results supported our main hypothesis that participants had greater psychological ownership towards the sports bottle with a textured surface than the one with a smooth surface (Ms = 3.44 vs. 2.57; $F(1, 50)$ = 6.61, p < .05), with no significant differences on all other attributes of the bottle (all ps > .10). We expected a difference in terms of the easiness to hold each bottle, as it was an indicator of physical control. Yet the results only showed the expected pattern, but with the difference being non-significant (Ms = 4.04 vs. 3.71, $F(1,50)$ = .50, p > .10). We suspect it was because the single item did not reflect all aspects of physical control and thus was not a good measure.

Study 2 sought to replicate and extend the findings of Study 1 using a behavioral measure. Specifically, we asked participants to view and evaluate commercial posters on the computer. They were required to view at least six ads. After six ads, they could continue to view more ads or stop at any time as they wished, as we told them in the instructions: "If you are enjoying the task, continue to view ads. If you are not enjoying the task, feel free to stop at any time after the first six ads." Participants were randomly assigned to one of the two conditions, which differed only in the computer mouse used. In one condition, we used a normal mouse with its surface being relatively smooth, whereas in the other condition, we used the same mouse but made its surface rough. Consistent with our hypothesis, compared to the smooth mouse, participants using the rough mouse viewed and evaluated more posters (Ms = 21.77 vs. 15.29; $F(1, 146)$ = 5.27, p < .05), and felt that they had more control over the mouse (Ms = 5.87 vs. 5.29; $F(1, 146)$ = 6.17, p < .05). However, we failed to find that control mediated the effect of roughness on the number of posters viewed.

Both Study 1 and Study 2 involved real touch. According to Peck, Barger and Webb (2013), however, even haptic imagery would increase perceived ownership. Therefore, we wanted to explore, in Study 3, whether the effect of haptic roughness would still hold when touch is imagined. In specific, participants were presented with a poster of a mug and were then asked to imagine they were holding and playing with the mug with their hands for approximately 30 seconds. At the end of study, participants indicated their perceived ownership toward the mug (α = .88). The only manipulation was the verbal description on the poster: we described the mug as textured in the textured condition and smooth in the smooth condition. Consistent with our hypothesis, the results revealed a significant positive effect of haptic roughness on perceived ownership (Ms = 4.21 vs. 3.17; $F(1, 42)$ = 5.82, p < .05).

In Study 1, participants felt more ownership of the textured bottle compared to the smoother bottle. We expected this to be due to the increased physical control, an antecedent of ownership. However, this did not reach statistical significance. Study 2 revealed that using a rough mouse (compared to a smooth one) affords more control and participants viewed more ads when using the rough mouse. However, control did not mediate the relationship between texture and ownership as expected. In the final study haptic roughness increased ownership feelings, even when participants were not actually touching, but imagining touch. From our research, we conclude that a tex-

tured surface, compared to a smoother surface, encourages longer interaction and more ownership. However, while control may be increased with a textured surface, this may not be the only mechanism through which texture leads to more ownership. Further research is required to delve more deeply into the process by which this occurs.

Good Vibrations: Consumer Responses to Technologically-Mediated Social Touch

EXTENDED ABSTRACT

Device notifications are often administered with vibrotactile sensations (e.g. on mobile phones, wearables), yet little research has examined the psychological and behavioral implications of this haptic feedback. We explore how vibrotactile alerts can represent technologically-mediated social touch, and ultimately influence both performance and certain incidental judgments (e.g. sender attributions).

While gadget designers have traditionally focused on visual and auditory functions of user interfaces, increasing attention has turned to haptic considerations in technological product design (Vanhemert 2015). Vibration is by far the most widely used haptic feedback mechanism in small devices (e.g. mobile phones and wearables), because the technology is compact and relatively low in power usage (Bark et al. 2008). Yet despite the widespread use of vibrotactile feedback, surprisingly little research has examined consumers' psychological and behavioral responses to it. Some work has documented the attentional and efficiency-based benefits of vibrotactile feedback (e.g. vibrotactile warnings improve reaction times of fighter pilots, Sklar and Sarter 1999). However, in everyday consumer product applications, vibrotactile stimulation is often accompanied by a message, call notification, reminder, or other communications content. We suggest that in addition to performing the utilitarian function of alerting consumers, these vibrotactile sensations may also carry conceptual importance. Specifically, we propose that telecommunication content accompanied by a haptic alert might be perceived differently than the same content accompanied by alerts in alternative modalities (e.g. auditory). This hypothesized distinction is supported by research that suggests our sense of touch operates differently than other modalities, in that it represents our "most proximal" sense (Montagu and Matson 1979). That is, in contrast to visual, auditory, and olfactory cues, which might be perceived while a stimulus is at a distance, haptic cues typically require the stimulus to contact one's body (Jones and Lederman 2006, Peck 2010). This characteristic is especially important in a telecommunications context, where interpersonal correspondence transpires over a distance. We argue that because haptic sensations are so uniquely associated with immediate proximity and contact, telecommunications accompanied by haptic sensations should help make the exchange feel more personal and human-like.

Scholars in computer science indeed suggest that vibrotactile feedback technology can allow consumers the ability to "touch" each other in the distance, and have deemed this a form "mediated social touch," in that it allows users to convey and receive haptic information through technology (Haans and Ijsselsteijn 2006). This conceptualization implies that in certain instances, vibrotactile feedback may essentially function as a surrogate for interpersonal touch. Interpersonal touch itself has been shown to evoke a sense of closeness and human connection, and effectively influence people's social behavior (e.g. increasing compliance with requests, improving attitudes towards services, and strengthening bonds between people; see Gallace and Spence 2010 for a review), regardless of whether or not the tactile contact itself is remembered explicitly. In the cur-

rent research, we argue that just as interpersonal touch can improve consumer responses, so can technologically-mediated social touch.

We hypothesize that vibrating alerts will lead consumers to perceive communications as more personal, and this technologically-mediated social touch should ultimately improve individuals' evaluation of the interaction and their performance on related tasks. Three laboratory studies provide support for our hypothesizing. In study 1, participants (N=60) received mobile phones set to either beep or vibrate upon receiving text messages. Participants received a series of text messages intended to provide encouragement (e.g. "You're doing great! Keep it up,") while attempting a physical challenge (balancing on one leg for 5 minutes). Binary logistic regression confirmed a significant main effect of message alert on performance (χ^2=4.29, p<.04), in that participants in the vibrotactile alert condition were more likely to successfully remain on one leg for the duration of the challenge than those in the auditory alert condition.

In study 2 (N=86), we explored the impact of vibrotactile alerts in a different product category (smartwatches) and a different task (a "steps challenge," where participants marched to get as many steps as possible in five minutes). Participants again received a series of encouraging text messages. Messages were accompanied by one of three alerts: auditory vs. vibrotactile vs. auditory+vibrotactile. Adding the third condition allowed us to test whether Study 1 effects were driven by the inclusion of vibrotactile sensation or by the absence of auditory cues. Pedometers on participants' smartwatches recorded the number of steps achieved, and ANOVA results confirmed a significant main effect of message alert on the steps achieved by participants (p <.02). Planned contrasts demonstrated that while there was no difference in performance between the vibrotactile vs. auditory+vibrotactile conditions, subjects in both these conditions outperformed those in the auditory condition, suggesting that improved performance was driven by the inclusion of a vibrotactile cue.

Study 3 (N=56) was similar to study 2, but in addition to measuring performance, we collected several potential process measures: sender attribution ("Who do you think was sending the text messages?" rated on by whether attribution was to an automated system/machine or a human source), message evaluation (e.g. "The text messages were nice,"), and self-reported arousal. Further, we measured overall technological competence as a potential moderator, since previous research suggests low competence should exaggerate the value of haptic feedback. ANOVA results confirmed a significant positive effect of vibrotactile alerts on the number of steps participants performed (p<.02). While there was a marginal effect of vibrotactile alerts on arousal (p<.07), this did not mediate the effect on performance, and the impact of vibrotactile alerts on performance was still significant when controlling for arousal (p<.04). We used a sequential mediated moderation model to examine the mechanism through which a message alert x technological competence interaction might influence task performance. The sequential mediation analysis (Hayes 2013, model 6) supported our hypothesized path: Message Alert x Technological Competence interaction → Sender Attribution → Evaluation of Messages → Task Performance (95% CI excluding zero). This suggests that especially for those low in technological competence, the positive effect of the vibrotactile alert on task performance was due to increased human attribution and evaluation of the communication respectively.

In sum, our studies support that vibrating alerts lead consumers to perceive communications as more human-like. This technologically-mediated social touch improves individuals' evaluation of the interaction, contingent on their level technological competence, and, subsequently, their performance on related tasks. These findings have important implications for consumer compliance in multiple domains such as health or physical performance training.

Multisensory Integration of Touch and Vision During Product Evaluation and Choice

EXTENDED ABSTRACT

Touching a product affects evaluation of that product. Here we demonstrate for the first time that grasping one product increases choice of another haptically similar product, and that this effect is mediated by visual fluency and moderated by the visual density of the product display.

Touching a product affects perception and evaluation of that product (Grohmann et al., 2007; Krishna, 2006; Peck & Childers, 2003; Streicher & Estes, 2015). Shape perceptions from touch activate a corresponding shape representation in the visual cortex (Masson et al., 2015; Snow et al., 2014), and hence haptic exposure to a familiar object facilitates visual recognition of that object (Reales & Ballasteros, 1999; Pesquita et al., 2013). Can haptic exposure to an object facilitate visual processing and choice of *other* seen products of the same shape and size? This would be important because consumers often visually evaluate products while grasping some other object (e.g., another product, a cell phone, etc.).

Grasping a Red Bull slim can should increase the *visual fluency* of other slim cans, because the haptic exposure activates a visual shape representation, which then visually primes recognition of objects with that shape. And given that fluency improves product evaluations (e.g., Janiszewski & Meyvis, 2001; Lee & Labroo, 2004), we predicted that grasping a product increases choice of another product that is haptically similar but spatially distant ($\mathbf{H_1}$), and that this effect is mediated by visual fluency ($\mathbf{H_2}$).

As visual perception becomes less reliable (e.g., blurred), haptic perception assumes a greater role in object recognition (Ernst & Banks, 2002; Pesquita et al., 2013). One marketing factor that may influence the reliability of visual information is the density of the product display: Relative to sparse displays, crowded displays reduce the visual focus on any given product. We therefore predicted that the effect of haptic exposure on product choice is larger among crowded product arrays than among sparse arrays ($\mathbf{H_3}$).

Study 1 tested $\mathbf{H_1}$ and $\mathbf{H_2}$. Participants (N = 140 students) extended their right arm directly out to the right while viewing a computer display straight ahead. Some participants had a 0.5-litre plastic bottle or 0.33-litre aluminum can of Fanta placed into their hand (*visuo-haptic* group), whereas others viewed the display without grasping anything (*visual-only* group). Simultaneously with placement of the product in the hand (or not), original-size images of a Fanta bottle and can appeared on the computer display straight ahead. Because the right arm was extended laterally while the gaze was directed ahead, participants were unable to see the haptic stimulus. The haptic stimulus was always the container appearing on the right position of the display. Participants rated the visual fluency of both products (adapted from Labroo et al., 2008), and chose one of them to have as reward for participating.

A product (left, right) × group (visual-only, visuo-haptic) ANOVA on visual fluency ratings indicated an interaction, $F(1, 138) = 4.57$, $p < .05$: Whereas the left product was equally fluent across groups, $p > .3$, the right product was more visually fluent in the visuo-haptic group than in the visual-only group, $t(138) = 2.33$, $p < .05$. The right product was also chosen significantly more often among the visuo-haptic group (60.0%) than among the visual-only group (42.9%), $\chi^2 (1) = 4.12$, $p < .05$, thus supporting $\mathbf{H_1}$. Visual

fluency ratings mediated that effect of haptic exposure on product choice (95% *CI* of indirect effect = .0848–2.622), supporting **H₂**.

Study 2 tested **H₃**. Participants (*N* = 205) stood with their eyes closed and extended their right arm backward. An experimenter placed one of three chocolates (i.e., 50-gram bar, a 60-gram square, or an egg) in the participant's hand, and participants then viewed a product arrangement on a table. The *sparse display* group saw one chocolate bar and one chocolate square on the table, whereas the *crowded display* group saw 18 replicates of each. In the *haptic match* condition, participants grasped either the chocolate bar or the chocolate square, whichever was presented on the right of the display. In the *haptic mismatch* condition, participants grasped the chocolate egg. An experimenter then removed the haptic stimulus and product arrangement, and participants chose one of the previously seen products as reward for participating.

A logistic regression with haptic exposure (mismatch = 0, match = 1), visual density (sparse = 0, crowded = 1), and their interaction as predictors, and with product choice (left = 0, right = 1) as the criterion, revealed a main effect of haptic match, *Wald* χ^2 = 4.15, *p* < .05. Participants were more likely to choose the product on the right of the display while grasping something of the same shape than while grasping something of a different shape. The interaction was also significant, χ^2 = 5.73, *p* < .05, revealing a stronger haptic effect with crowded displays (χ^2 = 9.99, *p* < .01) than with sparse displays (χ^2 = 3.52, *p* = .06). In sum, grasping one product increased choice of another haptically similar product, especially with crowded visual displays, thus supporting **H₃**.

Discussion. Prior studies had shown that grasping a product can affect consumer behaviors toward that grasped product (e.g., Grohmann et al., 2007; Peck & Childers, 2003; Streicher & Estes, 2015), and neuroscientists speculated that haptic exposure to one object may facilitate visual processing of another object (Gephstein et al., 2005). The present research provides the first evidence that grasping one product can affect the visual processing and choice of another product that is haptically similar but spatially distant. Moreover, our experiments controlled both conceptual fluency (because the product choices were always of the same brand and product) and motor fluency (because the haptic matches and mismatches entailed the same body posture and motor action) while targeting a specific perceptual modality (i.e., vision), thus isolating the processing mechanism to visual fluency. Another novel contribution is to demonstrate the compensatory relationship between vision and touch in product evaluation. When visual information is somehow degraded (e.g., by decreasing clarity), then haptic information assumes a greater role in object recognition (Ernst & Banks, 2002; Pesquita et al., 2013). Consequently, we showed for the first time that the effect of touch on product choice is accentuated by crowded product displays, which may overload the visual system and hence increase reliance on haptic information.

It Feels Softer Than It Looked: Contrast-Priming Effects of Touch-Screen Users in Multi-Channel Shopping

EXTENDED ABSTRACT

In multi-channel retailing, very little research has examined the impacts of webrooming (researching product options online) on subsequent offline retail experiences. In this study, we examined (1) whether webroomers evaluate physical products differently from single-channel shoppers and (2) whether computer device types moderate webroomers' product evaluations.

Before purchasing a product, consumers often compare product options in multiple retail channels by switching between online stores and brick and mortar stores. One of these multi-channel phenomena is called *webrooming*, which involves extensive online product comparisons followed by visits to a brick and mortar store (Stilson, 2014). In 2014, about 88% of consumers said that they webroomed, in that they regularly researched products online before purchasing from a physical store (Interactions, 2014). In this paper, we examined whether webrooming influenced consumers' final product evaluations and how the evaluations differed by computer device type.

Research has found that repeated exposure to a trait activates the meaning of the trait, and the meaning further primes or activates closely associated trait categories (Higgins, Rholes, & Jones, 1977). This assimilation/contrast effects are visible in retail environments. Consumers tend to make judgments that either assimilate or contrast to the primed trait of a salesperson (Stafford, Leigh, & Martin, 1995). When primed to a positive brand, consumers evaluate other brands negatively (Levin, 2002). When primed to price, consumers choose a more affordable product considering price over quality (Mandel & Johnson, 2002). It is likely that webroomers encounter similar priming experiences because they browse multiple products with similar properties. For example, when they view multiple blankets, they are repeatedly exposed to the softness of blankets. However, very little research has examined the impacts of extensive online browsing on subsequent offline retail experiences even though webrooming has been one of the common shopping trends for the last few years. In this study, we examined (1) whether multi-channel shoppers (webroomers) evaluate physical products differently from single-channel shoppers and (2) whether computer device types moderate the impacts of webrooming on product evaluations.

Experiment 1

We used a 2 (objects: soft vs. firm) x 2 (devices: touch interface vs. mouse) between-subjects design. Participants were randomly assigned to four different conditions, which differed by the type of object and device. Eighty university students participated in the experiment.

We conducted the experiment in a behavioral research lab. The touch-interface conditions used a tablet PC, and the mouse conditions used a desktop computer with a mouse, a keyboard, and a desktop monitor. In each device condition, twenty browsed soft objects only while the other 20 interacted only with firm object. After viewing similar *firm* products online, participants evaluated a physical target object as being *softer* than those who had been primed to softness. After viewing *soft* products, they evaluated the same target as being *firmer* than those exposed to firmness. However, this effect was statistically significant among mouse users only (*p* < .001), and the device type did not differ from each other (*p* > .05).

Experiment 2

To compare product evaluations between multi-channel and single channel shoppers, we added a single channel condition to the previous design, using 2 (objects: soft vs. firm) x 3 (channels: touch interface vs. mouse vs. no device) between-subjects design. The no-device condition (single channel) did not have online sessions prior to examining a set of physical products while the two other conditions (multi-channel) browsed either soft or firm products online using either a touch interface or a mouse. We conducted this experiment in the same lab where we conducted the first experiment, and 213 university students participated.

We found a significant interaction effect between channels and products on product texture evaluations (*F*(2, 207) = 33.66, *p* < .001). Both multi-channel conditions (touch interface and mouse)

evaluated the same products they saw online as being firmer than the single channel condition, indicating significant contrasting effects. In the soft-object conditions, touch-interface users (vs. mouse) evaluated the same products as being firmer ($p < .03$), but the device effect was not significant in the firm conditions ($p = .12$). Attitudes toward the same physical products were more positive in the single-channel conditions than in the multi-channel conditions ($F(2, 207) = 10.63$, $p < .001$), and this difference was significant in the soft-object conditions only.

Overall, the findings of this study contribute to marketing research and practitioners in several ways. First, our study is one of the first studies on webrooming behavior and fills the gap in the multi-channel retail literature. Second, this study provides strong evidence that webrooming behavior affects consumers' product evaluations at brick and mortar stores. Third, this evidence suggests that practitioners should better capture an integrated analysis of their customers' activities in both online and offline channels in order to reduce the gap between webroomers and single-channel shoppers. Lastly, the findings highlight the role of computer input devices in multi-channel shopping experiences and suggest that consumers are more likely to find the texture of physical products different from what they see online if they use a touch interface (vs. mouse).

Paper #4: Peripheral Endorsement: How Perceptual Congruence with Celebrities Can Benefit Brands

Dan Rice, Louisiana State University, USA
Andrew Kuo, Louisiana State University, USA
Rebecca Rast, Louisiana State University, USA

SESSION OVERVIEW

Celebrities are featured in 20% of all advertisements (Solomon 2009). This form of influence significantly affects brands featuring celebrities (Feldman 2007). Interestingly, close to half of the ads aired during the 2016 Super Bowl featured celebrities, presumably because research finds that celebrities have a direct influence on brand stock (Agarwal and Kamakura 1995). However, as the forms of media that consumers use evolve, so might the ways in which consumers perceive and interact with celebrities. For example, with the propagation of social media, seeing celebrities living their "real lives" is increasingly common. In addition, the proliferation of celebrity endorsements has led to increased attention to the fact that celebrities are being paid by companies and may not truly believe in the brand. These changes to the marketing environment may, in turn, have implications for the effectiveness of traditional celebrity endorsement. Given the billions of dollars spent on celebrity endorsements, the continued examination of celebrity influence and endorsement effectiveness is of keen interest to marketers.

Unlike previous endorsement research, we explore novel pathways of celebrity influence and examine how new media and placement types impact celebrity endorsement. In the first paper, Samper, Wu, Mathras and Morales consider how brands can take advantage of the increased visibility of celebrities' real lives by examining the effect of "celebrity product placement" relative to more traditional forms of celebrity endorsement. The results reveal that celebrity product placement is more effective than celebrity endorsement in improving brand attitudes and purchase likelihood. This effect is driven by increased celebrity trustworthiness and perceptions that the celebrity sincerely likes the brand.

In the second paper, Dunn, Hoegg and Borah examine how certain forms of social media alter the nature of consumer-celebrity interactions, impacting the effectiveness of celebrity endorsement. This paper finds that social media platforms which feature conversational design (e.g., Twitter) imply direct celebrity-consumer communication and enhance consumers' perceptions of their similarity to and connection with the celebrity. This connection has positive outcomes

for celebrity endorsement, including decreasing reliance on product-celebrity match and increasing positive response to negative publicity.

The third paper examines another novel form of celebrity endorsement practice wherein ads featuring celebrities are placed within media content featuring the same celebrity. Dimofte finds that while this strategy has a positive effect on attention and recall, attitudes require a celebrity-product match and must appear during current media content. This effect is driven by the consumer's motivation to process the celebrity.

Finally, the fourth paper discusses how the proliferation of celebrity endorsements raises consumers' persuasion knowledge. Rice and Kuo explore a unique avenue through which celebrity endorsements can persuade consumers through the peripheral route - perceptual congruence (e.g., perceptual overlap with brand features).

Overall this session questions several issues with regards to the effectiveness of traditional celebrity endorsement practice in today's marketplace and demonstrates how newer forms of media have the potential to change the nature of celebrity influence. Overall we expect this session to be of interest to researchers studying celebrity endorsement, product placement, and digital marketing.

Consumers with Stars in their Eyes: The Influence of Celebrity Product Placement on Brand Perceptions and Behaviors

EXTENDED ABSTRACT

The promotion of a product or brand through candid use by celebrities, also known as "celebrity product placement," is becoming an increasingly popular strategy to garner mass media exposure (Ashbrook 2011). For example, the success of popular brands such as UGG has been attributed to candid photos of celebrities wearing the sheepskin boots in their daily lives (Jones 2007). These photos are highly desired by consumers and entertainment news magazines alike, and if a brand is pictured being used by a celebrity, it can serve as a valuable marketing tool. Accordingly, "celebrity gifting," or the practice of sending celebrities free products in hopes that they will be photographed using them, has grown in recent years (Blackall 2010). While researchers have documented the effects of traditional product placement in television and film (e.g., Russell 2002, Wiles and Danielova 2009), attention to celebrity product placement (CPP) in the academic literature is scant at best. In the present research, we examine the effectiveness and underlying driver of this underexplored marketing strategy compared to typical celebrity advertisements in improving brand attitudes and purchase likelihood.

Unlike celebrity endorsements, ads or traditional product placement, consumers are much less savvy to the influence of CPP. Indeed, a pretest of 124 MTurk participants confirmed that 65% felt that the products depicted in paparazzi photos were ones celebrities purchased themselves (vs. were given to them for free). This lack of awareness allows CPP to capitalize on the positive associations imbued by the celebrity to the focal product (McCracken 1989) while operating outside the realm of persuasion knowledge. Because of the ostensibly candid nature of CPP, we propose that it increases beliefs that the celebrity sincerely likes the brand being used. This notion is consistent with the correspondence bias, which states that when people observe a behavior, such as a celebrity using a product in a paparazzi photo, they are inclined to believe that the behavior

corresponds with the individual's genuine disposition (Gilbert and Malone 1995); that is, the depicted celebrity's true interest in the product. Because consumers imbue the products that celebrities use and like with positive meaning (McCracken 1986), CPP use should increase brand favorability and purchase intentions.

Study 1 provides initial evidence that CPP is more effective at increasing brand attitudes than a celebrity advertisement. Participants (N=190) were randomly assigned to one of two conditions: celebrity advertisement versus CPP. All participants saw the same image of Ryan Gosling with a brief description of how he drinks Bucks County Coffee (the focal brand). However, the ad condition displayed the "Bucks County Coffee" logo while the CPP condition displayed the word, "Stargazing" (implying a candid photo). Participants viewed the images, completed filler measures, and indicated how positively they viewed Bucks coffee. They also completed measures of Gosling's perceived interest in Bucks. Results revealed that participants rated Bucks (but not other coffee brands) more favorably in the CPP (M=4.06) versus ad condition (M=3.72; p<.03). Further, participants believed Gosling was more sincerely interested in Bucks in the CPP (M=4.92) versus ad condition (M=3.83; p<.0001). A serial bootstrapping mediation analysis supported our predicted pathway whereby CPP vs. Ad → Celebrity Interest in the Brand → Brand Ratings (B=.20; 95% CI=.03, .40).

In Study 2, we replicate these findings with celebrity Jessica Alba and the 'nau' clothing brand. As in Study 1, CPP vs. endorsement increased brand ratings, which were driven by increases perceptions that Alba sincerely liked the brand. The same mediation pathway was significant.

In Study 3, we investigate a boundary conditions. Specifically, we manipulate trustworthiness to mitigate this effect. We reasoned that if participants did not trust the celebrity, then the celebrity's sincerity of interest would no longer be predictive of brand interest. Participants (N=150) were randomly assigned to a 2 (image type: CPP vs. ad) x 2 (trustworthiness: low vs. high) between-subjects design. Participants first read a short magazine article. In the low trustworthiness conditions, this article stated that Alba's own 'Honest' natural goods line (an unrelated brand) involved questionable business practices. In the high trustworthiness condition, the article described the noble goals behind Alba's 'Honest' brand. In an ostensibly unrelated study, participants were presented with a CPP or ad image of Jessica Alba wearing 'nau' clothing. After completing filler questions, participants rated how positively they viewed the 'nau' brand along with 9 other filler brands. A 2 x 2 ANOVA revealed a significant image type x trustworthiness interaction for nau (p=.01) but not for the other brands. Whereas in the high trustworthiness condition, CPP (M=4.83) increased evaluations of nau relative to the ad (M=4.22; p=.01), in the low trustworthiness condition, there was no such difference (p>.75), revealing that suppressing perceived trustworthiness can attenuate the benefits of CPP.

In Study 4, we further explore our underlying process by manipulating our mediator, the perceived sincerity of the celebrity's interest in the brand, with a new celebrity and product. Participants (N=246) were randomly assigned to a 2 (image type: ad vs. CPP) x 2 (sincerity of interest manipulation: article vs. control) between-subjects study. To manipulate sincerity of interest, half of the participants read a magazine article describing how celebrity paparazzi shots, though seemingly candid, are typically staged. The other half did not read an article. Next, all participants viewed either an ad or CPP image with Jennifer Lawrence wearing MiH jeans, a new luxury brand. Participants rated their likelihood of making a purchase from MiH along with 9 other filler brands. A 2 x 2 ANOVA on purchase likelihood revealed a significant image type x sincerity of interest interaction for MiH jeans (F(1, 242) = 4.36, p <. 04) but for not the

other brands. Whereas participants in the control condition indicated greater intentions to purchase from MiH in the CPP (M=2.70) versus ad condition (M=1.86; p=.001), no such difference emerged for those who were led to believe celebrity interest was insincere (p>.60).

In sum, four studies reveal that celebrity product placement is indeed more effective than traditional advertisements and mediated by perceived celebrity interest in the brand.

Social Media and Celebrity Endorsement: How Social Connections can Impact Endorsement Effectiveness

EXTENDED ABSTRACT

Celebrity endorsement has been employed as a marketing strategy for over 150 years and makes up 20-25% of all advertisements (Feldman 2007; Shimp 2000). Advertisements containing celebrity endorsers are rated more favorably and garner higher purchase intention than non-celebrities endorsers (Atkin and Block 1983). The shift in marketing communications through social media for both firms and celebrities warrants renewed investigation into how celebrity endorsement impacts consumer decision making. In regards to celebrity endorsement, social media has effectively changed the way in which consumers relate to celebrities. Traditionally, celebrities were at arm's length from the public – elegant and glamorous, but mysterious and unknown. Gone are the strictly scripted interactions with consumers. Social media such as Twitter allows celebrities to communicate directly with their fans. This research examines how this shift in communication has implications for the effectiveness of celebrity endorsements.

Endorsement research has generally found that celebrity endorsement is an effective promotions strategy, as celebrities make advertisements more believable and enhance message recall (Agrawal and Kamakura 1995). Several criteria have been identified as contributing to the effectiveness of a celebrity endorsement, including the attractiveness and likeability of the celebrity, the extent to which consumers believe the celebrity genuinely likes the product, the perceived fit between the celebrity and the product (Atkin and Block 1983; Kahle and Homer 1985; Kamins 1990; Kamins and Gupta 1994). This paper argues that another important factor to be considered is the perceived similarity between the celebrity and the consumer. We propose a two-step process whereby consumers who feel connected to the celebrity will feel more similar and subsequently find the ad more effective.

This research demonstrates that microblogging social media sites like Twitter enhance perceived dialogue (a form of interaction) between consumers and celebrities and thus, may enhance the social connectedness that consumers feel. Social connection can be created through direct or indirect interaction with another and can increase liking for the individuals within a group and enhance perceived similarity among group members (Forsyth 1999). Thus, we predict this social connectedness should lead to perceived similarity to the celebrity. Perceived similarity can increase liking and susceptibility to persuasive consumer appeals (Jiang, Hoegg, Dahl and Chattopadhyay 2010). Thus, this perceived similarity should lead to more effective celebrity endorsements. Specifically, we hypothesize that this perceived similarity reduces the "product fit" problem of celebrity endorsement, whereby there must be a fit between the celebrity and endorsed product in order for consumers to believe the veracity of the endorsement. In addition, we show that perceived similarity buffers both a celebrity and endorsed brand against negative publicity.

In Study 1a, we show that following a celebrity on a microblogging site causes consumers to feel more similar to the celebrity than following them on a standard social network. We manipulated whether participants read a scenario about an article about a celebrity's social

media usage. The participants read that the celebrity's favorite social media platform was either Twitter (microblogging) or Facebook (social networking) and that they either followed the celebrity or did not. Results showed that participants that followed the celebrity on Twitter felt more connected and more similar to the celebrity than either those that followed the celebrity on Facebook or did not follow the celebrity on Twitter. In addition, we found that social connectedness mediated the relationship between social media usage and similarity.

In Study 1b, we use a 2(Social Media: Twitter v. Facebook) x 2(Person: Celebrity v. Publicist) between-subjects design and show that this increase in social connection and similarity through Twitter usage only occurs when the celebrity (not a publicist) runs the social media account. In addition, results show that within each media type, those participants who show higher degrees of connectedness feel more perceived similarity to the celebrity. Together, studies 1a and 1b demonstrate that microblogging sites appear to bolster perceptions of similarity through perceived social connectedness.

In Study 2, we extend this social media impact on perceived similarity paradigm by showing a positive impact on celebrity endorsement. To test this, we created actual celebrity endorsement ads for celebrities that were either known to use Twitter (Neil Patrick Harris and Kim Kardashian) or not use Twitter (Paul Rudd and Megan Fox). These ads either featured an endorsement for a product that matched the celebrity (high product fit) or did not match the celebrity (low product fit). Results found that for non-Twitter celebrities, there was a traditional positive effect of product fit on brand attitudes. However, when the ads featured Twitter celebrities, there was no difference in brand attitude for high or low product fit advertisements. As in studies 1a and 1b, the Twitter celebrities were seen as more similar to the participants than the non-Twitter celebrities. Finally, we found that participants rated the low fit product as a significantly better fit for Twitter celebrities than non-Twitter celebrities. Study 2 shows that not only does social media engagement lead to higher perceptions of similarity, but that these perceptions can reduce the necessity of product fit in subsequent celebrity endorsements.

In Study 4, we show that not only does increased perceived similarity enhance endorsed-product evaluation regardless of fit, but they also buffer brand evaluations against negative celebrity information.

The primary goal of this research was to demonstrate how the unique aspects of microblogging sites versus social networking sites can influence the effectiveness of celebrity endorsement. Little research thus far has looked into the impact of social media sites on traditional marketing efforts. Our research provides one of the first empirical investigations of how different forms of social media maintain distinct communication purposes for consumers. We show that nuanced differences in the sites impact the perceptions of connectedness that consumers have toward celebrities, which subsequently alters feelings of similarity between consumers and celebrities. These feelings enhance the persuasiveness of celebrity endorsements. The current research contributes to this body of work by revealing how celebrities can be perceived as more similar to consumers—through feelings of social connection—effectively resulting in an additive influence of attractiveness and similarity on endorsement.

When Celebrity Ad Placements Backfire

EXTENDED ABSTRACT

Firms often employ "attention-getting devices" (Broniarczyk and Gershoff 2003) such as a practice referred to as "context-sensitive advertising." In a particular instantiation of this technique, ads are being created to feature celebrities that are also being featured in the surrounding media context (e.g., TV show, magazine article, website content, etc.).

The intuition behind using celebrities in advertising was captured by early consumer research. McCracken (1989) argued that in this case a meaning transfer process occurs from the celebrity onto the promoted product, while subsequent work by Kamins (1990) suggested that a certain degree of congruity between celebrity and the product is necessary for this transfer to be successful. Presumably placing such ads within editorial content that features the same celebrities (e.g., sitcom actors, football players) would only bolster these effects through enhanced fluency, although consumer research has not addressed the issue directly. Furthermore, prior research has shown that the impact of the mere announcement of a brand celebrity endorsement on stock returns is positive, suggesting that the use of celebrities in advertising is viewed as a worthwhile investment by the financial markets (Agrawal and Kamakura 1995).

This work assesses this positive perception of celebrity advertising and cautions that the indiscriminate use of celebrities in ads can in fact have deleterious effects on brand equity. In particular, it looks at celebrity ads that are placed within media content that features the same celebrities (e.g., a Papa John's pizza ad featuring quarterback Payton Manning during a Denver Broncos football game in which Manning plays). The research also attempts to explain the mechanism that underlies the presumed positive effects of such ads, as two potential explanations appear credible: consumers may pay more attention to ads featuring the same celebrity as the preceding media content due to either the enhanced fluency they experience (i.e., an ability-to-allocate-attentional-resources account) or the superior motivation they have (i.e., a willingness-to-allocate-attentional-resources account). Finally, this work looks at the temporal fit between the celebrity's dual roles (i.e., ad plus live football game vs. old sitcom episode rerun) to argue that a temporal mismatch can produce negative consumer brand attitudes.

In Study 1, participants (373 students from a business school's marketing subject pool) were exposed to a recent magazine article about Hollywood that referenced the actress Eva Longoria, which was then followed by three print ads, including (in the second position) the focal one for the Starbucks coffee brand. In the treatment condition, the ad featured Eva Longoria enjoying a cup of coffee. The control condition involved a similar ad featuring actress Penelope Cruz (the two celebrities were equally familiar to our sample and the ads were judged comparably across a variety of dimensions; both actresses were seen as a good fit for the brand). Contrasts on the main attitudinal measure found that that ad wherein the celebrity was the same as in the contextual material was evaluated significantly more favorably than the celebrity ad lacking this match (on a 7-point scale, $M_{no.match} = 4.14$, $M_{match} = 4.49$, $t(371) = 2.63$, $p < .01$).

To assess mediational effects, the related SPSS macros provided by Preacher and Hayes (2004) were employed. All of the criteria for mediation were established (including a significant Sobel test: $z = 3.48$, $p < .001$), providing evidence that motivation to process completely mediates the effect of celebrity fit on attitudes. A nonparametric bootstrap estimate of the indirect effect was estimated to lie between 0.0253 and 0.1879 with 99% confidence, suggesting that the indirect effect was significantly different from zero. Importantly, similar analyses for the ease of processing variable found no evidence of mediation.

A holdout sample from the same population was exposed to a version of the study wherein the treatment condition involved the actress Sofia Vergara (pretests found that she was seen as a relatively less appropriate brand spokesperson). This lack of fit produced the expected drop in consumer attitudes: $M_{no.match} = 4.05$ vs. $M_{match} = 3.53$; $t(371)$

= 3.23, p < .001. As predicted, the context-ad match created by the use of the same celebrity creates more consumer motivation, but this leads to more careful scrutiny of the ad and the fit that this celebrity has with the promoted brand. When this fit is lower, attitudes suffer.

In Study 2, participants (244 students from a business school's marketing subject pool) were exposed to an excerpt from a car-themed old episode of the *Seinfeld* sitcom series (from 1996) or one from a recent episode of Jerry Seinfeld's *Comedians in Cars Getting Coffee* web series that was then followed by three video ads, including (in the second position) the focal one for the Acura car brand (in particular its new NSX model). In the treatment condition, the ad featured Jerry Seinfeld demonstrating his desire for the car in various humorous situations. The control condition involved a similarly humorous ad that featured British celebrity chef Gordon Ramsey (pretests suggested that both celebrities were equally familiar to our sample and that they were a good fit for the car brand; the ads were judged comparably across a variety of dimensions). As expected, the new car model was judged most poorly when promoted by Jerry Seinfeld after an old episode of the *Seinfeld* sitcom (on a 7-point scale, M = 2.84), moderately when promoted by Gordon Ramsey (M = 4.04), and most favorably when promoted by Jerry Seinfeld after a current episode of his *Comedians in Cars Getting Coffee* web series (M = 5.28).

Overall results suggest that using celebrities in advertising should be pursued while accounting for (1) the extent to which media content employs the same celebrity, (2) the perceived celebrity-product fit, and (3) the extent to which the media content is current. Studies in progress expand on the latter aspect by assessing the role that consumers' temporal construal plays in the process and the extent to which the temporal mismatch may occasionally be beneficial (e.g., for a modern car an old *Seinfeld* prime may be detrimental, but the same prime may be advantageous for a wine brand).

Peripheral Endorsement: How Perceptual Congruence with Celebrities Can Benefit Brands

EXTENDED ABSTRACT

Celebrity endorsements have been shown to benefit brands in multiple ways, including improved brand attitude (Kahle & Homer, 1985; Kirmani & Shiv 1999), transferred meaning (McCracken 1989; Langmeyer & Walker 1991), strengthened self-brand connection (Dwivedi et al. 2014), improved brand recall (Kamins et al. 1989; Ohanian 1991; Kelting & Rice 2013) and raised stock prices (Elberse & Verleun 2012). A recent study found that 14-19% of advertising in the U.S. utilized celebrity endorsements (Creswell 2008); as the percentage is even higher in other countries (e.g., Japan at 43%) and increasing worldwide (Pringle 2015), scholars and practitioners alike realize the importance of understanding how consumers are influenced by these endorsements.

The Elaboration Likelihood Model (Petty & Cacioppo, 1986) is a theoretical framework commonly applied to explain consumer response to celebrity endorsement. This model proposes that a persuasive appeal (such as advertisements) may influence consumers through two potential routes of persuasion, the central or high involvement route, and the peripheral or low involvement route. Consumers will often scrutinize the "source congruence" between a celebrity and a brand as a critical argument of the endorsement to be evaluated, influencing the brand measures through the central route (e.g., Kamins et al., 1989; McCracken 1989; Kirmani & Shiv, 1998; Rice et al., 2012). Conversely, consumers may also rely on simple peripheral cues when making brand evaluations through a low involvement route (e.g., Kahle & Homer 1985; Kirmani & Shiv 1998; Kang & Herr 2006; Rice et al. 2012).

As the use of celebrity endorsements becomes more prevalent in advertising, the level of consumer persuasion knowledge (Friestad & Wright 1994) of the tactic increases. This increased knowledge could lead to mitigation of the benefits of the practice as consumers adjust for this knowledge in their responses. This mitigation may be particularly in the central route to persuasion where consumers evaluate the degree of congruence as the strength of a persuasive argument and think extensively about the connection (Petty & Cacioppo, 1986; Kirmani & Shiv, 1998), which could make the persuasive appeal more obvious. The risk of losing the benefit is even greater in light of recent findings that negative associations with the celebrity are often more likely than positive associations to transfer to brands (Campbell and Warren 2012). Thus, as consumers scrutinize the endorsements, those with weak congruence or negative associations may lead to less favorable brand evaluations.

Notably, prior research has typically described source congruence as a conceptual construct, based on factors such as the overlap between a celebrity meaning and the brand (McCracken 1989) or the expertise of the endorser in relation to the product category (Ohanian 1990). Conversely, the current research investigates whether celebrities with no conceptual overlap with a brand may still be of benefit to the brand through an overlap of perceptual factors (e.g., phonetic similarity between the celebrity and the endorsed brand), even in the absence of conventional endorsements. We define this term as perceptual congruence, and we explore the mere association effect (Dimofte & Yalch, 2011) and the fit-as-fluency effect (Kuo & Rice, 2015) as competing pathways through which perceptual congruence may influence brand assessments.

Experiment 1 (N = 197) tests whether a brand could benefit from perceptual congruence with a celebrity. We created four conditions to which participants were randomly assigned by manipulating the presence or absence of an article on a celebrity's charity work prior to ad exposure as one factor and the perceptual congruence of the brand as a second factor (by changing a sporting good's brand name from one that was phonetically similar to the celebrity featured in the article to one that was dissimilar). Brand attitude toward the sporting good (which was identical except for the brand in all conditions) was the critical dependent variable. ANOVA revealed a significant article presence x brand name interaction ($F(1,193)$ = 3.94, p < .05). Planned contrasts demonstrate that there was no difference in brand evaluations due to presence or absence of the celebrity article when the brand was phonetically dissimilar (p > .7). However, when the article featuring the celebrity was present, the perceptually congruent brand was rated significantly more favorably by respondents than when the article was not shown ($F(1,193)$ = 5.58, p = .019, M = 5.63 vs. M = 5.04). Further analyses revealed mediation effects of perceptual congruence.

Experiment 2 (N = 141) offers additional evidence of the effects of perceptual congruence by introducing a new category, motor oil. The experiment also explores two mechanisms through which perceptual congruence could act on brand attitude, a fit-as-fluency (Kuo and Rice, 2015) type effect due to previous exposure to a phonetically similar celebrity name, or a mere association (Lee & Labroo, 2004; Dimofte & Yalch 2011) effect caused by positive associations transferring from the perceptually related (but conceptually incongruent) celebrity by adding negative and neutral article valence conditions to the design and removing the no article conditions of experiment 1. ANOVA results revealed a significant valence x brand interaction ($F(2, 135)$ = 3.32, p = .04). Replicating the results of the first study, there was no significant effect of valence within the brand with no perceptual congruence (p > .6), but the perceptually related brand attitude was significantly more favorable for the positive ce-

lebrity article valence (M = 6.15) than either the neutral (M = 5.45) or negative (M = 5.56) article conditions (p's < .03)

If brand attitude was solely influenced by the perceptual fluency of the brand name, the data would show a main effect of brand such that the perceptually congruent brand was always favored across valences. However, the results are more consistent with a mere association mechanism, where the data show an interaction in which the positive article about the celebrity led to (1) significantly more favorable brand attitude than the negative and neutral articles for the perceptually congruent brand of motor oil, and (2) no difference among article conditions for the brand of motor oil with no perceptual congruence.

SESSION OVERVIEW

This session highlights the complex ways gender stereotypes are both perpetuated and challenged in today's marketplace across a variety of contexts, and through the use of varying methodologies. Conflicting stereotypes and treatments of men and women are persistent in society and play out in billion dollar industries, from fashion to beauty products to video games. Women are on the one hand shown distain and contempt, and on the other defended and coddled (Glick and Fiske 1996). Both sexes are expected to adhere to gender norms, which are reflected and reinforced in marketing (Mazur 1986; Zayer and Coleman 2015; Zayer and Otnes 2012). The current research investigates i) the treatment of men and women by industry and society and its relevance to the marketplace, and ii) how gender stereotypes are maintained and combated in these intersecting domains. This session explores these issues across a wide range of intersecting domains (industry, consumer protection/regulation, online communities, and male-dominated subcultures) with methodological diversity (qualitative methods, experiments, and archival data analysis).

The first paper identifies a novel way in which gender stereotypes play out in the marketplace and its implications for firms and consumer protection. Across tens of thousands of consumer complaints with various agencies, consumers were more likely to complain about a harmful product failure when the victim was a woman as opposed to a man. Experimental evidence further supports this finding. Evidence for the role of gender stereotypes in this process is also presented (i.e., men are seen as independent agents while women are cherished and protected).

The second paper presented looks at how women are stereotyped and treated in the historically male-dominated domain of video gaming, where women are sexualized and seen as imposters. Drawing from social dominance theory (which explains the origin and maintenance of social hierarchies and oppression), female gamers were interviewed to understand the harassment experienced by women in gaming (both on and offline). Women's experiences of disempowerment and vulnerability caused by interactions with the gaming industry and culture decrease their expectations for cultural change.

The third paper offers a more positive outlook on the possibility for change by drawing from institutional theory to explore the macro forces that contribute to the resistance of gender stereotypes in advertising institutions. This research analyzes in-depth interviews with advertising professionals from the United States, United Kingdom, and Turkey, in order to shed light on the regulatory, normative, cultural and political forces that facilitate or hinder individuals within these organizations in resisting gender-stereotypical content in advertising.

Finally, the fourth paper utilizes social media as a tool for examining how consumers are reacting to changes of beauty stereotypes in the media. Brands have begun to feature plus-size models in the media more frequently. This research uses an iterative approach to identify themes in Facebook comments that represent consumer sentiment and attitudes about shifting stereotypes about beauty in the media. Overall, although there is approval for diversifying the definition of beauty, a strong discourse of promoting obesity and unhealthy behavior is also present.

Identifying and Explaining the Sex-Gap in Consumer Responses to Product Failures: Gender Stereotypes Create Victims out of Women

EXTENDED ABSTRACT

Every year, thousands of consumer complaints are made to regulatory agencies, including the Consumer Product Safety Commission, Federal Trade Commission, among others. These incidents often cause severe injury or death, and cost the U.S. more than $1 trillion annually (CPSC). They are the basis for numerous lawsuits and recalls, and can cost companies millions of dollars. Therefore, consumers' perceptions of harm, blame, and desire for punishment, are of great consequence for many institutions.

The current research asks if the sex of the victim matters is how such incidents are interpreted and reported. We draw from ambivalent sexism theory (Glick and Fiske 1996) to understand how gender stereotypes shape consumers' perceptions of product failure incidents. Specifically, because gender stereotypes present men as independent agents and women as dependent and requiring protecting, we proposed that when a woman (vs. a man) is a victim of a product failure, consumers will i) see increased harm done, ii) blame the company more, and iii) show an increased tendency to complain about the product failure.

Benevolent sexism is a specific form of sexism that presents women as, fragile, pure, and requiring protection (Glick and Fiske 1996). This paternalistic view of women has the consequence of denying women agency and efficacy; those seen as more capable of suffering are increasingly seen as passive and as victims of negative outcomes (Gray and Wegner 2009). Conversely, men are stereotyped as tough, independent agents, and these traits are associated with a diminished capacity for suffering and pain (Gray and Wegner 2009; 2011). Thus, gender stereotypes have the consequence of presenting women (vs. men) as more capable of being victims. We should there-

fore observe that consumers will be more likely to complain about a product failure when the victim is a woman vs. a man.

Study 1 analyzed over 13,000 consumer complaints to the Consumer Product Safety Commission (CPSC) and found that a disproportionate number of complaints were made for female vs. male victims, despite the fact that a) male injuries were on average more severe, and b) hospital records show that men are more frequently the victims of product-related injuries (National Electronic Injury Surveillance System 2014). Moreover, female victims most outnumbered male victims when a husband was complaining about a harm done to his wife vs. a wife complaining about a harm done to her husband. These results are consistent with stereotypes of men as being tough, independent agents, and women as fragile and requiring protection. To help support this claim, a state-level measure of gender stereotyping (associating men with careers and women with housework) was obtained from a large dataset (Xu, Lofaro, Nosek, and Greenwald 2016; n = 926,310).Using hierarchical linear modeling, it was found that state-level endorsement of traditional gender stereotypes predicted the victim sex-gap in consumer complaints at the state-level, controlling for the ratio of men and women in each state.

For Study 2, a similar analysis was conducted on 833,112 vehicle complaints made to the National Highway and Traffic Safety Administration's Office of Defects. Victim sex could not be assessed directly, but we searched each complaint for the words "wife" and "husband," which largely corresponded to husbands referring to incidents involving their wife, and vice versa (respectively). As in Study 1, there was a significant victim sex-gap in consumer complaints, despite the fact that men get in more accidents and drive 1.5 times more miles per year than women (Insurance Institute for Highway Safety 2015).

Having illustrated a real-world tendency to increasingly report product failures when the victim is a woman (vs. man), we conducted a series of experiments to further capture and illuminate this effect. In Study 3, participants (100 men, 105 women, M_{age} = 37.76) were presented with a scenario adapted from a complaint filed with the CPSC, where a parent complained that their child's finger was able to get stuck in the viewing hole of a kaleidoscope toy and required medical assistance. We manipulated the sex of the victim in a between-subjects design. Participants then rated the blameworthiness of the child, parent, and manufacturer. As predicted, participants saw the female victim as less at fault than the male victim, and saw the manufacturer and the parents as more at fault when the victim was female (vs. male).

Past work has shown that benevolent sexism, and paternalistic stereotypes more broadly, depict groups such as women as high on warmth (kind, sociable, sincere), but low on competence (e.g., efficacy, confidence) (Glick and Fiske 1996; Fiske, Cuddy, Glick and Xu 2002). Targets perceived in this way are easier to think of as victims (Gray and Wegner 2009; 2011), and elicit sympathy, pity, and the desire to help and protect (Cuddy, Fiske, and Glick 2007; Grey and Wegner 2011; Fiske et al. 2002). Study 4 (n = 342, M_{age} = 39.03) tests the role of these perceptions in judgments of male vs. female victims and company blameworthiness. Participants read a scenario where a man vs. woman was the victim of a reading lamp exploding, causing cuts and lacerations. Participants rated the seriousness of the incident, their emotional response (sympathy, pity, desire to help and protect), and manufacturer blame (seeing the manufacturer as at fault, wanting reimbursement for the victim, and wanting to complain to a regulatory agency or file a lawsuit).

Results found that participants saw the situation as more serious, and blamed the manufacturer more, when the victim was a female (vs. male). Moreover, the effect on manufacturer blame was mediated by perceived harm and the participants' emotional response to the victim (i.e., sympathy, pity, desire to help and protect). In other words, gender stereotypes make it easier to see women (vs. men) as victims, and explained the observed effect of victim sex on manufacturer blame.

Across 4 studies, we provide evidence of a sex-gap in how people attribute blame to companies for product failures, and that gender stereotypes (i.e., men as independent agents and women as requiring protection) can help explain this sex-gap. Implications for consumers, companies, and consumer regulation are discussed.

Female Gamers: An Investigation of Gendered Consumer Vulnerability

EXTENDED ABSTRACT

In 2014, an Internet culture war ensued called #Gamergate, in which an alliance of anti-feminist video gamers began criticizing and threatening feminist gaming advocates who argued for greater positive representation of women in the video gaming industry (Parkin 2014; Schroeder and Borgerson 2015). Despite the recent surge in public harassment and sexism against women in the gaming community, females represent a growing demographic in the $15.4 billion video gaming industry. However, both men and women believe playing video games to be a "particularly masculine pursuit" (Selwyn 2007, p. 533). In a consumption context largely categorized as a "man's world", our research aims to understand how female video gamers experience, navigate, and cope with the male-dominated culture.

We ground our analysis in social dominance theory, which explains the origin and consequence of social hierarchies and oppression and assumes that we must understand the processes that maintain and produce discrimination at multiple levels of analysis, including cultural ideologies, institutional practices, and relations of individuals (Pratto, Sidanuis and Levin 2006). Our investigation takes a similar approach to understand how multiple processes, at different levels, work together to create a potentially vulnerable consumption environment (Baker, Gentry, and Rittenburg 2005). Our research employs a phenomenological approach that focuses on the lived experience (Pollio 1982) of thirteen female gamers between the ages of 20-29, who were interviewed to better understand how female gamers experience and make meaning from their interactions within a gendered consumption context.

Our findings suggest the gaming subculture is characterized by a prevalence of gender-based consumer harassment, systematic disempowerment in the marketplace, and a defeatist attitude toward future cultural change. Due to space limitations, we use one participant's experiences to exemplify our collective findings.

Prevalence of Gender-based Consumer Harassment

"Gamer girl" stereotypes contribute to an environment wherein female gamers are harassed and disrespected through verbal abuse in online chat communication and being hounded within games themselves.

> It's kind of like we are not taken seriously. We have to be separated from "real gamers." Like the game is not for us; they just forget about us as gamers. But, there are not other options really, you just have to do or not play. And sometime people can be just mean. You get called all sorts of really derogatory things, whether you are winning or

losing. You are losing because you are a girl or winning because you are a whore. (Corrine)

Corrine, a video game store manager and gamer, agrees with other participants that "gamer girls" are stereotypically sexualized and perceived as imposters in the gaming community.

Disempowerment in the Marketplace

Female gamers' negative gendered experiences extend to the offline, retail environment, as participants discussed discrimination in purchasing video games. Female gamers develop coping strategies to merely shop for games—not just play them. Corrine states that while she is working, customers often seek out advice from men and she advises female colleagues to "develop tough skin." She also experiences gender-based disempowerment as a female shopper.

> For us, going into a [video game store], everyone just assumes that you are there buying a game for a significant other. Going in as a shopper, a lot of time you are approached differently because you can't be there buying a game for yourself…right? … I don't think that they are realizing they are doing it, I don't think it's a purpose able thing but it's just an ingrained thing. It's a male thing. (Corrine)

Corrine's warnings reflect a disempowerment discourse similar to Henry's (2005) work, identifying experiences of disempowerment as a function of self-perceptions emerging from systematic inequities (e.g., social class, access to material and economic resources). Our research highlights gender disparities in the gaming community, as women often adopt the role of "impotent reactors" who must constantly confront the potential for subjugation and "prove" themselves in the gaming community.

A Defeatist Attitude toward Cultural Change

Participants discussed potential solutions to improve the female gaming experience; however, participants were doubtful the industry or gaming community would change. Corrine discussed her pessimism.

> Their hands are tied, they really are…because they don't want to lose the male gamers or the female gamers. They have systems where you can report a player, and yes if they get reported so many times they get removed from the game and their computer code is band from playing the game. But with a quick reset of the computer, you can get back on…their hands are tied. (Corrine)

Corrine and others remain doubtful that the actors and marketplace institutions, with the power to bring about change, are actually motivated to do so.

Collectively, our findings suggest consumers experience multi-dimensional vulnerability (e.g., individual, marketplace, and cultural) in a gendered consumption environment. At the individual level, our findings depart from existing consumer research by highlighting how consumers can experience discrimination and harassment in multiple dimensions during a consumption encounter; experiencing negative social value both "in play" through in-game harassment and "at play" through verbal assaults in chatrooms while playing. At the marketplace level, gendered disempowerment is rarely explored as part of the shopping process. In addition, the gendered retail employee perspective offers dimensionality to an understanding of vulnerable experiences in a consumption field. At the cultural level, female gamers experience hopelessness associated with the prospect of changes within the field. The culturally embedded gamer girl stereotype provides a foundation upon which characteristics of consumer vulnerability flourish, including a culture of gender-based consumer harassment, systematic disempowerment in the marketplace, and conflicting actions and attitudes toward future cultural change.

Resistance to Gender Stereotyping in Advertising Institutions

EXTENDED ABSTRACT

Scholars have pointed out the long history between marketing and gender (Maclaran 2012; Bettany et al. 2010). Research exploring gender portrayals in advertising across different countries has often been examined using Hofstede's cultural values of masculinity/femininity (Hofstede 1980) or has focused on identifying stereotypical portrayals. Other scholars have taken a macro perspective revealing how advertisers think about gender in the creation of ads, but focus on one site of study (see for example Shao, Desmarais and Weaver 2014 work on ad practitioners in China). More recent research advocates for an institutional perspective in examining gender portrayals in advertising (Zayer and Coleman 2015) where multiple actors contribute to an iterative process whereby certain gender ideologies are privileged and disseminated throughout society. The current research uses institutional theory as a foundation to examine how advertising professionals engage in "institutional resistance" (Lawrence 2008) with regard to the use of gender stereotypical messages in advertising.

Specifically, through the analysis of in-depth interviews, we examine how advertising executives across the U.S., UK, and Turkey conceptualize the use of gendered messages in their advertising institutions and the strategies they engage in to resist (or comply with) stereotypical gendered practices.

Forty-three in-depth interviews were conducted with advertising professionals across a range of agencies and cities, and with professionals serving in varying ad functions including strategy, creative, account planning. The three countries were selected as sites for data collection because they provided an opportunity to observe varying institutional forces at play—differing regulatory environments, varying cultural values and norms. Initial exploratory analysis was conducted to compare and contrast how ad professionals conceptualized the use of gender in advertising and how (if) they engaged in resistance to the use of gender stereotyping.

In the U.S., three strategies were identified with regard to how individuals engaged in resistance to employing gender stereotypical advertising messages. These included 1) personal normative stances 2) resistance based on incentives and 3) resistance based on perceived cultural norms. That is, individuals engaging in resistance drew from narratives and discourses at various levels—the personal, organizational and socio-cultural levels.

In the UK, our exploratory analysis reveals similar resistance strategies to those in the United States. Comparative analysis of these contexts, in which regulatory and cultural influences are different, exposes specific ways in which varying individual and institutional factors inform each other to either facilitate or impede resistance or conformity strategies. In applying their own personal beliefs and values, some of the advertising professionals resisted perceived normative dilemmas and, further, demonstrated a sense of responsibility to consumers to produce engaging, rewarding content. Some also referenced governmental and industry regulatory measures, which in some cases supported their resistance efforts or affected the saliency of resistance concerns. Further, these regulatory measures reflected

or affected perceived cultural norms. At other times, when regulation and personal normative stances were absent or not salient, professionals referenced business-driven incentives.

Ad professionals in Turkey possessed a keen understanding of the importance of gender issues in advertising and discussed how the Turkish advertising landscape remained plagued by structural (ie. decision making processes within the agencies, agency-client relationship) as well as cultural problems in the appropriate portrayals of gender. In addition, the agency environment was described as one of the most gender equal working spaces within the country, with women dominating top management teams. However, despite this, professionals pointed to the fact that in the current structural and cultural systems and political climates of Turkey, they were largely not able to resist stereotypical gendered advertising practices. Turkey was described as experiencing an increasing level of conservatism with meaningful class and ethnic differences. As such, advertising professionals tried to negotiate the advertising landscape, including balancing the demands of clients who were risk-averse in this dynamic culture. This unique climate may provide one explanation for the discrepancy between personal and institutional objectives stated by ad professionals in the responsibility that advertising executives felt with regard to gender stereotyping.

In sum, our initial analysis suggests that the strength and interaction of regulatory structures and cultural norms influences individual advertising professionals' resistance (or conformity) strategies by framing the ways in which they approached issues of gendered representations. When both cultural and regulatory practices reinforced stereotypically gendered messages, professionals had more difficulty resisting problematic depictions. Yet, they were highly aware of the importance of gender issues, in part as they had to negotiate cross-cultural issues between global clients and national markets. When regulatory and cultural practices discouraged stereotypical representations, concerns over stereotypical representations posed a less salient dilemma and did not require professionals to grapple with personal normative critiques.

Perceptions of Changing Beauty Norms: An Exploratory Study

EXTENDED ABSTRACT

Society has long struggled with how women are portrayed in the media, particularly stereotypes of beauty. The traditional beauty stereotype depicts ultra-thin women – sizes that are unobtainable for most women. Indeed, the negative effects of idealized imagery on female self-perceptions are well documented (Micu, Coulter and Price 2009). Recently, some brands have diverged from the thin-ideal by featuring women of different sizes and shapes. How are consumers reacting to this divergence of beauty? Provided the public calls to feature more realistic size women, it could be consumers are embracing these changes. However, prior work has demonstrated female consumers prefer thin imagery, despite it impairing their self-perceptions. Thus, there seems to be contradictory findings in how consumers perceive images of beauty in the media. The purpose of this study is to examine consumer response to recent events in which brands have demonstrated more inclusivity of different body types.

A qualitative study was conducted to address the research question: How are consumers reacting to changing images of women in the media that deviate from traditionally constructed beauty norms? To examine this research question, we concentrated on three specific events in the past year: the plus size clothing retailer Lane Bryant's lingerie ad campaign #Imnoangel, plus size model Tess Holliday being featured on the cover of People magazine's "body issue,"

and plus size model Ashley Graham being featured on the cover of Sports Illustrated magazine. Consumer comments posted to stories from the Facebook page of CNN, Yahoo, NBC, and Huffington Post were downloaded. These outlets were chosen because they are representative of mainstream media. To gauge initial consumer response we downloaded comments that were published at the time of the event. A total of 6,000 posts were downloaded. Specifically, for each news outlet's Facebook page, a total of 500 comments were downloaded. This resulted in a total of 2000 comments for each event. To ensure an authentic catalog of response was captured, the comments included consumer posts in the form of response to the story as well as dialogue between consumers. For each event the downloaded comments were posted within 48 hours of the story.

As is customary in qualitative research (Belk, Fischer, and Kozinets 2013), our analysis iterated with our data collection. Though this process, both researchers independently sought to identify emergent themes, while referring back to the literature (Spiggle, 1994). We then deliberated, debated, and iterated to identify a set of convergent themes. Following the guidelines offered by Miles and Huberman (1994, p. 62) our coding was influenced by our research question.

The following findings represent the prevailing theme from each event identified at this stage of analysis.

The most prevalent theme emerging from comments related to Tess Holliday's appearance on the cover of People magazine focuses on health concerns related to obesity and whether it is appropriate to make a clinically overweight woman into a "role model." Additionally, the tone of comments discussing Holliday's unhealthy weight tended to be vitriolic critiques: *"Enjoy your diabetes, heart disease, high blood pressure, increased stroke risk, increased risk of pregnancy complications and birth defects, and certainty of being an UNEMPLOYED model once this silly 'fat acceptance' fad is over."*

While obesity and health concerns are present in online comments about Ashley Graham's Sports Illustrated swimsuit edition cover, the most prominent discourse here centered around whether or not a body type such as Graham's belongs on the cover. Commenters who felt Graham was overweight tended to criticize Sports Illustrated for featuring an unattractive larger woman in the issue. Additionally, there was a strong sentiment that this particular cover pandered to an overly politically correct society: *"That large girl should not be in that tiny swimsuit. If she wants to pretend that she's attractive and pretend that she's not overweight, that's fine for her. But I don't need your 'curves' agenda shoved into my face when I'm trying to enjoy reading a magazine."*

Interestingly, the dominant discourse surrounding the Lane Bryant #Imnoangel campaign was less about the appropriateness of featuring plus size models and more about whether the models truly represented "plus-size" women or were a more idealized version of plus-size: *"All these girls in this pic are a size 14-16, which is the smallest size Lane Bryant offers. Lane Bryant why don't you market to the type of clients who really shop from your stores? To me-this company is still marketing the "smaller" sized females and are fearful to advertise the real BIG GIRLS!!"*

Across all three events, the predominant theme identified thus far focuses on the health of the featured plus size models. The majority of these comments indicate anger and frustration that unhealthy women are being presented in mainstream media outlets and lament that these changes only further the obesity crisis facing the US.

These findings lend evidence to the notion that consumer schema has a significant and important impact on attitudes. Congruity theory is a helpful framework for understanding how consumers respond to brand images that are not consistent with their existing

schema. TIn the case of the Sports Illustrated swimsuit edition, the dominant discourse is one that indicates many consumers found the image of a plus sized model to be incongruent with their brand schema for the magazine. This lead to negative comments about both the model and the brand. Similarly, the strongly negative sentiment toward Tess Holliday appears to be rooted in consumers' perceptions of what the cover model of People magazine's "body issue" issue represents as a role model. On the other hand, Lane Bryant is a brand identified with plus size women so we see the discourse is less focused on the models being too big and rather on whether they were plus sized enough.

SESSION OVERVIEW

Consumers regularly keep track of their time by attending to the passage of time (Sackett et al. 2010), planning out their activities (Lynch, Netemeyer, & Spiller 2010; Tsai & Zhao, 2011), marking their time (Zauberman et al. 2010), and monitoring their behavior over time (Kivetz, Urminsky, & Zheng 2006). The papers in this session build on and extend this literature by examining unique outcomes of tracking time. Together, they explore how tracking time by attending to the unfolding of a current experience (paper 1), by scheduling (paper 2), by estimating temporal distance (paper 3), and by recalling personal events over time (paper 4) influence consumers' perception of the current experience (paper 1), time (papers 2 and 3), and the self (paper 4).

The first paper, by **Tsai, Zhao, & Robitaille**, examines how tracking progress toward the end of a negative experience influences the unpleasantness of the experience. In particular, the authors propose that the unpleasantness of negative experiences can depend on the amount of time left until the end of the experience. While consumers predict that a negative experience will become less aversive over time, the authors demonstrate that experiences become more unpleasant when there is less time until the end.

Next, paper 2, by **Tonietto, Malkoc, & Nowlis**, examines how tracking time through scheduling influences consumers' unscheduled time by creating boundaries around free time. The authors argue that boundary tasks increase the salience and rigidity of the endpoint of time intervals, leading the endpoint to feel perceptually more finite and thus contracted. The authors demonstrate that unaccounted time that ends in a boundary scheduled task feels subjectively contracted, leading consumers to do less with their available time.

The third paper, by **Caruso & Van Boven**, examines how consumers track time by judging psychological distance from the present. In particular, movement through time is perceived analogously to movement through space, leading physical movement toward (vs. away from) an event to reduce psychological distance. Analogous

to physically moving forward or back, consumers perceive that they are continuously moving towards events in the future but away from events in the past. In line with this, the same objective length of time feels shorter if projected into the future than into the past.

Finally, the fourth paper, by **Molouki, Bartels, & Urminsky**, examines how consumers track personal change over time. In particular, the authors compared predicted, actual, and recalled personal change over the course of a year. They demonstrate that both prospectively and retrospectively, consumers underestimated personal change while overestimating perceived improvement. Although consumers tend to both improve and decline over time, they are more likely to remember past improvements and selectively neglect declines, and made nearly uniformly positive predictions of future change.

Together, the papers in this session contribute to our understanding of how consumers track their time and their ensuing judgments. In so doing, the papers identify unique drivers of biases in both prospection and recall (papers 1 & 4), asymmetries between past and future judgements (paper 3), and the malleability of time (papers 2 & 3).

How "Time until the End" Influences Actual versus Predicted Consumer Experiences: A Resource Allocation Account

EXTENDED ABSTRACT

Consider two passengers, Chloe and Debra, who have just passed two subway stations. Chloe has two more stations to go, whereas Debra has ten more. Who would feel more tired now? While their experience should be similar given the same distance traveled, in the present research, we posit that their experiences can be a function of the amount of time left until the end of the trip. Further we propose that time until the end will have differential effects on predicted and actual experiences. Specifically, when predicting a future experience, people are forward looking and thus would focus on the affective state following the end of the experience (Elster and Loewenstein 1992; Loewenstein 1987; Tversky and Griffin 1990). Therefore, for negative consumption events, people might focus on the relief at the end and expect the events to be less aversive toward the end. However, when actually experiencing the events, people might focus more on the ongoing experience (Tversky and Griffin 1990). Therefore, time until the end signals the effort that they have exerted (Drolet and Gibb 2003), which affects their experience negatively ("I am tired because I have used up nearly all my coping resources or mental effort").

To test our hypothesis, we first conducted a field study using subway passengers. Participants were passengers who were either riding (experiencers) or waiting for (predictors) the subway. Participants were either asked to report how they felt during their subway ride (experiencers) on a 7-point scale (1 = not at all tired, 7 = extremely tired) or predict how they would feel after riding the subway for two stops (predictors) on the same 7-point scale. To calculate participants' current location and total trip distance, we asked participants to record at which subway station they got on (experiencers) or were waiting (predictors). Experiencers also reported which subway station they had just passed. All participants reported at which station they planned to get off.

As expected, predictors who had shorter trips (shorter time until the end) predicted the experience of riding the subway for two stations into their journey as less negative than those who had longer trips (longer time until the end), even though they would have travelled the same distance ($t(1, 80) = 3.86$, $p = .053$). By contrast, the results reversed among experiencers: regression analysis showed that passengers rated their experience *more* negatively when they had less time until the end of their trips ($\beta = -1.69$, $t = -2.30$, $p = .02$). To compare experiences and predictions, we examined the ratings for experiencers who had traveled two stops when taking the study. As expected, those on shorter trips rated their experience more negatively than passengers who still had a long way to go ($t(1, 33) = 8.85$, $p = .006$). The results supported our hypothesis.

In study 2, we replicated our findings with university students. Study 2 employed a 2 (role: predictor vs. experiencer) x 2 (time until the end: short vs. long) between-subjects design. Participants were told that they would need to do eight or 18 sets of a handgrip exercise. To control for effort and task difficulty, we asked participants to hold up an object for three seconds during each set using their non-dominant hand. After trying out the handgrip, predictors forecast how pleasant, negative/positive, and tired they would feel after doing seven sets of exercise by moving unmarked sliders (not at all; extremely/positive/very tired). At this point, time until the anticipated end would either be three seconds (1 set left; 8-set condition) or 33 seconds (11 sets left; 18-set condition). Experiencers did seven sets and then evaluated their experience. To explore the underlying mechanism we asked all the participants to report how painful they would expect the rest of the task to be. All the items were measured using unmarked sliders with proper anchors. Data were recorded by the computer using a 0–10 continuous scale.

Consistent with study 1, a two-way ANOVA revealed a significant two-way interaction ($F(1, 102) = 9.95$, $p = .002$). Planned contrast showed that predicted experience was less aversive when time until the end was shorter ($p = .03$). (Higher number indicates less aversive experience.) However, the results reversed for the experiencers ($p = .02$), even though they all did seven sets. Mediation analysis using 5000 bootstrap (Hayes 2013) confirmed that the anticipated pain partially mediated the direct path.

Study 3 further tested our hypothesis concerning the experiencers and employed a 2 (time until the end) x 2 (need to conserve energy) between-subjects design using a similar handgrip exercise. If participants felt they had ample energy during the exercise, they would expect the remaining exercise to be less aversive and have lower need to conserve and allocate their energy during the exercise, thereby weakening the effect of time until the end.

All participants sampled a fruit juice prior to the handgrip exercise. They were told the beverage was either a new energy drink (low need to conserve energy) or a new fruit juice (control – need to conserve energy). They then proceeded to the handgrip exercise. A two-way ANOVA revealed a significant two-way interaction ($F(1, 107) = 5.41$, $p = .02$). As in study 2, control participants rated the experience as more aversive when they had less workout time remaining ($p = .03$). However, the effect disappeared when participants thought the juice was an energy drink ($p > .24$).

In sum, evidence from three studies demonstrate that people intuit that a negative episode feels less aversive if the end is near, but in reality, the episode actually feels worse when the end approaches. Our findings add to research on duration knowledge and affective misforecasting.

When an Hour Feels Shorter: Salient Endpoints Contract the Perception and Consumption of Time

EXTENDED ABSTRACT

Scheduling is a widely adopted strategy for organizing time, and consumers often schedule several of their activities while leaving intervals of "free" time open in between (Southerton 2003). While prior research has examined effects of scheduling on the individual scheduled tasks (Milkman et al. 2012; Tonietto and Malkoc, forthcoming), how the intervals of unscheduled time created by scheduling may be perceived and consumed remains unexamined. In the present work, we propose that intervals bounded by scheduled tasks will feel subjectively contracted, limiting the use of that time. In particular, we propose that by creating boundaries that mark a salient end to intervals of free time, scheduled tasks can make these intervals feel perceptually more finite and thus contracted.

Perceived finitude is driven by two principles: the salience and the rigidity of the endpoint such that time feels perceptually more finite (1) when the end of the interval is more salient (Kaufman, Lane, and Lindquist 1991; Weiss 2014), and (2) when the end represents a rigid and sharp change (Weiss 2014). We propose that because boundary tasks embody both of these principles when they mark a salient, rigid end to an interval, such intervals will feel perceptually more finite compared to equivalent intervals that lack such boundaries, leading time to subjectively contract. Importantly, only boundaries that fulfill the two principles of perceived finitude should contract time. Therefore, we predict that only terminating (vs. initiating) boundaries that mark a rigid (vs. flexible) end to an interval will contract time. Importantly, we argue that boundary tasks will also have downstream consequences for the consumption of available time. In particular, once time feels contracted, it should also feel less sufficient and more constrained, reducing consumers' willingness to spend their time. As such, we predict that intervals that saliently end in a scheduled boundary task will be consumed less effectively and productively. Eleven studies provide support for these propositions.

The first set of studies provided initial evidence that boundary tasks contract time, using a correlational field study (Study 1A) and a randomized lab experiment (Study 1B). In Study 1A, conference attendees estimated the time before a presidential address to be shorter if they had scheduled to attend it, compared to those who had not planned to attend. In Study 1B, participants evaluating a one-hour interval indicated that time felt shorter when it was bounded by an upcoming task than when it was not, and this effect was mediated through perceived finitude of the interval. To establish that boundary tasks uniquely contract subjective, but not objective time, in Study 2, we asked participants to estimate both the objective time they had and the subjective amount of time they felt they had to spend reading a book during a one-hour interval. We find that while objective estimates of time did not differ, participants evaluating a bounded interval felt that they had subjectively less time. Thus, we find that temporal contraction is driven by subjective, rather than objective differences in perceived time.

In Study 3, we aimed to show that boundary tasks would contract time perception for both desirable and undesirable boundary tasks, establishing that savoring towards a future task could not account for our effect. To test this, participants imagined either an hour available later (no boundary), an hour available before a dinner with friends (desirable boundary), or an hour before a dentist appointment (undesirable boundary). Countering a savoring based account, we find that time felt contracted prior to both the desirable and undesirable boundary tasks. Importantly, anticipating a fun dinner did

not differ from a dentist appointment, demonstrating that the mere presence and not the valence of the boundary task drives the effect.

In Study 4, we next sought to examine whether the effect would uniquely manifest for boundaries that terminate (vs. initiate) the interval, in line with the first principle of perceived finitude. Participants were given a hypothetical calendar for the day and indicated their perceived duration for four intervals throughout the day. Two of these intervals preceded a terminating scheduled task where one of the intervals (bounded) ended when the terminating task began. The other two intervals followed from an initiating scheduled task where one of the intervals (bounded) began when the initiating task ended. Replicating earlier results, time subjectively contracted prior to a terminating boundary. However an initiating boundary did not contract time. Building on this result, in Study 5, we tested whether the effect would only occur if the boundary task was specifically (vs. roughly) scheduled, and thus represented a rigid end to the interval. To test this, participants indicated the perceived duration of an interval that was either bounded or unbounded by either a specifically (i.e., coffee from 2:00pm-3:00pm) or roughly scheduled task (i.e., coffee sometime between 2:00pm and 5:00pm). Consistent with the second principle of perceived finitude, only the specifically scheduled task contracted time. That is, a boundary task only contracts time when the end is rigid and inflexible such that the terminating task must specifically mark the endpoint of the interval in order to contract time.

Finally, five studies (Studies 6A-6E) explored whether bounded time, in addition to feeling shorter, may also be underutilized. We find that people choose to take part in fewer tasks during bounded intervals (6A-6B), and perform fewer productive and extended tasks, opting instead for shorter and less productive tasks (6A and 6C). In addition, during bounded intervals, participants forgo both desirable leisure and productive work activities (6D), as well as financially superior options (6E) that could objectively be completed within the available time.

Together, these results identify a unique driver of time perception, finding that intervals bounded by a terminating scheduled task feel contracted. Our results establish that how consumers structure and organize their day around scheduled tasks has important implications for how they perceive and consume their free time.

Movement through Time and Space
Shapes Psychological Distance

EXTENDED ABSTRACT

Time is an abstract concept that is only experienced indirectly, which makes the very notion of time difficult to comprehend. Once people move beyond the narrow spans of time that their biological clocks, broadly speaking, are capable of tracking, they conceptualize time by building mental representations that draw from their direct experience with spatial distances (e.g., Boroditsky, 2000; Lakoff & Johnson, 1980, 1999). The idea that travel through time has a direction—reflected in numerous metaphors, such as the "arrow of time" and "moving through time"—implies a spatial relationship. As a result of this mapping of time onto space, both literally and metaphorically, people's movement through space can affect their representation of movement through time (Boroditsky, 2000; Casasanto & Boroditsky, 2008; Miles, Nind, & Macrae, 2010).

Here we explore two implications of the metaphorical mapping of time and space. We suggest that people's experience of movement through time is analogous to their experience of movement through space in that they perceive the distance between the self and future events as continually diminishing whereas they perceive the distance between the self and past events as continually increasing. Just as diminishing spatial separation makes objects seem spatially closer and increasing spatial separation makes objects seem spatially more distant, diminishing temporal separation makes events seem temporally closer and increasing temporal separation makes events seem temporally more distant. We hypothesize that this spatial metaphor of events in time implies two phenomena. First, physical movement toward events in space should reduce their psychological distance to the present. Second, there should exist a fundamental asymmetry in the psychological distance of past and future events whereby future events are psychologically closer to the present than past events of equivalent objective distance. We tested these predictions in a series of studies.

Study 1 tested our prediction that physical movement toward events in space would reduce their psychological distance to the present. Participants wrote down six personally-relevant events (e.g., "my final exams") on separate sheets of large paper, which an experimenter taped to a door at the end of a long hallway. All participants reported how psychologically distant each event was. Some participants made these evaluations from a stationary position approximately 4 feet away from the posters; some participants made these evaluations from a stationary position approximately 30 feet away from the posters; and some participants made these evaluations after physically moving toward the posters (i.e., walking from 30 feet away to 4 feet away) or away from the posters (i.e., walking from 4 feet away to 30 feet away). We found that people who walked forward reported that these events were psychologically closer than did people who walked backward or who were in a close or far stationary position.

The next two studies tested whether future events are psychologically closer than past events of equivalent objective distance. In each study, participants were asked to imagine a point in either the past or in the future, and to report the point's psychological distance. When considering specific times (one month, one year; Studies 2a-2b) or specific events (Valentine's Day; Study 3), people reported that the future was closer than the past.

In Study 4, we experimentally reversed the spatially-grounded arrow of time by manipulating the direction of participants' apparent physical movement, which we reasoned would influence their orientation to the past and future. Some people had the (virtual) experience of moving forward in space, consistent with their natural orientation of thoughts, whereas others had the (virtual) experience of moving backward in space, reversing their natural orientation of thoughts. Consistent with our predictions, we found that people's virtual movement moderated the temporal asymmetry in psychological distance, such that backward movement eliminated the tendency for future times to be psychologically closer than past times.

The existence of this temporal asymmetry has important implications for theories of psychological distance that assume temporal symmetry (e.g., Trope & Liberman, 2010), and for theories of episodic memory that assume people remember the past in largely the same way that they imagine the future (e.g., Addis, Wong, & Schacter, 2007). More broadly, we believe that the temporal asymmetry in psychological distance reflects a general "bias toward the future" whereby people are psychologically oriented toward the future more than the past (Parfit, 1984). This future orientation is highly functional, as future events can typically be acted upon more successfully than past events. The fact that action can facilitate the realization of future desires but not past ones may help explain why people devote more resources to prepare for things that lie ahead than for things that lie behind. This is in part why it makes sense for car windshields to be bigger than rearview mirrors and for the meteorologist to dis-

cuss the weather for the upcoming week rather than the preceding one. Thus, just as people mobilize resources to prepare for approaching sights and sounds, they apparently have a more general tendency to prepare for the (approaching) future by reducing its psychological distance from the here and now.

Neglecting Decline: Biased Views of Personal Development Driven by Failure to Recall and Predict Negative Change

EXTENDED ABSTRACT

Imagine yourself ten years in the future. Will you be fundamentally the same person you are today, just with grayer hair? Or will you be a significantly changed individual with different preferences, values, and personality characteristics? Because our conception of what we will be like in the future is central in guiding our decisions (March, 1978), making incorrect predictions about how we will change (or not change) over time can lead to undesired outcomes. For example, consumers who hold inaccurate views about their own future preferences might make suboptimal product choices, whether they are selecting between snacks (Simonson, 1990; Kahneman & Snell, 1992) or cars (Busse, Pope, Pope, & Silva-Risso, 2014). More generally, anticipating major change in what defines the self can undermine the motivation to reduce spending (Bartels and Urminsky 2016) and preserve resources for the future (Bartels and Urminsky 2011). Therefore, exploring how people see themselves changing over time and identifying any consistent errors in these beliefs is crucial for understanding and guiding future-oriented behavior.

Research has revealed that people seem to exhibit systematic biases in evaluations of their own personal change. A large portion of this work suggests that people overestimate positive change, seeing themselves on a trajectory of constant improvement (e.g., Wilson & Ross, 2001; Kanten & Teigen, 2008). In contrast, other research suggests that people view themselves as relatively stable going forward. For example, Quoidbach, Gilbert, & Wilson (2013) found in a large cross-sectional study that people systematically underestimate the absolute magnitude of future personal change when compared to the absolute magnitude of remembered past change (though their design did not allow for assessments of actual within-participant change, which left the specific form of the bias unclear).

Taken together, these findings present a puzzle. Do people believe that they have stopped changing, or do they believe the biggest improvements are yet to come? In our study, we directly compare participants' beliefs about their own (absolute and directional) change to their actual change in a one-year longitudinal study in order to develop a more complete understanding of predictive and retrospective biases.

College students from across the United States were recruited by a research firm to answer two online surveys about their self-perceptions, separated by one year. A total of 155 participants completed both surveys. Using similar stimuli to those in Quoidbach et al. (2013), we measured change in three domains: personality (Big Five traits; Goldberg, 1992), personal values (Schwartz, 1992), and preferences (favorite food, type of music, hobby, book, and vacation spot, best friend). At Time 1 (December 2013), each participant provided measures of current personality traits, values, and preferences as well as a prediction of these items one year in the future. At Time 2 (December 2014), participants again provided current measures as well as a recollection of their evaluations one year ago.

In our analyses, we distinguish between degree of absolute change (combining increases and decreases) and directional change (amount of net improvement vs. decline). To analyze directional

change, we conducted a pre-test (N=100), which confirmed that increases in the personality traits and values we measured were viewed positively and decreases in the same were viewed negatively, and identified in which preference categories people saw change negatively or were open to change.

We found that both predicted and remembered absolute change were significantly underestimated relative to actual absolute change for personality ($ts(154) > 8.39$, $ps < .001$) and values ($ts(154) > 5.54$, $ps < .001$). However, on average, participants also demonstrated a self-improvement bias. That is, for both personality and values, participants predicted ($ts(154) > 4.02$, $ps < .001$) and remembered ($ts(154) > 2.38$, $ps = .018$) greater improvement than they had actually experienced. This is because people were much more likely to predict and remember positive (vs. negative) changes, despite the fact that our sample actually underwent positive and negative change in equal proportions. Nonetheless, participants were significantly more likely to report remembering negative change than they were to predict it, resulting in a somewhat attenuated positivity bias in recall compared to prediction. Further analysis revealed that the largest errors were made by the subset of people who in fact declined over the course of the year. On average, these participants ignored their decline and instead reported a smaller improvement, simultaneously leading to both an overall underestimation of the absolute magnitude of change and an overestimation of improvement.

Participants also predicted that an average of 1.04 of their initial preferences (out of 6) would change over the following year, while, in actuality, 1.33 out of 6 preferences changed ($z = 2.31$, $p = 0.02$). However, we found that the degree of underestimation differed across the preference questions, $F(5, 766) = 3.86$, $p = .002$. Change was underestimated for items in categories where change was rated as undesirable in our pretest (hobby, music, and best friend), $t(151) = 3.35$, $p = .001$, but not for items where change was rated as neutral (food, book, and vacation), $t(153) = 0.85$, $p = 0.40$. This finding again supports the idea of a positive directional bias: people denied change in preferences when they viewed this change as a bad thing.

Our study reconciles previous findings by demonstrating that people can underestimate the absolute magnitude of personal change while simultaneously holding beliefs that they will continue to improve. Notably, this result emerges because people do not equally underestimate all types of change, but especially deny changes that are viewed in a negative light. Whereas actual change in our sample was evenly peppered with improvements and declines, and individuals acknowledged this variability to a certain extent in their past, the future was seen as uniformly positive. Thus, we suggest that people's self-views do not in fact resemble an "End of History Illusion," with the present moment marking the end of their personal development (Quoidbach et al., 2013). Instead, people think of the present moment as a watershed moment of a different sort: it is the moment when their somewhat rocky past will resolve into a consistent upward trajectory from now on.

"Mostly, we talk to impress.
And sometimes we shut up to impress, too." – N. Al-Araby

SESSION OVERVIEW

Strategic self-presentation is ubiquitous and is an important driver of word of mouth communication (Schlenker 1980, Berger 2014). Yet, many unanswered questions remain about what drives individuals to select a specific self-presentation tactic while pursuing their self-presentation goals, as well as the behavioral consequences of consumers' self-presentation efforts. Moreover, the proliferation of online outlets for consumers to discuss their purchases, ranging from online rating communities such as Yelp and TripAdvisor to social media sites such as Facebook and Twitter, raises the important question of when and how self-presentation concerns influence online WOM. The four papers in this session address a set of related questions focused on the drivers and consequences of strategic self-presentation in online contexts.

The first two papers in the session explore factors that influence consumers' choice of self-presentation tactics given a specific self-presentation goal. **Valsesia, Nunes and Ordanini** document how members of online rating communities such as Yelp.com are concerned about being perceived as *knowledgeable* by others community members. Moreover, their ratings record affects the particular *self-presentation tactic* they choose to adopt in order to appear knowledgeable: displaying their ability to make good choices early on and exhibiting critical skills later, which results in their ratings becoming increasingly more negative. **Chen** focuses instead on how self-presentation goals and tactics vary depending on the target of the self-presentation effort. She shows WOM is often driven by a desire for social acceptance and that people take *different* approaches (tactics) to fulfill this goal when *sharing* with strangers versus friends. Individuals *self-enhance* when communicating with strangers in order to form relationships, but alternatively focus on connecting socially when sharing with friends in order to maintain existing ties.

The second two papers of the session shift the emphasis to the consequences of individuals' self-presentation efforts. In particular, **Kristofferson and White** focus on the behavioral consequences for the self-presenter of an indirect impression-management tactic: communicating the prosocial behaviors of others. They find that when individuals publically communicate the positive behaviors of others, the communicator tends to behave less pro-socially on subsequent tasks. Finally, **Barasch, Levine and Schweitzer** look at consequences of self-presentation efforts for the *receivers* of WOM communication. They examine whether the magnitude of emotional displays (e.g., happiness) affects social judgment and interpersonal behavior, and find that very happy people are perceived to be naïve and thus are exploited more frequently. This effect is driven by the common belief that overly positive communicators shelter themselves from negative information.

Taken together, this combination of research sheds light on important factors affecting how consumer choose to present themselves both online and offline, as well as the consequences of individuals' self-presentation efforts, both for the self-presenter and for the targets of their efforts. We expect this session to generate interest among researchers studying impression management and self-presentation, social influence and social judgment, online and offline word of mouth, as well as consumer decision-making more broadly.

The Influence of Self-Presentation Concerns on Online Reviews

EXTENDED ABSTRACT

It is a *truism* that the Internet allows individuals to freely express opinions uninhibited by concerns about the impressions they make on others. A common assumption is that opinions regarding products and services found in online rating forums (e.g., Angieslist.com, Tripadvisor.com, Yahoo Local, and Yelp.com) are unaffected by reviewers' concerns about what readers will think of them, and therefore more reliable. The belief that opinions expressed online are unfiltered is supported by academic research, and the primary argument in support of this is that individuals are protected by the anonymity granted by the web (Sussman and Sproull 1999; Kiesler and Sproull 1992; Dubrovsky, Kiesler and Sethna 1991).

Yet, the most popular consumer opinion platforms have moved away from the notion of "strict" anonymity. Instead, they now encourage social interaction and compel users to build and maintain a reputation within their communities. Consider, for example, Yelp. Each reviewer ("Yelper") has a public profile page on which, at the extreme, they can use their real name and an actual photograph. The profile summarizes their rating record, including designations of any reviews seen as especially "useful," "funny," and/or "cool" by visitors to the site. Further, Yelpers can "befriend" and "follow" other Yelpers, and publicly compliment them on their profile page. The "best" Yelpers are rewarded publicly by Yelp with status by being designated an "Elite Member." The presence of reputation systems adds a social dimension to online reviewing and has been credited with stimulating participation by promoting accountability (Resnick et al. 2000; Dellarocas 2003). We propose that the absence of absolute anonymity, caused in part by the inclusion of reputation systems on opinion sites such as Yelp and TripAdvisor, results in reviewers who are concerned with what others think about them.

This research is the first to document the influence of self-presentation concerns – and the desire to appear knowledgeable (i.e., competent, skilled and intelligent) in particular – on ratings and reviews published on less than strictly anonymous user-generated review sites. We show these concerns have meaningful downstream consequences, significantly influencing the valence of ratings *dy-*

namically over time. The causal mechanism proposed and validated is as follows. Reviewers are more positive early on because, while new to a community, they are more concerned with being seen as *having made good choices* as a way to display their knowledgeability as reviewers. As the number of reviews in their rating record grows, reviewers become increasingly concerned with being seen as possessing the *critical skills* necessary to discriminate between experiences, and therefore relatively more negative. The result is a meaningful negative trend in ratings based on the number of past ratings in a reviewer's profile.

Three laboratory studies and the analysis of real world data provide compelling evidence in support of the proposed causal mechanism. In study 1A, we asked 126 college students to rate a song, with the aim of either showing they make good choices or are critical and discriminating. Reviewers concerned with showing they make good choices gave consistently higher ratings than reviewers concerned with displaying critical skills ($M_{GoodChoice=}$5.68 vs. $M_{Critical=}$3.98, F(1,124)=19.83, $p < .01$). In study 1B, we show how the relative importance of these two self-presentation concerns evolves over time, as a function of a reviewer's rating history, in turn influencing the valence of reviewers' ratings. We asked 90 college students to rate 2 songs with the goal of showing: (1) they make good choices (Good Choice condition), (2) are critical and discriminating (either Critical condition), or, (3) more broadly, are knowledgeable reviewers (Knowledgeable condition). Respondents rated the 1st song as if they just joined an online community of music lovers and the 2nd song, after a significant time delay, as if it were the 81st rating they provided. Among respondents giving their first rating, those assigned the goal of showing knowledgeability behave no differently from those in the Good Choice condition ($M_{Knowledgeable}$ = 6.07 vs $M_{GoodChoice}$ = 5.73, F(2,87)=.65, p=.52), but differently from those in the Critical condition ($M_{Critical}$ = 4.66, F(2,87)=5.11, $p < .01$). The opposite occurred when giving their 81st rating. They behaved no differently than those in the Critical ($M_{Knowledgeable}$ = 4.97 vs $M_{Critical}$ = 4.24, F(2,87)=1.45, p=.24), but differently from those in the Good Choice condition ($M_{GoodChoice}$= 6.00, F(2,87)=5.55, $p < .01$). The results reveal a declining trend in ratings for reviewers who want to appear knowledgeable ($M_{First=}$6.07 vs. $M_{EightyFirst}$=4.97, F(1,87)=4.61, p=.03).

We find additional support for our explanation by moderating the effect of declining ratings in Study 2. Consistent with our proposed causal explanation, we document how the effect of providing more positive reviews early on manifests only for reviewers who are *high* in public self-consciousness (concerned with how they present themselves to others – Fenigstein et al 1975), and not for those *low* in in public self-consciousness ($β_{PSCXPreviousRatings}$=.58, $p < .01$).

Finally, in study 3, we examine real-world data from Yelp consisting of 190,065 reviews by 48,108 individual reviewers. As expected, the data reveal a significant negative trend in ratings as a function of the number of businesses rated previously, controlling for other factors ($β_{PreviousRatings}$=-.0031; p=.003). Lending additional support, written reviews tends to be more positive early in a reviewer's rating history ($β_{PreviousRatings}$=.540; p=.003).

Using a multi-method approach, this research contributes to the literature on both impression management and word of mouth. First, we identify specific self-presentation tactics that individuals adopt in order to appear knowledgeable. Second, and more importantly, we show that an individual's use of different tactics evolves over time in a predictable fashion. In the context of online ratings, this implies the same individual can be more or less critical in their opinions with the same self-presentation goal in mind – appearing knowledgeable. Third, we demonstrate that reviewers express online are influenced not only by the rating behavior of *other* community members (Schlosser 2005), but also by reviewers *own* past ratings behavior.

Social Acceptance and Social Sharing

EXTENDED ABSTRACT

Consumers are increasingly sharing product experiences online with both strangers and friends. Despite the prevalence of Word of Mouth (WOM), little is known about *how* and *why* WOM differs based on whether people are talking to strangers or friends. The current paper theorizes that WOM behavior is driven by an overarching goal of gaining social acceptance.

Research in interpersonal relationships theorizes that relationships move primarily through two stages: the *formation* stage and the *maintenance* stage (Clark and Beck 2011). At the formation stage, where people are strangers to one another, potential partners engage in evaluation processes where they attempt to assess the worthiness of each other. In this stage, one important task is to signal one's attractiveness as a potential partner (i.e., make one seem worthy as a potential friend, Clark and Beck 2011). For those who move beyond this initial phase, the relationship moves into the maintenance stage and that people are fully engaged in an interpersonal relationship and are motivated to stay socially connected to one another (Clark and Lemay Jr. 2010).

Given that people's need for social acceptance is fundamental and active in most everyday situations (Baumeister and Leary 1995), it is reasonable to expect this motivation to drive WOM decisions. When communicating with strangers – or people at the initiation stage of the relationship – one's goal is to make oneself appear attractive as a potential friend going forward and so WOM is likely driven by the desire of *self-enhancement*. When communicating with friends – or people in the maintenance stage of a social relationship – one's goals shifts away from self-enhancement since the relationship has already commenced. In this case, WOM is likely shared to socially connect with others, which helps maintain existing relationships. These ideas are tested and confirmed in a series of six methodologically diverse studies.

Studies 1A and 1B show that self-enhancement is an important driver of sharing with strangers. Prior research suggests that being responsible for a good consumption is self-enhancing because it allows people to signal expertise and competence (Wojnicki and Godes 2013) and Study 1A shows that being responsible (vs. not responsible) for a good purchase increases people's willingness to share their purchase experience more with strangers than friends. Study 1B looks at the impact of transparent incentives (i.e., incentives that are easily observed by the WOM recipient, e.g., "tell the hairdresser I told you about him") on sharing. Transparent incentives may be viewed as image-damaging since one could appear avaricious/opportunistic. Consistent with our predictions, the presence of image-damaging transparent incentives (vs. no incentives and non-image-damaging incentives) reduced WOM more with strangers than friends.

Testing the second half of our framework, Study 2 examines whether social sharing among friends fulfills connection goals. Participants were asked to write about a negative personal experience to either a friend or a stranger. If our predictions are correct in that social sharing with friends achieves the goal of maintaining connection, then the act of writing about an experience should generate stronger feelings of social connection when the audience is composed of friends than strangers. To elucidate the connection mechanism, half of participants were instructed to write the WOM with a social connection goal in mind. Based on our theory, explicitly

activating (vs. not activating) this goal before sharing WOM should make people feel more connected to strangers but it should have little effects on friends since the goal of establishing social connections is naturally activated when people share WOM with friends. These predictions are confirmed in Study 2.

Study 3 tests our overall framework and shows mediation. Building on the ideas that positive WOM is often shared to self-enhance (De Angelis et al. 2012; Wojnicki and Godes 2013) and negative WOM is often shared to connect (Pennebaker, Zech and Rimé 2001), we show that people are relatively more likely to share positive (vs. negative) WOM with strangers than friends. Moderated mediation analysis confirms that the relative preference for sharing positive WOM with strangers is driven by self-enhancement concerns and that the preference for sharing negative WOM with friends is driven by social connection concerns.

If Study 3 results are driven by the fundamental desire for social acceptance as we hypothesize, then these effects should attenuate when social acceptance concerns are less salient. To test this, we experimentally reduce social acceptance concerns by manipulating the word of mouth setting in Study 4. In most WOM contexts (e.g., Facebook, Yelp), people can interact with each other in the form of posting replies, asking questions, etc. We theorize that by removing this ability to interact with each other (i.e., people can only post WOM, but not have the opportunity to receive responses from others) social acceptance concerns are reduced since there is little opportunity for having future social interactions/relationships with WOM receivers. Consistent with this line of thought, we show in Study 4 that Study 3 results are mitigated when social acceptance desires are reduced experimentally.

Study 5 provides a final test of our framework and examines people's sharing behavior in the context of an online product platform. Building on the ideas that individuals are more likely to offer help when attempting to self-enhance (since it signals compassion and competence) and seek help when making connections (since it shows vulnerability, Beck and Clark 2009; Clark and Beck 2011), results reveal that relative to strangers, people are *less* likely to offer (vs. seek) advice to friend than strangers on online platforms.

The current work makes three important contributions. First, it provides an overarching framework to understand *how* and *why* people share WOM (to achieve social acceptance). Second, it shows how seemingly unrelated findings from prior research (which are rooted in the stranger context) can be synthesized to show the same thing: people attempt to self-enhance with strangers. Third, the current work shows that previously established drivers of social sharing (found in the stranger context) may not hold in the friend context given the shift in relationship goal from formation to maintenance.

Unintended Consequences of Indirect Impression-Management

EXTENDED ABSTRACT

We all know at least one of *those* people-individuals who post about the positive behaviors of others they are connected to (e.g., sister running a marathon, colleague volunteering at a local charity). What is unclear is the effect that communicating a close other's positive behavior has on the communicator's own subsequent behavior. Does publically communicating the athletic sister's accomplishment motivate the communicator to behave consistently (go for a run) or reduce the likelihood to follow through with the behavior (go for a hamburger)? This research examines the consumer consequences of publically communicating a close other's positive behavior and highlights the role impression management plays in this context.

Consumers have multiple avenues available to present themselves positively to others, such as purchasing products that donate profits to charity (Krishna 2011) or engaging in token support for a social cause (joining a Facebook group; Kristofferson et al. 2014). However, research shows that explicit self-presentation tactics can lead others negatively interpret the target's actions (Berman et al. 2015; Fein 1996). To mitigate this drawback, consumers can resort to less invasive, or indirect impression-management techniques, such as communicating the positive behaviors of others.

We propose that publically communicating the positive behaviors of another other leads to a subsequent decrease in the communicator's own positive behaviors. We propose that when the act of communicating the positive actions of another person is done in a public (vs. private) manner this allows the consumer to feel positively from presenting a positive image to others. As a result, the consumer is less inclined to engage in subsequent positive behaviors themselves. We offer further support for our impression-management claim by varying the communication target (close other vs. acquaintance, S2) and showing this effect among high public self-conscious consumers (S3). Finally, we identify a boundary condition: accountability for the consumer's own behavior (S4).

A pilot study demonstrated this effect in the domain of positively-viewed athletic behavior using a dataset taken from a social networking site (Strava) of a competitive cycling team (76 cyclists, 1,249 communications/kudos, 29,516 KM). Athletes can publically communicate a fellow cyclists' performance by giving 'kudos' for the teammate's performance. As predicted, high communicators cycled significantly shorter average distances than low communicators ($F(1,74)=4.02, p < .05$).

Study 1 tested our predictions in a field study using personal Facebook posts. We recruited individuals (n=62) to participate in a Facebook study by offering an entry in a draw to win an iPad. Participants wrote a Facebook post about one of three behaviors: helpful behavior of a close other, average/everyday behavior of a close other, or a helpful behavior that they had performed. At the end of the study, participants were offered the opportunity to be helpful by forgoing their entry in the iPad draw in exchange for us making a $10 to the World Wildlife Fund (0=No, 1=Yes). Participants who publically communicated a helpful behavior of a close other were significantly less likely to be helpful themselves than participants who communicated an average behavior of a close other ($P_{Other-Helpful}=33.3\%$ vs. $P_{Other-Control}=66.7\%$; b =-1.39, $p < .05$), but no different from those who communicated their own helpful behavior ($P_{Other-Helpful}=33.3\%$ vs. $P_{Self-Helpful}=35.0\%$).

Study 2 replicated the field study using blogging as the public communication medium, and supported our impression-management claim. Undergraduates (n=132) were assigned to conditions in a 2 (Task: Communicate, Introspect) x 2 (Target: Close Other, Acquaintance) design and completed the study in groups. Participants in the publically communicate (introspect) conditions wrote a blog post (introspected) about a charitable behavior of either a close other or acquaintance with other participants (~20) in the room with them. Shortly after, they indicated how willing they were to volunteer their time. The expected interaction emerged ($F(1,128)=3.88, p=.05$). Participants who publically communicated the charitable behavior of close other (vs. acquaintance) were less likely to volunteer ($F(1, 128)=3.82, p=.05$). This group was also less marginally less likely to volunteer than those who introspected about a close other ($F(1, 128)=3.45, p < .07$).

Study 3 further supported our impression-management claim by investigating public self-conscious consumers. Undergraduates (n=121) were assigned to conditions in 2 (Communication: Public,

Private) x continuous (Public Self-Consciousness) design. Participants in the public (private) condition wrote a blog post (confidential reflection) about another person's behavior as in study 2 and completed the dependent variable as in study 2. At the end of the study, participants completed the seven-item public self-consciousness scale. The expected interaction emerged (b=.43, SE=.17, t=2.50, p=.01). Results showed that high (low) public self-conscious participants were less likely to volunteer when they publically (privately) communicated a close other's behavior (HPSC: +1.99SD, $B_{JN=}$ .68, SE=.34, p=.05; LPSC: -.75SD, $B_{JN=}$-38, SE=.19, p=.05).

Study 4 examined a boundary condition: accountability. Undergraduates (n=133) were randomly assigned to one of four conditions in a 2 (Communication: Public, Private) x 2 (Accountability: High, Low) design. The procedure and manipulation used in the communication task is identical to that of study 3 with one change. Immediately after communicating the behavior of a close other, participants were told their subsequent responses would be either discussed (high accountability) or be confidential (low accountability). Participants then completed the dependent variable from studies 2 and 3. The expected interaction was significant (F(1,129)=4.05, p < .05). When accountability was low, participants publically (vs. privately) communicating the charitable behavior of a close other were less charitable (F(1, 129)=3.79, p=.05), but no differences emerged when accountability was high (F(1, 129)=82, p > .35).

In conclusion, we investigate the consequences that communicating the positive behaviors of others have on our own behavior. We demonstrate that publically communicating the positive behavior of close others makes consumers less likely to engage in the behavior themselves, and this decrease is driven by the reception of impression-management benefits.

Bliss is Ignorance: Happiness, Naiveté, and Exploitation

EXTENDED ABSTRACT

Social media has become a ubiquitous channel of communication. Each day, people share billions of items online, including photos and text, and this trend is only increasing (Facebook 2013; Systrom 2014). Through this content, people convey different sentiments to their audience. For example, people might post a happy photo of themselves on vacation or an angry story about bad customer service.

Prior research has shown that individuals automatically infer personality traits from others' emotional expressions (Frijda 1986; Parkinson 1996). For example, scholars have found that expressions of happiness signal affiliation and warmth, whereas expressions of anger signal dominance and competence (Knutson 1996; Tiedens 2001). As a result, emotional expressions have powerful effects on cooperation/competition and bargaining (Dehghani, Carnevale, & Gratch 2014).

Although extant research has advanced our understanding of how valence and other dimensions of emotion (e.g., certainty) influence trait inferences, we know surprisingly little about how a single emotion *expressed at different levels of intensity* is perceived. But the emotional expressions on social media vary in magnitude, and are oftentimes extreme in nature (e.g., an extremely happy photo or an enraged story). In fact, due to selection in what people post, sentiments in these contexts tend to be more extreme than what people experience more generally (Chou & Edge, 2011). Thus, it is important to understand how the magnitude of emotional displays affects social judgment and interpersonal behavior.

We examine this question in the context of expressed happiness. While prior work has shown that conveying moderate happiness can

increase individual's perceived attractiveness, competence, and liking (Harker & Keltner 2001), we document one cost of displaying happiness at the extreme. Specifically, people perceive very happy individuals to be more naïve than moderately happy individuals. These perceptions reflect the belief that very happy individuals limit their exposure to negative information and use biased information processing strategies to maintain their positive feelings (Isen 1984; Batra & Stayman 1990) As a result of these inferences, individuals are more likely to take advantage of very happy people by offering them biased advice.

Five studies test these propositions with a variety of manipulations, measures, and paradigms. **Study 1** (n=390) used a subtle, controlled manipulation of emotion: a target's response on an emotional inventory (similar to the "quiz results" people often post on social media). Participants viewed one of five conditions showing the results of this inventory for another individual, ranging from neutral (6 on an 11-point happiness scale) to moderate happiness (8 of 11) to extreme happiness (10 of 11), and then rated the individual on a 4-item Naiveté scale. Individuals who displayed high levels of happiness were perceived as more naïve than individuals who displayed moderate levels (B=.24, SE=0.06, t(387)=3.91, p<.001). These perceptions also followed a curvilinear trend (B=.11, SE=0.04, t(387)=2.94, p<.01), suggesting that inferences of naiveté are particularly strong at extreme levels of happiness. We observed this pattern of results for both male and female targets.

Study 2 (n=209) replicated these naiveté findings (F(2,206)=4.95, p<.01) and explored the underlying mechanism. Focusing on three of the five happiness levels from the previous study, a one-way ANOVA revealed a significant effect of emotion on a 7-item scale measuring perceptions of Biased Processes (F(2,206)=4.88, p=.009). Participants believed that the individual engaged in more biased search and inference processes when he/she was very happy (M=4.47) than when he/she was moderately happy (M=3.99, t(139)=2.71, p<.01) and when he/she was neutral (M=3.98, t(135)=2.73, p<.01). In addition, this belief mediated the link between expressions of happiness and perceived naiveté (95% C.I.=[0.053,0.238]). We also ruled out two alternative mechanisms: perceptions that very happy people do not set challenging goals for themselves and that very happy people are overly optimistic.

Study 3 (n=239) replicated these findings using facial expressions in photographic stimuli: male and female targets expressing different levels of happiness (naiveté: F(2, 236)=9.62, p<.001; biased processes: F(2,236)=9.38, p<.001; 95% C.I.=[0.078,0.240]). We also demonstrated that inferences do not extend to perceptions of very happy individuals' general competence or likeability.

Study 4 (n=216) identified a boundary condition. Using a 2 (Emotion: *happy, very happy*) x 2 (Seeks-information: *control, high*) between-subjects design, we also manipulated whether the target seeks out negative information about a neighbor's house that just burned down. A two-way ANOVA revealed a significant interaction on naiveté (F(1,212)=4.92, p=.03), such that we replicated the effect of happiness magnitude in the control condition (F(1,212)=7.91, p<.01), but when very happy individuals sought out negative information, emotion expressions no longer influenced perceptions of naiveté (F(1,212)=.11, p=.74). Inferences about biased processes again mediated the effect on naiveté (95% CI=[0.193,0.775]).

Study 5 (n=115) demonstrated a behavioral implication of expressed happiness. We used a conflict of interest paradigm (Sah & Loewenstein, 2012) in which participants gave advice to a partner for an estimation task (guessing how much money was contained in different jars of coins) and could financially benefit if their partner overestimated the amount. We calculated the percentage by

which participants' advice deviated from the median estimate of each jar's contents, and found that people gave more biased advice to very happy partners (M=2.46) than to happy partners (M=1.46; $F(1,113)$=8.01, p<.01). This was mediated by perceptions of naiveté (95% C.I.=[0.021,0.608]). In other words, people took advantage of the opportunity to profit from very happy individuals by giving them biased, self-serving advice. Presumably, they expected very happy individuals to be naïve enough to believe it.

Our research underscores the importance of examining emotional expressions at different magnitudes, and has important implications for self-presentation. People who express high levels of happiness on social media may convey the impression that they are naïve and thus may be prone to exploitation. This disadvantage of expressing happiness should also inform "display rules" that prescribe expressions of happiness in many contexts, such as customer-employee interactions and sales (Barger & Grandey 2006; Pugh 2001). By demonstrating the impact of emotion magnitude on impression management, social cognition, and conflicts of interest, the present research offers novel insights for psychology and consumer research and would be of interest to a wide audience at ACR.

Paper #4: The Broader Scope of the Experience Superiority—Just Listen!

Wilson Bastos, Católica-Lisbon, Portugal
Sarah Moore, University of Alberta, Canada

SESSION OVERVIEW

Online and offline word of mouth are the most credible forms of advertising for consumers around the world (Nielsen 2015). What social factors influence whether and how consumers decide to initiate word of mouth communication about products and brands? On the flipside, how do social factors influence how word of mouth communication is received? The four papers in this session address these and related questions.

The first two papers focus on social factors that influence the decision to initiate word of mouth communication as well as the content of such communication. **Valsesia, Nunes and Ordanini** focus on online consumer ratings by examining how the number of previous ratings posted for a given product influences the ratings and reviews it receives. They show how the number of ratings already posted for a product influences future reviews due to feelings of psychological ownership for those who come first. **Ilhan, Pauwels, and Kuebler** investigate how fans of a brand interact with the social media ecosystem of rival brands and their fans (e.g., Samsung fans visiting Apple's Facebook page to spoof Apple). The authors define this interactive, intercommunal, and inter-brand practice as 'Dancing with the Enemy' (DwE) and show how it is a behavioral manifestation of rival brand engagement in social media. They study the types, triggers, and consequences of DwE through a multi-method study combining netnography, content, sentiment, and time-series analysis.

The second two papers look at how social factors influence the receiver' reaction to word of mouth communication and their reaction to WOM communication. **Ordabayeva, Cavanaugh and Dahl** look at the receivers of online product reviews to show how negative reviews can sometimes actually be good for brands. They find negative reviews from low- (vs. high-) status reviewers motivate consumers to distance themselves from reviewers perceived as different in status. Social distancing causes negative reviews from low-status reviewers to be less detrimental, albeit the effect is moderated by the consumer's own status. Finally, **Bastos and Moore** look at factors that can increase feelings of social connection in word of mouth communication for the receivers of the content. They show that hearing about others' experiential purchases makes consumers happier than hearing about others' material purchases. They find the effect is mediated by perceived conversation substantiveness, which in turn increases feeling of social connection with the initiator of the communication.

Taken together, this research sheds new light on how social factors influence the decision to initiate word of mouth communication, as well as the reactions of the receivers of such communication. The authors in this session utilize an array of methodological approaches (ranging from laboratory experiments to content analysis and the analysis of secondary data). We expect the session to generate interest among researchers studying both online and offline word of mouth, social influence and social judgment, as well as consumer decision-making.

I Got Here First! Feelings of Psychological Ownership and Consumer Ratings

EXTENDED ABSTRACT

The rating website Yelp.com confers special status to the first individual who reviews a business on the site. Not only will the reviewer see the number of "Firsts" grow on his or her profile page, but so will other reviewers. Further, first reviews contribute to his or her chances of becoming an "Elite Reviewer," and the reviewer's identifying information (username) will appear prominently on the business' page under the tag "first to review." One obvious motivation for Yelp to introduce this type of incentive resides in its competitive strategy aimed at increasing market coverage. However, the motivation for reviewers – why they care about being the first to rate a business – is less clear.

Previous literature has argued that late reviewers might be discouraged to review a product online if they see a high number of previous ratings, because they might feel they have nothing new to add to the conversation (Wu and Huberman 2008). Moreover, the first individuals to review a product online can often times be qualitatively different compared to late reviewers in their levels of engagement towards the product (Li and Hitt 2008, Godes and Silva 2012). In this paper we argue that being among the first to review a product or service can actually influence *how* an individual feels about the product and hence his or her ratings and reviews. We show reviewers who rate a business early (versus late) are generally more positive due to a tendency to become psychologically attached to businesses for which they can lay claim to being early adopters.

This research is the first to document how consumers who rate products and services online will have a differential feeling of psychological ownership towards the product or service (a distinct type of ownership, which is independent of legal ownership, see Pierce et al. 2003) depending on how many people have evaluated the product previously. More specifically, we show that consumers who are early to rate a product online will have a greater sense of ownership towards the product compared to those who see that many other consumers have already rated product. This is consistent with findings suggesting consumers have a more positive attitude towards products they own (Heider 1958, Beggan 1992) as well as a greater desire to generate positive word of mouth about such products (De Angelis et al 2012). Consequently, we expect reviewers who are among the first to rate a product to be more positive in their ratings and reviews compared to late raters and we expect this effect to depend on their sense of psychological ownership towards the product or service.

Five laboratory studies provide initial evidence in support of the proposed causal mechanism. Study 1 tests whether individuals do in fact systematically provide higher ratings when they are "early" to review a product as opposed to "late." We find that two hundred and seventy-eight students instructed to rate a video provide higher ratings if they thought only 2, as opposed to 100, other students had rated the video before them (M_{Low}=9.29 vs. M_{High}=8.95, $F(1,274)$=5.38, p=.02).

In study 2, we asked three hundred and eighty-three respondents to rate the work of two contemporary photographers. Each respondent rated the work of one photographer as an "early" reviewer and the other as a "late" reviewer (the order in which they did so was counterbalanced). We find ratings to be higher when respondents believed they were early reviewers (β=.17, p<.01). Moreover, we find our effect to be driven by feelings of psychological ownership. Respondents felt they had more ownership towards the work of an artist they were early to rate (β=.16, p=.02) and this influenced their evaluation of the work ($\beta_{INDIRECT\ EFFECT}$=0.05, 95% CI: 0.01, 0.10).

In study 3 we found our effect held even when respondents were told they were *not* responsible for discovering the product. We asked two-hundred and forty-two college students to imagine they had found a YouTube video that they really liked. The video had either 3 or 325,000 "likes". We find that respondents felt greater ownership towards the video if only three people "liked" it before them (M_{Early}=3.34 vs M_{Late}=2.77, $F(1,238)$=4.67, p=.03). Moreover, they were significantly more likely to "like" the video themselves (M_{Early}=4.59 vs M_{Late}=3.88, $F(1,238)$=4.60, p=.03) and this effect was driven by the higher feeling of psychological ownership ($\beta_{INDIRECT\ EFFECT}$=0.24, 95% CI=0.04 0.53).

Next, in study 4 we introduce an important moderator of our effect. One-hundred and seventy-seven college students listened to one of two songs, pre-tested to be either liked or disliked by this population (Valence: Positive vs Negative). They were told that the song came from a music website where it had been rated either two or 252 times. We find respondents have a greater feeling of ownership if they listen to a song that has been rated only twice, as opposed to 252 times. Yet, this happens only if they listen to a positive song (M_{Low}=4.61 vs. M_{High}=3.47, $F(1,173)$=7.69, p<.01) and not when they listened to a negative song (M_{Low}=2.26 vs. M_{High}=2.67, $F(1,173)$=1.14, p=.29, $F_{Interaction}(1,173)$=7.53, p<.01). Once again, feelings of psychological ownership have a positive influence on the song's ratings, but only if the song had a positive valence ($\beta_{INDIRECT\ EFFECT}$=.71, 95% CI=0.07 1.41).

Finally, in study 5 we dig deeper into the process. We asked one-hundred and ninety students to read about a hypothetical experience they had at a restaurant and told them they had decided to review it on Yelp. We replicate our effect and also show that feelings of psychological ownership towards a restaurant that respondents were early (as opposed to late) to review were driven by a heightened sense of control over the destiny of the restaurant ($\beta_{INDIRECT\ EFFECT}$=.03, 95% CI=0.00 0.07).

Taken together, the results suggest one reason why consumer ratings tend to decline over time is a decreasing sense of ownership among reviewers given more people have rated the product before them. Such systematic influences on reviews are important to understand for both the review sites (e.g., Yelp) and consumers who utilize these sites.

Dancing with the Enemy: Dynamics, Drivers, and Outcomes of Rival Brand Engagement

EXTENDED ABSTRACT

Have you ever felt the desire to spar with the fans of the opposing team, whether in sports, politics, or in other arenas? Have you ever acted on this desire, for example, like some Samsung fans who travel to Apple's Facebook page to slam Apple's new products? In the Apple-Samsung brand rivalry, Samsung fans' interaction with the "enemy" Apple brand and its fans at Apple's Facebook site reveal a new type of social media practice propelled by the eminent brand rivalry and by the connected consumers of the digital age who can easily access a number of platforms and connect with other consumers to express their likes, dislikes, and their fanaticism. When it comes to engagement among rivals, it's not only technology brands like Apple and Samsung that garner fervent fans. We see it in consumer brands (e.g., Coca Cola versus Pepsi, Colgate versus Crest), presidential candidates (Hillary Clinton vs Bernie Sanders), sports apparel (Nike versus Adidas), and entertainment products (Xbox versus PlayStation). Our study is driven by real-life observations that fans of a brand engage and interact with the social media ecosystem – touchpoints and fans – of the rival brands, a practice we refer to as "dancing with the enemy" (DwE). As social media increasingly mediates the consumer-brand relations, these interbrand and intercommunal practices become common for consumers while providing immense opportunities for brand managers to respond to the competition, influence the rival brand's customers, and amplify the brands' WOM. Our study is guided by the following research questions: 1) How do consumers engage with the rival brands and rival brand communities in social media? (2) What are the dynamics of rival brand engagement? (3) What are the drivers and consequences of rival-brand engagement?

Consumer engagement has been defined as a positively valenced consumer state "that occurs by virtue of interactive, co-creative customer experiences *with a focal agent/object (e.g. a brand)*" (Brodie et al. 2011, 260, emphasis added). Likewise in practice, social-media marketing and digital brand-management efforts are limited to managing, measuring, and facilitating engagement with company-owned or operated social media accounts on Facebook, Instagram, LinkedIn, or Twitter (e.g., Rooderkerk and Pauwels 2016). The brand-specific focus of academics and managers alike ignores consumers' interaction with the rival brands. Although previous studies have identified competitors and competitive actions as a possible "strong contextual forces affecting customer engagement" (van Doorn et al. 2010, p. 258), these cross-competitive effects, their potential dynamics, and outcomes on customer engagement behavior have not yet been explored.

Before the advent of social media, marketing literature studied consumers' relation with the rival brands mostly from the transactional perspective of purchase loyalty (e.g., Hotelling 1929) or with a relationship-marketing lens (e.g., Fournier 1998). Those studying popular-brand communities identified oppositional loyalty as a collective communal attitude that dictates consumer's interaction with rival brands and enforces we-ness in the specific brand community (Muñiz and O'Guinn 2001). Building on the existing approaches of engaging with rival brands, we introduce a quad model that offers a new conceptualization of rival-brand engagement in social media that incorporates rival brands and their communities. Our analysis takes a quadratic approach that goes beyond the dyadic approach (consumer-brand) of loyalty and relationship studies and the triadic approach (consumer-consumer-brand) of the brand community lit-

erature and allows for an interdependent and synergistic conceptualization of rival-brand engagement in social media.

Our multimethod and multicontext study identifies rival-brand contexts that are likely to induce DwE behavior and that display varying degrees of polarization between rival brands operating in different duopolistic markets. We collect data from the main rival brands in mobile phone technology (Apple-Samsung), carbonated beverages (Coke-Pepsi), fast food (McDonald's-Burger King) toothpaste (Crest-Colgate), and sports apparel (Nike-Adidas). We draw on several years of data from the official Facebook pages of each brand.

Through our qualitative analysis, we distinguish three types of DwE: (a) *across*, fans interacting with the social media of both brands in the dyad (b) *discourse*, rival brand fans communicating their thoughts through words on the central brand's social media; and (c) *ripple*, central brand fans reacting to rival brand fan's posts and words on the central brand's social media. Consistent across the studied brands, the results show that DwE occurs for 3.35% of all posts, indicating that our operationalization is distinctive. DwE Across involves 1.45% of all posts, clearly demonstrating the migratory behavior. In each analyzed industry, we observe that rival brand fans migrate and post negative comments on the Facebook page of the focal. Moreover, we note that the % of DwE is the smallest among high-tech brands (e.g. 1.10% and 1.30% for Apple and Samsung, given the higher amount of technical questions and answers), medium for fast moving consumer goods and highest for products associated with competition, such as Nike (6.10%). This aligns with our expectations and implies that DwE is even more prominent in winner-takes-all polarized competition such as rivaling sport teams (e.g. UCLA vs. USC) and in politics (e.g., Hillary-Bernie).

Time series analysis reveals that, for each brand, DwE Ripple is driven by both DwE Across and DwE Within. We find that *DwE is a substantial dynamic driver of both Volume and Valence* metrics of engagement. At the same time, these brand triggers (mostly marketing actions) do drive DwE activity, offering managers concrete levers to pull if it is desirable to increase DwE. DwE activity can be influenced by variables (largely) under managerial control.

In sum, our finding that the fans of a rival brand can positively impact the brand performance of the brands in a brand rivalry broadens the academic understanding of engagement and enriches our understanding of the dynamics of WOM. Existing social-media performance metrics are losing their significance, especially for product categories that are dominated by two major players. Going beyond the commonly adopted war analogies of rivalry, our study illustrates that competition in the dynamic, multichannel, social, and interdependent digital brand landscape is not a zero sum-game, particularly for rival brands that can benefit from collaborative and synergistic approaches to competition.

Social Distance in Online Reviews: When Negative Reviews Prove Positive for Brands

EXTENDED ABSTRACT

Prior research suggests that negative reviews generally have pervasive detrimental effects for product perceptions and sales (Chevalier & Mayzlin, 2006; Goldenberg et al, 2007). This is because negative information is considered to be more diagnostic than positive information (Herr, Kardes & Kim, 1991; Skowronski & Carlston, 1987). However, this literature has overlooked the fact that negative information or product feedback might also be perceived as threatening, especially when it is perceived as highly relevant to the self (Tajfel & Turner, 1986). Since many brands and products are highly relevant to consumer identity (Belk, 1988), negative information about such products, just like negative information about the self, may be perceived as a self-threat. We therefore propose that, under certain conditions, negative reviews of identity relevant products can be positive for brands. Our work expands the literature on the curious effects of negative reviews (Berger, Sorensen & Rasmussen, 2010). It also examines the previously overlooked effects of reviewers' and consumers' status in facilitating this phenomenon.

We predict that when brands and products are highly relevant to consumers' identity, a negative review of such a product will be perceived as threatening, and it will motivate consumers to look for ways to distance themselves from the negative (but not positive) information. As a result, a negative review will have less detrimental consequences for products following the negative comments of a socially distant reviewer. Consumers' perceptions of their own status will further determine reactions to low-status and high-status reviewers: high-status consumers will perceive greater distance with a low-status negative reviewer, while low-status consumers will perceive greater distance with a high-status negative reviewer, leading to the opposite effects of a negative reviewer's status on purchase intentions. Provided the central role that identity threat plays in facilitating the effects of negative information, the hypothesized effects will only emerge when the product is relevant to consumers' identity. Three studies test these predictions.

Study 1 (N=253) employed a 2 product review valence (positive/ negative) x 2 reviewer status (low/ high) between-subjects design to examine consumer responses to an identity-relevant product (Apple Watch). Drawing on the fact that social status is often reflected in individuals' use of language arising from developmental and educational differences (Fernald, Marchman & Weisleder, 2013), status was manipulated by adjusting language (i.e., grammar) within the review. We manipulated the valence of the review to feature either a 5-star product rating with positive comments (and hence non-threatening), or 1 out of 5 star rating with negative comments (and hence more threatening). The review length and product features covered were held constant across conditions. Participants were asked to indicate purchase intentions and perceived similarity (i.e., distance) with the reviewer.

Results revealed that purchase intentions were generally higher after positive (vs. negative reviews and after low-status (vs. high-status) reviewers. However, these main effects were qualified by a significant valence × reviewer status interaction ($F(1,249)=5.10$, $p=.025$). Whereas the status of the reviewer did not influence purchase intentions for positive reviews, purchase intentions were higher after negative reviews written by low-status reviewers rather than high-status reviewers. Perceived similarity ratings revealed an identical pattern of results: participants distanced themselves more from the low-status (vs. high-status) reviewer but only when reviews were negative. Perceived distance mediated the effect of the valence × reviewer status interaction on purchase intentions.

Study 2 (N=140) tested the moderating role of consumer status and product identity relevance using a 2 product identity relevance (manipulated: high/ low) x 2 reviewer status (manipulated: low/ high) x consumer status (measured: low/ high). Lab participants read descriptions and negative reviews of the same web series (i.e., episodic scripted videos released on the Internet) written and produced by students at the same university (high identity relevance) or by students at another university (low identity relevance). They then indicated their interest in each series and assessed their own status.

Results revealed a negative marginal effect of reviewer status (product interest was higher after a low-status than a high-status reviewer), which was qualified by a significant three-way reviewer status × product identity relevance × consumer status interaction

(b=-1.45, p=.001). Reviewer status and consumer status did not significantly change interest in identity-*ir*relevant series. However, for identity-relevant series, high-status consumers distanced themselves more and expressed greater interest in the series following the negative review by low-status (vs. high-status) reviewers, while low-status consumers distanced themselves more and expressed greater interest following the negative review by high-status (vs. low-status) reviewers.

To enhance generalizability, Study 3 manipulated consumer status and manipulated reviewer status differently. ***Study 3*** (N=121) consisted of a 2 consumer status (high/ low) x 2 reviewer status (high/ low) between subjects. Drawing on Galinsky, Gruenfeld and Magee (2003), participants recalled a time when they had higher (vs. lower) status (defined as a social and a financial position) than people around them. Next, all participants read negative reviews. We manipulated reviewer status by providing a short profile of the reviewer including their occupation (vice president vs. receptionist), education (Ivy League vs. community college) and wardrobe staple (Prada vs. Payless shoes). A pre-test verified that the high-status profile created significantly higher perceptions of the reviewer's social status than the low-status profile.

Results revealed a significant two-way consumer status × reviewer status interaction (b=.81, p=.002). From the viewpoint of a high-status consumer, a product was perceived to be more attractive if the negative review originated from a low-status rather than a high-status reviewer. However, from the viewpoint of a low-status consumer, a product was perceived to be more attractive if the negative review originated from a high-status rather than a low-status reviewer.

Taken together, our findings demonstrate that negative online reviews are not always detrimental for the reputation of brands and sales of products. Rather, when brands and products are identity relevant, consumers seek to defend them from negative information, particularly when this information comes from sources perceived as socially distant. Hence, the interplay of reviewer status and consumer status is important to managing and understanding the impact of negative reviews.

The Broader Scope of the Experience Superiority—Just Listen!

EXTENDED ABSTRACT

Experiences advance more happiness than objects (Van Boven and Gilovich 2003), and we now know an array of reasons for and boundary conditions of this experiential superiority (e.g., Nicolao et al. 2009). Of note, this thriving field has focused solely on the person making the purchase, so, what we do not yet know is whether the experiential superiority can manifest outside of the actual purchaser's realm. The present work broadens the scope of this research stream and investigates whether the experiential superiority reaches people in other situations. A situation when we are exposed to purchases without necessarily being purchasers ourselves is when we participate in conversations and listen to others share about their own experiences and objects. Does listening to others share about their experiences versus objects bring us different levels of happiness? If so, why?

Looking at the listener, we demonstrate that the superiority of experiential (vs. material) purchases also manifests in people who did not make the purchase and whose only link to it is a conversation. Moreover, we identify a two-step serial mechanism that underlies this effect: conversation substantiveness and social connection (see figure). We conceptualize conversation substantiveness as an involv-

ing conversation where meaningful information is transmitted (Mehl et al. 2010); and social connection as "a person's subjective sense of having close and positively experienced relationships with others in the social world." (Seppala et al. 2013, 412).

Supporting the first pathway, research indicates that experiential purchases are closer to a person's self (Carter and Gilovich 2012), making them particularly suitable for self-narratives. Additionally, conversations about experiences (vs. objects) have a typical narrative structure with a beginning, a middle, and an end (Van Boven and Gilovich 2003), allowing for captivating storytelling and, consequently, a more involving interaction between conversation partners.

In line with the second pathway, research suggests that sharing substantive information is a critical component for the very formation of social relationships (Jourard 1971). This perspective is consistent with social penetration theory, holding that interpersonal relationships improve as individuals share continuously deeper information (Altman and Taylor 1973). By the same reasoning, experience-related conversations carrying higher levels of substantive information appear particularly favorable to social bonding.

In support of the third and final pathway, social connections are one of the most important factors in the cultivation of happiness (Argyle and Lu 1990). In fact, past evidence suggests that healthy social connections are a necessary factor for happiness (Diener and Seligman 2002).

We test these relationships across 3 studies which involve actual, recalled, and hypothetical conversations.

Experiment 1 used a between-subjects design to test the social connection link. Seventy-four participants were randomly assigned to the role of either a teller or a listener. Next, each group was taken to a separate conference room. In the tellers' conference room, participants were given a questionnaire that asked them to recall and write about a previous material or experiential purchase they had made. Next, the questionnaire instructed the tellers about the upcoming sharing activity. In general, they were asked to share about the purchase as they normally would with a friend.

Simultaneously, in a separate conference room, listeners were instructed about the upcoming sharing activity. In general, they were asked to listen to the teller and react as they would in a normal conversation with a friend.

Next, tellers and listeners rejoined and formed pairs of one teller and one listener. Then, each pair went into an individual room. Before starting the sharing activity, they engaged in a two-minute ice-breaking activity designed to get them familiar with each other and acclimated with the idea of conversing. Finally, they begun sharing.

Upon the end of the sharing activity, tellers and listeners returned to their initial conference rooms. Listeners answered 7-point scales (1=Not at all; 7=Very much) designed to assess happiness (How much happiness did you draw from listening about that purchase?), and social connection (e.g., How likely is it that you could be friends with this person?).

As expected, experiential listeners reported greater happiness (M=4.65, SD=1.66 vs. M=3.59, SD=1.41, F(1,36)=4.28, p=.046); and this effect is mediated by their perception of having built a stronger bond with their conversation partner (indirect effect: β=.64, SE=.31, CI(95%)=.07,1.34), confirming the explaining role of social connection.

In experiment 2, we tested the replicability of experiment 1's finding and, importantly, examined our model in its entirety.

Sixty-one Mturk participants were asked to recall and write about a time when someone shared with them about either objects or experiences. Next, participants answered a two-item measure on substantiveness (e.g., "The topics of our conversation were involv-

ing." r=.587), an extended five-item measure on social connection (α=.916), and an extended four-item measure on listener happiness (α=.974).

Results confirmed that participants gained more happiness from conversations about experiences (M_{exp}=4.94, SD=1.86 vs. M_{obj}=3.62, SD=1.89, $F(1,59)$=6.86, p=.011), and that the serial mechanism via substantiveness and social connection (PROCESS, model 6) accounts for that effect (β=.50, SE=.22, CI(95%)=.16,1.05).

Study 3 employed a different approach to reexamine our model while addressing potential concerns associated with recall-biases and comparisons between objects and experiences that may be deemed incompatible.

Using a framing procedure, experiment 3 instructed 100 Mturk participants to read a text that had supposedly been written by another Mturk person sharing about her/his BBQ grill. The text focused on either the material or experiential aspects of the grill. After reading it, participants were asked to write what they thought the rest of the conversation would be like (a task designed to increase participant engagement in the conversation). Following, they answered the same measures as in experiment 2 on substantiveness (r=.818), social connection (α=.959), and happiness (α=.969).

Results show higher happiness from conversations focusing on the experiential (M=4.04, SD=1.77) than the material properties of the BBQ grill (M=3.31, SD=1.79, $F(1,98)$=4.22, p=.042); an effect serially mediated by substantiveness and social connection (indirect effect: β=.31, SE=.14, CI(95%)=.08,.65).

Together, findings from experiments 1-3 support the following conclusions: Listeners of experiential sharing gain more happiness from the interaction than do listeners of material sharing; and conversation substantiveness and social connection sequentially mediate that effect. This research shows that the scope of experiential purchases' superiority is wider than previously known.

SESSION OVERVIEW

The interplay among politics, markets, and consumption is of increasing interest to consumer researchers. One stream of past research has looked at how commercialism tends to have depoliticizing effects, transforming political movements and ideas into commodities, Consider, for example, the study on countercultural co-optation in the context of the organic food movement (Thompson and Coskuner-Balli 2007), the work on resistance through cathartic festivals like Burning Man that ultimately supports the market system (Kozinets 2002) or the critical perspective on green marketing (Giesler and Veresiu 2014). Another stream has focused on how consumer groups politicize brands in order to galvanize political resistance (e.g., Holt 2002; Kozinets and Handelman 2004; Izberk-Bilgin 2012; Sandlin and Callahan 2009; Varman and Belk 2009).

However, what remains understudied in this canon is the way in which the markets that situate brands and consumer practices are themselves shaped by political discourses and conflicts, especially neoliberal ones. The purpose of this special session is to elucidate these relationships, which we refer to as the politicization of markets. The session brings together four studies that blend historical analyses of different market systems (and their distinctive institutional characteristics) with insights into how market actors (consumers, producers, institutions, administrators, politicians, popular culture) interpret and shape each system and their actions within it. Thus, the works in this special session seek to collectively unpack the politicization of markets at the nexus of macro-level processes, marketplace resources and micro-level actions and interpretations.

In detail, Veresiu and Giesler begin by presenting an institutional analysis of political mythmaking in Canada to illustrate market-based multiculturation strategies through which market and political institutions collaborate in the creation of an ethnic consumer subject. Next, Hartmann, Brunk, and Giesler mobilize the context of the po-

litical re-unification between West and East Germany to elucidate how the market for East-German retro brands is shaped by the underlying political conflict between capitalism and socialism. Third, Bjerregaard and Kjeldgaard unfold the discursive formation of a global market for welfare services in the context of Danish eldercare export to China and discuss how this discursive formation and its mythical resources are embedded in wider ideological tensions over the legitimacy of pervasive welfare states. By using the context of the Slow Food movement, Thompson and Kumar will lastly illuminate the continuities and discontinuities that arise as food political discourses are transposed onto different institutional fields and intersect with other discursive systems.

This session is timely because it expands previous perspectives and conceptualizations on various politicized aspects within markets. Thus, the session is particularly relevant for consumer researchers interested in understanding the deeply-rooted politicized and politicizing nature of markets and how this in turn shapes and contours individual consumer actions and interpretations. The session informs theoretical debates on commercial and consumer mythmaking, as well as the formation and shaping of new markets and consumer subjectivities.

Market-Mediated Multiculturation: The Institutional Shaping of the Ethnic Consumer Subject

EXTENDED ABSTRACT

In the current global climate characterized by increased population mobility, ethnic consumers have become a central concern for consumer researchers. Prior research has investigated the consumer behaviour of African-Americans, Latinos, and Native Americans in the U.S. (e.g., Crocket and Wallendorf 2004; Deshpande, Hoyer, Donthu 1986; Sexton 1972; Shim and Gehrt 1996; Stayman and Deshpande 1989; Wallendorf and Reilly 1983), followed by consumer acculturation agents and outcomes of various (im)migrants in different parts of the world (e.g., Askegaard, Arnould and Kjeldgaard 2005; Chytkova 2011; Dion, Sitz, and Remy 2011; Hu, Whittler and Tian 2013; Jafari and Goulding 2008; Oswald 1999; Penaloza 1994; Üstüner and Holt 2007; Vihalemm and Keller 2011), and most recently, even indigene consumers' responses to immigrant consumer behaviour (Luedicke 2015). However, according to Askegaard and Özçaglar-Toulouse (2011, 220), "while many studies have highlighted the socio-historic structure of ethnicity, little research really focuses on the interactions between individuals, groups (ethnic and non-ethnic groups), and institutions." Hence, by focusing on the lived experiences of different ethnic groups, this body of literature has yet to understand how and why an ethnic consumer subject is created in the first place.

Rather than prioritizing the experiences of individual consumers (Askegaard and Linnet 2011), this paper focuses on understanding the institutional shaping of an ethnic consumer subject. This is a great concern given that "[in] many countries, migration and ethnic diversity represent major challenges at the dawn of the twenty-first century, dividing opinions and assessment between the extremes of multicultural enrichment and the threat to local identities" (Askegaard and Özçaglar-Toulouse 2011, 217). Furthermore, although Zhao and Belk (2008, 241) aptly note that "[t]hroughout history,

consumption has seldom existed outside politics, […] and the state has been actively involved in the definition and representation of consumers," few studies have unpacked the relationship between the state, institutions, ethnicity, and consumption in greater empirical detail.

In pursuing this increasingly important research imperative, we turn to the sociology of governmentality. According to Michel Foucault (2001, 241), governmentality represents "[t]he ensemble formed by the institutions, procedures, analyses and reflections, the calculations and tactics that allow the exercise of this very specific albeit complex form of power, which has as its target population, as its principal form of knowledge political economy, and as its essential technical means apparatuses of security." In other words, governmentality can be understood as a process for managing populations through which the shaping role of institutions operates. One such mode of governmentality is neoliberal multiculturalism (Hale 2005; Kymlicka 2013; Mitchell 2004). According to Kymlicka (2013, 109), "neoliberal multiculturalism is the belief that ethnic identities and attachments can be assets to market actors and hence that they can legitimately be supported by the neoliberal state." Hence, when neoliberal multiculturalism is understood as a market-mediated mode of governmentality, intuitions may create ethnic consumer subject positions to manage increasingly diverse populations through the market and consumption.

In this paper, we build on the notion of neoliberal multiculturalism, as well as our institutional analysis of Canada's multicultural marketplace to introduce the concept of market-mediated multiculturation. We define market-mediated multiculturation as a fourfold process of consumer socialization through which an ethnic consumer subject is created in order to manage increased population diversity by means of consumption and ensure a nation's economic success. Based on our multiyear analysis of the Canadian marketplace, which includes both institutional and consumer data, we find that market-mediated multiculturation takes the shape of four interrelated processes: inception, identification, proliferation, and adoption.

During the first phase of inception, institutional and political actors envision an ideal citizen-type in the form of an ethnic consuming subject. This phase is triggered by different minority groups' public crises of legitimacy. During the second phase of identification, industry leaders, analysis, and other business professionals create measures, analyze data, and publish reports on who the ethnic consumer actually is. In this third phase, both public and private institutions proliferate ethnic consumers in the arts, entertainment, media, and other cultural creative spheres. Finally, in the last phase, which we term adoption, indigene and immigrant individuals alike adopt their prescribed ethnic consumer position by engaging with different ethnic products, services, and experiences. During the adoption phase, individuals internalize the idea that ethnic tensions and crises of group legitimacy can best be solved through market forces by naturalizing that their ethnic identity is best expressed through their consumption choices.

Our study contributes to extant scholarship on ethnic consumers, consumer subject formation, and the role of neoliberalism in shaping markets and consumers. First, while past work has looked at how ethnic individuals experience the marketplace (e.g., see Luedicke 2011 for an overview), we highlight how institutions shape this ethnic consumer experience. As such, we also contribute to the literature investigating consumer subject formation (Cayla and Eckhard 2008; Giesler and Veresiu 2014; Karababa and Ger 2011; Moisander and Eriksson 2006). This emergent stream of research has not yet investigated the relationship among consumption, ethnicity, and multicultural ideologies, which our study unpacks. Finally, we

extend the literature on neoliberalism and consumption (Askegaard and Linnet 2011; Bonsu and Polsa 2011; Giesler and Veresiu 2014; Shankar, Cherrier, and Canniford 2006; Zwick, Bonsu, and Darmody 2008) by developing a theorization that explains how the neoliberal political ideology of multiculturalism influences citizens' consumer behaviour.

Brand Retrofication: How East German Consumers Animate a Retro Brand Market to Create a Revisionist Eastern Consumption Culture

EXTENDED ABSTRACT

How and why do retro brand markets emerge? Consumer and marketing researchers have shown increasing interest in the rise of retro brands defined as 'relaunched historical brands with updated features' (Brown, Sherry, and Kozinets 2003a p.19). Previous studies in this area portray the emergence of retro brands primarily as a marketer-driven process. For example, Brown, Sherry and Kozinets (2003b) investigate the pre-requisites for retro brand re-launch and elucidate brand meaning negotiations through which producers and consumers invest retro brands with meanings of authenticity, enchantment, and paradox (Brown, Sherry, Kozinets 2003a).

Although Brown (1999) suspects that, sociologically, the rise of retro brands can be explained with Davis's (1979) nostalgic ethos prevalent in societies undergoing turbulence and transformation, thus creating desires to consume bygone brands as symbolic restoration of a past condition, relatively little is known about how retro markets emerge within and are shaped by larger socio-political trajectories and related ideological tensions. While Thompson and Tian (2008) highlight the role of diverging ideological aims of commercial mythmakers creating competing reconstructions of the American South, and Brown McDonagh, and Shultz (2013) emphasize the role of mythic underpinnings in retro phenomena, the particularities through which consumers mobilize retro brands to serve their ideological aims remains a theoretical mystery. Thus, in this study we ask: how are retro brand markets animated by consumers as a mechanism serving ideological interests? We bring sociological theories of popular memory/countermemory (Foucault 1977; Lipsitz 1990; Thompson and Tian, 2008) and cultural branding to bear on an in-depth analysis of consumers' brand narratives to introduce the concept of brand retrofication as a market-based mechanism through which consumers imbue suppressed market objects from the past with identity significance, thereby animating these brands to potent, in-demand retro brands serving consumers' ideological aims.

To explore these issues, our finished fieldwork leverages the context of the rise of retro brand consumption after Germany's political re-unification, previously a microcosm of geopolitical order (Boyer 2001). Since the end of WW2, the subsequent division of Germany by the Allied Forces into a Western and an Eastern occupation zones—leading to the founding of the two German national states of FRG and GDR, respectively—heralded a specific mythic topology lending East and West Germany dualistic allegorical quality for the larger world views that governed them. While West Germany adhered to capitalist consumer culture, East Germany was characterized by a socialist consumer culture. Thus, consumption has in this context always been a strongly politicized point of competition between capitalist and socialist market ideologies (Merkel, 2006).

Since then, and from the viewpoint of the West, East Germany has been frequently portrayed as an economically, socially, and culturally desolate landscape, contrasting the free and prosperous West with the isolated and backwards GDR. Following the fall of The Berlin Wall, however, East Germans faced a situation of immediate ac-

cess to the desired Western consumption system, but also the instant wipe-out of East German brands and products, inducing inevitable processes of dealing with a neoliberal market system and a capitalist culture of consumption. Alongside these developments, the mythic contrast between East and West took a colonialist turn and provided a template for commentaries on pre-reunification and post-reunification conditions in the two consumer cultures.

In this climate, thriving East German retro brands emerge such as the GDR school kitchen tomato sauce, hotels re-creating the GDR experience, and various everyday GDR products like washing detergents, soft drinks, and snacks, some of which outrival their once-longed-for Western counterparts. Our empirical material collected in this context consists of East German consumer brand narratives collected through introspections and interviews (Brown 1998; Gould 1995; McCracken 1988), netnographic material (Kozinets 2002) collected in various online forums and communities dedicated to GDR brands, as well as historical and pop-cultural material allowing to historicize the rise of GDR retro brands (Brown et al. 2013).

After genealogically tracing the Mythic (German) East, we explore how Eastern German consumers' investment of redeeming meanings into products from the socialist past combats (Western) caricatures of the post-reunified East while creating commercially thriving retrobrands. Thus, we show how GDR retro brand consumption creates a Revisionist Eastern consumption culture by linking ideologically redeeming meanings to cultural and market objects from the past that can be readily mobilized by Eastern consumers to rebuke some of the disparagements perpetuated by stigmatizing political myth. A resulting market-mediated mechanism is the emergence of a retro brand market infused with and shaped by ideological agendas of East German consumers negotiating the dominant popular (Western) memory by creating (Eastern) countermemories.

Based on this, we develop a conceptual model of brand retrofication that highlights co-constitutive identity and retro branding relationships of commercial and political mythmaking. The concept of brand retrofication helps elucidating how and why retro brand markets emerge and foregrounds how retro brand markets are shaped by political ideology negotiations by consumers seeking to create symbolic shelters for (national) identity consumption as well as political and commercial mythmakers. This consumer-driven process of brand retrofication resurrects bygone market objects symbolizing the previous condition of a socialist consumer culture through mobilizing capitalist market mechanisms.

These findings have implications for theoretical debates on commercial mythmaking, retro branding, and national identity consumption. As for commercial mythmaking literatures, our study contributes by foregrounding consumers' ideological aims in co-constitution with commercial and political mythmakers vis-à-vis previous accounts of the ideological aims of commercial mythmakers in reconstructions of the past (Thompson and Tian, 2008). Our study informs retro branding literatures by firstly, how consumers animate retro brands to serve their ideological aims, complementing previous accounts of retro-brand animation serving marketer interests; and secondly, by foregrounding how in these animation processes, historical brands are not necessarily technologically updated by marketers as previously depicted, but rather undergo ideological updating by consumers whilst leaving other brand attributes preferably untouched. Our findings further contribute to literatures on national identity consumption by foregrounding its political dimensions.

Myth Market Formation and the Irony of Neoliberalism: Insights from the Export of Danish Eldercare to China

EXTENDED ABSTRACT

"The new bacon." These were the words employed by a politically leading Danish news media to describe the prospects of exporting Danish eldercare services to China (often referred to as *welfare export)* in a news article published in January 2014. The metaphoric reference to the commercial success of Denmark's long tradition for bacon exports highlights a culmination of past decades' marketization of Nordic welfare models. Here the process of marketization is no longer mobilizing a domestic reorganization of welfare systems alone. It is also seen to take on an outward orientation where public welfare services are discursively reframed as commodities and wishfully associated with a significant commercial potential on global markets.

In this paper we explore the dynamics illustrated above as a process of cultural commodification in a domain not historically associated with market logics, namely public welfare services. The empirical context is the idea of exporting 'Danish' eldercare services to an ageing Chinese society – an idea that was introduced to Danish stakeholders in 2011 with the launch of an export promotion program by the Danish Trade Council in China. While the program was abandoned within less than two years, the idea of exporting Danish eldercare to China had already gained a significant foothold in Danish public debate and had set in motion a series of other activities targeted to the emerging Chinese eldercare sector. We offer a study of the media representations related to this series of events with an analytical emphasis on the discursive framing of export activities and the tropes and metaphors (Lakoff and Johnson 1980) employed to give body and meaning to news stories and public debate.

Significant for the news coverage of the events related to the export of Danish eldercare to China is the general application of a somewhat premature market logic that serves as an overarching frame for the reporting of events. With its consistent emphasis on commercial potential and profit, this dominant market logic may be contrasted with representations of welfare export in the early 1990s where the overarching frame was guided by an altruistic logic prioritizing *helping* or *development* as main motives for export endeavors.

While the more recent prioritization of a commercial motive may be argued to reflect the pervasiveness of a neo-liberal ideology even in social democrat welfare states such as Denmark, the use of tropes and metaphors reveal a second layer in the media representations studied, namely the mythologization of the market for welfare services. This relates to the articulation of the Chinese market for eldercare through a global frontier myth echoing Applbaum's (2000) notion of globalization as a key cultural concept acting as "myth and charter" for transnational corporations' geographical expansion. In this sense, we see the Chinese market potential consistently referred to as an "export adventure," we see the demand assessed in (relative to Danish traditions) mythic proportions, and an urgency inferred with the emphasis on "seizing the opportunity."

Second – and more noteworthy, is the articulation of the market offering through the myth of Nordic welfare. This is seen in how the offering to be exported is often described in curiously ambiguous terms such as "welfare knowledge" or "warm welfare hands." And while referred to with barely concealed pride, the notion of welfare remains detached from its historical and political underpinnings (Barthes [1957] 2012). Discursively, the notion of welfare is thus treated as a depoliticized signifier but endowed with commercial potential that drives the welfare export endeavor.

Contemporary political tensions and issues (Holt 2004, Thompson 2004) are revealed, however, in how the Chinese market for Danish eldercare services is described by way of metaphors that derive from the domestic debate on the quality of the largely public Danish eldercare sector and the future viability of the extensive Danish welfare sector in general. In this way, it is seen how the projection of domestic issues onto a largely imagined international market serves to mediate and negotiate tensions at a national level concerning the role of the nation-state in a competitive global economic order. As such, we understand the mythic articulation of welfare services as a marketable offer, as a collective endeavor at national level that ties into popular memory (Thompson and Tian 2008) of the 'heroic' establishment and continuation of the welfare state. The idea of a global market thus serves as a mediator of national political tensions and becomes a catalyst for collective sense-making regarding the legitimacy and future viability of the extensive welfare system.

While the pervasiveness of the neo-liberal ideology has become a "truth" within both scholarship and popular discourse, few scholars have explored neo-liberalism as something more than an implicit background explanatory framework (Mudge 2008). In this paper we address this gap by discussing the relationships between state and market as it plays out in the context of Danish welfare exports. We find that the employment of neo-liberal principles does not necessarily mark out a one-way road to the diminishment of states in lieu of global markets.

Through the glorification of the market as the mediator of exchange between states, the legacy of a state's cultural and ideological history is mythologized and provided with a commercial value - it becomes a *brand*. Conversely, this articulation of the cultural ideology of the extensive welfare state in commercial terms is used for renewed legitimacy of such a state.

Neoliberalism is hence mobilized as a resource for a renewed legitimization of the welfare state in a globalized world. Neo-liberalism provides a discursive resource or framework for social discourses/practices that simultaneously take neo-liberalism to new heights and turn neo-liberalism on its head using neoliberal logics as a means to a non-neoliberal end.

Political Consumerism as Neoliberal Therapy: How An Actually Existing Neoliberalism Produces Entrepreneurial Passion

EXTENDED ABSTRACT

In recent years the politicization of markets has garnered much attention by marketing scholars. One research stream has focused on the depoliticizing effect of commercialism i.e., the transformation of political movements and ideas into commodities —for example in the work on countercultural co-optation (Zwick, Bonsu, and Darmody 2008) or perspectives on green marketing and agro-food movements that criticize them for promoting the idea that privatized and voluntary solutions to societal problems are preferable to collective organization, legal, political, and regulatory remedies (Guthman 2008; Soneryd and Uggla 2015). Another stream focuses on how activist groups politicize brands in order to galvanize political resistance (Izberk-Bilgin 2012). Within this stream of research, an understudied issue is how markets that situate brands and consumer practices are themselves shaped by political discourses and conflicts. Consumer research on the ideological shaping of consumer identities has recently begun to focus on the structuring influences exerted by neoliberal discourses (Askegaard and Linnet 2011; Binkley 2007; Bonsu and Polsa 2011; Fitchett, Patsiaouras, and Davies 2014; Giesler and Veresiu 2014; Shankar, Cherrier, and Canniford

2006; Zwick, Bonsu, and Darmody 2008; Zwick and Cayla 2010; Zwick and Ozalp 2010). However, these studies tend to analyze neoliberalism as a hegemonic ideology that instills a moralistic belief in consumers that broader societal problems can be resolved through socially responsibilized consumer choices, and in a more self-interested vein, that they can shield themselves from systemic risks through their dietary choices, self-care regimens, etc. (Giesler and Veresiu 2014; Moor 2010; Rose 2007). According to these critical readings, political consumerism (as an ostensible practice of consumer resistance) serves to more deeply ingrain neoliberal ideas and beliefs into the fabric of everyday life through the process of consumer responsibilization.

This interpretation, however, often fails to distinguish between neoliberal interpellations and discursive structures whose histories long predate the era of neoliberalism's pronounced socio-cultural influence on consumer responsibilization such as the Protestant work ethic and the myth of the self-made man, as well as overlook how these neoliberal discourses are re-embedded in contextualized marketplace cultures. Using the context of the Slow Food movement we trace out continuities and discontinuities that arose as discourses that emerged from Slow Food's historical grounding in radical leftist politics were transposed onto different institutional fields with their inherent socio-economic discrepancies and intersected with neoliberal discourses and a therapeutic market logic (Moisio and Beruchashvili 2010; Thompson 2003) as Slow Food became a global brand. We seek to understand the moralistic governance regimes (Foucault 2008) that shape the actions and interpretations of consumers and producers who are embedded in a Slow Food network.

This research is based on in-depth interviews with 19 participants of a North American Slow Food movement network and participant observation at Slow Food events over the course of twelve months. We draw on Foucault's analytic lens of governmentality. Rather than relying upon disciplinary means, modern modes of governance sought to organize the social field in which actions could be taken or to exert a directive influence upon the ways in which individuals construct themselves as social and ethical actors and concomitantly develop the authority to guide the conduct of others (Foucault 2008; Lemke 2001). Prior studies have tended to suggest that responsibilized consumers have been ideologically induced to act in accordance with neoliberal economic orthodoxies (e.g., Giesler and Veresiu 2014) and to see their personal interest as being aligned with the profit maximizing aims of corporate strategies. However, Foucault's concept of governmentality is a de facto critique of top-down, hegemonic accounts of ideological domination. Instead, it presents a topological, rather than hierarchical, conceptualization of power relations (Collier 2009). We adopt this topological orientation to study "actually existing neoliberalisms" (Brenner and Theodore 2002, 351).

By tracing the genealogy of Slow Food we find that its ideological origins are far removed from neoliberal doctrines and can be traced to its historical roots in radical Italian political movements and their suspicions of formal institutions and centralized decision making. As the Slow Food movement emerged from this political ferment (subsequently adapted to social changes that lessened popular support for more radical expressions of leftist politics), it began to promote the idea that consumers' could challenge and even disrupt capitalist imperatives, such as efficiency and instrumental assessments of value, by seeking out autonomous pleasures and self-valorizing activities, with food and eating providing a primary context for these acts of everyday resistance. Over time, Slow Food gradually placed a greater reliance on the market as a vehicle for social change such as creating fairer outcomes for workers and sus-

taining threatened culinary traditions, thereby linking consumption with particular neoliberal ideals of responsible citizenship. Rather than consumer responsibilization per se, our findings suggest that Slow Food practices and discourses enact a neoliberal ideal of passionate enterprise which creates an alignment between its members' communal identity, and its historical emphasis on the emancipatory potential of consumption pleasures created outside the auspices of capitalist rationalization, and neoliberalism's edifying vision of entrepreneurial skill building as a path to personal achievement and self-actualization. These invocations of passion need to be affirmed through the experiences of guiding others toward this construction of ethical selfhood. To sustain this alignment, reformulated therapeutic motifs are leveraged to legitimate these passionate engagements and to negate the elitist connotations, and latent sense of class conflict, which have long plagued the Slow Food movement.

This study contributes to the understanding of the heretofore undertheorized relationships among actual existing neoliberalisms, the governmental rationalities that operate through political consumerism and the ideological shaping of consumer identities. It highlights the contextualized processes of socio-economic and cultural restructuring that arise through the intersections among neoliberal discourses (and their normative prescriptions), different institutional fields and the particular histories of marketplace cultures. This topological view of neoliberal governmentalities also explicates how subtle, non-coercive power relations operate as technologies of the self as well as how actors gain or lose ethical authority through market-mediated social interactions and consumption practices.

SESSION OVERVIEW

Consumers regularly engage in creative thinking. For instance, consumers come up with unconventional ways to use existing possessions (Burroughs and Mick 2004), seek out purchases that enable creativity (Dahl and Moreau 2007), and play an active role in customizing new products (Moreau and Herd 2010). In addition, companies have recently been turning to consumers for creative insight, harnessing their creative ideas through online crowdsourcing platforms (Terwiesch and Xu 2008). Yet, in contrast to the importance and ubiquity of creative thinking in consumption, little research has investigated the mechanism of creative thinking. Specifically, what are the key motivational and cognitive processes underlying creativity?

The aim of this session is to contribute to this dialogue of what makes consumers creative and bring attention to this relatively underexplored topic that both consumers and companies value. We will begin with contextual elements of creativity—surroundings and color—and examine how these factors influence creative cognition. Then, we will shift our focus onto the motivational processes of creativity in the context of idea generation contests, examining the effect of goal-setting and social comparison (i.e., observing others' ideas) on creative performance.

First, Vohs, Labroo, and Dhar examine how environmental cues can influence creativity though environmental mimicry. In three experiments, they demonstrate that a messy room enhances three aspects of creative cognition: problem solving, divergent thinking, and convergent thinking. In the second paper, Youn, Shin, and Lee find that another environmental factor, color harmony, can impact not only creative production, but also the perception of creativity. Across six studies, they demonstrate that disharmonious color combinations induce processing disfluency, which activates abstract thinking, leading to improved performance on creativity tasks and intensified perceptions of innovativeness in product and logo evaluations. In the third paper, Brucks and Huang demonstrate that the pursuit of creativity in idea generation competitions could be counterproductive. Through three studies, they show that pursuing the goal to be creative reduces the number of creative ideas generated because the goal-directed monitoring process inhibits divergent thinking. Lastly,

Hofstetter et al. examine how seeing the ideas of others in innovation contests influences creative performance. Across four studies, including a field study using an actual open innovation platform, they demonstrate that seeing prior ideas from other users can facilitate creative performance or hamper creative performance, identifying competition salience as a key moderator.

Together, the four papers in the session enhance our understanding of when and why consumers are creative by capturing creativity in a variety of ways in the lab and in the field: from classic creativity paradigms (e.g., the remote association task, drawings, and insight problems) and perceptions of innovativeness to performance in open innovation contests. Collectively, these papers draw from a wide spectrum of literature including construal level theory, mimicry, goal-setting, self-efficacy, and competition to provide insight into the motivational and cognitive processes of creative thinking. By approaching creativity from different angles, methods, and literatures, we believe that this session will attract a broad audience, facilitate interesting discussions, and cultivate collaborations on topics related to consumer creativity.

The Upside of Messy Surroundings: Cueing Divergent Thinking, Problem Solving, and Increasing Creativity

EXTENDED ABSTRACT

Society frowns upon mess. Mess is presumed to reflect low productivity, income, education, and intellect (Abrahamson & Friedman, 2007). Messy people are stereotyped as uncivil, children are admonished for messiness, workplaces often mandate orderliness, and religions assert that cleanliness and orderliness are next to godliness (Abrahamson & Friedman, 2007). In this research, however, we argue for the upside of mess and propose that messy surroundings cue creative thinking.

There are reasons to believe that messiness and creativity are associated. Everyday language reflects a deep-rooted connection between mess and creativity. Creativity is associated with "outside the box" thinking (Leung et al., 2012), and considered literally, putting away things in a box organizes surroundings. Creativity is linked to wild imagination, and wild is is ambiguous, unpredictable, and flexible. So is mess.

A recent paper by Vohs, Redden, & Rahinel (2013) showed — in one study with a fairly small sample for today's requirements — that disorderly surroundings can make people break away from convention and increase novelty-related thoughts. Building on these findings, we posit messy environments cue all sorts of creative thinking. We tested our premise in three experiments.

Experiment 1 employed a 2 (room: messy vs. orderly) between-subjects design. Fifty-one students participated. Depending on condition, participants were placed in an area with neatly-ordered papers or disordered paper. Participants were provided with a puzzle allegedly being tested by marketers. This puzzle is comprised of two loops that are linked and needed to be unlinked. The best solution is to twist the links in disparate ways. Participants were timed completing the puzzle. A one-way ANOVA revealed the expected effect of condition, $F(1, 37) = 4.44$, $p < .05$. As predicted, participants were quicker to solve the puzzle when seated in messy (M = .93 minutes) rather than orderly surroundings (M = 2.22 minutes).

Experiment 2: A limitation of experiment 1 is that the task is not one conventionally used in creativity research. Moreover, this exper-

iment did not include a cleared (empty) room condition. It is possible that a cleared room encourages creativity just as much as a messy room. Accordingly, experiment 2 made two changes: we employed a standard test of creativity, and we included a cleared room condition which we expected would be similar to the orderly room condition.

Experiment 2 employed a 3 (room: cleared vs. messy vs. orderly) between-subjects design in which performance on the RAT served as the key dependent variable of interest. The cleared and orderly room conditions were expected to serve as conceptual replicates. Seventy-three students, native English speakers, participated. As in experiment 1, participants in the messy or orderly room conditions were seated individually in a workspace comprised of disordered or orderly papers and folders, respectively. In the cleared room condition, the area was clear.

Their task involved reading word-triads and listing a fourth word that connected to each word in the triad. For example, "body" is the solution to the triad, "soul, busy, and guard." Correct responses to each of the eight remote associates were tabulated into a creativity-index.

The results showed that, as expected, participants in the messy room performed significantly better relative to those in the cleared (M = .32), $t(39) = 2.08$, $p < .05$, or orderly room (M = .47), $t(49) = 1.89$, $p = .05$. In sum, participants in the messy room were more creative. Ancillary analyses (not reported due to word constraints) showed that distraction or distress were not issues that accounted for the results.

Experiment 3 employed a 3 (room: cleared vs. messy vs. orderly) between-subjects design testing creativity of spontaneous drawings. Sixty undergraduate students participated. Participants were randomly assigned to a clear, messy, or orderly condition. Participants drew, on paper, whatever spontaneously came to mind. We adapted Amabile's (1982) method of judging creativity, which was defined as "anything unexpected that produces effective surprise in the observer." Pictures were coded by two independent judges (1 = not at all, 5 = very), which were correlated, r = .68, $p < .01$, and averaged. An ANOVA revealed the expected effect of surroundings, $F(2, 57) = 13.17$, $p < .01$. As expected, pictures by participants in messy room (M = 3.63) were significantly more creative than those in clean (M = 2.17) or orderly rooms (M = 2.29), which did not differ.

General Discussion. People are hardwired to respond to environmental cues. Three studies found that messy surroundings resulted in more disparate and disorderly ideas, which increased creativity in a convergent creativity task, a puzzle, and picture drawing task. The effects were observed independent of mood or attention to task. They were also not a function of chronic messiness, but resulted from experiencing situational mess.

While people non-consciously mimic others in their social environments (Tanner et al., 2008), people also seem to mirror their environments in non-social situations, perhaps to better understand and navigate those environments. Thus messy surroundings, which are unpredictable, increase fresh creative thinking.

An interesting question is why people in messy surroundings assimilate thinking towards rather than away from creative cues. Extremely messy surroundings may create sensory overload and shut down thinking altogether, resulting in rejection of a contrast away from creative thinking. Future research should investigate these issues systematically.

The Creative Power of Color Harmony

EXTENDED ABSTRACT

While prior research focuses on the influence of color on creativity via the symbolic meaning that each color conveys (i.e., growth for green, and openness for blue; Lichtenfeld et al., 2012; Mehta & Zhu, 2009), the current research explores how color may influence creativity via an abstract thinking style that certain color combinations may evoke. We posit that exposure to moderately disharmonious (vs. harmonious or disharmonious) color combinations will result in a disfluent experience that induces abstract thinking (Alter & Oppenheimer, 2008, 2009; Mehta et al., 2012), leading to enhanced cognitive flexibility and creativity (Förster et al., 2004; Mehta et al., 2012). We defined harmonious, moderately disharmonious, and disharmonious color combination of any chosen colors using Moon and Spencer's (1944) theory of color harmony as applied to Munsell's (1919) color system.

The results of six studies provided support for our moderate disharmony hypothesis. In the first study, we compared moderately disharmonious color combinations with "proven" creative colors and showed that instructions printed on green or blue background color induce greater creativity in terms of generating ideas to protect the environment than red or gray, replicating prior research; but more importantly, moderately disharmonious combinations of blue and green lead to greater creativity than the single colors of blue and green.

Study 2 replicated the moderate color disharmony effect on insight problem solving as well as on the Remote Associates Test (RAT) designed to access creative performance. The results showed that participants' processing disfluency experience and their level of construal (BIF; Vallacher & Wegner, 1987) mediated the effect of color harmony on creativity.

In Study 3, we presented participants with a picture of an office, the walls of which were painted different colors, and asked them to imagine working in that office. Participants generated more creative ideas and perceived the company to be more innovative when situated in an office with moderately disharmonious (vs. harmonious or disharmonious) colors. Disfluency and abstract thinking again were shown to mediate the color harmony effect on creative idea generation and perception of company innovativeness.

Study 4 demonstrated the robustness of the color harmony effect in the context of a company logo. Participants judged the company with the moderate disharmonious (vs. harmonious and achromatic) color logo to be more innovative, and considered the logo to be more appropriate for an entertainment company; whereas they considered the company with the harmonious color logo to be more reliable and the logo was more appropriate for a bank.

Study 5 and 6 replicated the color harmony effect on product evaluation using the contexts of a computer mouse (Study 5) and a digital camera (Study 6). Further, the results of Study 6 showed that the color harmony effect carried over to actual behavior—those presented with a moderately disharmonious (vs. harmonious and disharmonious) color design of a camera were more likely to sign up to receive a catalog that provides more information on the camera.

Taken together, these findings provide convergent evidence for a color harmony effect on creativity. People exposed to moderate disharmonious color combinations were more creative; they also perceived environments (e.g., office) and targets (e.g., computer mouse, camera) with moderate disharmonious color designs to be more innovative. This effect is shown to be mediated by their processing disfluency experience that in turn activates an abstract, high level of construal.

The Pursuit of Creativity in Idea Generation Contests

EXTENDED ABSTRACT

Technological advances in the past ten years have provided easy access to consumer creative insight through online crowdsourcing. Platforms are sprouting all over the Internet enabling companies to create contests to solicit creative ideas from consumers. For example, Lay's recently held a "do us a flavor" contest, promising a $1,000,000 reward to the consumer with the most creative idea for a new chip flavor. The present research explores how pursuing a goal to be creative influences the creativity of the ideas generated in these contests.

Specifically, we propose that the pursuit of creativity can be counterproductive, leading to fewer creative ideas. We motivate our argument by drawing upon the literature of goal pursuit and early creative cognition. When consumers start generating new ideas, they engage in divergent thinking, wherein one must leverage the weak ties in memory and combine this retrieved knowledge into novel ideas (Mednick 1962; Burroughs, Moreau, and Mick 2015). Importantly, this means that divergent thinking is effortful and thrives on unfocused search, which can be inhibited by narrow thinking and judgment. Given that divergent thinking is effortful and that goal pursuit enhances motivation, compared to having no goal at all, pursuing a goal to be creative should enhance creative performance, as previous literature has shown (Shalley 1995). However, goal pursuit also engages a monitoring process that focuses attention on goal-directed behaviors and compares them to the standard set by the goal (Carver and Scheier 1982). We posit that this monitoring process hinders divergent thinking by narrowing attention and judging (blocking) early ideas against a specific and high standard of creativity. Thus, taking both effort and monitoring into consideration, we predict that in highly motivating contexts like idea generation competitions, introducing a specific and high standard to "be creative" will counterproductively reduce the number of creative ideas generated.

We conducted three studies to examine the effect of pursuing creativity on creative performance as well as the underlying mechanism. In Study 1, 152 participants competed in an idea generation contest to come up with alternative uses for a sunglasses case. Participants were randomly assigned to set either a creativity goal (i.e., "to win this competition, your task is to list as many CREATIVE uses for a sunglasses case as possible") or a quantity goal serving as the control group (i.e., "to win this competition, your task is to list as MANY uses for a sunglasses case as possible"); the quantity goal was similarly motivating but did not set a specific standard for the quality of ideas one should generate.

We followed procedures from prior literature on creativity (Friedman and Förster 2001; Vohs, Redden, and Rahinel 2013) to have two independent raters code and compute two dependent measures of creative performance—the number of ideas scoring above a high threshold on novelty (high novelty count) and both functionality and novelty (high creativity count). Participants who had the goal to be creative produced significantly fewer highly novel ideas (M=2.99 ideas) than participants with a quantity goal (M=3.55 ideas, p<.01).

If setting a goal to be creative is counterproductive because it engages a monitoring process that narrows attention, our hypothesized effect should be especially prevalent among people who are high on trait attentional regulation (i.e., high ability to focus). In Study 2, we replicated the effect in Study 1 with a different contest and tested the moderating role of trait attentional regulation. 201 participants first responded to an attentional regulation scale (Diehl,

Semegon, and Schwarzer 2006) embedded in filler scales and then competed in an idea generation contest to come up with names for a new Weather App. Replicating Study 1, we found that participants pursuing the goal to be creative came up with significantly fewer novel (M=6.26) and creative (M=3.11) ideas relative to the quantity condition (Ms=7.91 and 3.82, respectively, ps<.001). Importantly, this effect was moderated by trait attentional regulation (b = .08, z = 1.80, p = .07), such that the counterproductive effect of setting a creativity goal was significant among high attention regulators (trait regulation scores of 3 or above on 5-point scale), but not among low attention regulators.

We posit that the monitoring process hinders divergent thinking by narrowing attention to judge/block ideas using a specific and high standard of creativity. Study 3 directly manipulated the standard set by the goal of the contest to examine this mechanism. 400 participants competed in a competition to come up with non-food related uses for peanut butter and were randomly assigned to a creativity goal (specific and high standard), a quantity goal (no specific standard for the quality of ideas generated), a childish goal (specific but achievable standard: come up with as many CHILDISH non-food related uses for peanut butter) or a baseline condition without any goal. All goal conditions performed better than the baseline, replicating past work that having a goal increases creativity relative to none at all. In addition, as in the previous two studies, participants pursuing a creativity goal came up with fewer novel (M=3.25) and creative ideas (M=0.71) relative to the quantity condition (4.2 and 0.95 respectively, ps<.01); mediation analysis confirmed the driving role of standard clarity/specificity between these two conditions, such that having a creativity (vs. quantity) goal was counterproductive because it set a specific standard. Importantly, participants pursuing a childish goal also performed significantly better (Ms=4.78, .97 respectively, ps<.01) than participants with a creativity goal; mediation analysis confirmed the driving role of standard achievability between these two conditions, such that having a creativity (vs. childish) goal was counterproductive because it set a standard that was low in perceived achievability.

These findings show that pursing the goal the be creative can be counterproductive due to a goal-driven monitoring process that narrows attention and compares ideas to a specific and high standard of creativity. Our findings connect the literature of goal pursuit with creative cognition and have important implications for theories on creativity, divergent thinking, goal-setting, and monitoring, as well as marketing practices of idea generation contests and consumer creativity.

Creativity in Open Innovation Contests: How Seeing Others' Ideas Can Harm or Help Your Creative Performance

EXTENDED ABSTRACT

Public open innovation contests are becoming an increasingly popular way for firms to generate new ideas. In this research, we investigate how seeing ideas of others (denoted as "prior ideas") in an open innovation contest influences the creative performance of individuals. We propose that the number of prior ideas an individual sees before generating his or her own ideas can both discourage and stimulate creative performance and that competition salience (i.e., when individuals are highly aware of the fact that their ideas are competing against other's performance) drives these effects.

Specifically, we argue that seeing numerous prior ideas in a competition will discourage creative performance due to an increase in the perceived difficulty of the task that in turn negatively impacts

the competence one feels in being able to generate original ideas (H1). Indeed, when the competitive aspects of an open innovation contest are made salient, the prior ideas one is exposed to will directly influence the assessed difficulty in proposing original ideas, i.e. ideas that go beyond what has already been identified (Guilford 1968). The salience of numerous prior ideas as competitors, rather than sources of information or inspiration, will heighten the challenge of separating one's ideas from the pack. Previous research on parallel search in innovation contests adds to this argument by identifying that some ideas occur more frequently with some, the so-called "idea-hubs", being frequently mentioned by different individuals independently (Kornish and Ulrich 2011). Participants' exposure to numerous prior ideas is likely to involve such idea hubs, which then interfere with the individuals' idea generation process by discouraging the expression of ideas that are similar to already mentioned ideas. Similar to production blocking in group creativity tasks (Diehl and Strobe 1987; 1991), seeing similar competing prior ideas may inhibit individuals from verbalizing their ideas as they occur and distract their own thinking. Consequently, the task of generating original ideas becomes more difficult to participants exposed to an increasing number of prior ideas. Competition salience triggers this effect as it introduces the need to distinguish one's ideas from the prior ones, in order for them to be perceived as original. Task difficulty in turn influences individuals' feelings of competence, which have been found to be malleable and sensitive to task-related cues (Gist and Mitchell, 1992; Tierney and Farmer 2002). Harming felt competence thus reduces individuals' willingness to expend effort (Eccles and Wigfield 2002) and their inner passion to perform the task (e.g., Deci and Ryan 1985; Ryan 1992), undermining their creative performance (Amabile 1998; Tierney and Farmer 2002).

In contrast, drawing inspiration from the cumulative innovation paradigm (Nijstad et al. 2002; 2006; Scotchmer 1991) we also expect that viewing more prior ideas can better stimulate creative performance and increase feelings of competence by making an individual's memory more accessible to the creative process (H2). Cognitive stimulation occurs from prior ideas because they activate concepts and topics that otherwise would not have been activated, potentially leading to new ideas that contain or combine such activated elements in new ways. Nijstad, Stroebe, and Lodewijkx (2002) showed how example ideas stimulate the ideation process of individuals by presenting a series of example ideas prior to participants' own idea generation. This stimulation was shown to enable creative performance as individuals built on the initial examples by leveraging them in their own creations. Dugosh et al. (2000) showed that greater stimulation and creativity can be expected if more example ideas are shown. Competition salience, however, harms this positive effect, and we find that only when competition is less salient does the positive influence of more prior ideas proffer. We thus propose that prior ideas can play a "dual role" in influencing creative performance.

From a managerial perspective, finding ways to reduce the negative effects of prior ideas on creative performance is crucial to ensure the success of open contests. We predict that the negative influence of prior ideas can be mitigated when prior ideas are related in such a way that feelings of competence are not threatened, either by validating an individual's abilities before exposure or by showing more unique prior ideas that impose less constraints on the ideation process. Indeed, numbing the competitive influence of prior ideas can decrease their demotivating effect (Ryan and Deci 2000a), and instead harness the creative benefits of viewing others' proposals.

Our contribution to the literature is defined by the empirical testing of our conceptualization. In a first study, we test the compet-

ing predictions of prior research (Boudreau, Lacetera, and Lakhani 2011; Dugosh et al. 2000; Nijstad and Stroebe 2006; Nijstad, Stroebe, and Lodewijkx 2002) that increasing the number of prior ideas can both stimulate and hinder creative performance utilizing an actual open innovation platform, European-based Atizo.com. Utilizing different measures of creative performance, we find consistent empirical evidence for a negative effect. Our second study varies the salience of competition finding that this contextual difference moderates the identified negative effect, i.e., the competitive threat of prior ideas triggers their negative influence. However, when competition is less salient, the positive effect of prior ideas is shown to manifest. Mediation analyses reveals that an increase in perceived task difficulty and a loss of felt competence underlie the negative effect (after controlling for objective winning chances), and cognitive stimulation provided by prior ideas drives the positive effects identified. In a third study, we buttress participants' abilities by explicitly having them recall a situation where they were successful in generating ideas and find that this approach mitigates the negative effects of prior ideas on competence and results in a more creative performance. Study four identifies the moderating influence of the nature of prior ideas (i.e., whether the prior ideas are unique in nature versus more redundant) on the negative effect. Here we find that the negative effect of exposure to prior ideas is mitigated when unique ideas are shown.

SESSION OVERVIEW

Religion plays an important role in many people's daily lives. Worldwide, 80% of people affiliate with a religion (Pew Forum 2012) and over 70% of Americans report that their daily behaviors are influenced by their religious beliefs (Pew Forum 2008, Mathras et al. 2016). Despite the significant impact of religion, few articles published in major marketing journals have systematically investigated its role in consumer behavior, and some articles have treated religion as a demographic control variable or a moderator in studies rather than as a main theoretical construct (Mathras et al. 2016).

The current session brings together four papers answering the call to uncover the psychological mechanisms through which religion may influence consumer behavior. The first two papers explore the role of religiosity in individual decision making, focusing on the acquisition or disposition of products. The next two papers also investigate the role of religiosity in decision-making, but do so by exploring how religiosity influences consumers' susceptibility to external influence such as advertising and others' choices.

The first paper by Xu, Olson, and Ahluwalia demonstrates the divergent effects of religiosity on consumers' attitudinal loyalty and behavioral loyalty. Attitudinal loyalty refers to consumers' psychological attachment or commitment to a brand, whereas behavioral loyalty focuses on repeat purchase behavior or switching behaviors (Ahluwalia and Kaikati 2010). The results show that religious consumers report stronger psychological attachment to their favorite brands, yet they are more likely to switch to a competing brand offering a switching incentive at the time of acquisition.

The second paper by Qin, Staelin, and Fitzsimons explores the role of religiosity in pricing one's own possessions at the time of disposal. In particular, because religiosity increases consumers' contentment with their possessions, religious sellers tend to ask for a significantly higher selling price, resulting in a stronger endowment effect. The hypotheses are supported by results of both experiments and archival data analysis.

The next two papers investigate the effects of religiosity on consumers' susceptibility to the influence of external information. The third paper by Wu and Cutright suggests and finds that when God is salient, consumers feel that they will be supported during hard times, and this sense of available support makes them less likely to comply with fear appeals.

The fourth paper by Qin and Xu focuses on the differences in felt attachment to God (i.e., close to God vs. distant from God) among consumers who believe in the existence of God. Results show that strong attachment to God reduces consumers' need for affiliation with other people, who are consequently less likely to conform to the choice of the majority. Moreover, this effect holds for products chosen for private consumption but is attenuated when products are chosen for public consumption.

Given the fundamental role of religion in people's daily lives and the variety of novel findings uncovered in the four papers above, this session should be of interest to a diverse audience, from academics studying religiosity to those researching brand loyalty, decision making, advertising, and social influence more broadly.

Love It but Leave It: The Divergent Effects of Religiosity on Attitudinal versus Behavioral Brand Loyalty

EXTENDED ABSTRACT

Brand loyalty has recently been termed the "holy grail" of marketing (Shugan 2005), representing not only the ultimate goal but also the most challenging one for marketing practitioners (Ahluwalia and Kaikati 2010). The concept of brand loyalty has two facets – attitudinal loyalty and behavior loyalty. Attitudinal loyalty refers to the psychological attachment or commitment of consumers to a brand. Behavioral loyalty focuses on overt behaviors such as repeat purchase behavior or switching behavior (Ahluwalia and Kaikati 2010). Given loyalty has been increasingly defined as a combination of attitudinal attachment and overt loyalty behaviors (Oliver 1999), little work has explored situations in which attitudinal loyalty and behavioral loyalty may diverge.

Ahluwalia and Kaikati (2010) identified three major factors leading to brand loyalty in the literature: consistent performance, consumer-brand connection, and incentives such as loyalty programs. We assume that affect-laden consumer-brand connection is a more important determinant of attitudinal loyalty; whereas incentives are a more important determinant of behavioral loyalty.

We propose that religiosity enhances consumer-brand connection because religious consumers are more likely to incorporate brands into their self-concept, which thus increases their psychological attachment to their favorite brands. At the same time, religiosity also enhances decision accountability, because religious consumers may constantly perceive that God is watching them and they need to make justifiable decisions. Consequently, when a competing brand offers a switching incentive (e.g., a price promotion), thereby providing an alternative that can be justified by more objective means than one's subjective psychological attachment (e.g., "The competing brand was cheaper" is more objectively justifiable than "I like my favorite brand"), religious consumers are more likely to switch to the competing brand.

Study 1 considered the impact of religiosity on consumers' attitudinal brand loyalty. Participants listed their favorite brand from specific product categories (i.e., a hedonic category – chocolate, and a utilitarian category – toothpaste). After listing each brand, they then indicated their attitudinal loyalty to the brand by responding to a 4-item brand attachment scale from Park et al. (2010). Finally, after a filler task, participants completed the Religious Commitment Inventory (Worthington et al. 2003) as a measure of chronic religiosity. A linear regression with brand attachment averaged across product categories revealed that religiosity was positively related to participants' attachment to their favorite brands.

Study 2 expanded on study 1 by manipulating rather than measuring religiosity, and by exploring the mechanism driving religiosity's positive association with attitudinal brand loyalty. The study used a procedure similar to that of study 1, but before participants listed a favorite brand, half were randomly assigned to a religiosity condition in which they wrote about what religion means to them and how it impacts their life, and half were assigned to a control condition. Additionally, after participants reported their attachment to the favorite brand, their tendency to incorporate various people and things into their self-concept was measured using items adapted from Aron et al. (1992). Replicating the findings of study 1, an ANOVA showed that participants in the religiosity condition (vs. control) were significantly more attached to their favorite brands. Furthermore, this effect was mediated by their enhanced tendency to incorporate other entities into their self-concept, as the mean indirect effect from a bootstrap analysis was significant.

Study 3 investigated whether religiosity's positive effect on attitudinal brand loyalty would translate to greater behavioral loyalty as well. Participants were randomly assigned to either the religiosity priming or control conditions from study 2. All participants then completed a set of scenarios in which they listed their favorite brand in a specific product category (i.e., a hedonic category – ice cream, and a utilitarian category – toothpaste), and indicated on 7-pt scales (*not at all/very much so*) how likely they would be to switch from that brand if a comparable brand entered the market with some type of bonus (e.g., 10% discount). Product category had no effect on participants' switching intentions, so results were averaged across products to form a single switching intention measure for each participant. We expected religiosity to have a positive effect on switching. Consistent with this prediction, participants in the religiosity condition (vs. control) were significantly more likely to switch from their favorite brands to the brands offering an incentive.

Study 4 built on the previous studies by simultaneously examining religiosity's effect on both attitudinal and behavioral brand loyalty. For the same product categories used in study 4, participants first listed their favorite brand. They then indicated their attitudinal loyalty to the brand by completing the 4-item brand attachment scale from Park et al. (2010). Finally, they indicated how likely they would be to switch to a comparable brand offering a bonus (as in study 4). After a short filler task, religiosity was measured as a chronic trait using the Religious Commitment Inventory (Worthington et al. 2003). We predicted that religiosity would be associated with both greater attachment to *and* greater likelihood of switching from favorite brands. Supporting these hypotheses, religiosity was positively related to attachment to favorite brands, but also positively related to switching from favorite brands to other brands offering an incentive. Thus, religiosity was associated with greater attitudinal loyalty but less behavioral loyalty for the same brands.

The Price of Faith:
Religion's Role in the Endowment Effect

EXTENDED ABSTRACT

We put forth a new explanation for the endowment effect, namely that sellers' asking prices will be influenced by their religiosity and the associated religious teachings that remind the individuals to be content with what they have, such as the Ten Commandments. Although the Ten Commandments are generally regarded as moral standards in the Judeo-Christian context, other religions (e.g., Samaritan) embrace it as well. Eastern religions teach people to be content as well, including The Ten Disciplines in Hinduism and The Four Nobel Truths in Buddhism. With fourteen experiments that either manipulate or measure participants' religiosity, we assess the ways that their religiosity is related to the endowment effect. We also analyze two archival datasets on the posted selling prices of used consumer durables and test how they vary with individual religiosity.

First, we manipulated the salience of religion and tested if it strengthens the endowment effect. In Study 1a, we found that although the endowment effects were present in both conditions, it was significantly stronger in the religion condition, compared to the control condition ($p < 0.001$, $p = 0.05$). Across the two conditions, owners in the religion condition asked for a significantly higher price ($M = 3.94$, $SD = 1.09$; $M = 2.23$, $SD = 1.47$; $p < 0.001$), but no such differences were found in buyers' willingness to pay ($M = 1.80$, $SD = 0.96$; $M = 1.62$, $SD = 1.38$; ns). We also ruled out the alternative explanations of intuitive thinking and fairness concerns. We replicated the findings of Study 1a in four other studies (Studies 1b-1e) with different religion primes and items for sale. All these studies consistently show that when religious beliefs are salient, the endowment effect becomes stronger, compared to the control condition. This is because sellers increase their asking prices when they are temporarily exposed to religion.

These findings on the temporary exposure to religion imply that individuals who have stronger religious beliefs will show stronger endowment effects compared to people who have weaker beliefs. In the next group of studies, we measured participants' religiosity and tested if it was related to asking or buying prices. In study 2a, after the endowment task, the participants indicated their frequency of religious practice by answering "How frequently do you worship or practice religious rituals (e.g., pray, meditate, read scripture)?" on a 6-point scale from "Never" to "Daily" (median, once a week). We found no significant effect of religious practice on buyers' prices ($\beta = -0.16$, ns). In contrast, sellers significantly increased their selling price as their religious practice became more frequent at the marginal level ($\beta = 0.21$, $p = 0.08$). A Johnson-Neyman analysis (Spiller et al. 2013) shows that only the top 76% of the participants on religious practice frequency (i.e., those that indicate they practice slightly more than rarely) defines the region where selling prices are significantly higher than buying prices. We replicated these results with a different measure for religiosity (Study 2b), real transactions (Study 2c), and broader samples (Studies 2d and 2e).

Next, we examined if these effects were caused by participants' contentment beliefs. In one study (Study 3a), we activated religion thoughts in two different ways: religion as a source of security or religion as a source of contentment. Any difference in these two conditions would show that not all aspects of religion equally influenced the endowment effect. We found that the endowment effect was only present in the "religion as contentment" condition ($\beta = 0.84$, $p < 0.001$), but not in the "religion as security" condition ($\beta = 0.18$, $p > 0.4$) or the control condition ($\beta = 0.32$, $p > 0.11$). In three other studies (Studies 3b-3d), we found that only among participants who

strongly supported the values of the Ten Commandments, when they were primed with religion or characterized by strong religious beliefs, they overvalued what they owned and asked for higher selling prices.

Finally, we used two archival datasets to confirm the external validity of our results (Studies 4a-4b). We collected the religiosity ranking using the county-level number of congregations per 10k people in 2010, and the asking prices for iPhone 5 and for three types of popular cars. In the iPhone 5 dataset, we found that controlling for economic environment, demographics and phone conditions, as our measure of religiosity increased, asking prices increased ($\beta = 1.45$, $p < 0.01$). In the car dataset, we not only collected selling prices by individuals but also dealers' pricing. We used the latter to control for unobserved spatial factors that were common for both groups. Heightened contentment involving all the cars on their lot should not be a factor in car dealers' pricing, because their pricing is often determined by financing agreement, refurbishing costs, and the models they are currently promoting. A Johnson-Neyman analysis indicates that dealers' prices do not significantly change with the number of congregations, whereas individuals' prices significantly increase as the number of congregations increases ($\beta = 75.21$, $p < 0.001$).

Our findings offer a wide range of implications for both firms and consumers. First, our results complement current marketing strategies that are targeted at increasing people's purchase likelihood. For example, in highly religious regions, salespeople might want to encourage people to test their products, and thus activate feelings of ownership and increase their likelihood of purchasing. Because consumers with strong religious beliefs may be resistant to trade-in or buy-back programs, managers can frame the message to emphasize how good their used products are and how well they will be taken care of, messages that align with consumers' contentment with their belongings. Second, our findings provide insights into people's pricing behaviors. A recent 2015 survey released by the Pew Research Center shows that Americans are becoming more secular and less religious. It would be interesting to see if the endowment effect becomes weaker over these years. If so, people in the secondhand market might change their prices over time.

In God's Hands: How Religion Dampens the Effectiveness of Fear Appeals

EXTENDED ABSTRACT

For many consumers, the concept of God or another divine being plays a central role in their everyday lives. However, despite the importance of God and religion for many consumers and the extent to which they use such ideology to view the world and make decisions, the implications for marketing are not well-understood. In the current research, we focus on understanding how religion might affect consumer compliance with fear-based advertising.

Fear appeals are persuasive messages that are designed to frighten consumers into compliance with the message's recommendations and they have been used to promote a broad range of consumer products and services, and to address many important public health and safety issues. Research on fear appeals suggests that many factors, including message features (e.g., format, Keller 1999) and individual differences (e.g., self-construal, Block 2005; socioeconomic class, Burnett and Oliver, 1979) determine fear appeal effectiveness.

Research on religion suggests that God and religion often serve as resources that aid consumers in coping with threats and negative emotions. For instance, relative to nonreligious individuals, religious individuals report higher overall subjective wellbeing (suggesting that they cope effectively with everyday negativity) (Myers 2000;

Ellison 1991) and cope better with chronically negative situations (e.g., Koenig, Larson and Larson, 2001), discrete negative life events (e.g., McIntosh, Silver and Wortman, 1993; Newton and McIntosh, 2010), and states of uncertainty (e.g., Kay et al., 2010).

In the current research, we draw on research on fear appeals, religion and coping to suggest that when God is salient, consumer persuasion and compliance with fear appeals is dampened. Specifically, we suggest that when God is salient, consumers feel that they will be supported during hard times, and that this sense of available support leads them to be less likely to comply with the appeal's recommendations.

In study 1, we prime individuals with a standard religion prime or with a neutral prime (e.g., Shariff and Norenzayan 2007) before having them evaluate a fear appeal (an ad for an ADT security system). We find that individuals in the religion condition exhibit less persuasion and compliance to the fear appeal relative to individuals in the neutral condition ($p = .03$).

We replicate this basic finding in study 2. After manipulating the salience of God through an essay writing manipulation, participants evaluated either a high or low fear appeal for flood insurance. Both ads were adapted from a real ad circulated by the National Flood Insurance Program. Consistent with study 1, participants exhibited less compliance in response to a high fear appeal when God was salient than when God was not ($p = .0005$).

In study 3, we explore whether physical settings might serve as a more naturalistic prime of religion. Participants were randomly assigned to participate in our study in either Sage Chapel (a campus Chapel) or Sage Hall (a campus building). Participants evaluated either a high or low fear appeal about the importance of using BPA-free water bottles. Results show that within the high fear conditions, individuals in the chapel condition exhibited lower compliance and persuasion than those in the neutral building ($p = .03$). This difference did not exist in the low fear ad conditions.

In study 4, we identify an important boundary condition for when God salience will and will not dampen fear appeal persuasion: different conceptions of God. Prior research suggests that individuals can vary in the extent to which they perceive God as caring and supportive or as vengeful and punishing (e.g., Shariff and Norenzayan 2011; Harrison et al., 2001). In the context of the present research, we expect that God salience will be associated with support only when perceptions of God are positive. Thus, we assigned participants to scrambled sentence conditions that either heightened benevolent, punishing, or no conceptions of God. Participants then saw either a low or high fear ad about the importance of wearing sunscreen. Results show that when God is perceived as benevolent and supportive, individuals exhibit less compliance to a fear appeal than when God is perceived as punishing ($p = .05$) or when God concepts are not activated ($p = .02$).

In study 5, we examine whether the dampening effect of God salience on fear appeals might be unique to God, or whether the salience of other supportive entities might lead to the same effect. As pre-testing indicated that family/friends and health care providers can serve as important sources of support in individuals' lives, we manipulate whether participants are thinking about God, family/friends or health care providers and measure their intentions to comply with a fear appeal. Results reveal that participants reported lower fear appeal compliance intentions when God was salient relative to each of the other conditions where God was not salient ($ps < .05$). In other words, our effect appears to be unique to the sense of support that is evoked from thinking about God. Together, these studies enhance our understanding of both religion and advertising by revealing how notions of God provide a psychological buffer that

may unintentionally reduce consumers' compliance with fear-based appeals.

Attachment to God Reduces Conformity to the Choice of the Majority

EXTENDED ABSTRACT

Attachment is a strong disposition for people to seek proximity to and contact with a specific figure (Bowlby 1969). The figures individuals are attached to can be parents, peers, partners, and even pets (Kurdek 2008). In this project, we focus on one particular attachment figure that is understudied in the marketing field: God (e.g., Kirkpatrick 2015).

Previous literature has shown that a close relationship with God has positive effects on individuals' well-being, self-image, and meaning in life (e.g., Stroope, Draper, and Whitehead 2013), due to enhanced feelings of love, support, and approval. We propose that close attachment to God and the accompanying sense of support may reduce individuals' need to be affiliated with others (i.e., make them more independent). In marketing contexts, consumers who have acquired an independent self-construal are more likely to make decisions based on their own preferences rather than conforming to the choice of the majority. This effect occurs only when consumption decisions are made for private consumption. When the public consumption context highlights the social pressure to conform, consumers are more susceptible to the choice of the majority.

In all studies, we focused our investigations on consumers who believed in the existence of God. In study 1, participants indicated their chronic attachment to God by rating the extent to which they agreed with three statements (e.g., I know God is there when I need him/her). They then watched a 30-second commercial on bottled water and rated how much they enjoyed the ad and how interesting the ad was on 11-point scales. Bogus ratings of other participants were provided on the rating sheet, and they ranged from 9 to 11 (Janes and Olson 2000). Conformity was measured by assessing a) whether participants' ratings fell into the range of the bogus ratings, and b) the average ratings of participants. Analyses of both dependent variables indicated that as attachment to God increased, participants' ratings were less likely to conform to the bogus ratings. This study demonstrates the negative correlation between attachment to God and conformity. In the next study, we manipulated attachment to God to establish causality.

In study 2, we manipulated attachment to God through an essay-writing task. Participants were asked to think and write about a moment when they felt close to God (high-attachment condition) or a moment when they felt distant from God (low-attachment condition). They then indicated how they conduct themselves regarding conformity (e.g., non-conforming, obedient; Duckitt et al. 2002) on 5-point scales. Conformity was measured by averaging the four ratings. Results showed that priming attachment to God reduced participants' tendency to conform to others. Study 3 replicated the results of study 2 by using a different prime and a different measure of conformity. Specifically, attachment was manipulated through scramble sentence tasks and conformity was measure by the choice between two equally priced artworks – one was endorsed by 80% of previous customers, whereas the other was endorsed by 20%. We found that participants primed with attachment to God were significantly less likely to choose the more popular artwork.

Study 4 further demonstrated the negative influence of attachment to God on choice conformity with behavioral measures. Participants first completed the essay-writing prime, and then were told that they could choose a notecard as a gift. Two different types of notecards, which were pretested to be equally attractive, were presented on a table together with a bogus sign-up sheet. The relative popularity of each type was manipulated by varying the number of cards taken (as indicated on the number of sign-ups on the bogus sheet) and the number of cards still available. Specifically, there were 21 sign-ups for the more popular card and only 5 were still available; whereas there were 6 sign-ups for the less popular card and 15 were still available. The popularity of both cards was counterbalanced. The results show priming attachment to God reduced participants' likelihood of choosing the more popular card.

Our conjecture of the above effect was that attachment to God could be a substitute for attachment to other people. If so, priming attachment to God should make individuals feel more independent and subsequently less likely to follow the crowd. Study 5 tested this underlying mechanism. Participants first completed the essay-writing task that manipulated attachment to God. They then made choices between two artworks and between two coffee tables. One option in each pair was endorsed by 80% of previous customers, whereas the other was endorsed by only 20%. The likelihood of choosing the more popular options across both product categories served as the main dependent variable. In addition, participants rated four statements (e.g., When I think of myself, I often think of my close friends or family also) assessing their relational interdependence self-construal on 5-point scales. Again, priming attachment to God reduced choice of majority endorsed products, which was mediated by reduced relational interdependence self-construal.

Study 6 tested a boundary condition of the proposed effect. We hypothesized that attachment to God should only reduce conformity when products are consumed privately. The proposed effect should be attenuated when products are consumed in public. We used the same essay-writing priming task and then asked participants to choose between two decoration options either for their bedroom (private context) or for their living room (public context). The results revealed a significant two-way interaction of attachment to God prime and consumption context. Simple effect analyses showed that priming attachment to God reduced conformity only when participants chose a decoration for the bedroom, but had no effect when they chose a decoration for the living room.

In sum, this research demonstrates the negative influence of attachment to God on conforming to the majority choice. It also enhances our knowledge of the role of religion in consumer decision-making and contributes to the social influence literature by uncovering a new antecedent of choice conformity.

Paper #4: Choice and Quantity in Conflict: Post-Taste Food Consumption and Inferences of Self-Control

Ga-Eun (Grace) Oh, Hong Kong University of Science and Technology, China
Anirban Mukhopadhyay, Hong Kong University of Science and Technology, China

SESSION OVERVIEW

Consumers are frequently exposed to a wide range of sensory cues in their consumption environment. Inputs from such incidental sensory cues can have a far reaching impact on consumption preferences (Krishna 2012; Krishna and Schwarz 2014). The primary objective of this session is to contribute to our understanding of sensory marketing by elucidating the interactive relationship between sensory cues and consumer decision making. Each of the four papers included in the session focuses on a different sensory modality, thus allowing for a broad, yet coherent understanding of research on sensory marketing. The first two papers explore the impact of extrinsic sensory cues, color of product packaging and ambient music, on consumer preferences. The latter two papers complement the first two papers by investigating the impact of intrinsic sensory cues, such as the sound and the taste of food, on consumption behaviors.

The session will begin with a focus on the impact of a highly prevalent visual sensory cue, color of product packaging, on consumption preferences. Specifically, the first paper by Zhang, Wadhwa, and Chattopadhyay focuses on the impact of darkness of colors on one's preference for indulgent consumption. Their findings show that the impact of darkness of color on indulgent consumption depends on whether the positive or negative aspect of the indulgent consumption is made salient. When the positive (negative) aspect of indulgent consumption is made salient, darker colors increase (decrease) preference for indulgent consumption.

The second paper by Deng, Yang, Jia, and Lee extends the scope of the first paper by investigating the effect of a different sensory cue, auditory cue, on consumer preferences and decision making. Their findings show that exposure to lyrical music, compared with instrumental music, evokes a higher level of mental construal. Conse-

quently, while exposure to lyrical music increases consumers' preference for products that are superior on desirability features, exposure to instrumental music increases consumers' preference for products that are superior on feasibility features.

The third paper by Elder and Mohr compliments the first two papers by examining the impact of intrinsic sensory cues on consumption behaviors. They explore the impact of product-related auditory sensory cue, the sound the food makes, on consumption quantity. Their findings show that the salience of the food sound can serve as a monitoring cue to help consumers regulate their food intake. Specifically, they find that increasing the salience of the food sound reduces consumers' consumption quantity.

The fourth paper by Oh and Mukhopadhyay investigates the impact of yet another
product-related sensory cue, taste of food, on consumer choices and consumption
decisions. Their findings show that people's consumption behaviors based on the sensory cue of taste exhibit very different consumption patterns from what one might have predicted based on the choices, which were driven mainly by the visual cues.

Together, this session brings together four papers, which are in final stages of completion, that provide cutting edge insights into how sensory cues prevalent in our market place drive consumer choice and consumption decisions. In addition to attracting researchers interested in the domains of consumer perception and sensory marketing, we expect further interest from those who work within the application areas represented, and those interested in consumer welfare.

The Color of Indulgence: How Dark Color Influences Indulgent Consumption

EXTENDED ABSTRACT

As a ubiquitous visual cue in the marketplace, color plays a crucial role in driving consumers' purchase decisions (Bercea 2012). One important dimension of color, which is imbued with powerful symbolic meanings, is the degree of darkness (i.e., value) of color. In this research, we examine the impact of dark colors on consumers' preference for indulgent consumption.

Recent research suggests that people associate dark colors with sin in moral judgments (Sherman and Clore 2009). This research seems to suggest that dark colors should lead consumers to think of indulgent behaviors as sinful, thereby reducing indulgent consumption. However, in the current research, we argue that dark colors could also enhance indulgent consumption. Specifically, we propose that dark colors are more broadly associated with indulgence. Anecdotal evidence provides some support for this proposition. For example, in everyday language, phrases such as "dark temptations" or "dark desires" are often used to describe indulgent behaviors. Findings from two pilot surveys we conducted provide further support for this association between dark colors and indulgence. Since indulgence contains both positive aspect of pleasure and negative aspect of sin (Khan and Dhar 2006), we argue that the impact of dark colors on indulgent consumption depends on consumers' relative focus on positive versus negative aspects of indulgence. Specifically, when consumers focus on the positive aspect, darker colors can enhance

consumers' preference for indulgent consumption. In contrast, when consumers focus on the negative aspect, darker colors can reduce consumers' preference for indulgent consumption.

We tested the aforementioned color of indulgence hypothesis across four studies. In all studies, holding the hue and chroma dimensions constant, we manipulated only the degree of darkness (i.e., value) of the color cues. Study 1 followed a 2 (color: bright vs. dark) × 2 (focus: pleasure vs. sin) between-subjects design. Specifically, we instructed participants to focus on either the negative (high calorie content) or positive (tastiness) aspect of an indulgent product (movie popcorn). We used red as the hue of the packaging color and manipulated the degree of darkness of the packaging color. Our findings show that when participants focused on the pleasurable aspect (i.e., tastiness of the popcorn), dark (vs. bright) packaging color enhanced their intention to consume the popcorn (M = 6.98 vs. M = 5.75, $t(199)$ = 2.82, $p < .01$). However, when participants focused on the sinful aspect (i.e., calorie content of the popcorn), dark (vs. bright) packaging color reduced their intention to consume the popcorn (M = 5.35vs. M = 6.24, $t(199)$ = -2.63, $p < .01$).

Study 2 replicated the color of indulgence effect by using a different hue (blue) and a different indulgent product (buttercream cupcake). The study followed a 2 (color: bright vs. dark) × 2 (focus: pleasure vs. sin) between-subjects design. As in study 1, we instructed participants to focus on either the sinful (calorie content) or pleasurable (tastiness) aspect of the cupcake and manipulated the level of darkness of the product wrapper. In addition to replicating the findings of study 1, this study further shows that when consumers focused on the pleasurable (vs. sinful) aspect of indulgence, dark, as compared with, bright color induced a greater sense of feeling right toward the indulgence. This subjective sense of feeling right toward indulgence mediated the impact of dark colors on indulgent consumption (b = 0.97, bootstrapped 95% CI excluded zero: 0.56 to 1.42).

In study 3, we examined a non-food indulgent consumption context—impulsive purchase. In particular, we used a promotion card for designer sunglasses and manipulated the level of darkness of the color of the card. The study followed a 2 (color: bright vs. dark) × 2 (goal prime: pleasure-seeking vs. self-control) between-subjects design. Findings of this study show that the effect of dark color on consumers' impulsive purchase intention for a pair of designer sunglasses was moderated by the relative salience of the goal state. When participants were primed with a pleasure-seeking goal, dark (vs. bright) color increased the sense of feeling right toward the indulgence, thus increasing the intention to purchase the designer sunglasses (M = 4.60 vs. M = 3.84, $t(278)$ = 1.96, $p = .05$). However, when participants were primed with a self-control goal, dark (vs. bright) color decreased the sense of feeling right toward the indulgence, thus decreasing the intention to purchase the design sunglasses (M = 2.76 vs. M = 3.46, $t(278)$ = -1.79, $p = .07$).

In study 4, we provided further support for the color of indulgence effect by examining the impact of dark versus bright colors on consumption of entertainment news. The study followed a 2 (color: bright vs. dark) × 2 (goal prime: pleasure-seeking vs. self-control) between-subjects design. Subsequent to the goal-priming manipulation, participants were told that they would read a total of 10 blog articles from two websites: Business Buzz (business and financial news) and Entertainment Buzz (fashion and celebrity news). Descriptions of the two websites were presented on either a dark or a bright color display background. Participants indicated the number of articles they would like to receive from each website, and they subsequently took their time to read the corresponding composition of 10 news articles they had selected. Our findings show that participants primed with a pleasure-seeking goal chose to read a greater number of entertainment news blogs when exposed to dark (M = 6.72) versus bright (M = 5.94, $t(239)$ = 2.02, $p = .04$) color background. However, this effect was reversed when participants were primed with a self-control goal (M = 5.57 vs. M = 6.26, $t(239)$ = -1.77, $p = .08$).

Together, these results provide converging support for the color of indulgence effect. When consumers focus on the pleasurable aspect (vs. sinful aspect) of indulgence, dark colors as compared with bright colors increase (vs. decrease) consumers' preference for indulgent consumption. Our results also show that this color of indulgence effect was mainly driven by the dark color. Our findings provide important implications for both marketing and consumer welfare.

Strumming the Chords of Your Mind: The Effects of Lyrical Music versus Instrumental Music on Construal Level and Choice

EXTENDED ABSTRACT

Past research has investigated how music genre, tempo, volume, etc. affects consumer behavior. The vocal versus instrumental component of music, however, has not been studied. Voices and instruments are the two performing media of music (Kamien and James 1988). We use the term "lyrical music" to refer to vocal music with lyrics (i.e., songs) and the term "instrumental music" to refer to the instrumental version of a song which is devoid of lyrics or singing. We examine the effects of lyrical music versus instrumental music on consumers' mental construal and their subsequent product decisions.

We first posit that listening to lyrical music activates a high level of construal because lyrics connect the auditory stimuli to broader, more abstract concepts such as love, betrayal, happiness, sadness, etc. and help listeners interpret what they are hearing in higher level terms. The lyrics of many songs are scripted under common themes (Desmond 1987). These song themes readily activate the existing cognitive schemas in listeners (Schank and Abelson 1977). As a result, listeners often process song lyrics in a top-down, schematic fashion (Hansen and Hansen 1991), deriving the main theme of a song based on a few key lines or even a few key phrases of its lyrics which are sung repetitively. Previous research shows that quite often there is a lack of word-by-word, localized processing of song lyrics (Greenfield et al. 1987) and even when lyrics are available, its comprehension is imperfect and listeners oftentimes include schema-consistent contents (though not existent in the song) when asked to recall the lyrics of the song (Hansen and Hansen 1991).

Second, we theorize that listening to instrumental music induces a relatively lower level of construal because the lack of song lyrics renders schematic processing less likely and higher order meanings not available for average listeners. Instrumental sounds per se do not provide meaning due to the lack of well-accepted conventions that connect musical expression (the audible aspect, or sound) to musical content (the semantic aspect, or meaning) (Baroni 1983). As such, the auditory experience is semantically obscure (Kamien and James 1988). It is also perceptually "concrete" (Baroni 1983, p. 182) because perceiving a musical piece as a whole first requires a bottom-up, localized processing of individual musical elements to understand the syntactical relationships among them (Tillmann, Bigand, and Madurell 1998). For average listeners, however, this localized processing is sticky. Based on music puzzle tasks, Tillmann et al. observed that "…local processing of harmonic cadences prevails over global processing" (p. 160) and listeners focus on individual musical segments and interpret them in narrower, more isolated contexts rather than the overall structural of the musical piece.

We test our key assertions in studies 1-3 using well-established measures of construal level. In Studies 1-2, participants listened to the song *A Whole New World* (with vocals) or the song's instrumental version (without vocals). Both versions lasted for about four minutes and were identical except that the lyrical version included sung words. Participants in Study 1 completed the 25-item Behavioral Identification Form (BIF, Vallacher and Wegner 1989). Analysis conducted on the BIF scores (0-25 with higher numbers indicating a tendency to engage in high-level interpretation) revealed that those listening to the lyrical (vs. instrumental) music were more likely to use high-level description to identify a target behavior ($M_{lyrical}$ = 13.95 vs. $M_{instrumental}$ = 12.55; $F(1, 73)$ = 7.69, p = .01). Participants in Study 2 engaged in a shoe categorization task (Lee, Deng, Unnava, and Fujita 2014). Analysis performed on the categorization scores (0-1 with higher numbers indicating a tendency to categorize based on functional form, a high-level feature, versus aesthetic details, a low-level feature) showed that those listening to the lyrical (vs. instrumental) music were more likely to categorize based on functional form ($M_{lyrical}$ = .91 vs. $M_{instrumental}$ = .78; $F(1, 88)$ = 5.98 , p = .02).

In Studies 3AB, participants listened to the lyrical versus instrumental version of *Before I Fall in Love*. Study 3A utilized a video segmentation task (Lee et al. 2014) in which participants segmented a stream of behavior into meaningful sections by clicking their mouse when, in their judgment, one meaningful action ended and another began. Study 3B employed a picture segmentation task in which participants divided the floorplan of a house into as many areas as made sense to them. We anticipate that lyrical (vs. instrumental) music leads to segmentation that highlights fewer (vs. more) chunks. Analyses showed that those listening to the lyrical (vs. instrumental) music had fewer clicks ($M_{lyrical}$ = 15.12 vs. $M_{instrumental}$ = 17.65; $F(1, 90)$ = 4.15, p = .045) in Study 3A, and indicated fewer areas ($M_{lyrical}$ = 10.38 vs. $M_{instrumental}$ = 12.02; $F(1, 83)$ = 4.59, p = .035) in Study 3B.

The next two studies show that the higher (vs. lower) level of construal activated by listening to lyrical (vs. instrumental) music, as a procedural mind-set, can influence consumers' subsequent product decisions. In Study 4, after listening to the lyrical versus instrumental version of *Take Me to Your Heart*, participants made a choice between a restaurant with superior primary (food) but inferior secondary (dining view) features and a restaurant with inferior primary but superior secondary features (Wan and Agrawal 2011). The analysis revealed that lyrical (vs. instrumental) music induced greater preference for the restaurant with superior primary feature ($M_{lyrical}$ = 7.49 vs. $M_{instrumental}$ = 6.71; $F(1, 64)$ = 4.62, p = .04).

Study 5 tests the proposed mediation mechanism by priming global versus local processing. If lyrical (vs. instrumental) music indeed activates a global (vs. local) processing style, then the effect of music should be *strengthened* when participants are primed with a *consistent* processing style (i.e., global/lyrical and local/instrumental) but *weakened* when the priming task is *inconsistent* (i.e., local/lyrical and global/instrumental). After the music manipulation (same as in Study 4), participants viewed a map of a foreign city and were instructed to focus on its global shape versus details (Förster, Liberman, and Kuschel 2008). They then made a choice between a furniture with superior desirability aspects and a furniture with superior feasibility aspects (Aggarwal and Zhao 2015). A 2 (lyrical vs. instrumental music) × 2 (consistent vs. inconsistent prime) ANOVA revealed a significant interaction effect ($F(1, 116)$ = 3.95, p < .05): among participants assigned to the consistent primes, those in the lyrical/global (vs. instrumental/local) condition reported the highest (vs. lowest) preference for the furniture with superior desirability ($M_{lyrical/global}$ = 7.00 vs. $M_{instrumental/local}$ = 5.07; $F(1, 116)$ = 8.93, p = .003);

whereas participants assigned to the inconsistent primes (those in the lyrical/local and instrumental/global conditions) reported very similar preferences for the furniture with superior desirability ($M_{lyrical/local}$ = 6.22 vs. $M_{instrumental/global}$ = 6.13; F < 1, n.s.).

In addition to contributing to literature on music effects by shedding light on how listening to lyrical versus instrumental music may alter consumers' level of information processing, this paper advances construal level research by adding a novel, sensory factor to the repertoire of antecedents of construal level. The ease of implementation of this factor suggests that marketers can use lyrical versus instrumental music as a convenient nudge to influence consumers.

The Crunch Effect: Food Sound Salience as a Consumption Monitoring Cue

EXTENDED ABSTRACT

We expand the research focusing on intrinsic sensory cues on consumption by exploring how the intrinsic auditory cues elicited during consumption impact consumption quantity. Across three studies, we show that increased attention to the sound the food makes, or food sound salience, leads to reduced consumption. Our research adds to the literature showcasing the impact of sound on flavor perception (Christensen and Vickers 1981; de Liz Pocztaruk et al. 2011; Demattè et al. 2014; Spence 2012). We choose to focus on food sound salience as sound has traditionally been the "forgotten" flavor sense (Spence 2015), leading to its underutilization in flavor perception.

An important determinant of food regulation is whether consumers are provided with the opportunity to monitor their consumption. Just as the sight of consumed food helps consumers monitor their food intake (e.g., Geier, Wansink, and Rozin 2012), we predict that drawing attention to the sound of the food may also serve as a consumption monitoring cue. Formally, we hypothesize that increasing (vs. decreasing) food sound salience will lead to less food consumption. The sound that a crunchy food makes when it is consumed provides an intrinsic cue of consumption such that when the consumer no longer hears the sound of the food, an auditory pause in the consumption experience is created. Alternatively, when the crunch of the food is not salient, and the natural pause points created by the sound are not available, the ability to monitor consumption is impaired.

In our pilot study, 223 undergraduates rated the importance of each sensory experience in what they eat, how much they eat, their level of enjoyment, as well as how quickly they get bored of the eating experience. As we hypothesized, sound was expressed to be less important, compared to vision, taste, smell, and texture, in determining when participants decide to start eating, stop eating, and how much participants would enjoy the meal (all comparisons with sound Bonferonni corrected, p < .05). Participants also stated that they become bored of the sound of eating food more quickly than they do of the other sensory modalities (Bonferonni corrected, all p < .05).

In study 1, 181 undergraduates were randomly assigned to one of three conditions. Participants were told to eat cookies as they normally would, as loudly as they could, or as quietly as they could. The latter two conditions were manipulations of food sound salience, while also allowing us to explore any differential impact of intensity. Participants were instructed to eat at least one cookie, but could then eat as many as they wished. Despite finding no significant differences in perceived taste or quality of the cookies across conditions, we found our predicted significant main effect of food sound salience. Specifically, the food sound salience conditions led to less consumption than the control condition ($M_{food\ sound\ salience}$ = 2.61, $M_{control}$ = 3.38; $F(1, 179)$ = 4.73, p < .05). As the predicted effect of food

sound salience on quantity consumed might be a function of making other sensory cues more salient as well, the primary aim of study 2 was to directly manipulate food sound salience without incurring an additional effect of mindfulness on the eating situation.

In study 2, 67 undergraduates were randomly assigned to either a high or low food sound salience condition. Food sound salience was manipulated by adjusting playing sound through headphones during consumption (-29.5 dbFS for high food sound salience, 14.5 dbFS for low food sound salience). We pretested this manipulation, with louder levels of white noise leading to a weaker ability to hear oneself chew than quieter levels of white noise. Participants were given a bowl of pretzels to consume while listening to the noise in their headphones. As predicted, participants in the high food sound salience condition consumed significantly fewer pretzels than those participants in the low food sound salience condition (M_{low} = 2.75, M_{high} = 4.11; $F(1, 64)$ = 5.27, p < .05).

In study 3, we explored the managerial implications for food sound salience. One hundred twenty-three undergraduates were assigned to either the high or low food sound salience condition. We manipulated food sound salience through a verbal product advertisement for pita chips, with the high (low) food sound salience condition focusing on sound (taste) attributes. Participants read the advertisement, and then were instructed to eat as many pita chips as they wished. As a result of this manipulation, participants ate significantly fewer pita chips in the food sound salience condition than in the taste salience condition (M_{sound} = 4.79, M_{taste} = 5.86; $F(1, 120)$ = 4.21, p < .05).

Across three studies, in which we operationalize food sound salience through different methods, we show a consistent negative relationship between the salience of a food's sound and food intake. Our findings also illuminate the importance of understanding sensory cues as influential factors in food consumption. While existing research places little importance of the role of intrinsic sound in the consumer food environment, we demonstrate that the salience of a food's sound can in fact significantly impact the quantity of food a person eats.

Choice and Quantity in Conflict: Post-Taste Food Consumption and Inferences of Self-Control

EXTENDED ABSTRACT

Imagine you have to choose between chocolate cake and fruit salad, a classic measure of self-control introduced by Shiv and Fedorikhin (1999). Since chocolate cake is relatively more tasty but unhealthier (i.e., a vice; Wertenbroch 1998), a choice of chocolate cake is interpreted as lack of self-control. Correspondingly, a choice of fruit salad (a virtue) is interpreted as high self-control. The simplicity and intuitive appeal of this heuristic have led it to be widely adopted by consumer researchers. However, it is not without its shortcomings. First, people may simply choose an option because of a dislike for the alternative, with no implication for self-control. More importantly, food choice may not be indicative of quantity. After having tasted some appetizing food, the decision of when to stop eating is also indicative of self-control, and independent of the decision of which food to eat. You may choose the chocolate cake (and thereby be classified as having low self-control), but only eat a single forkful – evidence for high self-control that is completely missed by the researcher. In this research, we explicitly test how trait self-control relates to choice versus quantity in situations such as this, and find that actual intake is in fact systematically discrepant from choice.

Food consumption can be analyzed as a two-stage process: consumers make a choice and then decide how much to eat (Wansink and Chandon 2014). Hence, choice and quantity intake should both be investigated to fully understand the operation of self-control. However, most research has studied choice (with Fedorikhin and Patrick 2010 being an exception), and this is potentially problematic since food consumption quantity is heavily dependent on the sensation of taste (Metcalfe and Mischel 1999), which only occurs post-choice. Consequently, simply basing inferences on observed choices may lead researchers to ignore important consequences such as actual calorific intake.

The over-consumption of calories is the most significant contributor to obesity (Livingston and Zylke 2012). While vices are of course best consumed in moderation, overconsumption of virtues may also be problematic. For example, salads can be higher in calories than burgers (Melnick 2013), and these virtue calories tend to go under the radar. In this research, we report two studies that measure actual intake conditional on choice of vice versus virtue. We tested how individual differences in dietary self-control maps onto (a) the choice between a virtue and a vice, and (b) actual calorie consumption.

Study 1 followed Shiv and Fedorikhin (1999), employing a single-factor between-subjects design with food type manipulated as vice vs. virtue and dietary restraint measured (Herman and Polivy 1980) as domain-specific self-control. Participants (N=124) were given a "taste test" and asked to choose either M&Ms or almonds (pretested). They were then given 40 grams of their chosen food in a plastic cup to taste as they worked on a puzzle solving task, designed to constrain processing resources during consumption. Participants were free to eat as much as they wanted while they worked on the puzzles, and their cups were weighed after they left the lab to estimate their calorie consumption.

Interestingly, dietary restraint had no influence on choice. Since we allowed free choice and then measured intake of the chosen item conditional on choice, there is a potential endogeneity problem. To address this, we analyzed consumption quantity using an endogenous treatment regression model, which follows a two-stage procedure (similar to the analysis of purchase quantity conditional on brand choice; Krishnamurthi and Raj 1988; see also Galoni and Noseworthy 2015). The data did not have a significant endogeneity problem (ρ = -.49; σ = 4.79; p = .48). The regression revealed a significant interaction between food type and restraint (B = -2.08; p = .05). Follow-up analyses revealed, importantly, that unrestrained eaters ate more if they had chosen the virtue than if they had chosen the vice (p < .05). In contrast, restrained eaters tended to eat directionally less of the virtue than of the vice (p = .12). Similar patterns were obtained using a simple linear regression. These results are surprising because the choice of the virtue did not lead to uniformly low consumption quantity or calorie intake. Rather, chronic self-control influenced food intake in a different way from food choice—unrestrained eaters ended up consuming higher calories when they chose the virtue than when they chose the vice.

Study 2 (N=390) extended study 1 by adding a cognitive load factor, exactly as in Shiv and Fedorikhin (1999). We manipulated cognitive load by instructing participants to memorize either an 8-digit or a 2-digit number, following which they continued to the food tasting task as study 1.

Unrestrained eaters were more likely to choose the vice under high (vs. low) cognitive load (p < .01), successfully replicating Shiv and Fedorikhin (1999; study 2). Unlike in study 1, the test for consumption quantity contingent on choice revealed endogeneity—there was a significant correlation in residuals (ρ = -.77; σ = 11.02; p < .01). Accounting for this, the discrete-continuous model revealed a significant interaction between cognitive load, food type, and restraint (B = -5.63; p = .01). Follow-up analyses revealed that restrained eaters consumed less of the virtue when under high (vs. low) cognitive load

($p < .05$). In contrast, and replicating study 1, unrestrained eaters ate more of the virtue when under load ($p = .06$). Moreover, under high cognitive load, unrestrained eaters consumed significantly more calories from virtues than from vices ($p = .01$). Cognitive load did not have an effect at any level of dietary restraint for those who chose vices.

By measuring actual intake after food choice, two studies show convergent evidence that consumption patterns tell a very different story from what may be inferred by simply observing choice. Given a choice of a virtue, cognitive load increased intake among unrestrained eaters while it decreased intake among restrained eaters. Essentially, the decision to continue versus stop eating is very different from the decision (of what) to start eating, and has very different implications for inferences of self-control.

SESSION OVERVIEW

Mental accounting, or the way in which consumers catalog, analyze, and recall their spending, has important consequences for happiness and financial health. Research in this domain has uncovered several features that affect both spending and satisfaction, such as categorization, representation in different currencies, and purchase timing. The goal of this session is to present novel and complementary insights on the rich dynamics of mental accounting through examining these features.

This series of four papers explores how consumers' methods of mentally and emotionally tracking their purchases and consumption decisions influence their subsequent choices and satisfaction. We collectively demonstrate that this mental tracking can influence the amount consumers spend, what they spend on, and how they feel about those expenses across different resources (money, loyalty points, and self-control).

In the first paper, Zhang, Hsee, and Sussman show how price promotions can *reduce* purchasing. The authors show that consumers may view the quantity at which the price increases in such a promotion (e.g. after reaching unit X under a promotional discount on the first X units) as a stopping point in their purchase decisions; this cue shifts mental budgeting, which can reduce the quantity purchased.

The second paper extends the focus from single-item mental budgeting into category-wide financial budgeting. Jia, Li, and Lee establish that consumers set higher budgets when they budget for multiple component subcategories rather than creating a single overarching budget. Consumers tend not to naturally consider more indulgent expenses, but actively estimating expenses in component subcategories fosters greater elaboration on these non-essential purchases. Actual shopping decisions reveal that this elaboration can lead consumers to spend more overall.

Next, Chun and Hamilton compare consumers' willingness to spend loyalty points and money when they have equivalent budgets in both currencies. The authors show that the design characteristics of loyalty point programs, such as the numerosity of points awarded, systematically influence consumers' choices between spending cash and spending points. Although use of non-cash currencies can reduce the pain of paying, especially for indulgences, making loyalty points more fungible can undermine this benefit.

The final paper extends mental accounting to the emotional pain that accompanies indulgence. Duke and Amir demonstrate that consumers can emotionally "pre-pay" their guilt by mentally budgeting in advance for an indulgence, which boosts net utility at the point of consumption. This is accomplished by decoupling the guilt associated with *choosing* from the guilt stemming from *consuming* indulgence, and allowing the former to depreciate in the period preceding consumption.

Collectively, these four papers provide a fresh understanding of methods consumers use to mentally track their resources and purchases. Counterintuitively, we find that price discounts can encourage consumers to buy *less*, that budgeting with more careful thought and elaboration – especially on indulgences – can encourage consumers to buy *more*, and that making loyalty points easier to use can *lower* consumer satisfaction. We believe this session will have a broad appeal, drawing researchers investigating financial decision-making, pricing, context effects, hedonic consumption, and self-control, as well as judgment and decision-making.

A Price-Purchase Paradox

EXTENDED ABSTRACT

We investigated how changes in the price of a product influence consumers' purchasing and consumption behaviors. Specifically, we examined cases where the first few units are discounted or free. Intuitively, offering discounts or free samples should boost sales. However, we propose that there are situations when consumers purchase fewer units of a product when a discount or free sample is present versus absent, a pattern contrary to economic price sensitivity. Further, we find that this pattern is moderated by the number of products available for purchase at a discounted price. Consumers may take the quantity at which the price increase occurs as a stopping point in their purchase decisions, but only if the quantity is within a reasonable range of their initial preference. We tested our hypotheses across 5 studies in a variety of domains ranging from food to consumer products to energy consumption.

In Study 1, we told college students that they could eat as few or as many M&M's as they wanted over a 5-minute period. Participants received either 1 M&M or 5 M&Ms as free samples. Each additional piece would cost 1 cent and the cost would be deducted from their final payment. We found that participants ate significantly fewer chocolates when the first five pieces were free than when only the first piece was free (Ms = 8 vs. 16; p < .05), despite the fact that participants in the former case on average paid a lower unit price for each of the chocolates they consumed (0.38 vs. 0.94 cents). Further testing revealed that participants ate fewer chocolates when they received five free samples than when there was no free sample present (Ms = 8 vs. 17; p < .05), suggesting that, contrary to normative predictions, consumers may purchase fewer units of a product when more units of that product are discounted.

We replicated the basic effect in the next two studies, with other forms of price increases than price discounts and free samples. In Study 2, we asked MTurk workers to imagine that they were buying an espresso machine. We manipulated the price increase in the form of a sales tax. Participants were told that the sales tax varied in their state from 2% to 8%. In the no-increase condition, the sales tax was always 8%. In the other condition, the sales tax was 2% for items

under $50 and 8% for each dollar spent above $50. We found that participants opted to purchase a significantly less expensive espresso machine when the sales tax was initially low but would increase beyond $50 than when the sales tax was always high (Ms = $71 vs. $64; p < .01).

In Study 3, we manipulated the unit price of household electricity consumption in a hypothetical scenario, and found that participants chose to consume less energy per month if the unit price of electricity started to increase at a relatively high household consumption level than if it increased at an extremely low level.

We further looked into the mechanism underlying these effects in Studies 4-6 and tested boundary effects as well as possible mediators. We propose that consumers are not only sensitive to prices, but also sensitive to price increases. They take the quantity at which the unit price increases as a stopping point in their purchasing decisions, but they do so only if the quantity is within a reasonable range, a range that is close to their initial preference. For example, if consumers are offered a 10ml free sample of yogurt and they initially prefer eating around 50ml, they may still purchase 40ml or more after trying the free sample since 10ml is too little to satiate their appetite. However, if consumers are offered a 30ml free sample, then they might be sufficiently satiated and prefer not buying any more since the price of the next 20ml is higher. Here, in our definition, 30ml would be within the reasonable range of their initial preference, but 10ml would not be.

To test the relevance of the reasonable range, we ran Study 4 with two parts. In a pretest, we elicited participants' perceptions of a reasonable range for the price of a new keyboard (i.e. the minimum and maximum prices they would spend on a keyboard) as well as their preferred price. Based on the pretest, we manipulated price increases in the form of a sales tax. In the central experiment, we told participants that a 9% sales tax applied to items above a preset cost. The cost varied in terms of where it fell in the pre-tested range of reasonable keyboard prices. We found that participants were willing to spend significantly less on a keyboard if the tax applied to a keyboard at a reasonably low price but not if the tax applied at an unreasonably low price. However, we also found that participants were willing to spend significantly more if the tax applied at a high price, irrespective of whether it was reasonably or unreasonably high.

We manipulated the reasonable price range and price increase in Study 5, in which participants reported their willingness to pay for a sofa set. Participants were told that they would pay for the sofa with two credit cards, one with a high interest rate and the other with a low interest rate. The low-rate card had a spending limit of $100 (vs. $400). We replicated the basic effect in the narrow range conditions (i.e. an expert suggested that this purchase should cost around $500 to $1,000), but found the opposite in the wide range conditions (i.e. purchase should cost $100 to $1,300). We tested perceived reasonability of certain prices as possible mediators of the effect in Study 6.

In summary, we found that 1) consumers may purchase fewer units of a product if the unit price of the product is discounted (or free) up to a certain quantity than if there is no discount; 2) this basic effect is moderated by how close that quantity is to the quantity that consumers initially preferred.

The Influence of Categorical Framing on Budgeting

EXTENDED ABSTRACT

Consumers frequently set budgets for various types of consumption. The budget that they set for various mental accounts can have a significant impact on their subsequent spending behavior (Cheema and Soman 2008). In this work, we investigate how different ways of setting budgets affect the size of the budget that consumers set and, in turn, their actual spending.

Specifically, we test two methods that consumers typically use in personal-finance budgeting. First, consumers can set budgets for different constituent categories in order to derive an overall budget ("categorical framing"). Alternatively, they may set an overall budget with or without considering its constituent categories or components ("overall framing"). We propose that consumers set a higher overall budget when they do so under categorical framing than under overall framing.

Our reasoning consists of two steps. First, categorical (versus overall) framing increases elaboration of the constituent subcategories during budgeting. Prior research on numeric judgment has revealed that unpacking an overall category into its subcategories increases elaboration of each subcategory (e.g., Kruger and Evans 2004; Tversky and Koehler 1994). Second, increased elaboration makes individuals think more about the items that they want and desire. Overall framing limits elaboration, hence individuals are more likely to consider only the expenses that are salient in their minds, which, in most cases, are the necessities; categorical framing leads to increased elaboration, hence individuals are more likely to consider the items that they want and desire besides the necessities. Therefore, categorical framing leads individuals to set a higher overall budget than overall framing.

Study 1 was conducted to test this hypothesis. Participants (N = 117) were randomly assigned to one of three conditions. In the *categorical* condition, participants were asked to set individual budgets for their next-month spending in six major consumption domains (i.e., accommodation or rent, food and drinks, transportation, entertainment, clothing, and other expenses). The budgets set for the six categories were then summed to derive their overall budget for the month. In the *overall-with-reminders* condition, participants were asked to set an overall budget for their next-month spending, with the six aforementioned consumption domains provided as examples. Finally, in the *overall-without-reminders* condition, participants were asked to set an overall budget without being reminded of the consumption domains.

An ANOVA revealed a significant effect of budget framing on participants' set budgets (F(2, 114) = 10.07, p < .001). Contrast analysis further indicated that participants set a larger budget under categorical framing (M = $785.39, SD = $537.20) than either overall-with-reminders framing (M = $478.27, SD = $321.06; p = .003) or overall-without-reminders framing (M = $387.24, SD = $329.49; p < .001). There was no significant difference in budget between the two overall-framing conditions (p = .22).

Since study 1 did not reveal a significant budget difference between the two overall-framing conditions, we included only the *overall-with-reminders* condition in the studies reported later as a more conservative test: Compared with overall-without-reminders framing, overall-with-reminders framing provides individuals the same amount of information about constituent subcategories as categorical framing does.

Study 2 was conducted to test whether the effect of categorical framing on set budget is due to greater consideration of wants and desires that categorical (vs. overall) framing induces. The procedure of study 2 was similar to study 1 with two exceptions. First, we asked participants (N = 96) to set budgets for *next-week* spending. Second, we added a process measure. Specifically, we asked participants to indicate the extent to which they agreed with the following statements on a 7-point scale: "I focused on the items that are desirable;" "I focused on the items that I would love to spend on;" "I focused

on what I want to buy" (These three items were averaged to derive a *want-focus* index, α = .76).

Replicating the results of study 1, participants set a larger budget under categorical framing (*M* = $170.41, *SD* = $111.12) than overall framing (*M* = $127.00, *SD* = $81.50; *F*(1, 94) = 4.84, *p* = .03). As expected, categorical framing (*M* = 4.80, *SD* = 1.22) made participants focus more on what they wanted than overall framing (*M* = 4.34, *SD* = 1.35; *F*(1, 94) = 3.04, *p* = .08). Furthermore, mediational analysis (Preacher and Hayes 2008) revealed that categorical framing had a marginally significant effect on want focus (β = .46, *p* = .08), and that controlling for categorical framing, want focus had a significant effect on set budget (β = 18.92, *p* = .01). Because the 95% confidence interval ([.26 to 27.56]) for the indirect effect did not include 0, the mediation was significant.

Study 3 was conducted to test whether categorical (vs. overall) framing increases individuals' spending. At a department store entrance, shoppers (N = 230) were approached to complete a short survey in exchange for a free-gift coupon. Embedded in the survey was the framing manipulation. In the *categorical* condition, shoppers were asked to estimate how much they would spend in each of the nine product categories sold by the department store. In the *overall* condition, they were asked to estimate how much they would spend in the store overall with the nine product categories provided as examples. After participants had finished their shopping, we collected shoppers' receipts when shoppers redeemed their coupons.

Replicating the results of studies 1 and 2, shoppers set a larger spending budget under categorical framing (*M* = $197.36, *SD* = $171.91) than overall framing (*M* = $80.17, *SD* = $50.64; *F*(1, 228) = 50.25, *p* < .001). More importantly, using actual spending as the dependent variable, an ANOVA revealed that shoppers spent more under categorical framing (*M* = $81.70, *SD* = $89.10) than under overall framing (*M* = $61.62, *SD* = $66.21; *F*(1, 228) = 3.79, *p* = .05).

In conclusion, we demonstrate across three studies that categorical (vs. overall) framing leads individuals to set a higher budget and also spend more. This framing effect is due to categorical (vs. overall) framing leading individuals to think more about what they want.

Spending or Stockpiling: Consumers' Decisions to Redeem Loyalty Program Points

EXTENDED ABSTRACT

Loyalty programs are designed to reward customers for buying more or buying more frequently from a firm. Typically, customers earn points for the dollar value of the purchases they make (e.g., United Airlines' Mileage Plus program awards points for each dollar spent) or the number of purchases they make (e.g., My Starbucks Rewards customers initially earned stars for each transaction), which can then be exchanged for products and services. In a sense, these loyalty program points function as a currency that consumers can spend on products and services instead of spending money.

Over the past several years, many loyalty programs have tried to make the points earned by their members more valuable by making them more fungible (e.g., allowing members to redeem points on other ecommerce sites and to pay with a combination of points and money; Dreze and Nunes 2004). However, we argue that there are key differences in the way consumers spend points compared with money. For example, consumers may feel more justified in spending loyalty points than cash on indulgences (Kivetz and Simonson 2002), and using currencies other than cash reduces the pain of paying (Prelec and Loewenstein 1998). Moreover, research suggests that consumers may derive value from "stockpiling" rather than spending loyalty program points, even when the points are easy to redeem and the points have no value outside the loyalty program (Stourm et al. 2015).

We examine differences in the way consumers think about loyalty program points as compared to money, and how they choose whether to make a purchase with loyalty program points or money. We find that consumers' choices to use loyalty program points or money for a specific purchase are systematically shaped by the design characteristics of the loyalty program. For example, loyalty programs vary in the number of points they award per dollar spent. Some programs, like My Starbucks Rewards, give customers very few points per dollar: one star is awarded per multiple dollar transaction. Other programs, like United Airlines' Mileage Plus, give customers many times more points than the dollars they spend: for non-elite members, five points are awarded per dollar spent. Recent research on numerosity effects suggests that the conversion ratio between loyalty program points and the currency consumers typically use can lead to systematic overspending or underspending when redeeming loyalty program points (Raghubir and Srivastava 2002; Wertenbroch et al. 2007). Raghubir and Srivastava (2002) show that when the nominal value of a new currency is a multiple of the home currency (e.g., points in the Mileage Plus program), consumers tend to spend less, but when the nominal value of a new currency is a fraction of the home currency (e.g., stars in My Starbucks Rewards), consumers tend to spend more. Thus, loyalty program design characteristics, such as the number of points awarded per transaction or per dollar spent, can shift consumers' preferences for using loyalty points or money when purchasing goods and services.

In a series of studies, we show that consumers' willingness to spend points vs. money is systematically influenced by several loyalty program design characteristics that influence the perceived conversion rate between points and money. In our first study, 358 participants imagined that they were purchasing airline tickets for a series of five trips they would take over the next year. For each trip, they were given a budget in both points and dollars, and they decided whether to redeem their points or pay in dollars and save the points for other trips. We varied between subjects whether participants received training to help them understand the conversion between dollars and points, the ease of mentally converting points to dollars, and the numerosity of loyalty program points. We also varied the price level of the flights within subjects. Consistent with past research (Stourm et al. 2015), we find that participants tend to "stockpile" loyalty points even though points have no value outside the decision context. We also find significant effects of training, numerosity and price level on participants' willingness to redeem points. These manipulations influence the perceived conversion ratio between loyalty program points and money, such that points seemed more valuable relative to money in some decision contexts than in others. However, one limitation of our first study is that we do not know whether these results are due to the specific nature of loyalty program points or whether they are more general to spending in an unfamiliar currency.

In our second study, we addressed this limitation by comparing consumers' choices between spending loyalty program points vs. money to their choices between spending in a familiar vs. unfamiliar currency. We asked 386 participants to imagine they would be visiting friends in three different cities. In one condition, participants chose whether to spend loyalty program points vs. dollars, and in another condition, they chose whether to spend foreign currency vs. dollars. The foreign currency we chose for this study has been used in previous work examining numerosity (Wertenbroch et al. 2007). Using this hypothetical currency allowed us to manipulate the numerosity and stability of the exchange rate for the loyalty program

points and foreign currency in exactly the same way, providing a relatively clean test of the generalizability of our results across multiple currencies.

Across these two studies, we see quite clearly that the design characteristics of loyalty programs – such as the numerosity of loyalty program points, the stability of points prices, and the price level of the items that can be purchased with points – have systematic and significant effects on consumers' willingness to spend loyalty program points instead of stockpiling them. Because these design factors influence the perceived value of loyalty program points, they are critical to consider when thinking about how to motivate consumers to join loyalty programs and earn points as well as when thinking about how to engage members as they stockpile and redeem their points.

Mental Accounting of Guilt: Decoupling Guilt from Consumption

EXTENDED ABSTRACT

Indulging, or consuming a vice, elicits two separable outcomes: intrinsic enjoyment and guilt (Ramanathan and Williams 2007; Chen and Sengupta 2014). We propose that the timing of a decision to indulge in relation to the indulgence episode itself can alter consumers' overall utility *during* consumption by decoupling the guilt associated with the choice from that associated with consumption. In particular, we demonstrate that "precommitting" or planning in advance to consume a vice reduces guilt, but does not affect intrinsic enjoyment, providing higher net utility at the time of consumption.

Failure at self-regulation is one common source of consumer guilt (Dahl, Honea, and Manchanda 2003), an unpleasant emotional state characterized by feeling one has fallen short of his/her internal standards of conduct (Baumeister, Stillwell, and Heatherton 1994). This self-conscious emotion can emerge quickly (Ramanathan and Williams 2007) and decays over time (Kivetz and Keinan 2006). We propose that consumption of a vice elicits guilt associated separately with the *choice* to indulge and with the *experience* of indulgence. Reaching the decision to indulge brings about the former, which can then decay in the period leading up to the actual indulgence experience. As a result, the net guilt felt at the point of consumption will be lower.

The result of this decoupling process aligns with that of Prelec and Loeweinstein (1998), who find that the awareness of having to pay for an experience reduces utility during the experience itself. For example, going on a cruise vacation and knowing one must pay for it later can reduce enjoyment of the vacation in the moment. However, pre-paying for the vacation before it begins can prevent this attenuation effect. In a similar fashion, we show that consumers can mentally pre-pay for the "sin" of consuming a vice and increase utility from consumption.

In study 1, participants who recounted a time in which they precommitted to indulge (vs. those who recounted a time in which they made the decision in the spur of the moment) indicated feeling less guilty ($t(200) = -4.55$, $p < .001$) and regretting the indulgence less ($t(208) = -2.98$, $p < .01$). In turn, these participants also indicated higher overall enjoyment of the indulgence ($t(208) = 2.44$, $p = .02$), and felt happier about having indulged ($t(206) = 3.57$, $p < .001$). According to our theorizing, decision timing should affect net enjoyment through its influence on negative self-conscious emotions, but should not affect the intrinsic pleasure the experience itself provides. As expected, after controlling for feelings of guilt and regret, the effects of condition on enjoyment and net happiness were no longer significant.

In study 2, we sought to directly control for any differences due to the types of indulgent experiences to which participants may choose to precommit. Participants read three scenarios in which two focal actors both indulged in the same experience. However, in each scenario, one actor reached the decision to indulge with more time before the indulging episode. As predicted, across all scenarios, this actor was expected to feel less guilty (p's $< .001$), to experience less regret (p's $< .001$), and to feel happier about having indulged (p's $< .01$).

In study 3, we directly induced indulgence guilt in a controlled laboratory setting. At the beginning of the experiment, half of participants ("precommitters") were told they would be taking part in a taste test later in the session and could choose between ½ of a Krispy Kreme glazed donut and 3 baby carrots. They made their selections and then proceeded to a filler task. The other half of participants began the filler task immediately upon entering the laboratory. One-by-one, each participant in this "immediate" condition was taken to a separate room, learned about the taste test, chose a food option, and immediately consumed the selected food. After eating, each participant was interviewed by research assistants about his/her food choice and the thought process that led to its selection. After each participant in the immediate condition had completed the taste test and the interview, the precommitters individually consumed their preselected items and were interviewed. The percentage of participants choosing the indulgent food (the donut) over the virtue food (carrots) did not differ by condition (precommitters: 61.1%; immediate condition: 60.0%; $\chi^2(1) = 0.01$, $p = .9$).

The vocal responses of participants who had selected the indulgent food (the donut) were analyzed using Layered Voice Analysis software to identify several emotions (Nemesysco 2009). These emotions loaded onto 3 factors (1: energetic, excited, angry, and concentrated; 2: upset, stressed, uncertain, and embarrassed; and 3: content). Responses differed by condition only on factor two: precommitters expressed significantly less stress, uncertainty, embarrassment, and upsetness in the interview than did immediate participants ($M_{precommit} = -0.17$ vs. $M_{immediate} = 0.18$, $t(121) = -2.03$, $p < .05$). Thus, precommitting to indulge lowered the negative emotions participants experienced during an indulgence episode.

In study 4, we will show that precommitting to vices changes consumers' actions and intentions following consumption. Existing research suggests that guilt induces a motivation to atone for transgressions and engage in reparative behaviors (e.g. Tangney et al 1996; Lindsay-Hartz, De Rivera, and Mascolo 1995). As precommitting to consume a vice results in less guilt at the time of consumption, it should produce less motivation to engage in reparative actions thereafter.

In four studies, we find that separating the decision to consume from a consumption episode can reduce the amount of guilt experienced during consumption, increasing net utility at the point of consuming. This work suggests an additional benefit of a decision to "precommit to an indulgence." Kivetz and Simonson (2002) propose that consumers may select an indulgent reward (rather than cash) to receive in the future as a means to precommit to treating themselves to pleasurable products and experiences, which they otherwise might forgo for more utilitarian necessities. We build on this work to suggest that, not only will consumers experience more indulgences by precommitting to consume them, but they will also appreciate those indulgences more.

Competitive Papers—Full

Keep It Simple Stimuli: Brain-Vetted Elements of Movie Trailers
Predict Opening Weekend Ticket Sales

Samuel B. Barnett, Northwestern University, USA
Hope M. White, Northwestern University, USA
Moran Cerf, Northwestern University, USA

ABSTRACT

We propose a novel method to predict movie ticket sales based on the stimulus complexity of the associated advertisements (i.e. movie trailers). We identify characteristics of movie trailers (e.g. semantic and visual clarity) that promote neural similarity (i.e. Cross-Brain-Correlation) among moviegoers at a commercial theater and foreshadow commercial success.

INTRODUCTION

The film industry has enticed consumers with movie trailers for over a century. When the first movie trailer debuted in 1913, it was heralded as "an entirely new and unique stunt" (Hoefling 2010). Now ubiquitous and highly competitive, movie trailers are the products of substantial investment. A single movie trailer can take six months to produce and Hollywood spends over $3 billion per year on cinematic advertising (Faughnder 2015). Putting that into perspective, annual movie trailer production costs more than buying a movie ticket for every person in the United States (average ticket price is $8.70, IMDb.com, Inc., Seattle, Washington; US population is 323 million, US Census Bureau).

Given the film industry's high upfront advertising costs, there is substantial interest in advance predictions of the commercial success of movies. Researchers have identified potential early indicators of financial outcomes such as aspects of a movie's script or whether the movie is a sequel (Eliashberg et al. 2006). In particular, Eliashberg et al. report that sequels tend to outperform stand-alone movies in ticket sales and that advertising for sequels is more efficient since moviegoers have prior knowledge of the base story. Additionally, there has been a rapid increase in scholarly attention to the effects of individual cast members on film revenue. A star actor's participation in a film is often interpreted as implicit endorsement of the project, and endorsements by popular figures have been broadly successful in advertising campaigns (Choi et al. 2005). Specifically, a star actor garners an average of $3 million in additional ticket sales for a film, but often the compensation paid to these actors cancels out the marginal increase in theatrical revenues to the film studio (Elberse 2007). Eliashberg et al. also cites the rising cost of talent (especially for sequels) as a factor that complicates revenue predictions.

High revenue movies, by definition, attract a wide audience, which suggests that the corresponding movie trailers were broadly appealing to the moviegoer population. Qualitatively, members of a captivated audience behave similarly: laughing, flinching, or gasping at the same time, looking in the same direction, and maintaining an attentive physical posture. Recent research has identified neural underpinnings for such behavioral resemblances; neuroscientists have discovered that brains act similarly while processing certain stimuli, such as memorable movies, television shows, advertisements, and stories (Hasson et al. 2004, Furman et al. 2007, Hasson et al. 2008ab, Avidan et al. 2009, Regev et al. 2013, Barnett et al. 2015). These results suggest that measuring neural similarity is a promising technique to distill aspects of stimuli that contribute to collective appeal and action.

In this work, we offer a neuroscientific lens to characterize basic elements of successful movie trailers. We use portable electroencephalography (EEG) systems to record the neural activity of moviegoers at a commercial movie theater, and then we compute neural similarity throughout each of the trailers (Study 1: EEG Field Study). We hypothesize that movie trailers that promote relative neural similarity will be more memorable (i.e., higher recall rates) as measured in a survey immediately following the movie. In this survey, we also confirm the supremacy of trailers by asking moviegoers which factors influence their decision-making process; the majority of moviegoers use trailers to decide which movie to watch.

After movies are released, there are countless factors that influence moviegoer purchase decisions, including online user reviews, recommendations, popular excitement, and critical acclaim. However, before the movies are released, most of the aforementioned factors are unavailable (by definition) to moviegoers; therefore, trailers are even more important regarding purchase decisions of opening weekend movie tickets. Therefore, we measure the commercial success of a trailer as its corresponding movie's opening weekend domestic ticket sales. Thus, we additionally hypothesize that neural similarity during movie trailers will correlate with their respective opening weekend box office performances.

In Study 2 (Characterization of Stimuli), we dissect quantifiable stimulus attributes of movie trailers. We hypothesize that numerous measures of complexity will be negatively correlated with neural similarity; conversely, simpler advertisements have more uniform effects across multiple brains. We investigate standard measures of semantic complexity, such as the number of words, sentences, questions, and unique speakers per unit of time (Flesch 1948, Kincaid et al. 1975). Additionally, we measure the proportion of speaking time versus non-speaking. We also study visual complexity, which we assess as the average entropy (i.e., statistical randomness) of each frame of the movie trailer; low-entropy images are relatively uniform in intensity whereas high-entropy images have many bright areas and dark areas (see example in Figure 1). Accordingly, high-entropy images often have many focal points for visual attention (Itti et al. 2005). In turn, we hypothesize that these stimulus characteristics will correlate with neural engagement and will subsequently influence opening weekend ticket sales.

Lastly, we propose a linear model to predict the commercial success of a movie based on its trailer. Our model incorporates previously studied indicators (i.e., whether the movie is a sequel) along with the semantic and visual complexity of its advertisement. We seek to demonstrate that stimulus attributes that facilitate neural processing can, themselves, be applied towards predicting theatrical revenues.

METHODS

Study 1: EEG Field Experiment

Subjects and Procedure

Fifty-nine subjects watched trailers and movies while undergoing EEG recordings at a commercial theater that we partnered with for the study (AMC Theatres, Northbrook, Illinois; NYSE: AMC). Subjects were given free admission to a movie of their choice that they had not previously seen from a list of the theater's regular showtimes. Subjects were also offered free soft drinks and popcorn before the movie, but were not allowed to consume these concessions while undergoing the EEG recordings to avoid interfering with the neural measurements. Subjects were fitted with an electrode cap with a circumference of either 54cm or 58cm depending on head size and comfort with the cap's tightness. While the subjects were wearing the caps, a washable conductive gel was placed with a syringe at each electrode site on the subjects' scalps. For each showtime in our study (n = 44), we collected data from multiple subjects seated next to each other at a preferred row dedicated for the study. All subjects were native English speakers with normal hearing who provided informed consent. Additionally, we explained the experiment to other moviegoers and theater staff (not participants) in the vicinity to avoid interruptions.

EEG Data Acquisition

Subjects' neural data were collected using 32-channel EEG systems (Brain Products GmbH, Gilching, Germany) at a rate of 250 samples per second. Each electrode connection was verified to be functioning properly (i.e., detecting electrical activity from the scalp) before starting the recording. Neural data were acquired from diverse brain regions; the 32 EEG electrode sites were distributed across the entire scalp according to the actiCAP 64Ch Standard-2 (green holders) montage (Brain Products GmbH, Gilching, Germany).

Free Recall and Survey Data

Immediately following the movie, subjects were asked to participate in a survey about the content that they viewed (e.g., movie plot recall, movie trailer recall), their general movie preferences (e.g., favorite genre), and factors that influence their movie selection (e.g., user reviews, scores, recommendation from friends, spontaneous decision at theater, viewing trailers).

Cross-Brain-Correlation Computation

We computed moment-to-moment synchrony in EEG data across subjects experiencing the same audiovisual stimuli, which we deem Cross-Brain-Correlation (CBC). At each electrode site, we measured neural activity over time as the power (dB) of alpha oscillations (also known as Berger's wave; cf., Berger 1929) in the recorded EEG data, which are commonly associated with attention to visual stimuli (Klimesch 2012, Dmochowski et al. 2014). To do this, we performed a Short-Time Fourier Transform (STFT) of the raw EEG signal at each timestep, filtered the resulting Power Spectral Density (PSD) matrix, and multiplied the common logarithm (base 10) of the PSD matrix by 10; we then assembled a time series of activity at the given electrode site that was then correlated with the stimulus-matched time series of activity at the corresponding site for each subject. At each timestep, we averaged the correlations at a given electrode site for every pair of subjects. Finally, we averaged across the 32 electrode sites to arrive at a single value of neural similarity at each timestep, thus producing the CBC time series. The CBC values were normalized to range from zero (minimum) to one (maximum) for ease of comparison. Additionally, as a control for eye blinks and muscle movements, which primarily affected the front two electrode sites on the forehead (Fp1 and Fp2), we repeated our CBC computations without those channels and found that these differences were negligible with respect to all of our findings.

Stimuli. Across all 44 trials, subjects viewed 5.84 ± 1.26 trailers (*mean ± standard deviation*) prior to their selected movie. Subjects' movie selections corresponded with 13 trailers presented more than once and subsequently recalled by more than one subject. These trailers represented movies that ultimately earned over $1.25 billion in domestic ticket sales. Trailers were consistent in length (136 ± 20 seconds), but diverse across other dimensions of visual and semantic complexity. Five of these trailers corresponded with sequels while the other eight advertised movies were stand-alone original stories.

Study 2: Characterization of Stimuli

Movie Trailer Transcription and Coding

We manually transcribed each trailer in order to perform programmatic text analysis. We used standard word processing applications to count sentences and words. We also manually coded each trailer to determine the proportion of speaking time (i.e., character dialogue or narration) relative to the entire video clip. Additionally, we manually counted the number of questions and the number of unique speakers for each trailer with one exception (an advertisement for a nature documentary did not lend itself to these two measures).

Visual Complexity Computation

We programmatically measured the entropy (i.e., statistical randomness) of the intensity image. For a uniformly intense image (meaning every pixel has equal brightness), entropy is zero; conversely, an image of random pixel intensities (e.g., "snow" displayed on analog televisions when no signal is received) is maximally entropic (normalized to 1). Next, we computed the average entropy across all frames for each trailer, which corresponds to its overall level of visual complexity (i.e., disorder).

Supplemental Stimuli

We extended our data by adding the trailers corresponding to the ten all-time highest grossing movies according to the Internet Movie Database (IMDb.com, Inc., Seattle, Washington), seven of which were sequels. We repeated the same steps to characterize the stimuli (manual transcription and coding, programmatic word counts and visual complexity computations). Accordingly, the combined dataset in this study consists of 23 movie trailers (12 sequels and 11 stand-alone original stories).

RESULTS

In Study 1 (EEG Field Experiment), we found that viewing trailers was the single most important factor influencing movie selection: 33 subjects (55.9%) reported deciding which movie to watch based, in whole or in part, on viewing trailers. Out of the remaining 26 subjects (44.1%), subjects were approximately split between deciding based on user reviews, recommendations, and other factors (e.g., showtime). Subjects' preferred genre had a mild effect on the use of trailers: 50.0% of those that prefer action, 54.5% of those that prefer comedy, and 61.1% of those that prefer drama reported making purchase decisions based on trailers.

Subjects' average Cross-Brain-Correlation (CBC) values throughout each movie trailer were highly correlated ($r = .66$, $p = .01$) with their associated levels of recall following the movie, which is consistent with previously documented links between neural similarity and memory (Furman et al. 2007, Hasson et al. 2008a, Barnett et al. 2015). Furthermore, movie trailer CBC was highly correlated

(r = .51, p = .08) with the corresponding opening weekend domestic ticket sales. However, the CBC-sales relationship was weaker (r = .22, p = .45) for later weeks of distribution presumably as other influential factors besides trailer viewing (e.g., user reviews, recommendations) became available.

In Study 2 (Characterization of Stimuli), we observed that CBC was negatively correlated with numerous measures of stimulus complexity. (In other words, simpler movie trailers tend to generate higher CBC). For example, a movie trailer's proportion of speaking time, which relates to the amount of speech processing undertaken by audience brains, has a strong negative correlation (r = -.78, p < .01) with CBC. Similarly, CBC was negatively correlated with words per minute (r = -.77, p < .01), sentences per minute (r = -.67, p = .01), questions per minute (r = -.58, p = .05), and unique speakers per minute (r = -.61, p = .04). Visual complexity (average entropy per frame; see Methods) also had a strong negative correlation with CBC (r = -.72, p < .01).

Next, we used the aforementioned stimulus characteristics that correlated strongly with neural similarity to predict opening weekend ticket sales for all 23 movies in our extended trailer dataset. Collectively, these movies comprised $1.96 billion in opening weekend sales; however, there was wide variation in the opening weekend success of each movie, which ranged from $113,301 (*Bad Words*) to $247,966,675 (*Star Wars: The Force Awakens*; all-time highest grossing opening weekend performance). On average, a movie in our data set earned $85.10 ± $78.68 million in its opening weekend.

The proportion of speaking time was again the most influential stimulus characteristic; proportion of speaking time had a strong negative correlation (r = -.67, p < .001) with opening weekend ticket sales. Words per minute, speakers per minute, and questions per minute each had correlations of approximately -.60 (p < .01), while sentences per minute had a slightly weaker, but still statistically significant, relationship with opening weekend performance (r = -.44, p = .04). Likewise, visual complexity had a strong negative correlation with opening weekend sales (r = -.62, p < .01). Additionally, all of these characteristics were negatively correlated with ticket sales in later weeks, although these relationships were consistently weaker (see Table 1 for all correlation values).

These measures of stimulus complexity can be used in concert to produce even stronger predictions of opening weekend ticket sales. To demonstrate this point, we present a simple linear model that incorporates both semantic complexity and visual complexity. Additionally, given the prior literature suggesting that sequels outperform stand-alone movies (cf., Eliashberg et al. 2006), we incorporate whether or not a movie is a sequel. Therefore, we determined model coefficients via linear regression with three variables: (i) proportion of speaking time, (ii) visual complexity (entropy), and (iii) a sequel indicator variable (one if the movie a sequel; zero otherwise).

Furthermore, since ticket sales cannot be negative, our prediction equals the greater of zero and the result of the following expression (coefficients rounded; units in $ millions):

267 – (142 × *Proportion of Speaking Time*) – (241 × *Visual Complexity*) + (82 × *Sequel*)

Despite the model's simplicity, its predictions are highly correlated with actual opening weekend ticket sales (r = .89, p < .001; see Figure 1 for illustration). Moreover, the model is particularly diagnostic regarding whether or not an opening weekend will exceed $90 million (the optimal binary threshold value). Nine of the 23 trailers were assigned predicted opening weekend sales in excess of $90 million, and all of those movies indeed earned over $90 million in their opening weekends; conversely, none of the other 14 movies earned over $90 million in their opening weekends. Therefore, although limited to our dataset of 23 movies, our "$90 million test" has 100% sensitivity (0% false negatives) and 100% specificity (0% false positives). (see Figure 1)

DISCUSSION

The collective results of both studies offer numerous insights into the elements of movie trailers that engage brains and ultimately promote ticket sales. Measures of complexity throughout movie trailers consistently opposed both neural similarity and the commercial success of the corresponding movies. Therefore, the film industry should heed time-honored minimalistic design principles (cf., US Navy's "keep it simple, stupid") in order to maximize impact to the brains and wallets of moviegoers.

Nonetheless, our work has substantial limitations and many opportunities for refinement. For example, we average neural activity across all 32 electrodes in our computations of neural similarity; however, we believe that a subset of brain regions could produce more precise, modality-specific measures (e.g., the most posterior electrode sites correspond with visual processing areas). Relatedly, our predictive model is not meant to suggest that the perfect movie trailer has no speaking and no visual complexity; our model assumes that trailers will conform to the same overall style and communicate key information about the upcoming movie in an orderly manner.

The specific format and distribution of movie trailers also makes it difficult to generalize our conclusions to other areas of advertising, but our studies provide an experimental paradigm by which the techniques discussed herein can be tested. Our approach may be applicable in other areas of cinematography; perhaps optimizing stimulus attributes can help make the feature films themselves (i.e., not just their advertisements) more engaging. Outside of entertainment, fields such as education (i.e., to minimize classroom distractions) and politics (i.e., streamlining persuasive arguments)

Table 1: Movie Trailer Stimulus Complexity is Negatively Correlated with Neural Similarity and Ticket Sales. Descriptive measures of each stimulus characteristic are presented in the table; as indicated by the high standard deviations, trailers varied significantly along these dimensions. The table also displays correlations of each characteristic with CBC, with opening weekend ticket sales, and with later week sales (*, **, and *** represent p-values less than .05, .01, and .001, respectively).

Stimulus Characteristic	Mean ± Standard Deviation	Correlations		
		Neural Similarity (CBC)	Opening Weekend Sales	Later Sales
Proportion of Speaking Time	35.77% ± 18.93%	-.78**	-.67***	-.33
Words/Minute	81.13 ± 37.56	-.77**	-.63**	-.26
Sentences/Minute	14.16 ± 8.08	-.67*	-.44*	-.24
Speakers/Minute	2.72± 1.18	-.61	-.61 **	-.37
Questions/Minute	2.04 ± 1.74	-.59*	-.59**	-.43*
Visual Complexity (Entropy)	.71±.17	-.72**	-.62**	-.48*

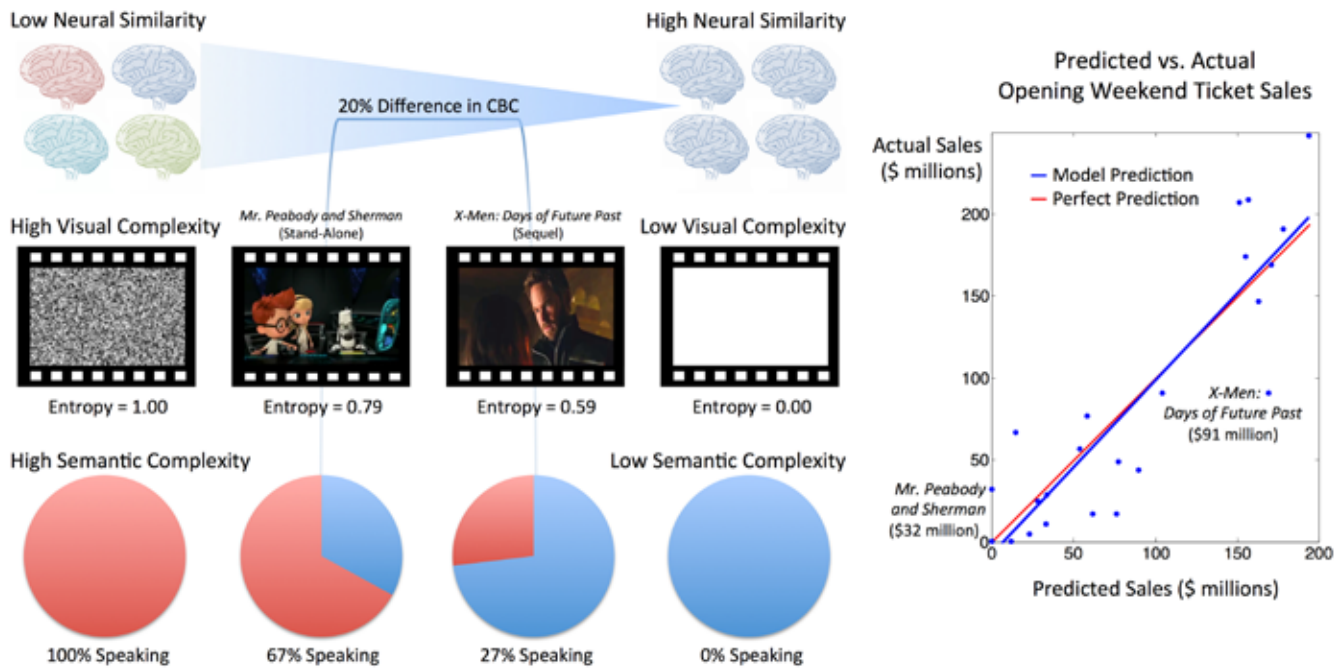
*,**, and *** represent p-values less than .05, .01, and .001 respectively


Figure 1: Movie Trailers with Less Visual and Semantic Complexity Generate Higher Neural Similarity and Ticket Sales. The left portion of the figure presents sample data from two trailers: *Mr. Peabody and Sherman* and *X-Men: Days of Future Past*. The latter achieved 20% higher CBC and 184% higher opening weekend ticket sales than the former. These sample images were selected because they each had entropy values within 2% of the average entropy throughout their respective trailers; therefore, these images illustrate the difference in visual complexity between the two trailers. For comparison, an image with maximal entropy (normalized to 1) is displayed on the left and a blank screen (zero entropy) is displayed on the right. The pie charts below indicate the proportion of speaking time (red) versus non-speaking time (blue). The graph on the right plots the predicted versus actual opening weekend ticket sales for each trailer. The predictions were calculated according to the aforementioned linear model. The blue line depicts the best-fit regression of the model predictions, which nearly matches the red line that depicts the hypothetical perfect prediction (i.e., predicted sales always equal actual sales)

could similarly benefit from a bottom-up approach to improving their respective stimuli.

In particular, movie trailers are incredibly rich stimuli and our work merely addresses their most basic characteristics. Other factors including content familiarity, music, cinematographic style, story comprehensibility, sequencing of narrative events, stimulus dynamics, actor popularity, harmony of elements, and artistic novelty are more challenging to measure, but may offer even greater predictive power with respect to neural and commercial outcomes. The commercial success of a given movie may also be affected by external factors such as the competitive landscape (i.e., what alternatives moviegoers face at a particular time) and seasonal variation in movie theater attendance. Increasing content exposure time (i.e., by advertising for a longer period of time or by repeating messages) has been an effective advertising strategy across industries (Campbell et al. 2003), so advertising expenditure would be another variable to control for in future work.

Our results show that, with all other artistic and commercial qualities being equal, movie trailers that minimize extraneous complexity have more consistent positive effects on the minds and future purchases of moviegoers. Thus, reverse engineering advertising content with a neuroscientific lens is a promising avenue for continued study.

Revisiting The Ghetto:
How The Meanings of Gay Districts Are Shaped by The Meanings of The City

Jack Coffin, University of Manchester, UK
Emma Banister, University of Manchester, UK
Anna Goatman, University of Manchester, UK

ABSTRACT

This paper explores how LGBT consumers' understandings of their local LGBT district are negotiated alongside their understandings of the broader urban context. The data include 31 in-depth interviews. This paper contributes to the LGBT literature but also broader academic discussions about the meaning of place and space in consumer lives.

INTRODUCTION

This paper explores how Lesbian, Gay, Bisexual, and Transgender (LGBT) consumers interpret their local LGBT district in relation to other places in the city. Existing research has provided two competing understandings of LGBT districts, framing them as 'gay villages' (Haslop, Hill, & Schmidt, 1998) or 'gay ghettos' (Kates, 2002). The gay ghetto understanding has been cited more frequently, and is arguably the most influential of the two perspectives. However, it assumes that LGBT districts are embedded into cities where LGBT identities are not accepted. Drawing on data from 31 interviews with LGBT consumers in Manchester, UK, this paper argues that the gay village perspective may provide a more useful understanding. The gay village perspective frames LGBT districts as commercial servicescapes, rather than subcultural places of resistance and community. This paper contributes to the literature by exploring how recent social changes have transformed LGBT consumers' understandings of place, and how marketing and consumer researchers should adjust their own understandings accordingly. It also takes into account the experiences of lesbian and transgender consumers, who are often overlooked in existing accounts. Finally, this paper also contributes to the consumer research literature on place and space, exploring how the meanings of a place are negotiated in conjunction with the meanings of the broader context.

LITERATURE REVIEW

The original *ghetto* was a district of Venice where Jewish people were forcibly confined in the 1500s, but the term has since been adopted by sociologists to refer to any urban district dominated by a particular minority group (Ghaziani, 2015, p. 314). In the twentieth century LGBT 'ghettos' began to emerge in many Western cities (Hammack & Cohler, 2011). Following on from Soja's (1980) notion of the sociospatial dialectic, it could be argued that ghettos are the materialisation of "a conspicuous and locally dominant subculture that is socially isolated from the larger community" (Levine, 1979, p. 1739). One of the most famous, San Francisco's Castro district, was described by an LGBT activist as a "refugee camp for homosexuals [sic]… a ghetto, out of self-protection." (Wittman, 1970, pp. 67-68) This emic definition suggests that, in the LGBT context at least, the term ghetto is associated with segregation and stigmatisation, but also community and safety (Hubbard, Gorman-Murray, & Nash, 2015).

In marketing and consumer research, Steven Kates (1998, 1999, 2000a, 2000b, 2001, 2002, 2003, 2004) is the key author for those interested in understanding the 'gay subculture of consumption' (Kates, 2002). He adopted an ethnographic approach to data collection, immersing himself in "the downtown gay ghetto" of a Canadian city to generate insights about the gay subculture (Kates,

2002, p. 385). This LGBT district features prominently in his understanding, and his choice of the term 'ghetto' was deliberate. Kates (2002, p. 386) argued that "homosexuality was still somewhat stigmatized" in the Canadian city that he studied, so the gay ghetto was a place of "community" where LGBT consumers "felt safe and secure to walk, talk, behave, and consume in as open a way as they wished". Gay ghettos could be understood as heterotopian places, "where alternative forms of social organisation take place" (Chatzidakis, Maclaran, & Bradshaw, 2012, p. 497). It is within the ghetto that LGBT consumers re-learn how to consume, use consumption to express subcultural affiliations, and resist the heteronormative mainstream market (Kates, 2001, 2002, 2004).

In many cities local residents and tourist marketers adopt the term 'gay village' rather than gay ghetto (e.g. Collier, 2014; Nash, 2006, 2013; Simpson, 2012). The term village suggests geographical concentration without invoking the connotations of segregation or stigmatisation that come with the word ghetto (Hubbard et al., 2015, p. 290). Haslop et al. (1998, p. 318) studied the gay village of Manchester, a city in the North West of England. They noted how their participants did not express feelings of 'community' or 'safety' when discussing the gay village. These participants experienced far less homophobia in the rest of Manchester, and thus "did not feel compelled to visit a bar purely on its homosexual status" (Haslop et al., 1998, p. 322). Instead, Haslop et al. (1998) argued that Manchester's gay village should be understood as a servicescape because it was more like a tourist destination than a subcultural refugee camp (see also Binnie & Skeggs, 2004; Simpson, 2012). Gay villages are commercial places that differ from other locations in a largely superficial or aesthetic way, rather than being heterotopic or subcultural places.

In marketing and consumer research there has been little attempt to compare or contrast the gay village and the gay ghetto perspectives. In sociology and geography these two perspectives have been considered alongside one another, but largely through a chronological narrative where gay ghettos transform into gay villages as LGBT people become more accepted (Ghaziani, 2015; Hubbard et al., 2015). Indeed, some researchers propose that many Western countries have entered a 'post-gay' era where LGBT people experience stigmatisation so rarely that they no longer see their sexuality as a defining or dominant identity (Ghaziani, 2011; Ng, 2013). In 'post-gay' cities the demand for gay villages is low, making them economically unviable and thus under threat of dissolution (Brown, 2014; Ghaziani, 2014; Nash, 2013).

All three perspectives, but particularly the chronological narrative, implicitly suggest that the meanings of a LGBT district can only be understood in relation to the broader urban contexts in which they are embedded. However, the chronological narrative overlooks those LGBT consumers who continue to experience discrimination (Brewis & Jack, 2010; Duggan, 2002; Heaphy, 2011; McDermott, 2011), and who may therefore still seek out places of safety and community (i.e. ghettos). It also fails to acknowledge that some LGBT-oriented places and festivals, such as gay pride events (Ammaturo, 2015), continue to thrive. Finally, the account overlooks the fact that Haslop et al. (1998) published their gay village perspective four years before Kates (2002) wrote about gay ghettos. These 'out of sync' exceptions question the chronological narrative. However, they do not challenge

the underlying assumption that the meanings of LGBT districts are defined (in part) through comparisons and contrasts to other places within a city. This paper seeks to provide a more nuanced understanding of LGBT districts by exploring this implicit semiotic relationship in more detail.

CONTEXT AND METHOD

This paper revisits the research context of Manchester, almost two decades after the research by Haslop et al. (1998). Manchester is a British city with a very "visible and publicly accessible" LGBT district, known locally as the Gay Village (Simpson, 2013, p. 284). Researchers have noted how this place is a "regional magnet" for LGBT people (Simpson, 2012, p. 1) and cosmopolitan heterosexuals (Binnie & Skeggs, 2004; Haslop et al., 1998). Of the many intersecting streets within the Gay Village, Canal Street is the most famous and is often used synecdochically to refer to the whole LGBT district. This street was made particularly famous by the 1999-2000 television show *Queer as Folk,* a show that presented the gay subculture to the masses in positive, but sometimes shocking, ways (Skeggs, Moran, Tyrer, & Binnie, 2004).

In 2015 a show by the same writer, *Cucumber*, explored contemporary LGBT lives in Manchester. Notably there were only a few fleeting scenes set in Manchester's Gay Village. This representation of LGBT Manchester echoes discussions in the local and national media about the diminishing role of Manchester's Gay Village (e.g. Collier, 2014). The argument goes that Manchester is renowned for tolerating and even celebrating LGBT people (Senior & Dalton, 2011; Simpson, 2012, p. 2), so LGBT-specific places are no longer necessary. At the same time, LGBT social groups (such as gay rugby clubs), specialist venues (such as saunas), and specialist events (like Sparkle, the transgender festival) still thrive in Manchester (see Simpson, 2014, p. 152). This contradictory evidence suggests that Manchester and its LGBT district defy easy categorisation under a single, overarching narrative. Instead there may be multiple to explore.

To explore these narratives the first author conducted 31 semi-structured interviews with LGBT residents of Manchester. Existing research has generally constructed LGBT samples through ethnographic immersion in a LGBT district (Haslop et al., 1998; Kates, 2002). As sampling from Manchester's gay village could potentially limit the range of experiences that would be expressed, a directory of LGBT leisure groups was used to identify potential participants (see Simpson, 2014). Three groups agreed to participate. The committee of each group disseminated an information sheet about the study via email, and individuals volunteered to participate by contacting the researcher directly. Interviews were audio-recorded, transcribed, and then analysed in NVivo. As the interviews and data analysis continued the first author began approaching members selectively (Glaser & Strauss, 1967), seeking to diversify the sample further. In the final sample six participants identified as lesbians, one as transgender, and one as asexual. Ages ranged from mid-twenties to late sixties, with a fairly even spread of participants in each age group (20s, 30s, 40s, and 50s). A range of occupations and economic backgrounds were covered, but the sample was predominantly white and university educated.

The interviews varied in length from 23 to 115 minutes, but generally lasted just over an hour. They were conducted in locations that were suitable for audio recording but also comfortable for participants. Interviewees were given no remuneration for participation. The interviews were fully transcribed, at which point details were omitted or altered to ensure participant anonymity. Interviews covered a range of topics connected with the participants' sexual identity and their lifestyle. Analysis followed an initial process of open coding, where the research identified interesting themes in the data, followed by a process of categorising, where these themes were organised to reveal recurring patterns (Belk, Fischer, & Kozinets, 2013).

FINDINGS

The findings suggest that LGBT consumers interpreted Manchester's Gay Village in multiple different ways. Manchester's Gay Village featured as a topic in all of the interviews, often being raised by the interviewees before the first author asked a specific question on the topic. During analysis the authors began to notice that participants' understandings of Manchester's Gay Village were often related to their understandings of Manchester as a city.

A number of the interviewees argued that an LGBT-specific district was unnecessary in contemporary Manchester because the city was such an accepting place for LGBT people. Several participants spoke about how they felt comfortable holding hands with their partners in public. Participants provided only a couple of passing references to homophobic incidents in Manchester, none of which were based participants' own experiences. Within this context of acceptance, participants did not associate the gay village with strong feelings of safety (c.f. Kates, 2002; Levine, 1979; Wittman, 1970). Many participants interpreted the gay village as a site of consumption, rather than a place of community. When seeking new consumption experiences or pleasant consumption environments, these participants ranked features such as price, atmosphere, food, or décor above the "homosexual status" of a place (Haslop et al., 1998, p. 322). Participants described Manchester's gay village as overpriced, lacking atmosphere, alcohol-oriented, and generally an undesirable place to be.

Given the above, it is perhaps unsurprising that many interviewees rarely socialised in the gay village. One of the most frequent visitors was Lee, a gay man in his late 20s, but even he only visited once a week. Other participants could not even remember the last time that they had been to the gay village. These participants were highly critical of those who visited Canal Street regularly, arguing that they 'ghettoised' themselves by doing so. Such over-consumption was viewed as tantamount to self-imposed social segregation, at least in an accepting city such as Manchester. Kates (2002, p. 393) noted that those who consumed "exclusively in the geographic and social confines of the gay area" were referred to as 'ghetto queens'. The data here suggested that this symbolic threshold was far lower in Manchester. It was not just those who consumed 'exclusively' in the LGBT district that were viewed with disdain, but also those who went there 'regularly'. Some participants saw weekly visits to the LGBT district as too regular, but for others even monthly consumption was described as unnecessary.

The re-interpretation of the gay village as a consumption site was a common theme across the majority of interviews. However, participants who defined themselves as lesbians or as older gay men tended to distance themselves from the gay village more than most. In contrast to the more upmarket or 'mature' consumption venues that could be found in the rest of Manchester, they argued that the bars and clubs found in the gay village were mostly oriented towards the lifestyle of young, single gay men. For instance, most bars in the gay village offered cheap alcoholic drinks and played loud dance music, rather than providing high-quality food and places where people could talk to one another. Young, single gay men in the sample often echoed this interpretation. Some even argued that the gay village should diversify to better serve the needs of other LGBT people. However, these consumers also re-interpreted the gay village in a more positive way. The cheap drinks and 'unsophisticated'

music found in these places were described as the perfect setting for 'trashy' nights out and weekends of excessiveness. The gay village became a site for "trash and excess", a cultural trope that has long been associated with LGBT consumers (see Visconti, 2008, p. 124). These young and single gay men felt that the gay village provided unique (and even tailored) consumption experiences that could not be found elsewhere in Manchester. Importantly, such experiences of trash and excess were carefully "compartmentalised" (Goulding, Shankar, & Elliott, 2002, p. 263). The young and single gay men in the sample felt that the gay village was somewhere that they should only visit from time to time (c.f. Kates, 2002, p. 386).

While a number of venues in the gay village focused on young, single gay men, other venues had identified alternative target audiences. Mary's House was a bar styled around the theme of a traditional English pub; it had quiet ambient music, real ale, and good quality food. Other venues provided high tea, carnivalesque drag shows, and other experiences that could not be found in the rest of the city. The participants who spoke about these alternative venues in their interviews were also the participants that spoke about Manchester as a multicultural city. The gay village was framed as a place within which to experience 'LGBT culture', with Manchester being understood as a mosaic of different cultures. This understanding was most clearly articulated by Hannah, a lesbian in her 40s, who compared "gay bars" in present-day Manchester to "Jazz clubs" or "Irish pubs". In other words, LGBT venues were themed places where different LGBT cultures were packaged and sold as experiences. This contrasts with Kates' (2002) understanding of LGBT districts as subcultural ghettos.

While the majority of participants described Manchester as an accepting place for all LGBT consumers, some were reflective that Manchester was not always so inclusive. A number of participants described transgender consumers as a potentially vulnerable group that continued to use Canal Street as a place of safety and community. Robin, who was the only self-identifying transgender person to be interviewed in this study, described how the gay village was the hub of the regional transgender community. Robin cited Sparkle, a national transgender festival based in the city of Manchester, as an illustrative example of this. Robin also felt that venues in the gay village were far more likely to be considerate of transgender issues than venues in other parts of Manchester. For instance, one bar constructed a unisex changing area specifically for transgender patrons. Robin argued that the gay village remained an important place for the transgender community because transgender people still experienced discrimination in the rest of Manchester. While other participants described few experiences of discrimination, Robin provided two personal accounts of transphobia. Transgender consumers were not the only vulnerable group mentioned by participants. Lesbian, gay, or bisexual people from certain religious, ethnic, or socioeconomic backgrounds were also cited as groups who might continue to experience discrimination, even in an accepting city like Manchester. For such consumers the gay village was understood as a place of safety and community (i.e. a positive ghetto) because the rest of Manchester was seen as a socially and physically dangerous place to consume openly as LGB or T.

DISCUSSION

The findings suggest that LGBT consumers' understandings of their local LGBT district depend, at least in part, on their understandings of the broader urban context. Understanding these places within their urban context avoids adopting a single overarching narrative, a zeitgeist of stigmatisation or acceptance. Rather it provides a more nuanced account that takes into consideration the multiple coeval

perspectives of consumers. The findings suggest that the gay village understanding provided by Haslop et al. (1998) is still the most appropriate way to understand Manchester's Gay Village. Participants use the gay village as a source of unique consumption experiences, a place to consume a commodified gay culture. This suggests an alternative narrative to the inevitable decline of LGBT places provided by recent research (i.e. Ghaziani, 2014). However, the data also suggest that Kates' (2002) ghetto perspective can also be useful to understand some LGBT consumers' experiences in supposedly 'post-gay' cities. The findings suggest that instead of one narrative or theoretical understanding, researchers should use multiple perspectives simultaneously to explore diversity of experiences that can co-exist within the same city.

Haslop et al. (1998) argued that gay villages could be understood as servicescapes (see also Rosenbaum, 2005). The findings here provide some support for this argument. Building on Hannah's suggestion that venues in the gay village are like 'Jazz clubs' or 'Irish pubs', it is argued here that the literature on themed environments may be helpful (Borghini et al., 2009; Kozinets et al., 2002). The owners of LGBT venues may carefully design their environments to draw on cultural tropes, just like the sports-themed ESPN Zone draws upon sporting culture (Sherry Jr et al., 2004). Future research may seek to draw more links between the culturally informed research on servicescapes (Diamond et al., 2009; Kozinets, Sherry Jr, et al., 2004), and research into commodified subcultures (Goulding & Saren, 2007; Rinallo, 2007; Schouten, Martin, & McAlexander, 2007). In doing so, new insights into the relationships between subcultures, commodification, and servicescapes may be gleaned. Researchers may also wish to adopt a more critical perspective than the exploratory approach adopted here. For instance, what negative consequences might the commodification and thematisation of LGBT culture have for LGBT people and politics?

Cresswell (2004, p. 7) defines a place as "a meaningful location". The interpretation offered here suggests that the meanings of LGBT districts are negotiated within a web of other meaningful urban locations. This interpretation may provide some transferrable insights for marketing and consumer researchers who are interested more broadly in space, place, and consumption. According to Visconti, Sherry Jr, Borghini, and Anderson (2010, p. 513), places can be understood as "appropriated sites where social interactions, sense of belonging, collective memories, and shared identities occur." However, researchers generally focus on interactions *within* a particular location when they explore how consumers, producers, materialities, and practices co-construct the meanings of places (Borghini et al., 2009; Kozinets, Sherry, et al., 2004; Sherry Jr et al., 2004). Only fleeting attention is given to relevant influences outside of these spatial borders (Diamond et al., 2009; Penaloza, 1998). The findings here suggest further attention should be given to the semiotic relationships *between* places. For instance, Exarcheia is understood as an anti-capitalist heterotopia partly through its contrast to the rest of Athens, which is pro-capitalist (Chatzidakis et al., 2012). However, residents and visitors that interpret Athens differently may construct an alternative understanding of Exarcheia as a place.

Future research could overcome the limitations of this study by developing a more diverse sample. Particular attention should be paid to recruiting more transgender and bisexual participants. It may also be interesting to include heterosexuals in the sample, people who consume places in the gay village without self-identifying as LGBT. Future research may also seek to include the perspectives of LGBT venue owners, managers, or designers. Such perspectives would allow researchers to consider whether producers also interpret (and design) gay villages as themed environments. Finally, the

analysis of this study is limited to the urban context of Manchester. It may be useful to conduct a comparative study of two or more cities with LGBT districts. Indeed, following Visser's (2013) critique that LGBT districts are a largely Western phenomenon, it would be particularly interesting to study cities where LGBT districts have not formed. For example, Visconti (2008, p. 118) describes the "limited number of gay pubs and meeting places" in the Italian context, while Hsieh and Wu (2011, p. 400) describe a number of "gay havens" that are dispersed across Taiwan. Such isolated places may have different meanings for LGBT consumers than geographically concentrated LGBT districts. Investigating these places may provide new theoretical perspectives that fall outside the existing tripartite framework of ghettos, villages, or dissolution.

How Sexy can a Paper Clip get?
Evidence for the Transfer of Erotic Meaning to "Unsexy" Products

Georg Felser, Harz University of Applied Sciences, Germany

ABSTRACT

Marketing practitioners claim that sex in advertising only works for products that are related to sex. The presented experiment underpins that this folk hypothesis is not true. Via semantic conditioning (a variant of evaluative conditioning) erotic meanings can be transferred to any product including those totally unrelated to sex.

INTRODUCTION

Practitioners of advertising repeatedly claim that sex in advertising only works when the product is related to sex (Ogilvy, 1985). Advertising Professor Jef I. Richards from the University of Texas is cited with the statement: "Sex sells, but only if you're selling sex." (Kalb, 2012).

In their comprehensive analysis of research on the effectiveness of sex in advertising Lull and Bushman (2015) come to the conclusion that sex does not sell at all. However, most of the research reviewed solely considers variables like memory, valence of an attitude or intention to buy. In contrast, for many cases the primary intent of sex in advertising would be to load up the product with erotic content in order to give it an erotic image. Only little attention has been paid to the question whether sex in advertising is successful in reaching this goal. Moreover, the practitioner's claim cited above has rarely been challenged: Is it really impossible to "sex up" an unsexy product?

To address this issue we use a variant of evaluative conditioning. This kind of conditioning can be defined as the classical conditioning of liking or disliking by pairing a neutral stimulus (CS) with an unconditioned stimulus (US) which has a clear positive or negative valence (De Houwer 2009). The mechanisms behind evaluative conditioning, however, are not limited to elicit liking alone. Procedures similar to those of evaluative conditioning have also proven to be effective in changing meanings of the conditioned stimuli. These procedures have been labeled as a kind of "concept learning" (Glaser and Walther 2013) or "non-evaluative conditioning" (Förderer and Unkelbach 2011). For instance, Förderer and Unkelbach (2011) were successful in making neutral people seem more athletic by repeatedly presenting them with athletic people.

We use the paradigm of non-evaluative conditioning to prove that in the case of transferring erotic meaning to a product the effect is not restricted to certain stimuli. To do this we add an additional factor to the standard conditioning procedure: We present erotic and non-erotic US along with products that do have an erotic meaning on their own as well as with products that do not.

Moreover we hypothesize that the conditioning effect is not due to an effect on confounding variables. It can be argued that pairing neutral CSs with erotic USs may not go beyond evaluative conditioning after all: Since "erotic" for most people is a positive attribute the conditioning procedure may only transfer valence but no meaning. If the pairing of a product with an erotic stimulus results in higher evaluations on an attribute like "erotic" this may only be the result of an unspecific and general enhancement of the product's evaluation. To make sure that the product really gets a different meaning it should be demonstrated that the conditioning effect cannot be reduced to valence alone. Accordingly, we hypothesize that pairing a neutral CS with an erotic US has a much stronger effect on the ascription of attributes like "erotic" and semantically similar attributes (e.g., "exciting") than on the evaluation on attributes like "good".

To test these hypotheses we conducted an experiment in which erotic meaning was transferred to both "sexy" and "unsexy" objects. The acquisition of the attribute was captured by explicit ratings but also by an indirect measure, a semantic version of the affect misattribution procedure (AMP; Payne, Cheng, Govorun, and Stewart 2005). The indirect measure was important to make sure that the objects really acquired an erotic meaning and that the effect was not due to demand characteristics or explicit memory of the exposure during the conditioning stage.

METHOD

The experiment used a standard EC procedure (Walther, 2002) to transfer the attribute erotic from erotic pictures (USs) to pictures of neutral objects (CSs). However, in contrast to regular conditioning procedures, we used two different sets of stimuli for CSs: One set of six objects consisted of objects which presumably were well suited for being charged with an erotic meaning while another set comprised six objects which were totally unrelated to sex and was thus not unsuitable for a transfer of erotic meaning. We will refer to these two sets of stimuli as "sexy" and "unsexy". This results in a two by two factorial design in which all conditions were varied within groups. The two factors were conditioning (erotic vs. nonerotic USs) and suitableness ("sexy" vs. "unsexy" objects).

As "erotic" is most likely a positive concept we controlled for valence in two ways: Firstly, we selected USs which were equal in valence. Secondly, we collected ratings of CSs valence and erotism to be able to control for valence statistically.

Material

Conditioned stimuli

As CSs we used a sample of twelve objects half of which were regarded as very "unsexy" whereas the other half was supposedly well suited for being connected to an erotic content. We took these stimuli from the results of a preliminary study. More specifically, a sample of N = 32 participants was instructed to name objects which are well suited for being charged with an erotic meaning as well as objects which are very poorly suited to acquire an erotic meaning. These lists consisted of classes of objects. For example furniture or office supplies were frequently mentioned as "unsexy" objects, whereas jewelry, candles or alcoholic beverages were frequently mentioned as "sexy" objects. As CSs two sets each containing six pictures were chosen which showed either potentially erotic or unerotic objects (see figure 1 and 2 for examples).

"Sexy" (i.e., potentially erotic) objects were: Candles, strawberries, jewelry, chocolate, perfume and beer

"unsexy" objects were: Writing desk, chair, sticky notes, paper clip, writing pad, folder

To make sure that the objects were otherwise neutral (except for their potential erotic content) pictures did not show any hint on an existing product or brand.

Unconditioned stimuli

USs were generated from ratings participants gave in the first stage of the main experiment. In this stage participants rated a sample of 40 pictures, presented in randomized order, on a scale from 1 to 7 as to whether they consider this picture to be erotic (= 7) or not (= 1). The pictures comprised of males, females, and couples (hetero- and

Figure 1: Example for a "sexy" (left) and an "unsexy" object (right) both used as CSs that were well or poorly suited for gaining erotic meaning

homosexual) in different degrees of nudity but not in pornographic poses. For each participant the six pictures with the highest ratings were adaptively chosen as USs for the conditioning stage. This was done as long as the highest ratings were not lower than 4. For participants who did not give a rating of 4 or more for at least six pictures USs were taken from a standardized set of pictures, the International Affective Picture System (IAPS; Lang, Bradley and Cuthbert, 2008). The six erotic IAPS Items were chosen from the sample of "erotic couples". This ensured that they would appeal to both men and women. The IAPS stimuli are standardized – among others – with respect to valence and arousal. To make sure that the chosen pictures were equally attractive and arousing for both sexes we chose stimuli for which the difference of the mean values for valence and arousal for men and women were minimal.

As nonerotic USs we chose stimuli depicting sport and adventure (e.g., skiing, paragliding). The rationale behind this selection is that control stimuli should closely match the erotic material with regard to positivity and excitement. Analyses of the IAPS stimuli showed that sport-pictures closely matched the chosen erotic pairs in three respects: Arousal, positivity and minimum difference between men and women on both dimensions. So if one has to look for pictures that are just as positive and exciting as erotic pictures without the erotic content, pictures of sports and adventure would be a good guess. Note however that the control stimuli we employed are not an exact match of the erotic UCs as long as participants chose their own erotic material in the first stage.

Participants and procedure

N = 112 participants completed all dependent measures. 56 women and 52 men took part in the experiment. Four participants provided no information on their gender. Participants were mostly students or visitors on the open house of a public university. Mean age was 24.30 (SD = 7.75). Participation was completely voluntary. There were no incentives such as monetary payments nor course credits. However, participants were served coffee and cake while being debriefed in a different room after the experiment.

For the programming we used Inquisit 4.0.4.0 (2013) by Millisecond Software. During the experimental sessions participants were seated in front of a PC and were told that they would see a number of pictures they should evaluate. Participants were placed in semi-cubicles during the experimental sessions. This ensured that they were not able to interact with each other. They were also told about the other parts of the experiment, one of which – the conditioning stage – consisted of a mere presentation in which no input was required. Participants were also informed that in the third part of the

experiment they were asked again to evaluate pictures or symbols. The initial instruction explicitly hinted on the total duration of about 20 minutes. Participants were asked to abort the experiment at the beginning if they should be afraid not to have this 20 minutes time for being concentrated on the experiment.

At the beginning of the experiment participants rated a number of erotic pictures on a scale ranging from 1 "not erotic at all" to 7 "very erotic". Participants could take any time they wanted for this task. A new picture was presented whenever participants provided their rating by entering the appropriate number and hitting the return button. Based on these ratings the computer selected the USs for the following conditioning stage by taking the pictures which were rated highest as erotic stimuli. As mentioned above, control stimuli for the conditioning stage were a fixed set of stimuli depicting sports and adventure.

The following stages of the experiment roughly follow the procedure employed by Förderer and Unkelbach (2011). In the conditioning stage, CS–US pairs were presented. They were assigned randomly anew for each participant. Since there were six "unsexy" products and six "sexy" (i.e., potentially erotic) products a total of twelve pairs were presented. Half of the CSs were presented together with an erotic US, the other half was presented along with unerotic USs. Each pair was presented six times, resulting in 72 pairings. CSs were visible for 1,5 s alone, then the respective US appeared for another 2.5 s. CSs were presented in the upper half of the screen and USs in the lower half. After a pause of 1.5 s, the next pairing was presented.

For the dependent measures, half of the participants completed the indirect measure (SMP) first and then rated each CS on a number of six attributes on 5-point scales; the other half completed the ratings first and afterward the SMP.

For the explicit ratings each CS was presented on the right side of the screen while ratings could be done on the left side. The attributes were "sexy", "erotic", "good", "likeable", "wild" and "exciting". The main dependent variable on the explicit measure was the mean of the two ratings for "sexy" and "erotic". Ratings of the other attributes should account for two potentially confounding variables: Valence and arousal.

For the SMP, participants were instructed they would see two pictures in rapid succession, the first being a familiar picture and the second being a chinese character, a Kanji. They were told that the first picture served as an orientation stimulus and they should decide whether the Kanji represents a word with an erotic or nonerotic meaning as fast as possible. They should react only to the Kanji and not to the preceding picture. Each trial consisted of a CS being visible for 75 ms, followed by a blank screen for 125 ms and a Kanji for 100 ms. A black-and white noise picture immediately replaced the Kanji until participants made their decision by pressing one of two marked keys on the keyboard (see Imhoff, Schmidt, Bernhardt, Dierksmeier and Banse, 2011, for a similar approach). Since Kanji were judged on a conceptual level the procedure is labeled SMP for "Semantic Misattribution Procedure" After finishing the dependent measures all participants were thanked and debriefed.

RESULTS

In the following paragraphs CSs that were paired with erotic USs will be labeled "erotic". CSs that were paired with nonerotic USs will be labeled "nonerotic". Remember, that half of our CSs supposedly were unfit for being charged with an erotic meaning. These stimuli are labeled "unsexy". Accordingly those stimuli for which an erotic meaning seemed appropriate are called "sexy".

Gender of the participants had no effects in all analyses, therefore we omit this factor from the analysis report.

Direct Rating. The six explicit ratings for each CSs were aggregated to three variables: one rating for "erotism" as the mean of the single ratings of the attributes "erotic" and "sexy", another rating for "valence" as the mean of "good" and "likeable" and a third rating for "arousal" as the mean of "wild" and "exciting".

We calculated participant's mean ratings of these three variables for the six erotic CSs and the six nonerotic CSs and compared them within a repeated-measures ANOVA. As predicted, CSs repeatedly paired with erotic USs were rated as being more erotic ($M = 2.35$, $SD = 0.98$) than CSs paired with nonerotic USs ($M = 1.92$, $SD = 0.73$; $F(1, 111) = 25.25$; $p < .001$). Valence ratings for erotic and nonerotic CSs did not differ significantly ($M = 2.87$, $SD = 0.76$ vs. $M = 2.94$, $SD = 74$; $F(1, 111) = 1.89$; NS). However, erotic CSs were also rated as more arousing ($M = 2.21$, $SD = 0.86$) than nonerotic CSs ($M = 2.03$, $SD = 0.80$; $F(1, 111) = 10,91$; $p = .001$). So it seems that the conditioning effect does only spread to a conceptual confound of "erotic" but not to an evaluative confound. This supports the assumption that the conditioning procedure indeed transfers meaning and not valence alone.

But are erotic stimuli only effective in charging suitable objects with an erotic meaning? To address this question we assessed the conditioning effect separately for "sexy" and "unsexy" CSs. The mean ratings for erotism can be found in table 1. They were analyzed in a two (conditioning: erotic US vs. nonerotic US) by two (suitableness: "sexy" vs. "unsexy" products) ANOVA. Results indicate both a strong effect for conditioning ($F(1, 109) = 21.72$, $p < .001$) and for suitability ($F(1, 109) = 235.06$, $p < .001$). This latter effect suggests that the "unsexy" products we chose were indeed not sexy at all. But that does not mean that the pairing with the erotic USs had no effect. When paired with an erotic US "unsexy" products got higher ratings for erotism than after pairing with a neutral US. The effect of the conditioning procedure is not stronger for suitable products than for unsuitable ones (see table 1). The interaction between conditioning and suitableness is not significant ($F(1, 109) = 0.31$, $p = .58$, NS).

SMP. Of course the direct and explicit evaluation of an object that has repeatedly been paired with erotic stimuli goes along with high experimental demand. Therefore it is important to replicate the results with a more indirect method. Participants completed a variant of the Affect Misattribution Procedure (AMP, Payne et al. 2005) in which they had to decide whether the meaning of a Kanji comes from the field of sexiness, sensuality, erotism or affectionateness.

We computed the probability to judge a Kanji as having an erotic meaning when it appeared after erotic compared to nonerotic CSs. Table 1 presents these probabilities. We analyzed them with the same ANOVA as the direct ratings: Kanji following erotic CSs were more likely judged as erotic than Kanji following nonerotic CSs ($F(1, 109) = 11.03$, $p < .001$). The probability of an "erotic" judgment was also significantly higher when the Kanji was preceded by a "sexy" product as opposed to an "unsexy" product ($F(1, 109) = 4.13$, $p = .044$). However, again there was no interaction: The effect

of pairing with an erotic stimulus was not stronger for "sexy" than for "unsexy" products ($F(1, 109) = 1.60$, $p = .21$, NS).

So in all cases conditioning of an erotic meaning was successful: Regardless of the measure (direct or indirect) or the type of CS (sexy or unsexy) erotic meaning was significantly stronger for stimuli paired with an erotic US.

DISCUSSION

The results clearly support the notion of a transfer of meaning from USs to formerly neutral CSs. By simple repeated pairings with erotic stimuli neutral objects acquired an erotic meaning. It should be noted that only few studies have demonstrated a transfer of a specific attribute through evaluative conditioning independent of and beyond valence (see Förderer and Unkelbach, 2011, or Glaser and Walther, 2013, for exceptions). The transfer seems robust in the sense that conditioning of erotism can be proved on direct and indirect measures. Highlighting the attribute through priming (like Olson, Kenrik and Fazio, 2009, did) was unnecessary.

The main purpose of this study was to challenge the popular notion that sex in advertising only works for products that are related to sex. To do this we extended the regular conditioning procedure by including an additional factor: the expected suitability of the CS for conditioning. Or results suggest that erotic advertising works for any product, at least if you consider an erotic evaluation of the product as a main target of sex in advertising.

Our results also raise questions concerning the real effects of sex in advertising. After all it has already been demonstrated that erotic advertising has poor if not adverse effects on variables such as memory, favorability of attitude or purchase intention (Lull and Bushman 2015). It seems, however, that one obvious variable has been neglected in this discussion. When it comes to the actual content of an attitude toward the product, sex in advertising seems to have exactly the effect that the advertiser must have had in mind.

What does that mean for marketing and consumer behavior beyond the refutation of a popular notion? Maybe research on the effectiveness of sex in advertising has asked the wrong questions. Whether erotic advertising has a positive effect depends on the variable under consideration. Pairing a product with erotic stimuli may not affect buying intentions, memory or favorability directly, but it does affect the attributes ascribed to that product, which in turn may have their own effects on memory, attitudes or buying intention. Thus the effect of sex in advertising on variables more relevant to marketing may be more indirect. For instance, erotic advertising may affect implicit attitudes more than explicit evaluations. It may also affect implicit memory instead of explicit memory.

Future research should also address the issue of product choice after erotic conditioning. Existing evidence (e.g. Lull and Bushman 2015) does not encourage the expectation that sex has a strong and direct effect on product choice. This may be because erotic image interacts with other variables before it affects product choice. For instance some consumers may act on the (implicit) rule that an erotic paperclip may have poor quality. Another interacting variable may

Table 1: Mean Eroticism-Ratings and mean probabilities of erotic responses for "sexy" and "unsexy" products after presentations along with erotic or nonerotic stimuli

	Erotic US				Non-erotic US			
	"sexy" products		"unsexy" products		"sexy" products		"unsexy" products	
	M	SD	M	SD	M	SD	M	SD
Mean erotic-Ratings1	2.88	1.07	1.79	1.09	2.46	0.97	1.31	0.57

$N = 112$; [1] Values range from 1 to 5; higher values indicate high ratings of eroticism

regard self concept: It has been shown that brand personalities "rub off" on consumers, especially when they contribute to a desired self (Park and Roedder John 2010). As it seems sexiness can be part of a product's attributes even if the product itself has little relation to sex and the attribute is ascribed only in an automatic and implicit manner. Still it is possible that in situations in which sexiness contributes to a desired self the more erotic product is preferred over the unerotic one, regardless of the product category and regardless of where the erotic attributes come from. From the same reasoning follows that it should be questioned if experiments in controlled settings are appropriate to evaluate effects of sex in advertisements on consumers' preferences, since in a typical experimental situation participants are rather unlikely to desire a self in which sexiness plays a dominant role.

Among the limitations of the study is the narrow scope of products which were supposed to be unfit for erotic advertising. Although our results strongly support the expectation that our "unsexy" products were not related to sex we only used products from two classes: furniture and office supplies. Future research should demonstrate that the results really can be generalized to other "unsexy" products.

Another limitation is that we only showed short time effects of conditioning. It has already been demonstrated that conditioned responses to products can persist over weeks (Grossmann and Till 1998). It remains an open question, however, whether this stability also applies to effects of semantic conditioning.

Finally, our data of course do not support a null hypothesis according to which there is no difference whatsoever between suitable and unsuitable products when it comes to the effectiveness of sex in advertising. It may still be that conditioning works better with some products than with others. What the data suggest, however, is that – contrary to what many advertisers and consumers believe (Kalb 2012) – via conditioning almost any product can be "sexed up".

Perpetual Dispossession: An Exploration of Ownership without Possession

Matthew Hall, University of Nebraska - Lincoln, USA
Xin Zhao, Lancaster University Management School, UK

ABSTRACT

We examine disruptions in the consumption cycle as possessions are divested of meanings but never disposed. This perpetual process of dispossession results in legal ownership of objects without explicit incorporation into the self. Through an ethnographic approach we examine factors contributing perpetual dispossession and discuss implications for the extended self.

INTRODUCTION

The consumption cycle is a process consisting of object acquisition, consumption, possession, and disposition (Arnould and Thompson 2005). A separate process called dispossession is used to remove meaning from objects prior to their disposition, which is the final act of physical and/or legal severance of control over an object (Roster 2014; Young and Wallendorf 1989). This study examines factors that disrupt disposition, as well as the processes by which consumers indefinitely retain dispossessed objects. We refer to this process as perpetual dispossession, in which an object is emotionally or psychologically dispossessed but never physically disposed. This understudied phenomenon results in a disruption of the consumption cycle causing objects to enter a purgatory-like state in which they are neither incorporated into the self nor discarded.

Previous literature has examined intrinsic individual factors contributing to object retention. However, this stream of research has failed to consider extrinsic factors that deter disposition of unvalued objects. Likewise, previous research has examined objects incorporated into the extended self without legal ownership (Chen 2009), but the inverse relationship remains unexplored. This paper attempts to address these gaps by examining multiple factors that disrupt disposal causing unvalued objects to be legally owned but perpetually dispossessed.

LITERATURE REVIEW

Consumption Cycle

Previous work has conceptualized the consumption cycle as a process of acquisition, consumption, possession, and disposal (Arnould and Thompson 2005). Possessions are often consumed and/or incorporated into the extended self as a function of their value. Such objects derive value in a number of ways including acting as props for social roles and identity narratives (Ahuvia 2005; Kleine and Kleine 2000), and by signifying relationships (Kleine, Kleine, and Allen 1995). Other important factors in determining an object's value are its associated feelings of attachment, meaning, and satisfaction (Kleine and Baker 2004). High-attachment objects are closely linked with the possessor's self-worth, which increases the strength of the self-possession link and serves as a deterrent to disposal (Ferraro, Escalas, and Bettman 2011). When attachment, meaning, and satisfaction begin to decrease, objects decline in value and typically become candidates for disposal (Jacoby et al. 1977; Parsons and Maclaran 2009).

Prior to disposal objects are dispossessed, which entails the use of various processes to psychologically or emotionally detach oneself from a possession (Roster 2001). Once an object is removed from the self, it is ready for disposal, which signifies the final physical and legal severance of control over an object (Roster 2001). Objects are often disposed if they no longer provide utility, meaning, or satisfaction (Vanier et al. 1987), fail to contribute to the owner's identity or self-image (Belk 1988; Phillips and Sego 2011), and during role transitions (Young 1991).

While we believe this traditional view of the consumption cycle is accurate, we show that there may be disruptions in the cycle that prevent objects from reaching the final disposal stage. In this study, we focus on disruptions in the liminal process between dispossession and disposition, in which objects are psychologically and emotionally dispossessed, but not physically disposed for an indefinite period.

Intrinsic Traits Influencing Object Retention

Nearly all prior work on object retention has examined how intrinsic personal traits increase the likelihood of object retention. Most recently, Haws et al. (2012) introduced the concept of product retention tendency as a "consumer lifestyle trait that reflects an individual's general propensity to retain consumption-related possessions." This is similar to what Coulter and Ligas (2003) refer to as a "packrat". Additional traits including consumer frugality (Lastovicka et al. 1999) and materialism (Richins and Dawson 1992) can also deter disposition. Similarly, Rindfleisch, Burroughs, and Wong (2009) found that individuals retain unneeded objects in order to maintain a sense of security. While these previous studies examine how individual differences can contribute to object retention, we add to the literature by examining how object or storage characteristics can contribute to perpetual dispossession.

Hoarding

Hoarding is a psychiatric disease recognized by the American Psychiatric Association (Herring 2014). It is important to distinguish the behaviors of our informants from those of clinically diagnosed hoarders (Haws et al. 2012). Hoarding is characterized by holding on to possessions too long, cluttering the home, failing to clean, and harboring too many things (Herring 2014). These possessions are typically "stored" in non-marginal living spaces causing clutter and disorganization (Maycroft 2009). In this study, we spent considerable time in informants' homes and made efforts to identify characteristics of hoarding as described in previous literature (Herring 2014). No hoarding behaviors were observed in our participants.

METHODS

This study employed an ethnographic approach combining observation and depth interviews. Semi-structured interviews (McCracken 1988) were conducted with 16 informants (10 female, 6 male; age range from 24 to 75). Each interview lasted from 40-80 minutes. All interviews were conducted in informants' homes and were audio recorded. Informants were recruited through personal networks and snowballed through the networks of initial informants. Informants were purposively selected to gain insight into the pheneomenon and provide a diverse range of perspectives.

Each long interview began with grand tour questions (McCracken 1988) about storage and disposition habits, followed by a discussion of each informant's storage spaces. Next, the interviewer was led on a tour of the informant's storage spaces, during which the informant identified objects with little current value in terms of associated meanings and attachment (Sivadas and Venkatesh 1995). When an object was found in the ambiguous state of being neither currently valued nor disposed, it was discussed in detail to understand the processes by which the object was dispossessed but re-

tained. This process was repeated with multiple objects to elicit various discourses regarding the meaning associated with these objects, factors contributing to retention, and the potential for future disposal.

Our data collection and analysis were iterative. Initial interviews were analyzed to develop understandings of emic motifs by allowing the "emergent nature of the phenomena reveal its characteristics to the researchers" (Tadejewski 2006). Comparisons were made to refine, challenge, and modify these themes during subsequent data collection and analysis (Spiggle 1994).

FINDINGS

While the objects we found varied greatly across informants on a number of factors (acquisition, length of ownership, monetary value, etc.), they were all discussed as having little sentimental or functional significance causing owners to express uncertainty about retention. Previous studies have discussed how intrinsic personal characteristics can increase the likelihood of retention. Our findings replicate this work by showing that individual traits such as high product retention tendency, materialism, waste reduction, and collecting tendencies can lead to object retention. In addition, our findings also show that certain properties of the object or disposal situation can prevent disposition

Object Disruption Factors

Our findings indicate that certain characteristics of the object can influence retention, even if the product is not incorporated into the owner's extended self.

Investment Guilt

Investment guilt occurs when past investment in an object disrupts disposition by creating feelings of guilt associated with disposal. In these situations, individuals did not place current value on the object in terms of incorporation into the self, but rather felt some connection to its past valuation. Grace offers an example:

> "I bought this this blender like 5 years ago…I used it a few times and realized it wasn't going to work for what I needed. Since I had already used it, I couldn't return it…since it was so expensive, I didn't feel right about getting rid of it…That being said, it hasn't moved off that shelf in probably 5 years…"

Relational Guilt

Previous research has explored the relational significance of possessions (Csikszentmihalyi and Rochberg-Halton 1981). Such objects can serve as mementos of key relationships in the life narrative (Ahuvia 2005) and as sources of "inalienable wealth" in the case of heirlooms (Curasi, Price, and Arnould 2004). However, in these situations, the object is still incorporated into the self. Our findings suggest that a dispossessed object's value is often not derived from the object itself or from the relationship it signifies. Rather, its significance can stem from the value the third party places on the object. Ellie discusses how disposing of such objects might evoke feelings of guilt:

> "This is a bunch of my old stuff from when I was a kid. I will probably get rid of most of it when my mom dies, which sounds terrible, but it's the truth. I know she loves that I have it, so in my mind it is better to keep it for her sake than to throw it out. [I: So do you feel any attachment to the objects because of your mother?] Not really. I don't even know what most of it is. I just keep it because I know mom likes that I have it."

Connell and Wong (2011) also found that individuals use consumption relationships with close others as an attempt to extend their personal identity. If that extension is rejected, it can cause feelings of resentment or abandonment from the extender. Thus, our informants felt guilt over the potential resentment that would accompany disposal.

Future Value

Informants also reported keeping objects for their potential future value. In each case, the object either had been stripped of value through dispossession or was never incorporated into the self upon acquisition. However, these objects were retained for future use if the need should arise.

> Frank: "These [golf clubs] used to be my uncle's…I always wanted to get into golf so he gave them to me. I've probably had them for 15 years. I just never got around to playing but always wanted to keep them just in case I ever decided to give it a try."

Frank reported keeping his golf clubs because they signify an ideal role he hopes to one day assume. Other informants reported keeping objects for roles they plan to assume in the near future. Previous studies have found that individuals keep objects because of their potential future value for themselves or others (Coulter and Ligas 2003) and that possessions can act as props or signifiers of past, present, and future roles (Kleine et al. 1995). Prior research has also discussed identity-related possessions as objects an individual perceives to be useful for enacting a particular identity or role (Kleine et al. 1993) and that objects play various roles in different life stages (Gentry, Baker, and Kraft 1995). Our findings show that objects providing no value or significance for the current self may be kept for their value in a future role, even if the individual is uncertain when, or if, this future role will be assumed.

Passing on the responsibility of disposal

When feelings of guilt were associated with the thought of disposal, informants discussed their plans to pass the responsibility of disposal on to others.

> "My mother in law gave me this handmade [item]. I think it's hideous, so of course I don't put it out. It just sits in a closet. [I: Will you ever get rid of it?] I never could. I will probably give it to one of the kids. Whichever one of them is [lucky] enough to get it can figure out how they want to get rid of it."

Alice's response shows that her actions will free her from the guilt of disposal by making another individual responsible for disposition. This guilt is relational in nature, and respondents self-regulated their behavior in order to avoid guilt associated with transgressing against another (Baumeister, Stillwell, and Heatherton 1994).

Effort Disruption

We also found that various factors can prevent disposal when ongoing value assessments are conducted (Roster 2001). The first is effort disruption, in which owners compare disposal effort with retention value.

> Ellie: "I guess I could have a garage sale, but that sounds like a lot of time and energy that I don't have. I guess I could just donate them…but who knows if I'll get around to it. It just seems easier to leave them where they are as long as we have the space. I know that's a terrible explanation, but it just seems so much easier than the alternatives…."

Ellie's motive for retention is greater than the effort required for disposal. Although some individuals may inherently be more likely to expend effort for disposal, our findings suggest that there are characteristics about the object and the storage location that can increase the perceived disposal effort.

Locational Disruption

Linda: *"I mean, I don't know why I would throw any of this stuff away as long as we have the space to keep it. If we did throw it away, then our basement would just be empty."*

As shown in Linda's discourse, the availability of storage space was also found to significantly influence the intrinsic, object valuation and disposal effort factors that disrupt disposition. This relates to previous work on the rise of consumerism and increasing average house sizes in America (Jacobs 2015). As available space and the desire to accumulate possessions increases, it becomes more difficult for individuals to dispose of things, even unvalued objects.

In addition, an object's storage location can deter disposition by preventing ongoing value assessments from occurring. Many informants described objects as "out of sight, out of mind". This metaphor often described objects kept in marginal storage locations (McCracken 1986).

Beth: *"I need to put those things on a garage sale or take them on my next trip to goodwill. But the next trip or the next sale will come and go and I'll never remember to get them. It's kind of an out of sight out of mind kind of a thing. I see them periodically, but not often enough to remember to do something with them."*

Informants also reported that objects in storage tend to hide in plain sight. An object's location can become so seemingly natural that the owners fail to notice them.

Ellie: *"See, when I said that I don't even notice this stuff, I meant it. Here sit two old, metal sifters that we have probably had for three years sitting on this shelf…I think they have just been sitting on that shelf for so long that I think they belong there…It's like they aren't even there. The only way I would notice them is if they weren't there. You know, if they weren't in their spot."*

Ellie's discussion of the sifters show little attachment, nor do they serve as a link to other people, yet they have sat in the same spot on the garage shelf for years. The absense of explicit significant meanings indicates the sifters are not part of Ellie's current sense of self. They have been divested of meaning but not disposed, resulting in perpetual dispossession. Ellie's discourse also indicates that dispossessed objects seem to have a "place" in their storage location (Strasser 1999). Therefore, not only do objects blend into their environments, but owners also feel that they belong there. This blending effect was common across most informants and was more prevalent in high traffic storage areas. Clearly disposition cannot occur when the owner is not aware of the object's existence. This reinforces findings by Korosec-Serfaty (1984) who found that consumers often lose track of their accumulated possessions.

DISCUSSION

Our findings show that the process between dispossession and disposition is often disrupted, causing objects to enter a state of perpetual dispossession, in which they are legally owned but not explicitly incorporated into the owner's sense of self. In other words,

objects become mired in this purgatory-like state when they are divested of meanings, but not disposed. While previous research indicates that dispossession occurs only after possessions are selected for disposal, our findings show that objects can be dispossessed when disposal is not the ultimate intent. In these situations, meaning is removed from an object in terms of its contribution to the owner's current extended self, but the object is retained due to characteristics of the object or its storage location.

The objects we examined did not explicitly contribute to the owners' current senses of self. Rather, objects were valued for something they once contributed in the past or may contribute in the future. This indicates that objects can have liminal significance as they once contributed to a past role, become obsolete in current roles, but may again be needed in some future role. This relates to the notion of liquid modernity, as individuals have more fluid and less well-defined extended selves through the assumption of various identities, roles, and relationships (Bauman 2000). Thus, product retention may occur due to anticipated or potential future shifts in identity. If an object is retained due to one of these aforementioned factors, owners often experience feelings of guilt associated with disposal. When individuals experience such guilt, the object is dispossessed indefinitely until the disposal responsibility can be passed on.

Available storage space also disrupts disposition by initially causing owners to retain divested objects or by preventing objects from being evaluated as candidates for disposal. The increasing availability of storage space and its importance to the American consumer is a sociocultural phenomenon influencing consumption in the United States as the household is seen as a "box to be filled with commodities" (Hayden 1984). This phenomenon can be traced to post-World War II America as the government established policies encouraging urban dwellers to move to new suburban developments with larger houses, creating an association between dwelling space and affluence (Jacobs 2015). This caused house size and the accumulation of possessions to become synonymous with success and prosperity, resulting in an increasingly materialistic culture. This has also resulted in what Cushman (1990) refers to as the "empty self", an identity in which individuals are soothed by consumption, but are never satisfied. The combined effect of these phenomena is increased retention of dispossessed objects, regardless of their current value or contribution to the self.

In addition to increasing storage space, lack of object visibility can also disrupt disposal. In some instances, visibility was low due to storage in inaccessible or marginal locations. Additionally, many informants reported that objects in more accessible locations tended to blend into their storage environments. Many informants reported not noticing objects in plain sight or that objects had a "spot" in the storage space. This is similar to Coupland's (2005) findings on the "Invisible Brand" in which "household members are so habituated to the stable presence of the brand over time that it recedes into the background… [and] can go unnoticed for lengths of time" (Coupland 2005). Our findings show that Coupland's framework extends beyond household brands and includes dispossessed objects kept in storage. One possible explanation for this lack of visibility is increasing clutter in the American home (Arnold and Lang 2007). Clutter is more common because the average American household has accumulated double the possessions as their counterparts 25 years ago (Schor 1991). Increased accumulation results in a mismatch between the amount of owned goods and amount of space in which to store them (Whybrow 2005), resulting in increased difficulty when selecting objects for disposal.

Our findings also show that the effort associated with disposal is another significant factor that impedes disposition. Disposal effort

is very complex, consisting of intrinsic traits like procrastination and laziness, cognitive factors like object valuation, and situational factors like the storage location (Senecal, Lavoie, and Koestner 1997). The perception that much effort is required for seemingly simple tasks such as disposing of small, mundane objects may result from increasing consumer busyness. This sociocultural phenomenon results in Americans associating high levels of busyness with success or affluence (Greenfeld 2005). As individuals create the illusion of self-importance through busyness, mundane tasks like the disposition of unwanted goods may seem too menial to warrant valued personal time. Thus, goods are retained through perpetual dispossession.

In addition to the retention of dispossessed objects, our results can have broader implications in regards to our understanding of the extended self. Belk's (1988) original conceptualization of the extended self suggested that all things considered "mine" are considered "me", or incorporated into the extended self. Subsequent work has distinguished between possessions that are "me" and "not me" in terms of their relevance to particular identity narratives (Kleine et al. 1995). Our findings support Kleine et al.'s position that certain owned objects are incorporated into the extended self while others are not. We refer to the latter as a state of owning without possessing.

While previous studies have examined the use of possessions and consumption to help solidify identities during transitional periods (Mehta and Belk 1991; Noble and Walker 1997), we find that objects are often purposely held in a state of perpetual dispossession as owners wait for various identities to be assumed. Our findings also further develop this conceptualization by presenting the extended self as a fluid state in which objects are incorporated and dispossessed as they do or do not provide value in terms of functionality, sentiment, and attachment (Ball and Tasaki 1992; Kleine and Baker 2004), contribution to roles and identity narratives (Ahuvia 2005), and relationships (Wallendorf and Arnould 1988). In other words, while our findings do support previous research that possessions have value to the self in these various ways, they also suggest that this contribution can be temporary in nature. Possessions can be incorporated into the self for a period as they provide value, but then be dispossessed when this value diminishes or is no longer relevant to the owner.

Our findings also indicate that divestment of meaning, or dispossession, is not an end-all process only used to prepare an object for disposal. Rather, divestment processes (McCracken 1986) may be used to temporarily or indefinitely remove meaning. Objects often stay in this state of perpetual dispossession until their value is rediscovered or assumed in a different role or identity, at which point the object is reincorporated into the self (Noble and Walker 1997). Further research should explore the repeated dispossession and reincorporation of possessions into the self as a result of various roles and identities being assumed.

Consuming a Machinic Servicescape

ABSTRACT

Consumer encounters with servicescapes tend to emphasize the harmonic tendency of their value-creating potential. We contest this assumption from a critical non-representational perspective that foregrounds the machinic and repressive potentiality of such consumption contexts. We offer the airport servicescape as an illustrative example.

INTRODUCTION

The site of the service encounter, the *servicescape* (Bitner 1992; Hooper, Coughlan, and Mullen 2013; Wakefield and Blodgett 1994), has become a mainstay in the literature on the threshold of managerial and consumer marketing. While the literature on servicescapes typically describes how service encounters are facilitated, provide value, or engage consumers in value creating activities (Ezeh and Harris 2007), little in terms of critical scholarship has been directed towards the idea of servicescapes, even though our society is increasingly colonized by commercially motivated spatial configurations that promise meaningful consumer experiences (Denzin 2001; Holt 2002; Kozinets and Handelman 2004; Sherry 2008).

Notable exceptions from cultural perspectives notwithstanding (Kozinets et al. 2004), servicescapes have largely been conceptualized from the marketing perspective as manageable, logic-bound spaces that, providing they are efficiently planned and operated, offer harmonious opportunities for value co-creation (Grönroos 2011; Vargo, Maglio, and Akaka 2008). Under this lens, service failure constitutes a preventable outcome of service fault: an anomaly of the system rather than the system in its 'natural' state (Ezeh and Harris 2007). For Hoffman and colleagues (2003), for instance, service failure occurs when a service is either missing, slow, defective, poorly articulated, or else contaminated. Nilsson and Ballantyne (2014) contend provider firms are "not always able to influence the value-creation process in ways they would like", unless they recognize the "underlying functional, technical, symbolic and social dimensions which frame the meaning of a particular servicescape" (p. 377). A unifying theme of managerially oriented contributions is that servicescapes can and ought to be managed.
