Brand logos contribute to a distinct corporate image (Henderson and Cote 1998) and create brand equity (Bharadwaji and Menon 1993; Park et al. 2013). Broadly, positive customer-based brand equity (CBBE) develops when consumers acquire two types of brand knowledge: brand awareness and brand image (Agarwal and Rao 1996; Keller 1993; Mackay 2001). Brand awareness involves cognitive knowledge of the brand's core identity (e.g., brand name; Tolba and Hassan 2009). While brand image refers to unique brand associations that determine the overall valence of brand attitude and affect (Aaker 1991; Agarwal and Rao 1996; Keller 1993). Importantly, CBBE-models propose a sequential order to the development of these knowledge types wherein consumer acquisition of brand awareness precedes the formation of brand image (Aaker 1991, 1996; Keller 1993).

Prior research suggests that text provides knowledge central to acquiring brand awareness better than images. For example, compared to images, text provides more cognitively-based information about a brand's identity (Carr et al. 1982; Lieberman et al. 2002) by offering less ambiguous and more certain meaning than images (Scott 1994). As such, we hypothesize that, in the absence of brand name awareness, consumers will (a) respond more favorably to text-based than to image-based logos, and (b) this effect will be mediated by perceptions of brand name certainty. Conversely, research sug-

gests that, compared to text, images more effectively evoke personal feelings that contribute to a positive brand image. Images do so by offering a more emotional response than text (Aron et al. 2005; Mikulincer and Shaver 2003). Of note, brand attachment occurs when a brand feels personal (Bhattacharya and Sen 2003; Thomson, Macinnis, and Park 2005; Malär et al. 2011). We therefore hypothesize that, in the presence of brand name awareness, consumers will (a) respond more favorably to image-based logos than to text-based logos, and (b) this effect will be mediated by feelings of brand attachment. We tested our predictions in six studies: five laboratory experiments and an analysis of independently collected secondary data on real-world brand performance.

Using a real brand, study 1 examined actual consumer purchase behavior. Consumers reviewed an advertisement for a real product – Kicker’s Energy Spray – and were given a chance to purchase it. As predicted, sales results revealed a significant interaction ($Wald \chi^2(1) = 6.90, p = .01$) whereby consumers without brand name awareness were more likely to make a purchase when shown the ad with a text-based logo (36.7%) than an image-based logo (16.1%; $\chi^2(1) = 3.32, p = .06$), while those with brand name awareness were more likely to purchase in response to an ad with an image-based (42.5%) versus a text-based logo (20%; $\chi^2(1) = 3.93, p = .04$).

Studies 2A and 2B used a joint versus separate evaluation design (Hsee et al. 1999). In the separate evaluation mode, when text- and image-based logos were rated individually and without explicit brand name information provided, the text-based logo ($M = 3.11, SD = 1.43$) was rated higher than the image-based logo ($M = 2.42, SD = 1.32; t(79) = 2.23, p = .03$). However, in the joint evaluation task, participants chose the image-based (75.6%) more than the text-based logo (24.4%; $\chi^2(1) = 10.76, p < .01$). Presumably, in joint evaluation mode, the simultaneous display of both logo formats for the same brand increased choice of the image-based logo because the text-based logo ensured brand name awareness amongst all participants. Study 2B replicates these results on a different population (students rather than Mturk workers), using a different (fictitious) brand name and corresponding logos.

Study 3 provided evidence of our proposed processes. As predicted, there was a significant interaction between brand name awareness and logo format on consumers’ brand attitude ($F(1, 185) = 11.96, p < .01$). Additionally, we found that in the absence of brand name awareness consumers’ positive response to text-based logos was mediated by brand name certainty (95% BC bootstrap CI of .01 to .36). Feelings of brand attachment, conversely, mediated the positive effect of image-based logos on brand attitudes when brand name awareness was present (95% BC bootstrap CI of -.64 to -.02). Study 4 replicated the results from study 3 (interaction effect, $F(1, 169) = 7.78, p < .01$), while controlling for the abstractness of logos; ruling out alternative explanations and expanding managerial implications.

Finally, Study 5 generalized our findings using a secondary dataset (Brand Finance 2016) of 441 existing brands. On a composite brand attitude measure ($\alpha(4) = .87$), we found a significant interaction between brand familiarity (a conservative proxy of brand name awareness) and logo format ($F(1, 436) = 5.84, p = .02$). At one SD below the mean of brand familiarity, firms with primarily text-based logos received higher consumer brand attitude ratings than firms with primarily image-based logos ($b = -.13, SE = .08, t(436) = -1.71, p = .09$). At one SD above the mean, firms with image-based logos received higher consumer brand ratings than firms with text-based logos ($b = .12, SE = .07, t(436) = 1.74, p = .08$).

This research is the first to consider text- versus image-based logos, and their differential impact on consumer-brand relationship. We offer a surprising moderator, brand name awareness, to common

empirical findings that images evoke a more beneficial response than text, and in doing so, we validate a critical assumption in branding and advertising research which suggests that brand awareness precede the development of brand image and attachment. Moreover, our findings provide brand managers specific recommendations on how to optimize logo design and use throughout the consumer-brand relationship.

Meaningfulness versus Happiness: The Psychological Impact of High and Low Art

EXTENDED ABSTRACT

Art has been a central component of human cultures around the world throughout recorded history (Dutton 2009). Today, governments and private citizens alike expend time, effort, and money on the creation and presentation of artworks. Consumers support a flourishing art business, and school children are even taught about art and brought to art museums, with the apparent notion that these activities provide some special value.

But how does art contribute value to people’s lives? Specifically, what is the value of complex, ambiguous, or challenging art (Belke, Leder, and Carbon 2015; Berlyne 1971; Zeki 2001) if ease of processing determines aesthetic pleasure (Reber, Schwarz, and Winkielman, 2004)? We propose that processing fluency encourages happiness but that the interest sparked by challenging art engenders a sense that life has meaning.

Although happiness and meaningfulness may have substantial overlap, there are also clear differences between them (Baumeister et al. 2013; Diener 2000). Meaningfulness depends less on pleasure than it does on growth and learning, often through the interpretation of culturally significant stimuli. As such, the concept of interest—central in work on the psychology of art (Tan 2000; Silvia 2006)—may be particularly relevant to meaningfulness.

People assess art as interesting when they feel they understand the work’s complexity (Silvia 2005). This notion is related to integrative complexity, which is defined in terms of two cognitive structural variables: differentiation and integration (Tetlock, Bernzweig, and Gallant 1985). At the simple end of the integrative complexity continuum, people rely on rigid, one-dimensional thinking, whereas at the complex end, they combine disparate pieces of information into unified, higher-order representations. We predict that integrative complexity associated with art determines the degree to which the art is deemed interesting, which in turn encourages a sense that life is meaningful. Last, while we expect processing fluency to engender happiness, we also expect that the rewarding nature of an interesting art experience (Lacey et al. 2011) may contribute to a sense of happiness (Baumeister et al. 2013; Silvia 2006).

To test our hypotheses, we took advantage of a distinction known in the art world as high versus low art. High art contains challenging, complex qualities, whereas low art tends to be simple, straightforward depictions (Levine 1988; Shrum 1996). Consistent with prior work, images (depicting the same subject matter) were evaluated by study participants as high versus low art (Hagtvedt and Patrick 2008a; Lacey et al. 2011).

In Studies 1a and 1b, participants rated the high-art versus low-art images on ease of processing and interestingness, as well as the degree to which they perceived their life to change in terms of happiness and meaningfulness from seeing that type of image. As predicted, we found that low (vs. high) art contributed more to happiness, but high (vs. low) art contributed more to meaningfulness. In both studies, interest mediated the effect of artwork on life’s meaningfulness, whereas both interest and fluency mediated the effect of artwork on happiness.

In Studies 2a – 3, we focused on deepening our understanding of the influence of art on meaningfulness. As discussed, the role of complex, challenging art in imbuing life with meaning is arguably the least well understood aspect of the current investigation. In Study 2a, we demonstrated the capacity for high (vs. low) art to stimulate integrative complexity. In Study 2b, we demonstrated a three-step mediational process, in that integrative complexity stimulated by high (vs. low) art leads to the experience of interest, which in turn encourages a sense that life has meaning. Study 3 followed up these findings by testing the notion that appreciation of the artwork may depend on the viewer's capacity to generate complex, integrated thought patterns. This experiment demonstrated that participants with high (low) need for closure—encouraged via a time-constraint manipulation—exhibited a preference for the high art (low-art) image.

Taken together, these results shed light on how and why both high-art and low-art images are appreciated. Further, this research reconciles seemingly contradictory perspectives on fluency, interest, and features such as novelty and complexity, while providing detailed insights into how art contributes meaning to consumers' lives.

Muji versus Maharaja: When (and Why) Minimalist versus Maximalist Design Differentially Influence Consumer Self-Brand Connection.

EXTENDED ABSTRACT

Recent research in consumer behavior has identified a broad set of aesthetic features in packaging design that impact consumption experiences (Hagtvedt and Patrick 2008; Deng and Srinivasan 2013; Sundar and Noseworthy 2014). The current research investigates how a specific design style—how simple (minimalist) or ornate (maximalist)—can influence consumer self-brand connection (SBC).

We define minimalist and maximalist designs as follows. Minimalist design (Meyer 2000) is characterized by simplicity through basic geometric shapes, limited decoration, and abundant white space. In contrast, maximalist design (Rivers 2007) is characterized by richness and a profusion of decorative patterns with minimal white space. Although their visual elements diverge, some of the most successful brands have utilized minimalist and maximalist designs to convey luxury appeal. For instance, Apple's minimalist design represents a brand image of luxury and high fashion, as does Versace, whose brand image is epitomized by ornate decorative patterns.

Why is it that some people adore gilded ornate objects, while others can only find comfort in nearly empty blank canvas? We propose that certain types of aesthetics, such as minimalist vs. maximalist, arouse distinct functional attitudes. Functional theories of attitudes (Katz 1960) suggest that people hold attitudes because they are useful. Certain attitudes serve important social functions, including allowing people to express their own values (value-expressive attitudes) and facilitate self-presentation (social-adjustive attitudes).

We posit that minimalist design elicits more value-expressive attitudes. When people view minimalist art, the “traditional gallery-going experience” is often transformed into one where the viewer can engage with the work by supplying their own interpretation (Kleiner and Mamiya 2005). Similarly, when minimalist design is used in brand communication, consumers supply their own meaning of the brand instead of simply receiving a message. For instance, the Japanese retail brand MUJI employs the concept of “emptiness” in its marketing which emphasizes simplicity and white space. Thus, MUJI creates a capacious vessel that consumers can fill with their own beliefs and perceptions of the brand, from “simplicity”

to “refinement” (Hara 2011). Given the freedom of self-expression inherent in its visual aesthetics, we predict that minimalist design enhances SBC through facilitating value-expressive attitudes.

In contrast, we hypothesize that maximalist design elicits more social-adjustive attitudes. We draw from people's direct experience with maximalist aesthetics, which often occur in social settings that make self-presentation-related goals salient. For instance, people often encounter intricate pattern moldings when going to cathedrals or extravagant decor in a five-star hotel. Thus, consumers seem to have developed the predisposition for maximalist designs when they seek to present desirable self-image. Further, people tend to associate maximalist design with impression-management motives, such as signaling social prestige. Throughout history, authoritative figures often use astounding creations to represent their stature, such as the grandiose exterior of Saint Peter's Basilica in Vatican City or the ornate interior in the Palace of Versailles (Kleiner and Mamiya 2005). Given that maximalist aesthetics are frequently used for gaining social approval, we predict that maximalist design enhances SBC through eliciting social-adjustive attitudes.

Because of the differences in attitudes elicited by minimalist and maximalist designs, we propose power as a moderator for our effects. Defined as “asymmetric control over valued resources in social relations” (Rucker et al. 2012), power can foster agentic or communal orientations. Feeling powerful leads people to become more agency-oriented (i.e. focus on one's self) because being higher in social hierarchy gives people the freedom to pursue their own values. In contrast, feeling powerless makes people more communal-oriented (i.e. focus on others) because being lower in social hierarchy means people need to depend on others for valued resources. As such, we predict that minimalist design will enhance SBC for high-power consumers, while maximalist design will enhance SBC for low-power consumers.

We tested our hypotheses across five studies. Packaging design was manipulated by varying only the decorative elements while keeping all other features constant. In study 1, participants evaluated the minimalist versus maximalist packaging design of a fictional tea brand and assessed their value-expressive and social-adjustive attitudes. As predicted, we found that minimalist design elicits more value-expressive attitudes while maximalist design elicits more social-adjustive attitudes. Interestingly, both packaging designs are perceived as equally attractive and luxurious. We also found that value-expressive attitudes mediated the effect of minimalist packaging design on SBC (95% CI: [-1.65, -.22]), whereas social-adjustive attitudes mediated the effect of maximalist packaging design on SBC (95% CI: [.03, 1.32]).

In study 2, we found evidence for the moderating effect of power. We found significant interaction effect ($F(2,272) = 27.93, p < .001$) where high-power participants felt stronger SBC to minimalist design while low-power participants felt stronger SBC to maximalist design. Study 3 replicated the interaction effect using a different product category (laptop cover) and also provided evidence for our proposed processes. As predicted, there was a significant interaction ($F(2,227) = 29.77, p < .001$). Additionally, our moderated mediation analysis revealed that value-expressive attitudes explained why high-power participants experienced greater SBC for minimalist design (95% CI: [-1.81, -.70]), while social-adjustive attitudes explained why low-power participants experienced greater SBC for maximalist design (95% CI: [1.79, 4.13]). Study 4 bolstered our findings by manipulating participants' value-expressive and social-adjustive attitudes.

Finally, Study 5 extended the observed effects of minimalist and maximalist designs into the service settings (hotels) and tested

a boundary condition in which high-power consumers might prefer maximalist design when impression-management (IM) motives are made salient. Participants were given a choice between minimalist and maximalist hotel suite after having read a high IM vs. low IM scenario. As expected, we found 61% (39%) of the high-power participants chose the maximalist (minimalist) room in the high-impression condition, compared to 16% (88%) of the high-power participants in the low-impression condition. IM conditions did not have an effect on low-power participants ($p=.25$)

In sum, the current research demonstrates the complexity of brand aesthetics by identifying how minimalist versus maximalist designs elicit different attitudes towards the brand. Further, we contributed to the aesthetics literature by providing some insights into the influence of power on consumer responses to aesthetic elements.

Beauty and Control in Collecting:

How Desire for Control Drives the Aesthetic Pursuit of Complete Collections

EXTENDED ABSTRACT

Collecting is a well-observed consumer behavior that is often related to aesthetic experience, and the completion of a collection serves as a representative moment of beauty (e.g., Danet and Katriel 1989; Pomian and Wiles-Portier 1990). However, little is known about why consumers crave the beauty of complete collections. In this research, we propose a novel hypothesis that completing a collection – the fulfillment of the aesthetic experiences in collecting – serves to restore personal control, the sense that consumers can successfully manage the events and outcomes in their lives.

Desire for control (DC henceforth) is a crucial human motivation. To affirm that important aspects of their lives are under control, consumers need to be convinced that outcomes are not generated randomly. Therefore, consumers high in DC tend to reject the idea of a random/chaotic world (Kay, Moscovitch, and Laurin 2010; Legare and Souza 2014) and favor structured items/patterns (Cutright 2012; Whitton and Galinsky 2008).

Aesthetic literature has documented the relationship between beauty and structure. Structured items' nature of being easy to process (i.e., processing fluency) gives rise to aesthetic pleasure (e.g., Forster, Leder, and Ansorge 2013; Reber, Schwarz, and Winkielman 2004). Of relevance here, completing a collection is a human endeavor creating a structure that both produces aesthetic experience and repels chaos and randomness. This characteristic of collection completion should render a complete collection more desirable for individuals high (vs. low) in DC.

More formally, we hypothesize that consumers are more likely to complete a collection when they are high (vs. low) in DC. This theoretical lens provides insights on how aesthetic pursuit such as completing a collection can serve consumer needs as fundamental as DC. Across five experiments, we provide convergent evidence supporting this hypothesis. We also explore key psychological processes underlying this central effect.

Experiments 1A and 1B examine the moderating role of DC in the tendency of completing a collection in real choice sets. In Experiment 1A, 177 undergraduates were endowed with a three-place holder and an incomplete set of magnetic clips. Participants in the experimental condition were endowed with two clips that were thematically related while the control participants were endowed with unrelated clips. All participants were then offered a third clip (to fill in the three-place holder) from a choice set including a target item and three thematically unrelated clips. Choosing the target item would create a thematic set of three clips for the experimental group, but not

the control group. DC was measured as a personality trait on a scale adapted from Burger and Cooper (1979). As predicted, the interaction between trait DC and experimental condition was significant ($B = 1.89$, $SE = 0.76$, $Wald = 6.15$, $p < .05$). A floodlight analysis indicates that as trait DC increases, participants in the experimental condition become more likely to choose the target item to complete their sets, compared to controls (Johnson-Neyman Point = 4.60, $B = 1.06$, $SE = 0.54$, $p = .05$, $CI = [0, 2.11]$). Experiment 1B replicated this finding with three important differences: (1) DC was experimentally manipulated (rather than measured) and (2) a collection set of four rather than three items; and (3) stamp collecting served as the context. Data from 178 student participants replicate the interaction ($B = 1.33$, $SE = 0.67$, $Wald = 3.92$, $p < .05$) and pattern reported for Experiment 1A.

In Experiment 2, we simultaneously manipulated (as a state) and measured (as a trait) DC to further test the role of DC. Undergraduates ($N = 296$) collected seashells that were framed as a completable set. Apart from the significant main effects of both state ($B = 3.49$, $t(292) = 3.15$, $p < .01$) and trait DC ($B = 0.36$, $t(292) = 2.33$, $p < .01$) that replicate the findings from Experiment 1A and 1B, a significant interaction ($B = -0.67$, $t(292) = -3.18$, $p < .01$) between state and trait DC reveals DC as the process underlying the found effect. Specifically, consumers whose DC was experimentally manipulated high demonstrated an increased desire to complete their collections as their trait DC increases. When the state DC was low, however, this pattern was reserved. This experiment shows that DC is the process underlying the tendency to complete a collection.

Experiment 3 examines the link between collecting and aesthetics, namely the structure underlying collections. mTurkers ($N = 184$) were asked to imagine that they were hypothetically collecting of €1 euro coins. We manipulated theme (present, absent) and appearance of set completeness (yes, no) and measure DC as a trait. As predicted, the three-way interaction was significant ($B = 1.72$, $SE = 0.87$, $Wald = 3.87$, $p < .05$). Results show that the opportunity to merely extend the collection (theme condition) does not affect choice when the collection was depicted as only partially complete in size. High DC participants chose the "matching" item only when it was possible to fully complete the collection.

Experiment 4 supports the process underlying previous experiments with real collectors and their collections of experiences. For consumers collecting experiences with US national parks, DC indeed predicted how many parks they checked off a list ($N = 324$, $B = 4.06$, $t(323) = -2.62$, $p < .005$).

In sum, across five studies, we demonstrate that the structure underlying complete collections, which is also a source of aesthetic experiences in collecting, can satisfy DC. As a result, DC becomes a crucial motivator for the aesthetic pursuit of collection completion. This conclusion is robustly obtained via various contexts, set sizes (from three to 60), two ways to operationalize DC (measure and manipulation), and three ways to operationalize collections (hypothetical, actual endowment, and collections that collectors already possess). Together, our findings contribute to aesthetics literature by demonstrating that the pursuit of beauty can serve to fulfill very fundamental human needs such as DC. Also, contributing to literature of collecting, we identify control as an important motivation of collecting (more specifically, the complete thereof), adding to other established motivations such as justification (Gao, Huang, and Simonson 2014) or productivity (Keinan and Kivetz 2011).

Erik Hoelzl, University of Cologne, Germany
Carlos Alós-Ferrer, University of Cologne, Germany

SESSION OVERVIEW

The quest for authenticity plays an important role in consumers' lives. Some marketers have even called authenticity "the 'it' word of the decade" (Byron 2016). As an illustration, the hashtag "liveauthentic" is associated with over sixteen million photos on Instagram, and a Google search for "how to be authentic" returns over 800,000 results.

Given consumers' obsession with authenticity, it is no surprise that it is a way to their wallets. Consumers are willing to pay more for products that they perceive to be authentic (Newman and Dhar 2014) and are more willing to buy works of arts when they perceive their creators to be authentic (Moulard et al. 2014). But just as authenticity positively affects firms' well-being, authenticity can also positively affect consumers' well-being. For instance, feelings of authenticity are associated with higher self-esteem (Davis et al. 2015; Heppner and Kernis 2007; Kernis and Goldman 2006; Schlegel and Hicks 2011; Wood et al. 2008), life satisfaction (Boyraz, Waits, and Felix 2014), subjective well-being (Sheldon et al. 1997), and decision satisfaction (Schlegel et al. 2013), and being perceived as authentic is associated with healthy social relationships (Brunell et al. 2010; Lopez and Rice 2006).

The four papers in this session explore the important role of authenticity in consumer behavior through questions concerning the definition, antecedents, and consequences of authenticity both at the brand level (what makes brands look authentic) and the consumer level (what makes consumers look and feel authentic).

The first paper (Moulard, Raggio, and Folse) explores the meaning of authenticity. These authors present the Entity-Referent Correspondence Framework of Authenticity. This framework results in an overarching definition of authenticity and outlines three authenticity types that are consistent with the overarching definition.

The second paper (Smith, Newman, and Dhar) explores inferences of brand authenticity. How might brands maintain perceptions

of authenticity? These authors find that products authentic due to their history are met with consumer backlash when they are updated—a cost of authenticity—but this backlash can be prevented when consumers perceive the change to be connected to the initial conceptualization of the product.

The third paper (Crain, Bettman, and Luce) explores inferences of consumer authenticity. How might consumers maintain perceptions of authenticity? These authors combine insights from attribution theory and signaling theory to propose and exhibit that observers discern the authenticity of a signaling consumer by inferring the consumer's willingness to accept the costs of their signal.

The final paper (Kokkoris, Hoelzl, and Alós-Ferrer) explores feelings of consumer authenticity. How might consumers maintain feelings of authenticity? These authors demonstrate that acts of self-control may enhance or undermine feelings of authenticity depending on consumers' lay rationalism.

Despite the public's interest in authenticity, it is a relatively nascent topic area in consumer research. Together, these four papers, which are comprehensive in approach (theoretical and empirical) and topic (brand and consumer authenticity), advance our understanding of the role of authenticity in consumer behavior.

The Entity-Referent Correspondence Framework of Authenticity

EXTENDED ABSTRACT

While consumer researchers agree that authenticity contains various meanings, little consensus exists concerning the number of meanings and what those meanings entail (Beverland and Farrelly 2010). Thus, the purpose of this research is to introduce the Entity-Referent Correspondence (ERC) Framework of Authenticity that (1) suggests a unifying meaning of authenticity beyond synonyms such as "real" or "true," (2) delineates three authenticity types that are consistent with our overarching authenticity definition, and (3) proposes specific theories that explain how consumers form perceptions of each type.

Based on the correspondence theory of truth (Newman 2002), the ERC Framework proposes that authenticity is the degree to which an entity (e.g., object, person, performance, claim) is *true to* or matches up with something else. We label this "something else" a referent—the point of reference to which the entity is compared. For instance, a bowl of gumbo (entity) is authentic if it is *true to* a traditional gumbo recipe (referent). Thus, we assert that *authenticity is the degree to which an entity corresponds to a referent. Perceived authenticity is a consumer's perception of this entity-referent correspondence. Additionally, the framework proposes three distinct authenticity types: true-to-ideal, true-to-fact, and true-to-self.*

True-to-ideal authenticity is defined as the extent to which an entity corresponds with a socially determined standard. The closer the entity matches up with an accepted archetype, the more the entity is true to ideal. This prescribed ideal is a *social construct* as described by social constructivism theory (Guba and Lincoln 1994; Wartofsky 1968). Social constructs are human inventions; they are not absolutely occurring phenomena that are independent of human thought. As such, an ideal is not fixed and, thus, may change and is often debated.

These ideas are best exemplified by Brown, Kozinets, and Sherry's (2003) finding that some *Star Wars* fans thought the *Phantom Menace* prequel was inauthentic, as the prequel (i.e., entity) did not correspond with the *Star Wars*' brand essence (i.e., the ideal). The fact that fans disagreed on the brand essence underscores the notion that an ideal is a social construct that is not fixed and may differ across consumers. In addition to adhering to brand essence (Spiggle et al. 2012), prior work suggests to remain authentic, a brand's products (i.e., entities) should match the brand's traditional or classical design and style (i.e., ideals) (Beverland and Luxton 2005; Morhart et al. 2015; Spiggle et al. 2012). Socially determined ideals also exist at the product category level. Real wine (i.e., the ideal) is expected to be that which is "old world" (e.g., from France) and is bottled with a cork (Moulard et al. 2015). Such expectations also exist at more specific category levels (e.g., Abbey beer [see Beverland et al. 2008]), may have stronger consensus, and often specify particular production methods (e.g., champagne's "méthode champenoise"). Thus, to appear authentic, a brand may emphasize its use of a traditional production method and its origin (e.g., "heritage") (Beverland and Luxton 2005; Napoli et al. 2014; Spiggle et al. 2012), as these conform to the product category ideal. Categorization theory (Cohen and Basu 1987) can be used to understand perceived true-to-ideal authenticity, as an ideal is analogous to a consumer's category structure.

True-to-fact authenticity is defined as *the extent to which that which is stated or implied about an entity corresponds with the actual state of affairs*. The state of affairs, or a fact, is something that is the case—what has occurred or what is (Wittgenstein 1922). Thus, true-to-fact authenticity entails the extent to which information communicated about the entity corresponds with the entity's actual characteristics or with events that actually occurred. In contrast to the fluctuating ideal, a fact is static—unable to change. Thus, a fact is consistent with notions of realism, which suggests that phenomena exist independent of the mind—that there is an underlying reality (Halverson 1976; Stump 1996; Wartofsky 1968).

A gold-colored necklace, implying it is made of gold, is only true-to-fact authentically gold if it is actually gold (see Grayson and Martinec 2004). Yet true-to-fact authenticity extends beyond whether objects are originals versus imitations. It also refers to the degree to which one is being transparent about their activities and outputs (e.g., products). Audi's emissions cover up and plagiarism are examples of true-to-fact inauthenticity, as are fake foods, fake news, and fake Match.com profiles. Interestingly, one may be true-to-fact inauthentic about the other types of authenticity; a "champagne" brand may claim its grapes are from the Champagne region (suggesting true-to-ideal authenticity) when, in fact, they are not. The truth effect (Hawkins and Hoch 1992) and reality monitoring (Johnson 2006) can explain how consumers may perceive a claim as real, whereas the expectancy-violation model (Bond et al. 1992) can explain how they perceive a claim as fake.

True-to-self authenticity is defined as *the extent to which an entity's behaviors correspond with its intrinsic motivations as opposed to its extrinsic motivations*. Self-determination theory posits that being true to self involves intrinsically motivated activities—those that are innately enjoyable—as opposed to extrinsically motivated activities—those that are motivated by external rewards or punishments (Ryan and Deci 2000). Like a fact referent, one's true self is proposed to be a fixed entity rather than a socially constructed one, as laypersons perceive the true self as a collection of immutable, innate attributes (Jung 1953; Rogers 1959). Nonetheless, a self is distinguished from a fact due to its psychological nature.

Prior research has proposed brand authenticity entails producers who are passionate about producing their products (intrinsically

motivated) as opposed to caving in to market demands and, thus, becoming too commercial (extrinsically motivated) (Beverland et al. 2008; Moulard et al. 2014; Moulard et al. 2016). This type is consistent with existential authenticity, yet that term has focused the consumer's self rather than another's self (Leigh, Peters, and Shelton 2006). Attribution theory (Kelley 1973) can be used to explain how consumers form perceptions of another's true-to-self authenticity (Moulard et al. 2015, 2016), as it addresses whether individuals attribute another's behaviors to one's dispositions versus situational factors.

The Curse of the Original: When Product Change Undermines Authenticity

EXTENDED ABSTRACT

One strategy brands employ to enhance product appeal is through highlighting a product's history or origin. Indeed, information about a product's heritage is often an antecedent of perceptions of authenticity and value (Beverland et al. 2008; Grayson and Martinec 2004; Newman and Dhar 2014). While prior work has focused on the benefits of this "heritage branding" (Wuestefeld et al. 2012), this article explores a potential cost of making history an important part of a product's identity. Specifically, companies often meet consumer backlash when these kinds of products are changed, even when the product is functionally or materially improved. For instance, Converse's Chuck Taylors has benefited from its well-known history, with a design touted to have been unchanged for 100 years; at the same time, this positioning has made it challenging for the company to make desired improvements to the shoe. Perhaps most infamously, the consumer backlash Coke received with the release of "New Coke" crystallized the problem these kinds of authentic products face.

We theorize that when consumers value or are informed of a product's heritage, changes to the product, even those that functionally improve it, decrease product value relative to the original product. This is because the product origin is seen as core to the product's identity (or essence). Changes from the origin are thus seen as a violation of the product's authenticity and subsequently the product is less desirable. Thus, products known for their history can find themselves stuck at an impasse, wherein, the very quality that are valued for—their connection to origin—is the same quality that prevents them from being able to be improved upon. In the following studies, we show that this backlash is driven by specifically by authenticity perceptions as opposed to quality inferences or inferences related to time or product longevity.

Study 1 tested whether highlighting a product's history, while having an initial positive effect on authenticity perceptions and valuation, decreases product value when the original product is changed relative to the same product where no history is mentioned. Participants viewed an ad for a restaurant that specializes in burgers. Product history was manipulated by either having indexical cues (e.g., est. date, lineage of founder, historically accurate font, etc.) (Beverland et al. 2008; Grayson and Martinec 2004) present or not in the ad. Further, participants were randomly assigned to rate a burger that was unchanged or changed from the original. Results revealed the predicted interaction on willingness to purchase the burger ($F(2, 395) = 16.25, p < .001$). Specifically, the original burger was rated as more appealing in the history condition ($M = 7.07, SD = 1.89$) compared to the original burger in the no-history condition ($M = 5.93, SD = 2.44; t(172) = -3.41, p = .001, d = .52$). However, the changed burger in the history condition ($M = 5.25, SD = 2.58$) was rated as less appealing relative to the changed burger in the no-history con-

dition ($M = 6.08$, $SD = 2.57$; $t(223) = 2.42$, $p < .016$, $d = .32$). This interaction was mediated by authenticity [95% CI for indirect effect = -1.17 to $-.39$] but not quality [95% CI for indirect effect = $-.66$ to $.17$].

Study 2 ruled out a salient alternative explanation. Specifically, the backlash could be driven by the fact the original is seen as having “stood the test of time,” and hence is rationally inferred to be of higher quality than the updated product. In all conditions, participants viewed the same backpack. Between-subjects, participants learned that the company had been making the backpack for 50 versus 5 years and, that the backpack had either changed or not changed from the original design. Further, the history of the product was otherwise held constant across all four conditions. Results revealed a main effect of change, with the original ($M = 5.62$, $SD = 2.32$) valued more than the changed bag ($M = 5.12$, $SD = 2.44$; $F(1, 382) = 4.56$, $p = .033$). Importantly, there was no main effect of time ($F(1, 382) = .79$, $p = .374$), or an interaction between time and change ($F(2, 382) = 1.58$, $p = .210$). In other words, the fact that the company was around for a long versus short time did not interact with the backlash against the changed product. In addition, mediation analysis revealed that this drop in value was mediated by perceptions of authenticity [95% CI for indirect effect = $-.72$ to $-.26$] and not perceptions of quality [95% CI for indirect effect = $-.40$ to $.13$].

Study 3 examined how to shut off the backlash effect. We hypothesized that a change to the original would be accepted to the extent to which consumers perceive it to be connected to the initial conceptualization of the product. To manipulate this, participants watched a clip from a classic animated movie (*The Lion King*). In all conditions, participants were told that the version they would view had been changed from the original. Between-subjects, participants were told either that the change was a bonus scene, added to the film after the original production (less connected to origin), or a deleted scene, made during the original production of the film (more connected to origin), but withheld from the original release. As predicted, the deleted scene ($M = 6.20$, $SD = 1.42$) was rated as more enjoyable than the bonus scene ($M = 5.37$, $SD = 1.75$; $F(1, 131) = 9.00$, $p = .003$, $d = .52$). Further, authenticity perceptions significantly mediated the relationship between condition and enjoyment [95% CI for indirect effect = $-.73$ to $-.04$].

This article explored one cost of products valued for their authenticity. Specifically, products authentic by dint of their history run into challenges when they are changed or updated. In these cases, consumers use the origin to define the essence of the product. Thus changes, even those that would otherwise improve or enhance the product, result in lower perceptions of authenticity and decrease value. Changes believed to be connected to the product’s origin attenuate this backlash.

Signal with Cost: When and Why Identity Signals Are Perceived to Be Authentic

EXTENDED ABSTRACT

Signaling is a common consumer behavior. However, signals are sometimes not perceived as true. We examine when and why identity-signaling consumers are perceived to be authentic, or acting in accordance with their true self (Kernis and Goldman 2006).

Prior research finds that effort is perceived to be negatively correlated with ability (Kum and Weiner 1973), and spontaneity is associated with meaning (Morwedge, Giblin, and Norton 2014), which may suggest that consumers who obtain their signals easily will be perceived as the most authentic. Signaling theory, however, suggests that “true types,” or agents who truly have the trait that a signal rep-

resents, engage in costlier signaling than “false types” (e.g., Spence 1973). Furthermore, attribution theory, a psychological theory of causal inferences, suggests that the role of a given cause in producing a given action is augmented if inhibitory forces, like costs, are also present (e.g., Kelley 1973). Combining insights from these theories, we suggest that consumers who intentionally engage in costly signaling (e.g., buy an expensive team jersey or wear that jersey to a rival team’s home game) will be perceived as more authentic (e.g., an authentic team fan) due to their apparent willingness to accept the cost (“WTAC”) of that signal. Six studies test this theory.

Studies 1A – 1C tested the basic premise that costly signals are perceived to be more authentic. Study 1A tested this proposition with temporal costs. Participants ($N = 201$) read a story about a consumer who was wearing a fictional band (“Blue Lightning”) t-shirt. The consumer drove 15 minutes or 6 hours to see the band perform. As expected, the consumer was perceived to be a more authentic band fan (e.g., “Indicate the extent to which this consumer is an authentic ‘Blue Lightning’ fan”) when he engaged in the more ($M = 8.04$) vs. less ($M = 6.92$) costly behavior ($p < .001$). Studies 1B and 1C generalized this result using monetary and social costs and different identities. These effects were mediated by inferences of the consumer’s WTAC (e.g., “How willing is this consumer to accept the potential costs of seeing ‘Blue Lightning?’”).

Study 2 extends the finding of Study 1 by exploring relative costs. Participants ($N = 216$) read about a consumer who either had more or less free time. Then, similar to Study 1A, participants learned that this consumer was wearing a fictional band’s t-shirt and drove 3 hours to see the band perform. Suggesting that cost is relative to resources, the consumer was perceived to be a more authentic band fan when he was low ($M = 7.95$) versus high ($M = 7.66$) in resources ($p = .05$). This effect is mediated by inferences of the consumer’s WTAC of their signal.

If WTAC drives perceptions of authenticity, only intentional costly signaling should be seen as authentic. If costly signaling is unintentional, it should not promote authenticity perceptions because the critical “willingness” element of WTAC is absent. In Study 3, we tested intent as a moderator. Participants ($N = 410$) were randomly assigned to a 2 (price paid: high vs. low) \times 2 (intent: yes vs. no) between-subjects design. Participants read a story about a consumer who purchased an environmentally-friendly all-purpose cleaner. In the intent condition, the consumer intentionally paid a \$5.99 regular price (high price) or a \$2.99 sale price (low price) for the cleaner. In the unintentional, low price condition, the consumer thought that the product was regular price at the time of purchase but was surprised to find on her receipt when she got home that the product was on sale. In the unintentional, high price condition, the consumer thought that the product was sale price at the time of purchase but was surprised to find on her receipt when she got home that the product was regular price.

As expected, intent moderated the effect of signal cost ($p < .001$). The consumer who intentionally paid a high price ($M = 6.11$) was perceived to be a more authentic environmentalist than the consumer who intentionally paid a low price ($M = 5.44$; $p < .001$). The consumer who unintentionally paid the low price (i.e., expected to pay the high price; $M = 6.37$) was perceived to be more authentic than the consumer who unintentionally paid the high price (i.e., expected to pay the low price; $M = 5.34$; $p < .001$). Moderated mediation analysis indicated that the effects were mediated by WTAC and moderated by intent.

Study 4 explored liking and purchase intent as downstream consequences of perceptions of authenticity. Participants ($N = 362$) were randomly assigned to a 3 (cost: low, moderate, high) \times continuous

(participant's experience) between-subjects design. They read the same scenario as in Studies 1A and 2. In this study, the consumer drove 10 minutes (low), 1 hour (moderate), or 10 hours (high) to see the fictional band. Participant's then rated the consumer's authenticity as a band fan, how much they liked the consumer, and how likely they would be to download one of the band's songs for \$0.99. They also reported the longest (in hours) they've traveled to see a band. We predicted and found that cost increases perceptions of authenticity ($b = .38, p < .001$), which was not moderated by the participant's experience ($p = .92$).

The consumer's willingness to accept the costs of being a fan may be intimidating to people who themselves are not willing to accept that cost. Therefore, we expected that liking and purchase intent would diverge from perceptions of authenticity for participants who had not traveled far to see a band. As expected, the distance the participant had traveled themselves moderated the effect of signal cost ($p < .01$). For participants who had not traveled far (-1 SD), cost decreased liking ($b = -.40, p < .01$). For participants who had traveled far (+1 SD), cost did not affect liking ($b = .13, p = .36$). For participants who had traveled farther (+2 SD), cost increased liking ($b = .49, p < .01$). Results for purchase intent mimicked these results.

Self-controlled but Not Myself: When Restraint versus Indulgence Undermines Consumers' Authenticity and Decision Satisfaction

EXTENDED ABSTRACT

Although the benefits of self-control for psychosocial adjustment and subjective well-being have been extensively demonstrated (Hofmann et al. 2014; Tangney et al. 2004), much less is known about its potential detriments (Kivetz and Keinan 2006). We contribute to this understudied topic by introducing the idea that self-control may undermine decision satisfaction for some consumers by making them feel less authentic.

Research shows that authenticity, i.e., the subjective experience of acting in accord with one's true self (Kernis and Goldman 2006; Schlegel and Hicks 2011; Wood et al. 2008), is a determinant of decision satisfaction (Schlegel et al. 2013). However, not all people feel authentic under the same conditions; whereas for some the true self is revealed through reason, for others it is revealed through feelings (Newman et al. 2014). Thus, we argue that individual differences in lay rationalism, i.e., the relative reliance on reason versus feelings in decision making (Hsee et al. 2015), determine whether exerting or losing self-control makes consumers feel more true to themselves and thereby more satisfied with their decisions. We predicted that consumers would experience lower decision satisfaction after restraint (vs. indulgence) if they are low in lay rationalism, but lower decision satisfaction after indulgence (vs. restraint) if they are high in lay rationalism. We explain this effect in terms of state authenticity (Sedikides et al. 2017): consumers low (high) in lay rationalism should experience restraint (indulgence) as temporary suppression of their true selves.

In Study 1 ($N = 265$), we first assessed individual differences in lay rationalism ($\alpha = .80$; Hsee et al. 2015). We then asked participants to imagine experiencing a conflict between the desire to buy a cheesecake and the conflicting personal goal to lose weight, and randomly assigned them to imagine finally either buying it (indulgence) or not (restraint). We then asked them to assess their anticipated satisfaction with their decision (single item). Results indicated a significant interaction between decision (0 = indulgence, 1 = restraint) and lay rationalism ($B = 1.01, SE = 0.23, p < .001$). As predicted, restraint yielded lower anticipated decision satisfaction among consumers

low in lay rationalism, whereas indulgence yielded lower satisfaction among consumers high in lay rationalism.

Study 2 ($N = 252$) replicated Study 1 in another consumer domain (a conflict between the desire to buy a sweater and the conflicting personal goal to save money) and further examined the underlying mechanism (authenticity). We measured state authenticity ($\alpha = .91$), that is, authenticity in a specific situation (Kifer et al. 2013), decision satisfaction (single item), and lastly lay rationalism ($\alpha = .77$) to avoid consistency effects. Results for decision satisfaction showed the same interaction pattern as in Study 1 ($B = 1.22, SE = 0.23, p < .001$). Moreover, a moderated mediation analysis (model 8; Hayes 2013) revealed that the interaction effect was mediated by authenticity (95% CI = [.269, .673]). Consumers low (high) in lay rationalism were less satisfied with restraint (indulgence) because this decision made them feel less authentic.

Study 3 ($N = 248$) replicated Study 2 by adding a measure of trait self-control to rule out the possibility that lay rationalism is confounded with self-control. Controlling for trait self-control, the interaction on decision satisfaction remained statistically significant ($B = 0.91, SE = 0.23, p < .001$), and so did the moderated mediation through authenticity (95% CI = [.254, .813]).

Study 4 ($N = 403$) tested whether this effect generalizes to real-life consumer conflicts by asking participants to recall the most recent self-control conflict they had experienced in a shopping context and report whether they resolved this conflict by buying (indulgence) or not buying (restraint) the desired item. We measured again authenticity ($\alpha = .88$), decision satisfaction, and lay rationalism ($\alpha = .79$). Results for decision satisfaction showed the same interaction pattern between decision and lay rationalism ($B = 0.61, SE = 0.19, p = .001$). The moderated mediation through authenticity was also statistically significant (95% CI = [.212, .582]). Thus, the proposed effect does not concern only anticipated satisfaction with hypothetical decisions but also satisfaction with past decisions in real-life consumer conflicts.

Finally, Study 5 ($N = 265$) examined whether this effect drives compensatory authenticity seeking to restore authenticity deficits. Building on compensatory mechanisms (Mandel et al. 2017), we predicted that consumers low (high) in lay rationalism would respond more favorably to an ad with an authenticity claim following restraint (indulgence). After presenting participants with the same scenario as in Studies 2 and 3, we asked them in an ostensibly unrelated study to evaluate an ad of a brand of tea advertised with an authenticity slogan ("Be true to yourself"). We created a favorability index ($\alpha = .95$) by combining measures of attitude to the ad, attitude to the brand, identification with the slogan, and purchase intention (all loading on one factor). The interaction effect was significant ($B = -0.36, SE = 0.16, p = .028$), indicating that participants low (high) in lay rationalism who imagined restraint (indulgence) responded more favorably to authenticity advertising.

Taken together, results of five studies show that restraint decreases decision satisfaction for consumers low in lay rationalism, whereas indulgence decreases decision satisfaction for consumers high in lay rationalism. Moreover, this effect is driven by feelings of authenticity and motivates compensatory authenticity seeking affecting attitudes toward products advertised with authenticity claims. Our research advances a nuanced understanding of the psychological consequences of self-control and warns against the pitfalls of "one-size-fits-all" approaches that treat self-control as unconditionally beneficial. Moreover, our research has practical implications for policy making, and especially current discussions on nudging and choice architecture. In designing welfare-maximizing interventions (e.g., with regards to eating, spending, or saving), policy makers

need to take a global approach to consumer welfare by taking into account not only the normative, instrumental effects of increased self-control, but also by attending to the welfare value of consumers' subjective experiences.

Paper #4: Prevention versus Treatment: How Negative Emotion and Charitable Appeal Affect Donation Behavior

Tatiana Fajardo, Florida State University, USA
Anthony Salerno, University of Cincinnati, USA

SESSION OVERVIEW

The act of giving to those in need is a fundamental value held by American consumers (Bendapudi, Singh, and Bendapudi 1996). However, it is not fully known what motivates consumers to donate to charitable organizations (Liang, Chen, and Lei 2016; Small and Verrochi 2009). This lack of understanding is evidenced by the fact that charities in the United States lose out on an estimated \$47 billion in donations every year from failing to meet the needs of potential donors (Camber Collective 2015). In this session, we will focus specifically on understanding how the framing of different *charitable appeals* (i.e., messaging used in the donation solicitation) influences consumer giving. Four papers provide new insights into when charitable appeals are effective at encouraging giving based on the underlying needs of the donor.

The first paper (Munz, Jung, and Alter) shows that donors give more when the charitable appeal highlights that the recipient of the donation shares (versus does not share) the same surname as the donor. The beneficial effect of a donor/recipient surname match was said to be driven by implicit egotism, whereby people inherently gravitate towards others who resemble themselves. The second paper (Samper, Chan, and Hamilton) examines giving when the charitable appeal is made on a recipient's gift registry (i.e., donating to a charity in lieu of gifts to the recipient). Their results show that charitable appeals made on gift registries result in significantly less given by donors compared to gifts directly to the recipient, even if the recipient has explicitly asked that the donation be their gift. The decreased giving was shown to be driven by the donor's perception that their donation to a charity is not an actual gift to the recipient. The third paper (Shehu, Clement, Winterich, and Langmaack) shows how donor reactivation rates increase when a charitable appeal highlights the use of the prior donation (versus appeals that simply acknowledge the prior donation or detail future donation use). The beneficial effect of an appeal based on prior donation use on reactivation rates was found to be serially-mediated by the donor's sense of having

an impact and warm glow. The fourth and final paper (Fajardo and Salerno), explores how negative emotions influence giving depending on the type of charitable appeal used. Specifically, they find that anger (sadness) increases giving when the charitable appeal emphasizes the prevention (treatment) of its cause. Furthermore, the beneficial effect of anger (sadness) is shown to be driven by a need to take corrective action (need to foster social bonding).

Thus, the objective of this session is to address two key questions: (1) what are the ways in which the framing of a charitable appeal influences giving and (2) through what psychological mechanisms do such effects occur? Four papers demonstrate that consumers vary dramatically in their giving depending on how the charitable appeal is framed. We expect ACR attendees interested in the topics of prosocial behavior and consumer well-being to be our primary audience with the session also being of general interest given the scope of theoretical constructs covered.

Charitable Giving to Teachers with the Same Name: An Implicit Egotism Field Experiment

EXTENDED ABSTRACT

We examined the external validity of name effects and implicit egotism by conducting a large field experiment.

Implicit egotism is the tendency for people to like identifiers associated with themselves, including their own names and the numbers of their birthday, and to apply these positive associations to decisions, objects, and other people that resemble them. Researchers have documented implicit egotism in areas such as altruistic behavior (Burger et al. 2004; Chandler, Griffin, and Sorensen 2008; Garner 2005; Guéguen, Pichot, and Dreff 2005; Oates and Wilson 2002) a first name (Study 2, consumer decision making (Brendl et al. 2005; Garner 2005; Kachersky 2011) a choice phenomenon we call "name letter branding." We propose that during a first stage an active need to self-enhance increases the positive valence of name letters themselves and that during stage 2 positive name letter valence transfers to product-specific attributes (e.g., taste of a beverage, decisions about whom to marry (Jones et al. 2004; Pelham and Carvallo 2015), where to live (Pelham, Mirenberg, and Jones 2002), and organizational behaviors (Anseel and Duyck 2008; Nelson and Simmons 2007; Pelham and Carvallo 2015; Pelham et al. 2002; Polman, Pollmann, and Poehlman 2013).

However, there is significant controversy as to whether these effects hold in the real world, or instead may be artifacts of analysis (Dyjas et al. 2012; Gallucci 2003; McCullough and McWilliams 2010; Simonsohn 2011a, 2011b). Specifically, most of the evidence for real world effects comes from archival data collected for other purposes. The challenges (typical of correlational research) include the potential for reverse causality (Simonsohn 2011a), cherry-picking in selecting variables or data sets to analyze (McCullough and McWilliams 2010), third-variable explanations (Simonsohn 2011a), and failing to perform the correct analysis (Dyjas et al. 2012; Gallucci 2003). In the face of these major challenges, some have claimed, "the current state of empirical evidence for implicit egotism, as indicated by the most recent publications in two of psychology's top journals is that it holds up in the lab but seems to be spurious in the field" (Pelham and Carvallo 2015, 693).

We helped address these challenges by conducting a large field experiment. We partnered with DonorsChoose.org, an online charitable giving platform that connects primary and secondary school teachers requesting funding for projects in their classrooms with potential donors who can browse and donate any amount desired to a project of their choosing. DonorsChoose owns an email list of past donors, some of whom we sent an email request for donation to aid either a teacher with the same surname as the donor or a teacher whose name did not match.

We implemented a form of two-group yoked design. From the population of potential donors whose name matched at least one teacher and who were not family relatives, potential donors were randomly assigned to one between-subjects condition. *Teachers* appeared exactly once in *each* condition. Thus the teachers (used as stimuli) were the same in each condition. All that varied between conditions was whether or not the teacher surname matched the donor surname. In order to facilitate this design, we first had to randomly reduce the size of the list to achieve a two-to-one ratio of donors to teachers. No deception was employed in our field experiment; all of the teachers were actual teachers requesting funding.

We sent an email including the teacher's name in the subject line to participants in each condition. The email asked donors to support a project led by the subject teacher, who shared a surname with the donor in the match condition but not in the non-match condition. The dependent measures were the count who opened the email, clicked on the link, and donated, and the donation amount.

The name match manipulation positively affected all measured outcomes. Name match email recipients were significantly more likely to open the email (35.1% vs. 27.6%; $\chi^2(1, N = 30,302) = 196.0, p < .001$) and to click on the link in the email (6.9% vs. 4.6%; $\chi^2(1, N = 30,302) = 69.4, p < .001$). Conditional on opening the initial email, the likelihood of clicking on the link was significantly greater in the name match condition (19.6% vs. 16.8%; $\chi^2(1, N = 9,497) = 12.1, p < .001$). Those in the name match condition were significantly more likely to donate than those in the non-name match condition ($\chi^2(1, N = 30,302) = 3.4, p = .004$), and on average they donated more than twice as much ($M = \$0.20, SD = \7.98) as those in the non-name match condition after a natural-log transformation ($M = \$0.09, SD = \$5.46; F(1, 30295) = 8.02, p = .005$).

However, as suggested elsewhere (Simonsohn 2011a), observed effects attributed to name matching could alternatively be due to in-group favoritism. That is, certain names convey lots of information about ethnicity, and people may be favoring their own ethnic group rather than favoring their own surname. While our data do not contain information about ethnicity, to attempt to control for this possibility we used data from the 2000 US census. The data set provides the percentage likelihood that each surname belongs to a particular ethnicity, including percentages for six ethnicities. We appended these percentages to our data for both the potential donor's surname and the corresponding teacher's surname.

To attempt to control for ethnicity matching, we examined the 88.8% of cases for which the most likely ethnicity of the potential donor matched the most likely ethnicity of the teacher. All our reported outcomes were robust to this selection criterion (all $ps < .02$). We found similar results when instead utilizing all ethnicity information in the census data and calculating Euclidean distances for each name-pair.

Within the non-match condition we also checked for name letter effects (Nuttin 1985), a standard paradigm of implicit egotism. By chance, 742 (6.1%) donor surnames in the non-match condition shared a first letter with the teacher. After selecting for ethnicity matching as above, the results provide consistent directional evi-

dence for small name letter effects on all variables and significant differences on opening the email ($\chi^2(1, N = 11,789) = 5.2, p = .023$) and average donation ($F(1,11787) = 3.93, p = .048$). By testing for name-letter effects in a randomized field experiment and controlling for ethnicity matching, we provide the most unbiased test of implicit egotism in the field to date.

Giving to Versus on Behalf of: Charitable Gift Requests Lead to Less Generous Giving

EXTENDED ABSTRACT

Gift registries requesting charitable donations in lieu of gifts have gained popularity, adding a new layer of magnanimity to the prosocial act of gift giving. At first glance, this seems like an optimal way to make both givers and receivers happy while raising a substantial amount of money for a good cause. First, since the recipients explicitly ask for a donation, one avoids the pitfall of a prosocial gift being underappreciated by receivers (Cavanaugh, Gino and Fitzsimons 2015). Further, by giving recipients exactly what they have requested (Gino and Flynn 2011) and not diverging from the registry (Ward and Broniarczyk 2016), recipients will be happier while givers have an easier task.

Yet how do givers respond to these requests? Does the type of registry influence how much money they give? One might assume that the amount a giver decides to spend on a gift should not be determined by the type of gift requested by the recipient—that is, whether the gift is *to* or *on behalf of* a recipient should not rationally influence the amount allotted to a wedding gift. However, this research demonstrates that gift givers give less money to charity registries than to cash registries. We propose that despite people explicitly considering contributions as their gift to a recipient, givers are less likely to view such a contribution as a true gift and therefore give an amount commensurate with what they consider a typical charitable donation. We test this effect across four studies.

In study 1, participants were asked to imagine they were invited to a close friend's wedding an hour away. They were told that the couple had requested no boxed wedding gifts, and instead had a cash registry fund and a charity registry fund. Participants were asked how much money they would give to each fund, allocating the money as they wished. We found that participants gave much less to the charity registry than to the cash registry ($M_{\text{Charity}} = \$61.10, M_{\text{Cash}} = \$130.08; F(1, 62) = 36.88, p < .0001$).

In study 2, we conceptually replicate the finding that participants give less to charity gift registries using a 2 (gift registry: charity, cash) \times 2 (recognition: public, not stated) between-subjects design. In a similar wedding scenario, participants imagined that they had been invited to a wedding and that the couple had registered for either donations for renovations to their local homeless shelter (charity registry) or cash for renovations to their home (cash registry). We also tested whether the effect would persist even when participants knew that their name and the amount of money they chose to give would be emailed to the couple (public recognition) to rule out perceived accountability to the couple as an alternative explanation. We found only a main effect of registry type ($F(1,184) = 11.59, p = .0008$). The effect of public recognition and the registry by recognition interaction were not significant ($ps > .61$). Charity registry participants gave less ($M_{\text{Public}} = \$57.45$ and $M_{\text{Not stated}} = \51.86) than those in the cash registry conditions ($M_{\text{Public}} = \$78.70$ and $M_{\text{Not stated}} = \77.26).

In study 3, we moderate our focal effect. We propose that people give less to charity (vs. cash) registries because they do not think of their donation as an actual wedding gift. Thus, we aimed to see if people would give more to the charity registry if we reminded

them of the amount of cash they typically give as a wedding gift beforehand. Participants were assigned to a 2 (gift registry: charity, cash) \times 2 (intervention: control, reminder) between-subjects design. In the control condition, participants read about a similar scenario as in study 2. Participants in the intervention condition were first presented with either a charity or cash reminder prior to the study: "How much do you think a person should give when they give a one-time charitable donation / wedding gift." Results revealed a significant interaction ($F(1, 291)=5.68, p=.02$). In the control condition, replicating prior studies, participants gave significantly less to the charity (vs. cash) registry ($M_{\text{Charity}}=\$59.29, M_{\text{Cash}}=\85.53). Yet, in the reminder condition, there was no longer a difference ($M_{\text{Charity}}=\$82.13, M_{\text{Cash}}=\76.97).

Finally, in study 4, we extend our effects to a baby shower registry and examine how registries that donate a proportion of money given (e.g., ECHOage) may influence the amount given. We also explicitly test for process. Participants were randomly assigned to one of five conditions in a between-subjects design that varied the amount going to charity: 0% (pure cash gift), 25%, 50%, 75% and 100% (pure charity gift). Participants imagined that their friend was having a baby and had put together a registry. For conditions 25% and above, participants learned that a certain percentage of their gift would go to a charity fund for the research and treatment of birth defects, an organization chosen by their friend. Participants were asked how much they intended to give and, to further test our proposed process that participants' perception that the amount given was a gift to the recipient (rather than a charitable donation), rated the extent to which they would feel like they were giving a gift. A one-way ANOVA revealed a marginal effect of amount ($F(4,591)=2.22, p<.07$): $M_{0\%}:\$43.96, M_{25\%}:\$44.96, M_{50\%}:\$48.98, M_{75\%}:\$44.98, M_{100\%}:\$36.52$). Replicating prior studies, participants gave marginally less in the pure cash (0%) vs. pure charity (100%) conditions ($p=.09$). Moreover, this difference was mediated by the degree to which they felt like they were giving a gift ($CI_{95\%} -9.06, -2.34$). Participants were also more willing to part with their money in the 50% versus pure charity (100%) condition ($p=.004$), revealing a quadratic effect ($p=.02$) as the charity amount increases.

Across these four studies, we find robust evidence that givers give less when a gift registry requests charitable donations than when they request cash. This effect persists even when it is clear that the couple will know how much givers had contributed and can be moderated by reminding participants that the donation is a form of a gift or by linking the gift amount to the charity amount.

"You Saved a Life": How Past Donation Use Increases Donor Reactivation via Impact and Warm Glow

EXTENDED ABSTRACT

Increasing competition and demographic changes are forcing non-profit organizations (NPOs) to focus on reactivation strategies for lapsed donors. Due to the pro-social nature of donations, NPOs cannot use monetary incentives which are usually used for customer win-back in commercial contexts (Homburg, Hoyer, and Stock 2007; Thomas, Blattberg, and Fox 2004; Tokman, Davis, and Lemon 2007). Research has demonstrated that in pro-social contexts, monetary incentives lead to crowding out of donor motivations (Benabou and Tirole 2006; Frey and Jegen 2001; Heyman and Ariely 2004). Consequently, NPOs need reactivation strategies that do not impair, but trigger motives that lead lapsed donors to re-donate. The need for reactivation strategies is high as donors are difficult to retain. For example, data from the German Red Cross Blood Donation Services show that dropout rates or active donors may go up to 17.8%.

In practice, NPOs often use mailings that acknowledge lapsed donors' past donations. Indeed, such practices are supported by literature on charitable behavior which has shown that recognition is an important motivator of donation behavior in general (Fisher and Ackerman 1998; Karlan and McConnell 2014; Supphellen and Nelson 2001; Wang and Tong 2015; Winterich, Mittal, and Acquino 2013). However, we still know little how recognition of past donations may affect donor reactivation. On the one hand, informing lapsed donors of the past donation use may increase transparency, and hence, donation impact, leading to higher reactivation. One of the main motivations for many donors is to help others, as evidenced by both the warm glow theory of giving (Andreoni 1990), as well as the impact theory of philanthropy (Duncan 2004). NPOs act as intermediaries and manage the transfer between donors and donation recipients, such that donors oftentimes are unsure of what happens with their donation (i.e., whether it was really used to help a person in need). On the other hand, information of past donation use may lead to licensing (Mazar and Zhong 2010). Literature on donor reactivation shows also limited insights on how information from past donation use may influence reactivation. Most of the studies investigate personalization of reactivation mailings based on information from past donations (e.g., amount of money donated). In some settings, such as after disasters, suggested donation amounts based on a lapsed donors' previous donation backfires (Ryzhov, Han, and Bradic 2016), whereas in general reactivation attempts such as giving requests, using the last donation amount in reactivation mailings increases reactivation behavior (Verhaert and Van den Poel 2011). However, there are no insights on how including the use (rather than personalized information from) past donations affects reactivation.

We propose that informing lapsed donors of their past donation use influences reactivation behavior positively, and that this effect is transmitted through a serial mediation via donation impact and warm glow. In a field experiment conducted in cooperation with the German Red Cross, we investigate the effectiveness of past donation use on reactivation behavior. We compare the influence of appeals based on past donation use to a best-practice mailing which simply acknowledges the past donation, as well as to a mailing based on future donation use. The results indicate that providing information on past donation use increases the probability of re-donation compared to both other appeal types.

In two online studies we replicate this effect for blood and monetary donations and investigate the psychological transmission mechanism behind it. We propose and demonstrate that the influence of past donation use on the intention to re-donate is transmitted through increased *warm glow*. Specifically, the transmission is a serial mediation, in which past donation use increases the perceived donation impact, then induces warm glow which translates into a higher intention to donate in future. Our results support the serial mediation for blood and monetary donations.

Our work provides much needed academic evidence and our results are relevant for managers and researchers alike. Our work contributes to the literature on donor reactivation, and more generally to literature on pro-social behavior. With respect to donor reactivation, we start first by linking literature on warm glow and donation impact with the literature on lapsed donor reactivation to show that warm glow is an important driver of donor reactivation. Specifically, we show that for donor reactivation purposes, it is not sufficient to merely incorporate personalized information from the past donation history, or acknowledge a past donation. NPOs should rather incorporate information that is able to increase the perceived donation impact, and the warm glow. Second, we add to the theoretical understanding of how different types of reactivation appeals work, and

expand the literature on how donation appeals can be utilized for reactivation strategies.

With respect to the literature on pro-social behavior, this study adds to the current stream of literature on the role of warm glow in pro-social processes. Current studies have shown how warm glow mediates service satisfaction for participants in a green program (Giebelhausen et al. 2016). We show that warm glow is an important motivator of re-donation behavior in reactivation campaigns and for pro-social behavior. In addition, our findings are also relevant for literature on recognition effects (Wang and Tong 2015; Winterich et al. 2013). We show how recognition should be framed in the reactivation context and describe the underlying process.

Lastly, our research also relates to the current research on customer win-back (Kumar, Bhagwat, and Zhang 2015; Pick et al. 2016), and shows how win-back strategies work in the pro-social context. Consequently, besides the academic relevance, our work is highly relevant for NPO managers. Our proposed strategy, which informs lapsed donors of their past donation use can be easily implemented by NPOs. Many NPOs rely on donor relationship systems, so that information from past donation use is easily available. In fact, blood donation services in Sweden have implemented this strategy (although not exclusively for lapsed donors) and inform donors on the use of their last donation.

Prevention versus Treatment: How Negative Emotion and Charitable Appeal Affect Donation Behavior

EXTENDED ABSTRACT

A consumer's decision of whether to donate to a charity is oftentimes driven by emotion (Andreoni 1990; Batson 1990). Prior research has focused largely on the role of negative emotion in shaping donation behavior, although a consensus has not been reached as to whether its effect is beneficial or detrimental (Andrade and Cohen 2007; Fisher, Vandenbosch, and Antia 2008).

We propose that these divergent findings are because most donations research has (1) examined negative emotion using a valence-based approach (i.e., negative mood) rather than an emotion-specific approach and (2) not considered how the charitable appeal (i.e., messaging used in a donation solicitation) may be received differently depending on a person's emotional state. This research is the first to examine each of these two factors concurrently. We chose to focus our efforts specifically on the effects of anger and sadness based on prior research showing that anger discourages helping (Polman and Kim 2013), whereas sadness encourages helping (Small and Verrochi 2009). Thus, prior research suggests that anger (sadness) will discourage (encourage) donations.

The current research challenges this conclusion by considering how each emotion might influence donations differently, depending on the type of charitable appeal used. We find that both anger and sadness potentially encourage donations. However, for this to occur, the charitable appeal must be framed in a way that matches the underlying function of each emotion. Specifically, we propose that anger should encourage donation behavior when the appeal emphasizes the prevention of the charitable cause (what is being done to stop victimization from occurring). This effect occurs because an underlying function of anger is to empower consumers to take corrective action (Frijda 2005). By contrast, we propose that sadness will encourage donation behavior when the appeal emphasizes the treatment of the cause (i.e., what is being done to manage the consequences of victimization). This effect occurs because an underlying function of sadness is to motivate consumers to foster social bonding (Keller and Nesse 2006). We tested these predictions in four studies.

Study 1 used a 3 (donors' emotional state: neutral, anger, sadness) x 2 (charitable appeal: prevention, treatment) between-subjects design. All participants read about histiocytosis (a life-threatening health disease). Emotion was manipulated via emotional contagion (Small and Verrochi 2009). Specifically, participants saw a picture and quote from a histiocytosis victim who either expressed anger, sadness, or neutrality about the diagnosis. Participants then received a donation solicitation from the Histiocytosis Association that either appealed to the prevention ("sponsoring medical research that would ultimately prevent this disease from claiming new victims") or treatment ("providing life-saving treatment and care to improve the well-being of victims") of histiocytosis. Donation behavior was assessed via the actual amount of money donated by participants (\$0-\$4). Results showed a significant interaction between the emotion and appeal factors ($F(2, 129) = 5.12, p < .01$). Participants in the anger (sadness) envy condition donated significantly more money when the appeal was framed in terms of the prevention (treatment) of the disease.

Study 2 provided process evidence for the hypothesized psychological mechanisms driving the interactive effect of a donor's emotional state and charitable appeal on donations. A 2 (donors' emotional state: anger, sadness) x 2 (charitable appeal: prevention, treatment) between-subjects design was used. The procedure was identical to study 1, except that once participants indicated their willingness to donate, they were asked two questions about the decision: (1) whether their decision was driven by the need to fix what is wrong (need for corrective action) and (2) whether their decision was driven by the need to feel close to others (need for social bonding). A significant interaction emerged between the emotion and appeal factors ($F(1, 137) = 11.44, p < .01$), replicating the results of study 1. Moderated mediation analyses revealed that the beneficial effect of anger (sadness) on donation behavior framed in terms of prevention (treatment) was mediated by a need for corrective action (need for social bonding).

We hypothesized that anger encourages donations under a prevention appeal because the act of donating addresses the need to take corrective action. If this is so, an opportunity to partake in corrective action prior to a solicitation may attenuate the positive effect of anger on donations. Study 3 examined this possibility using a 2 (need for corrective action: control, addressed) x 3 (donors' emotional state: neutral, anger, sadness) x 2 (solicitation orientation: prevention, treatment) between-subjects design. Emotions were manipulated by having participants watch a video pretested to either elicit anger, sadness, or neutrality. Next, participants in the need addressed condition wrote a letter to the university about a problem at their university and how it could be solved (control condition did not complete this task). Participants then received a donation solicitation that either focused on the prevention or treatment of Isiolo fever (described as a life-threatening fever). Results revealed a significant three-way interaction ($F(2, 290) = 3.15, p < .05$). The control condition replicated studies 1-2. In the action addressed condition, angry participants no longer donated more under a prevention (versus treatment) appeal.

Study 4 examined whether an opportunity to reaffirm one's social belongingness prior to a solicitation may attenuate the positive effect of sadness on donations. A 2 (need for belongingness: control, addressed) x 3 (donors' emotional state: neutral, anger, sadness) x 2 (solicitation orientation: prevention, treatment) between-subjects design was used. Emotion manipulation was identical to study 3. In the need addressed condition, participants wrote about a friendship they currently have and value (control condition did not complete this task). Results revealed a significant three-way interaction ($F(2, 289) = 3.26, p < .05$). The control condition replicated studies 1-2.

In the action addressed condition, sad participants no longer donated more under a treatment (versus prevention) appeal.

Collectively, this research contributes to the literatures on emotion, donation behavior, and prosociality. The findings illustrate how negative emotion has a more nuanced influence on donation behavior than previously thought. Finally, this research also highlights the importance of considering how the donation behavior of consumers may vary based on the appeal used by the charity.

SESSION OVERVIEW

Our session looks at novel framing effects in consumer decision-making. The first paper demonstrates that depending on how questions about consumer preference are framed, consumers seem to express contradictory preferences for hedonic and utilitarian goods. The second paper provides evidence that framing decision types to match decision domains allows consumers to feel more confident in their decisions. The latter two papers apply framing effects to marketplace settings. In the third paper, the authors illustrate that framing Facebook advertisements to match a consumer's personality profile increases advertisement effectiveness. Finally, the fourth paper demonstrates that framing decisions over pre-assembled choice sets as design processes can increase consumer utility.

In both hypothetical and incentive-compatible settings, O'Donnell and Evers demonstrate that consumers indicate different preferences for hedonic and utilitarian goods depending on the elicitation method (i.e., how they are asked). Specifically, consumers choose hedonic goods, but pay more for utilitarian goods. These findings indicate that varying elicitation methods can induce consumers to maximize on distinct product dimensions, yielding fundamentally different expressed preferences.

Perfecto, Galak, Simmons, & Nelson demonstrate that consumer confidence can be affected by whether a decision is framed in an attribute-consistent (e.g., choose positive or reject negative) or -inconsistent (e.g., choose negative or reject positive) way. That is, consumers who choose from positive or reject from negative options feel more confident about their decisions. On the other hand, consumers who are asked to make an attribute-inconsistent decision express less confidence about their decisions. Critically, these findings demonstrate that by merely framing a decision in an attribute consistent way, consumer can feel significantly more confident about their decisions.

Matz, Bos, Stillwell, and Kosinski show that framing based on personality predictions from digital footprints can increase the ef-

fectiveness of Facebook advertising campaigns. When marketing messages were framed to match the audience's personality, conversion rates (number of purchases) were up to 100% higher. Beyond personality-matched messages, Matz and colleagues also show that one can predict the appeal of images for individuals with different personalities using automated feature extraction and machine learning algorithms. These estimates of personality appeal can then predict liking of new images as well as brand attitudes and purchase intentions.

Moon and Bos demonstrate that choice framing can also influence consumer judgments. Consumers enjoy customization. The authors investigated whether product decisions can be framed to make consumers feel as though their product is customized, even when it is not. Across several studies, presenting decisions as a design process (versus a simple choice) leads to greater perceived customization. The authors distinguish between several explanations and find that multi-stage processes increase the feeling that the consumer designed the product themselves, thereby increasing perceived customization.

Taken together, this session demonstrates the powerful effects of framing in the consumer decision-making process at multiple critical junctures. From the development and elicitation of preferences (O'Donnell & Evers) to evaluating decision outcomes (Perfecto et al.) and within digital (Matz et al.) and physical marketplaces (Moon & Bos), differential decision frames can be used to elicit more desirable outcomes.

Elicitation Dependent Preference Reversals Over Consumer Goods

EXTENDED ABSTRACT

If a person is willing to pay more for trash bags than for ice cream, the axiom of procedure invariance in preference elicitation holds that, if given a choice between the two, she should also choose the trash bags. These procedures should yield the same result – they are thought to be tapping an intrinsic preference, with differences in procedure representing different frames of the same decision. To choose otherwise implies a preference reversal, and a violation of procedure invariance (Tversky, Slovic, & Kahneman, 1990).

Despite this violation of rational choice theory, we find that participants show preference reversals in numerous studies, seven of which we detail here. Specifically, we find that when a decision is framed as a choice between two goods, participants appear to mostly rely on their affective responses to the choice options (Slovic et al., 2007), while they engage in a more deliberative weighting strategy when a decision is framed as one requiring them to indicate WTP. These reversals cannot be explained by scale compatibility, which has been cited as the mechanism for other instances of preference reversals (Tversky, Slovic, & Kahneman, 1990).

In Study 1a-c, we randomly assigned participants to indicate WTP or choose between different pairs of consumer goods (in 1a, trash bags and ice cream; 1b, a pen and chocolate; 1c, toilet paper and ice cream). In Study 1a, 82.6% of participants in the WTP condition preferred the trash bags, while only 27.7% did so in the choice condition. This difference is significant, $X^2(1, 289) = 87.13, p < .001$. In Study 1b, 25.6% of participants in the WTP condition prefer the pen, whereas 12.5% in the choice condition prefer the pen. This differ-

ence is significant, $X^2(1, 186) = 5.18, p = .02$. In Study 1c, 89.59% of participants in the WTP condition prefer the toilet paper, whereas 49.48% in the choice condition prefer the toilet paper. This difference is significant, $X^2(1, 193) = 36.55, p < .001$. Together, through Studies 1a-1c, we consistently demonstrate that participants show preference reversals, with expressed preferences depending on whether preference elicitation is framed as choice or willingness to pay.

Next, we carried out an experiment in an incentive compatible setting, using real money and real products. In Study 2, we recruited 612 participants; half of the participants were given \$2 cash, and we used the BDM method to elicit WTP for a tube of toothpaste and a chocolate bar. The other half of the participants chose between toothpaste and chocolate. In this incentivized study we still find evidence for preference reversals – whereas 52.4% of participants preferred toothpaste in the WTP condition, only 40.6% did in the choice condition, $X^2(1, 564) = 7.86, p = .005$.

We then sought to test whether differences in expressed preference are due to expressing preference a binary decision in the choice condition versus indicating a continuous measure of price in the WTP condition. To rule out this explanation, and bolster support for our affect driven hypothesis, we added two new conditions. In addition to choice and WTP, we added an attractiveness condition and a WTP-dichotomous condition. In the attractiveness condition, participants rate each product on a 20-point continuous measure of attractiveness; while in the WTP-dichotomous condition participants selected the good they would be willing to pay more for. We expected results in the attractiveness condition to resemble the choice condition, and, results in the WTP-dichotomous condition to resemble the WTP condition. Participants in the choice and attractiveness conditions preferred trash bags the least, 26.72% and 16.55%, respectively. However, participants in the WTP and WTP-dichotomous conditions preferred trash bags at a greater rate than either of the affect-driven conditions, 84.35% and 50% respectively. Replicating the basic preference reversal effect, the comparison between the choice and WTP conditions is significant, $X^2(1, N = 278) = 93.99, p < .001$. Moreover, the WTP-dichotomous condition differs significantly from the WTP $X^2(1, N = 283) = 38.22, p < .001$, choice $X^2(1, N = 267) = 15.27, p < .001$, and attractiveness conditions, $X^2(1, N = 281) = 35.65, p < .001$. The attractiveness condition differs from the WTP $X^2(1, N = 292) = 134.25, p < .001$, pay more $X^2(1, N = 281) = 35.65, p < .001$, and choice conditions $X^2(1, N = 276) = 4.23, p = .04$. Taken together, we see that preference elicitation methods that are framed as affective responses yield stronger preferences for hedonic goods, whereas elicitation methods that are less affective tend not to see as strong a preference for hedonic products.

Finally, we tested our hypothesis that participants utilize a more elaborative process when indicating WTP (as compared to making choices) by asking participants to deliberate. We expected this to attenuate the difference between the WTP and choice conditions. In Study 3, we recruited 402 participants from MTurk and assigned them to one of four conditions in this 2 (WTP vs. choice) \times 2 (control vs. deliberation) between subjects design. Using a logistic regression, we found a main effect of elicitation method, $z = 7.76, p < .001$. Consistent with our prediction, we found an interaction between elicitation method and deliberation, $z = 1.89, p = .059$. Probing this, we find that in the WTP conditions, participants did not differ based on whether they deliberated, 81% of participants in the non-deliberation condition and 82.9% in the deliberation condition preferred the trash-bags, $X^2(1) = .13, p = .72$. However, in the choice conditions, participants who deliberated were more likely to choose the trash bags (44.2%) compared to participants who did not deliberate (27.3%), $X^2(1) = 11.39, p = .001$.

These studies question the idea that consumers have stable preferences that are insensitive to elicitation method. At a minimum, the results indicate that WTP and choice are not equivalent measures of preference, despite their usage in research. More significantly, they indicate that when consumers indicate preferences over goods; differential framing of a decision-making task yields fundamentally different preferences.

Attribute Matching Increases Confidence

EXTENDED ABSTRACT

A wide variety of factors affect consumers' confidence in their decisions. Some of these are more objective—such as the quality and quantity of information available—whereas others are more subjective, involving feelings coming from how the decision was made. This latter category has spawned a number of literatures investigating these psychological determinants of confidence. Work on fluency, for example, has shown that making a decision feel easier increases confidence (e.g., Kelley & Lindsay 1993). Similarly, work on regulatory fit, suggests that using a decision strategy that “fits” with one's current mode of thinking increases motivation and certainty regarding one's choice (e.g., Higgins 2000).

In the present paper, we expand upon these two literatures and propose that attribute matching can also elicit these psychological effects on confidence. Rather than focusing primarily on how people approach the stimuli (as does regulatory fit) or on the stimuli themselves (as does fluency), we suggest this “feeling of rightness” that increases confidence can be more general, coming from either source, or both. Across five studies, we manipulate salient attributes of the decision frame and options so that participants do or do not experience attribute matching, and find higher reported confidence when they do. In addition, we show this increase in confidence has downstream consequences for consensus estimates, and is mediated by metacognitive ease.

Study 1 (N=306) demonstrates this basic effect. Participants were shown 16 pairs of women's faces—8 were pretested to be attractive (positive valence), 8 were pretested to be unattractive (negative valence)—and asked to select a face from each pair for a hypothetical advertising campaign. To make this choice, half of participants were asked which face of the pair they would choose (positive valence) and half were asked which face of the pair they would reject (negative valence; Shafir 1993). After each choice, participants reported how confident they were in their preference on a 9-point scale and what percentage of other respondents would also make that choice. The predicted interaction obtained: when the valence of the stimuli matched the valence of the decision frame (i.e., for both attractive/choose and unattractive/reject), confidence was significantly higher than in mismatched conditions ($t_s > 12.11, p_s < .001$), with confidence mediating consensus.

Study 2 (N=302) extends this phenomenon to multiple levels of attribute intensity, again with valence. Participants evaluated 20 pairs of words that were pretested to be very positive (e.g., love), slightly positive, slightly negative, or very negative (e.g., vomit). As in Study 1, half were asked which word they would choose and half were asked which they would reject. Again, after each choice, participants reported their confidence and consensus estimates. Replicating Study 1 and in line with our predictions, we found a strong linear relationship between the intensity of the attribute match and confidence and consensus ($t_s > 16.67, p_s < .001$), as well as confidence mediating consensus.

Study 3 (N=406) moves beyond valence and preferences to a more objective domain. Participants evaluated 6 pairs of foods, pre-

tested to be perceived as very high or very low in calories. Half of participants were asked which food has more calories and half were asked which food has fewer calories. As in Studies 1-2, participants reported their confidence and consensus estimates after each trial. In line with previous results, on matched trials (i.e., reporting which high-calorie food has more calories or which low-calorie food has fewer), participants reported higher confidence and consensus estimates than on mismatched trials ($t_s > 4.70$, $p_s < .001$), with confidence mediating consensus.

Having established the basic effect and one downstream consequence, in Studies 4 and 5, we move to confirm our “feeling right” mediator. Study 4 ($N=300$) replicates Study 2, but with only the 10 very positive and very negative word pairs. Additionally, participants reported how easy the choice seemed on a 7-point scale before reporting confidence and consensus ratings. In addition to replicating our matching effect on confidence and consensus ($t_s > 9.77$, $p_s < .001$), we found these feelings of ease fully mediating both effects.

Study 5 ($N=500$) employs an alternative approach to test our proposed mediator: debiasing. If participants are alerted to this irrelevant source of decision ease, then they should correctly attribute it to the manipulation, rather than their own confidence. Using the 10 positive and negative word pairs and choose/reject manipulation from Study 1, half of participants were told that the valence of the question and choices may impact how easy choosing felt, after choosing but before providing confidence and consensus estimates. Control participants did not receive this additional text and replicated our standard matching effect in confidence and consensus. Critically, debiased participants did not, and, in fact, showed an unpredicted reversal (3-way interaction: $t_s > 9.0$, $p_s < .001$).

Together, these five studies show a highly consistent pattern: attribute matching increases confidence ratings (which, in turn, increase consensus estimates) because matched-attribute decisions foster metacognitive ease, a sense of “feeling right.” We find this pattern emerges not only for questions of preference, where intuition would be leaned on the most, but also for questions that have a correct answer. We look forward to future research investigating other types of matching effects in judgment.

Psychological Framing as an Effective Approach to Real-life Persuasive Communication

EXTENDED ABSTRACT

Past research suggests that persuasive communication is more effective when messages are tailored to a consumer’s psychological profile (e.g. Hirsh, Kang, and Bodenhausen 2012). For example, matching computer-generated advice to consumers’ dominance level elicited higher ratings of source credibility, and increased the likelihood of consumers changing their initial opinions in response to the advice (Moon 2002). While the effectiveness of using psychological matching in persuasive communication is well-established in controlled laboratory studies, the questionnaire-based nature of psychological assessment has hindered the application and evaluation of such technologies in the real world. Consequently, the effectiveness and practical feasibility of psychographic persuasion outside the lab is questionable.

Recent research, however, suggests that consumers’ psychological traits can be predicted from digital records such as personal websites, Twitter messages or Facebook profiles (e.g. Kosinski, Stillwell, and Graepel 2013; Park et al. 2014). Hence, our digital records might disclose information that goes beyond merely *what we do*, and provide insights into *who we are*, making questionnaire measures obsolete.

Capitalizing on this new form of *digital psychometrics*, we conducted two large-scale field experiments showing that matching marketing messages to consumers’ dominant personality trait increases clicks and conversions. Our experiments were conducted using the Facebook advertising platform. As of now, the Facebook advertising platform does not allow marketers to directly access Facebook users’ digital footprints or to target them based on their psychological traits. However, it does so indirectly by offering the possibility to target users based on their Facebook Likes. Suppose, for example, that liking “Lady Gaga” on Facebook correlates with the personality trait of extroversion, and liking “Philosophy” goes hand-in-hand with introversion. By targeting consumers associated with each of these Likes, one can, in fact, target extroverted and introverted consumer segments.

We used the outlined approach to target individuals based on their psychological traits of Extroversion in Study 1 and Openness-to-experience in Study 2 (McCrae and John 1992). Using the mypersonality.org database (Kosinski et al. 2015), which contains the Facebook Likes of millions of users alongside their scores on the 100-item IPIP personality questionnaire, we selected 10 Likes characterized by the highest and 10 Likes characterized by the lowest aggregate extroversion and openness scores. These Like-sets were then used in the “Interest” section of the Facebook advertising platform to define our consumer segments (we validated the feasibility of this approach).

We used psychographic targeting to promote the online shop of a large UK-based beauty retailer in Study 1 and two apps available on the Google play store in Study 2. Professional content creators developed ads that were specifically tailored to the psychological characteristics and needs of our target audiences. Using a 2 (Ad personality: low vs. high trait) \times 2 (Audience personality: low vs. high trait) between-subjects, full-factorial design, we promoted the products in real Facebook advertising campaigns

Together, the campaigns reached 3,214,169 users and attracted 11,476 clicks, and 890 conversions (either purchases on the beauty retailer’s website or downloads from the Google Play store). For both studies, we conducted hierarchical logistic regression analyses for clicks (click = 1, no click = 0) and conversions (conversion = 1, no conversion = 0), using the Audience personality, the Ad personality and their two-way interaction as predictors. Confirming our hypothesis, the interaction between Audience personality and Ad personality was highly significant for conversions in both studies (Study 1: $z = 4.30$, $p < 0.001$; Study 2: $z = 3.35$, $p < 0.001$). These effects were robust after controlling for age and its interactions with ad personality, indicating that psychographic targeting adds value above and beyond demographic targeting. Averaged across the two studies, users in the congruent conditions were 1.43 times more likely to convert (purchase from the online store or download the app) than users in the incongruent conditions. While there was a significant interaction effect on CTR in Study 2 ($z = 3.35$, $p < 0.001$), there was no significant interaction effect in Study 1 ($z = 0.07$, $p = 0.943$).

The results of the two studies provide converging evidence for the practical feasibility and effectiveness of psychographic targeting in the real world. By tailoring the marketing messages for the exact same product to the psychological characteristics and needs of user groups, we were able to significantly increase the number of conversions and clicks (in the Openness campaign only) of two marketing campaigns on Facebook. Although we focused on only two psychological traits, namely extroversion and openness, previous laboratory studies suggest that similar results could be achieved with other psychological characteristics such as regulatory focus (Cesario, Grant, and Higgins 2004) or need for cognition (Wheeler, Petty, and Bizer 2005).

The capacity to carry out psychographic targeting in the real world highlights several opportunities as well as ethical challenges. On one hand, personalized communication in the form of psychographic targeting offers a way to alleviate the problem of choice overload (Schwartz and Ward 2004) by prioritizing content that is likely to be of interest to individual users. In addition, there is plenty of evidence that psychologically-customized health messages are effective in changing behaviors among patients and groups that are at risk (Noar, Benac, and Harris 2007) it is currently not known if or to what extent tailoring works. The current study provides a meta-analytic review of this literature, with a primary focus on the effects of tailoring. A comprehensive search strategy yielded 57 studies that met inclusion criteria. Those studies-which contained a cumulative $N = 58,454$ -were subsequently meta-analyzed. The sample size-weighted mean effect size of the effects of tailoring on health behavior change was found to be $r = .074$. Variables that were found to significantly moderate the effect included (a. On the other hand, psychographic targeting could be used to exploit “weaknesses” in a person’s character. For example, the same technique that we used could be applied to identify and target individuals who are prone to compulsive or addictive behavior, e.g. targeting online casino advertisements at individuals who have psychological traits associated with pathological gambling.

Choosing or Creating? Framing Choices as Design Processes Increases Perceived Customization of Products

EXTENDED ABSTRACT

Consumers enjoy customization (e.g., Valenzuela, Dhar, & Zetelmeyer, 2009; Huffman & Kahn, 1998). However, producing customized products can be costly for companies. As a solution, many companies have opted for mass customization (mass producing different versions of a product to suit individual wants and needs), which allows consumers to choose a personal product while still keeping the number of options - and therefore production costs - low. Is mass customization a successful strategy? That is, can mass produced products *feel* customized?

Past research has shown that physically building products (e.g., IKEA furniture) allows consumers to feel as though their product is uniquely theirs, thus increasing valuation of their built products (Norton, Mochon, & Ariely, 2012). Extending this research, we hypothesized that merely framing decisions in certain ways could lead consumers to feel as though their product is uniquely made for them. Specifically, we examined whether framing a product decision as a multi-stage selection process (choosing one attribute then another) versus a simple choice would lead to increases in perceived customization. We conducted a series of studies in a context in which customization is particularly valued: the realm of gift-giving (e.g., Moreau, Bonney, & Herd, 2011).

Study 1

One hundred ninety-nine participants were asked to imagine that they were purchasing a gift for a friend. In the Choice condition, participants were asked to choose between 6 mugs that varied by 3 colors and by 2 designs. In the Create condition, participants were first shown a blank mug. They were then asked to choose one of the 3 colors for the mug, followed by one of the 2 designs for the mug. The available options were the exact same options as in the Choice condition. The dependent variable was how customized the mug seemed on an 11-point scale (0=Not at all customized; 10=Extremely customized).

Results

Supporting our hypothesis that a multi-stage selection process would increase perceived customization, participants in the Create condition felt that their mug was more customized ($M=5.88$; $SD=2.58$) than participants in the Choice condition ($M=3.95$; $SD=2.79$), $t(197)=5.06$, $p<.001$.

Study 2

One difference between the Choice and Create conditions in Study 1 is that the Create condition required making more than one choice (color then design). Although we believed that the increased perceived customization was due to feeling like they were creating the mug, we tested this alternative hypothesis in Study 2 ($N=301$) by including a third condition (Filter condition) in which participants filtered the options (i.e., *rejected* by color, then by design) they did not want. The Filter condition thus included the action of making multiple choices, but rather than engendering the feeling of creating a product, the Filter condition was intended to engender the feeling of discarding products. We used the same stimuli as in Study 1, and in the Filter condition, participants were asked to reject 2 of the 3 colors for the mug, then reject one of the 2 designs of the mug. Again, the available options were the exact same options as in the other two conditions, and the dependent variable was how customized the mug seemed on an 11-point scale.

Results

Replicating Study 1, participants in the Create condition felt that their mug was more customized ($M=6.09$; $SD=2.44$) than participants in the Choice condition ($M=3.06$; $SD=2.69$), $t(200)=8.39$, $p<.001$. Participants in the Filter condition ($M=5.12$; $SD=2.78$) fell in between the Create condition, $t(198)=2.62$, $p<.01$, and the Choice condition, $t(198)=5.33$, $p<.001$. This suggests that although making multiple choices increases perceived customization, the multi-stage selection process increased perceived customization beyond simply making multiple choices.

Study 3

Why does this creation process increase perceived customization? Past research on customization has pointed to one particular mechanism: the “I designed it myself” feeling (e.g., Franke, Schreier, & Kaiser, 2010). Study 3 ($N=199$) aimed to replicate our effect and investigate our proposed mechanism: how much participants felt they had designed the product themselves on a 7-point scale (1=Not at all; 7=Very much).

Results

Replicating Studies 1 and 2, participants in the Create condition felt that their mug was more customized ($M=5.52$; $SD=2.69$) than participants in the Choice condition did ($M=2.83$; $SD=2.71$), $t(197)=7.06$, $p<.001$.

Consistent with our hypotheses, participants in the Create condition felt more like they designed the mug themselves ($M=4.41$; $SD=1.62$) compared to participants in the Choice condition ($M=2.82$; $SD=1.90$), $t(197)=6.36$, $p<.001$. Importantly, feeling as though they designed the product themselves partially mediated the influence of the condition on perceived customization – that is, the indirect effect was significant (95% CI: [1.12, 2.37]).

When shopping for products, consumers are increasingly valuing not only a wealth of options but also options that feel customized to their wants and needs. We find that merely changing the way choice options are presented influences consumers’ perceived customization. Across three studies, we found that framing a product decision as a multi-stage selection process (versus a simple choice)

increased how much people felt they designed the product themselves, which in turn, increased their perceived customization of the product. Discussion will focus on consequences of perceived customization for consumers and marketers.

Paper #4: How Do Wealth and Time Horizon Affect Investors' Risk Tolerance? Evidence from the Field

Ethan Pew, Stony Brook University, USA

SESSION OVERVIEW

Time and money are two of the most important, yet frustratingly scarce, resources that consumers have at their disposal. In fact, most of the tradeoffs we face involve expenditures or savings of time and/or money. For example, we spend money purchasing desired goods and time enjoying those purchases. Conversely, we save money by switching to cheaper products and time by paying others to do time-consuming things for us (e.g., food delivery services). We therefore need to understand how consumers perceive their (relative) access to these two resources. An equally important goal, given their scarcity, is understanding how consumers approach trade-offs involving money and time.

The four papers in this session present a variety of new findings and novel insights into consumers' beliefs, attitudes, and preferences regarding time and money as scarce resources. At the same time, they all address the same broad, yet important, questions: Do consumers treat time and money similarly or differently? How do they perceive and navigate fundamental tradeoffs and constraints in these two resources?

The first two papers compare perceptions and preferences concerning access to time and money resources, for self versus other. First, Olivola and Han examine the 'X-effect'—the tendency for people to assume others are willing to pay more for goods than they are—and show that it extends to time: they find that people also believe others are willing to wait longer (in line) to obtain free products. They further show that the X-effect is not due to self-other discrepancies in time/money opportunity cost considerations. Next, Berman and Gurdamar show that consumers tend to believe similar others have more money and time resources than they do. Yet, consumers also believe (paradoxically) that similar others *spend* more money and time than they do. However, these self-other differences disappear when consumers are asked to compare themselves to a specific, known other (as opposed to a generic, unknown other).

The next two papers examine people's preferences for trading-off money and time, and how access to time and money affect preferences. First, Litovsky and Olivola show that subtly focusing consum-

ers on time versus money leads to preference reversals for identical tradeoffs between these two important resources. In particular, focusing on time (versus money) decreases willingness to spend time in order to save money (e.g., waiting in line to receive a discount on a purchase). Similarly, focusing on time (versus money) increases willingness to spend money in order to save time (e.g., paying extra to obtain an express train ticket). Next, Pew uses a large dataset of real investors to examine how access to money and access to time influence risk preferences. He finds that consumers become less risk averse the greater their access to money (relative wealth) or time (age and years-to-retirement).

Attendees will leave this session with greater understanding of the way consumers perceive and respond to tradeoffs involving time and money.

Consumers Overestimate Others' Willingness to Pay AND Wait for Goods: New Findings and Insights Concerning the "X-Effect" Bias

EXTENDED ABSTRACT

Frederick (2012) documented a puzzling, but highly robust, bias: people systematically overestimate others' willingness to pay (WTP) for a broad array of goods. This bias, which Frederick coined the "X-effect", reveals a fundamental error in consumer judgment that has important marketing implications. For example, it could lead producers and retailers to overestimate the profit-maximizing prices of new products and these products' likelihoods of successfully selling at a given price. The net result would be overpricing and/or excessive market entry for many new products, followed by disappointing sales (relative to expectations).

Interestingly, Frederick found that the X-effect did not extend to several other types of valuation measures: there were no significant self-other discrepancies in selling prices, judgments of liking, or "working prices" (the maximum number of pencils someone would be willing to sharpen to obtain the good). These latter results suggested the X-effect might be limited to WTP judgments, and thus seemed to rule out several possible accounts of the X-effect.

Here, we show that the X-effect is not limited to monetary payments: the same pattern emerges for willingness to wait (WTW) judgments (the maximum amount of time a person is willing to wait in line to obtain the good). In doing so, we reveal parallel biases in self-other valuation discrepancies along the money *and* time dimensions. Our studies also examine a possible account of the X-effect: that people are less likely to consider others' opportunity costs of spending money (or time) on goods than they are to consider their own opportunity costs. Such a tendency to underappreciate the fact that others also have "better things to do" with their money (or time), could plausibly explain why consumers typically overestimate others' WTP (or WTW). Although consumers already tend to neglect their own opportunity costs (e.g., Frederick et al., 2009; Read, Olivola, & Hardisty, 2016; Shafir & Thaler 2006; Spiller, 2011), there are good theoretical reasons to expect that they might do so to an even larger extent for others (e.g., Pronin, Olivola, & Kennedy, 2008).

Studies 1A and 1B were designed to test whether the X-effect could be explained by a self-other discrepancy in opportunity cost consideration.

In Study 1A, participants ($N = 233$) were randomly assigned to either report their own WTP for 10 different goods (drawn from Matthews, Gheorghiu, & Callan, 2016), or to predict another person's WTP for those same 10 goods (specifically, the WTPs of the next participant to complete the same study). In addition, half of the participants were asked to consider other ways that they (or the other person) could spend that money, before providing their WTP judgments. This manipulation was used to increase consideration of opportunity costs. First, we replicated the X-effect: participants predicted that others would be willing to pay more for each good than they would themselves (ANOVA with the 10 product-WTPs as repeated-measures: $F(1, 2290) = 69.89, p < .0001$). We also found a separate main effect of highlighting opportunity costs: WTP judgments were significantly lower (for both self and other) when participants were explicitly asked to first consider opportunity costs ($F(1, 2290) = 7.30, p < .007$). However, highlighting opportunity costs did *not* mitigate the X-effect; if anything, it strengthened the effect (the interaction was only significant for log-transformed WTP: $F(1, 2290) = 6.10, p = .014$).

In Study 1B ($N = 394$), we varied the same factors, but the self-other manipulation was within-subject (i.e., every participant reported their own WTP *and* predicted the other's WTP for each good, in counterbalanced order). The results of Study 1B replicated those of 1A: WTP was higher for other than for self ($F(1, 7839) = 196.70, p < .0001$), and lower when opportunity costs were highlighted ($F(1, 7839) = 42.98, p < .0001$). Once again, the X-effect was directionally stronger when participants were explicitly asked to consider opportunity costs (the interaction was only significant for log-transformed WTP: $F(1, 7839) = 9.66, p < .002$).

Studies 2A and 2B examined whether the X-effect extends to the time dimension (i.e., willingness-to-wait / WTW). These studies employed the same designs as 1A and 1B (respectively), with the only difference being that participants were asked to report the maximum amount of time (in minutes) that they would be willing to wait for a good that was being offered for free at a store with long lines. In addition, the opportunity cost consideration manipulation asked participants to think of other ways they (or the other person) could spend that time (instead of waiting in line).

The results of Study 2A ($N = 401$) paralleled those of Study 1A: We replicated the X-effect in the time dimension: participants predicted that others would be willing to wait longer for each good than they would themselves ($F(1, 3970) = 150.23, p < .0001$). We also found a separate main effect of highlighting opportunity costs: WTW judgments were significantly lower (for both self and other) when participants were explicitly asked to first consider opportunity costs ($F(1, 3970) = 18.29, p < .0001$). As with WTP, highlighting opportunity costs of spending time did *not* mitigate the X-effect for WTW, but instead strengthened it (interaction: $F(1, 3970) = 6.93, p < .009$).

The results of Study 2B ($N = 410$) replicated those of 2A in a within-subject design: WTW was higher for other than for self ($F(1, 8194) = 327.94, p < .0001$), and lower when opportunity costs were highlighted ($F(1, 8194) = 22.29, p < .0001$). Moreover, this X-effect for time was again directionally stronger (but not significantly so) when participants were explicitly asked to consider opportunity costs.

Taken together, the results of our four studies reveal novel findings and insights regarding the X-effect. First, by showing that the X-effect is not mitigated (and in fact seems to grow stronger) when opportunity costs are highlighted, we rule out a self-other discrep-

ancy in opportunity cost consideration as an account of the X-effect. Second, by showing that the X-effect also occurs for WTW judgments, we extend the scope of this bias to the time dimension.

Subjective Resource Deprivation: Consumers Feel More Constrained For Spare Resources Than Similar Others

EXTENDED ABSTRACT

Decision-making would be much easier if consumers were not faced with resource constraints. Most consumers would like to spend more, save more, and do more with their time, but are confronted with the reality that they cannot have it all. Moreover, feeling that one's resources are scarce greatly affects consumer decision-making and welfare, often for the negative (Roux et al., 2015; Shah et al., 2012; Zaubermaier & Lynch, 2005). Yet, we know little about what causes individuals to feel relative flush or constrained for available resources (but see Etkin et al., 2015).

The present research examines how individuals assess subjective feelings of resource availability by investigating how consumers compare themselves to others. Across 7 studies we find that consumers feel relatively deprived of spare resources, reporting that, on average, they spend less, save less, and have less spare time than similar others. The results we present are consistent with an availability bias in self-other judgments (cf. Davidai & Gilovich, 2016; Frederick, 2012) whereby individuals are highly aware of the constraints on their resources, but are less aware of the constraints on others. As a result, individuals feel particularly limited by their budgets, and do not recognize that others experience the same limits as they do.

Study 1 evaluated how consumers compare their savings to others by examining data from the 2014 Federal Reserve SHED survey. Respondents ($N = 2,587$) were asked "How do you think that the percent of your income that you saved in the past 12 months compared to the average percent saved by other people your age with similar incomes?" (-2 = "much less" to +2 = "much more"). On average, respondents felt that they saved less than others (Mean = -0.20; SE = 0.03, $p < .001$). Responses were positively correlated with income ($r = .25$), and a follow up floodlight analysis (Spiller et al., 2013) revealed that, on average, those who earn less than \$100,000 believed that they saved less than others, while those who earn more than \$120,000 believe that they saved more than others. In all subsequent studies, relative judgments were uncorrelated with income.

These initial results show that, on average, people believe that they save less than others. One possibility is that results are due to differential information about individuals' savings, whereby people have good information that they save little, but do not have good information about the savings of others (Moore & Small, 2007). If so, then when individuals assess their spending levels, we should expect to find the reverse effect, whereby presumably individuals believe that they save less than others because they spend more. However, if individuals feel particularly limited by their own constraints, then we should find that they feel that they both feel limited by their ability to save and spend, and report doing so less than others. Study 2a-2d tests these contrasts.

In Study 2a ($N = 301$), participants made indirect comparisons of saving and spending estimates to others (Moore, 2007). Specifically, participants made four evaluations, reporting how much they spent and saved in the previous year as well as how much they estimate the average person their age and income level spent and saved in the previous year (1 = "very little" to 7 = "an extreme amount"). Results show that participants felt that they both saved less than others (Mean_{SelfMinusOthers} = -.26, SE = .09, $p = .003$) and spent less than others (Mean_{SelfMinusOthers} = -.18, SE = .09, $p = .04$).

Study 2b ($N = 401$) tests robustness by asking participants to make evaluations in dollar amounts instead of a subjective scale. We replicate our previous results, finding that participants felt that they both saved less (Median Difference_{Saving} = $-\$25$, $p < .001$) and spent less than others (Median Difference_{Spending} = $-\$82$, $p < .001$) in the past month.

Study 2c ($N = 402$) asked participants to estimate how much they and an average person their age and income level spent in the past month on nine different expenditures (rent/mortgage; utilities; groceries; entertainment; transportation; medical; clothing; savings; and all other expenses. When summed, the total expenditures for the self were less than others (Median_{TotalSelf} = $\$1,900$ vs. Median_{TotalOthers} = $\$2,450$; $p < .001$), replicated our previous results.

Study 2d ($N = 303$) asked participants to place themselves in a distribution, and asked them to evaluate how they compare to 100 people chosen at random with the same income as them. On average, participants evaluated themselves to be below the 50th percentile in both saving (Mean_{Percentile} = 45.7, $p = .005$) and spending (Mean_{Percentile} = 47.0, $p = .02$) levels.

We argue that consumers are highly attuned to the constraints they face, but less attuned to the constraints of others. If so, then manipulating how constrained individuals feel should impact their estimation of the budgets of others. In Study 4 ($N = 200$), participants were given a fixed budget ($\$225$) to allocate towards five different expenditure goals. We manipulated whether the line items were more or less costly (e.g., a fancy dinner vs. a casual lunch; saving for a new car vs. a new couch). Participants were insensitive towards the constraints of others: when the line items were costly, participants assumed others could afford these expenditures, over estimating the total expenditures of others (Median = $\$269$) significantly more than when the line items were less costly (Median = $\$232$, $p < .001$).

Study 4 ($N = 257$) tests whether the same effect holds for spare time. Students were asked to evaluate their own spare time and the estimated spare time of the average student in their city. Students felt that they have less spare time ($M = 3.55$, $SD = 1.40$) than others ($M = 3.91$, $SD = 1.08$, $p < .001$), suggesting that these results hold for time as well as money.

In sum, this research shows that people feel particularly constrained for spare resources, believing that they spend less, save less, and have less spare time than similar others.

The Resource Focus Effect Nudging Consumer Preferences in Time-Money Tradeoffs

EXTENDED ABSTRACT

Consumers regularly face tradeoffs between saving time and saving money—two of the most valuable resources we have. For example, they can spend time to save money (e.g., waiting in line to obtain a discount on purchases or traveling to a distant store that offers the same product at a lower price) or they can spend money to save time (e.g., buying a more expensive express train ticket). Therefore, it is important that we understand how consumers choose among these time-money ‘tradeoff-bundles’ and whether their choices are affected by normatively irrelevant factors.

While there is a rich literature on our valuation of money (e.g., Kahneman & Tversky, 1979; Tversky & Kahneman, 1992) and a sparser literature on our valuation of time (e.g., Odaka & Hoch, 2004; Monga & Saini, 2009), very few studies have examined decisions concerning time-money bundles (e.g., Olivola & Wang, 2016), and fewer still have done so in the context of real-world consumer decisions. Here, we compare consumer preferences for *identical* time-money bundles under two normatively equivalent elicitation

procedures. Specifically, before presenting them with the key decision, we have consumers either focus on the amount of time that is equivalent to a given amount of money (time-focus condition) or the amount of money that is equivalent to a given amount of time (money-focus condition). In theory, a rational consumer should exhibit consistent preferences for time-money bundles and display similar levels of patience, regardless of how the decision problem is framed. We show, however, that consumers’ preferences for time-money bundles—and, by extension, their implied levels of patience—depend on which resource is brought into focus. Focusing on time decreases their likelihood of spending time to save money and increases their likelihood of spending money to save time—essentially, encouraging less patience. Conversely, focusing on money increases willingness to spend time to save money and decreases willingness to spend money to save time, thereby encouraging more patience. Across 4 studies, we document this *resource focus effect*, and rule-out alternative explanations for the observed preference reversal among time-money bundles.

Study 1 ($N = 707$) presented participants with one of two hypothetical time-money tradeoff scenarios, in which they imagined choosing between purchasing a $\$100$ coat at full price versus spending time (traveling or waiting in line) to purchase the same coat at a discount. Within each scenario, participants were randomly assigned to either a time- or money-focus condition. In the time-focus condition, the discount on the coat was fixed at $\$30$, and participants were asked to consider the amount of time they would be willing to wait/travel for this discount, using a choice-ladder method; specifically, they indicated whether they would be willing to wait/travel 10, 20, 30, 40 and 50 minutes for the $\$30$ discount. In the money-focus condition, the time expenditure was fixed at 30 minutes and participants were asked to consider the amount of money they would need to save to wait/travel this length of time, using a choice-ladder method; specifically, they indicated whether they would be willing to incur this 30-minute time cost for a $\$10$, $\$20$, $\$30$, $\$40$ and $\$50$ discount. In both conditions, the five binary-choice tradeoffs were presented on a single page, in either ascending or descending order. Critically, participants in both conditions were presented with one identical time-money tradeoff-bundle: spending 30 minutes to save $\$30$. We compared their likelihood of opting for this bundle (vs. paying full price) across the two conditions, and found that participants in the money-focus condition were more likely to spend 30 minutes to save $\$30$ (willingness-to-wait scenario: $M_{\text{money-focus}} = 92\%$ vs. $M_{\text{time-focus}} = 80\%$, $Wald = 5.23$, $p = .022$; willingness-to-travel scenario: $M_{\text{money-focus}} = 85\%$ vs. $M_{\text{time-focus}} = 70\%$, $Wald = 5.07$, $p = .024$).

Study 2 ($N = 554$) replicated the previous design but reversed the order in which time and money were mentioned in the binary-choice tradeoff statements. For example, “I would wait 10 minutes to receive the $\$30$ discount on the coat” was replaced with: “To receive the $\$30$ discount on the coat, I would wait 10 minutes.” Despite the altered word order, Study 2 replicated the *resource focus effect* ($M_{\text{money-focus}} = 91\%$ vs. $M_{\text{time-focus}} = 76\%$, $Wald = 10.14$, $p = .001$), thereby ruling-out word order as a potential confound.

In the two previous studies, the scenarios involved spending time to save money. In Study 3 ($N = 560$), we instead used a scenario that involved *spending money* in order to *save time* (buying an express train ticket to shorten travel time). Here, a focus on money again significantly increased the level of patience, but this time it was manifested by a *lower* willingness to spend $\$30$ in order to save 30 minutes, indicating that the *resource focus effect* occurs regardless of whether time (or money) is being saved or spent ($M_{\text{money-focus}} = 14\%$ vs. $M_{\text{time-focus}} = 21\%$, $Wald = 6.24$, $p = .013$).

Finally, in Study 4, we combined the main design elements from Studies 1-3, but we presented the five binary-choice tradeoffs one-at-a-time and in random order. Study 4 replicated the results of Studies 1-3 (willingness-to-travel scenario: $M_{\text{money-focus}} = 87\%$ vs. $M_{\text{time-focus}} = 81\%$, $Wald = 4.85$, $p = .028$; express-train scenario: $M_{\text{money-focus}} = 21\%$ vs. $M_{\text{time-focus}} = 41\%$, $Wald = 25.75$, $p < .001$), indicating that the effect does not require simultaneous or monotonic presentation of the binary-choice tradeoffs.

In sum, we identify a novel preference reversal phenomena for time-money tradeoff-bundles: focusing consumers on expenditures or savings of money increases their willingness to spend (and decreases their willingness to save) time, whereas focusing them on expenditures or savings of time has the opposite effect. Moreover, we show that this *resource focus effect* is robust to various features of the elicitation procedure (such as wording, ordering, etc.) and that it occurs regardless of whether consumers are considering spending time to save money or spending money to save time.

How Do Wealth and Time Horizon Affect Investors' Risk Tolerance? Evidence from the Field

EXTENDED ABSTRACT

In selecting an asset allocation, investors must choose an appropriate mix of lower-variance instruments (such as bonds) that offer relatively certain, but lower returns and higher-variance instruments (such as stocks) that provide the potential for both greater gain and greater loss. Fundamentally, this establishes a continuum ranging from a 100% bond allocation (0% stocks) to a 100% stock allocation (0% bonds), with the appropriate mix being determined by the investor's preference and tolerance for trading-off risk and return. However, little is known about how risk tolerance is affected by time (e.g. investment time horizon, age) and money (e.g. absolute and relative wealth). For example, should wealthy investors be more risk-averse or relatively risk-seeking? On the one hand, a concave utility function might suggest that risk aversion increases as wealth increases. Alternatively, investors might be risk-seeking at higher levels of wealth, as additional assets afford the opportunity to take risks. Furthermore, these questions are complicated by behavioral biases such as risk aversion and loss aversion (Kahneman & Tversky, 1979; Tversky & Kahneman, 1992), as well as questions concerning the generalizability of small stakes lab findings to field settings (Charness, Gneezy, & Imas, 2013; Dean & Ortoleva, 2015). Yet, it is undeniable that wealth and time horizon are critical elements in investment decision-making. To shed light on how temporal and monetary factors affect risk preference, cross-sectional analyses of a large-scale, field data set were conducted.

Data from a dynamic, risk tolerance titration questionnaire along with corresponding investor and advisor profile information were obtained from a FinTech firm. In total, data are available for 15,241 unique respondents. These individuals answered a series of risk tolerance questions at the request of their professional investment advisor knowing their advisor would, in turn, use the "risk score" generated from their responses to determine an appropriate asset allocation mix. The survey begins with preliminary items about specific investment goals and at what age the individual expects to retire (or did retire). The respondent then goes on to complete a dynamic titration questionnaire by making selections between a certain outcome (which could be a gain or a loss) and a risky outcome (50/50 chance of a specified gain/loss). Based on each selection, the subsequent question reflects an increase or decrease in risk and corresponding return. The process continues iteratively until the software identifies an indifference point for the respondent. Because

advisors are deploying the questionnaire to their clients, each client's investable portfolio size is known with precision (based on the accounts managed and tracked by the investment advisor). And, substantively, the titration questions are calibrated to the respondent's wealth. For example, an investor with \$300,000 in investable assets would respond to questions for which the certain and risky outcomes are based on an initial wealth state of \$300,000.

Separate regression analyses were conducted for the risk aversion and loss aversion measures. Both measures were calculated from responses to the titration questions.

Descriptively, risk aversion follows an S-shaped curve as a function of time (both in age and years-to-retirement metrics). Risk aversion is largely stable for younger individuals (age 25-49) who are far from retirement. As retirement approaches, risk aversion increases sharply through retirement and then stabilizes. In contrast, loss aversion declines slowly as a function of age and then drops precipitously in the ten years preceding retirement.

Regression results appear in the table below and reveal interesting differences between risk aversion and loss aversion. Loss aversion is predicted only by relative wealth ($p < .001$). That is, within each age bracket, individuals who are comparatively wealthy (top half of the wealth distribution relative to age) are slightly less loss averse compared to those who are relatively less wealthy (at that same age). Risk aversion, on the other hand, is influenced by relative wealth and temporal factors including age, years-to-retirement, (with quadratic and cubic effects representing the S-shaped curve described above) and their interaction. Overall, this complex set of results simplifies to just two effects. Individuals who are relatively more wealthy are more risk-averse compared to those who are less wealthy at the same age. However, when re-plotted as years-to-retirement (rather than age), the relative wealth differences disappear. That is, individuals who are less wealthy at a given age expect to retire later than those who are more wealthy. This result is supported by the interaction between age and years-to-retirement ($p < .05$). Notably, no effects are observed for absolute wealth. This is not particularly surprising since wealth and age move together. However, it underscores the importance of examining relative wealth and the temporal dimension findings. That is, nudges to increase retirement savings may benefit from factoring in whether an investor is ahead or behind in retirement savings. The presentation will discuss implications for developing investment advice and advocate for a more sophisticated understanding that incorporates time horizon effects into analyses of financial decision-making research.

SESSION OVERVIEW

Much work has revealed how visual images affect consumers' conscious attitudes. But how do visual images affect consumers nonconsciously, and do their visual patterns affect their choices? This session brings together four papers that address these under-researched questions in different, but synergistic ways. The first two papers explore eye movements and choice, whereas the second two examine nonconscious visual imagery.

Pieters, Erdem and Martinovici report a large-scale eye-tracking experiment with 342 U.S. consumers. They test what kinds of eye movements best predict choice and the extent to which they mediate brand ownership effects on choice. The model accommodates eye-fixations (overall attention) and brand-, attribute-, and other-saccades (jumps between attributes, brands, and brand-attribute combinations) as choice predictors. They find that brand-saccades, which reflect processing by brand, are best at predicting choice. Moreover, brand preferences build up remarkably rapidly, so that eye movements predict brand choice well before it is implemented. Thus, eye movements reflect fundamental, fast preference formation processes.

Streicher, Büttner and Estes focus on the magnitude of the field of attention. They theorize that activating broad (vs. narrow) attention increases visual exploration of product assortments. In one lab study and two field experiments they manipulate broad (vs. narrow) attention by asking participants to name objects that randomly appear in the center or the periphery of a computer screen. Mouse-clicks and eye movements show that inducing broad attention increases visual exploration of product displays, increasing choice of peripherally-located products and ultimately increasing unplanned purchasing. This effect of attentional focus on unplanned purchasing is accentuated among impulsive buyers.

Cian, Krishna, and Longoni investigate ads that visualize a desired transformation either via before/after visuals (i.e., the starting and ending points of a weight loss program) or through progression visuals (i.e., also including intermediate steps). Across five studies, they show that the less frequently used format, the progression ad,

is actually more credible and improves attitudes towards the ad and product. They theorize that, to be effective, ads promising transformation should facilitate mental imagery of the trajectory of the change. Indeed, progression ads demystify the promised transformation, making it more credible and leading to more positive attitudes.

Jia, Krishna and Li examine how shapes affect perceptions. Many marketing problems relate to whether a given set of products or procedures is a "complete set," so that missing one element might create a psychological void. For example, social marketing campaigns promoting healthy eating should ensure that every element of information reaches the audience. They study the effect of shape on the sense of completeness. In three studies, they show that circular shapes increase the sense of completeness amongst constituent elements, and consequently increase the perceived importance of each component. Distinctive visual cues (e.g., colors) of components attenuate this effect.

Audience members should gain a more nuanced understanding of how eye movements can predict brand choices, and how manipulating those eye movements can affect actual purchases. Additionally, audience members should gain insight into how visual imagery can nonconsciously influence perceptions such as credibility and importance.

Rapid Evidence Accumulation during Brand Choice: An Eye-tracking Analysis

EXTENDED ABSTRACT

Consumers frequently make rapid choices between complex products on websites that display detailed information on multiple brands and attributes side-by-side. Remarkably little is known about the processes driving such choices, which occur in less than a few minutes only. We develop and test an evidence accumulation model that is calibrated on eye-movements to address the issue. The model is rooted in recent developments in cognitive science and economics (Krajbich and Rangel 2011; Reutskaja et al. 2011), and relies on the idea that over and above their role in information search, eye-movements reflect fundamental preference formation processes. This builds on seminal research about the implications of task complexity for information processing (Jacoby, Speller, and Kohn 1974; Payne 1976; Russo and Rosen 1975) and the visual perception and information processing literature (Wedel and Pieters 2008). The model is calibrated on data collected in a large scale field experiment (N = 342) among regular consumers. The findings have implications for search and choice theories, and for the brand management and information design.

Under normal conditions, visual attention, information processing and comprehension processes are strongly connected to the eye-movements that people make during task performance (Just and Carpenter 1980; Wedel and Pieters 2008). Prior research on attention and choice (Krajbich, Armel, and Rangel 2010; Pieters and Warlop 1999; Shi, Wedel, and Pieters 2013; Yang, Toubia, and de Jong 2015) has often focused on one type of eye-movements: eye-fixations, which are brief moments (200-400 milliseconds) when the point of regard is relatively still and which indicate attention intensity. The very fast jumps (20-40 milliseconds for typical stimuli) between successive fixations are defined as eye-saccades.

While eye-fixations, eye-saccades provide information about the specific attentional processes that people are engaged in (Rayner 1978). Specifically, for consumers making a choice from an attributes-by-brands matrix, eye-saccades reflect specific processing styles that are central to brand choice. We hypothesize that consumers engage in rapid brand comparison and information integration processes, which are reflected in, respectively, attribute-saccades and brand-saccades (jumps between brands within an attribute and jumps between attributes within a brand, respectively), and that in particular brand-saccades predict choice, over and above the effect of mere eye-fixations. In addition, we hypothesize that prior ownership predicts choice and this is mediated by attention. Task complexity is expected to influence attention measures as consumers need to adapt their processing style to the amount of product information available on the display.

We develop a multivariate latent growth and choice model, estimated using MCMC techniques, to examine the extent to which attention predicts brand choice, the effect of ownership on choice, and the extent to which attention mediates it. The model is calibrated on data collected from consumers who had expressed to be in the market for a smartphone, randomly drawn from large, locally representative participant pools, from three locations in the continental US: Washington DC, Cincinnati, and San Diego. Stratification led to representation of three user segments: owners of one of the smartphone brands on display ($N = 246$), owners of a different brand ($N = 25$), and current non-smartphone owners ($N = 71$). User segment information combined with choice data, allows testing differences between loyal consumers, brand switchers, and consumers new to the market.

The results not only show that attention predicts choice, but more importantly that it does so from the very start of the choice task (39% correct brand choice predictions after only one quarter of the decision time, $p < .01$ when compared to random choice). We find support for a positive feedback loop over time between attention and choice meaning that (1) consumers focus more on the brand they eventually choose, and (2) this brand focus also increases the probability of choice. The influence of brand ownership on choice is mediated by specific attention types: brand-saccades and overall attention. Task complexity influences the total time spent in the task, but not how the specific attention types evolve during the choice task, which counters common ideas in the decision-making literature. Both brand-loyal and brand-switching consumers are found to focus on the owned brand and to compare its attributes to the other brands during the first half of the decision. In the second half these groups differ in attention towards the owned brand, but have similar attention patterns towards the chosen brand.

Our research provides strong evidence that over and above the mere intensity of attention (eye-fixations), the type of attentional processes (brand-saccades) predicts choice. It reveals that preference formation during brand choices proceeds very early and our research is the first to document this “early saccade preference effect”. It also is the first to show the attentional processes that account for ownership effects on choice.

Eye Buy: Attentional Scope Affects Product Choice via Visual Exploration

EXTENDED ABSTRACT

Marketing studies suggest that with increasing exploration of shopping environments unplanned purchasing also increases (e.g., Hui et al. 2013; Inman, Winer, and Ferraro 2009; Stille, Inman, and Wakefield 2010). Recent eye-tracking studies, in turn, show that

chronic impulse buying, a trait which links to unplanned purchasing, correlates with increased exploration of non-focal products in shoppers' visual periphery (Büttner et al. 2014). The present research therefore tests, for the first time, whether the scope of attention influences unplanned purchasing by visual exploration of shopping environments. Measuring mouse-clicks, eye movements, and actual purchases, we show that activating broad (vs. narrow) attention increases visual exploration of product displays, ultimately increasing unplanned purchasing.

Prior marketing studies have described visual exploration of product assortments as relatively stable and unmalleable gaze patterns with a bias towards the horizontal center of shelves (Atalay, Bodur, and Rasolofarison 2012). In contrast, we theorize that activating broad (vs. narrow) attention increases visual exploration of the periphery of product assortments, because attentional scope may affect spatial dispersion of gaze patterns in subsequent situations (Friedman et al. 2003). We further predict that this increased attention to the visual periphery should increase choice of peripheral products, because viewing those peripheral products may remind shoppers of forgotten needs (Inman and Winer 1998), increase product preferences (Orquin and Mueller Loose 2013) or trigger an impulsive desire to possess that product (Hoch and Loewenstein 1991). Hence, broad attentional scope should increase purchasing products from the periphery by increasing visual exploration (i.e., mediation). And given that more choice options fall into the visual consideration set as visual exploration of the shopping environment increases, a broad (vs. narrow) scope of attention should ultimately increase unplanned purchasing.

The results of Büttner et al. (2014) also suggest that chronic buying impulsiveness may moderate the effect because non-impulsive shoppers are effective in shielding and filtering irrelevant stimuli from the visual periphery. And conversely, highly impulsive individuals are more susceptible to irrelevant stimuli and more affected by their direct surroundings (Kasof 1997). Hence, impulsive shoppers should be more susceptible to the influence of attentional scope on unplanned purchasing.

Using a visual manipulation of attention, Study 1 establishes that broad (vs. narrow) attention increases hypothetical choice (mouse-clicks) of peripheral products presented onscreen. Study 2 shows via eye-tracking in a field setting that both choice quantity (i.e., total number of chosen products) and choice variety (i.e., number of different brands chosen) increase as a function of broad (vs. narrow) attention by increasing visual exploration of products on shelves. Using real shoppers in a supermarket, Study 3 finally shows that activating broad (vs. narrow) attention increases unplanned purchasing, and that high buying impulsiveness accentuates this effect.

In all studies, attentional scope was manipulated by showing participants 20 object pairs on a computer display, one pair at a time (2 sec). Critically, each pair included one object in the center and one in a random corner (periphery) of the display. Participants in the *narrow attention* group were instructed to name the object appearing in the center of each display, whereas participants in the *broad attention* group named all objects appearing in the periphery. All participants saw and named the same objects. In study 1, participants ($N = 129$) then viewed a horizontal arrangement of nine refrigerators containing frozen food and they were instructed to click on any products they would be interested in purchasing. We calculated the horizontal distance of each click from the center of the display, and then we averaged those distances per participant. Participants in the broad attention group chose products further from the center of the display ($M = 10.55$ cm) than those in the narrow attention group ($M = 8.39$ cm), $t(127) = 2.97, p < .01$.

Study 2 was conducted in a small retail shop (400 m²) with shoppers ($N = 79$) who wore eye-tracking glasses. After the attentional manipulation, participants were asked to make hypothetical purchases from a specific shelf area containing candy and snack food. The broad attention group hypothetically spent more money ($M = €6.57$), chose more products ($M = 3.16$), and chose more brands ($M = 3.16$) than the narrow attention group (spending $M = €5.01$, $t(77) = 2.20$, $p < .05$; chosen products $M = 2.48$, $t(77) = 1.97$, $p = .05$; chosen brands $M = 2.40$, $t(77) = 2.20$, $p < .05$). Participants in the broad attention group visually examined 62% of all shelf compartments, whereas the narrow attention group examined only 50% of the shelf compartments, $t(71) = 2.72$, $p < .01$. This visual exploration also mediated all three variables of hypothetical purchasing (Hayes 2013, model 4; all CIs excluding zero; all direct effects $p > .05$).

Study 3 was conducted in a large supermarket (3000 m²). First, shoppers ($N = 99$) indicated their planned purchases and then were released for shopping after the attentional manipulation. After their shopping, the experimenters recorded their unplanned purchases and chronic buying impulsiveness (Rook and Fisher 1995). The broad attention group purchased more product categories unplanned ($M = 2.00$) than the narrow attention group ($M = .96$), $t(97) = 3.18$, $p < .01$, and also spent more money unplanned ($M_{broad} = €5.59$ vs. $M_{narrow} = €3.22$, $t(97) = 2.01$, $p < .05$). As predicted, this effect interacted (Hayes 2013, Model 1) with chronic buying impulsiveness ($B = .55$, $t(95) = 2.06$, $p < .05$), with 63% of shoppers showing a significant effect of the attentional manipulation on unplanned category purchases as a function of increasing buying impulsiveness.

Thus, attentional scope seems to be an important mechanism that explains how many different products shoppers attend to and discover during shopping, ultimately affecting unplanned purchasing. Practically, in-store communications (e.g., screens) could be optimized by displaying product offers in the periphery, thus inducing broad attention.

Communicating a Promise of Change: Visual Steps Enhance Process Imagery

EXTENDED ABSTRACT

Humans often desire change: we want to be thinner, look younger, have more hair. Marketers respond to such desires by offering products promising to deliver the corresponding changes: weight-loss programs, wrinkle removers, hair regrowth solutions. The visuals in the advertisements (ads) for these products typically focus on the desired final outcome by featuring a before and an after visual (e.g., a person at the beginning and at the end of a weight loss program; *before-after ads*). Very few *change-ads* include visuals of the intermediate steps between the before and the highly desirable after (e.g., a person gradually slimming down throughout the weight loss program; *progression ads*).

Although neglected in the marketplace and by future marketers, across seven studies we show that progression ads are superior to before-after ads across multiple consumer domains. We theorize that, to be effective, ads promising transformation should facilitate mental imagery of the trajectory of the change, i.e., the consumer should be able to imagine herself going through the transformation from “before” to “after.” Progression ads (but not before-after ads) evoke this kind of spontaneous *process imagery* -- thoughts and images about the means and ways leading to a change. In turn, spontaneous process imagery increases the credibility of the ad and leads to more favorable attitudes toward the product (serial mediation).

Through a content analysis of 250 ads of the top five weight-loss programs in the US (source: Consumer Affairs) we show that

before-after ads are more common than progression ads: 36% were “before-after” whereas only 0.8% were “progression.” Another pilot study asked participants ($N=122$) to draw the ad for a weight loss program. While 22.95% of participants drew before-after ads, only 1.64% drew progression ads ($z = 5.07$, $p < .001$; remaining ads coded as “others”). Overall, these pilot studies show that progression ads are neglected by both current and future marketers.

In studies 1a ($N=116$) and 1b ($N=139$), we show that adding intermediate steps to a before-after ad increases the credibility of the ad. In both studies and using different stimuli (stylized figures and actual photographs), the progression ad was more credible than the before-after ad. One pretest ensured that the stimuli used did not differ on visual appearance, informativeness, complexity, familiarity, and novelty (all p 's $> .1$).

In study 2 ($N=134$), we test the downstream consequences of credibility on attitudes toward the product. Participants rated credibility and reported their attitudes toward one of two versions of an ad for a fictitious hair growth product. The before-after ad featured a drawing of a person before using a hair growth treatment and a drawing of the same person at the end of the treatment. The progression ad contained an identical drawing with the addition of drawings of four intermediate outcomes. As predicted, the progression ad was associated with higher credibility ($M_{before-after} = 2.91$, $M_{progression} = 3.79$; $F(1, 132) = 5.99$, $p < .05$) and more positive attitudes ($M_{before-after} = 3.71$, $M_{progression} = 4.73$; $F(1, 132) = 7.35$, $p < .05$) than the before-after ad. In a mediation model, credibility fully accounted for the effect of ad type on attitudes (95% CI: .16, 1.43).

Studies 3a ($N=143$) and 3b ($N=80$) we use open-ended and close-ended responses to show that progression ads evoke greater process imagery than before-after ads, even though both ads only have visuals of outcomes. In study 3a we coded the content of the spontaneous thoughts and images that either a before-after or a progression ad evoked in participants. Indeed, the progression ad generated more spontaneous process imagery than the before-after ad ($z=5.11$, $p < .01$). The two ads did not differ on outcome imagery ($p > .5$) or amount of imagery (i.e., response length, $p > .5$). In study 3b participants rated the extent to which a before-after ad or a progression ad evoked process and outcome imagery (through six randomly presented statements, three reflecting process imagery ($\alpha = .89$) and three reflecting outcome imagery ($\alpha = .70$) adapted from Taylor et al. 1998; Escalas and Luce 2004; Zhao et al. 2007; 2011). Again, the progression ad led to higher process imagery than the before-after ad ($M_{before-after} = 4.11$, $M_{progression} = 6.92$; $F(1, 78) = 41.53$, $p < .01$) and to the same outcome imagery ($p > .5$).

Study 4 ($N=142$) tests the links between the constructs investigated in the previous studies. Results show how the progression ad leads to greater process imagery than the before-after ad, which then results in higher credibility and consequently more positive attitudes toward the product (full serial mediation, 95% CI: .18 and .89).

Study 5 tests a boundary condition and shows that ambiguity (operationalized through size of change) moderates the effect of ad type on attitudes. We expected to replicate study 4 in the large change condition (high ambiguity because the transformation is large), with a full serial mediation whereby the progression ad leads to greater process imagery, credibility, and ultimately better attitudes than the before-after ad. However, when the change is small (low ambiguity because the transformation is trivial), the progression ad should no longer be more persuasive than the before-after ad. Indeed, within the large change condition, there was a full serial mediation (95% CI: .45 and 1.86). However, and as predicted, within the small change condition, the serial mediation was not significant (95% CI: -1.00 and .20). Importantly, the full mediations in studies 2, 4, and

5 via process imagery indicated that the process mechanism driving the observed effect is not the amount of information contained in the ad (or these mediations would be partial).

Theoretically, and differently from prior research on mental simulation, we bring attention to an understudied yet important typology of mental imagery: spontaneous mental simulation of process (*process imagery*), and highlight its critical role in the persuasiveness of advertised change. Second, we add to the literature on process versus outcome focus by showing how process imagery can be spontaneously generated through outcome visuals. Substantively, we show that before-after ads, currently prevalent in the market place, may be an ineffective way to credibly promise positive change.

The Effect of Visual Cues on the Sense of Completeness

EXTENDED ABSTRACT

When brand managers introduce a new product category to their existing portfolio (e.g., when Colgate introduced mouthwash), they are frequently concerned with how to leverage on the popularity of their existing products (e.g., Colgate toothpaste). When a city tourism board wants to promote some lesser-known attractions, a solution might be to link these attractions to better-known ones. Similarly, when social marketing campaigns aim to promote disease prevention or healthy eating, an important issue is to ensure that every element of information gets across to the audience. The marketing problems discussed above can all relate to “a sense of completeness” – whether consumers perceive a given set of products or procedures as being a complete set, so that missing one element might create a psychological void.

In this research, we study the effect of visual cues on the sense of completeness. Specifically, we examine the role of circular shapes. Prior research has documented that circular shapes activate a “softness” association (Jiang et al. 2016), are related to harmony and friendliness (Zhang, Feick, and Price 2006), and are related to groups and belonging (Zhu and Argo 2013). We contribute to this literature and demonstrate that circular shapes increase the sense of completeness amongst constituent elements.

We first conducted a pilot study to test whether the association strength between circles and completeness is indeed greater than that for the other shapes. Participants (n=118) were shown six shapes (i.e., triangle, square, rhombus, circle, rectangle, and trapezium), and were asked to indicate which shape gave them the greatest feeling of completeness. We found that 67.8% of the participants indicated that out of the six shapes, circle gave them the greatest feeling of completeness (16.1% chose square, the next popular shape; $t(117) = 7.43, p < .0001$).

Because circular shapes are associated with a high sense of completeness, grouping a set of components in a circular (vs. square, based on our pilot) shape should increase the perceived completeness of the set. Study 1 confirmed this. Participants (n=125) were asked to view a flyer on the prevention measures for the Zika virus. When study 1 was run, the Zika virus was widespread in the city where the study was conducted. Four prevention measures were listed in the flyer (e.g., “use insect repellents regularly,” “wear long-sleeved shirts and long pants”), and each was illustrated with a figure and verbal descriptions. Participants were randomly assigned to one of the two conditions. In the *circle [square]* condition, the four measures were grouped in a circular [square] shape. After participants viewed the flyer, they were asked to indicate the extent to which the four measures formed a complete prevention process for the Zika virus (1 = not at all, 7 = very much). An ANOVA revealed that participants perceived the set of prevention measures to be more complete

when the four measures were grouped in a circular versus square shape ($M_{\text{circle}} = 4.75, M_{\text{square}} = 4.26; F(1, 123) = 5.52, p = .02$).

Study 2 was conducted to test whether circular shapes would increase the perceived importance of the components. Participants (n=123) were asked to view an ad for an oral care product collection. The collection included three products of a brand: toothpaste, mouthwash, and dental floss. Participants were randomly assigned to one of the two conditions. In the *circle [square]* condition, the product collection was grouped in a circular [square] shape. Two dependent variables were measured: (1) the completeness perception of the set; and (2) product importance rating. We asked participants to rate the importance of mouthwash – which was not in the oral care routine for most of the participants (as determined by a pre-test).

ANOVA analyses revealed that a circular (vs. square) shape made participants perceive the product collection to be more complete ($M_{\text{circle}} = 4.67, M_{\text{square}} = 4.30; F(1, 121) = 3.99, p < .05$), and made participants perceive the mouthwash to be more important ($M_{\text{circle}} = 4.48, M_{\text{square}} = 3.97; F(1, 121) = 3.86, p = .05$). A mediation analysis further revealed that the completeness perception fully mediated the effect of the circular (vs. square) shape on the importance rating.

Study 3 (n=293) was conducted to test the moderating role of distinctive visual cues. We predict that distinctive visual cues (e.g., colors) will reduce the sense of completeness, and thereby attenuate the effect of circular shapes. We employed a 2 (shape: circle vs. square) 2 (component color: same color vs. different color) between-subjects design. In the *same color* condition, we used the same design as we did in study 2. In the *different color* condition, we used different background colors for the three component products. After participants viewed the ad, they responded to the same importance measure as we used in study 2. A two-way ANOVA revealed a significant interaction effect between shape and component color ($F(1, 289) = 4.13, p = .04$). A contrast analysis revealed that when the background of the components had the same color, a circular (vs. square) shape made participants perceive the mouthwash to be more important ($M_{\text{circular}} = 4.48, M_{\text{angular}} = 3.91; F(1, 289) = 5.94, p = .02$); when the components had different background colors, a circular versus square shape did not affect the perception of mouthwash importance ($M_{\text{circular}} = 3.96, M_{\text{angular}} = 4.07; F(1, 289) = .23, p = .63$). The main effects of shape and component color were non-significant ($ps > .10$).

Our research demonstrates that a circular (vs. square) shape increases the perceived completeness of a set of products or items, which has rich implications for the design of product campaigns and marketing materials.

SESSION OVERVIEW

A great deal of work in consumer behavior has explored why consumers seek variety (e.g., Ariely and Levav 2000; Etkin and Migliner 2016; Kahn and Isen 1993; Kahn 1995; Ratner, Kahn, and Kahneman 1999). For example, variety-seeking can be driven by people's needs to buffer against future preference uncertainty (Simonson 1990), accommodate multiple needs or users (McAlister and Pessemier 1982), have stimulation (Etkin 2016; Menon and Kahn 1995), or signal information to others (Ratner and Kahn 2002; Sela, Morgan, and Maimaran 2016).

By comparison, relatively less is known about the relationship between variety-seeking and the self. How does variety affect properties of people's selves; and how might properties of people's selves, in turn, influence variety preferences? This session addresses these questions by shedding light on the bi-directional relationship between variety-seeking and diverse properties of the self—including thoughts about the self, biological traits, and emotions—using mixed methodologies (e.g., panel data; experiments; field data) across multiple domains.

The first two papers explore how variety influences properties of people's selves, such as self-continuity and emotions during goal pursuit. Paper 1 (Rifkin and Etkin) examines how the perceived variety in consumers' self-expressive choices undermines self-continuity. Four experiments demonstrate that perceiving greater variety in an assortment chosen to express the self elicits inferences of unstable preferences, which undermines self-continuity. Paper 2 (Rafieian, Huang, and Kahn) examines how the variety among goal-inconsistent (consistent) behaviors affects anticipated guilt (reward). Five experiments demonstrate that when a self-regulation goal is primed, greater variety among goal-inconsistent (consistent) behaviors generates more anticipated guilt (reward); accordingly, people choose less variety among goal-inconsistent behaviors to minimize guilt (and more variety for goal-consistent behaviors to maximize reward).

The second two papers examine how variety-seeking behavior is, in turn, influenced by properties of people's selves. Paper 3 (Hmurovic and Inman) investigates how feelings of power affect variety-

seeking patterns. Using experimental and panel data, two studies demonstrate that low- and high-power consumers differ on whether they seek variety in high- (e.g., brand) vs. low-level (e.g., flavor) product attributes. Finally, drawing from research in chronobiology, paper 4 (Gullo, Berger, Etkin, and Bollinger) examines how people's fluctuating circadian rhythms affect preferences for variety throughout the day. Using experimental, panel, and field data, four studies demonstrate that consumers' preferences for variety are lowest in the morning and increase throughout the day.

Taken together, these four papers explore how variety can influence, and be influenced by, properties of people's selves. The papers approach this topic by examining the psychological and biological underpinnings of variety preferences, as well as how the perception of variety influences self-perception and emotion. This session also provides perspectives on some open questions in the literature: how might chosen or perceived variety affect the way consumers see themselves and their emotions, and how might aspects of people's selves—such as their chronobiology or feelings of power—influence variety-seeking patterns? This session will have broad appeal to scholars interested in variety, self-related processes, such as chronobiology and judgments of self-continuity, self-regulation, and mixed-method research.

How Variety in Self-Expression Undermines Self-Continuity

EXTENDED ABSTRACT

From dating profiles to social media accounts to streaming services, consumers are often asked to communicate their preferences by constructing assortments. For example, LivingSocial's "Pick Five" campaign encouraged social networkers to list their "five favorite" movies and songs on their profiles (Sullivan 2009). Yet while consumers often construct such assortments to communicate information about who they are, might these assortments impact how consumers see themselves? What aspect(s) of the assortment might play a role?

The present research proposes that the perceived variety in a self-expressive assortment can impact how consumers see themselves. Recent research demonstrates that variety-seeking can accommodate for unstable and changing preferences (Sela and Maimaran 2016; Simonson 1990). Integrating this work with Self-Perception Theory (Bem 1972), which argues that people learn about their preferences by observing their own actions, we theorize that perceiving greater variety within a self-expressive assortment should elicit inferences that one's preferences in the choice domain are less stable (e.g., greater perceived variety in one's music choices signals that one's music preferences are unstable). Because instability implies change over time, we reason that this inference of preference instability should affect judgments of similarity with past and future selves (self-continuity; Bartels and Urminsky 2011). We thus propose that by leading consumers to infer that their domain-specific preferences are less stable, perceiving greater variety in a self-expressive assortment will undermine self-continuity.

Four studies support our predictions. In study 1, participants ($N = 80$) created a personal profile of their five favorite types of tea for a fictitious tea delivery service. To manipulate perceived variety, we provided participants with (false) feedback about the composition of

their choices (high vs. low variety), then measured self-continuity using a measure from the literature (future-self connectedness; Bartels and Urminsky 2011). As predicted, perceiving greater variety in their self-expressive assortments undermined participants' self-continuity ($M_{\text{high-variety}} = -.08$ vs. $M_{\text{low-variety}} = .32$, $F = 5.40$, $p = .023$). We also replicated this effect using a different manipulation of perceived variety (i.e., visually categorizing participants' choices into more vs. fewer categories).

Study 2 explores the proposed underlying process by measuring the proposed mediator (domain-specific preference stability) and by separately measuring two components of self-continuity (future-self similarity vs. future-self liking; Molouki, Bartels, and Hershfield 2016). First, participants ($N = 122$) created an online personal profile and chose an "ideal collection" of book genres or public radio programs (depending on which activity they indicated doing more often) that represented their personal tastes. After receiving (false) feedback about the variety in their assortments (high vs. low), we measured future-self similarity, future-self liking, and the underlying mechanism, domain-specific preference stability. As predicted, perceiving greater variety in their assortments decreased future-self similarity ($M_{\text{high-variety}} = 5.40$ vs. $M_{\text{low-variety}} = 5.87$, $F = 6.30$, $p = .013$) due to reductions in preference stability ($M_{\text{high-variety}} = 5.25$ vs. $M_{\text{low-variety}} = 5.74$, $F = 4.64$, $p = .033$; Mediation 95% CI [-0.35, -0.04]). Importantly, however, perceived variety had no effect on future-self liking ($F < 1$, $p > .6$), suggesting that greater perceived variety negatively affects self-continuity by diminishing a sense of similarity with—and not liking for—one's future self.

Prior work suggests that beyond feeling connected to future selves, we can also feel connected to past selves (Milligan 2003; Sedikides et al. 2008). If our self-continuity effect is driven by inferences of preference instability, as we suggest, then the effect may extend to past-self continuity. To test this, study 3 participants ($N = 183$) chose their "ideal collection" of book genres for an online profile and received false feedback about the variety in their choices (high vs. low). Then, we measured future-self and past-self continuity. Supporting our predictions, perceiving greater variety reduced not only future-self connectedness ($M_{\text{high-variety}} = -.18$ vs. $M_{\text{low-variety}} = .20$; $F = 7.61$, $p = .006$) and similarity ($M_{\text{high-variety}} = 5.51$ vs. $M_{\text{low-variety}} = 5.91$; $F = 6.99$, $p = .009$), but also past-self similarity ($M_{\text{high-variety}} = 5.19$ vs. $M_{\text{low-variety}} = 5.59$; $F = 4.08$, $p = .045$). Further, all three effects were driven by a reduction in preference stability ($M_{\text{high-variety}} = 4.81$ vs. $M_{\text{low-variety}} = 5.55$, $F = 11.79$, $p = .001$; all 3 mediation CIs exclude 0), providing support for our proposed mediating process.

Critical to our theory is that a chosen assortment says something about who one is (i.e., it is self-expressive; Belk 1988). If a chosen assortment were not self-expressive, by contrast, we would not expect to observe our effect. To test this, participants in study 4 ($N = 222$) first indicated a domain that is least (vs. most) self-expressive from several options (books, radio, music, public radio). Then, while choosing "five favorite" items for a social media profile (as in prior studies), we manipulated whether participants chose from the domain previously selected as their most or least self-expressive. We manipulated the perceived variety of the assortment and measured self-continuity and participants' belief that they would outgrow the social media platform. A 2 (perceived variety) \times 2 (self-expressiveness) ANOVA revealed the predicted interaction ($F = 3.75$; $p = .054$): When choosing from one's most self-expressive domain, perceiving greater variety among one's assortment reduced future-self connectedness ($M_{\text{high-variety}} = -.32$ vs. $M_{\text{low-variety}} = .11$; $F = 6.21$, $p = .013$); but when choosing from one's least self-expressive domain, however, the effect disappeared ($M_{\text{high-variety}} = .11$ vs. $M_{\text{low-variety}} = .09$; $F < 1$, $p > .8$). Thus, only when a chosen assortment is self-

expressive does greater perceived variety undermine self-continuity. In addition, greater perceived variety enhanced participants' belief that they would "outgrow" the social media platform, particularly when choosing from their most (vs. least) self-expressive domain (high self-expressiveness: $M_{\text{high-variety}} = 5.31$ vs. $M_{\text{low-variety}} = 4.60$; $F = 5.35$, $p = .022$; low self-expressiveness: $M_{\text{high-variety}} = 5.26$ vs. $M_{\text{low-variety}} = 4.86$; $F = 2.08$, $p = .151$).

Together, these findings demonstrate that greater perceived variety in a self-expressive assortment has implications both for consumers' self-continuity and for marketers who care about long-term customer relationships. This research contributes to the literatures on symbolic consumption, self-continuity, and variety-seeking.

Variety Counts: How Variety is Perceived in the Presence of Self-Regulatory Goals

EXTENDED ABSTRACT

Consumers set various goals in their daily lives. Achieving these goals requires consumers to avoid the allure of goal-inconsistent behaviors (Loewenstein 1996). The act of trying to avoid goal-inconsistent behaviors results in relief and contentment when successful and guilt and anxiety when unsuccessful (Carver and Scheier 1982).

In this research, we propose that when consumers pursue a self-regulatory goal, they tend to think about the future evaluation of their current choices. So, if they are anticipating violating a self-regulatory goal by consuming indulgent options, they think about ways to minimize anticipated guilt. If they are behaving consistently with a self-regulatory goal by consuming virtuous options, however, they think about ways to maximize anticipated reward. We suggest that when consumers are choosing items to consume that are either consistent or inconsistent with a self-regulatory goal (holding the number of options consumed constant), they consider the variety of the chosen options, and not just their preference for those options.

Specifically, we hypothesize that when people are primed with a self-regulatory goal, less (more) variety in goal-inconsistent (goal-consistent) acts results in less anticipated guilt (more anticipated fulfillment and perceptions of progress). People who are not primed with a goal, however, try to maximize the enjoyment of their current consumption and thus, focus on their preferences and not future evaluations of their current choice. These two different perspectives result in different behaviors depending upon the preference structure of the options in the choice set: When consumers are making choices between equally preferred indulgent options, they opt for more (less) variety in the absence (presence) of a self-regulatory goal. In the absence of a goal, variety is perceived as positive in hedonic current consumption (Ratner, Kahn, and Kahneman 1999), but negative when considering anticipated guilt. By contrast, when virtuous items are not equally preferred, consumers choose to consume their more preferred item repeatedly when no goal is primed, but choose more variety—even at the expense of consuming a less preferred item—if a goal is primed. Formally, we hypothesize:

Hypothesis 1a: Variety in goal-inconsistent choices leads to higher levels of anticipated guilt for people with a goal than for those without a goal.

Hypothesis 1b: Variety in goal-consistent choices leads to higher levels of anticipated satisfaction for people with a goal than for those without a goal.

Hypothesis 2a: People with a goal seek less variety in goal-inconsistent activities than those without a goal, adjusting for the preferences of the options consumed.

Hypothesis 2b: People with a goal seek more variety in goal-consistent activities than those without a goal, adjusting for the preferences of the options consumed.

We argue that when a health goal is activated, consumers are motivated to count the number of their goal-relevant choices, as a means of monitoring their goal progress. We further contend that, in these situations, the variety of options chosen will be perceived as a way to count how many goal-consistent, or inconsistent, options have been consumed. For instance, for the delicious (but unhealthy options) a higher variety of items, holding actual quantity constant, will be perceived as more goal inconsistent activities. On the other hand, when consuming vegetables (healthy snacks) or exercise activities, more variety will be perceived as more goal-consistent, again holding quantity of consumption or activity constant.

We test our predictions across five studies. The self-regulatory goal that is primed for consumers is a health goal. The first three studies test the hypotheses in a vice category (eating unhealthy snacks). The stimuli used in these studies were pretested to ensure that participants have statistically even preferences for them. The last two studies test the claims in a virtue category (exercising and eating vegetables), with the preference structure manipulated individually for each participant.

In the first study, we show that thinking about having variety in vice options leads to higher anticipated guilt, and that this happens because by choosing more (than less) variety in vice categories, consumers with a health goal think they have consumed more of those goal-inconsistent options.

In studies 2 and 3, we show that priming participants with a health goal leads them to incorporate less variety in their choice of vice options. In study 2, half of participants were primed with a health goal. All participants were then asked to choose two pieces from two available snack types. A smaller percentage of participants in the goal group (than in the control group) chose two different snacks. In study 3, we replicated these findings this time with real snacks (participants were asked to choose three pieces from four available snack types in the lab).

In studies 4 and 5, we tested our predictions in virtue categories. In study 4, participants were asked to rank five exercise activities. Participants then thought about a routine with different levels of variety in exercise activities. While the non-varied routine involved only the highest-ranked (most liked activity), the varied routine involved the highest-ranked, the mid-ranked, and the lowest-ranked activities. This ensured that seeking variety would have to come with the cost of incorporating an activity that participants had ranked the lowest. Participants in the variety condition felt they had made more progress and that their routine had involved more activity than did participants in the no-variety condition. In study 5, participants ranked seven different vegetables, then got an individualized choice set including their high-ranked and low-ranked vegetables. Participants with a health goal chose more variety although it meant consuming a vegetable they did not like.

Get on My Level: Power and Differential Patterns of Attribute-Level Variety Seeking

EXTENDED ABSTRACT

Power is defined as the “asymmetric control over valued resources in social relations” (Magee and Galinsky 2008, p. 361), and exists both as a chronic and situationally-evoked psychological state (Rucker et al. 2012). There is growing recognition that power can have profound effects on consumer behavior and cognition (e.g., Dubois et al. 2012; Inesi et al. 2011; Rucker and Galinsky 2008), with recent work finding that increased action tendency triggered by high-power states increases consumer switching behavior (Jiang et al. 2014). Although prior power research suggests that action orientation may lead overall levels of variety-seeking to differ between low and high-power consumers, this research is silent regarding how the *pattern* of variety-seeking may differ. If low-power consumers make less varied purchases, is the variety they do select equivalent to that of high-power consumers? That is, do low and high-power consumers seek variety on the same types of product attributes, just to a different degree? In the current paper, rather than focusing on differences in the intensity of variety-seeking for low and high-power consumers, we investigate differences in the patterns of variety-seeking they pursue. Specifically, we propose that both low and high-power consumers seek variety, but do so more intensely on different product attribute levels.

Product attributes can be categorized as higher-level or lower-level, depending on their degree of abstractness (e.g., Liberman et al. 2002). Just as prior work has shown consumers can seek variety more intensely on some product attributes more than others (e.g., sensory vs. nonsensory attributes; Inman 2001), we posit that low and high-power consumers differ in the relative intensity to which they seek variety on different product attribute levels (higher vs. lower). Given research evidencing that high-power consumers process information at higher, more abstract levels (Smith and Trope 2006), we argue that variety-seeking occurs more intensely at the level at which consumers’ attention is directed—higher-level product attributes for high-power consumers and lower-level product attributes for low power consumers.

Study 1 tested this prediction using historical purchase data from the Nielsen Homescan Consumer Panel in three product categories (i.e., chips, pasta sauce, and carbonated beverages) over a twelve-year period (2004-2015). We restricted our analyses to single-person households to more reliably capture individual-level variety-seeking behavior (Kahn et al. 1986). Nielsen-specified UPC attribute and category classifications were used to code low- and high-level attributes. Flavor served as a low-level attribute for all product categories. Higher-level attributes varied in availability between product categories and included brand, type (e.g., kettle-cooked), form (e.g., waffle), module (e.g., tortilla), and style (e.g., extra thick). Consistent with prior research, we calculated the degree of consumer variety-seeking using the Herfindahl-Hirschman Index (i.e., HHI; the sum of squares of choice shares), which was subtracted from 1 so that larger scores indicate greater variety-seeking (Nowlis et al. 2010). Subtracting the higher-level index from the lower-level index generates an indicator of relative variety-seeking, with positive values signaling greater lower-level (vs. higher-level) product attribute variety-seeking.

Because income reflects a literal control over economic resources and is tightly linked to experiences of power (e.g., Dubois et al. 2015), income was used as an indicator of individuals’ chronic sense of low (<\$12,000; n=2,462) and high (≥\$100,000; n=1,034) power. To minimize the possibility that variety-seeking could be attributed

to recent income changes, only panelists who remained at the same income level for at least two consecutive years were included in the sample, and only purchase data from the longest spell of consecutive years at the same income level were retained for analysis.

Separate regression analyses were performed for each index of relative variety seeking within each product category, including power as the primary predictor (1 = high, 0 = low) and controlling for both income stability (i.e., total number of years at same income level) and total spent (i.e., total amount spent on all trips in which target product was purchased). In the chip category, although there was no difference in relative variety-seeking on flavor versus brand ($b = -.003, p = .706$), low-power consumers engaged in significantly more variety-seeking on the lower-level attribute of flavor than the higher-level attributes of form ($b = -.080, p < .001$), type ($b = -.164, p < .001$), and module ($b = -.024, p = .020$), as compared to high-power consumers. Similar results emerged in the other product categories, with low-power consumers demonstrating greater variety-seeking on flavor than all other higher level attributes except for brand (sauce style: $b = -.024, p = .035$; beverage type: $b = -.070, p < .001$). This suggests that high-power consumers engage in more intense variety-seeking on higher-level (vs. lower-level) product attributes to a greater degree than low-power consumers.

Study 2 sought to replicate the results of Study 1 using a direct (but subtle) power-state manipulation. MTurk participants ($n = 177$) imagined receiving a promotional punchcard for six free bagels (one per week). After viewing the bagel shop's 16 options listed below a chalkboard sign reading "We all feel powerful [powerless] in the morning...have a bagel!" (i.e., phrasing adapted from Dubois et al.'s 2012 successful manipulation), participants sequentially chose which bagel they wanted for each of the following six weeks. Flavor categorization constituted different product attribute levels, with each specific flavor (e.g., everything) representing the lower-level attribute the broader flavor categorization (i.e., sweet, savory) as the higher-level attribute. Replicating Study 1, an index of relative variety seeking on product attribute levels was computed. ANCOVA results, controlling for income (to examine unique effects of situationally-induced power), reveal that low-power participants, relative to high-power participants, seek more variety on low-level flavor attributes than the higher-level flavor categorization, as predicted ($F(1,174) = 3.79, p = .053$). Thus, Study 2 supports our thesis that variety-seeking occurs relatively more intensely at higher-level product attributes for high (vs. low) power consumers.

In sum, converging evidence from both actual and hypothetical product choices using both chronic and situationally-induced power states suggests that the relative intensity with which high and low-power consumers seek variety differs by product attribute level. As such, this research not only differentiates between relative and absolute variety-seeking intensity, but also identifies a novel dimension on which to examine consumer variety-seeking—product attribute level.

Does Variety-Seeking Vary by Time of Day?

EXTENDED ABSTRACT

Variety is the proverbial spice of life. From mundane choices, like what to eat, to important decision, like how to spend one's time, people often seek variation (Kahn 1995; McAlister and Pessemier 1982). But might this preference vary by time of day? Might grocery-shoppers pick less varied options, for example, if they go shopping in the morning rather than the evening?

We suggest this possibility based on research regarding chronobiology. Various internal biological processes naturally oscillate

over an approximately 24-hour period. The rhythms are endogenous (Aschoff et al. 1971), but are often adjusted, or synchronized, by external cues (e.g., light). Most relevant to the current research are diurnal variations in arousal. People tend to feel lower arousal or less alert in the morning (Kleitman 1987; Thayer 1978, 1989), and given that variety is stimulating (Berlyne 1960; Raju 1980), people may seek less variety in the morning.

Four studies support this hypothesis. Compared to other times of day, variety-seeking is lower in the morning: people pick items that are more similar to what they chose previously, and choose less-varied portfolios of options to consume at a later date. Further, the effects are moderated by factors that impact circadian rhythms (i.e., sunlight and individual differences in circadian preferences). On mornings when people feel more alert (i.e., earlier sunrise), they show greater variety-seeking, and people who feel more alert in the morning (i.e., morning types), prefer more variety than as well.

In Study 1, we analyzed the supermarket shopping behavior of over 1 million households across a 25-month period. We use scanner panel data from a single California location of a major grocery chain. Each purchase includes time of day and a unique household identifier for consumers using a loyalty card. This allows us to track the same household over time and isolate the time-of-day effect using within-household-category variation. We analyze the variety purchased within each category for a given shopping trip, i.e., the ratio of unique products purchased within that category to the number of total products purchased within the category. For example, someone buying two yogurts might purchase two of the same flavor (i.e., less variety) or two different flavors (i.e., more variety).

Results indicate that people choose less variety in the morning than the rest of the day ($p < .0001$). Extensive control variables rule out potential alternative explanations, such as shopping basket composition or variation across households.

We also test the underlying process by examining whether the effect of time of day is moderated by sunlight. Light itself can be stimulating and boost arousal (Cajochen 2007) light is intuitively linked with an alert or wakeful state. Compared to the effects of light on human circadian rhythms, little attention has been paid to its acute alerting action. Here I summarize studies from the past two decades, which have defined and quantified the dose (illuminance levels, so if stimulation plays a role in these effects, as we suggest, then variety-seeking should vary with seasonal changes in day length. We collected sunrise time for the 761 days in the dataset, and estimate an alternative regression where we interact within-day time trends with sunrise times. Diurnal variation in variety-seeking is moderated by sunlight ($p < .05$). Morning variety-seeking is higher on days when the sun comes up earlier.

Study 2 looked at meal consumption. We measured what a panel of participants ($N = 135$) ate every day for breakfast, lunch, and dinner over a multiday period. Then, for each meal, independent coders ($\alpha = .87$) rated how much variety existed among that meal across days. Considering dinners, for example, someone who ate the same thing every meal across days (e.g., all pasta and vegetables) would receive a lower variety score than someone who ate completely different things each dinner.

As predicted, people ate less variety for breakfast ($M_{\text{breakfast}} = 2.54$) than lunch ($M_{\text{lunch}} = 3.40, p < .0001$) and than dinner ($M_{\text{dinner}} = 3.79, p < .0001$). Ancillary analyses cast doubt on a host of alternative explanations. While one could argue that people eat more variety for lunch and dinner because they eat out (rather than at home), eat with others (rather than alone) or eat food others make (rather than prepare themselves), results hold controlling when for all these factors, casting doubt on these alternatives.

To test diurnal variation in variety-seeking more broadly, Study 3 examines a non-food context. Participants ($N = 783$) were shown a list of activities (e.g., watch a movie) and asked to pick a total of six they would like to do over the coming week (adapted from Etkin 2016). They could pick six different activities, or the same activities multiple times so long as they selected six total activities. Variety preference was measured as the number of unique activities they selected. To examine whether variety preferences varied over the course of the day, we surveyed 80 people each hour from 5am to 11pm.

As predicted, variety preferences were positively correlated with time of day ($r = .07$, $p < .05$); people chose less variety in the morning than they did later in the day.

Study 4 examined the moderating role of individual differences in circadian preferences. People vary in sleep/wake and alertness patterns. Morning types go to bed and wake up earlier, and feel more alert and energized in the morning (Natale and Cicogna 1996; Wilson 1990). If less variety-seeking in the morning is driven by stimulation, as we suggest, morning types might seek greater variety in the morning compared to other individuals. Participants completed the morningness scale (Smith, Reilly, and Midkiff 1989) and filled out the variety measure from Study 2, either in the morning, mid-day, or evening.

Consistent with the hypothesized underlying role of circadian rhythms, individual differences in circadian preference moderated the results. In the morning, variety-seeking was correlated with morningness ($b = .016$, $p < .05$), but not in the mid-day or evening (all p 's $> .2$).

Taken together, these four studies use diverse methodologies and contexts to support the notion that variety-seeking varies throughout the day. These results provide insight into drivers of variety-seeking and the biological basis of decision making more broadly.

SESSION OVERVIEW

Daily life is filled with tons of information, only some of which can be processed at a given time (Kahneman 1973). Given limited consumer attention and sensitivity to context, how this attention is directed is critical. Retailers, advertisers, and other marketers can make various benefits or costs of products salient and sway consumer opinion.

But, why and how does making some information salient affect how consumers evaluate products? There are many different possible pieces of information to make more or less salient, whether it's the restrictions to a deal, product attributes, or numbers on a product page or advertisement. With recent advances demonstrating how saliency may influence consumer product evaluations (Milosavljevic et al. 2012; Towal, Mormann, and Koch 2013), there are still many open questions about the nature of this relationship and whether it applies to a multitude of contexts. For example, does the numeric information formatting affect saliency and product valuation? Does the saliency of time versus money influence intertemporal tradeoffs? Can saliency effects occur even when consumers are not overwhelmed with information? Does the effect of saliency persist over several weeks, or is it short-lived? Can emphasizing certain elements of a deal affect consumer perceptions of that deal and purchase?

This session deals with these and other questions across laboratory, eye-tracking, and field experiments to develop the understanding of how saliency shapes consumer behavior. **Romero, Craig, Kumar, and Mormann** study how number format (symbolic versus verbal) affects product evaluations. Using eye-tracking they demonstrate how negative temporal attributes representation affects attention and evaluation: people fixate quicker on symbolic numbers, which depress product valuations. **Weingarten and Hutchinson** examine how saliency biases occur even when all information is accessible and relevant. They find product valuations can be biased by both cognitive saliency (i.e., greater elaboration on some attributes) and perceptual saliency (e.g., position effects), but that cognitive saliency effects may decline as people make more decisions. **Raghuram, Inman, and Wakefield** investigate, in lab and field studies, how making "reward" versus "restriction" (i.e., strings attached) aspects

of a deal salient for promotions affects deal evaluations and purchase behavior. They find that framing a deal as a restriction and then a reward bolsters deal positivity. Finally, **Xu and Urminsky** demonstrate how consumer patience changes based on whether calling attention to time or money in eliciting intertemporal preferences. They find more impatience when consumers pick how long to wait for a large reward than when determining the money they would forego for a sooner payout.

Taken together, we will discuss how saliency shapes consumer behavior in different choice contexts including time-money and price-quality tradeoffs, product valuations, and product choice. Overall, we examine how saliency affects product valuations and choice through several different instantiations of saliency, which have direct applications even to advertising and retailing.

Given the importance of these effects to the theory and practice of consumer behavior, this session should appeal to multiple audiences with attention and perception, retailing, intertemporal choice, differences in money and time, advertising, and heuristics and biases.

The Influence of Number Format on Consumer Attention

EXTENDED ABSTRACT

As a consumer, would you evaluate the cost of purchasing a gym membership any differently if its price was expressed as "50 dollars a month" rather than "Fifty dollars a month"? This research proposes that consumers process symbolic representations of numbers (e.g., 5) differently than word representations (e.g., five), which ultimately leads to changes in quantity estimations and product evaluations. While previous work on numerical cognition has looked at changes in unit presentation (e.g., 3 weeks vs. 21 days) or precision (e.g., 115 vs. 120), the present research uniquely studies whether the visual notation of quantitative information can influence consumer judgment even when keeping magnitude and unit constant.

Arabic symbols have long been associated with precision and accuracy (Windschitl and Wells 1996). Moreover, due to their ideographic notation (Besner and Coltheart 1979), Arabic numbers (when compared to verbal numbers) possess shape features that make them more visually salient (Treisman and Gormican 1988; Wolfe and Horowitz 2004). Centered on these cognitive and perceptual characteristics, we propose that symbolic numbers (vs. verbal numbers) increase attention to quantitative information presented.

Attention eliminates distractions from the stimulus, allowing consumers to process information more efficiently (Posner and Rothbart 2005). Attention has also been known to bias magnitude perception upward. For example, a package that attracts more attention is associated to higher volume (Folkes and Matta 2004). Because number magnitude is a judgment of relative "size" (Dehaene 1992; Coulter and Coulter 2005) and given that Arabic numbers should increase attention to quantitative information, we expect that they should also lead to higher magnitude perceptions. Furthermore, we propose that the direction in which Arabic numbers will affect product evaluation depends on whether higher magnitudes of the advertised attribute is a positive addition to the product.

Our initial objective is to demonstrate that number notation can influence attention to quantitative information. Thus, in our first study, we manipulated number notation as well as the amount of product information presented in each product package. Based on

the principles of attention, we expect that when the amount of product information presented is large, there will be more competition for attention among product elements. Hence, symbolic numbers should lead to greater attention to quantitative information when the display is visually complex. However, when the amount of information presented is small, consumers will be able to attend equally to quantitative information regardless of the number format, and hence, our effects will be attenuated.

We created seventeen different stimuli for consumer products that highlighted a quantitative benefit. For nine out of seventeen products, we included a large amount of information in the package design. A pretest confirmed that consumers correctly identified the amount of information manipulation.

Our main study used eye-tracking technology to provide evidence for an attention-based mechanism. Sixteen students (43.8% female, average age = 23.25) from a large US University participated in a mixed factor design. Number format (symbolic vs. verbal) was manipulated between-subjects and amount of information was measured within-subjects. Participants evaluated three products as a part of a practice trial. Subsequently, they evaluated 17 different products (e.g., a cheese cracker, a light bulb, a car, etc.). Across conditions, the products only differed on the numerical notation (e.g., the cracker cheese content as “4 cheese” versus “Four cheese”). Once participants viewed the image, they pressed the spacebar to continue. In the session, we continuously recorded the participant’s eye movements using Tobii eye-tracking apparatus.

We separated the results by amount of information presented in the package (small vs. large). We ran a repeated-measure Analysis of Variance (ANOVA) with number format (symbolic vs. verbal) as a between-subjects factor. The time to first fixation for each product category created (small vs. large information) was the within-subjects factor. The results confirmed a significant main effect of amount of information ($F(1,14) = 68.10, p < .001$) and a marginally significant number format \times amount of information interaction ($F(1,14) = 3.37, p = .09$). In line with our attention-based hypothesis, it took less time for consumers to fixate on the symbolic (vs. verbal) number when the products presented a large amount of information ($M_{\text{symbol}} = 5.04, M_{\text{verbal}} = 7.06; F(1,14) = 4.38, p = .05$), however, this effect was attenuated when the products contained small amount of information ($M_{\text{symbol}} = 1.86, M_{\text{verbal}} = 2.10; F(1,14) = .31, p = .58$).

In Study 2, we explored the influence of number notation on product evaluations. Seventy-three MTurk panelists (39.7% female, average age = 32.7) participated in a single-factor between-subjects design (number notation: symbol vs. verbal). We created an advertisement for a new refrigeration product, VTex, that can chill any food item in 45 (vs. forty-five) seconds. Because the main purpose of this product is to chill food items quickly, higher magnitudes should be associated with lower product evaluations. Participants looked over the ad. Subsequently, they provided their attitudes toward brand VTex ($\alpha = .94$) and indicated how likely they would be to purchase the product if available locally ($\alpha = .96$). As expected participants evaluated VTex more negatively when the temporal attribute was presented in symbolic rather than verbal format ($M_{\text{symbol}} = 5.13, M_{\text{verbal}} = 5.83; F(1, 71) = 6.12, p < .05; \eta^2_{\text{partial}} = .08$). Similarly, participants were less willing to purchase the product when the temporal attribute was presented in symbols rather than words ($M_{\text{symbol}} = 4.38, M_{\text{verbal}} = 5.22; F(1, 71) = 4.23, p < .05; \eta^2_{\text{partial}} = .05$). The results of this study suggest that number notation influences downstream evaluations depending on the valence of the information.

Can the mere notation of a number shape magnitude judgments and product perceptions? We propose that due to cognitive (i.e., precision) and perceptual (i.e., salience) differences between symbolic

and verbal numbers, consumers direct more attention to quantitative information, which in turn, affects downstream evaluations. Given the essential role numbers play in forming consumer judgments, the findings of this research have important managerial implications. This research proposes and provides evidence that managers should use these different representations selectively depending upon the message they would like to emphasize.

Perceptual and Cognitive Salience and their Effects on Product Valuations

EXTENDED ABSTRACT

How do consumers evaluate products? Myriad papers and models have suggested how consumers tend to integrate information about products they view (e.g., Anderson 1971; Bettman et al. 1998). Yet, there are common instantiations of consumers employing more salient but irrelevant information while neglecting less salient but relevant information (e.g., Carpenter, Glazer, and Nakamoto; Klayman and Ha 1987). In some such cases, salience may even affect the valuation of given information (Hutchinson and Alba 1991; Towal, Mormann, and Koch 2013).

We propose a model of interactions among salience and valuation in consumer decision-making. This model expands upon the accessibility-diagnostics framework from Feldman and Lynch (1988). In their memory-based model, accessibility is the readiness (based on recency or frequency) to apply informational inputs (Higgins 1989). Inputs that are accessible are then judged for their diagnosticity (here, valuation), and inputs that are inaccessible do not enter the decision process. Accessibility, which is a memory-based analog of salience, is thus treated categorically: either information is accessible or it is not. In this paper we show salience is not merely categorical and exists a graded effect when all information is accessible and relevant.

The present model also contributes to the literature by distinguishing between two unique sources of salience: perceptual salience (based on location or noticeability in the immediate environment) and cognitive salience (based on elaboration in working memory). Further, we examine the temporal dynamics of salience biases over repeated judgments. If the bias declines over time, then the explanation of the bias may be one of familiarity, whereas if the bias increases over time, the bias may be explained through polarization.

We use a rating-based conjoint paradigm in three studies and multiple product categories to demonstrate the influence and temporal dynamics of the salience bias. We present participants with one of three product categories (cars, cell phone plans, Disney vacation packages), each of which had four attribute identities with two levels each. For example, for cars these attributes were MPG (28, 33), sound system (Basic, Advanced), warranty (1 year, 4 years), and safety level (3.5 Stars, 4.5 Stars). Participants were asked to make willingness-to-pay (WTP) judgments for sixteen combinations of these attributes in two phases: a learning phase in which they made two judgments per page, and a test phase in which they made one judgment per page. All participants saw the same products in the learning phase and test phase, but we manipulated the order of products in the learning phase between-subjects. We used the WTP judgments in each phase to calculate each attribute’s part-worth valuation in each phase separately (Green et al. 2001).

In this setup, we manipulate perceptual salience (salience determined by immediate environmental position) based on the position of an attribute in a list: attributes in more extreme positions should be more salient than those in the middle (Dayan and Bar-Hillel 2011; Mantonakis et al. 2009). We control for attribute identity by position

by using four orders of attribute presentation from a 4x4 Latin square such that all attribute identities, across participants, appear in each position (Rosenthal and Rosnow 2008).

We manipulate cognitive salience (likelihood of elaborating on information) by changing the order of presentation of product versions in the learning phase: in the Biased condition, subjects only saw one attribute vary on a page for four pages in the learning phase: this was the fourth (bottom) attribute. In the Control condition, three attributes differed on each page of the learning phase. We predict attributes made more cognitively salient (by being the only attribute to vary on each page) in the learning phase in the Biased condition, here the bottom attribute (attribute four), will receive higher valuations than in the Control condition in the test phase that was common to all participants.

In Study 1, participants used a slider scale to indicate WTP, and were randomly assigned to see one of three goods (cars, cell phone plans, Disney vacation packages). Consistent with perceptual salience, we found attributes in extreme positions (one and four) to have higher valuations than those in middle positions (two and three); $F(1, 750) = 59.95, p < .001$. Consistent with cognitive salience, we found the attribute to be made more salient in the learning phase (attribute four) was valued higher than other attributes in the Biased condition versus the Control condition ($F(1, 750) = 24.48, p < .001$).

Study 2 replicates Study 1 but with three changes. First, participants made sixteen additional judgments in two test phases that followed the first test phase, and they consisted of one judgment per page for 16 pages. These additional two test phases were meant to examine whether the salience bias observed in Study 1's test phase would persist for additional, repeated judgments. Second, we also created another learning phase with different product versions for some participants to ensure the result generalized past the learning phase design from Study 1. Finally, participants indicated their WTP on slider scales.

Study 2 again found evidence of perceptual salience and cognitive salience ($F(1, 807) = 18.44, p < .001$), but these effects declined by test phase III (interaction of cognitive salience and phase: $F(3, 807) = 12.99, p < .001$). Therefore, although salience may bias valuation, its impact may be self-correcting.

Study 3 replicated Study 2, but this time it manipulated the cognitive salience of the third attribute for robustness. Study 3 also added another Control condition with another design matrix in the learning phase to ensure robustness. Again we found evidence of perceptual salience and cognitive salience ($F(2, 606) = 7.45, p < .01$), but an interaction of phase and salience such that the impact of salience declined by the end of test phase III ($F(6, 606) = 5.17, p < .001$).

We make three contributions over three studies for how salience influences valuation: we demonstrate salience may exert a graded (non-categorical) bias on valuation, salience biases may be perceptual or cognitive in nature, and that over repeated decisions, this bias may decline.

Promotion Emotion: The Salience of Restrictions vs. Rewards in Framing a Deal

EXTENDED ABSTRACT

Sales promotions affect sales through economic, informational, and affective components (e.g., Raghurir, Inman, and Grande 2004). While offering incentives to purchase, sales promotions often require a cost to the customer in the form of a restriction, such as time expirations, off-peak times, limited quantities, or purchase preconditions (Inman, Peter, and Raghurir 1997). How do consumers weigh the benefits

against the costs associated with such restrictions? Can a reward offer be made to appear even more rewarding? Can an offer restriction be made to appear less restrictive?

Chandon, Wansink, and Laurent (2000) suggest sales promotions have a hedonic benefit (e.g., entertainment) over and above utilitarian benefit (e.g., savings, quality). Some derive satisfaction from being the "smart shopper" who takes advantage of "good" deals to signal positive traits to self and others (Schindler 1992). Being the "smart shopper" also affects the manner in which deals are evaluated (Shimp and Kavas 1984). Promotions often include explicit purchase limits (e.g., two per customer) or precondition restrictions (e.g., minimum purchase). Wansink, Kent, and Hoch (1998) report the value of a purchase limit on a sales promotion increased the average purchase quantity – suggesting people use the limit amount as an anchor to decide how much to purchase. Preconditions requiring complementary purchases or imposing time limits may serve to accentuate deal value and act as "promoters" of promotions (Inman et al. 1997) by heuristically signalling value to a customer. In their review of sales promotion research, Grewal et al. (2011) recognize the importance of framing or design of deals, suggesting future research should examine the relative effectiveness of multiple ways of communicating restrictions, such as buy-one-get-one-free and other deal limitations.

Across two field studies and a series of experiments, we examine the effect of varying the salience of a "reward" versus a "restriction" in framing a deal. We propose and show the counterintuitive effect that presenting the restriction first, followed by the reward (rather than leading with the reward, followed by the restriction) makes the restriction salient and leads to viewing the entire offer as more of a reward than a restriction and a more positive response. We examine these effects across restrictions for specific times/seats in a sports mobile marketing context (Study 1a, 1b, 2a, 3), offer available to the first few customers (Study 2b, Study 3), purchase preconditions (Studies 4 and 5), and limited time discount offers (Study 6). We find promotions that are ex ante perceived to be more restrictive than rewards (e.g., specific seats/ times) can be made to appear less restrictive and those perceived to be more of a reward than a restriction (e.g., available for the first few fans) can be made to appear as more of a reward.

Our field studies demonstrate the behavioral response to restriction-first promotions, while our experiments test the process. For example, Study 1b reports the results of a field study conducted in cooperation with Major League Baseball. An email offer was delivered prior to the last series of home games in the season to a sample of 21,883 individuals who previously purchased single game tickets from the team. The standard ticket discount offers contain restrictions regarding the seats ("Get a discounted price on seats in these select areas") and dates. In this case, the seats were restricted to selected areas in the stadium and available for only two selected games (Thursday and Sunday) in a four-game span. We adapted the standard offer to provide a reward message frame, but otherwise presented an identical deal. The regular message copy employed the email subject line of, "A special ticket offer for valued TEAM fans" while the email subject line for the reward frame message was, "A special reward for valued TEAM fans." The regular frame offer had a slightly higher open rate compared to the reward frame (38.8% compared to 36.2%). However, among those opening the regular frame email ($n = 4,234$), only 16.6% clicked-through to the ticket purchase page to consider the offer. In comparison, 23.6% of those who opened the reward frame email continued on to the ticket purchase page. Thus, the reward frame was significantly ($p < .001$) more likely to motivate click-through to purchase. This led to an increase in revenue from the reward frame compared to the regular frame (\$2,744 vs. \$1,646).

Study 5 is an experiment in which 161 business school undergraduates participated in a 2 (frame: reward vs. restriction) \times 3 (25% off, 50% off, or one free) between-subjects design. Subjects were asked to assume they needed to replenish household coffee supplies and needed at least three boxes (12 cups; Keurig) or three bags (beans or ground coffee). They were told that while searching online, an ad directed them to the Distant Lands Coffee website, where they were asked to read a company description. Directed to a website with assorted coffees, participants were instructed to select three they would like. On average, subjects spent two minutes and five seconds reviewing the webpage. Participants in a reward-first condition were exposed to an offer such as "Get 50% off one Distant Lands Coffee Blend when you buy two at the regular price," while the order was reversed for participants in the restriction-first condition. Our analysis reveals that deal evaluation was higher for the restriction-first frame (4.87) than the reward-first frame (4.56, $p < .05$, one-tailed) and that the effect is mediated by deal enjoyment. The results suggest a restriction-first frame leads to more favorable deal evaluations than a reward-first frame and is judged to be a more enjoyable promotion.

In sum, our research examines the role of varying the salience of rewards versus restrictions on deal perceptions and deal response. Given that deals often offer a reward with some strings attached (restrictions), we examine the effect of explicitly making the reward or restriction differentially salient in the offer as well as implicitly manipulating salience in the offer through manipulating the presentation order of the discount and the restriction. Implications for research and practice will be discussed.

How Tradeoff Framing Impacts Attribute Focus and Shifts Choices

EXTENDED ABSTRACT

People's choices in tradeoffs depend on which attribute is salient as compensating for the other. In measuring tradeoffs, researchers often present a series of choices between a fixed option and an option varying in only one attribute, to identify the indifference point where the consumers' preference switches. For example, the indifference point in a size-price tradeoff could be elicited by fixing volume and varying price or by fixing price and varying volume (e.g. asking consumers to choose between a \$14, 20-oz bottle and a 25-oz bottle with a price of \$15, \$18, \$21 etc., or between a \$14, 20-oz bottle and an \$18 bottle with a volume of 21-oz, 25-oz, 29-oz, etc.) Normatively, the framing implied by the elicitation method should not influence how consumers trade one attribute for another. However, we predict that consumers focus more attention on the attribute that varies across the choices. In the example above, the amount they are willing to pay for the larger bottle is more salient in the first version and the amount of extra volume they would need to justify the higher price is more salient in the second version. As a result, we propose that this difference in framing will shift consumers' indifference point, and more generally affect their valuation and choices.

In studies 1 – 3, we tested this proposition in the context of intertemporal choice, which is most often measured using discount rates from a monetary titration task (Urminsky & Zauberman 2016). We propose that this approach may make the monetary (vs. temporal) aspect of the tradeoff more salient, potentially highlighting the attractiveness of the LL. In contrast, we predict that fixing the monetary amounts and varying the time delays across pairs of options in a titration task (i.e., time titration) may shift consumers' attention to the temporal aspect.

Study 1 (N = 459) tested whether the discount factor measured would be different in a money-titration versus in a time-titration task

and used a 2 (SS: immediate vs. delayed) \times 2 (elicitation type: money titration vs. time titration) between-subjects design. Participants were asked to finish one titration task. Results showed a significant effect of elicitation type on both discount factor ($F(1, 455) = 33.09, p < .01$) and self-reported relative attribute weight ($F(1, 455) = 13.48, p < .01$). The discount factor was lower (e.g., greater impatience was observed) in the time-titration cells than in the money-titration cells (.9918 vs. .9943), and participants in the time-titration (vs. money-titration) cells thought the time delay (vs. money amounts) mattered more (3.65 vs. 3.01). Importantly, attribute weight partially mediated the effect of elicitation type on discount factor.

Study 2 (N = 418) tested the effect of attribute salience on discount factor by having participants directly indicate their indifference point. Participants in one condition indicated the amount of money (X) in 8 weeks that would make them indifferent between that and receiving \$50 now, and after a filler task, indicated the number of weeks of delay that would make them indifferent between receiving \$50 now and receiving \$X after that delay. Participants in the other condition, first estimated a delay, and then an amount of money based on that delay. The effect of task type and order on discount factor were significant ($F(1, 414) = 19.49, p < .01$; $F(1, 414) = 46.56, p < .01$, respectively). Discount factors were lower (people were more patient) when participants indicated time (vs. money) (.8796 vs. .8953), and when participants indicated time first and money later (vs. the reverse) (.8554 vs. .9229).

Study 3 (N = 186) tested the spillover effect of making time or money more salient via the elicitation method on a subsequent intertemporal choice, using a 2 (elicitation type: indicating money vs. indicating time) \times 2 (role: creditor vs. debtor) between-subjects design. Participants first indicated their indifference point and then made a choice between two fixed options. For example, in the indicating-time-creditor condition, participants indicated N so that receiving \$65 today and receiving \$N in 6 weeks were indifferent, and then made a fixed choice between receiving \$65 today and receiving \$90 in 6 weeks. The effect of elicitation type on discount factor was significant ($F(1, 182) = 51.54, p < .01$). Pairwise comparison results showed a lower discount factor (greater impatience) when indicating time (vs. money), for both creditors (.8673 vs. .9473) and for debtors (.9329 vs. .9789). Meanwhile, consistent with our proposition, a higher proportion of creditors chose to wait to receive \$90 in 6 weeks after indicating money than indicating time (73.3% vs. 31.8%), while a higher proportion of debtors chose to pay \$65 today after indicating money than indicating time (92.0% vs. 80.9%).

Study 4 (N = 114) extended the attribute salience effect in time-money tradeoffs to a price-quality tradeoff in a travel package choice. We used a 2-condition (elicitation type: indicating cost vs. indicating rating) between-subjects design. For example, participants in the indicating-cost condition reported the cost that would make them indifferent between an 84%-quality-rating package for 3,780 yuan and a 93%-quality-rating package for the specified cost, and then made a choice between an 84%-rating/3,780-yuan-cost package and a 93%-rating/5,130-yuan-cost package. We found a significant effect of elicitation type on the price-quality indifference ratio ($F(1, 112) = 69.86, p < .01$). Moreover, a higher proportion of participants in the indicating-cost (vs. indicating-rating) condition chose the low-cost-low-rating package (87.7% vs. 59.6%). We also did another study to test this effect in a desirability-feasibility tradeoff and found similar results.

In summary, this research shows that different decision modes can influence discount factors and intertemporal choice, and provides initial evidence that decision mode may influence how consumers trade one product attribute for another.

Paper #4: Consumers and Managers Reject (Superior) Algorithms Because They Fail to Compare Them to the (Inferior) Alternative

Berkeley J. Dietvorst, University of Chicago, USA

SESSION OVERVIEW

Product reviews and recommendations have become a ubiquitous facet of the consumer landscape. For this reason, it is important to understand how and when consumers use online reviews and recommendations. Specifically, the research in this session strives to understand the general features of online reviews (Paper 1), how the characteristics of online reviews, such as their variance, can affect consumer preferences (Paper 2), how consumers differentially use online reviews for experiential and material goods (Paper 3), and how consumers choose between user-generated recommendations and algorithmic recommendation systems (Paper 4).

In Paper 1, Schoenmueller et al. investigate the underlying causes of the positive skew (J-shaped distribution) found in many online reviews. The authors analyze over 130 million reviews to show that the most prevalent distribution of reviews is indeed J-shaped (heavily skewed towards the high end of the review scale). While there is some platform dependency in the shape of the review distributions, the authors show that the main driver is one of self-selection. Specifically, consumers are more likely to post reviews for products that they have evaluated extremely. This self-selection may lead to loss of information and bias in consumers’ reliance on average review ratings as a source of information.

While Paper 1 evaluates the underlying causes of review distributions, Paper 2 investigates how a key feature of review distributions—variance—affects consumer choice. Specifically, Webb and Simonson show that the variance in user-generated reviews, holding average rating constant, moderates various context effects. The authors find that when consumers evaluate products with high variance (versus low variance) in the reviews, they choose less variety, they show a reduced susceptibility to the compromise effect, and they are less likely to defer choice. The authors find that these effects occur because consumers find low variance reviews less useful, leading them to rely on relative value considerations or risk-reduction strategies instead.

In comparison to Paper 2, which focuses on a feature of reviews that moderates reliance on reviews (variance), Paper 3 identifies an-

other moderator—product type. Dai et al. find that consumers rely on reviews less when they are for experiential (vs. material) goods. The authors find this occurs because consumers believe their preferences are more unique for such product types and are thus not well-represented by the reviews of other customers. This underlying process—perceived preference uniqueness—acts as a moderator for the use of consumer reviews in decision-making.

Finally, in Paper 4, Dietvorst investigates why consumers and managers often prefer human generated recommendations and judgments over those generated by algorithms. Dietvorst finds that consumers and managers fail to use algorithms that outperform human judgment because they hold algorithms to a higher standard. Instead of choosing algorithms that beat the best alternative (human judgment), many people only choose algorithms that also meet their lofty goals for forecasting performance.

Together, the research in this session helps consumer researchers and marketers better understand the psychological processes underlying the use of online reviews and recommendations in consumer decision-making and judgment.

The Drivers and Downstream Consequences of the J-Shaped Distribution of Consumer Online Reviews

EXTENDED ABSTRACT

Consumer online reviews have become an integral part of consumers’ decision-making process. Based on a recent study, 90 percent of consumers read online reviews before visiting a store (Invespro 2015) and 88 percent of consumers trust online reviews as much as a personal recommendation (DeMers 2015). Consumer reviews have also been shown to have an economic impact (e.g., Chevalier and Mayzlin 2006; Liu 2006; Moe and Trusov 2012). Recently, several meta-analyses summarize the impact of the number (volume) as well as the average rating (valence) of reviews on products sales (Babić et al. 2016; Floyd et al. 2014; You, Gautham, and Joshi 2015).

One common finding in the study of online reviews has been that reviews are heavily skewed to the positive end of the rating scale, with a few reviews in the mid-range and some reviews at the negative end of the scale (Hu et al. 2009). This has been often referred to as the J-shaped distribution of online ratings (e.g., Dalvi, Kumar, and Pang 2015; Feng et al. 2012; Gao et al. 2015; Hu et al., 2009). This finding is surprising given that online reviews represent crowdsourcing of experiences of a large body of heterogeneous consumers, which based on the law of large numbers and previous findings should converge towards a normal distribution. The extreme positive skewness of reviews has fueled the debate on how informative consumer reviews actually are (Fritz 2016; Hickey 2015), and whether these consumer reviews mirror “true” product quality (De Langhe, Fernbach, and Lichtenstein 2015).

While several studies have demonstrated the existence of the skewness of rating distributions, the prevalence, the reasons behind, and the implications of the J-shaped distribution of online reviews has been given considerably less attention compared to the impact of overall rating statistics such as the volume and valence on product sales. Accordingly, the objective of this study is threefold. First, we test how prevalent and robust the J-shaped distribution of reviews is by collecting a large-scale data set across various online review and e-commerce platforms that span across a large number of products

and services. Second, we investigate what could be the main reasons for the J-shaped distribution of reviews and to what extent it reflects a bias or self-selection of consumers' preferences and opinions. We employ a multi-pronged approach, including: secondary data analysis, experiments, and surveys. Third, we investigate the information loss and the bias introduced by the J-shaped distribution in capturing consumer preferences and behavior.

Using a large-scale dataset of over 130 million online reviews from 18 different platforms such as Amazon, Yelp, and Expedia, involving more than 10 million products, reflecting different types of platforms (e.g., e-commerce sites, reviews sites, comparison sites) various product categories (e.g., books, beers, hotels, restaurants and services) and various formats of review scales, our analysis reveals that, while indeed the most dominant distribution of reviews across platforms and product categories is a J-shaped distribution, several platforms have consumer reviews and ratings that are not J-shaped distributed and the distribution of the ratings of the same product or service can differ across platforms.

Our results show that while some product selection by the platforms exists, the main driver behind the J-shaped distribution is a reviewer level self-selection mechanism. Using secondary datasets, survey data as well as data collected in several lab experiments, we find that consistent with consumers' tendency to report and spread WOM for extreme experiences (Anderson 1998), consumers are more likely to review products or services for which the experience or evaluation was extremely positive or extremely negative. We name this *polarity self-selection*. Specifically, we find that reviewers who are less selective in the products they chose to review exhibit less polarity in their reviews. Furthermore, consumers who were asked to review the last book they read or restaurant they visited, gave less extreme ratings than consumers who selected the product they wish to review. Furthermore, we disentangle the effect of polarity self-selection from purchasing self-selection.

Building on empirical evidence from our large-scale dataset of reviews that suggests that shorter scales may lead to scale truncation as a potential driver of the J-shaped distribution, we use several experiments to test the impact of rating scales on review distributions. Our experiments rule out that the J-shaped distribution is driven by factors related to the usage of different rating scales or wording across online platforms. We further find evidence that cognitive dissonance increases the positive skewness of consumer ratings. Finally, we demonstrate that review fraud possibly explains ratings at the negative extreme of the rating scale but not at the positive extreme of the J-shaped distribution.

We find that the J-shaped distribution of reviews, while somewhat decreasing over time, is fairly robust over the product and the reviewer lifecycle. In summary, our results show that the common J-shaped distribution of online reviews mainly emerges from two selection mechanisms and that reviewers' self-selection has an impact over and beyond platforms' product selection.

Finally, we find that polarity self-selection, causing the J-shape distribution, leads to an information loss. We show that for review distributions with a high intensity of self-selection, the average ratings metric commonly used in online review platforms and academic research is less related to the actual sales than the number of reviews. Additionally, we find that inconclusive results in previous research regarding the relationship between the average ratings and sales can be explained by polarity self-selection and the predominance of the J-shaped distribution.

Using Reviews to Determine Preferences: How Variance in Customer-Generated Reviews Affects Choice

EXTENDED ABSTRACT

User-generated product reviews have become an important input in consumer decision-making (Floyd et al. 2014; de Langhe, Fernbach, and Lichtenstein 2016; Simonson 2016). Consumers are now able to use product reviews to learn about products and gather information about their options. While past research has found preferences can be manipulated by context (e.g., the compromise effect, variety-seeking, and choice deferral) (Simonson 1989; 1990; Simonson and Tversky 1992; Kahn 1995; Dhar 1997) the question of how product review information affects these choice effects remains. Beyond the sheer content of reviews, their observed variance and the implied consensus (or lack thereof) among reviewers provides additional, potentially useful information about the drivers of product preferences and the expected consumer experience.

Thus, in this research we examine the impact of user-generated review variance or dispersion, and especially, the implications for consumer susceptibility to context effects. We show that product reviews with greater variance/dispersion attenuate variety-seeking, reduce choice shares for a compromise option, and decrease choice deferral rates relative to products associated with reviews with less variance/dispersion. Greater review variance indicates that evaluations are a matter of taste (Spiller and Belogolova 2016), thereby allowing the consumer to deviate from the safe norms (e.g., compromising or hedging). Paradoxically, this means that dispersed reviews are more useful and informative and encourage consumers to follow their own tastes based on the options' absolute values.

In Study 1 ($N = 279$), we tested the effect of review variance on variety seeking. Participants were assigned to one of two between-subjects conditions (High vs. Low review variance). Participants in both conditions were told to imagine they were grocery shopping through an online grocer and were asked to choose options across several product categories (yogurt, ice cream, soup, and snacks) for three weeks of consumption. Participants viewed six options in each category. They were informed that each product had reviews from customers who had purchased the product in the particular store. Participants in the High condition viewed options that had high variance/widely distributed product reviews (reviews that were dispersed across the entire rating scale); participants in the Low condition viewed options that had low variance/narrowly distributed product reviews (reviews that were clustered at the high-end of the rating scale). All products in both conditions and across categories had the same average rating (4/5 stars), and only the variance differed across options. We found that for all product categories, participants who chose among options with high variance reviews chose significantly less variety than participants who chose from options with low variance reviews ($p < 0.04$). We also found that across conditions, participants believed they would feel significantly happier ($p = 0.03$) and marginally significantly more personal responsibility ($p < 0.10$) for a positive outcome with a product associated with higher variance reviews. This finding is consistent with the notion that higher review variability allows consumers to feel that they "own" the choice based on their personal tastes.

In Study 2 ($N = 393$), we investigated whether review variance moderates the compromise effect. In this study, we used a standard compromise effect (two set) test with participants assigned to either a 2-option or 3-option choice set; we compared the relative shares for the middle option between the two sets. Participants made choices in two product categories: TVs and restaurants. The design was a 2 (Variance: High, Low) x 2 (2-option, 3-option), such that partici-

pants saw high variance reviews for one product and low variance reviews for the other (and 2-options for one and 3-options for the other). Again, the reviews all had the same average rating (4/5 stars), but the variance differed across products and was either high or low (depending on condition assignment). We found that choice shares for the compromise (middle) option were significantly higher when participants chose from products with low variance reviews ($p < 0.001$ for TVs; $p = 0.03$ for restaurants). Thus, consumers are less likely to choose a compromise option when they are choosing among products with high variance reviews relative to products with low variance reviews.

In Study 3 ($N = 425$), we evaluated how ratings variance affected choice deferral. Participants were assigned to one of two between-subjects conditions: High variance or Low variance. Using a standard choice deferral set-up, participants were shown two product options from a randomly assigned product category (Microwave or Coffee Maker). Participants in the High (Low) condition, chose between two options with high (low) variance customer reviews. Participants also had the option not to choose (defer). We found that deferral rates were marginally significantly lower across both product types when participants were in the High condition relative to the Low condition ($p = 0.08$). This suggests that consumers are less likely to defer choice when they are choosing across products with high variance customer reviews than when they are choosing across products with low variance customer reviews.

In Study 3 we further assessed the mechanism underlying the effect of review variance on choice. Specifically, we found that participants choosing from products with high variance reviews found the reviews significantly more useful, trustworthy, and relied on them to a greater extent than participants choosing from products with low variance reviews ($p = 0.01$). These results suggest that consumers find reviews with lower variance less informative and helpful, and thus employ relative valuation strategies (e.g., compromise effect) that minimize risk (e.g., by choosing greater variety and deferring choice).

Overall, our empirical results suggest that customer review variance can act as an important moderator of various choice effects. Further, review variance also moderates how much consumers use and rely on product reviews (with higher variance reviews being rated as more useful and trustworthy). Additional studies are currently being designed to gain further insights regarding the process underlying the impact of reviews' dispersion. This research thus contributes to our understanding of the psychological processes underlying the use of online reviews and suggests that attributes of the reviews themselves (e.g., variance) can affect how and to what extent reviews are used in consumer judgment and decision-making.

**“Don’t Tell Me What to Do!”
Shoppers Rely Less on Consumer Reviews for
Experiential than Material Purchases**

EXTENDED ABSTRACT

Consumer reviews are a pervasive form of word-of-mouth communication. We examine whether and why the type of purchase—experiential or material—affects shoppers' reliance on consumer reviews. An archival field study and six experiments reveal that shoppers rely on reviews less when making experiential (vs. material) purchases because they believe their own evaluations (preferences, tastes, and quality judgments) are more unique from other consumers' evaluations for experiential purchases.

Study 1 analyzed 6,508,574 Amazon.com consumer reviews written over 5 years and found that shoppers are less likely to as-

sign a “helpful vote” to reviews for experiential purchases than for material purchases ($p < .001$). In Studies 2A-2B, participants contemplating a future experiential (vs. material) purchase (Study 2A; $N = 168$) or focusing on the experiential (vs. material) aspects of the same purchase (Study 2B; $N = 203$) reported they would rely less on consumer reviews (both p 's $\leq .02$).

Study 3 tested the influence of positive and negative consumer reviews among participants ($N = 215$) deciding between either two cooking classes (experiential) or two coffee makers (material) for a prize in a real lottery. Participants were less likely to choose the positively-reviewed option in the experiential (vs. material) condition ($p = .02$), suggesting participants relied less on reviews when deciding on the experience.

In Study 4, participants relied less on consumer reviews for a Broadway ticket (experiential) than for speakers (material; $p < .05$), but there was no difference for company-provided information ($p = .16$), indicating the effect is specific to consumer-generated information.

In Study 5, participants ($N = 404$) asked to choose between reading consumer reviews or company-provided information were less likely to choose consumer reviews for a concert (experiential) than for a digital camera (material; $p < .001$). This was mediated by shoppers' beliefs that their evaluations would be more unique from other consumers' evaluations for the experiential purchase.

In Study 6, participants ($N = 469$) were presented with chips (experiential) or a flashlight (material), and they either tried or saw a picture of the product. All participants then rated the actual or perceived similarity of a randomly-selected review. Reliance on reviews was again lower for experiential (vs. material) purchases and mediated by perceived preference uniqueness; further, people overestimated how unique their evaluations were for experiential purchases.

Furthermore, in Studies 1, 5, and 6, our additional analyses suggest that people's lesser reliance on consumer reviews for experiential purchases cannot be simply explained by the belief that evaluations of experiences are more diverse across all consumers.

In sum, shoppers are skeptical about the similarity of others' evaluations of experiential purchases to their own, and thus rely less on consumer reviews for experiential (vs. material) purchases. This highlights that these purchases differ not only in their post-consumption enjoyment, but also in their pre-decision processes. Our findings also inform the field's understanding of the types of purchases influenced by word-of-mouth and contribute to an emerging literature that examines the psychological processes underlying the perceived usefulness of consumer reviews. We identify the role of perceived preference uniqueness—a novel mechanism that captures the extent to which people view their own purchase evaluations as unique from others'. Extending prior research showing that consumers are more receptive to the opinions of seemingly similar others based on shared demographic characteristics, our investigation suggests that people are apt to hone in on the similarity between theirs and other consumers' preferences, and that there are particular purchase domains in which consumers are motivated to perceive their preferences as unique, thus relying less on other consumers' reviews.

**Consumers and Managers Reject (Superior) Algorithms
Because They Fail to Compare Them to the (Inferior)
Alternative**

EXTENDED ABSTRACT

Now more than ever, consumers and managers have the opportunity to use algorithms to make important predictions and decisions under uncertainty. For example, consumers can use recommendation

systems to decide which products to buy, use matchmaking algorithms to decide whom to date, and use algorithms to forecast the future prices of airline tickets. Professionals can use algorithms to forecast demand for products, decide which job applicants to hire, and choose which investments to make. Algorithms already outperform humans in the majority of the forecasting domains that have been tested (see Ægisdóttir et al., 2006; Camerer, 1981; Dawes, Faust, & Meehl, 1989; Grove et al., 2000; Kaufmann, Reips, & Wittmann, 2013; Kaufmann & Wittmann, 2016; Kuncel, Klieger, Connelly, & Ones, 2013; Meehl, 1954), and algorithms will become more accurate and abundant as we collect more data and develop new methods of leveraging those data. However, these algorithms cannot help consumers and managers make better predictions if they are unwilling to use them.

People are often hesitant to use forecasts from algorithms, even when they are the best alternative available. Professionals often underuse algorithms when making predictions (e.g. Fildes & Goodwin, 2007; Sanders & Manrodt, 2003; Vrieze & Grove, 2009). Similarly, laypeople often prefer using forecasts from humans to forecasts from algorithms (Arkes et al., 2010; Diab, Pui, Yankelovich, & Highhouse, 2011; Eastwood, Snook, & Luther, 2012; Önkál et al., 2009; Promberger & Baron, 2006). However, it is still unclear what decision process leads people to use (inferior) human forecasts instead of (superior) algorithmic forecasts.

I propose that people choose between forecasting methods by (1) using their status quo forecasting method by default and (2) deciding whether or not to use the alternative forecasting method by comparing its expected performance to their performance goal. This process leads people to reject a superior algorithm when (1) the algorithm serves as their alternative forecasting method and (2) the algorithm performs better than their default forecasting method but fails to meet their performance goal. In other words, people often use human judgment by default and when deciding whether or not to switch to an algorithm they ask, “will the algorithm meet my performance goal?” instead of asking “will the algorithm outperform my default forecasting method?”. Given that algorithms only perform 10% - 13% better than human judgment on average in many forecasting domains (see Ægisdóttir et al., 2006; Grove et al., 2000) and that people often have unrealistically high expectations about forecasting performance (see Dietvorst, Simmons, and Massey, 2015), it is frequently the case that algorithms outperform human judgement but fail to reach people’s lofty performance goals.

I report the results of five studies that are consistent with the notion that people decide whether or not to use an algorithm by comparing its performance to their performance goal. In each study, participants decided whether to use their own judgment or an algorithm to complete an incentivized forecasting task. I manipulated participants’ performance goals by incentivizing them to reach different levels of performance between conditions and tested whether or not this manipulation affected participants’ choice of forecasting method.

In Study 1, participants in the “higher performance goals condition” could earn \$0.40, \$0.30, \$0.20, or \$0.10 for estimates that were off by 5, 15, 25, or 35 percentiles respectively, and participants in the “lower performance goals condition” could earn \$0.20 or \$0.10 for estimates that were off by 25 or 35 percentiles respectively. I found that participants in the lower performance goals condition were significantly more likely to choose to use the algorithm (69%) than those in the higher performance goals condition (52%), $\chi^2(1, N = 544) = 15.87, p < .001$. This finding is consistent with the notion that the majority of participants used human judgment by default and compared the algorithm’s expected performance to their perfor-

mance goal when deciding whether or not to use it. In study 2, I replicated this finding, $\chi^2(1, N = 553) = 5.14, p = .023$, and ruled out the alternative explanation that participants in the lower performance goals condition believed that the algorithm performed significantly better than themselves.

In Study 3, participants received a summary of their own forecasting performance after making a set of 10 practice forecasts. Next, participants were assigned to one of five conditions in which they would need to achieve an absolute error of 12, 14, 16, 18, or 20 to earn a \$0.25 bonus. Finally, participants chose between using the algorithm’s forecast and their own by indicating how good the algorithm’s past performance would have to be in order for them to use its forecast instead of their own. I found that participants required the algorithm’s past performance to be significantly better when they were assigned to harder incentives, $t(506) = 2.21, p = .027$, even though participants in each condition believed that the algorithm was the better performing alternative, $t_s(>=98) \leq -3.61, p_s < .001$, and participants’ estimates of the algorithm’s performance advantage was not related to their assigned condition, $t(505) = -0.60, p = .552$. In Study 4, I replicated the main finding from Study 3, $z(N = 508) = 4.01, p < .001$, found that 66% of participants reported using their assigned incentives to decide on their requirement for the algorithm’s performance, and that the same 66% participants did not use their own past forecasting performance (i.e., the performance of the alternative) when deciding on their requirement for the algorithm’s performance.

In Study 5, I changed the participants’ default – participants used the algorithm’s forecast by default and reported how well they would need to perform in a set of 10 practice forecasts in order for them to use their own forecast instead of the algorithm’s. Under these conditions participants’ behavior reversed. Participants required *their own* past forecasts to be significantly better when they were assigned to harder incentives, $z(N = 508) = 4.44, p < .001$, and the majority of participants (64%) reported using their assigned incentives to decide on their requirement for *their own* performance.

SYMPOSIUM OVERVIEW

What constitutes a moral violation in the modern consumer’s mind, and what are the consequences of those moral judgments? Although morality is becoming an increasingly popular topic across fields, our understanding of the determinants and consequences of negative moral judgments in consumer contexts is underdeveloped. This is especially relevant in the modern world, with the increasing use of morally relevant technology (e.g., genetic modification), attempts for firms to be viewed as moral (e.g., corporate social responsibility), and exposure of consumers to moral violations through news and social media outlets. Our four papers draw on and contribute to the moral values and judgment literature (Barasch et al. 2014; Baron and Spranca 1999; Graham et al. 2013; Haidt 2001; Rozin 1999) by exploring how consumers’ moral values lead them to view certain products (**Scott, Inbar, and Rozin**), firms’ behavior (**Kelly and Small**), and their own behavior (**Lin, Reich, and Kreps**) as moral violations, and examining consumption consequences of being exposed to those violations (**Lin, Reich, and Kreps; Dong and Zhong**).

Scott, Inbar and Rozin find that genetic modification (GM), which is increasingly prevalent across the world, is widely met with moral opposition. They examine different roots of this opposition across cultures (US and Europe), and further find that opposition is only somewhat mitigated when consumers read about potential moral benefits of GM (e.g., saving lives). Thus, technological advancements that can serve moral ends can ironically be viewed as immoral. **Kelly and Small** also examine when consumers view actions that achieve objectively “good” outcomes as immoral. They investigate this question in the increasingly common context of corporate social responsibility and find that second-mover companies (i.e., following another company’s CSR behavior) are viewed as less authentically motivated, and are thus seen as less virtuous than first-movers.

Moving away from firms and products, **Lin, Reich, and Kreps** examine when people’s own consumption is judged as immoral, touching on both antecedents and consequences of moral violations. They show that after exposure to moral violations, consumers desire to feel negative emotions, and thus view hedonic consumption as a moral violation and avoid it (e.g., getting ice cream after the Holo-

caust Museum). Consumers also feel uncomfortable when negative moral content is followed by hedonic frivolous content in popular social media contexts (i.e., Twitter). **Dong and Zhong** further examine consumption consequences of moral violations. They find that, after exposure to moral violations, consumers choose products that conform to majority preferences (e.g., products with higher market share). Furthermore, they provide evidence that they choose such products to restore the social order disrupted by those violations.

Our papers use diverse methodologies and theoretical perspectives to examine the role of moral judgment in consumer behavior. Furthermore, while clearly focused around moral violation, our papers cover a wide range of topics (GM, CSR, hedonic consumption, conformity), and each contributes uniquely to the moral judgment literature while offering practical implications for marketers and consumers. Thus our session should appeal to a broad audience at ACR.

Explaining Moralized Opposition to Genetically Modified Food in the U.S. and Europe

EXTENDED ABSTRACT

Genetically modified (GM) food has become prevalent. Eighty-three percent of soybean plants and 29% of corn grown worldwide is GM (ISAA 2015). Yet, consumers are very opposed to GM food. Protesters from the Philippines to Australia to the United States continue to destroy genetically modified crops (Harmon 2013). A wealth of research has focused on the rational and quasi-rational factors underlying opposition to GM, such as beliefs about risks and benefits (Gaskell et al. 2004; Siegrist 2000). In the present research, we expand the scope of explanations about opposition to GM food. We find GM food opposition is moralized and based on sacred values (Baron and Spranca 1997; Rozin 1999). Consumers view the very process of genetic modification as morally repugnant, regardless of its risks and benefits. We use this moralization framework to investigate two puzzles about GM food: 1) consumers’ (in)sensitivity to risk-benefit arguments and 2) why Americans and Europeans have different attitudes to GM food, despite the cultural similarity between the U.S. and Europe.

First, we examine whether attitudes to GM food are moralized in a representative U.S. sample ($N = 540$). We asked participants a number of agree/disagree questions regarding “genetically engineering plants and animals for human consumption”, including 1) “I oppose this”; 2) “This should be prohibited no matter how great the benefits and minor the risks from allowing it”. Following Baron and Spranca (1997) and Scott, Inbar, and Rozin (2016), we defined GM moralization using questions 1 and 2. The majority (64.9%) of consumers in the U.S. were opposed to GM (said “yes” to Q1). Moreover, the majority of this opposition was moralized opposition (said “yes” to Q2; 81.3% of opponents, which is 52.8% of the total sample). These moralized opponents indicated they are *evidence-insensitive*, and they would oppose GM food no matter the cost-benefit analysis.

In order to directly assess evidence-insensitivity of moralized opponents, we randomly assigned moralized opponents to view one of two opposition challenges: a moral benefit challenge and open-ended challenge (adapted from Baron and Spranca, 1997). In the moral benefit challenge, consumers considered and rated the acceptability of golden rice, a crop produced by non-profit companies to reduce death and blindness from Vitamin A deficiency. In the open-ended challenge, consumers wrote about any situation in which

GM would be acceptable, if they could think of such a situation. In both conditions, consumers were given the opportunity to change their moralization position and indicate that they would be willing to change their minds depending on the risks and benefits (i.e., re-answer Q1 & Q2, see above). Only 26.3% of moralized opponents shifted their position after viewing the moral benefit challenge; even fewer (13.7%, $p < .001$) shifted their position after viewing the open-ended challenge. Moralized consumers were evidence insensitive to both challenges.

Next, we examined the difference between attitudes in Europe (Germany & France) and the United States. Prior work suggests that Europeans find GM food more unacceptable than Americans (Gaskell et al., 1999), but it is unclear whether Europeans and Americans oppose GM food for the same or different reasons. We find that Europeans are more moralized towards GM than the United States, and that the bases of moralization differ across countries.

We administered the same survey described above to a representative sample of French ($N = 500$) and German ($N = 519$) participants. Europeans were more moralized than Americans. Moralized opposition was more prevalent in France and in Germany as compared to the U.S. (85.21% in France vs. 52.82% in USA, $t = 10.40$, $p < .001$; 72.69% in Germany vs. 52.82% in U.S., $t = 6.40$, $p < .001$). Even among only opponents (i.e., excluding supporters), moralization was more prevalent in Europe (93.15% in France vs. 81.33% in U.S., $t = 4.80$, $p < .001$; 87.48% in Germany vs. 81.33% in USA, $t = 2.27$, $p = .024$).

Consistent with these self-report measures of moralization, Europeans behaved more insensitive to evidence. Whereas 26.3% of U.S. moralized opponents shifted to non-moralized opposition after viewing the moral benefits challenge, only 15.8% of French and 9.8% of German moralized opponents shifted after this challenge (U.S. v. France, $p = .021$; U.S. v. Germany, $p < .001$). Similarly, whereas 13.7% of U.S. moralized opponents shifted after viewing the open-ended challenge, a mere 3.3% of French and 6.6% of German moralized opponents shifted their opinions (U.S. v. France, $p = .036$; U.S. v. Germany, $p = .002$).

Finally, we examined two potential bases of opposition. We measured connectedness to the natural world (Schultz, 2001) and religiosity. Connectedness to the natural world might capture the intuition that humans shouldn't "tamper with nature." Connectedness to the natural world predicted increased GM opposition in all countries, and France and Germany felt more connected to the natural world than the United States. On the other hand, religiosity might capture the intuition that GM is the equivalent of "playing God." Religiosity was higher in the United States, and religiosity predicted increased GM opposition in the United States better than in France or Germany. These results were robust across many operationalizations of GM opposition, connectedness to nature, and religiosity and were robust to demographic controls.

Taken together, across 1559 participants and representative samples from three different countries we find strong support for a moralization or sacred values framework of GM opposition. Consistent with this framework, most opposition is moralized opposition, and these opponents are unmoved by strong arguments about risks and benefits. Instead they seem to be opposed to the very process of GM itself, which, regardless of risks and benefits is considered intrinsically reprehensible. Furthermore, opposition may be stronger and more moralized in France and Germany (vs. the U.S.) in part due to stronger connectedness to the natural world, but religiosity plays a bigger role in the United States.

The First-Mover Authentic Advantage: How Order of Entry Signals the Purity of Motives

EXTENDED ABSTRACT

Companies engage in costly "corporate social responsibility" (CSR) because they can gain increased customer loyalty (Maignan, Ferrell, & Hult, 1999) and purchase intentions (Elfenbein & McManus, 2010; Sen & Bhattacharya, 2001), improved product quality perceptions (Blair & Chernev, 2014), and an enhanced reputation (Brammer & Pavelin, 2006). However, they run the risk of losing credit if their good deeds are seemingly motivated by self-interested motives (Newman & Cain, 2014; Vlachos et al., 2009). This aversion to impure motives, or inauthenticity more generally, extends beyond the prosocial behavior of firms. Consumers value authenticity in a number of domains (see Newman & Smith, 2016 for review). For example, Newman & Bloom (2012) find that consumers devalue intentional copies of paintings, which is consistent with plagiarism research demonstrating an aversion to stealing credit, a very self-serving act (see Mandel, Fast, & Olson, 2015 for review).

These results underscore the importance of appearing authentic as well as the skepticism and even distaste towards copying. We build on these insights to predict that companies who copy the original prosocial actions of another company will be judged as less benevolent and that this will be due to an inference about the impurity of their motives.

While the idea of first-movers being inherently authentic has been discussed in the first-mover literature (Kamins & Alpert, 2004), it has yet to be explicitly tested. Rather, the first-mover advantage literature began simply with descriptive evidence that market pioneers have larger market shares than later entrants (Robinson, 1988; Robinson and Fornell, 1985; Urban et al., 1986). First-movers are generally perceived more favorably than followers and have a greater advantage the more similar the follower is to them (Carpenter and Nakamoto, 1989). Explanations for this advantage include: increased exposure frequency, familiarity, recall, and representativeness, as well as pioneer image/self-image consistency and the application of consumer beliefs about first-mover traits such as quality and reliability (see Niedrich and Swain 2003 for review). The present research seeks to enrich this evidence by examining the role of judged motives. In doing so, it sheds light on when the first-mover advantage is likely to be particularly strong.

In the context of CSR and other prosocial activities, we expect that first-movers will be perceived as more benevolent than followers. If a company is first to do some type of CSR action, being first suggests that that act must be consistent with the company's character (i.e. "good"). In contrast, a company that copies the CSR action of another will appear less genuine. We further expect that the motive purity of a first-mover will translate into more positive overall attitudes. Because motive purity is so important for prosocial actions (Barasch et al., 2014; Berman et al., 2015), we further hypothesize that the first-mover advantage will be greater for prosocial innovations than for self-interested innovations.

In Study 1 ($N = 301$), participants evaluated first-mover and follower companies with domain-related CSR programs. Participants rated both the first-mover and the follower on social goodness ($\alpha = .962$) and motive purity ($\alpha = 0.949$). Across three industry scenarios, first-movers were judged as more benevolent ($M = 5.52$, $SD = 1.10$) and purely-motivated ($M = 4.59$, $SD = 1.34$) than followers ($M = 4.67$, $SD = 1.08$; $M = 3.82$, $SD = 1.26$, respectively; all $ps < .001$), with motive purity mediating the effect on benevolence judgments here and in subsequent studies.

In Study 2 ($N = 160$), we examined whether the first-mover authentic advantage is larger for CSR activities than for self-interested activities. Participants evaluated first-movers and followers and either judged companies whose innovations (and copied innovations) were self-interested (cost-cutting for the company) or prosocial (better for the environment). Our key dependent variable moving forward is overall attitude judgments ($\alpha = 0.976$), because it allows us to examine a more general evaluation that is reasonable for participants to evaluate across both types of innovations. We find that first-movers are judged more positively overall ($M = 5.22$, $SD = 1.06$) than followers ($M = 4.32$, $SD = .96$; $F(1, 156) = 186.15$, $p < .001$). We also find that companies with prosocial innovations are viewed more positively overall ($M = 5.18$, $SD = .82$) than companies that innovate in a self-serving way ($M = 4.37$, $SD = .82$; $F(1, 156) = 37.27$, $p < .001$). Importantly, there is a significant interaction between first-mover status and innovation type ($F(1, 156) = 12.73$, $p < .001$) such that the first-mover advantage is larger for CSR innovations than for self-interested innovations. These same patterns emerge for judgments of social goodness and motive purity.

In Study 3 ($N = 200$), we conceptually replicate Study 2 using scenarios that lack any company- or innovation-specific information. This controls for any inherent differences across the CSR and self-interested innovation scenarios of Study 2. Our results parallel those reported in Study 2 (all $ps < .001$).

In Study 4 ($N = 149$), we examine whether it is better to copy the CSR of a competitor or to persist pursuing self-interest. Participants judged a CSR first-mover as well as a company that responds to the CSR innovation by a) copying it, b) innovating in a non-CSR way, or c) doing nothing at all. We replicate the finding that first-movers are judged more positively than each type of following competitor (all $ps < .01$). Nonetheless, CSR copiers are evaluated more positively overall ($M = 5.11$, $SD = 1.32$) than companies that innovate in a self-interested manner ($M_i = 4.20$, $SD = 1.13$) and proceed with business as usual ($M = 3.73$, $SD = 1.00$; all $ps < .001$). In other words, CSR copiers are penalized for having impure motives, but they still receive more credit than companies that do no good at all.

We demonstrate that being first at doing something benevolent signals something positive above and beyond the action. Put another way, copying a good action raises doubt about the purity of the company's motives, which lowers the amount of credit that the company reaps. This underscores the importance of inferred motives for CSR activities.

When Feeling Good Feels “Wrong”: Avoiding Hedonic Consumption When It Reflects Immoral Character

EXTENDED ABSTRACT

People judge others' moral characters based on their emotional responses to moral situations (Barasch et al. 2014; Szcurek, Monin, and Gross 2012), perhaps because emotions play such a strong role in moral judgments (Graham et al. 2013; Haidt 2001). We propose that people turn the same judgment inward, and that this judgment affects their desire to consume hedonic experiences. In particular, in contrast to traditional accounts of hedonic emotion regulation (Gross and Thompson 2007), we posit that people desire to experience negative emotions in response to moral violations and negatively valenced moralized content, because experiencing positive emotions would reflect poorly on their moral character. As a consequence, we predict that consumers will avoid repairing emotions through hedonic consumption after viewing negative moralized content, and that they will feel uncomfortable when their ability to feel negatively is disrupted.

Study 1 tested whether consumers feel moral self-reproach (i.e., guilt) when they do not feel negatively enough about negative moralized content using a 3 (emotion feedback: lower, higher, no feedback) \times 2 (moralized content: moralized vs. nonmoral) design. An experimenter attached a physiological measurement device to the participant's palm and informed participants that they would view a sad video clip while he (ostensibly) monitored their emotional response in the next room. Participants viewed a sad moral (from a documentary about Bullying) or a sad nonmoral (from ET) film clip. The experimenter then interrupted the clip, claiming that he had to stop the study because the participant was feeling less sad or sadder than previous participants, or because he was having trouble with the equipment. Participants then reported how guilty they felt. Those who viewed the moralized clip felt guiltier when they thought they felt less sad ($M = 2.07$, $SD = 1.14$) than others than when they thought they felt sadder than others ($M = 1.40$, $SD = .66$; $p < .001$), or when they were given no feedback, ($M = 1.54$, $SD = .94$; $p = .001$). In contrast, the level of guilt for those who saw the nonmoralized clip was not affected by emotion feedback others ($M_{\text{lower}} = 1.41$, $SD = .75$; $M_{\text{higher}} = 1.30$, $SD = .65$; $M_{\text{no feedback}} = 1.33$, $SD = .51$; $ps > .40$). A moderated mediation analysis revealed that the moral content, and not emotional intensity, of the clip explained this effect [.013, .357]. Thus, participants felt they had violated a moral standard by not feeling adequately negative about a moralized clip, suggesting that people desire to negatively in response to negative moralized content.

Studies 2-4 tested whether consumers are reluctant to repair their moods by engaging in hedonic consumption after viewing negatively valenced moralized stimuli. In study 2, participants created a hypothetical itinerary for a trip to Washington, DC. They read that they would visit a museum with moralized content (the Holocaust Museum) or nonmoralized content (an art museum). Participants scheduled two other activities: going for ice cream (hedonic) or taking a walk on the Potomac River (neutral). They chose which should come before and which after the museum. Participants sequenced the ice cream trip after the Holocaust Museum less frequently (62.63%) than after the art museum (86.02%), $p < .001$. This was mediated by how it would reflect on their moral character to eat ice cream after visiting the museum they visited [.033, .146].

In study 3, participants viewed Beyoncé's “Formation” music video, and focused on the aesthetic or moral aspects (e.g., themes of racial discrimination) of the video, thus holding content constant. Afterwards, they chose between viewing a clip from America's Funniest Home Videos or engaging in a meditative breathing task for the next study. Participants were less likely to choose America's Funniest Home Videos after focusing on the moral aspects (58.06%) the music video than when they focused on aesthetic aspects (68.75%), $p = .05$.

Study 4 ruled experienced affect out as an alternative explanation. Participants viewed the same negative moral and nonmoral film clips from study 1 (Bully documentary clip vs. ET clip). They then chose between viewing a Bud Light ad or sitting in silence for 30 seconds. Participants were less likely to view the Bud Light ad after the moralized clip (37.69% vs. 56.86%; $p < .001$). This was mediated by how poorly it would reflect on their moral character to view the Bud Light ad after the video they viewed [-.12, -.04] and held true when controlling for how sad the video made participants feel.

In study 5, we explored the consequences of being exposed to moral content directly followed by hedonic, nonmoral content by using Twitter “tweets.” Participants viewed six negative tweets—three moral (e.g., about rape culture on college campus) and three nonmoral (e.g., about a bacterial outbreak among olive trees). Each tweet was randomly followed by one of six positive tweets—three

virtuous (e.g., about a paralyzed student being thrown a prom that he missed), and three frivolous (e.g., about eating Chipotle every day). Participants rated how comfortable the tweets made them feel (appropriate, comfortable, good). When the second tweet was frivolous, participants felt more uncomfortable when the first tweet was moral ($M=3.00$, $SD=1.12$) than when it was nonmoral, ($M=3.47$, $SD=1.21$; $p=.02$). However, this was not true when the second tweet was virtuous, ($M_{\text{moral}}=3.90$, $SD=1.23$; $M_{\text{nonmoral}}=3.90$, $SD=1.18$; $p=.44$; interaction $p=.004$). Individual ratings of tweets revealed that, when the second tweet as high in frivolous content, moral content of the first tweet predicted discomfort whereas when they were low in frivolous content, $p=.002$, moral content of the second tweet did not predict discomfort, $p=.81$, interaction $p=.006$. Thus, people feel more comfortable repairing their moods through moralized positive content, rather than through a cheap laugh.

Practically, our research suggests that marketers should develop different strategies following negative nonmoralized and moralized content, and that social media outlets should build algorithms to separate negative moral content (e.g., tragic news stories) from frivolous content (e.g., celebrity gossip). Theoretically, we contribute to a broader understanding of the role that emotion plays in moral contexts (Haidt 2001), and when people are motivated to experience negative emotion (Coleman and Williams 2013; Tamir, Mitchell, and Gross 2008). We also qualify judgment and decision making literature on the preferences for sequences of events that improve over time (Loewenstein and Prelec 1993).

Witnessing Moral Violations Increases Conformity in Consumption

EXTENDED ABSTRACT

News reports of unethical behaviors have become a regular feature on TV programs, newspapers, radio stations, and websites. Consumers are constantly exposed to moral violations, from infamously fraud by such companies as Enron, Lehman Brothers, and, more recently, Volkswagen to everyday transgressions such as tax evasion and adultery. Such unethical behaviors violate established moral codes and principles held by the majority of the society (Haidt 2012) and are usually recognized as breaches of social order. Despite the prevalence of moral violations, little is known about how witnessing them may affect consumer choice.

The current research highlights a novel influence of witnessing moral violations on consumers' preference for majority-endorsed (vs. minority-endorsed) options. We propose that moral violations pose a threat to social order and that mere exposure to them could heighten individuals' endorsement of conformist attitudes (Murray and Schaller 2012) by inducing a desire to correct wrongs (e.g., punishing the moral transgressors) and prevent future transgressions (e.g., adhering to social norms). In the domain of consumption, the heightened conformist attitudes could manifest symbolically through one's preference for majority-endorsed (vs. minority-endorsed) products or brands (cf. Berger and Heath 2007; Dong, Dai, and Wyer 2015; Huang, Dong, and Mukhopadhyay 2014).

We further propose that the effect should be attenuated or eliminated under two conditions. First, if the moral violator has already been punished by third parties, the need to restore social order should be fulfilled and hence the desire to conform to the majority should be lessened. Second, if the proposed moral violation effect is driven by heightened desire to restore social order, then the effect should not hold if conforming to the majority-endorsed option is viewed as being complicit with the moral violation, which might create further

imbalance in social order. We describe four experiments which investigated these possibilities.

Experiment 1 intends to test the proposed causal relationship between exposure to moral violations and conformity tendency. Participants were randomly assigned to 3(moral violation vs. innocent error vs. natural disaster) between-subjects conditions. To manipulate exposure to moral violation, participants were asked to read and comprehend news article describing an immoral behavior (i.e., the London Interbank Offered Rate [LIBOR] financial scandal). In the innocent error condition, participants were asked to read a similar news article but words were changed to describe the LIBOR incident as an innocent error. We also included the natural disaster condition to test whether the effect may generalize to any negative events. Afterwards, participants were asked to choose between a majority-endorsed (vs. minority-endorsed) office magnet as a small token of appreciation. The choice results yielded that witnessing moral violation increased consumers' tendency to choose a majority-endorsed (vs. minority-endorsed) magnet (55.1%), compared with those in the innocent error (33.3%; $p=.01$) or natural disaster conditions (37.7%; $p=.04$), suggesting that this effect is specific to moral violations and cannot be generalized to any negative events.

Experiment 2 extended the investigation in two ways: first, rather than manipulating moral violations using news article comprehension task, participants were exposed to real moral violation behavior (i.e., cheating). Second, we investigated whether the effect is comparable for observers and direct victims of moral violations. It followed a 2(exposure to cheating vs. not) \times 2(incentive structure: observers vs. direct victims) between subjects design. To manipulate exposure to cheating, we had a confederate cheating in a verbal ability task, and the behavior was observed by other participants in the same session. We varied the structure of the incentives that we offered to participants in the verbal ability task such that the confederate's cheating behavior would either hurt the participants' own payoff (i.e., direct victims condition) or not (observers condition). We find that exposure to cheating (vs. not) increased consumers' subsequent conformity tendency measured using the same magnet choice task as in Experiment 1, regardless of whether they are observers (54.0% vs. 31.7%; $p=.033$) or direct victims (58.5% vs. 35.4%; $p=.029$) of the cheating behavior.

Experiment 3 replicated the effect using a different operationalization of moral violation (i.e., reading a story about a corruptive CEO) and a different measure of conformity tendency (i.e., preference for brands with higher versus lower market share) and provided direct evidence for the underlying mechanism. Participants were randomly assigned to 3(unpunished corruptive CEO vs. punished corruptive CEO vs. control) between subjects conditions. As predicted, participants who read about a story describing an unpunished corrupt CEO ($M=14.21$) were more likely to prefer brands that have larger market share, compared with those who read about a punished corrupt CEO ($M=13.50$; $p=.025$) or those who were in the control condition ($M=13.46$; $p=.017$). In addition, a multi-stage mediation analysis revealed that the effect is shown to be driven by the heightened perceived threat to social order which subsequently enhanced participants' endorsement of conformist attitudes.

Experiment 4 sought to further test our proposed underlying process by using a moderation-by-process design (Spencer, Zanna, and Fong 2005). It followed a 2 (exposure to: moral violation vs. innocent error) \times 2 (majority morality: immoral vs. control) between-subjects design. We followed exactly the same procedures as in Experiment 1 to manipulate exposure to moral violations. Then participants were asked to make a choice between joining a majority-endorsed and a minority-endorsed book club, and we manipulated

the perceived morality of the two clubs by varying the occupation information of the book club members. We find that exposure to moral violation (vs. innocent error) increased preference for the majority book club only if the majority book club is perceived as neutral or moral (44.7% vs. 25.4%; $p=.014$). The effect disappears if the majority club is perceived as immoral (19.2% vs. 23.4%; $p>.53$).

Taken together, this research provides fresh insights to the morality and conformity literature by (a) documenting a novel downstream consequence of exposure to moral violations on consumer choice and (b) advancing our understanding of the psychological functions of conformity in coping with negative consequences of witnessing moral violations. Theoretical contributions and marketing implications will be discussed.

Paper #4: The Effects of Warm versus Cool Ambient Scents on Calorie Consumption

Sarah Lefebvre, Murray State University, USA
Dipayan Biswas, University of South Florida, USA

SESSION OVERVIEW

The session addresses the broad question of how scents affect product evaluations and consumption. The session serves as a cohesive all-around inquiry, set up in diverse contexts of scent expression, like product scents, scented ads, olfactory imagery and ambient scents. The papers also introduce several novel effects, like scent as a cue for transferring product-essence and for inferring ambient temperature.

Sharma and Estes point out that although scent can be a powerful marketing tool, it is difficult to implement via advertising and packaging. They therefore investigate how pictures of scented objects (e.g., lavender, lemon) in ads and product labels affect product evaluations. Across four studies, they show that pictures of scented objects can evoke olfactory imagery, hence positively impacting product evaluations. However, this visual-olfactory effect occurs only when the scent is pleasant, when scents are relevant to the product, and when the offering is utilitarian. It backfires if the product category is scent-irrelevant or the associated scent is unpleasant.

Ruzeviciute, Kamleitner, and Biswas examine how scented ads improve the appeal and attractiveness of a product. They suggest that scents are able to transfer the essence of the product. In three studies, they show that scents increase the product appeal because of enhanced perceived proximity of the product to the consumer. However, scents increase perceived proximity only when there are scent expectations from the product, whereas the importance of scents to the product and explicitly informing consumers of the scent do not matter. The authors also rule out imagery as a potential alternate mechanism.

Carnevale, Hadi, Pogacar, and Luna focus on how brand names influence consumers' responses to a product's scent. In a field experiment and two lab experiments, they show that olfactory cues from a product affect consumer preferences when the brand name

is category-congruent, but not when the brand name is category-incongruent. They further show that this effect is mediated by increased fluent processing of category-congruent brand names. On the other hand, unpleasant smelling products (e.g., blue cheese) can benefit from using category-incongruent brand names, as the unpleasant olfactory cues are discounted from evaluations in this case.

Lefebvre and Biswas investigate how warm or cool ambient scents affect food/beverage consumption. In a field experiment and three lab experiments they show that warm ambient scents decrease calorie consumption and reduce the likelihood of choosing high-calorie foods, compared with cool scents. They further show that this effect is due to a difference in perceived ambient temperature by consumers. They theorize that lower perceived temperature in the case of cooler scents might signal higher anticipated energy expenditure, leading to an increase in high calorie food consumption. Surprisingly, this effect reverses with beverages instead of foods.

This session connects scents with product evaluations and consumption with several novel theoretical links, mechanisms and boundary conditions along with relevant practical implications to managers. These papers together show how scents can have broad as well as specific effects, hence illustrating the widespread effects of scent on a multitude of consumer behaviors.

Seeing is Smelling: Visual Images can Induce Olfactory Imagery and Improve Product Evaluations

EXTENDED ABSTRACT

Scented products are increasing in prevalence, so marketers need to advertise and package them effectively. Using scents in ads and in stores improves product evaluations (Morrin 2009), but the incorporation of scents is expensive in advertising and impractical in packaging. Alternatively, given that consumers may be "able to experience the sensation of smell when an appropriate stimulus is absent" (*olfactory imagery*; Stevenson and Case 2005), we investigated whether pictures of scent-inducing objects (like lavender) in ads or product packages can increase product evaluations via olfactory imagery (*visual-olfactory effect*).

Pictures lie at the heart of advertising and packaging, but the link between pictures and olfactory imagery is unexplored in consumer behavior. Murray et al. (2005) showed that visual exposure to an object can activate representations in other modalities, including smell. Moreover, because visual and olfactory neural circuits overlap substantially (Jadaui et al. 2012), the mere presence of a visual stimulus can evoke olfactory imagery. But does olfactory imagery affect product evaluations?

A large literature on scent suggests a positive impact of pleasant scents on consumer evaluation and behavior (Bosmans 2006; Morrin 2009). Olfactory imagery and olfactory perception exhibit highly similar hedonic patterns in the brain (Bensafi et al. 2007), therefore, we expect a positive impact of olfactory imagery on consumer evaluations. For example, Krishna et al. (2014) showed that olfactory imagery of food can increase consumption. We similarly expect a positive impact of olfactory imagery on consumer evaluations in non-food products (without the gustatory sense), avoiding interfering mechanisms like cravings (Kemps et al. 2004) and activation of taste and reward areas in the brain (Simmons et al. 2005). We further ruled

out an impact of other sensory modalities by using products with limited or no haptic or auditory involvement.

Study 1 tested whether product labels that evoke stronger (versus weaker) olfactory imagery are preferred. 95 participants viewed two product labels of a lemon-scented dishwashing liquid with a picture of either cut lemon or whole lemon. They indicated the label they preferred and rated the olfactory imagery and visual attractiveness of the labels. A significant majority of participants (77%) preferred the label with cut lemons, which evoked stronger olfactory imagery. A logistic regression showed a significant effect of olfactory imagery on likelihood of choosing the cut lemon label ($t=2.48, p<.05$), controlling for visual attractiveness.

In an ad/package, using pictures to indicate removal of unpleasant scents is common (e.g., air-freshener ads) but are such pictures beneficial or harmful for product evaluation? Study 2 compared pictures of pleasant or unpleasant scented objects, which we expected to increase and decrease product evaluations respectively. 292 respondents saw an oven cleaner with one of three labels between-participants: pleasant (lemon picture), unpleasant (fish picture) and no-scent (oven picture). All packages included the statements: "LEMON SCENTED" and "NEUTRALIZES FISHY SMELL". A one-way ANOVA confirmed more positive attitudes, $F(2,292)=77.79, p<0.001$, and more positive olfactory imagery, $F(2,292)=142.41, p<0.001$, in the pleasant condition than in the control condition, which was higher than the unpleasant condition. Mediation analysis showed that the lemon picture increased product attitudes via olfactory imagery (CI=.08 to .27), whereas the fish picture decreased attitudes via olfactory imagery (CI=-.77 to -.34).

The contextual-correction literature (Bosmans 2006) indicates that when consumers are aware of biasing effects of scents (like pictures impacting evaluations), they discount it while evaluating. We hypothesized that the visual-olfactory effect would be moderated by the relevance of scent to the product category (scent-relevant: cleaning-spray; scent-irrelevant: umbrella), because in the scent-irrelevant condition its biasing effect is apparent to the consumer. In study 3, 392 online respondents were assigned to one of 2 (Scent relevance: relevant, irrelevant) * 2 (image: present, absent) between-participants conditions. All packages were clearly labeled "LEMON FRAGRANCE". ANOVA showed a significant interaction on product attitudes, $F(1, 388)=11.29, p=.001$. The picture of a lemon on the package improved attitudes for the scent-relevant product (cleaning spray), $t(191)=2.25, p<.05$, but decreased attitudes for the scent-irrelevant product (umbrella), $t(197)=-2.06, p<.05$. A moderated-mediation analysis showed that for the scent-relevant product, the picture increased product attitudes via olfactory imagery (CI=.1 to .33), while for the scent-irrelevant product there was no mediation (CI=-.04 to .17).

Hedonic offerings are inherently emotional and sensorial (Voss et al. 2003), so counter-intuitively, the addition of a picture may have relatively little benefit to hedonic ads. That is, because hedonic offerings are already highly sensory, an additional sensory attribute (olfactory imagery) may have "diminishing returns" on attitudes. Utilitarian offerings, in contrast, tend to have fewer sensory attributes, so adding a picture could have an especially large effect on olfactory imagery and evaluation. In Study 4, 399 respondents were randomly assigned to one of 2 (service type: utilitarian, hedonic) * 2 (picture: present, absent) between-participant conditions. Participants saw a laundry service ad, with service type manipulated through typeface and textual content to be more utilitarian or hedonic, while a picture of lavender was present or absent from the ad. A 2 (service type) * 2 (picture) ANOVA on product attitudes indicated a marginally significant interaction, $F(1, 394)=2.11, p=.053$. The picture of

lavender improved attitudes for a utilitarian ad, $t(200)=2.35, p<.05$, but not for a hedonic ad ($p>.72$). A moderated-mediation analysis showed that the conditional indirect effect of the picture on attitude was significant (CI=.11 to .29) for the utilitarian ad, but not for the hedonic ad (CI=-.01 to .12).

These studies show that pictures of pleasant scented objects can improve evaluations via generation of olfactory imagery (a *visual-olfactory effect*). Our research extends the multisensory theory of evaluations to imagined scents. This research is the first to demonstrate in consumer research that pictures can implicitly generate olfactory imagery. It is also one of the few studies (e.g., Krishna et al. 2014) establishing positive impacts of pleasant olfactory imagery. Another important contribution of the paper is to establish that olfactory imagery is a controlled process. This effect is activated only when the product is scent-relevant, which strikes a conversation with the scent-congruence literature (Spangenberg et al. 2006). Similarly, we show that the visual-olfactory effect occurs only for utilitarian products.

I Smell it as if it Were Here: Can Scented Advertising Boost Product Appeal?

EXTENDED ABSTRACT

Drawing on the literature on magical contagion and essence transfer (Argo, Dahl, and Morales 2008; Nemeroff and Rozin 1994) we propose that scented advertising copy can boost the advertised product's appeal. More specifically, we suggest that it does so because scents are able to capture and convey essential qualitative information (Yeshurun and Sobel 2010) or even the very essence of their source (Meir 2005) and thus, serve as a cue for object proximity. Scent molecules are part of the scent emitting object itself (Köster 2002) and they can represent the object in its absence (Nemeroff and Rozin 1994). The ability of scent to traverse immediate experiences could also explain why, from early childhood onwards, certain scents are used for regulating distances to desired people or objects when they are physically absent (Shoup, Streeter, and McBurney 2008). For example, toddlers simulate the presence of the parent by smelling their favorite toy or comfort blanket when staying at a daycare facility (Schaal 1988). Likewise, sniffing at an unwashed partner's t-shirt enables adults to enhance felt proximity to an absent partner (Shoup et al. 2008). Given that print ads represent physically absent products, we propose that scent behaves similarly in the context of advertising – transfers the essence of the product and, thus, brings about the feeling of its proximity. Notably, as generally liked targets become even more appealing if they are proximate (Kahn and McGaughey 1977; Williams et al. 2014) we further posit that the scent elicited sense of proximity in turn enhances the appeal of the advertised product.

In three experiments, we test perceived proximity as a mechanism through which scented ads may affect advertised product appeal. In addition, we highlight the moderating effect of product category. Specifically, we show that a scented ad enhances proximity and appeal only if it credibly represents the essence of the advertised product. Moreover, we rule out imagery (Lwin, Morrin, and Krishna 2010) as an alternative process account.

In study 1, we tested the hypotheses and explored their robustness across different scent presentation strategies. Participants were randomly exposed to either a lavender scented or unscented soap print advertisement. Additionally, participants who received scented ads were either alerted about the scent on the ad (explicit scent presentation) or not (implicit presentation). All participants reported perceived proximity to (feels close/here), attractiveness

of and purchase intentions for the advertised soap (7-point scales). The results revealed a main effect of scent on perceived proximity ($F(2,114) = 8.38, p < .05$). Scented ads yielded higher perceived proximity ratings than control ads, regardless of scent presentation strategy. As predicted, scent elicited product proximity and in turn increased product attractiveness and purchase intentions (SPSS PROCESS, model 4, 95% CI's excluded zero).

Study 2 investigated product category moderation for the previously observed effect. We predicted that scenting an ad should only work if the scent can be considered part of the product. Additionally, we aimed to demonstrate robustness of the effect using different products and scents than in Study 1. Prior literature shows that scents facilitate vivid processing of information (Lwin et al. 2010) and that vivid product imagery leads to favorable product reactions (Kisielius and Sternthal 1986). Therefore, study 2 also addressed product imagery vividness as an alternative process. Participants were randomly assigned to an ad featuring a glass that was either framed as a drinking glass (scent unexpected) or as a glass containing an aroma-candle (scent expected). The ad was either unscented or had a vanilla scent. Using the same measures as in the previous studies, we find the predicted interaction. Scent increased the perceived product proximity ($F(1, 177) = 4.88, p < .05$) only when advertising a candle but not a glass. A moderated mediation analysis (SPSS PROCESS, model 7) confirmed the scent induced proximity mediation on increased product attractiveness and purchase intentions, but only for the product with scent expectations (candle) (95% CI's excluded zero). We further explored the role of mental imagery (assessed with mental imagery scale, Babin and Burns 1998) in driving product appeal in response to scented ads. However, we neither observed a main effect of scent nor an interaction with the product category (p 's $> .20$). A moderated mediation (model 7) test confirmed the limited role of mental imagery in driving product appeal when using scented ads, regardless of the advertised product (all 95% CI's included 0).

Even if we typically associate a product with a scent this does not mean that we consider its scent very important. Therefore, study 3 investigated whether the effect of scent on advertised product proximity could generalize across products that generally enjoy high scent expectations, but differ in how important scent is for a product. Study participants were exposed to a scented or unscented soap ad as in study 1. To manipulate importance of scent for a product, we additionally framed the soap as either moisturizing (less important) or aromatherapy (more important). Additionally to the measures used in studies 1 and 2, we assessed willingness to pay a price premium for the advertised soap. The results revealed only a main effect of scent ($F(1,182) = 14.10, p < .001$), signaling the effectiveness of scented ads in boosting product proximity regardless of soap type. A moderated mediation test (model 7) corroborated these findings and showed no evidence for moderation by soap type. Yet as predicted, scented advertising through elicited product proximity increased promoted soap attractiveness, its purchase intentions and the willingness to pay a price premium for it (95% CI's excluded zero).

Taken together, the studies show that scent can enhance consumer responses to the advertised product because it is able to transfer the essence of the product and thus, acts as its proximity cue. However, the hypothesized process only works for products whose essence could be credibly represented using scent, that is, products that are expected to have embedded scent. These results add to the literatures on multisensory marketing and proximal product experiences.

Follow Your Nose When it Sounds Right: How Brand Names Moderate the Influence of Olfactory Cues on Consumer Preferences

EXTENDED ABSTRACT

Product scents can be powerful differentiation tools for marketers, and academic research suggests olfactory cues can profoundly influence consumer memory and evaluations (e.g., Krishna, Lwin, and Morrin 2010). However, while the influence of product scent on consumer behavior has been examined, it has mostly been assessed in isolation, without investigating how other product-based cues may moderate its influence.

We begin to address this gap by examining how brand names might shape consumer responses to a product's olfactory properties. This examination is practically relevant, given that consumers typically see a product's brand (e.g., on packaging) before being exposed to its scent. However, this exploration is also theoretically motivated by the phonetic symbolism and olfactory processing literatures. Consumer research in phonetic symbolism suggests that the phonetic properties of a brand name can influence consumer perceptions (e.g., Klink 2000; Lerman and Garbarino, 2002; Lowrey, Shrum, and Dubitsky 2003). For non-word brand names, even the smallest unit of sound can evoke specific meaning. For example, front (back) vowels, such as the English sound "ee" ("o") are associated with lightness (heaviness) and softness (hardness; Klink 2000). Accordingly, certain brand names may be more or less congruent with particular product categories, and such congruity may influence consumer preferences (Lowrey and Shrum 2007). For instance, if lightness is typical in a category (e.g., tissues), a front vowel (e.g., the brand name "Deetal") would be category-congruent while a back vowel (e.g., "Dutal") would be category-incongruent.

Importantly, phonetic congruity (versus incongruity) not only affects product perceptions, but can also prompt more fluent (versus disfluent) processing (Topolinski and Strack 2010). The facilitation of fluent processing is critical to the current research, given that sensory cues in general (Stephenson and Palmgreen 2001) and olfactory cues in particular (DeBono 1992) tend to be processed in a peripheral, heuristic manner. Accordingly, a product's brand name should act as a germane antecedent determining the extent to which consumers rely on subsequent olfactory information when making product-based judgments and choices. Specifically, we propose that category-congruent brand names will encourage more fluent processing and facilitate consumer reliance on a product's olfactory cues, whereas category-incongruent brand names will generate disfluency, leading consumers to discount subsequent olfactory information.

Study 1 (N=191) was a field experiment with a 2(Brand Name: Congruent vs. Incongruent) x 2(Scent: Unscented vs. Pleasant Scent) between-subjects design. Experimenters set up a table in a public space and offered passerby \$5 to sample a lip balm. The lip balm was either unscented or vanilla-scented (a pretest suggested vanilla was a desirable scent for this product category), and was packaged with a brand name pretested as being either congruent ("Frosh") or incongruent ("Frish") with the lip balm category. After trying the lip balm, participants were told they could either "purchase" it for \$1 of their compensation, or relinquish it and receive full compensation. Logistic regression results revealed a significant interaction of Brand Name x Scent on purchase likelihood ($\chi^2=5.41, p=.02$, Odds ratio=5.83). Specifically, when the brand name was category-congruent, participants were significantly more likely to purchase the vanilla (versus unscented) lip balm (52% vanilla vs. 8% unscented; $\chi^2=17.62, p<.001$, Odds ratio=.08). However, when the brand name was category-incongruent, there was no significant difference in

purchase likelihood between the two scent conditions (36% vanilla vs. 21% unscented; $\chi^2=2.50$, $p>.1$, Odds ratio=.48).

Study 2 (N=140) was a laboratory experiment with a 2(Brand Name: Congruent vs. Incongruent) x 2(Scent: Congruent vs. Incongruent) between-subjects design. Participants sampled a hand lotion that had either a category-congruent (lavender) or category-incongruent (pine) scent (previous research suggests category-congruent olfactory cues are preferred, e.g., Krishna, Lwin, and Morrin, 2010), and was packaged with a brand name that was pretested as being either category-congruent (“Sait”) or category-incongruent (“Soot”). After sampling the product, participants were given the option to either keep the product, or choose an alternative lotion to take home with them. Results confirmed a significant interaction of Brand Name x Scent on Product Choice ($\chi^2=3.95$, $p<.05$, Odds ratio=11.66), and the pattern of contrasts mirrored those of study 1: when the brand name was category-congruent, participants chose the lavender (versus pine) lotion more often (23% lavender vs. 5% pine; $\chi^2=4.05$, $p<.05$, Odds ratio=.18). However, when the brand name category-incongruent, there was no significant difference in choice likelihood between the two scent conditions (6% lavender vs. 11% pine; $\chi^2=.70$, $p>.1$, Odds ratio=2.13).

Our final study (N=121) was a laboratory experiment with a 2(Brand Name: Congruent vs. Incongruent) x 2(Scent: Pleasant vs. Unpleasant) between-subjects design. The objective was to investigate the underlying mechanism and test whether an incongruent brand name might attenuate negative effects of mildly aversive product scents. Participants sampled a hand sanitizer that had either a pleasant (orange) or unpleasant (musty pine) scent (according to pretest results), and was packaged with pretested category-congruent (“Gimmel”) or category-incongruent (“Gommel”) brand names. After sampling the product, participants evaluated it on a series of bipolar dimensions (e.g., good-bad), and their evaluation time was measured as a proxy for processing fluency (Schwarz 2004). Results confirmed a significant Brand Name x Scent interaction on Product Evaluation ($F(117)=4.68$, $p<.05$). When the brand name was category-congruent, participants evaluated the orange (versus musty pine) sanitizer more highly. However, when the brand name was category-incongruent, there was no significant difference in evaluation between scent conditions. Further, a moderated mediation analysis (Model 8 of Hayes 2013) confirmed that when the brand name was congruent, processing fluency explained the effects of scent on evaluation (95% CI=-.37, -.01), but this was not the case when the brand name was category-incongruent (95% CI=-.02, .23).

Our research suggests that brand names can play a pivotal role in determining the influence of olfactory cues on consumers’ judgements and behaviors, and this has important managerial implications. For instance, when scent is an important selling point in a product (e.g., candles), category-congruent brand names may enhance consumer valuation of the scent. However, for products with inherently bad scent (e.g., nail polish, blue cheese), marketers may benefit from category-incongruent brand names, so that the influence of unpleasant olfactory cues on consumer responses is attenuated.

The Effects of Warm versus Cool Ambient Scents on Calorie Consumption

EXTENDED ABSTRACT

Can the temperature dimension of ambient scent influence total calories consumed? That is, can warm versus cool ambient scents (Krishna, Elder, and Caldara 2010; Madzharov, Block, and Morrin 2015) impact how much food a consumer eats? The results

of four studies show that warm (e.g., cedarwood) versus cool (e.g., eucalyptus) ambient scents influence the amount of food consumed and even choices between high versus low-calorie food options. Overall, we examine the sensory cross-modal influences of olfactory cues on haptic perceptions, which in turn influence gustatory factors

The human physiological system attempts to maintain an optimal core body temperature (at ~98°F). Research within physiology shows when ambient temperature becomes colder, the body evokes thermal regulation by increasing activities that will generate heat (e.g., shivering). As a result, there is greater energy expenditure and an increase in appetite to counteract the loss of stored calories (Moellering and Smith 2012; Warwick and Busby 1990; Westerterp-Plantenga et al. 2002). As a corollary, an increase in ambient temperature leads to loss of appetite due to reduced desire for activity (Herman 1993; Murray 1987).

Very little research has examined a temperature dimension of scent, with the two notable exceptions being Krishna, Elder, and Caldara (2010) and Madzharov, Block, and Morrin (2015); however, neither of which these studies examine the effects of warm/cool scents within a food context. We build on these two studies to develop our conceptual framework. From an evolutionary/historical perspective, scents associated with fire (e.g., sandalwood, cinnamon) came to be associated as warm scents and subsequently used during winter, while scents associated with watery properties (e.g., eucalyptus, peppermint), became associated as being cool scents and subsequently used for their cooling properties (Zarzo 2013).

Building on the physiological effects of ambient temperature and the emerging literature on the temperature dimension of scent, we hypothesize that ambient scents that induce warmer (vs. cooler) temperatures will lead to decreased calorie consumption and reduced choice likelihood of calorific foods. We test our hypotheses with the help of a field experiment and a series of lab studies.

Study 1a, a field experiment at an optometrist’s office, had two manipulated conditions (ambient scent: warm vs. cool). For the experimental manipulations, two commercial grade scent nebulizers were placed at the opposite ends of the retail store, which also functioned as the waiting area for patients. A glass bowl with individually wrapped chocolates was placed on the reception desk where all customers were required to sign in. There was a main effect of ambient scent on calories consumed ($M_{\text{warm}} = 29.55$ vs. $M_{\text{cool}} = 54.87$; $F(1, 2) = 47.09$, $p < .05$) supporting our primary hypothesis.

Study 1b replicated the findings of study 1a in a controlled laboratory environment with a mindless eating task. Consistent with the results of study 1a, participants in the warm (vs. cool) ambient scent condition consumed a lower amount of calories from the bite-sized breakfast biscuits ($M_{\text{warm}} = 53.21$ vs. $M_{\text{cool}} = 101.0$; $F(1, 51) = 10.31$, $p < .01$). The results replicate the main effects of study 1a in a controlled lab setting. Next, study 2 examines the extension of the effect of scent on choice and the underlying process.

Study 2 investigated the effect of ambient scent on food choice and the underlying process of perceived ambient temperature. Participants were given the choice of a low versus high calorie choice and asked to rate the temperature in the room as cold versus warm. We found those in the warm scent chose the low calorie item significantly more than those in the cold scent (Wald = 3.37, $p = .066$; $P_{\text{warm}} = 78\%$ vs. $P_{\text{cold}} = 56\%$). Mediation tests showed that the total indirect effect of a temperature dimension of ambient scent through the mediator, perceived ambient temperature, on food choice had a bootstrap 90% CI of .0168 to .7169 with an estimate of .8612, supporting mediation.

Study 3 examined the effects of warm/cool ambient scents on consumption of food versus beverages. We propose that the

effects will be in opposite directions for foods versus non-alcoholic beverages. This is because in hot environments additional beverage consumption cools the body and hence an increased ambient temperature is associated with a higher amount of beverage consumption (Wansink 2004). Participants were told in appreciation for their participation in the lab, they were provided with either a snack or a beverage. Results revealed a significant interaction effect of ambient scent and food/beverage on consumption volume ($F(1, 93) = 13.07, p < .001$). Follow-up analysis showed that in the “food” conditions, participants in the cool ambient scent consumed more ($M_{cool} = 50.2\%$) than those in the warm ambient scent ($M_{warm} = 20.54\%$; $F(1, 93) = 13.03, p < .001$). In the “beverage” condition those in the warm ambient scent drank more ($M_{warm} = 28\%$) than those in the cool ambient scent ($M_{cool} = 15.77\%$). The results indicate a reversal in consumption volume for food vs. beverage due to the temperature dimension of scent

The results of four studies showed that a warm (vs. cool) ambient scent leads to a reduced amount of food consumption both in field settings as well as in laboratory environments. The findings of this research contribute to our understanding of cross-modal influences involving olfactory cues, haptic perceptions, and gustatory outcomes. Specifically, while ambient scent is an olfactory cue, perceived warmth/coolness is a haptic perception, and food consumption is related to gustatory factors. This is possibly the first research to link olfactory cues to haptic perceptions and with outcomes for gustatory factors. Hence, the findings of this research contribute to the growing literature in the domain of sensory marketing (Krishna 2012).

Our findings have important conceptual and practical implications, especially given widespread concerns about obesity and the related focus on food overconsumption. Moreover, given the ease with which different types of ambient scents can be administered, consumers and marketers can potentially use the findings of this research to nudge healthful consumption.

SESSION OVERVIEW

Consumers engage in various strategies when facing difficult decisions, many of which can operate against their goals or interests. At times, for example, consumers delay the decision or avoid making a decision at all (Luce 1998; Luce, Payne, and Bettman 1999). Other times, they make uninformed decisions even when receiving relevant information would be costless (Ehrich and Irwin 2005; Golman, Hagmann, and Loewenstein 2017; Thunström et al. 2016; Wansink and Chandon 2005). And even when information is automatically provided, people may not incorporate it into their decisions (Downs, Wisdom, Wansink, and Loewenstein 2013). This previous research raises important questions pertaining to consumer decision making and the role of information in consumer choice. This special session provides new perspectives on this topic, connecting four papers that explore novel strategies consumers use when making difficult decisions, and identifying how information – whether it is present or absent – influences consumer choice.

The first two papers focus on strategies consumers use when faced with a hard choice. Steffel and Williams identify decision delegation as a novel way that people cope with anticipated regret when choices feel difficult. Nine experiments demonstrate that people prefer to delegate difficult decisions to others, regardless of the decision's importance or the potential surrogate's expertise. In the second paper, Woolley and Risen investigate information avoidance as an outcome of choice difficulty. Five experiments identify intuitive-deliberative conflict as a driver of information avoidance. Although consumers avoid information to protect an intuitive preference, they use the information when it is provided, suggesting consumers make a mistake either in avoiding information they use, or using information they would prefer to avoid.

The last two papers further explore how information influences consumers' decisions, specifically in the health domain. Sah, Read, and Savani examine the fallout when doctors fail to disclose negative information about their trustworthiness and conflicts of interest.

Rather than make negative inferences about these doctors, patients rate these doctors more positively than they would have otherwise, and are just as likely to select doctors with missing information to care for them as doctors with available, positive information. Finally, in a large-scale field experiment, Donnelly, Zatz, Svirsky, and John examine the influence of warning labels on the consumption of sugar-sweetened beverages (SSB). Whereas calorie and text-warning labels were ineffective at reducing the purchase of SSBs, graphic-warning labels successfully reduced SSB purchase from baseline by 14%.

Together these papers connect research on consumer's preferences when making difficult decisions, and the role of information in consumer choice. Further, by identifying the factors that lead consumers to avoid choices or information, and how withholding or providing this information influences decisions, these findings highlight important implications for encouraging consumers to make better decisions. This session should have broad appeal to scholars interested in decision making, choice deferral, disclosure, and information avoidance, as well as the connections between them.

Delegating Decisions: Recruiting Others to Make Choices We Might Regret

EXTENDED ABSTRACT

People generally cherish the freedom to make their own decisions. Even when choosing is costly, people prefer to choose themselves rather than let another person choose for them (Botti and Iyengar 2004; Botti and McGill 2006, 2011; Botti, Orfali, and Iyengar 2009). If the desire to make one's own choices is often so pervasive, when might people prefer to delegate? We suggest that delegation may often be an appealing alternative to choosing oneself because it enables people to avoid responsibility and regret for potentially choosing suboptimally while still enabling them to get something rather than nothing out of a decision. We predict that people are especially likely to delegate when choices feel difficult and the chance of choosing badly is high.

We first examine whether, despite their general preference for making their own choices, people prefer to have others choose on their behalf when choices feel difficult. In Experiment 1, an incentive-compatible design, participants were more likely to delegate a choice of headphones to take home after the experiment when given a difficult choice between two similar sets of earphones than an easy choice between two dissimilar sets of earphones (28% vs. 11%; $\chi^2(1, N = 366) = 16.72, p < .001, \phi = .21$). Experiment 2 found that people delegate difficult decisions regardless of the importance of the decision: participants were more likely to delegate a difficult than an easy decision, both for an important choice that was binding and for which switching was costly (41% vs. 29%; $\chi^2 = (1, N = 406) = 5.55, p = .02, \phi = .12$) and for a less important choice that was nonbinding and where switching was costless (48% vs. 28%; $\chi^2 = (1, N = 409) = 17.62, p < .001, \phi = .21$). And, Experiment 3 found that, although expertise made delegation overall more appealing, people delegated difficult decisions regardless of the expertise of the potential surrogate: participants were more likely to delegate a difficult than an easy decision, both when the surrogate had relevant expertise (79% vs.

57%; $\chi^2 = (1, N = 201) = 11.37, p < .001, \phi = .24$) and when they did not (54% vs. 30%; $\chi^2 = (1, N = 202) = 11.07, p < .001, \phi = .23$).

Experiment 4 tests whether people delegate to avoid the regret associated with being responsible for bringing about that bad outcome or to avoid the disappointment associated with a bad outcome, independent of whether they choose it or not. We manipulated choice difficulty by making the available options in the set either close or distant in appeal, and we manipulated the overall appeal of the choice options by making them all either attractive or unattractive. Participants were more likely to delegate when the difference in relative attractiveness was small and the choice was difficult than when it was large and the choice was easy ($F(1, 819) = 7.00, p = .008, \eta_p^2 = .008$), but equally likely when both options were attractive and when both options were unattractive ($F(1, 819) = .86, p = .36, \eta_p^2 = .001$). A serial mediation model (PROCESS Model 6) indicated that our relative attractiveness manipulation increased difficulty ($\beta = .71, SE = .12, t = 6.15, p < .001$), difficulty increased anticipated regret ($\beta = .29, SE = .03, t = 10.54, p < .001$), and anticipated regret increased delegation ($\beta = .14, SE = .06, t = 2.34, p = .02$).

Experiment 5 explored whether delegation may be preferred to deferral when choices feel difficult, so long as the options are somewhat appealing, because it enables people to avoid responsibility and regret for potentially choosing suboptimally while still enabling them to get something rather than nothing out of the decision. Indeed, when given the option to choose, delegate, or defer, participants were more likely to delegate than choose themselves when given a difficult choice between options that were close in relative attractiveness than when given an easy choice between options that were far in attractiveness (42% vs. 32%; Wald's $\chi^2 = 8.88, p = .003$, Odds Ratio = .48). This was especially true when the options were appealing (44% vs. 27%; Wald's $\chi^2 = 8.88, p = .003$, Odds Ratio = .48) than when they were unappealing (41% vs. 36%; Wald's $\chi^2 = .50, p = .48$, Odds Ratio = .83), but not when the options were both attractive versus when they were both unattractive (38% vs. 36%; Wald's $\chi^2 < .001, p = .99$, Odds Ratio = 1.00). Unsurprisingly, participants were more likely to defer their choice when the options were both unattractive than when they were both attractive (9% vs. 1%; Wald's $\chi^2 = 18.97, p < .001$, Odds Ratio = .11), but was equally common regardless of the relative attractiveness of the options (4% vs. 5%; Wald's $\chi^2 = .49, p = .48$, Odds Ratio = .74).

Finally, Experiment 6 tested whether giving people the option to delegate reduces choice deferral in situations in which people are otherwise prone to leaving empty-handed. We varied set size and salesperson presence and found a significant interaction between set size and salesperson presence on purchases (Wald's $\chi^2 = 8.90, p < .005$). When a salesperson was not present, fewer participants chose to make a purchase when there were many options than when there were few (37% vs. 64%; $\chi^2(1, 63) = 4.22, p < .05$). However, when a salesperson was present, *more* participants made a purchase when there were many options than when there were few (86% vs. 61%; $\chi^2(1, 69) = 5.13, p < .05$).

The present research provides new insight into the preference for choice determination by showing that the anticipated regret associated with being responsible for a bad choice can overwhelm people's general preference for making their own choices. Moreover, our work shows that the social context and the presence of a potential surrogate have a meaningful effect on consumers' choices, including whether or not to choose in the first place.

Avoiding Information to Protect a Strong Intuitive Preference

EXTENDED ABSTRACT

Rationally, more (relevant) information is better. But consumers sometimes choose to remain ignorant. Consumer behavior research largely conceptualizes information avoidance as a means of protecting emotions (Ehrich and Irwin 2005; Zane, Irwin, and Rezek 2015). The current research broadens this view to include the goal of protecting a preference, developing a theory of information avoidance within the context of intuitive-deliberative conflict.

We predict that when consumers have a strong intuitive desire that conflicts with their deliberative reasoning, they will avoid information in order to protect their intuitive preference. That is, if the information could encourage them to make a "rational" decision, they may avoid the information to make it easier and more likely that they will make the intuitive decision instead. Although people with an intuitive preference may also avoid information to minimize unpleasant emotions or challenges to their beliefs, we demonstrate that avoidance is driven in part by the motivation to protect the decision itself.

A pilot study established intuitive-deliberative conflict for the four situations used in the paper. We defined intuitive preferences for participants as "immediate, intuitive, emotionally-charged, gut reactions (e.g., follow your heart)" and contrasted this with deliberative preferences that result from "slow, deliberate, thoughtful, reasoned reflection (e.g., follow your head)" (Sloman 2014; see also System 1 vs. System 2: Kahneman and Frederick 2002; 2005; Milkman, Chugh, and Bazerman 2009; head vs. heart: Shiv and Fedorikhin 1999). Participants indicated their intuitive preference by answering, "Which option would you choose if you were following your heart?" and their deliberative preference by answering "Which option would you choose if you were following your head?" People's intuitive and deliberative preferences diverged in each of the scenarios ($ps < .001$).

Confirming that our scenarios reflect intuitive-deliberative conflicts, we test the prediction that people avoid information when they hold a strong intuitive preference, but use this information when it is provided. Participants in Study 1 imagined being tempted to order dessert even though they are concerned with healthy eating. Before deciding whether to order dessert, they indicated whether they want to know the dessert's nutritional information. A majority of participants (62.7%) choose not to receive calorie information. However, when assigned to receive information (385, 550, of 700 calories), the information influenced their decision to order dessert ($\beta = -.64, SE = .24, p = .007$), both for those who wanted to receive the information and those who wanted to avoid it.

Study 2A examined information avoidance for a decision with real financial consequences. Participants received a choice between working on a fun task that offered no bonus payment and working on a boring task that paid a real bonus. Before deciding which task to work on, participants indicated whether they wanted to know how much the boring task paid. Even though a majority (62.7%) choose to avoid learning the value of the bonus payment, when assigned to receive this information, it influenced their decision ($\beta = -.99, SE = .41, p = .017$). In a follow-up (Study 2B), we find that avoidance is predicted by the strength of participants' intuitive preference. The stronger participants' intuitive preference for the fun task, the more likely they were to avoid the bonus information ($\beta = .23, SE = .07, p = .002$). Again, as in Study 2A, participants were influenced by the information ($\beta = 1.49, SE = .43, p < .001$), even for those who preferred to avoid it.

Across Studies 3-5, participants decide whether to learn how much money they could earn by accepting an intuitively-unappealing investment (earning money if a sympathetic student performs poorly in a class or if a hurricane hits a third-world country). Although intuitively-unappealing, the investments are financially rational because they only have financial upside. If people avoid information to protect their intuitive preference, then avoidance should be more likely when an intuitive preference is especially strong and when information could influence the decision. In Study 3, we find that the strength of the intuitive preference moderates information avoidance. People who could earn money if a student performed poorly in class were more likely to avoid learning how much they would win than those who could earn money if the student performed well (57.8% vs 42.9%; $\chi^2(1, N = 200) = 4.49, p = .034$).

In Study 4A, we test whether information is avoided more when it can influence a decision (i.e., a decision has not yet been made) than when it cannot (i.e., a decision has already been made for participants). Participants imagined choosing a retirement plan. One plan included a "catastrophe bond" which would payout in the event of a hurricane striking a third world country. People were more likely to avoid learning how much this bond paid out when they had to make a decision about which plan to invest in than when they were automatically enrolled in the plan with this bond (58.4% vs. 41.4%; $\chi^2(1, N = 200) = 5.78, p = .016$). In a follow-up (Study 4B), learning the payout of the cat-bond influenced participants to make the financially rational decision (enroll in the plan with the cat-bond).

Study 5 tested this prediction for a consequential decision. Conceptually replicating Study 4A, participants avoided information more when they had a decision to make (i.e., to accept or refuse a bet that a student performs poorly) than if they were automatically assigned to accept the bet (61.2% vs. 43.4%; $\chi^2(1, N = 197) = 6.25, p = .012$).

Overall, we find that consumers avoid information to protect an intuitive preference, and that they are most likely to do so when the information is most valuable to have. When people have a strong intuitive preference that conflicts with a deliberative response, people avoid information that would make it harder for them to follow their intuition. Despite avoiding this information, people incorporate it into their decision when it is provided, suggesting that people may make a mistake, either in avoiding information they would otherwise use, or in using information they would prefer to avoid.

Disclosure and the Dog That Didn't Bark: Consumers Are Too Forgiving of Missing Information

EXTENDED ABSTRACT

According to rational disclosure theory, if there is an information asymmetry between two parties, and if the knowledgeable party can provide their private information credibly, then, unless the information is the worst possible from the perspective of the less knowledgeable party, they will disclose it. Similarly, the less knowledgeable party should interpret any failure to disclose as being due to the missing information being the worst possible. This is the central premise for 'unraveling' theory (Brown, Camerer and Lovallo 2012; Grossman and Hart 1983). We test unraveling theory in five experiments in which (mock) doctors decide how much of their record to disclose, and (mock) patients evaluate those doctors. The information of interest concerns the doctor's trustworthiness and any conflicts of interest he or she has. We find, contrary to standard theory, that (a) doctors almost always withhold even mildly negative information, and (b) patients are relatively unresponsive to that missing information, so that they judge doctors with missing informa-

tion as being fairly average on the missing dimension rather than, as unraveling theory would predict, very poor, and are just as likely to select doctors with missing information to care for them as doctors with good levels of present information. When asked, the doctors largely assume patients will not infer much from missing information, and believe that expressing it will be bad for business. We test whether the responses of patients are due to not noticing the missing information (salience hypothesis) or due to interpreting the missing information in an unduly positive light, even when its absence is noticed (charitability hypothesis). We find evidence for both salience and charitability effects. As the absence of information is made increasingly salient, first by adding empty boxes onscreen where missing information should be, then by indicating the doctor "declined" to provide the information in the box (and so on), patients judge the doctor as increasingly worse, supporting the salience hypothesis. But patient judgments never get close to the "worst possible" suggested by theory, and even when they directly reflect on the missing information and estimate the absent value they rate the doctor as much better than the worst possible on those dimensions. To encourage patients to make more rational inferences from withheld information, we created an intervention in which some patients were asked how likely doctors with high, medium, or low ratings would be to release their information, thus making salient the relationship between the service providers' quality and their likelihood to release versus withhold information. This manipulation brought patients' judgments closer to that predicted by the rational model: Compared to patients in the control condition, those in the intervention condition estimated that a doctor with a missing "patient satisfaction rating" received a lower rating and were less likely to choose that doctor. These findings reveal a different equilibrium for voluntary disclosure than unraveling theory would predict, and show that mandatory disclosure rules are likely to be essential if we wish to ensure consumers make informed decisions. In the absence of mandatory disclosure rules, an intervention that help consumers think more deeply about the lack of missing information can help them make the inferences in line with unraveling theory.

Graphic Warning Labels Curb Purchasing of Sugar-Sweetened Beverages

EXTENDED ABSTRACT

Consumption of sugar-sweetened beverages (SSBs) contributes to obesity (Ludwig, Peterson, and Gortmaker 2001) and has been linked to other health problems including diabetes (Schulze et al. 2004), heart disease (Fung et al. 2009), and dental caries (Heller, Burt, and Eklund 2001). To reduce purchasing and consumption of SSBs, several municipalities and states have proposed warning labels. San Francisco recently passed a policy, although not yet implemented, requiring text-warning labels on SSB advertisements (Wiener, Mar, Cohen and Avalos 2015).

How might warning labels impact SSB purchasing? They aim to educate consumers about the health risks associated with SSBs and increase their salience at the point of beverage selection. Indeed, research shows that text warning labels on tobacco products are associated with increased perception of health risks, motivation to quit, and sustained abstinence (Hammond 2011). However, informing people that their behavior is self-harmful does not always lead to positive change. In order to be effective, health information must be noticed, understood, and incorporated into the decision process while overcoming any cognitive biases or preferences toward unhealthy choices (Downs, Loewenstein, and Wisdom 2009). It is not

clear whether SSB text warning labels meet these criteria in the real world.

Prior research underscores the limits of information provision in inducing healthy behavior change (e.g., past research finds mixed evidence on whether calorie labels reduce purchasing of calories; Downs et al. 2013). Unlike calorie labels, however, text-warning labels *also* convey direct information about potential harm to health—which might increase their potency.

Health information *can* induce behavior change when communicated in a salient and intuitively comprehensible way (Korff et al. 2013). The potency of nutritional information is enhanced when conveyed in a simple red-yellow-green scale (Thorndike et al. 2012), and when calories are expressed in physical activity equivalents (Bleich, Barry, Gary-Webb, and Herring 2014). Such translation is even more compelling when it triggers a visceral response (Loewenstein 1996). Visually evocative cigarette warnings are more likely to be noticed and elicit negative visceral responses, perhaps helping to increase their effectiveness (Terry-McElrath et al. 2005). This suggests an opportunity to improve SSB warning labels.

Given the lack of field studies testing text or graphic SSB warning labels, we conducted a field experiment on the impact of calorie, text warning, and graphic warning labels on SSB purchasing.

The field experiment occurred in a hospital cafeteria in Massachusetts beginning with a two-week baseline to collect beverage sales data. Next, each SSB labeling intervention ran for two weeks, each followed by a two-week washout period when no labels were displayed. The hospital defined SSBs as any beverage with more than 12 grams of sugar per container (excluding milk and 100% juice). Drinks not meeting these criteria were not labeled.

The calorie label followed an FDA regulation and read: “120–290 calories per container. 2,000 calories a day is used for general nutrition advice, but calorie needs vary.” The text warning label used the language that will be implemented in San Francisco: “WARNING: Drinking beverages with added sugar(s) contributes to obesity, diabetes, and tooth decay.” The graphic warning label included the same text but also included images portraying obesity, diabetes, and tooth decay.

Our primary outcome measure was the daily proportion of bottles purchased that were SSBs. For secondary outcomes, we assessed changes in absolute beverage sales, beverage calories sold, and share of drink types.

During the study period an average of 2,617 ($SD = 323.2$) bottled drinks were purchased weekly (NS between weeks), approximately 21% of which were SSBs. During baseline, 21% of purchased drinks were SSBs, statistically indistinguishable from the share during both calorie (21%, $p = 0.99$) and text warning label (21%, $p = 0.94$) treatments. However, during the graphic warning labels treatment, the share of SSBs purchased decreased to 18%—a 14 percent reduction relative to baseline ($p < .01$). It was also significantly lower relative to both the calorie ($p < 0.01$) and text warning labels ($p < .01$). With the graphic warning label, the average calories per drink purchased dropped from 87 in baseline to 74 ($p < 0.001$). The substitution analysis indicated that during the graphic warning treatment, the proportion of water drinks purchased rose from 24% to 28% ($p < .01$), while the tendency to buy other drink types went unchanged. Therefore, it seems that graphic warning labels caused some consumers to buy water drinks in lieu of SSBs.

Our findings suggest that graphic warning labels reduce SSB purchasing, whereas calorie and text warning labels do not, and we find that this reduction is accompanied by a shift towards water drinks. We also find that SSB purchasing rebounded to baseline after

the graphic warnings were removed, which suggests the need for continued and salient exposure.

These findings suggest that evocative and visceral health warnings are much more effective at encouraging behavior change than messaging that appeals to intellect by providing information.

SESSION OVERVIEW

Power is defined by the asymmetric control over valued resources in a social relationship (Magee and Galinsky 2008). Although a significant amount of research has provided important insights on the consequences of power states and their implications for consumer behavior, little is known regarding the lay theories that underlie how consumers think about and are influenced by power states (Galinsky, Rucker, and Magee 2015). In this session, we bring together some of the leading researchers on power to present four papers demonstrating the interplay between power and lay theories in influencing consumer behavior. Across these papers, we discuss, (a) What are the lay beliefs that people have regarding the associations between brand power and other brand images? (b) How do perceptions of power differentials in a society influence the heuristics (i.e., lay theories) that people develop to make inferences about numeric information? (c) Why might feeling powerful magnify the influence of lay theories that people apply when making attributions? (d) How do consumers' lay theories on the changeability of their current power state (i.e., entity theorists vs. incremental theorists) moderate a motivational consequence of feeling powerless?

The first paper by Stoner and Torelli discovers that one means through which brands embody power is through perceptions of market dominance. However, brands with a warm image will be perceived as less market dominant and, thus, less powerful. This effect occurs because consumers hold the lay belief that being warm is in conflict with being powerful.

The second paper by Barone, Li, Lyle, and Winterich proposes that recognizing power differentials in a society can stimulate a vertical orientation, which in turn impacts the heuristics that consumers apply when judging the difference between vertically presented original price and deal price. Specifically, consumers with a vertical orientation tend to infer that vertically presented original and deal prices are very different from each other, regardless of their actu-

al difference. As a result, consumers with high vertical orientation judge small deals to be equally attractive as large deals.

The third paper by Kim, Han, Rucker, and Duhachek demonstrates that feeling powerful can magnify the influence of lay theories of attributing success to oneself and attributing failure to others (i.e., fundamental attribution error). Consequently, when encountering a self-failure, individuals who feel powerful generate stronger negative emotions of anger. When encountering a self-success, individuals who feel powerful also generate stronger positive emotions of pride.

The fourth paper by Xu, Shavitt, and Rucker explores the moderating role of lay theories (entity theorists vs. incremental theorists) in understanding a motivational consequence of feeling powerless. They propose and find that being in a state of low-power motivates individuals to change their current aversive state, and this motivation spills over to increase their preferences for messages or products signaling change over neutral ones or those signaling consistency. Moreover, the allure of change only holds for consumers who chronically believe, or have activated, the lay theory that their current (low power) state will not change naturally (i.e., entity theorists). That is, when people view their states as fixed, they seek change in power-irrelevant domains.

Given the important role of power in people's daily lives and the variety of novel findings uncovered by leading scholars in this research area, this session should be of interest to a diverse audience, from academics studying power to those researching branding, advertising, and pricing more broadly. Making connections between two research areas on power and lay theories also provides important avenues for future research.

Too Nice to Be Dominant: How Warmth Impacts an Embodiment of Power in Brands

EXTENDED ABSTRACT

A variety of constructs from psychology have been applied to brands (Aaker 1997, Torelli et al. 2012). The construct of power has yet to be applied to brands. What is a "powerful brand"? How are perceptions of power for a brand built?

In a pilot study, we discover that one means through which brands embody power is through perceptions of market dominance. This study confirms that a perception of market dominance is significantly correlated with an overall perception of brand power ($r = .62$). Therefore, we find it valuable to understand how consumers form perceptions of market dominance.

Research has shown that consumers are unaware of brands' market dominance (Kamins, Alpert, and Perner 2007), but even misperception as a market leader leads to positive consumer evaluations (Kamins, Alpert, and Perner 2003). Past research demonstrates that brand images can be used as cues for inferences regarding product quality (Jacoby, Olson, and Haddock 1971) and brand extensions (Aaker and Keller 1990). We hypothesize that when consumers are lacking direct knowledge about a brand's market dominance, the brand's image is used as an inference cue: specifically, brands with a warm image will be perceived as less market dominant.

Research shows that powerful people, a desire for leadership and perceptions of leaders have been related to dominance and dominant behaviors (Fragale, Overbeck, and Neale 2011; Lord, De Vader,

and Alliger 1986), which we propose conflicts with the image of high warmth brands (Aaker, Garbinsky, and Vohs 2012). We hypothesize and find that consumers perceive high warmth brands as being less market dominant due to market dominance's embodiment of power. Because competitiveness is believed as necessary for market dominance (Stalk, Evans, and Shulman 1992) and warmth has been negatively related to competitiveness (Fiske et al. 2002; Fiske et al. 1999; Russell and Fiske 2008), we further hypothesize that the negative impact of brand warmth on perceptions of market dominance is driven by decreased perceptions of market competitiveness.

Six experiments were conducted to investigate the impact of warmth on consumers' perceptions of market dominance. Studies 1 and 2 use real and fictitious brands to find evidence for our main hypothesis: warmth can negatively impact perceptions of market dominance. Study 3 explores perceptions of competitiveness as the mechanism behind our effect. Study 4 and 5 explore the boundary conditions and test the moderating roles of a) compatibility between warmth and dominance, and b) product category knowledge. Finally, Study 6 demonstrates downstream implications of this effect for brand preferences.

In Studies 1 and 2, we use real (Study 1) and fictitious brand (Study 2) in four product categories: cough syrup and fabric softener (Study 1) and pens and adhesive bandages (Study 2). Each participant was presented with two brands from each category: a high warmth brand and a low warmth brand. Participants were asked to estimate the market share of each brand. Consistent with our hypothesis, the high warmth brands were estimated to have lower market shares (Study 1: $M_s = 21.30$ vs 30.73 , $F(1, 103) = 26.62$, $p < .001$; Study 2: $M_s = 15.83$ vs 20.30 , $F(1, 80) = 21.94$, $p < .001$).

Study 3 builds on the first two studies by demonstrating that the effect of brand warmth on perceptions of market dominance is driven by reduced perceptions of competitiveness. This study used the cough syrup brands from Study 1 and scale measures of perceptions of competitiveness and market dominance. Again the high warmth brand was judged to be less market dominant ($M_s = 3.95$ vs 4.85 , $F(1, 102) = 10.98$, $p = .001$). Furthermore, this effect was significantly mediated by perceptions of competitiveness (95% CI of the indirect effect = $-.47$ to $-.02$).

Study 4 finds the effect disappears if the conflict between warmth and dominance is resolved. Participants completed either a neutral control sentence scramble task or one with sentences communicating compatibility of warmth and dominance (e.g. "The helpful nurse won the trophy"). Participants were asked the market share of the pen brands from Study 2. The interaction of compatibility and brand was significant ($F(1, 99) = 4.14$, $p < .05$). The high warmth brand was less market dominant than the low warmth brand ($M_s = 19.65$ vs 23.74 , $t(99) = 1.91$, $p = .06$) in the control condition, but this effect was attenuated in the compatibility condition ($M_s = 21.76$ vs 19.73 , $t(99) = 0.96$, *ns*).

In Study 5, we investigate category knowledge as a boundary condition. We used real brands in the product category, soup, where knowledge is highly variant for our college student participants. Consumers with high category knowledge should be more reliant on their own knowledge and less on inferential cues such as brand image. Thus, the high warmth brand image should not have the same negative impact on market dominance for knowledgeable consumers. Therefore, knowledge should positively predict perceptions of market dominance for a high warmth, market dominant brand. We find that category knowledge is a predictor of market dominance for a dominant, high warmth brand ($\beta = .41$, $t(55) = 3.79$, $p < .001$), but not for a low warmth brand ($\beta = .10$, $t(55) = .94$, *ns*).

Our final study demonstrates the downstream consequences of this effect on brand preference. Prior literature finds that dominant brands are preferred only when the choices are self-relevant (Kim et al 2008), therefore, high warmth brands that are perceived as being low in dominance should decrease brand preference in high self-relevant condition, but not in the low self-relevant condition. Participants picked products either to try themselves (high self-relevant) or for others to try (low self-relevant). They then viewed pairs of brand pictures for four product categories that communicated either high or low warmth. Participants responded with their brand preference on a 9-point scale (1 = Definitely Brand A, 9 = Definitely Brand B). Again, the high warmth brands were perceived as less dominant, but they were evaluated less favorably only in the high self-relevant condition ($M_s = 5.77$ vs 5.20 , $F(1, 124) = 6.35$, $p < .05$).

Turning a Blind Eye: When Views of Power Differentials Increase Deal Attractiveness

EXTENDED ABSTRACT

Across online retail websites and in-store displays, the regular price and sale price are frequently presented together, usually with one above or below the other. Although presenting prices vertically might be an unstated norm, the current research suggests that businesses may benefit from such presentations without offering a heavy discount. This research examines a novel factor that affects consumers' evaluations of deals with vertically presented prices: a vertical orientation (i.e., knowledge structure reflecting power differentials; Oyserman 2006).

High- (vs. low) vertical individuals possess strong associations between power differential and spatial locations, which likely guides information processing (Briley, Wyer, and Li 2014; Shavitt et al. 2009). Specifically, since vertical layout is associated with differentials in power, status, and standing in the minds of high- (vs. low) vertical people, high- (vs. low) vertical people likely infer that entities (e.g., prices) in vertical layouts must possess different levels of power, status, and standing (e.g., magnitude). Since the difference in price magnitude between regular and sale prices is inferred from merely the layout, the actual sale information is not attended to and the deal depth (difference between the regular price and sale price) is not processed systematically by high- (vs. low) vertical people. We hypothesize that for vertical layouts low-vertical people respond more favorably when deal depth is high than low and high-vertical people are indifferent of deal depth, and for horizontal layouts both high and low vertical people respond more favorably when the deal depth is high than low. In particular, the effect on vertical layout is driven by low-vertical (high-vertical) people's greater (equal) attention to sale price and higher (equal) motivation to process the deal when deal depth is high than low.

In study 1, participants ($n = 200$ undergraduate students) first responded to a scale that measured vertical orientation (Triandis and Gelfand 1998), and then reviewed a pizza cutter advertisement with regular price \$7 and sale price \$5. There were two versions for the advertisement: a vertical layout where sale price was below regular price and a horizontal layout where sale price was alongside the regular price. Finally, participants indicated their purchase likelihood of the pizza cutter. Regressing verticality (continuous), deal depth ('0' for low, '1' for high), layout condition ('0' for horizontal, '1' for vertical), and all possible interactions on purchase likelihood revealed a significant verticality \times layout \times deal depth interaction ($F(1, 192) = 4.14$, $p = .04$). The results showed that when price information was presented horizontally, both high- (+1 *SD*) and low- (-1 *SD*) vertical participants are more likely to purchase the pizza cutter when the

deal depth is high than low (high-vertical: $B = 2.18, t = 3.21, p < .001$; low-vertical: $B = 1.14, t = 1.59, p = .11$). More importantly, consistent with our hypothesis, when the prices were presented vertically, high-vertical participants (+1 *SD*) are equally likely to purchase the pizza cutter regardless of deal depth ($B = -.13, t = -0.20, p = .84$), but low-vertical participants (-1*SD*) are more likely to purchase the pizza cutter when the deal depth is high than low ($B = 1.57, t = 2.56, p < .05$).

Study 2 was similar to earlier studies but examined attention to sale price as a mediator to test the underlying mechanism. Participants ($n = 130$ mTurk workers) responded to the vertical orientation scale, viewed a pizza cutter advertisement with a vertical layout that varied in deal depth (high vs. low), indicated likelihood to purchase the pizza cutter, as well as how much attention they paid to the sale price. Regression analysis revealed a significant verticality \times deal depth interaction ($F(1, 124) = 4.49, p = .04$). As hypothesized, low-vertical participants (-1*SD*) are more likely to purchase the pizza cutter when the deal depth is high than low (-1 *SD*: $B = 2.22, t = 4.36, p < .01$), whereas high-vertical participants (+1 *SD*) are equally likely to purchase the pizza cutter regardless of deal depth (+1 *SD*: $B = .71, t = 1.41, p = .16$). In addition, attention to the sale price mediated the interaction of verticality \times deal depth on purchase likelihood (Hayes 2015; Model 8; indirect effect = $-1.99, se = 1.40, 90\% CI: -4.9735$ to $-.1835$). These results support that high- (vs. low) vertical consumers rely on the layout instead of sale price to when processing deals.

Study 3 ($n = 118$ undergraduate students) replicates this pattern when vertical orientation is temporarily activated. In the high (low) vertical condition, participants were asked to select two out of three statements taken from the vertical orientation scale (e.g., one should respect the decisions made by others who are more competent) with which they most agreed (disagreed) and to write a short paragraph detailing the reasons for their agreement (disagreement). Next, participants examined a promotion for dental floss in a vertical layout that varied in deal depth (high vs. low). Finally, participants indicated their deal evaluations, as well as how motivated they were while processing the price comparison. A 2×2 ANCOVA revealed a significant verticality \times deal depth interaction ($F(1, 59) = 4.09, p < .05$). Specifically, low-vertical participants were more likely to purchase the floss with a large ($M = 4.48, SD = .39$) than small ($M = 3.30, SD = .30$) deal depth ($F(1, 114) = 5.74, p = .02$). However, high-vertical participants were equally likely to purchase the floss with a large ($M = 2.84, SD = .30$) or small deal depth ($M = 3.41, SD = .39; F(1, 114) = 1.34, p = .25$). Also, processing motivation mediates the effect of verticality \times deal depth on purchase likelihood (Model 8: indirect effect = $-.4777, se = .29, 95\% CI: -1.2117$ to $-.0315$).

The current research adds to the literature that vertical orientation guides information processing in spatial space (Moeller et al. 2008; Robinson et al. 2008). Specifically, high (vs. low) vertical individuals assume price differentials upon seeing vertical layouts without processing information related to deal depth.

The Effects of Power on Emotional Responses to Self-Failure and Self-Success

EXTENDED ABSTRACT

Previous research suggests that power influences one's expression and experience of emotions (Berdahl and Martorana 2006; Keltner et al. 2003; Van Kleef et al. 2006). Specifically, high power results in increased positive emotions, whereas low power leads to elevated negative emotions. However, scant research has examined how power influences the experience of specific negative emotions. To fill this gap, the current research finds a context in which power

affects discrete negative emotion with a focus on anger and suggests that high power leads to greater anger when individuals encounter self-failure. The current research focuses on anger because the previous literature on anger in the context of self-failure suggests two competing predictions. Thus, the current research aims at resolving these competing predictions.

According to cognitive-appraisal theories of emotion (Lerner and Keltner 2001; Smith and Ellsworth 1985), individuals feel angry when they believe that others are responsible for negative outcomes or have high control over negative events (Averill 1983). Given that individuals in high power positions (i.e., leaders) feel more responsible for and control over a task than those in low power positions (i.e., employees, Anderson and Berdahl 2002), one may predict that high power will lead to reduced anger in the face of self-failure. However, given that increased power activates approach-related tendencies due to increased rewards and freedom whereas decreased power activates inhibition-related tendencies due to elevated threat, punishment, and social constraint (Keltner et al. 2003) and that anger is associated with an approach orientation (Labroo and Rucker 2010), one may posit that individuals in high power will feel greater anger when encountering self-failure. To resolve these two opposite predictions, the current research empirically examines the effect of power on anger in the self-failure contexts.

Additionally, this research suggests these emotional differences elicited by different levels of power are contingent on whether the task outcome is positive or negative. Specifically, we focused on pride (anger) as a focal positive (negative) emotion and examined how high power influences pride (anger) when individuals have success (failure) as an outcome. Prior work revealed that high power leads individuals to have agentic orientation because those who have high power are less dependent on others due to the greater ability and freedom (Rucker et al. 2012). Agentic orientation results in "self-protection, self-assertion and self-expansion" (Bakan 1966, p. 14-15). Thus, individuals with high power will be more likely to attribute one's success to them. According to self-agency appraisals, one feels pride when attributing positive outcomes to the self (Agrawal et al. 2013). Therefore, we posit that when facing a success, high (vs. low) power will lead to greater pride.

Study 1 examined the effects of power on anger when encountering the individual task failure to resolve the competing hypotheses. We predict that individuals in high (vs. low) power will be more likely to exhibit anger in the context of failure in the individual task. Although low (vs. high) power results in a more negative mood, we argue that high power may amplify the experience of anger when coupled with self-failure. It is because individuals in high power would be motivated to solve the negative events driving failure whereas those in low power would be less motivated (Keltner et al. 2003), and anger might help to solve the problem since it facilitates an effort to overcome the violation of what ought to be (Fischer and Roseman 2007). Participants were assigned to either the high or low power condition. We manipulated high (low) power by asking them to imagine to be a boss (employee) at a company. They read about the role and were instructed to vividly imagine that what it would be like to be in this role (Rucker, Dubois, and Galinsky 2011). After, all participants were asked to solve five insight problems and were informed that their score would be reported to them after completion. After 30 seconds of completion, all participants read that they failed the test. Next, participants indicated the degree to which they felt angry after learning about their test results (frustrated, angry, and irritated; Richins 1997). A one-way ANOVA with power as the independent variable and anger as the dependent variable revealed that

participants in the high power condition felt angry to a greater extent than did those in the low power condition ($p < .05$).

Study 2 investigated whether an outcome of the task (i.e., success versus failure) moderates the effects of power on emotions. In this study, participants were randomly assigned to one of four conditions in a 2 (Power: high vs. low) \times 2 (Outcome: success vs. failure) between-participants design. The power manipulation was identical to that in Study 1. However, in the success condition, participants were told that they passed the test. A two-way ANOVA as power and outcome as the independent variables and anger as the dependent variable a significant interaction ($p < .05$). Simple contrasts revealed that in the failure condition, participants in the high (vs. low) power condition reported anger to a greater extent ($p < .05$). However, in the success condition, there was no difference between high and low power conditions ($p > .7$). In addition, a two-way ANOVA as power and outcome as the independent variables and pride as the dependent variable a significant interaction ($p < .05$). Simple contrasts revealed that in the success condition, participants in the high (vs. low) power condition reported pride to a greater extent ($p < .05$). However, in the failure condition, there was no difference between high and low power conditions ($p > .2$).

Overall, our findings contribute to the consumer literature by providing evidence to understand the relationship between power and consumer's emotional responses to an outcome in a task as a function of the valence of the outcome.

Captivated by Change: A Motivational Consequence of Feeling Powerless

EXTENDED ABSTRACT

For generations, brands have used advertising appeals that position their products around change from the status quo. Apple's iconic "1984" commercial introduced the Macintosh personal computer as a heroine that gave humanity an alternative to conventional computers. Yet, surprisingly, little research exists on factors that affect whether and when consumers are receptive to persuasive appeals that emphasize change.

In this work, we explore how a critical psychological factor— one's sense of power— affects consumers' response to the idea of change. Given the aversive nature of a low-power state (Rucker and Galinsky 2008), we propose that being in a state of low-power triggers a desire, even unbeknownst to consumers, for change. As a consequence, triggering a low-power state in consumers can increase consumers' preferences for messages or products that signal the prospect for change over neutral ones or those that signal consistency. Moreover, we reveal this association is dependent upon consumers' implicit theories of whether their current states will naturally change. The allure of change only holds for consumers who chronically believe, or have activated, the implicit theory that their current (low power) state will not change naturally (i.e., entity theorists). Consequently, they seek messages or products that signal change. We conducted five experiments to test the above hypotheses.

Experiment 1 tested the automatic link between a low-power state and enhanced evaluations of change-related constructs using an Implicit Association Test (IAT). We first manipulated high versus low power by asking participants to recall a previous personal experience in which they felt powerful or powerless (Galinsky, Gruenfeld, and Magee 2003). Participants then completed a valence IAT (Greenwald, McGhee, and Schwartz 1998; Richeson and Ambady 2003) in which they categorized words from four categories including *change* (e.g., alteration, adjustment, shift), *stability* (persistent, enduring, lasting), *good* (joy, love, peace), and *bad* (agony, terrible, horrible)

in two main blocks of test trials. This study found that transient feelings of low power made change constructs evaluatively more positive and made stability constructs evaluatively more negative. This provides the first piece of evidence suggesting that a low-power state enhances the preference for things that symbolize change.

Experiment 2 investigated whether power affects conscious decisions that reveal a preference between change from the status quo and stability of the status quo. Power state was manipulated via the same power recall task as in experiment 1 and then reinforced by a Bonus Allocation Game in which participants played the role of either a powerful boss who made bonus allocation decisions for employees, or a powerless employee who indicated how much bonus she/he expected to get. In a subsequent consumer survey, participants saw twenty-seven adjectives that can describe the characteristics of suits, a third of which implied change/being different (i.e., trendy, up-to-date, recent), a third implied no change/staying the same (i.e., classic, standard, timeless), and a third were neutral (i.e., tidy, striped, lightweight). Participants were asked to check five adjectives that could best describe what they would find appealing if they were shopping for a new suit for themselves. The results revealed that participants placed in a low-power (compared to high-power) state chose more adjectives implying change/being different, fewer adjectives implying no change/staying the same, and the same number of neutral adjectives.

Experiment 3a and 3b explored the moderating role of people's implicit theory regarding the extent to which they believe their current states would change naturally. By both manipulating (experiment 3a) and measuring (experiment 3b) people's implicit theory, we demonstrated that the influence of low-power states on preference for change-signaling messages emerges among entity theorists, but not among incremental theorists. In experiment 3a, participants were randomly assigned into one of four conditions with a 2 (power: high vs. low; between-subjects) \times 2 (implicit theory: entity theory vs. incremental theory; between-subjects) \times 2 (slogan theme: change vs. control; within-subjects) mixed design. To manipulate participants' implicit theory, they read an excerpt from a news article, which supported either the entity theory or the incremental theory, and then wrote an essay to support the claims of the article (Park and John 2014). Participants' high versus low power state was manipulated by the same power recall tasks. Finally, participants evaluated four slogans embedded in banner ads that were designed for two brands, IBM and Panasonic. For each brand, one slogan indicated change whereas the other was the control. We calculated a relative preference for change index by subtracting the average evaluations of two control slogans from the average evaluations of two change slogans. A greater value indicated a stronger preference for change slogans. Analyzing this relative preference for change index as a function of power and implicit theory in ANOVA yielded a significant power \times implicit theory interaction. Planned contrasts indicated that primed entity theorists had a stronger preference for change slogans in the low-power condition than in the high-power condition. In contrast, among primed incremental theorists, power did not influence their preference for change slogans, *ns*. Experiment 3b used a similar design and measured participants' implicit theory. The results replicated Experiment 3a.

A final experiment replicated the basic effect of low power on motivation to seek signals of change, and also showed as expected that the effect was specific to the aversive state of low power and did not emerge for a more malleable negative state (negative mood induction).

SESSION OVERVIEW

This special session highlights recent research about social exclusion and consumer behavior in four diverse and impactful contexts: visual marketing, probabilistic selling, environmental behavior, and moral identity. Social exclusion (being alone, isolated, or ostracized) and loneliness are common experiences that shape consumer behavior (Duclos, Wan, and Jiang 2013; Lee and Shrum 2012; Mead et al. 2011; Wan, Xu, and Ding 2014; Wang, Zhu, and Shiv 2012). Although the existing research has greatly advanced our knowledge, some critical and important questions have yet to be unanswered. In particular, the research highlighted in this session answers questions about the effects of social exclusion on critical marketing activities and substantive problems facing society. For the former, how does feeling excluded influence judgement and decision making about visual marketing elements (e.g., density of a design pattern) and sales promotion practices (probabilistic selling)? For the latter, how does social exclusion influence pro-environmental behaviors like sustainable consumption and moral identity?

The first paper, by Su, Wan and Jiang, examines the relationship between social exclusion and visual density preference. The authors demonstrate that consumers who perceive themselves as socially excluded prefer products with visually-dense patterns more than their peers who do not feel socially excluded, and that the effect is mediated by feelings of emptiness.

The second paper, by Fan and Jiang focuses on studying the relationship between social exclusion and attitudes towards probabilistic selling. Probabilistic selling is when consumers are given the opportunity to purchase a product 'blind', knowing only broadly what they will receive. For example, an overseas holiday, but without knowing the destination. Social exclusion and probabilistic selling both involve a loss of control. As social exclusion dampens people's sense of control, and people always have a desire to defend against a loss of control, social exclusion was found to decrease consumers' favorability for probabilistic selling.

The third paper, by Naderi and Mead examines the influence of social exclusion on pro-environmental behavior. They examined competing mechanisms for the effect: reduced empathy (which has been shown to reduce helping) and willingness to sacrifice for society. They found that excluded people become reluctant to engage in pro-environmental behaviors because they are not willing to incur costs for the benefit of society, thereby shedding new light on the mechanisms through which social exclusion may impair other-oriented behavior.

Finally, the last paper, by Jiao and Wang investigates the impacts of loneliness in the context of moral behaviors. It reveals that, when participants are lonely, those with high (vs. low) empathy had higher moral identity. The paper has implications for moral consumption and draws further attention to the role of loneliness, an increasing phenomenon, on consumer behavior.

Taken together, these four papers shed light on how social exclusion and loneliness may influence and inform important marketing practices and timely societal problems. Given that the experience of social exclusion and loneliness is becoming increasingly prevalent, the session will be of interest to a broad audience at the Association for Consumer Research conference 2017.

How The Experience of Social Exclusion Influences Visual Density Preference

EXTENDED ABSTRACT

The experience of social exclusion is a painful but common part of our daily life. People often feel rejected, ignored, or left alone by individuals or social groups (Baumeister et al. 2005; Williams 2007). As social interaction is one of the most universal and fundamental human needs, social exclusion significantly impacts people's psychological and physiological functioning (DeWall and Baumeister 2006; Twenge et al. 2001; Williams 2007). The current research looks at a novel impact of social exclusion on consumer behavior: a preference for visual density involved in product aesthetic design.

We first propose that social exclusion will result in a feeling of emptiness – a sense of an inner void caused by perceived self-incompletion or a missing part of the self (Austin 1989; Bronstein 2014; Hazell 1984). Social exclusion effects two aspects of the self-concept; the personal self (aspects that differentiate one's self), and the relational self (aspects that reflect assimilation to others or significant social groups) (Sedikides and Brewer 2001). First, based on prior literature (Williams 2007), social exclusion threatens individual's values and sense of meaningful existence, which are basic elements of the personal self (Schulenberg et al. 2010). Secondly, social exclusion deprives individuals of their social interactions (Warburton and Williams 2005) dampens their sense of belongingness (Mead et al. 2011; Williams 2007), which constitute the relational self (Aron and Aron 1986).

Across the personal and relational selves, social exclusion leads to a loss in meaningful existence, belongingness, and connectedness. This triggers the feeling part of self-identity is missing, which is felt as emptiness. Emptiness is a *psychological* state of inner void, with the opposite state being a psychological perception of fillingness (Hazell 1984). Emptiness is unpleasant and painful; hence people

are motivated to suppress or remove the unappealing feeling of emptiness by metaphorically “filling in” their inner void.

Visual density refers to the number of visual elements or units contained in a unit area of a visual image (Geissler, Zinkhan, and Watson 2006; Morrison and Dainoff 1972; Rosenholtz, Li, and Nakano 2007). Embodied cognition states sensory input or bodily sensations -such as visual density- are metaphorically linked to cognitive or abstract thoughts (Landau, Meier, and Keefer 2010; Krishna and Schwarz 2014). We posit that visually-dense patterns provide a *visual* sense of fullness, which metaphorically compensates for the *psychological* need for filling psychological emptiness among socially excluded people. Stated formally,

Hypothesis 1: Socially excluded consumers have higher preference toward visually-dense patterned products than socially included consumers.

Hypothesis 2: Socially excluded consumers will have stronger feelings of emptiness than socially included consumers, which will mediate the effect of social exclusion on attitude for visually-dense patterned products.

Four experiments were conducted to test these possibilities.

First we tested the proposed effect by examining participants' real behavior. Participants (N = 154) were first randomly assigned to one of three conditions (exclusion, inclusion, and neutral) to prime social exclusion with a recall task (Mead et al. 2011). Next, the participants were requested to design a visual pattern for a smartphone case for themselves with a stamp. We measured the number of stamps each participant put on their smartphone case and found that social exclusion led participants to put a larger number of visual stamps on their smartphone cases (i.e., denser visual designs), than their counterparts in the socially included or neutral conditions.

Experiment 2 tested the proposed underlying mechanism of the feeling of emptiness by directly testing its mediational role. A 2 (exclusion vs. inclusion) × 2 (dense-patterned vs. sparse-patterned product) between-subjects design was used (N=158). We first manipulated social exclusion versus inclusion with the Cyberball game (Williams et al. 2000). Participants then rated their feeling of inner emptiness on three items (e.g., “I feel empty inside”; “I feel as though part of me is missing”; Poreh et al. 2006). They also reported their mood (Williams et al. 2000). Finally, participants were presented with and requested to rate either a dense-patterned or sparse-patterned T-shirt. The socially excluded consumers had a higher attitude towards the dense-patterned products than the socially included ones. No difference was found regarding sparse-patterned products. More importantly, the results from PROCESS 14 revealed that feelings of emptiness, not mood, mediated the evaluation of dense-patterned products.

In experiment 3, we further tested the filling-in-the-inner-emptiness mechanism by introducing a physical filling action as the moderator. A 2 (exclusion vs. inclusion) × 2 (filling vs. emptying action) between-subjects design was used (N=165). After manipulating social exclusion versus inclusion and measuring feeling empty, we had participants either fill or empty a water bottle. Afterwards, all participants evaluated a dense-patterned painting composed of various elements clustered in the center. While the effect of social exclusion was replicated in the emptying condition, we found that filling in the water bottle weakened the effect as it at least partially fulfilled the excluded participants' need for filling in their sense of emptiness.

In experiment 4, we extended our results by providing a different opportunity to fill the inner emptiness. A 2 (social relationship: exclusion vs. inclusion) × 2 (temporal density: busy vs. control) between-subjects factorial design was used. After manipulating social exclusion versus inclusion, the participants' sense of temporal density was too manipulated using a survey about life (Kim et al. 2015). Afterwards, all the participants evaluated a dense-patterned curtain. While social exclusion effect was replicated in the control condition, we found the social exclusion effect weakened if participants perceived themselves having a lot of tasks packed into a busy schedule.

Our research findings offer novel insights into how and why social exclusion leads to a preference for visually-dense patterned products. They add to the repertoire of behavioral consequences of social exclusion, and identify emptiness as a new psychological consequence of exclusion. This research also contributes to the product aesthetics design literature by focusing on the under-researched area of visual density. Finally, this work enriches the understanding of emptiness, which has hitherto been investigated by clinical psychologists.

The Impact of Social Exclusion on Consumers' Attitudes toward Probabilistic Selling

EXTENDED ABSTRACT

Probabilistic selling refers to the marketing practice in which a seller offers buyers a purchase choice involving a probability of obtaining a subset of the whole set of distinct products or services offered by a company (Fay and Xie 2008, 2010, 2015). Facilitated by its managerial advantages, an increasing number of companies have started to use this innovative marketing strategy, such as the fukubukuro (i.e., grab bags) from Apple, mystery flights/ hotels services from KAYAK, and blind vacation bookings from Srprs. me. From a consumer psychology perspective, the current research examines the impact of social exclusion on consumers' attitudes toward probabilistic selling.

Establishing and maintaining stable social relationships is essential for human survival (Baumeister and Leary 1995), yet social exclusion continues to be a characteristic of human society. Social exclusion refers to the situation in which an individual is ignored, rejected, or isolated (e.g., Baumeister et al. 2005). Recently, consumer researchers have demonstrated the impact of social inclusion and exclusion on various consumer behavior domains, such as affiliation-related consumption (Mead et al. 2011), financial risk-taking (Duclos, Wan, and Jiang 2013), uniqueness-seeking (Wang, Zhu, and Shiv 2012), and consumer switching behavior (Su et al. 2017).

One important consequence of social exclusion is that it deprives people of their sense of personal control; hence, excluded individuals usually exhibit high vigilance to additional threats to their sense of control (e.g., Williams 2001, 2007). Probabilistic selling is also likely to be considered a threat to one's sense of personal control because in a probabilistic selling context consumers cannot observe directly how the final outcome of their purchasing behavior (i.e., the product or service) is determined by their input (Alloy, Clements, and Koenig 1993). Therefore, we hypothesize that social exclusion decreases consumers' favorability toward probabilistic selling, driven by the defensive system they use to guard against further loss of personal control (e.g., Kay et al. 2008; Kay, Moscovitch, and Laurin 2010). We further predict that the effect is weakened when the lack of personal control is compensated for in other ways, or when vivid information about the probabilistic offer is provided.

In experiment 1, we first manipulated participants' feeling of social relationship through an imagination task (Pfundmair et al. 2015). Specially, college students ($N = 105$) were asked to put themselves into the role of the person in an either exclusion or inclusion scenario. After the participants finished imagining the scenario, an experimenter there told them that they could choose either a fixed reward option (a local restaurant coupon) or a probabilistic reward option (a mystery stationery bag containing various random stationery items) of similar monetary value. As expected, excluded participants were significantly less likely to choose the probabilistic reward than those in the inclusion condition.

Experiment 2 demonstrates that the observed effect was due to feelings of social exclusion decreasing the probability of consumers favoring probabilistic offerings, but not increasing consumers' evaluations of the fixed offering option. To do so, college students ($N = 194$) were randomly assigned to the four conditions of a 2 (exclusion vs. inclusion) \times 2 (fixed offering vs. probabilistic offering) between subject design. First, participants' feeling of social inclusion/exclusion was manipulated with a recall task (e.g., Duclos, Wan, and Jiang 2013). Then, as an ostensibly unrelated task, participants were asked to imagine they have ordered a laptop online and evaluated a delivery plan offering either an undetermined date or a fixed date (the undetermined date would be 4-8 days earlier than the fixed date). Consistent with our expectation, the excluded participants exhibited a more negative attitude toward the undetermined but earlier delivery offering than those in the inclusion condition. However, for the fixed offering condition, there was no significant difference between the preferences toward the delivery option by the two groups. This suggests that social exclusion does not enhance willingness to choose fixed options.

Experiment 3 provides direct process evidence by showing the mediating role of control deprivation and the moderating role of control restoration. We employed a 2 (exclusion vs. inclusion) \times 2 (control restoration vs. no restoration) between subject design. After participants ($N = 226$) finished the same recall task we used in experiment 2, we manipulated their sense of control through a reading comprehension task. The participants in the control restoration condition read and summarized an article about the controllability of people's health while the participants in the no-restoration condition read and summarized an article about the visual abilities of monkeys (Cutright and Samper 2014). Next, the participants responded to the three questions measuring their feeling of control (Cutright 2011). Finally, all participants imagined that they were given a mystery bag filled with random products—as a free gift. We found that the feeling of personal control mediated the effect of social relationship on probabilistic marketing offerings evaluation. And the previously observed effect of social exclusion disappeared when the feeling of control was restored via an external source.

Experiment 4 reveals a possible way to overcome consumers' negative attitudes by demonstrating the moderating role of information vividness through a 2 (exclusion vs. inclusion) \times 2 (high vividness vs. low vividness) between subject design. We first asked college students ($N = 105$) to complete the same imagination task used in experiment 1. Then, participants imagined that they were scheduled to take individual trips and evaluated a mystery hotel booking services. Information vividness was manipulated by either providing participants with pictures of the outcome of the probabilistic service, or not. As expected, when vivid product information was provided, the negative effect of social exclusion disappeared.

Taken together, the current research is the first to systematically examine the psychological mechanism under which consumers react to probabilistic selling. In addition, this research extends

our understanding of social relationship and personal control in the marketing context. Further, our research offers rich practical implication for marketers in terms of how to increase the acceptance and effectiveness of probabilistic strategies.

The Broken Bargain: Social Exclusion Reduces Willingness to Incur Personal Costs for the Sake of Society

EXTENDED ABSTRACT

People are lonelier than ever before (e.g., Klinenberg 2013). At the same time, the earth's natural resources may be in greater danger than ever before. Is there a relationship between the two?

Previous research suggests the answer may be yes. People who were socially excluded (vs. included) displayed less prosocial behavior (e.g., helping, cooperation) and that effect was explained by reduced empathic processing (i.e., lack of sensitivity for others' feelings; Twenge et al. 2007). If one assumes that pro-environmental consumption is an instance of prosocial behavior, then one would predict that social exclusion reduces sustainable consumption through reduced empathy.

It is possible, however, that prosocial and pro-environmental behaviors rely on different psychological processes. While empathy may be critical for motivating helping and cooperation toward specific group members (Batson 1991), it may not be so important for motivating behaviors that benefit the broader social group. Instead, behaviors that benefit the broad social group may be governed by an implicit bargain between the self and society. That is, people are willing to make sacrifices as long as they think the costs of those behaviors are offset by the rewards that come from belonging to a social group (Baumeister et al. 2005). If sustainable consumption is governed by an implicit bargain between the self and society, then exclusion from the social group should reduce sustainable consumption because it makes people unwilling to make sacrifices for the sake of society.

In four studies, we tested the theory that trait and state deficiencies in the need to belong are associated with reduced engagement in pro-environmental behavior. In addition, we tested the competing mechanisms for that effect – reduced empathy or a breakdown in the implicit bargain.

Study 1 was a basic test of the hypothesis that deficiencies in belonging are associated with reduced engagement in pro-environmental behaviors. One-hundred and fifty American MTurkers completed the 10-item UCLA loneliness scale (Russell 1996). Then they reported their engagement in a variety of environmentally-friendly behaviors (e.g., frequency of recycling; Karp 1996). As predicted, loneliness was negatively related to conservation behaviors, over and above the previously established demographic predictors of gender and income.

Study 2 tested the causal relationship between social exclusion and pro-environmental consumption. Eighty-seven undergraduate students were randomly assigned to write about a time they were either rejected or accepted (Maner et al. 2007). Preference for a “green” car versus a regular car was the dependent measure. As predicted, exclusion (versus acceptance) decreased participants' preference for the ecologically-friendly car.

In study 3 ($N = 87$), we aimed to elucidate the explanation for why social exclusion reduces pro-environmental consumption. To manipulate exclusion, participants were given bogus feedback about the future implications of their personality-test results (Twenge et al. 2001). Participants were told that their future would be full of social relationships (social inclusion), devoid of social relationships (social

exclusion), or full of mishaps and misfortune (misfortune-control condition). The latter group was included as a control for negative feedback that was not social in nature.

To measure empathic concern, participants read and responded to an essay that was ostensibly written by another student and which described a recent romantic-relationship breakup; participants indicated their feelings toward the peer (e.g., sympathetic, compassionate; Batson et al. 1995). To measure the breakdown of the implicit contract, completed a willingness to sacrifice for society scale developed by Stern et al. (1999; e.g., *I would be willing to accept cuts in my standard of living to benefit the society*). Participants then indicated their preference between two backpacks that were of the same brand and price: a regular backpack, which was superior on performance, and a green backpack, which was environmentally superior.

Conceptually replicating study 2, socially-excluded participants reported a lower preference for the green product relative to the socially-included condition. Consistent with the theory that reduced desire to buy the green backpack was due to negative feedback about one's social connections specifically rather than negative information generally, socially-excluded participants reported a lower preference for the green product than did misfortune-control participants. There was no difference between the misfortune-control and social-inclusion conditions. Process analyses which included empathy and willingness to sacrifice as competing mediators revealed that the indirect effect was significant for willingness to sacrifice but not empathy. Hence, reduced willingness to sacrifice for the sake of society was a better explanation for the effect of social exclusion on green consumption than empathy.

In Study 4, we framed the same green product as conferring social or financial benefits, expecting that social (vs. financial) benefits would restore excluded participants' willingness to buy pro-environmental products. To test this hypothesis, we presented a green car as a fuel-efficient model whose benefits were social (owners were perceived by others as nice, caring, and altruistic) or economical (saving money) The social exclusion manipulation was the recall task used in Study 2 (Maner et al., 2007). Sure enough, participants who recalled a time they felt socially excluded reported higher intentions to purchase the car when the benefits were social than utilitarian. In contrast, the opposite pattern was found among participants who recalled a time of acceptance.

The current research provides two novel insights into the critical challenge of motivating sustainable consumption. One, the need to belong is key to engagement in sustainable consumption. When people's need to belong was threatened by social exclusion or by feelings of loneliness, they became unwilling to incur the costs of sustainable consumption. Two, sustainable consumption is not merely another instance of prosocial behavior. Instead, the two outcomes can be explained by different psychological processes.

Is It Still Important To Be A Moral Person When You Are Lonely?

EXTENDED ABSTRACT

Most people feel lonely at some point in their life. It is estimated that about one out of five people feel lonely at any given time (Cacioppo & Patrick, 2008). The widespread use of screen-based communication in the last two decades has also contributed to social isolation and low attachment to parents and peers (Gross, 2004). Despite the pervasiveness of loneliness, how it affects consumers' moral behaviors remains to be an underexplored area. In this research, we examine how consumers' felt loneliness affects their moral identity and moral behaviors.

Loneliness refers to a complex set of feelings that occur when an individual feels socially isolated. Such undesirable subjective feelings of social isolation drive individuals to fulfill their need for social connections (Hawkley & Cacioppo, 2010). Loneliness is related to, but different from, social exclusion. Loneliness refers to either a chronic personality (Cacioppo & Patrick, 2008) or a temporary state of feelings that arise from a social exclusion incident. By contrast, social exclusion emphasizes a particular behavior or event (e.g., purposely excluding or ignoring someone in a group online game) (Wan et al, 2014), but it does not stipulate how the recipient feels or reacts to the behavior. Depending on the context and the individual personality, a particular social exclusion incident may or may not result in the individual's felt loneliness. In our research, we examine how loneliness moderates the effect of empathy on moral behaviors, whether the feeling of loneliness comes from chronic personalities or specific exclusion incidents.

Moral identity refers to the degree to which being moral is important for one's identity (Hardy & Carlo, 2011). Previous research has demonstrated that one important antecedent of moral judgment and behaviors is empathy. For example, empathy motives people to help those who suffer, even at a cost to oneself (Batson, 1991). Empathy can also reduce punishment for others. When participants felt empathetic toward another individual, punishment of a cheater disappeared, even though the cheater clearly intended to cheat and had no remorse in doing so (Condon & DeSteno, 2011).

Extant research has revealed a negative relationship between empathy and loneliness in both younger and older adults (Beadle, Brown, Keady, Tranel, & Paradiso, 2012; Margalit & Ronen, 1993; Marshall, Champagne, Brown, & Miller, 1998). Davis (1983) shows that lonely people have less empathy, which explains their reduced accuracy in perceiving the thoughts and feelings of others, because lonely people lack the ability to accurately detect others' thoughts and intentions in the social context. The negative correlation between loneliness and empathy (Beadle, et al., 2012; Margalit & Ronen, 1993; Marshall, et al., 1998) suggests that lonely people have lower levels of empathy than non-lonely people. If that were the case, the previously found effect of empathy on moral identity should be moderated by consumers' felt loneliness. Because socially-connected people already have high levels of empathy, an additional increase in empathy will not lead to higher levels of moral identity any more. On the other hand, a boost in empathy among the lonely consumers could potentially lead to higher moral identity.

Hence we predict that loneliness moderates the effect of empathy on moral identity. Specifically, when lonely people experience a higher level of empathy, they should have increased moral identity and be more likely to engage in moral behaviors. However, such effect of empathy on moral identity and moral behaviors should be much less pronounced for non-lonely people.

We present five studies to test our hypotheses that loneliness moderates the effect of empathy on moral identity. Study 1 (N=167) employed a 2 (loneliness: lonely vs. non-lonely) by empathy (continuous) between-subjects design. Participants in the lonely (*non-lonely*) condition wrote a story about a time they felt very lonely (*connected*). They then completed the empathy scale (Davis, 1980) and the moral identity scale (Aquino & Reed, 2002). As predicted, we found a significant interaction between loneliness and empathy ($b = .06, p < .01$), such that when participants were asked to write a lonely story, they had a higher moral identity when the empathy was high than low ($b = .17, p < .001$). When participants wrote a non-lonely story, empathy had a much less pronounced (though still significant) effect on moral identity ($b = .06, p = .01$). In study 2, we manipulated loneliness and empathy independently and replicated

the results of study 1. In study 3, we manipulated loneliness and measured empathy. We also added consumer ethics scale (Muncy & Vitell, 1992) as an additional dependent variable. We show that when participants were temporarily induced to feel lonely, those with high (vs. low) empathy had higher moral identity and were more likely to engage in ethical consumer behaviors. Whereas empathy also increased moral identity among non-lonely participants in this study, it did not affect their ethical consumer behaviors. In study 4, we manipulated loneliness and empathy independently and allowed participants to engage in real immoral behaviors (Amaral and Meyers-Levy, 2013). Again, we replicated the results of previous studies. In study 5, we measured loneliness, manipulated empathy, and gave participants an opportunity to cheat (Mazar, Amir, & Ariely, 2008). Our results showed that when participants were lonely, those in the high empathy condition cheated less than those in the low empathy condition. However, when participants were not lonely, there was no significant difference between the two empathy conditions.

Results across five studies provide strong and converging evidence that loneliness moderates the effect of empathy on moral behavior. We have demonstrated the same results with different operationalizations of moral identity (e.g., measured moral identity, measured consumer moral ethics, and tasks involving real moral behaviors). Our research integrates three substantial areas of literature and establishes connections among loneliness, empathy, and consumer moral identity.

SESSION OVERVIEW

Product prices, consumer report ratings, weather forecasts, or polls are only a few examples of the quantity and diversity of numerical information to which consumers are exposed to every day. In the last decade, the advent of data-driven marketing has generated a renewed interest in consumers' ability to navigate this complexity, and has rejuvenated an old debate between two perspectives.

A first perspective views the "man as an intuitive statistician". To them, probability theory and statistics are both a codification of individual's way of reasoning and a norm against which decisions and inferences can be judged (Peterson and Beach 1967). As such, they have advocated for people's ability to process numerical information to make better decisions. Other researchers have argued that people are "cognitive misers", who rely on heuristics that typically but not always provide correct answers (Kahneman and Tversky 1974). This perspective has encouraged sustained research efforts to uncover the many biases limiting people's ability to use numerical information.

The four papers presented in the session is taking a balanced stance, and highlight instances of accurate and biased intuitive statistics. In the first paper, **Urminsky, Skarsten, and Shen** documented a novel bias in statistical reasoning, and show that people judge a prediction to be more extreme when it is expressed as a chance forecast (chance of winning over opponent) than when it is expressed as a margin forecast (vote share margin over opponent). In the second paper, **Schley** investigates whether consumers are better at processing relative price differences (e.g. 10% off) versus absolute price differences (e.g. \$10 off). In the third paper, **André, Reinholtz, and de Langhe** show that if consumers can simultaneously learn the central tendencies of several distributions of prices, they cannot do so for the dispersion of prices. Finally, **Goldstein and Rothschild** discuss in a fourth paper the underlying causes of "the most significant of cognitive biases": overprecision (Kahneman, 2011).

We believe that this session provides a coverage of important questions, and that the research projects presented have significant implications for theory and practice. From a scholarly perspective first, as it is bringing together researchers with various training and therefore provides a nuanced view of consumers' abilities and

shortcomings in the processing of numerical information. From a methodological perspective second, as the papers are interrogating the appropriateness of certain elicitation techniques, and relying on state-of-the-art methods to collect and analyze consumers' perceptions (e.g. distribution builders, hierarchical Bayesian modeling). From a managerial perspective, finally, as our findings are not limited to identifying sources of errors, but also offer potential remedies and debiasing techniques.

For those reasons, we believe that the projects presented form a cohesive and important session, which should appeal to a large audience. Researchers who are themselves studying intuitive statistics first and foremost, but also researchers working on issues as diverse as pricing, consumer financial decision making, cognition, or decision under risk and uncertainty, would be interested in joining us to discuss the present and future of this stream of research.

High Chances and Close Margins: How Different Forecast Formats Shape Beliefs

EXTENDED ABSTRACT

Forecasts, for consumers and marketers alike, are a key tool for making sense of the future. While a large literature has studied how people make forecasts, and their accuracy under different circumstances, less is known about how lay people process and interpret forecasts. However, research on failures in normative statistical reasoning (Jones and Love 2011, Peters et al 2006, Tversky and Kahneman 1971, Urminsky 2016) suggests that people may not understand the uncertainty conveyed in forecasts in a statistically optimal way.

In this research, we contrast two common ways of communicating an uncertain forecast, either as a chance (e.g., the probability of winning a game) or as an expected margin (e.g., the point spread or predicted amount by which a game would be won). We find a robust chance-margin discrepancy, in which people tend to treat a chance forecast as conveying greater certainty about the directional outcome than the statistically equivalent margin forecast. This discrepancy is not explained by other accounts, such as anchoring or neglect of information, and has consequences for subsequent judgments.

Across five experiments, we tested this chance-margin discrepancy in voting, sports and statistical reasoning and with various judgment and decision variables. In Study 1 (N=126), we use forecasts from fivethirtyeight.com about the 2016 Presidential election, which were updated regularly based on aggregating public election polls, and which were communicated both in terms of the chances of each major candidate winning the election, as well as the expected vote margin. Participants were either presented with the site's forecast for chances and estimated the margin forecasts, or saw the margin forecasts and estimated the chance forecasts. When participants were shown the chance forecast (86.4% chance of Clinton winning) they over-estimated the forecast margin (64.7% vs. 54.2%, $t=3.87$, $p<.001$). Conversely, participants who were shown the margin forecast (54.2%) underestimated the chance forecast (62.8% vs. 86.4%, $t=11.46$, $p<.001$). This pattern was replicated in each of five other such studies conducted during the pre-election period, as the outcome forecasts varied (all $ps <.001$).

In Study 2 (N=143), we ruled out pre-existing beliefs and inattention to the forecasts as alternative explanations. Participants

It's Absolutely Relative: On the Processing of Absolute and Relative Differences

EXTENDED ABSTRACT

Consider a consumer deciding between a 40 inch TV and a 50 inch TV. When evaluating the difference in screen size the consumer can consider the absolute (i.e., 10 inches) or the relative (i.e., 25% larger) difference. Predominant decision theories assume that the marginal utility/value for additional inches of TV is a function of the absolute differences in size (Kahneman and Tversky 1979; von Neumann and Morgenstern 1947).

Although absolute and relative dimensions both reflect differences, they are not perfectly correlated, and consumers can as such use either or both dimensions when making decisions. For instance, prior research on proportion dominance has demonstrated sensitivity to relative differences. In the iconic jacket-calculator problem, 68% of participants were willing to drive 20 minutes to save \$5 on a \$15 calculator, but only 29% were willing to drive to save \$5 on a \$125 jacket (Tversky and Kahneman 1981).

The observation that consumers are sensitive to both absolute and relative differences is well documented (Krishna et al. 2002; Choi and Coulter 2009); however, disagreement exists regarding their respective influence. Within marketing and related literature, researchers have argued that processing relative differences is easier and more natural than processing absolute differences (Saini and Thota 2010; Azar 2007; Dehaene 2011; Choi and Coulter 2009). This line of reasoning suggests that when making decisions, consumer perceptions are informed by their Approximate Number System (ANS), the set of cognitive features that allow consumers to discriminate visual quantities (e.g., smaller vs. larger sets of dots). This system supposes that the mind only possesses a natural ability to process relative differences, and that representations of absolute differences must be constructed on the spot using this ANS. This system is what gives psychophysical functions their particular concave shapes (for a review see Dehaene 2011).

For consumer decisions that involve number-based judgments (e.g., was \$100 now \$90), researchers have made the opposite prediction, and suggested that processing relative differences is more cognitively taxing than processing absolute differences (Kruger and Vargas 2008; Chen and Rao 2007; Bettman, Johnson and Payne 1990). They argue that to understand that a sale price of \$90 is 10% off of an original \$100 price, the consumer has to first process the absolute difference (\$10) then divide by the base price (\$100). As such, the absolute difference is a necessary precondition for processing relative differences.

The current research aims to test the predictions of these two accounts and identify the cognitive antecedents of these two modes of processing. Whereas past research has studied these differences at the group level, the current research introduces a within-participant paradigm to assess the use of relative and absolute differences in different settings. In study 1, 301 participants were presented price promotions with relative (5%, 10%, 15%, 20%, 25% off) and absolute (\$5, \$10, \$15, \$20, \$25 off) discounts manipulated orthogonally.

For each level of prices promotion, participants indicated the furthest they would be willing to drive (WTD), in miles, to receive that particular promotion. To assess the influence of relative and absolute differences, data were analyzed using a Bayesian hierarchical linear model (HLM), allowing for the estimation of sensitivities to relative and absolute differences for each participant.

In study 1, participants were randomly assigned to either the control ("was \$A now \$B"), %-off ("was \$A now \$B, X% off"), or \$-off conditions ("was \$A now \$B, \$Y off"). Our results indicate that

saw either chance or share forecasts for the election in four unspecified states. We replicated over-estimation of share forecasts when shown chance forecasts and under-estimation of chance forecasts when shown share forecasts in each state. Furthermore, participant estimates were sensitive to the state-specific forecast information. In a follow-up study, we further address an anchoring account, by demonstrating that estimates based on forecasts were significantly different from (and less accurate than) estimates based on equivalent non-forecast anchors.

In Study 3 (N=220), we tested the discrepancy between beliefs based on chance forecasts and margin forecasts in a new domain. First, we used a similar design with forecasts of football game outcomes, both for forecasted chance of winning and margin of winning (e.g., point spread). Participants who were shown the point-spread significantly under-estimated the forecasted chance of winning (62% vs. 71%, $t=8.4$, $p<.001$). Participants who were shown the chances of winning only directionally over-estimated the point-spread (6.7 vs. 6.5, $t=1.31$, $p=.19$).

Study 4 (N=398) tested the effects of forecast framing using objective statistical information, and identified an important boundary condition. We presented participants with a statistical scenario involving a more or less informative sample of colored marbles drawn from one of two jars, for which we could calculate the objectively correct answers. When the sample was larger (and therefore more informative) participants shown the margin in the sample under-estimated the chance of the marbles coming from the more likely jar (60.7% vs. 78%, $t=15.1$, $p<.001$). Conversely, participants told the chances of the sample coming from the more likely jar overestimated the corresponding proportion in the sample (66.3% vs. 60%, $t=6.57$, $p<.001$). However, when the sample was small (and therefore less informative), both share and chance information yielded underestimation.

In the last study, we tested the consequences of forecast framing. In Study 5 (N=198), participants were shown the change over the prior ten days in fivethirtyeight.com's forecasts, either in terms of chances (from 85% Clinton/15% Trump to 69% Clinton/31% Trump) or in terms of margin (from 53% Clinton/47% Trump to 52% Clinton/48% Trump). Participants then answered several questions about their perceptions of the election, support for the candidates and behavioral intentions.

Participants who saw the change in chance forecasts (vs. change in margin forecasts) gave more extreme assessments of the change in the election ($t=3.25$, $p=.001$). Participants were more likely to judge the change in chance forecasts as "very good news" or "very bad news" (45%) than the equivalent change in margin forecasts (25.5%). The degree to which participants were worried about the election was unaffected. Participants' own intention to vote was high (77% "very likely") and unaffected by the forecast format. However, participants who were shown the change in chance forecasts were significantly more likely to say they would remind a friend or neighbor to vote (50% vs. 31.6% "very likely", $M=3.8$ vs. 3.2 , $t=2.71$, $p=.007$).

Overall, our results demonstrate that forecasts are seen as more extreme when framed as predicting chances rather than as predicting margins, even when the two formats are used to communicate equivalent information. Given that forecasts are often communicated in only one format, these findings suggest that the supposedly irrelevant choice of format for a forecast can have a remarkably meaningful impact on the interpretation of the forecast and even change one's attitude and behavioral intention.

participants in the control condition were more sensitive to absolute differences than relative differences ($b_{\text{absolute}} = 0.042$ vs. $b_{\text{relative}} = 0.009$, $p < .0001$). In the \$-off condition, the use of absolute (relative) differences increased (decreased) ($b_{\text{absolute}} = 0.050$ and $b_{\text{relative}} = 0.006$) compared to the control condition ($ps < .10$). This change was markedly larger in the %-off condition ($b_{\text{absolute}} = 0.030$ and $b_{\text{relative}} = 0.020$) compared to the control condition ($ps < .0001$), suggesting that participants are more prone to utilizing absolute differences, even when the relative-difference information is explicitly provided.

Results of study 1 also indicated strong negative correlations in the fixed ($rs = -.60$ to $-.34$) and random ($rs = -.47$ to $-.32$) effect parameters. Importantly these effects were asymmetric: while a greater reliance on absolute differences limits the use of relative differences, greater use of relative differences has a much larger attenuation effect on absolute-difference usage. This suggests that relative differences require fewer resources, and can thus be used while processing absolute differences. On the other hand, absolute differences are more cognitively taxing and prevent the use of relative differences. Taken together, those results can explain the conflicting evidence regarding absolute and relative differences: the within-participant-level analysis indicates that while relative-difference processing is indeed more automatic than absolute-difference processing, consumers utilize absolute differences despite its more laborious processing.

To ensure generalizability, studies 2a ($N=300$) and 2b ($N=299$) replicated the findings of study 1 using product attributes instead of prices (study 2a) and by only manipulating relative or absolute differences (study 2b). Similar results were found. In study 3, we investigated whether our findings would hold true when assessing visual quantities. Results suggest that visually-expressed quantities are more easily processed by relative differences compared to numeric quantities. Furthermore, consistent with study 1, processing of relative differences inhibited processing of absolute differences, but not the other way around.

A fourth study on 202 participants replicated the conditions from study 1, with the critical difference that the final price was omitted in the %-off and the \$-off conditions, so that the participants would have to compute it themselves. Opposite of study 1, results indicated a greater use of relative differences than absolute differences in both the %-off ($b_{\text{absolute}} = 0.015$ and $b_{\text{relative}} = 0.029$) and \$-off ($b_{\text{absolute}} = 0.020$ and $b_{\text{relative}} = 0.031$) conditions, $ps < .01$. Additionally, contrary to the previous studies, processing absolute differences inhibited relative-information processing and not the other way around. Taken together, results of studies 1-3 suggest that consistent with the numerical cognition argument, relative-information processing is more efficient, but consumers appear to utilize a different mode of processing quantitative differences when they must calculate the differences themselves (study 4).

Variance Spillover in Intuitive Statistical Judgments

EXTENDED ABSTRACT

For more than 50 years, researchers have been studying the intuitive statistical capabilities of humans (Peterson and Beach 1967). While some consensus has emerged, many unresolved questions remain. In this project, we address one of these questions, which has important marketing implications: Can consumers accurately encode and represent the distributional properties of multiple numerical distributions? Consumers frequently encounter numerical information (prices, qualities, quantities, etc.) and—to make optimal decisions—must remember and use this information. For example, when considering whether to buy a new computer, a consumer must assess the relative likelihood of finding a comparable computer at a better

price with continued search. The solution to this problem relies on the variance of computer prices on the market (and the consumer's search cost). Importantly, consumers make many decisions of this nature each year and thus—to make optimal decisions—must maintain mental representations of different price (and other numerical) distributions simultaneously.

When presented with a distribution of numerical values, previous investigations suggest that people are surprisingly accurate when making judgments about central tendency (e.g., the mean or median; Beach and Swensson 1966, Peterson and Miller 1964). However, there is less consensus regarding people's ability to judge dispersion (e.g., variance). People seem biased towards using absolute, rather than squared deviation, when judging variance (Beach and Scopp 1968, Goldstein and Taleb 2007). Further, people seem to conflate differences in coefficient of variation (variance divided by mean) with differences in variance (Hofstatter 1939, Lathrop 1967). Some recent research, however, is more optimistic. Goldstein and Rothschild (2014) found that people could reproduce distributions accurately from memory using a "distribution-builder", in which they can "draw" the distribution. This research suggests that people's mental representations of variance may be accurate and that previously identified biases may stem from the elicitation methods used.

The current investigation extends previous work to contexts in which people must learn about multiple numerical distributions at the same time: in the present research, distribution of prices for two different products. We believe this extension is particularly important for understanding consumer decision making. Consumers tend to learn about products over time through infrequent exposures to information and these exposures are often interspersed with exposures to information about other, different products. For example, you probably don't know the exact price of a banana at your local supermarket, but you probably have a pretty good idea, and could probably identify whether the current price is a good deal or a bad deal. However, you have probably never directed any real attention to learning about the price of bananas; instead, you've been exposed to banana prices irregularly and infrequently. And in the interim, you have seen prices for many other products (apples, cereal boxes...). In our research, we ask how accurately can people learn about numerical distributions in this type of context, and contribute to the literature on internal reference price formation (Mazumdar, Raj, and Sinha 2005).

In three studies, we presented people with a sample of prices for two different products (e.g., red wine and white wine, within the products there was no differentiation other than price). Prices were displayed one-at-a-time, for several seconds each, over-imposed on a picture of the target product. Prices for the two products were intermixed. After seeing all of the prices, participants were asked to reproduce the price distributions for each product individually (i.e., a separate distribution for each product) using a distribution builder tool (André 2016; Goldstein and Rothschild 2014). We then assessed the accuracy of these expressed distributions with respect to the actual distributions the participants had seen.

In study 1, we examined participants ability to simultaneously learn the central tendency of two different price distributions: prices of red wine and prices of white wine. Within each product category, the variance of prices was held constant ($SD = \$6$), but the mean price of each category varied between participants. The mean price for one product category was \$25 in all conditions (the focal product), but we varied whether the mean price of the other category was either \$10 higher, \$10 lower, or the same (the distractor product). This design allowed us to determine whether prices from the distractor distribution influence the estimate of central tendency from the

focal distribution. Our analysis suggests they do not: The means of the (reproduced) focal distribution were not different between conditions and, further, were not different than the true mean (\$25).

In studies 2 and 3, we instead examined participants ability to simultaneously learn the variance of two different price distributions. In study 2, we used a 2 x 2 between-participant design. In all conditions, the mean price of one product (e.g., red wine) was \$23 and the mean price of the other product (e.g., white wine) was \$28 (products were counterbalanced). We cross-manipulated the variances of the price distributions, such that each product was either high (SD = \$9) or low (SD = \$3). This design allowed us to test for “variance spillover”: whether participants’ impression of variance in prices for one category was influenced by the variance in prices for the other category. Our analysis suggests this is indeed the case: variances estimates were influenced by the true variance of the focal distribution, but also of the non-focal distribution. For example, when the true variance of the red wine price distribution was high, participants underestimated this variance when the variance of the white wine price distribution was low (vs. high).

In study 3, we examined a potential moderator of the variance spillover effect. This study largely reproduced study 2, but included an additional factor: whether the product categories were similar (red wine vs. white wine) or dissimilar (red wine vs. smartphone cases). We found that the variance spillover effect was attenuated, but not eliminated when the products were dissimilar. This suggests that categorization processes may underlie the observed result. In fact, the contamination of variance estimates may be adaptive from a Bayesian perspective—you can learn about the likely dispersion of one category by observing another similar category.

Combining Estimates of Epistemic and Aleatory Uncertainty to Reduce Overprecision

EXTENDED ABSTRACT

Overprecision, or excessive confidence that one knows the truth, is considered the most robust form of overconfidence (Moore, Tenney, Haran, 2016), and has been called “the most significant of the cognitive biases” (Kahneman, 2011). It is typically studied with the confidence-interval paradigm, in which people are asked to state two numbers that should bracket the true realization of an outcome with a given probability. Many prior demonstrations of overprecision show that people are miscalibrated: for example, stated 80% confidence intervals tend to contain the correct answers much less than 80% of the time.

Let us consider a person asked to construct a confidence interval for the price of gas at a given station in the USA. This person will face two sources of uncertainty. The first source is its epistemic uncertainty, which is tied to its ability to generate an accurate estimate about the average price of gas in the USA. Second, even if this person knew the average price of gas in the USA with absolute confidence, there would still remain some uncertainty about the price at this given station. This second type of uncertainty, called aleatory uncertainty, is tied to the standard deviation of the outcome: here, the typical amount by which a station deviates from the true average.

In the present research, we investigate the link between consumers’ perception of aleatory uncertainty, epistemic uncertainty, and overall uncertainty. In particular, we seek to uncover the sources of overprecision: is it a consequence of consumers’ inability to generate accurate estimates for aleatory and/or epistemic uncertainty? Or does it reflect a failure to incorporate both types of uncertainty when generating confidence intervals?

We develop a paradigm in which we ask people for three different kinds of confidence intervals. First, as done in past research on overprecision, we ask the standard confidence interval of what a particular outcome will be (such as the price of gas at a particular gas station, or the temperature on some future date in a particular city). Second, we ask participants to generate a measure of aleatory uncertainty, by asking them how much that value varies around the average (for example how much the price of gas around the country varies around the mean or how much the temperature in a particular city on a given day varies from year to year). Finally, we ask respondents to generate a measure of epistemic uncertainty, by asking them how far their estimate of the average is likely to be from the true average. Since the standard confidence interval should reflect both epistemic and aleatory, there is a direct theoretical relationship between first value (the standard confidence interval for the value), and the second and third values (variation around the true average and uncertainty in the location of the true average). As such, this paradigm allows us to investigate consumers’ accuracy in estimating aleatory and epistemic uncertainty, and their ability to combine both estimates into a single measure of confidence.

We observe, in line with previous research (e.g., Moore, Tenney, Haran, 2016), that people consistently create too-narrow confidence intervals: elicited 80% intervals contained the correct answer less than 80% of the time. We also document several important findings. First of all, we find that people have reasonable estimates of both aleatory uncertainty in the world and epistemic uncertainty in their minds. Second, the stated confidence intervals exhibit a strong correlation with the participants’ estimate of epistemic uncertainty, but a weak or null correlation with aleatory uncertainty. Those two effects are robust to the order of questions: if participants are asked to generate their measures of aleatory and epistemic uncertainty first, this does not make them incorporate both types of uncertainty into their predictions. In other words, consumers do not learn from the order of questions. However, we show that a procedure that combines peoples’ estimates of aleatory and epistemic uncertainty into a single estimate of confidence yield better-calibrated confidence intervals. The findings above are replicated in several consumer domains (such as estimates of prices and quality) as well as in general knowledge domains.

Our findings suggest that although people possess the ability to generate reasonably accurate estimates for both kinds of uncertainty, they do not incorporate aleatory uncertainty when asked to generate a confidence interval, they do possess the ability to do so with reasonable accuracy. This “aleatory uncertainty neglect” has significant implication for theory, as it suggests a strong causal mechanism for consumers’ overprecision. Furthermore, well-calibrated intervals can be obtained by mechanically combining separate estimates of two kinds of uncertainty. This result has implications the design of decision aids for consumers, and survey tools for pollsters and marketing researchers who wish to elicit well-calibrated confidence intervals.

David Gal, University of Illinois at Chicago, USA

SESSION OVERVIEW

People strategically disclose information about themselves as a mean of managing the impressions they make on others (Schlenker 1980, Berger 2014). The advent of social media such as Facebook, Instagram and Snapchat provided individuals not just with novel platforms but also novel practices to self-present easily and widely, using a range of topics and activities (e.g. purchases, trips, political opinions, etc.). Yet, many questions remain about the antecedents and consequences of these acts of self-disclosure. Connecting to well-established frameworks, this session explores the roles played by message, medium, senders and recipients in online self-presentation. Specifically, which type of personal information do consumers choose for self-presentation and which influences others' impressions the most? Which characteristics of the medium used for self-presentation play a significant role? For instance, does it matter whether the medium allows temporary (vs. permanent) sharing or whether the information is shared directly by the consumer or through an intermediary? Finally, how does feedback received to an act of self-disclosure influence subsequent self-disclosure decisions? The papers in this session address this set of related questions, with particular focus on information shared through social media platforms.

Valsesia and Diehl compare sharing information about one's material versus experiential purchases. They show that consumers strategically choose to share their experiential purchases when they want to make a favorable impression. This is a successful self-presentation strategy as those sharing experiential purchases are better liked, particularly in situations where individuals repeatedly share self-relevant content over time, as in the case of social media.

The next two papers address the role of the medium through which self-presentation occurs. **Ruppel, Hofstetter and John** ask whether temporary sharing using social media such as Snapchat influences what consumers choose to share and how it is perceived. They find temporary sharing causes people to take greater risks in their disclosures. This is driven by a dampening of privacy concerns

but can have negative consequences, as impressions based on indiscreet disclosures persist beyond the disclosure's temporary lifespan.

Scopelliti, Vosgerau and Loewenstein compare the effect of direct self-promotion to using an intermediary who delivers promotional content about a target individual. They show that promotional information elicits more positive and less negative emotions in recipients when disclosed by an intermediary (e.g. a friend, an agent) rather than oneself. Yet, while this practice enhances target perceptions it carries image costs for the intermediary.

Importantly, self-disclosure oftentimes involves feedback from others, which in social media takes the form of likes and comments. **Hu and Gal** examine how this feedback influences subsequent self-disclosure decisions. They find that the receipt of comments (vs. likes), particularly from distant others, reduces subsequent self-disclosure because comments are more likely perceived as a form of unwanted intimacy.

Taken together, these papers shed light on drivers and consequences of consumers' online self-presentation. All are at an advanced stage of completion with multiple studies completed. We expect this session to generate significant interest among researchers studying impression management, social influence and social judgment, as well as social media and word-of-mouth more broadly.

See What I Did or See What I Have: Impression Management Using Experiences Versus Material Goods

EXTENDED ABSTRACT

That people use material purchases to manage impressions is well established (e.g. Han et al 2010, Bellezza et al 2014, Warren & Campbell 2014, Griskevicius et al 2010). Experiential purchases, however, have not been examined as impression management tools, even though they play an important role in people's lives (e.g. Van Boven and Gilovich 2003). Prior work has not considered whether experiences can be used to manage impressions, likely because "on average, possessions are a more visible and more persistent signal" (Carter & Gilovich 2012 p. 1314).

However, there *do* exist various, common ways of making experiential purchases more observable and less ephemeral. For example, one may complement a fleeting, unobservable experiential purchase with a visible, lasting material purchase (e.g. buying a t-shirt at a concert and wearing it afterwards e.g. Goodman, Malkoc, Stephenson 2016). Further, with the advent of social media, making one's experiential purchases visible by posting about them online has become easy and prevalent (e.g. Barasch, Zauberger, and Diehl 2016).

Our research investigates the use of experiential purchases for impression management purposes. We show that consumers strategically use their experiential purchases to manage others' impressions of them because they consider experiential purchases to be better signals than material purchases. Moreover, we show that this is a successful strategy as those signaling with experiential purchases are indeed better liked compared to those using material purchases.

Four studies tackle our research goals. Study 1 is a field study testing the proposition that individuals trying to manage others' impressions favor using experiential over material purchases. During the first day of class, students were asked to write about a purchase that was important to them on a "Get to Know You" card. We varied

between sections whether they expected to read out their answers in front of the class (public) or not (private). Overall, students mentioned purchases that were more experiential than material in nature ($M=1.57$, $SD=2.92$, 95% CI [2.63, 3.27], $t(166)=6.98$, $p<.001$). Importantly though, and in line with our predictions, purchases in the public condition ($M_{Public}=2.02$, $SD=2.82$, 95% CI [1.42, 2.63]), were significantly more experiential than those in the private condition ($M_{Private}=1.11$, $SD=2.96$, 95% CI [0.46, 1.76], $F(1,165)=4.19$, $p=.042$, $\omega_p^2=.019$), presumably because the desire to make a favorable impression was particularly salient.

Study 2 provides further evidence for people favoring experiential purchases when trying to generate favorable impressions. We asked 112 mTurkers to write about a material or experiential purchase they had made. When asked whether they had actually posted about this purchase on social media, we find that they were more likely to have posted about their experiential rather than material purchase (56.9% vs. 20.4%, $X^2=15.64$, $p<.001$), in line with our predictions. Next, they wrote a Facebook post about their purchase and rated the impressions they expected post readers would form of them using a 4-item scale ($\alpha=.85$). Respondents expected to generate more favorable impressions if they posted about their experiential purchases ($M_{Exp}=6.75$ vs. $M_{Mat}=6.00$, $F(1,110)=10.31$, $p=.002$). Moreover, a mediation analysis with 2,000 bootstrap samples (Hayes 2013) showed expected impressions mediate the effect of purchase type on respondents' real-life decision of whether or not to *actually* post something about the purchase on social media (indirect=0.26, 95% CI =[0.036, 0.719]).

Study 2 also investigated how experiential purchases are actually perceived. A separate group of 148 mTurkers evaluated the posts written in the first part of the study on the same 4-item impressions scale ($\alpha=.90$). We combined the data of "writers" and "readers" and regressed impressions on the two manipulated variables: purchase type (1=experiential, -1=material), and evaluation (1=predicted, -1=actual). We only found an effect of purchase type ($B=0.410$, $t=3.39$, $p=.001$), suggesting that individuals are correct in expecting that others form better impressions of them based on experiential purchases.

Studies 3 and 4 tackle the questions of how *repeated* signals are chosen and received. Study 3 followed a 2 (purchase: experiential vs. material) x 2 (number of posts: 1 vs. 4) between-subjects design and examined how reading one versus four Facebook posts about either experiential or material purchases affects impressions. MTurkers ($N = 703$) reported forming more positive impressions when posts were experiential (vs. material) ($M_{Exp}=6.66$ vs. $M_{Mat}=5.82$, $F(1,699)=47.29$, $p<.001$) and when reading about one (vs. three) purchases ($M_{One}=6.40$ vs. $M_{Three}=6.08$, $F(1,699)=6.49$, $p=.011$). Most importantly, we found an interaction between purchase type and number of posts ($F(1,699)=4.10$, $p=.043$). Simple contrasts reveal that impressions decreased with the number of posts when posts mentioned material ($M_{One}=6.10$ vs. $M_{Three}=5.54$, $F(1,699)=10.56$, $p=.001$), but not experiential purchases ($M_{One}=6.70$ vs. $M_{Three}=6.63$, $F(1,699)=0.14$, $p=NS$), indicating that experiential purchases are better signals also in repeated impression management situations.

Finally, in Study 4 we asked 582 mTurkers (posters) to choose four consecutive times between posting an experiential or material purchase. Of these, 79.3% chose a combination of material and experiential purchases. Next, 543 different mTurkers (readers) evaluated the different Facebook profiles that emerged. As in Study 2 we combine poster and reader data and find that the number of experiential posts positively and significantly predicted impression formed by readers ($B=.19$, $t(1, 1121)=4.18$, $p<.001$). That effect, however, was not anticipated by posters for whom the number of experiential

purchases did not affect expected impressions ($B = -.04$, $SE = .06$, $t(1, 1121) = -.75$, $p = .456$), indicating that individuals are somewhat miscalibrated in repeated self-presentational efforts.

This research contributes to the literature on impression management by adding experiences to the repertoire of signals consumers use. It further contributes by examining whether and when experiential signals lead to favorable impressions and by testing how *repeated* signals affect impressions. Moreover, it adds to the literature on experiential versus material purchases by investigating how these different purchases affect *others*, rather than the purchaser herself. We expect these topics to be of interest to a wide range of researchers and expect it to generate interesting discussions and avenues for future research.

Temporary Sharing, Enduring Impressions: Self-Presentation in the Digital Age

EXTENDED ABSTRACT

In the advent of social media, the impressions people make on others are based increasingly on their digital disclosures. Yet such disclosures are forever catalogued in the cloud, and can thus come back to haunt (Rosen, 2010).

New technologies place expiration dates on online disclosures in order to balance the desire for privacy with the desire to disclose. Examples include Snapchat, with more than 150 million active users daily, which is now also the most popular social network amongst American young adults (Statista, 2017). From a narrow perspective, these technologies would seem to be a panacea. After all, content that no longer exists cannot come back to haunt.

Or can it? Prior research has shown that first impressions are sticky (Ambady & Rosenthal, 1992). Moreover, observers may overattribute sharing to the (bad) judgment of the sharer, and not adequately acknowledge the ephemerality of the sharing platform. Social psychologists have documented that people tend to overattribute others' behavior to enduring personality characteristics, failing to account for situational influence (Jones & Harris, 1967). We thus argue that that people's impressions of sharers are driven by the content of the photo, and not by sharers' choice of sharing medium.

This issue is potentially compounded because the promise of ephemerality may increase disclosure. Prior research points to this possibility. For one, in honoring the desire for privacy, it could assuage privacy concerns, causing people to "let their guard down," (Culnan & Armstrong, 1999), and in turn increase disclosure (Brandimarte, Acquisti, & Loewenstein, 2013). Therefore, we predict that temporary sharing causes people to take greater risks in their disclosures relative to more permanent forms of sharing and that this effect is driven by a dampening of privacy concerns. We tested our predictions in five experiments manipulating whether people shared content only temporarily or permanently.

In Experiment 1, we asked people ($N = 296$) in a public space on a Swiss university campus to take and share a selfie on a public display application and on Facebook either only temporarily or permanently.

People in the temporary condition were 1.22 times more likely to take and share a selfie relative to those in the permanent condition (70.00% versus 57.56%; $\chi^2(1) = 4.85$, $p < .05$). Moreover, participants in the temporary condition were 3.82 times more likely to take uninhibited selfies relative to the permanent condition ($M_{Temporary} = 46.67\%$ vs. $M_{Permanent} = 12.23\%$; $\chi^2(1) = 40.66$, $p < .01$). Finally, asking observers to rate the sharers and their photos indicated that those in the temporary condition were perceived as having worse judgment

than those in the permanent condition ($M_{\text{Temporary}} = 3.00$ vs. $M_{\text{Permanent}} = 3.88$; $F(1, 184) = 34.86$, $p < .01$).

We replicate this pattern of results in Experiment 2 in the lab: participants ($N = 191$), were asked to take and share a selfie via their webcams either permanently, temporarily or without any information regarding the lifespan of their sharing (baseline).

Sharers in the temporary condition were 1.77 times more likely to depict disinhibition relative to baseline ($M_{\text{Temporary}} = 48.28\%$ vs. $M_{\text{Baseline}} = 27.27\%$, $\chi^2(1) = 5.84$, $p < .05$); and 1.70 times more likely relative to the permanent condition ($M_{\text{Permanent}} = 28.36\%$, $\chi^2(1) = 5.26$, $p < .05$). Moreover, temporary sharers were viewed as having worse judgment relative to sharers from both the baseline ($M_{\text{Temporary}} = 3.72$ vs. $M_{\text{Baseline}} = 4.31$; $t(99) = 2.57$, $p < .01$) and permanent ($M_{\text{Temporary}} = 3.72$ vs. $M_{\text{Permanent}} = 4.26$; $t(99) = 2.32$, $p < .01$) conditions.

In Experiment 3 ($N = 201$) we asked participants to state how "goofy" (from 1-5) of a selfie they would share on a temporary (Snapchat) or a permanent sharing medium (iMessage) and measured their privacy concerns as well as predictions of the observers' attributions of their own sharing. Again, the temporary sharing medium induced uninhibitedness ($M_{\text{Temporary}} = 3.19$, $SD = 1.26$ vs. $M_{\text{Permanent}} = 2.17$, $t(199) = 6.02$, $p < .01$). Moreover, mediation analysis showed support for a mediating effect of a reduction in privacy concerns (Sobel test statistic = 2.35, $p < .05$), and participants were more likely to think that observers would attribute their disclosure choices to the platform warranting it in the temporary condition ($M_{\text{Temporary}} = 3.26$, $SD = 1.77$; $M_{\text{Permanent}} = 2.62$, $t(199) = 2.73$, $p < .01$).

In Experiment 4, we assessed the validity of this belief by testing whether observers temper their judgment of sharers based on the medium on which the selfies are shared. Each participant ($N = 428$) was shown either an uninhibited versus conventional selfie and; told that the subject had sent it on either a temporary medium (Snapchat) or a permanent medium (iMessage); and rated the extent to which the subject had good judgment.

Participants deemed people who appeared uninhibited as having worse judgment relative to those not appearing uninhibited ($M_{\text{Conventional}} = 5.11$ vs. $M_{\text{Uninhibited}} = 3.58$; $F(1, 424) = 104.13$, $p < .01$). These judgments were not tempered by sharing medium ($F(1, 424) = .03$, $p = .87$).

Experiment 5 tested whether observers' assessments of sharers' judgment may be tempered by personal experience with temporary sharing media. Participants ($N = 396$) were again shown either an uninhibited or conventional selfie and told that it had been shared on a temporary medium, before they rated the extent to which the target had good judgment. Prior to the rating task, half of participants were asked to upload and temporarily share a selfie of their own.

Again, participants deemed sharers who appeared uninhibited as having worse judgment relative to those not appearing uninhibited ($M_{\text{Conventional}} = 5.35$ vs. $M_{\text{Uninhibited}} = 4.00$; $F(1, 392) = 79.00$, $p < .01$). These judgments were not tempered by experience with temporary sharing ($F(1, 392) = .80$, $p = .37$).

In sum, we document psychological drivers behind the capacity for temporary sharing to induce disclosure: the dampening of privacy concerns and the false belief that others will factor the ephemerality of the medium into their judgments. Temporary sharing may bring back forgetting, but not without introducing new self-presentational challenges.

Bragging through an Intermediary

EXTENDED ABSTRACT

Self-promotion is a useful strategy to present a favorable image of themselves to others (Jones & Pittman, 1982), adopted in

situations where one needs to make her quality known to others, or is competing against others (Rudman, 1998). Self-promotion, however, can backfire and it reduces self-promoters' likeability when it is perceived as bragging (Godfrey, Jones, & Lord, 1986; Scopelitti, Loewenstein, & Vosgerau, 2015), suggesting the existence of a trade-off between conveying positive information about oneself and not being perceived as a braggart and as such undermining one's likeability. One possible strategy to address this trade-off would be to have another person disclose positive information on one's behalf. For example, Pfeffer, Fong, Cialdini, & Portnoy (2006) showed that job candidates and authors were perceived as more likeable when promoted by agents than when they were promoting themselves. Similar to the use of intermediaries to reduce perceived responsibility for morally questionable actions (cfr. Hamann, Loewenstein, & Weber, 2010), using an intermediary to convey positive descriptions may protect the individual being promoted from the adverse consequences of self-promotion (Inman, McDonald, & Ruch, 2004).

We argue that i) the use of an intermediary to convey positive information about a target person will elicit more positive and less negative emotions in recipients than direct self-promotion; ii) inter-mediation effectively enhances perceptions of the target person on the qualities being disclosed; iii) this effect persists irrespective of whether the intermediary is motivated by self-interest; iv) inter-mediation may damage the intermediary, in particular when the person praised has a higher status. We test these predictions in four experiments.

In Study 1, participants ($N = 190$) imagined logging into their Facebook account and reading a post about the volunteering activities in a developing country of one of their contacts. In the direct self-promotion condition, the post was in first person and appeared as being written by the protagonist. In the intermediary condition, a different person wrote the post and the protagonist was mentioned (tagged) in the post. Afterwards, participants indicated to what extent reading the post would make them experience *positive* and *negative feelings*, and a series of discrete emotions (*jealous, upset, happy, proud, annoyed, angry, inferior, and envious*) towards the protagonist. Direct self-promotion induced less positive and more negative emotions, and made readers feel more upset at, less happy for, less proud of, more annoyed by, and angrier at the protagonist ($ps < .001$) than the same information reported through an intermediary. No significant differences emerged for the three other emotions, i.e., envy, jealousy, and feelings of inferiority ($ps > .33$).

In Study 2, participants ($N = 133$) were assigned to one of two conditions (as in Study 1), reported their emotional reactions, and rated the target person and themselves (order counterbalanced) on the same 8 positive traits (*kind, brave, special, generous, honest, compassionate, hardworking, and selfless*). Participants evaluated the target person slightly more favorably than they rated themselves in the direct self-promotion condition ($p = .043$), but the effect was amplified in the intermediary condition ($p < .001$), suggesting that the act of self-promoting reduced the positive impact of the information conveyed.

In Study 3 we examined whether the observed effects persist even when the intermediary is motivated by self-interest by adding two conditions to Study 1. In these conditions participants were informed that the intermediary had a romantic interest or a professional interest (i.e., hoping to get a job at the target person's company) towards the target person, respectively. Participants ($N = 199$) read the post, reported their emotions, and rated the target person on a set of positive traits related to the content of the message (*kind, brave, special, generous, compassionate, and selfless*). Direct self-promotion induced less positive and more negative emotions than the same in-

formation reported through an intermediary ($ps < .001$), irrespective of the intermediary's self-interest. No differences emerged between the three intermediary conditions. The same pattern of results was observed on five of the six positive traits (all $ps < .05$), and marginally on one trait, *special* ($p = .08$).

In Study 4, participants ($N = 300$) read the post corresponding to one of the three intermediary conditions from Study 3 and reported their impressions of either the intermediary or of the target person (negative/positive; favorable/unfavorable; not highly at all/very highly regarded). Impressions of the intermediary were less favorable than impressions of the target person, marginally in the condition of no self-interest ($p = .07$), but significantly so in the two self-interest conditions ($ps < .003$).

In Study 5, participants ($N = 601$) read a scenario in which an intermediary publicly praised either a peer, or someone in a higher status position, or someone in a lower status position. Participants then reported their impressions of either the intermediary or of the target person as in Study 4. Impressions of the intermediary were less favorable than impressions of the target person ($p < .001$). Moreover, whereas impressions of the intermediary were lowest when the person publicly praised had a higher status position compared to the other two conditions ($p < .001$), impressions of the target person did not change across the three conditions ($p = .81$).

These studies show that disclosing the same positive information through an intermediary (vs. by direct self-promotion) elicits more positive and less negative emotions in recipients (Study 1), and increases the perceived superiority of the person being promoted on the traits being disclosed (Study 2), irrespective of the disclosure of self-interest by the intermediary (Study 3). However, intermediaries do not make as good an impression as the targets of their public praises, but, interestingly, more negative impressions of the intermediary are not reflected in more negative impressions of the targets they praise (Studies 4 and 5). In summary, being publicly praised by an intermediary seems to be beneficial for the target person, but it may carry hidden image costs for the intermediary.

How Audience Engagement (in the Form of Likes vs. Comments) on Social Media Posts Influences Subsequent Self-Disclosure

EXTENDED ABSTRACT

Audience engagement is a prominent feature of social media. We examine how different forms of audience engagement, namely likes and comments, influence the degree to which consumers disclose private information about themselves on social media.

Audience engagement with social media posts can formally be categorized into two main forms: single-click engagement (e.g., "likes") and composed content (e.g., "comments"). Prior research suggests that both forms tend to be perceived positively as forms of social approval (Burke & Kraut, 2013; Scissors, Burke, & Wengrovitz, 2016), and hence both might be expected to be positively reinforcing.

However, we propose that likes and comments might have different implications for the construal of intimacy with downstream consequences for self-disclosure. In particular, we posit that comments are likely to be perceived as reflecting a greater degree of intimacy than likes. The reason is that comments, because they must be read rather than automatically perceived, are likely to impose to a greater degree on the attention and consciousness of the recipient. Given that the ability to impose oneself on another is a key element of social closeness (Sharabany 1994), comments can be viewed as the social media equivalent of encroaching on one's personal space.

As a result, when comments are received from socially distant others, an intimacy violation can arise, thereby reducing the propensity to self-disclose.

We first examined our theorizing in a series of experiments. In a first study, participants were randomly assigned to either a "like" or "comment" condition in a study employing a single-factor between-subject design. Participants were asked to imagine that someone had posted a picture of themselves having fun with friends on a social media site such as Facebook or Instagram. Those in the "like" condition were asked to imagine that someone "liked" the photo and those in the "comment" condition were asked to imagine that someone posted a positive comment on the photo indicating that they liked the photo. Participants then evaluated how close the person that liked/commented on the photo was to the poster on a 7 point scale from "not at all" to "very." Participants rated the poster and the person that engaged with the post closer in the comment condition than in the like condition supporting the idea that there is a greater construal of intimacy associated with comments than with likes.

A second experiment assigned participants to either a like or comment condition in a single-factor between-subject design. Participants were asked to imagine that they had posted a picture of themselves having fun with friends on a social media site. Participants in like condition were asked to imagine that someone liked their post and those in the comment condition were asked to imagine that someone they did not know commented on their post, "Love this pic! You look like are having so much fun!" Participants then reported their perceived level of discomfort (which served as an operationalization of an intimacy violation) and, for the dependent variable, rated how cautious they would be in subsequently disclosing personal information. Consistent with the idea that comments received from individuals with which one has weak ties can be perceived as an intimacy violation, individuals reported greater discomfort after the receipt of comments than after the receipt of likes and this mediated the greater caution in disclosing personal information after receiving comments than after receiving likes.

Experiment 3 identified social distance as a moderator of the effect documented in Experiment 2, namely the greater discomfort associated with the receipt of comments (vs. likes) applied to socially distant others but not to socially close others. Experiment 4 provided evidence for our process account, showing that the degree of perceived intimacy violation evoked by comments was related to the degree to which the comment demanded the attention of the recipient. In particular, participants were asked to imagine they posted a picture of themselves having fun with family and that a commenter wrote, depending on condition, either "Looks fun" or "Looks fun! Was it?" The latter was perceived to demand greater attention and was perceived as a greater intimacy violation than the former when comments were received from strangers, but not when received from friends.

We continued our investigation through analysis of 187 million photos posted by almost 1 million users of the social media platform Instagram. We used the decision to disclose one's photo location as a proxy for self-disclosure more broadly. We found that the receipt of likes on a photo was associated with increased subsequent disclosure whereas the receipt of comments on a photo was associated with decreased subsequent disclosure. There was also an interaction effect, such that the effect of both likes and comments was enhanced when the location of the prior photo was disclosed (vs. not). These findings are consistent with the idea that likes are positively reinforcing whereas comments are negatively reinforcing of self-disclosure behavior.

This research thus shows that the implications of user engagement on social media arise not merely from the valence or content of the engagement but through the construal of intimacy implied through the behavior. We discuss practical implications for the design of social media platforms.

SESSION OVERVIEW

Goals and motivation have a tremendous influence on consumer behavior. Each dollar spent is linked to consumers' financial goals, each meal consumed is linked to people's health goals, and effort on a given task is likely to be shaped by whichever goals that task serves or competes with.

One way of understanding the influence of goals is through their effect on judgments and decision-making, particularly in the role of reference points (Heath, Larrick, and Wu 1999; Kahneman and Tversky 1979). Goals often serve as reference points, and reference-based judgments about outcomes, progress, and the impact of goal-related actions are central to motivation (Bonezzi, Brendl, and De Angelis 2011; Koo and Fishbach 2008; Soman and Cheema 2004). This perspective has provided valuable insights for consumer behavior and related fields, offering a unified explanation for many key findings in goals research including the goal gradient (Kivetz, Urminsky, and Zheng 2006), the performance benefits of high specific goals (Locke and Latham 1990; Ülkümen and Cheema 2011), and the motivational advantages of breaking long-term goals into smaller subgoals (Amir and Ariely 2008; Fishbach, Dhar, and Zhang 2006). At the same time, many important questions remain regarding the role of reference points in other key goal-related phenomena and the relationships (and distinctions) between goals-as-reference points and associated constructs.

The work presented in this session serves to address two broad questions, thereby expanding and clarifying understanding of how reference points influence motivation. First, what can we learn about consumer motivation and goal pursuit by extending and refining the concept of goals as reference points? Papers 1 and 2 explore the role of reference points in the effects of goal specificity (Wallace and Etkin) and in the simultaneous pursuit of multiple goals (Weingarten, Bhatia, and Mellers). Both papers' findings make valuable contributions to the theory of goals-as-reference points and shed new light on its implications for long-standing questions in goals research. Second, how can we conceptually and empirically disentangle the "reference point" aspect of goals from their other features and from related non-motivational cues? Papers 3 and 4 disentangle the reference-point effects of goals from the often-confounded effects of incentives and social norms (Chao and Larkin) and highlight the im-

portant conceptual distinction between motivational reference points and cognitive anchors in consumer financial decisions (Bartels and Sussman). These papers illustrate key applications of the theory of goals-as-reference points in consumers' lives, and their findings resolve important conceptual questions that arise from such applications.

Our research explores novel implications for pursuing specific versus non-specific goals, identifies how outcomes on multiple goals jointly shape satisfaction, and disentangles the motivational effects of reference points from related motivational factors (incentives, social comparisons) and non-motivational processes (anchoring). Together, this research offers valuable new insight into consumer motivation and goal pursuit. The session should have broad appeal to scholars interested in reference points, goal pursuit and motivation, financial decision-making, and judgment and decision-making.

Goal Specificity and the Dynamics of Consumer Motivation: The Role of Reference Point Focus

EXTENDED ABSTRACT

Consumers often pursue goals that lack specific end-states, such as goals to lose as much weight as possible or to pay off as much debt as possible. Yet despite considerable interest in the consequences of adopting non-specific (vs. specific) goals, how goal specificity impacts motivation during goal pursuit is less well understood. The current research explores the role of reference points in shaping goal specificity's effects. We propose that goal specificity alters what reference point consumers spontaneously adopt during goal pursuit: for specific goals, the end-state tends to be more salient, but for non-specific goals, the initial-state should be more salient.

The value function's features of diminishing sensitivity and loss aversion (Kahneman and Tversky 1979) offer a foundation for two key hypotheses that describe how this difference in focal reference points will impact the relationship between goal progress and motivation. First, we hypothesize that accumulating goal progress will decrease motivation for non-specific goal pursuers because they are moving away from their salient reference point (i.e., the initial-state), whereas it increases motivation for specific goal pursuers as they move toward their salient reference point (i.e., the end-state). Thus, due to diminishing sensitivity, there should be a crossover pattern of motivation depending on goal specificity. Second, we hypothesize that this crossover will be asymmetric because specific goal pursuers are in a loss frame (i.e., below their reference point) during goal pursuit, whereas non-specific goal pursuers are in a gain frame (i.e., above their reference point). Since the value function is steeper for losses, this difference should exaggerate the crossover effect when specific goal pursuers are more motivated (i.e., at high progress) and attenuate it when they are less motivated (i.e., at low progress). Five studies test these predictions.

Study 1 tests our predictions by assigning participants a specific or non-specific goal on an effortful proofreading task and measuring motivation at low, intermediate, and high levels of progress. Participants with a specific goal persisted significantly longer on an unsolvable task (i.e., finding nonexistent errors) as their accumulated goal progress increased, but those with a non-specific goal showed the opposite effect. Comparing across the two goal types, the effect of goal specificity emerged primarily at high progress, where motivation was significantly higher for specific versus non-specific goal pursuers. At

low progress, non-specific goal pursuers were directionally more motivated but the difference was non-significant. These findings support our predictions about the asymmetric crossover interaction between specificity and goal progress in determining motivation, produced by the effects of diminishing sensitivity and loss aversion.

Studies 2 and 3 replicate these findings in the domains of weight loss (Study 2) and debt repayment (Study 3). In both cases, motivation increases (decreases) with progress for specific (non-specific) goal pursuers, with the greatest effect of specificity at high progress and a smaller effect (in the opposite direction) at low progress. Furthermore, these studies measure the subjective impact of the next step of progress (e.g., the next pound of weight loss) for participants in each condition and find that differences in subjective impact mediate the observed effects on motivation. These studies also help to rule out alternative explanations by (1) testing our predictions in the absence of resource depletion, and (2) using specific goal levels that are calibrated from pretest data to be similar to participants' self-set aspirations (Study 2) or substantially lower (Study 3), minimizing any potential differences in goal difficulty.

Studies 4 and 5 provide a deeper test of our proposed mechanism by manipulating which reference point goal pursuers focus on, again in the contexts of weight loss (Study 4) and debt repayment (Study 5). As predicted, results show that specific goal pursuers "look like" their non-specific counterparts when both groups focus on the same reference point (i.e., the initial-state). Specific goal pursuers who focus on the initial-state (vs. end-state) reference point are significantly less motivated at high levels of progress and directionally more motivated at low levels of progress, and they are virtually indistinguishable from participants with a non-specific goal in both cases. Again, we find evidence of mediation by differences in the subjective impact of marginal goal progress. The findings of Studies 4 and 5 support the notion that a difference in reference point focus is central to understanding the dynamic effects of goal specificity on motivation.

This research advances understanding of the relationship between goal specificity, goal progress, and motivation, and in doing so, underscores the critical role that reference points play. Conversely, this work extends understanding of the motivational influence of reference points to the context of non-specific goals, an important but understudied aspect of consumer behavior. Our findings offer practical insight into how consumers can set important financial, health, and other personal goals to enhance their motivation.

Multiple Goals as Reference Points

EXTENDED ABSTRACT

Daily life pushes us up against multiple different goals across different domains: academic, health, finance, and social. While we would enjoy meeting all of these goals, it is not always possible. Sometimes people may hit their goals targets, while in other cases they may struggle and remain distant from reaching any of their goals.

How do people feel about success and failures relative to their goals? A prior literature on goals (target performance, or "mere goals," Heath et al. 1999) as reference points demonstrates that people's happiness compared to their goals follows the prospect theory value function. In one case, Markle et al. (2015) asked marathon runners' to predict their satisfaction with their performance relative to their time goal based on scoring above or below it. The results were consistent with the prospect theory value function's loss aversion (failing to hit the goal time had a greater impact on satisfaction than beating it) and diminishing sensitivity (changes in satisfaction

were larger based on changes close to the reference goal than further away from it) tenets.

We address how people feel about gains and losses with multiple goals. In addition to testing for loss aversion and diminishing sensitivity, we also examine whether additivity across the goal dimensions are met. That is, when making judgments of how they feel about outcomes on multiple goals, do people simply sum up how they feel about each outcome (additivity met), or are there interactions (additivity violated)? Dimensional additivity cannot be assumed given violations elsewhere in the literature (Birnbbaum and Stegner 1979; Einhorn 1970).

Four studies present evidence in favor of loss aversion and diminishing sensitivity, but they find evidence of violations of additivity.

Study 1a presents straightforward evidence of loss aversion. Participants were randomly assigned one set of two goals: 90 in English and 60 in Math, or 60 in English and 90 in Math. Participants then rated how they would feel (-50 = Extremely Unhappy, 50 = Extremely Happy) about three outcomes presented in a random order: achieving both goals, having a small loss (15 points) on one goal and a small gain (15 points) on another, and having a large loss and gain (30 points). Loss aversion predicts that losses should loom larger than gains, which suggests people will feel best about goal achievement and worst about the large loss (despite the equal-magnitude gain). Results supported loss aversion ($F(2, 168) = 89.17, p < .001$): participants were happiest with goal achievement ($M = 25.54$), then small losses ($M = 6.06$), and least happy with large losses ($M = -4.27$).

Study 1b supports a violation of additivity across dimensions. Participants read about a woman named Alice who had scored outcomes of a 60 in English and a 60 in Math. Participants rated how Alice would feel (-50 = Extremely Unhappy, 50 = Extremely Happy) about this outcome under four different pairs of goals: 90 in English and Math (two losses), 30 in English and Math (two gains), 30 in English and 90 in Math (one gain, one loss), and 90 in English and 30 in Math (one gain, one loss). Additivity predicts that the difference in happiness between having two gains and one loss and one gain should be similar to the difference in happiness between having one gain and one loss and two losses. A conjunctive interaction would predict a steeper drop in happiness between one gain and one loss and two losses. A disjunctive interaction would predict a steeper drop in happiness between two gains and one gain and one loss (Einhorn 1970). The results violated additivity and supported a disjunctive interaction: there was a steeper drop between two gains and one gain and one loss compared to the latter and two losses ($M = 11.57$; $F(1, 93) = 17.58, p < .001$). 63% of participants showed this pattern ($\chi^2(1) = 6.13, p = .013$).

Studies 2 and 3 use a larger design with model fitting to simultaneously test for loss aversion, diminishing sensitivity, and additivity. Participants read about Alice, but this time between-subjects we manipulated whether Alice's outcomes were 60 in English, 60 in Math, 70 in English and 50 in Math, or 50 in English and 70 in Math. We had participants make 49 judgments of how Alice would feel about these outcomes relative to a combination of goals built on 7 levels of Math (30, 40, 50, 60, 70, 80, 90) by 7 levels of English (30, 40, 50, 60, 70, 80, 90) that varied across 49 pages within-subject. These judgments enabled group-level and individual-level tests of our predictions through model fits.

Study 2 finds convergent evidence with Study 1a and 1b. Quantitative model fits on the group and individual levels suggest values of loss aversion >1 (consistent with the literature), sensitivity < 1 (consistent with diminishing sensitivity), and violations of additivity consistent with a disjunctive interaction. When there was at least one loss, participants' faced a displeasure approximately the size

of a moderate-sized loss on one goal. Models with parameters for loss aversion, diminishing sensitivity, and interactions fit better than models without them.

Study 3 replicates study 2 using a different context: exercises. Participants read about a character named Charles who had made progress on his goals for Pushups and Lunges at the gym. Just as in Study 2, participants rated Charles' happiness over 49 judgments with varying goals given a constant outcome. Study 3 again found evidence in favor of loss aversion, diminishing sensitivity, and violations of additivity. Specifically, there was again evidence of a disjunctive interaction in which the presence of one loss added an additional displeasure to Charles' rated feelings.

Ultimately, while we find evidence in favor of loss aversion and diminishing sensitivity, we do not find evidence for additivity across goal dimensions. That is, how people felt about their outcomes relative to multiple goals was not the simple sum of how they felt about each goal. We observe a disjunctive interaction: the presence of a loss added an additional displeasure to how people felt.

Why Do Goals Cause Cheating? Unpacking the Confounding Effects of Mere Goals, Social Comparisons, and Pay

EXTENDED ABSTRACT

Goal-based incentives are used by many firms to motivate their employees. A wide range of studies have estimated that specific and difficult goals consistently lead to higher performance than do-your-best alternatives in many tasks across the lab and field (Locke and Latham 1990, 2002).

However, scholars have warned that the use of goals can carry unintended consequences (Ordonez et al. 2009a, 2009b). Two studies claim that goals can increase worker cheating on a task (Schweitzer et al. 2004; Cadsby, Song, and Tapon 2010). These studies used laboratory experiments to show that subjects were more likely to cheat on a simple task when they were incentivized using a goal-based structure versus a do-your-best structure.

Advocates of goal-setting counter that these criticisms falsely ascribe some of the downsides of financial incentives to goals (Locke and Latham 2009). In particular, none of the aforementioned studies equated financial returns to cheating across conditions. The increased cheating in these studies could therefore be simply due to the differences in marginal or absolute pay, or to experimental subjects feeling that they would not be adequately paid if they did not cheat.

Additionally, studies on goals often confounded their results by using peer performance information to justify the assigned goal. Goal commitment is a key modulator for any effect of goals on performance, especially when tasks are difficult (Seijts and Latham 2001). To increase commitment, experimental studies on goals often inform subjects that many of their peers were able to attain the goal (e.g., Schweitzer et al. 2004). Importantly, subjects in non-goal conditions are not given information on peer performance, since there was no goal to justify. Increased cheating in the goal condition may therefore come from unfavorable social comparisons, and not from the use of goals.

In this study, we use a carefully-designed experiment that isolated the causal effects on cheating of the individual elements of goal-based incentive systems: mere goal use, social comparison use, and increased pay. Consistent with previous literature, we asked subjects to complete a word unscrambling task. Subjects were paid based on self-reported performance, although they did not know this when performing the task. To measure the effect of goals per se, we varied whether subjects were assigned a goal – to solve three or

more questions in the allotted time. For peer comparisons, we varied whether subjects were told that “many previous subjects were able to solve three or more questions in the allotted time.” For pay, we varied whether subjects were paid via a fixed rate or according to their performance. For each of these three factors, we measured the impact of changes to a single factor while equalizing the remaining two.

Subjects were not aware of our ability to detect cheating on the task. Subjects were instructed to throw away all of their worksheets after each step of the experiment in order to keep their desk clear for the next set of worksheets; trash bins were placed around the room such that subjects could do so without standing up. However, seat numbers and trash bins were strategically placed so that each trash bin served at most two subjects; for each pair of subjects, one had only blue pens at their desk while the other had only black pens. The pen colors allowed us to connect the contents of each trash bin to a seat number (but not to a subject name), allowing us to match the worksheets to the self-reported score from that seat number. We devised this method in order to avoid experimenter demand effects.

In total we had 8 treatment arms to our study, with each combination of goal use, social comparison framing, and financial incentives. This allowed us to measure the individual effects of all three incentive system elements on cheating, as well as all possible interaction effects.

We find that all cheating in this goal-based incentive system was driven by financial incentives and the use of social comparisons. Goals themselves did not increase cheating. Moreover, adding a goal to social comparison framing or to pay-for-performance still did not increase cheating. Simply put, our results suggest that goals in and of themselves do not impact cheating, although elements often used in conjunction with goals do increase unethical behavior.

Anchors or Targets? An Examination of Credit Card Statements

EXTENDED ABSTRACT

Anchors and targets differ in important ways. Notably, targets have motivational properties, whereas anchors act as neutral starting points for subsequent judgments. Research designs are often unable to disambiguate whether values are anchors or targets, and researchers have frequently been agnostic regarding this distinction. However, these differences may be critical in determining how people respond to them. For example, targets that are too high may backfire and lead people to pay less than they otherwise would, while targets that are too low may be demotivating once people have passed them. We would not anticipate parallel reactions to anchors. One area where this difference is particularly important is in the domain of personal finance and specifically, choices of credit card payment amounts in response to values appearing on credit card statements. Literature on this topic often refers to minimum values as anchors despite the fact that they appear to have many properties of targets (e.g., Stewart, 2009). This distinction may be important for understanding which values can effectively be used to increase chosen payments.

In this paper, we aim to better understand how people rely on cues in their environments. Specifically, we put forth methods for distinguishing anchors from targets based on distributional properties. This methodology is based on the premise that people will be motivated to exert additional effort to meet or exceed a target value when they are close to that target value, leading them to be more likely to end at a point just above the target value than just below it. However, people will have no parallel motivation with regard to an

anchor value. Therefore, they will be equally likely to end at a point just above or just below an anchor value. This leads to “piling up” in a distribution of people’s responses to target values, but a smooth distribution of people’s responses to anchor values. We highlight the importance of this distinction, examining how people use external cues as goals to motivate themselves, and formalize methodology for identifying differences in the distributions. From a practical perspective, we investigate how information provided on credit card statements influences subsequent payments.

After introducing a new methodology for distinguishing between anchors and targets, we validate this analytical approach by applying it to existing datasets with explicit anchors or target values, across a range of domains.

Next, we move to an investigation of how borrowers respond to values on their credit card statements. We begin by examining how participants select payments as a function of suggested values proposed to them on credit card statements, and find that people’s hypothetical payments align with distributions of responses to target values (Study 1). In Studies 2 and 3, we investigate whether suggested values take on other motivational properties consistent with targets as goals, namely loss aversion and diminishing sensitivity. We test for loss aversion by examining whether people feel different amounts of satisfaction if an identical payment is above or below the suggested amount and find that people are happier paying the same amount on a bill with the same overall value when then amount paid is above (vs. below) the suggested amount. We test for diminishing sensitivity by examining whether people have higher motivation to pay when they are close to (vs. far away from) their goal, and find support for this conclusion.

To test for the ecological validity of these findings, we turn to a large data-set of Chase cardholder payments. We examine distributions of payments around values that have been explicitly selected by cardholders as goals, and examine how inclusion of these values alters payments. Here, we find that consumer debt repayment patterns change when suggested values are introduced. Specifically, we observe large discontinuities in payment values around suggested amounts, with people being more likely to pay just above than just below these values. This pattern is again consistent with responses to targets. People are much more likely to pay just above the suggested amount than to pay just below it. Application of our newly introduced methodology to this data provides a similar result. Although this data provides an excellent context for examining whether backfiring occurs, we do not find evidence of backfiring within this self-selected group. Furthermore, rather than finding that low goals are demotivating, we show that a subset of people who select low values themselves are motivated to pay more than that amount, and will pay multiples of the initial value. We describe how our more nuanced understanding of values on credit card statements can be used to encourage debt reduction.

SESSION OVERVIEW

The purpose of this special session is to present research offering fresh theoretical perspectives and novel empirical contexts examining anthropomorphism in consumer behavior. The four papers are well-grounded in theory, and related in their focus on implications for consumer welfare and financial decision-making more specifically—areas that have been largely overlooked in empirical studies of anthropomorphism. We believe that this session would be of interest to researchers studying anthropomorphism, financial decision-making, and consumer welfare more generally. We think that the session will stimulate discussion among researchers in these subjects, and that the four papers will provide new ideas for future research in anthropomorphism and related areas.

The first paper by Wang, Kim, and Zhou finds that when money is anthropomorphized, people will save more money rather than spend it. This research has important implications for consumer financial decision-making and welfare, since it suggests that anthropomorphizing money might be an effective way to get people to save more money. Consumers do not save enough money, particularly in the United States where credit scores and spending continue to rise (Camara 2012).

The second paper by Kim, Puzakova, Kwak, and Jeong finds that brand anthropomorphization increases selling prices and decreases buying prices for used products, due to stronger emotional attachment by sellers, and perceptions of relationship-dissolution-stigma by buyers. Different financial valuations of humanized products by buyers and sellers may lead to a less efficient market for used goods, thereby negatively affecting consumer welfare.

While the first two papers focus on anthropomorphism's effects on saving, buying, and selling behavior, the latter two papers focus more generally on consumers' willingness to spend money on anthropomorphized products, while maintaining a focus on consumer welfare.

The third paper by Levy, Kim, and Reed II examines how a consumer's moral identity affects perceptions of and willingness to

purchase anthropomorphized brands. Drawing on two influential theories of morality—the expanding circle of moral regard (Singer 1981; Reed and Aquino 2003), and morality as mind perception (Gray, Young, and Waytz 2012), this paper finds that higher moral identifiers assign more humanness to anthropomorphized brands, leading them to be more willing to purchase these brands. Morality has strong links to consumer welfare, yet its implications for anthropomorphism have been previously unexplored.

The fourth paper by Chen and Wan investigates the influence of anthropomorphism on choosing multiple products from an assortment. Building on prior studies on anthropomorphism and person perception (Nisbett, Peng, Choi, and Norenzayan 2001), this research demonstrates that consumers are more likely to think in a holistic manner after thinking about products as anthropomorphized. In turn, holistic thinking leads consumers to choose whole sets of products, even when the assortment includes a less-preferred option. This finding is relevant for consumer finances and welfare, since consumers may decide to spend more money on, though experience less enjoyment from, the consumption of products that they prefer less.

In conclusion, these four papers provide novel theoretical viewpoints and empirical contexts for examining the relationship between anthropomorphism, financial decision-making, and consumer welfare.

Is Money Worth Saving? Money Anthropomorphism Increases Saving Behavior

EXTENDED ABSTRACT

Consumers do not save enough (Kotlikoff, Spivak, and Summers 1982), particularly in the United States, where credit scores continue to rise (Camara 2012). It is estimated that over 85% of Americans would be in immediate financial difficulty if they lost their jobs or had to deal with any other crises (Jones 2015). Accordingly, a lot of research has been devoted to developing effective interventions to help consumers to reach their optimal saving levels (Ersner-Hersfield et al. 2011; Soman and Cheema 2011; Soman and Zhao 2011; Ulkumen and Cheema 2011). However, previous research on money saving usually treats money as an object or an instrument. In this research, we focus on a seemingly simple psychological shift in construing money—namely, anthropomorphizing money. Specifically, we examined whether imbuing money with humanlike characteristics can impact the amount of money consumers are willing to save.

The current research suggests that anthropomorphizing money leads people to perceive money as having the capacity to feel and sense (Gray, Gray and Wegner 2007); thus, anthropomorphized money is perceived to be capable of benefiting from good or suffering from evil (Gray, Young and Waytz 2012). Consequently, compared to objectified money, anthropomorphized money is perceived to be more sensitive to harm and thus to be more vulnerable (Dijker 2010; Gray and Wegner 2009), which activates consumers' protective tendency. Therefore, we argue that money anthropomorphism would significantly increase consumers' saving intention, as consumers will attempt to protect anthropomorphized money from potential harm. We tested this prediction with five studies.

A pilot study examined consumers' natural tendency to anthropomorphize money, their general tendency to anthropomorphize non-human entities and their saving intention. Correlation analy-

ses showed that consumers' natural tendency to anthropomorphize money was positively correlated with saving intention, whereas their general anthropomorphism tendency was not. In the main studies, we manipulated money anthropomorphism to test its causal effect on saving intention and behaviors; more importantly, we also sought to understand the psychological process that mediates this causal relationship, as well as some boundary conditions in which this relationship does or does not emerge.

In Study 1a, the money anthropomorphism manipulation followed Aggarwal and McGill (2012), in that participants were instructed to imagine that money had come to life as a person and to describe the sort of person money would be. Study 1A showed that participants were more likely to save a higher percentage of their income when they anthropomorphized it than when they construed it as an object or when they anthropomorphized a financial institution (e.g., a bank). Participants who construed a financial institute as a human were more likely to save their income than participants who construed money as an object.

In Study 1B, we used a different method to manipulate money anthropomorphism, in which participants were instructed to imagine that money had come to life as a person and think about what type of personality money would have. They rated money's personality on five bipolar scales representing the Big Five personality traits (Gosling, Rentfrow and Swann Jr. 2003). To strengthen the manipulation, participants were also asked to describe what type of face money would have based on the personality they had described. Study 1B replicated study 1A's findings with a different population.

In study 2, we used the same money anthropomorphism manipulation as Study 1b, but we used a different measure of saving intention and measured the perception of vulnerability associated with money to test the underlying mechanism for the positive effect of money anthropomorphism on saving intention. A mediation analysis showed that the effect of money anthropomorphism on participants' intention to save money was mediated by increased vulnerability perception of money. That is, money anthropomorphism led people to consider money to be more vulnerable and thus made them more likely to protect it by saving it.

Study 3 examined a boundary condition for the money anthropomorphism effect. We hypothesized that when saving was construed as an unsafe option, saving money would not be an ideal way to protect money, and money anthropomorphism would not increase saving intention. Half of the participants were led to construe money saving as an unsafe option. Specifically, they read a news article that described a retirement account as not safe. The other half read a news article about food safety (i.e., control condition). The results revealed a significant interaction between money anthropomorphism and manipulation of perceived safety of saving money. Specifically, money anthropomorphism increased saving intention in the control condition, replicating the finding in the previous studies, but money anthropomorphism did not increase saving intention when participants construed saving money as an unsafe option.

Study 4 measured participants' real saving plans. Specifically, we contacted students from a list of students who had received a scholarship to business school. Right after participants received the scholarship, they completed a survey in which we implemented money anthropomorphism and measured their saving and spending plans for the scholarship. The results showed that participants indicated a higher saving intention after construing money as a human and allocated a higher percentage of their scholarship to saving compared to participants who construed money as an object. In the last week of the semester, we contacted the students again and asked them to recall their actual spending of their scholarship

money. The results showed that participants actually kept their saving plan and saved more money when they construed money as a human rather than as a mere object.

Beauty (Value) is in the Eye of the Beholder: How Anthropomorphism Affects the Pricing of Used Products

EXTENDED ABSTRACT

Marketers often strategically use anthropomorphism (i.e., imbuing nonhuman objects with humanlike characteristics; Aggarwal and McGill 2007) as a brand positioning strategy for their products and services. Overall, prior work in the area has shown the impact of brand anthropomorphism at different stages of brand relationship development and maintenance—on brand evaluations, consumer-brand interactions, and the relationship duration processes (Chandler and Schwarz 2010; Puzakova, Kwak, and Rocereto 2013). However, what is still missing from this past work is an understanding of the impact of brand anthropomorphism on consumer decisions after the relationships with the brand have dissolved. In this research, we fill this important gap by examining the impact of brand anthropomorphism on the valuation (selling vs. buying prices) of used products, the novel context in which consumer-brand relationships end with a pre-owner's decision to dispose of a used product. Therefore, the present research aims to make a critical contribution to prior work on the endowment effect by showing that buyers and sellers are both influenced by the same factor, namely, brand positioning strategy.

Prior research in anthropomorphism demonstrates that consumers are more likely to develop stronger emotional connections and experiences with humanized (vs. nonhumanized) brands (Chandler and Schwarz 2010). Here, we posit that even after consumers decide to end their brand relationships, they will have stronger self-brand connections to the products when they are humanized (vs. nonhumanized) leading to higher product valuations and, thus, higher product selling prices. Next, we build on research demonstrating that during the relationship dissolution stage, individuals become particularly concerned with extending themselves in time and being connected to their past (Richins 1994). More specifically, we rely on prior work showing that consumers with more positive (vs. less positive) attitudes toward the past develop greater attachments to objects and people present in their past. Thus, we propose that sellers' more positive attitudes toward the past are likely to facilitate their emotional connections to brands when they are anthropomorphized (vs. nonanthropomorphized), thus, resulting in higher selling prices for used products.

Next, in the buyer context, we propose a new social schema—relationship-dissolution-stigma—that buyers are likely to apply toward anthropomorphized brands while setting their prices for used products. In general, stigma is defined as an attribute that makes an individual to be perceived as deviant, less desired, and socially discredited (Goffman 1963). For example, past research delineates that people stigmatize others who ended their relationships (e.g., divorce, separation). Prior research indicates that divorced people tend to suffer from “informal, relational sanctions” and are perceived as less desirable as partners for new relationships (Konstam et al. 2016). Given that consumers also end relationships with their brands (Fournier 1998), we propose that buyers are likely to stigmatize anthropomorphized used products by perceiving them as “rejected” by a pre-owner, potentially unacceptable for other people, and as being responsible for relationship dissolution. Thus, an application of relationship-dissolution-stigma to an anthropomorphized (vs. nonanthropomorphized) used product is likely to decrease a buyer's evalu-

ation of this used product, thus, resulting in lower buying prices. Furthermore, prior research suggests that the activation of stigma can be attenuated by people's way of thinking. In particular, activating a creative mindset disrupts a reliance on stereotypical associations and results in incorporation of novel information into a decision-making process (Sassenberg and Moskowitz 2005). As such, we propose that consumers with more creative mindsets are less likely to apply the relationship-dissolution stigma toward anthropomorphized used products, thus, attenuating the negative effect of brand anthropomorphization on buying prices for used products.

We tested these ideas in three studies. In each study, participants were randomly assigned to either a buying condition or a selling condition. In Study 1 ($n = 120$), in the seller condition, participants viewed an ad for a fictitious brand of toasters (anthropomorphized vs. nonanthropomorphized), were asked to imagine buying and owning the product for a year, and then selling it on eBay. We measured the minimum starting bid price for the product. Similarly, in the buyer condition, participants indicated the maximum price they would bid for the same used product. Study 2 ($n = 124$) examined the impact of anthropomorphism on buying and selling prices for a fictitious brand of juicers in the fixed-price setting (e.g., deals on Craigslist). The results of both studies showed that participants reported higher selling prices (Study 1: $M_{\text{anth}} = \$28.21$, $M_{\text{nonanth}} = \$19.70$; $F(1,57) = 8.07$, $p < .05$; Study 2: $M_{\text{anth}} = \$33.58$, $M_{\text{nonanth}} = \$29.13$; $F(1,59) = 8.09$, $p < .05$) and lower buying prices (Study 1: $M_{\text{anth}} = \$23.37$, $M_{\text{nonanth}} = \$30.03$; $F(1,59) = 11.11$, $p < .05$; Study 2: $M_{\text{anth}} = \$17.06$, $M_{\text{nonanth}} = \$22.97$; $F(1,61) = 8.06$, $p < .05$) for a humanized (vs. nonhumanized) brand.

Next, in Study 3 ($n = 183$), in the seller condition, the results showed a significant main effect of brand anthropomorphization on selling prices ($\beta = 10.75$, $p < .05$) and a significant two-way interaction between brand anthropomorphization and consumers' attitudes toward the past ($\beta = 9.23$, $p < .05$), thus, supporting our prediction that sellers' attitudes toward the past moderates the core effect. In addition, we found that self-brand connection mediates the effect of brand anthropomorphization on selling prices only for respondents with more positive attitudes toward the past (a point estimate for the effect = 4.61; 95% CI = [.50, 12.73]). In the buyer condition, the results of ANOVA showed a significant main effect of brand anthropomorphization on buying prices ($M_{\text{anth}} = \$46.25$, $M_{\text{nonanth}} = \$55.70$; $F(1, 114) = 11.32$, $p < .05$) and a significant interaction between a consumer's mindset and brand anthropomorphization ($F(1, 114) = 4.11$, $p < .05$), with anthropomorphism decreasing buying prices only for consumers with less creative mindsets ($M_{\text{anth}} = \$41.63$, $M_{\text{nonanth}} = \$56.92$; $F(1, 114) = 14.29$, $p < .05$). Finally, relationship-dissolution stigma mediated the effect of brand anthropomorphization on buying prices only for participants with less creative mindsets (a point estimate for the effect = -1.69; 95% CI = [-4.90, -.10]).

Overall, we find consistent evidence that brand anthropomorphization increases (decreases) selling (buying) prices of used products leading to stronger endowment effect. Our research provides novel theoretical insights into the boundary conditions of the core effects, as well as sellers and buyers' differential psychological processes that influence prices of used products.

Moral Identity and Brand Anthropomorphism

EXTENDED ABSTRACT

Marketers frequently use anthropomorphized, or human-like representations of brands in their brand communications (Aggarwal and McGill 2007). For example, marketers can incorporate human-like facial features into their products, have a product "speak" to

consumers in an advertisement, and describe a product using first-person language. Consumer researchers have made good progress over the past decade in uncovering the types of situations in which consumers will have a more positive vs. negative evaluation of anthropomorphized brands.

However, most (if not all) consumer research has considered brands simply as anthropomorphized vs. non-anthropomorphized, without investigating these perceptions more deeply. Prior research has not examined what individual or situational differences might lead consumers to consider an anthropomorphized brand as more (vs. less) human, and downstream consequences of this perception. We redress this oversight by examining the relationship between moral identity, brand humanness perceptions, and preferences for and attitudes toward anthropomorphized brands.

An influential perspective of morality holds that being a moral person involves expanding the circle of moral regard and care to include entities that extend well beyond oneself and one's current situation (Singer 1981; 2009). For example, a highly moral person should give moral care to people in distant lands whom one may never actually meet, as well as to animals, nature, the environment, planet Earth, etc. Building on this perspective, research has shown that people higher in moral identity, defined as "a self-conception organized around a set of moral traits" (Aquino and Reed 2002), extend greater care to outgroups relative to in-groups (Reed and Aquino 2003). That is, people who place a greater importance on moral traits give more of their resources and care to social outgroups. A second major perspective on morality holds that "mind perception" is the essence of morality (Gray, Young, and Waytz 2012). Thus, individual and situational factors may impact whether an entity is perceived to have "mind" in the form of greater perceived humanness

Based on these conceptualizations of morality, we predict that one's moral identity should impact one's attitudes toward and preferences for an anthropomorphized brand. Though anthropomorphized brands are not actually human, by nature they possess human-like cues and characteristics. A critical factor in evaluating whether entities are anthropomorphized is whether relevant agent knowledge is elicited (Epley, Waytz, and Cacioppo 2007); that is, whether knowledge about humans is used and applied in a particular situation. We believe that higher moral identifiers should be more likely to recognize, accept, and prefer these humanized characteristics to a greater extent than would people lower in moral identity. Formally,

Hypothesis 1: Consumers higher in moral identity, relative to consumers lower in moral identity, will exhibit greater preference for an anthropomorphized brand (vs. a non-anthropomorphized brand).

Hypothesis 2: Consumers higher in moral identity, relative to consumers lower in moral identity, will perceive an anthropomorphized (vs. non-anthropomorphized) brand to seem more human, which will mediate the interactive effect of moral identity and anthropomorphism on brand preference.

Studies 1, 2, and 3 tested H1, and studies 2 and 3 tested H2. Each of the three studies used a different form of anthropomorphism, and a different product type, to ensure the generalizability of the findings. Study 1 manipulated anthropomorphism through a 1st vs. 3rd person description of a product- "JK Battery" (manipulation taken from Chen, Wan, and Levy 2017), and measured participants' moral identity using the Aquino and Reed (2002) moral identity scale. Results showed a significant interaction, whereby consumers higher in

moral identity displayed higher purchase intentions for the anthropomorphized (vs. non-anthropomorphized) brand. Interestingly, there was a negative main effect of anthropomorphism, such that people overall preferred the non-anthropomorphized brand. This suggests that brand anthropomorphism may not always be beneficial, but rather that its effects may depend on situational or individual factors such as one's moral identity.

In study 2 anthropomorphism was manipulated by having participants view either an anthropomorphized or non-anthropomorphized image of "Orange Vie" orange juice (manipulation taken from Puzakova, Kwak, and Rocereto 2013). Moral identity was measured. Consistent with the results of study 1, higher moral identity was associated with higher purchase intentions and brand attitudes when the brand was anthropomorphized (vs. not). Supporting the proposed psychological mechanism, a moderated-mediation test (Hayes PROCESS Model 7) showed that this result was due to higher moral identifiers ascribing greater humanness to the anthropomorphized brand.

In study 3, participants viewed either an anthropomorphized picture of the "M&M's characters" or a non-anthropomorphized picture of M&M's candies. In the anthropomorphism condition, participants were asked to think about the M&M's as if they had come to life as a person, while in the non-anthropomorphized condition they were asked to think about the attributes of M&M's candy (manipulation adapted from Aggarwal and McGill 2012). Participants' moral identity was measured. Results again showed an interaction effect, whereby higher moral identity led to higher purchase intentions and brand attitudes when the brand was anthropomorphized (vs. non-anthropomorphized). Moderated-mediation results (Hayes PROCESS Model 7) again showed that the underlying psychological mechanism was higher moral identifiers' ascription of greater humanness to the anthropomorphized brand.

In conclusion, this research is the first to examine how moral identity affects preference for anthropomorphized brands. It is also the first research we know of to examine whether an individual difference variable affects the degree to which an anthropomorphized brand is seen as human. We found that consumers higher in moral identity preferred anthropomorphized (vs. non-anthropomorphized) brands due to greater perceived humanness of the anthropomorphized brand. These results support the proposition that mind perception is an essential aspect of morality, and also provide evidence that higher moral identity is associated with expanding the circle of moral regard to include anthropomorphized brands.

The Influence of Anthropomorphism on Choosing Multiple Products from an Assortment

EXTENDED ABSTRACT

Anthropomorphism, defined as attributing physical features and mental capacities that are unique to human-beings to non-human agents (Epley, Waytz, and Cacioppo 2007), is commonly employed in marketing communication. Consumers often see talking cars (e.g., Ford) and chocolate candies with legs and arms (e.g., M&M's) in commercials. Recent consumer research on anthropomorphism has primarily focused on consumers' response to one specific product, such as consumer evaluation (Landwehr, McGill, and Herrmann 2011) and replacement intention (Chandler and Schwarz 2010) of an anthropomorphized product. But whether anthropomorphism can systematically influence consumers' choice of multiple options from a product assortment remains an intriguing and uninvestigated question. The current research aims to fill this research gap by investigating the effect of anthropomorphism on consumers' choice of multiple product options from the perspective of consumer thinking

style. In the following sections, we first review the research background to derive our predictions and then present three studies that test our hypotheses.

Previous research suggests that the mental processes involved in thinking about human-beings govern cognition about objects when people anthropomorphize objects (Castelli, Happé, Frith, and Frith 2000; Epley et al. 2007). In order to uncover the thinking style that dominates people's perception of anthropomorphized products, it is important to understand how people perceive other persons. Research in impression formation shows that people use both a person's category membership and his/her particular attributes to form general impression (Brewer 1988). But the category-based process, which is more holistic and follows gestalt principles, has priority over the attribute-oriented process, which is piecemeal and elemental (Fiske and Neuberg 1990). Consistently, the person construal system theory (Freeman and Ambady 2011) suggests that people detect physical features of a target person (e.g., body cues), and integrate such cues to form a holistic impression of the target person. These findings suggest that person construal involves the attention to the whole person. Drawing on anthropomorphism and person perception literature, we predict that anthropomorphism would promote holistic thinking style, which distributes attention to the whole (Nisbett, Peng, Choi, and Norenzayan 2001), in contrast to analytic thinking style which focuses more on the parts (Nisbett et al. 2001).

The theory of thought system (Nisbett et al. 2001) suggests that holistic thinkers have a greater tendency to draw relationships between objects. For example, holistic thinkers tend to indicate higher degrees of association between pairs of arbitrary objects, and they are good at connecting objects together (Ji, Peng, and Nisbett 2000). Marketing researchers have documented that holistic thinkers (vs. analytic thinkers) tend to perceive closer relationships between the parent brand and an extension, and also perceive higher brand extension fit (Monga and John 2007). That is, holistic thinkers are more likely to see the parent brand and the extension as an entity. We therefore predicted that holistic thinkers would be more likely to see all the product options as an entity, which in turn promotes the choice of all the product options. To test our predictions, we examined the effect of anthropomorphism on thinking style in experiment 1 and the downstream effect on consumers' choice in experiments 2 and 3.

Experiment 1 tested the effect of anthropomorphism on thinking style. We first manipulated anthropomorphism by asking participants to write down their thoughts of a laptop computer either as a person or an object (Aggarwal and McGill 2012). After that, we measured participants' thinking style by asking participants to complete the locus of attention scale (Choi, Koo, and Choi 2007) which is commonly used to assess holistic (vs. analytic) thinking style. We found that participants in the anthropomorphism (vs. non-anthropomorphism) condition tend to think more holistically.

Experiment 2 tested the effect of anthropomorphism on consumer choice. In particular, we examined consumer choice of products from an assortment. Participants first read a hypothetical scenario in which they shop around and find yogurts with four different apple flavors (i.e., red delicious, golden delicious, yellow transparent, and cripps pink). We followed the same method in experiment 1 to manipulate anthropomorphism. To measure consumer choice, we first asked participants to assume that they tried the sample of each flavor and form different preference scores for the four flavors (i.e., 4 for red delicious and yellow transparent; 6 for grimes golden and cripps pink; 1 = do not like the flavor; 7 = like the flavor very much). Then the participants were informed that retailer offers a promotion package (with special discount) containing four packs of yogurts, and that they can choose any combinations of flavor for the four

packs. For example, they can form the promotion package by choosing one pack of each flavor, or four packs of the same flavor, or two packs of one flavor plus two packs of another flavor. Results of this experiment revealed that participants in the anthropomorphism (vs. non-anthropomorphism) condition were more likely to choose the whole set of yogurts (i.e., putting one pack of each flavor in the promotion package).

Experiment 3 aimed to replicate the results of experiment 2 and to reveal the mechanism by measuring the mediator (i.e., holistic thinking). The procedure was the same as experiment 2 except the following two changes. First, we changed the four yogurt flavors to vanilla, coffee, strawberry, and mango. We asked participants to base their choice on their intrinsic preference for the four familiar flavors, rather than assume preference for the unfamiliar flavors used in experiment 1. Second, we measured participants' holistic thinking of the yogurts to reveal the underlying process. Results of experiment 3 suggested that participants in the anthropomorphism (vs. non-anthropomorphism) condition were more likely to choose the whole set of yogurts by including their less preferred flavors. A mediation analysis confirmed that the effect was mediated by holistic thinking.

The findings contribute to the literature by documenting a novel effect of anthropomorphism and by revealing the psychological process underlying this effect. And it advances the understanding of consumers' choice of multiple options from an assortment.

SESSION OVERVIEW

Intrinsic motivation, which involves an individual engaging in a behavior purely because the activity itself is interesting and/or spontaneously satisfying (Deci and Ryan 2000), is a fundamental drive of human behavior, profoundly affecting consumers' persistence, performance and well-being in the process of goal pursuit. As such, over the past decades, intrinsic motivation has received much attention from various disciplines. Researchers have made considerable progress in understanding how the effective functioning of intrinsic motivation is affected by extrinsic motivators, such as threats of punishment (Deci and Cascio 1972), deadlines (Amabile et al. 1976), rewards (Deci 1971) and monitoring measurements (Etkin 2016). Yet, our understanding of the psychological, emotional, and social determinants of intrinsic motivation remains limited.

The proposed session highlights the newest research on how the everyday feelings of scarcity and busyness and our tendencies towards social comparison and impression management might undermine intrinsic motivation. In an attempt to gain a better understanding of why we are not intrinsically motivated enough at times, four papers examine how and when the origination and expression of intrinsic motivation is hindered by resource scarcity (vs. abundance), subjective busyness (vs. non-busyness), malicious (vs. benign) envy, and the interviewee (vs. interviewer) role.

The first three papers examine how the origination of intrinsic motivation is affected by the psychological states of scarcity, busyness and envy, respectively. **Wu and Zhu** show that a general sense of resource scarcity (vs. abundance) hinders the origination of intrinsic motivation to learn by thwarting consumers' psychological freedom. Scarcity's negative effect on intrinsic motivation is mitigated by fulfilling the psychological freedom via choice. **Wilcox and Laran** demonstrates that the subjective feeling of busyness decreases intrinsic motivation because the perception of having many things to do makes consumers uncertain about their ability to accomplish their objectives, an effect that reverses when consumers overcome this uncertainty. Next, **Salerno, Laran and Janiszewski** examine how the social emotion envy impacts people's intrinsic motivation. Whereas malicious envy orients people towards extrinsically-moti-

vated outcomes, benign envy increases people's intrinsic motivation to exert effort. Finally, expanding our understanding of the interplay between social environments and intrinsic motivation, **Woolley and Fishbach** examine the expression of intrinsic motivation in the job interview context. The authors find that job candidates tend to underestimate how much others are impressed by their expressions of intrinsic motivation, and therefore choose suboptimal pitches that fail to express their intrinsic motivation during job interviews.

Taken together, the four papers (all in advanced stages) in this session provide novel insights into when and why consumers might lack, or fail to express, intrinsic motivation, suggesting multiple ways to enhance intrinsic motivation, such as increasing psychological freedom, overcoming feelings of uncertainty, and eliciting benign envy. As the session integrates diverse research to highlight newest theoretical developments in this important yet understudied area, it is expected to appeal to a broad audience, including researchers interested in goals and motivation, scarcity and resource constraints, emotion, social interactions, and consumer judgment and decision making.

Scarcity and the Intrinsic Motivation to Learn

EXTENDED ABSTRACT

While resource abundance has emerged as the norm in modern, industrialized societies, consumers are frequently exposed to contextual cues that may remind them of resource scarcity (Laran and Salerno 2013; Mehta and Zhu 2016; Zhu and Ratner 2015). In this paper, we examine how a scarcity (vs. abundance) mindset impacts consumers' intrinsic motivation to learn (i.e., doing a behavior because of one's internal volition rather than external contingencies; Black and Deci 2000; Deci and Ryan 2000, 2008; Vansteenkiste et al. 2004). For example, will individuals with a scarcity (vs. abundance) mindset exert more or less effort to learn in the absence of financial incentives? Will consumers people under scarcity (vs. abundance) enjoy learning more or less, or be more or less interested in intrinsically-rewarding learning materials?

Building on prior research suggesting a possible connection between scarcity and low psychological freedom (Haushofer and Fehr 2014; Mittal and Griskevicius 2014; Mehta and Zhu 2016), and a well-established linkage between the satisfaction of psychological needs to act freely and the origination of intrinsic motivation (e.g., Black and Deci 2000), we propose that a scarcity (vs. abundance) mindset lowers individuals' psychological freedom, which consequently hinders the intrinsic motivation to learn. We test our hypotheses in four experiments.

Experiment 1 examined the main thesis that a scarcity (vs. abundance) mindset undermines the intrinsic motivation to learn. Participants were first asked to recall incidents where they either felt they did not have enough resources ("scarcity" condition) or had plenty of resources ("abundance" condition; Fischhoff et al. 2003; Mehta and Zhu 2016; Roux et al. 2015). Next, all participants were given a learning task where they could read and learn about forty festivals in different countries. Participants read one festival description at a time (each festival was presented on the screen for a fixed duration), and they could stop the task whenever they wanted to. The number of the festival descriptions read served as the measure of intrinsic mo-

tivation. Supporting our hypothesis, participants in the scarcity (vs. abundance) mindset condition read a significantly smaller number of festivals, and spent significantly less time on the task.

Experiment 2 tested the proposed mediating role of psychological freedom in the relationship between scarcity mindset and the intrinsic motivation to learn. Participants first read a fictitious news article that was either about the scarce supply of natural resources (“scarcity mindset” condition) or the growing abundance of natural resources (“abundance mindset” condition). Next, participants responded to the measures examining the satisfaction of psychological freedom (Chen et al. 2015). Finally, all participants completed a joke-learning task in which they read and rated ten jokes (each of which was presented on the screen for a fixed duration; Woolley and Fishbach 2015). As a measure of the decreases of intrinsic motivation to learn, we assessed the extent to which participants perceived the joke-learning task as an obligation to work (Laran and Janiszewski 2011). As predicted, participants in the scarcity (vs. abundance) mindset condition were more likely to perceive the learning task as an obligation to work, which was mediated by the lower psychological freedom associated with a scarcity (vs. abundance) mindset.

The last two studies provided further evidence for the proposed mechanism of psychological freedom. If scarcity impacts the intrinsic motivation to learn through psychological freedom, we should be able to moderate this effect by experimentally threatening (experiment 3) or fulfilling participants’ psychological freedom (experiment 4). Experiment 3 manipulated both scarcity (vs. abundance) mindset and the presence of psychological freedom threat. Specifically, participants first completed the scarcity mindset manipulation as used in experiment 2. Next, participants in the “freedom threat” condition were asked to recall three situations where they felt forced to do things they would not otherwise choose to do, whereas those assigned to the “control” condition were asked to list three activities they did in the past week. Finally, all participants read ten festival descriptions that were randomly chosen from a festival book. The maximum amount of money that participants were willing to pay for this book (\$0-\$100) served as a proxy of the intrinsic motivation to learn. As predicted, in the “control” condition where the psychological freedom was not threatened, participants’ willingness-to-pay for the book in the scarcity (vs. abundance) mindset condition was significantly lower; this difference disappeared when psychological freedom was experimentally threatened. In addition, consistent with our theorizing, participants in “abundance mindset” conditions were willing to pay less for the book when their psychological freedom was threatened versus not threatened.

The last experiment manipulated the fulfillment of psychological freedom in addition to a scarcity (vs. abundance) mindset to further test the mechanism. Specifically, participants first completed the scarcity mindset manipulation as used in experiments 2-3. Next, participants were asked to read a sample of a magazine that introduced products launched in the market. In the “freedom-fulfillment” condition, participants could choose a magazine issue they would like to read amongst four options. In the “control” condition, the computer randomly chose one of the four magazine issues for the participants to read. All participants then read the same ten product descriptions. Enjoyment of the learning task and participants’ interests in signing up for a free subscription of the magazine were used to assess the intrinsic motivation to learn. As predicted, in the “control” condition where the psychological freedom was not fulfilled, participants’ enjoyment and interests in signing up for the magazine in the scarcity (vs. abundance) condition were significantly less; this difference disappeared when psychological freedom was experimentally fulfilled. In addition, participants in “scarcity mindset” conditions enjoyed the

learning task more and were more interested in signing up for the magazine when their psychological freedom was fulfilled versus not fulfilled.

Collectively, we demonstrate that a scarcity (vs. abundance) mindset lowers psychological freedom, which in turn undermines the intrinsic motivation to learn. These effects are moderated when consumers’ psychological freedom is experimentally threatened or fulfilled.

The Dual Effect of Subjective Busyness on Consumer Motivation

EXTENDED ABSTRACT

Consumers are increasingly living busy and active lives. Busyness has become an endemic aspect of modern society as the past several decades have seen a significant increase in self-reported busyness (Sullivan 2008). Previous research examining the relationship between busyness and task-related outcomes finds that being busy often has a negative impact on people’s ability to successfully achieve tasks. In this research, we offer another perspective on how busyness can impact task outcomes by examining how the psychological state of feeling busy influences consumers’ willingness to adopt and complete tasks (i.e., task motivation).

We conceptualize busyness as a subjective state that results from individuals’ assessment of their current and expected level of activity (Wilcox et al. 2016). Although this assessment is influenced by the amount of time people are engaged in activity, it is primarily determined by the perceived density of activity, such as the frequency and variety of tasks, relative to expectations (Gershuny 2005). Consequently, people feel busier when they recognize that they have many (vs. few) tasks to complete. We propose that the difficulty associated with completing many (vs. fewer) tasks underlies the influence of feeling busy on task motivation.

Specifically, we contend that subjective busyness can make consumers both less and more willing to perform certain activities. Subjective busyness can decrease task motivation because the difficulty associated with having many things to do makes consumers uncertain about their ability to accomplish their objectives. However, busyness can increase task motivation when consumers overcome this uncertainty. In these cases, those who feel busy demonstrate higher willingness to perform tasks compared to those who feel less busy. This effect is driven by busy people finding it more intrinsically motivating to perform effortful tasks.

The objective of study 1 was to demonstrate that subjective busyness makes individuals more uncertain about their ability to accomplish a focal task. We induced individuals to feel busy (vs. not) by showing them advertisements that prime feelings of busyness prior to measuring how uncertain they were about their ability to complete a task. We employed two measures of confidence. The first asked participants to set a self-imposed deadline for completing the task. The payment was structured in such a way that they would receive a lower payment for setting a longer deadline. The second was a direct measure of how confident they were that they would complete the task. As predicted, busy participants were less confident in their ability to complete the task compared to those who were not busy. Specifically, busier participants set longer deadlines (at a lower payment) and self-reported feeling less confident that they would meet the deadline.

The purpose of study 2a was to show that subjective busyness reduces task motivation as a result of people’s uncertainty about their ability to accomplish tasks. We manipulated busyness by having participants list ten vs. three tasks on their “to do” list. We then

asked participants about their willingness to engage in a common task: shopping. Specifically, we assessed their motivation to go to the store to take advantage of a sale on new appliances. As busyness should make participants more uncertain about their ability to get to the store, we expected that participants in the busy condition would be less motivated to participate than those in the not busy condition. As expected, busy participants indicated that they were less motivated to go shopping, an effect mediated by task confidence. Study 2b replicated the findings using the same advertising manipulation from study 2a. As a measure of motivation, we assessed their willingness to pay for a gift card that could only be redeemed in store.

The primary purpose of study 3 was to demonstrate that when task uncertainty is attenuated, consumers who feel busy become more motivated to perform a task than those who feel less busy. Our theory suggests that people reduce their task motivation when they feel uncertain about achieving an outcome because failure is a threat that is emotionally painful. Thus, in study 3 participants were primed (vs. not primed) to cope with their uncertainty by detaching themselves from the situation (Greco and Roger 2001). Consistent with previous studies, when participants were not instructed to detach themselves from the situation, busyness lowered motivation, an effect mediated by task uncertainty. However, when people were instructed to detach themselves from the situation they displayed greater motivation.

In study 4, we sought to demonstrate that the reversal of the effect of busyness on task motivation when participants overcome their uncertainty is driven by an increase in how intrinsically motivating they find performing the task to be. To accomplish this, we manipulated task uncertainty by giving people false feedback that they were either good or not good at getting tasks accomplished. When participants were told that they were not good at getting tasks accomplished, busyness reduced motivation. However, when participants were told that they were good at getting tasks accomplished, which made them more certain about their ability to accomplish tasks, busyness increased motivation. This effect was driven by participants finding it intrinsically satisfying to complete the focal task.

By advancing our understanding of busyness as a subjective state this research makes several contributions. First, previous studies on busyness have primarily relied on measures and manipulations of objective workload (i.e., number of tasks actually performed; e.g., Parkes 1995), which makes it impossible to isolate the effects of feeling busy from those that emerge from actually executing many activities. We show that subjective busyness can influence task motivation independently of objective workload by holding the actual level of activity constant. Second, we demonstrate that busyness does not always have a negative effect on task-related outcomes and that how people think about busyness determines its effect on task motivation. Finally, understanding how subjective busyness affects behavior has an array of implications, as companies may be able to use marketing communication to influence consumer purchasing behavior via their perceptions of busyness.

Process versus Outcome: How Envy and Goal Framing Affect Motivation

EXTENDED ABSTRACT

Envy occurs from a negative social comparison with another individual who holds a superior advantage on some desired quality, achievement, or possession (Parrott and Smith 1993). Envy is a self-conscious emotion that is cognitively complex and multifaceted in its experience (Crusius and Mussweiler 2012). Benign envy is said to happen when a person is envious towards another but perceives that the superior advantage of the envied individual is deserved, whereas

malicious envy arises when the envious individual believes that the superior advantage of the envied individual is undeserved (Crusius and Lange 2014; Van de Ven, Zeelenberg, and Pieters 2011a).

Prior investigations into people's motivational responses to envy have led to the consensus that benign envy motivates goal pursuit whereas malicious envy does not (Lange and Crusius 2015; Van de Ven, Zeelenberg, and Pieters 2011b). The current research challenges this conclusion by considering how each type of envy might affect goal pursuit differently, depending on how the goal under consideration is interpreted. We find that both envy facets potentially motivate goal pursuit. However, for this to occur, the goal must be framed in a way that matches the underlying motivational orientation of each envy type. Specifically, when benign envy is experienced, people are more motivated to pursue goals that are framed to emphasize the process (i.e., what you need to do to pursue the goal) of goal pursuit. This preference occurs because benign envy orients people towards intrinsically-motivated behaviors (i.e., exerting effort), and a goal highlighting the process of goal pursuit fits with that orientation. By contrast, malicious envy leads people to become more motivated to pursue goals that are framed to emphasize the outcome (i.e., what results you derive from goal attainment) of goal pursuit. This preference occurs because malicious envy orients people towards extrinsically-motivated behaviors (i.e., obtaining rewards), and a goal highlighting the outcome of goal pursuit fits with that orientation. We tested these predictions in four studies.

Study 1 examined the pursuit of a health goal, using a 3 (emotion: control, benign envy, malicious envy) x 2 (goal frame: process, outcome) between-subjects design. Participants in the benign (malicious) envy condition wrote about a time they were envious of another individual for something that was deserved (undeserved). In an unrelated consumer preference task, participants then indicated their interest in a new multivitamin that was described as either "helping people do the work necessary to reach their health goals" (process condition) or "helping people achieve their health goals" (outcome condition). Results showed a significant interaction between the emotion and goal frame factors ($F(2, 178) = 6.67, p < .01$). Participants in the benign (malicious) envy condition were significantly more interested in the multivitamin when framed in terms of the process (outcome) of one's health goal.

Study 2 found that the emotional experience of envy is necessary for the differences in deservingness between benign and malicious envy to exert an influence on goal pursuit as a function of goal framing. We examined this issue based on research showing that people's trust in their emotions shapes their emotional experience (Avnet, Pham, and Stephen 2012), using a 2 (emotion: benign envy, malicious envy) x 2 (trust in emotions: high, low) x 2 (goal frame: process, outcome) between-subjects design. Participants in the benign (malicious) envy condition were made to feel envy based on the job offer of a fellow student that was deserved (undeserved). Next, participants were manipulated to either trust their emotions (high trust) or not (low trust). Participants then completed the consumer preference task in study 1. Results revealed a significant interaction among the emotion, trust in emotions, and goal frame factors ($F(2, 178) = 6.67, p < .01$). The high trust in emotions condition replicated the results of study 1. In the low trust in emotions condition, participants in the benign (malicious) envy condition were no longer more interested in the multivitamin regardless of whether it was framed in terms of the process (outcome) of one's health goal.

Study 3 provided evidence for the hypotheses that benign (malicious) envy is driven by an underlying intrinsic (extrinsic) motivation to exert effort (obtain rewards). We examined these hypotheses during the pursuit of an academic goal, using a 2 (emotion: benign envy,

malicious envy) \times 2 (luck opportunity: absent, present) between-subjects design. After the envy manipulation, participants read a product review for a smartphone app purportedly geared towards the pursuit of one's academic goals. The app was either described to help people based on how many exercises they completed (luck absent) or that people may improve academically independent of how many exercises they completed (luck present). We then monitored goal pursuit via the number of anagrams attempted (supposedly an example exercise from the app). Results revealed a significant interaction between the emotion and luck opportunity factors on the number of anagrams attempted ($F(1, 198) = 8.28, p < .01$). Participants in the benign (malicious) envy condition attempted a significantly greater number of anagrams in the luck absent (present) condition. Moderated mediation analyses revealed that the beneficial effect of benign (malicious) envy on anagrams attempted as a function of luck opportunity was mediated by a focus on effort (focus on rewards).

Study 4 provided further process evidence by examining the influence of benign (malicious) envy on the pursuit of a fitness goal (i.e., real amount bid on a pair of Nike shoes) as a function of people's implicit theory of motivation (Murphy and Dweck 2015). A regression analysis revealed a significant interaction between emotion (benign envy, malicious envy; manipulated) and implicit theory (incremental, entity; measured) on the amount bid ($\beta = -11.46, p < .01$). Specifically, benign (malicious) envy led participants to provide a greater bidding amount when they held an incremental (entity) implicit theory.

Collectively, this research contributes to the literatures on envy, self-conscious emotions, and motivation. The findings illustrate how envy has a more nuanced influence on motivation than previously thought. Finally, this research also highlights the importance for considering how goal pursuit may vary based on the framing of the goal.

Underestimating the Importance of Expressing Intrinsic Motivation in Job Interviews

EXTENDED ABSTRACT

To successfully sell yourself in a job interview, what qualities should you highlight to impress the recruiter and secure a job offer? You clearly want to make a good impression, but knowing what others find impressive is not straightforward, especially in recruitment situations where attentional resources for perspective taking are limited (Apperly et al. 2006; Vorauer et al. 2009). Obviously, you should state your skills, ambitions and long-term goals – your extrinsic motivation. But to what extent should you also emphasize your intrinsic motivation—that you value interesting, fun work?

Intrinsic motivation refers to pursuing an activity because the process is rewarding, and is contrasted with extrinsic motivation where people work to achieve an outcome for which their work is instrumental (Etkin 2016; Fishbach and Choi 2012; Laran and Janiszewski 2011). Importantly, these motivations are not mutually exclusive, and most jobs offer a combination of both intrinsic and extrinsic rewards (e.g., extrinsic: opportunity for career advancement; intrinsic: some level of interest and self-expression).

We propose that when predicting what another person finds impressive, people get intrinsic motivation wrong. That is, people lack awareness that others value intrinsic rewards in the first place (DeVoe and Iyengar 2004; Heath 1999), leading them to underestimate how much others are impressed by their expressions of intrinsic motivation. As a result, people underemphasize their intrinsic motivation in recruiting.

Four experiments test our predictions. Experiment 1 assigned participants the role of job candidate or recruiter. Participants viewed

a list of personal motivations that candidates could use in describing themselves during an interview. Candidates predicted how these motivations influenced recruiters' hiring decisions, whereas recruiters indicated the likelihood of hiring someone who expressed each motivation. Traits mapping onto intrinsic motivation portrayed a person motivated by what she achieves while working (e.g., "I love doing my work."). Traits mapping onto extrinsic motivation portrayed a person motivated by what she achieves as a result of working (e.g., "I value advancing my career."). As predicted, candidates' expressions of intrinsic motivation had a greater influence on recruiters' decisions than candidates anticipated, $F(1, 206) = 6.56, p = .011$. However, candidates accurately predicted recruiters' valuation of extrinsic motivation, $F(1, 206) = .01, p = .905$.

Our theory assumes mispredictions—predictors fail to appreciate the extent to which their intrinsic motivation matters for others—yet, our theory does not imply that only job candidates mispredict. Recruiters will also underestimate the extent to which admitted candidates value a work place that emphasizes intrinsic motivation when deciding to accept a job offer. Experiment 2 tests both sides simultaneously.

Experiment 2 manipulated both role (candidate vs. recruiter) and perspective (predictor vs. evaluator). Replicating Experiment 1, candidates expected that their expressions of intrinsic motivation mattered less to recruiters than they did, $F(1, 77) = 5.28, p = .024$, with no effect for extrinsic motivation, $F(1, 77) = 1.15, p = .286$. We further examined whether recruiters persuading a job candidate to join their company mispredict how much candidates care about expressions of intrinsic, but not extrinsic motivation. We find this is indeed the case. Recruiters predicting what job candidates care for underestimated candidates' valuation of intrinsic motivation, $F(1, 77) = 6.03, p = .016$, with no effect for extrinsic motivation, $F(1, 77) = .40, p = .527$. Overall, evaluators cared more about intrinsic motivation than predictors anticipated, whereas predictors accurately assessed valuations of extrinsic motivation.

Do people mispredict how much others value expressions of intrinsic motivation because they fail to realize that others find intrinsic rewards at work important? To examine this underlying process, participants in Experiment 3 assumed the role of job candidate or recruiter. To measure recruiters' rewards from work, candidates estimated what recruiters care about at work, whereas recruiters provided their true valuations of intrinsic rewards (e.g., "Doing work that you are interested in") and extrinsic rewards (e.g., "Having job security at your work"; modified after Heath 1999). To measure the weight recruiters give to motivation in hiring, participants answered the same list of intrinsic and extrinsic motivations (traits) from Experiment 1 that candidates could express to recruiters during an interview.

As predicted, recruiters valued receiving intrinsic rewards at work more than candidates expected, $F(1, 206) = 14.91, p < .001$, with no effect for extrinsic rewards, $F(1, 206) = 1.87, p = .173$. Replicating Experiments 1-2, recruiters valued candidates' expressions of intrinsic motivation more than candidates anticipated, $F(1, 206) = 6.95, p = .009$, with no effect of extrinsic motivation, $F(1, 206) = .16, p = .693$. Mediation analyses revealed that candidates underestimate how much recruiters value their expressions of intrinsic motivation because they underestimate how much recruiters value receiving intrinsic rewards at work ($\beta_{\text{indirect}} = .23, SE = .06; 95\% \text{ CI } [.12, .36]$).

In Experiment 4, participants assigned the role of job candidate or recruiter both read two job pitches, an "Intrinsic Pitch" and an "Extrinsic Pitch." Recruiters selected the pitch for the candidate they preferred to hire, whereas job candidates were incentivized (lottery for \$100) to select the pitch they believed recruiters preferred to hear.

The Intrinsic Pitch highlighted the presence of intrinsic motivation as a strength and the absence of extrinsic motivation as a weakness; the opposite was true for the Extrinsic Pitch. As predicted, a majority (69.5%) of recruiters selected the Intrinsic Pitch, with only 43% of candidates selecting this pitch despite being incentivized to predict recruiters' preference, $\chi^2(1, N = 168) = 11.95, p < .001$.

Across four experiments, we find people underestimate how impressed others are by their expressions of intrinsic motivation, although they accurately predict how much others value their extrinsic motivation. This was true both for job candidates interviewing for an open position and companies trying to market their organization to new hires. As a result, people fail to emphasize their intrinsic motivation, leading them to be less persuasive to others.

SESSION OVERVIEW

Leisure is time that people spend with freedom of choice, intrinsic motivation and enjoyment (Shaw and Dawson 2001). We spend leisure time attending baseball game with friends, celebrating accomplishments with family, or volunteering in the neighborhood. As these examples suggest, many of the ways people spend leisure time involve social contexts and the presence of other people. As such, examining how the presence of others affects leisure choices and experiences is both theoretically important and substantively relevant. What activities do consumers prefer sharing with others, and when do consumers derive more utility from shared leisure experiences? How do consumers in the social contexts perceive another person's leisure choices?

Our session sheds light on these questions. The first three papers examine how the presence of others influences the anticipated and actual leisure experiences. **Yang and McGill** begin by discussing how the anticipation of activity partner's affective experience influences consumers' choice of sharing. Consumers are more willing to share affect-rich (e.g., desserts) than affect-poor resources (e.g., vegetables), because they expect more positive affective reactions from activity partners, which will in turn increase their own enjoyment. Such tendency is further amplified if consumers have an experiential (vs. material) goal.

Moving from the anticipation of shared experiences, **Wu et al.** examine how clarity about a partner's objectives influences the consumer's actual experience. When consumers are sharing experiences with others (e.g., visiting an art gallery), they may be unclear about the degree to which her friend prioritizes absorbing the artwork or socializing with her. A lack of clarity limits the consumer's ability to absorb consumption content and socialize, which can have downstream effects including reduced enjoyment. However, Many consumers do not spontaneously take simple steps to increase clarity.

Next, **Brick et al.** focus on a specific type of leisure activity—celebration, and examine the emotional and social benefits provided by cel-

ebrations. The authors find celebrations provide greater social support compared to other shared leisure activities because of the presence of more close others. Further, being the focal celebrant and/or organizing celebrations for others can further increase perceptions of social support.

Finally, **Olson et al.** examine how people in social contexts perceive another consumer's ethical choices, including spending leisure time on volunteering, based on income sources (welfare recipients vs. income earners). The authors show welfare recipients (vs. income earners) are perceived less moral when they spend much time on volunteering (e.g., in a museum) or make donations of material-possessions due to the stronger perception of wastefulness.

Together, this session investigates both social influences on people's sharing choices and actual leisure experiences, as well as the effects of leisure choices on others' impressions of them. These papers also suggest multiple ways to help consumers derive more utility from shared leisure experiences, including increasing objective clarity and the presence of close others. We expect this session to appeal to a broad audience, including researchers interested in social influence, social cognition, experiential consumption, moral judgment and consumer decision making.

The Decision to Share: From the Joy of Self-Possession to the Joy of Shared Consumption

EXTENDED ABSTRACT

Why do people share desserts, which feel good, but not vegetables, which are good? Little research has examined the decision to share in which resource re-allocation is targeted at, and immediately followed by consumption of the resources. In the present research, we investigate how people make such sharing decisions, and distinguish them from the conventionally studied giving decisions where resources are re-allocated without considering subsequent consumption outcomes (e.g., when allocating monetary tokens).

Such decisions to share arise before (or during) one's consumption of resources and involves the transfer of resources. As such, decision-makers face the tradeoff between two goals: to maximize one's possession, and to maximize one's experience from consumption. What maximizes one's possession is not necessarily the same as what maximizes one's experience. In particular, based on a distinction made between the affective value and the monetary value as two independent sources of value (Hsee and Rottenstreich 2004), we theorize that the monetary value of resources is crucial for evaluating one's possession, whereas the affective value of resources is more crucial for evaluating one's consumption experience, because it is during consumption that the affective value can be realized. Moreover, the involvement of others during consumption can augment one's own consumption experience (Boothby, Clark and Bargh 2014; Ramanathan and McGill 2007; Steinmetz, Fishbach and Zhang 2016). Thus, while people will be less willing to share resources of great monetary value, they may be more willing to share resources of great affective value, due to the spontaneous consideration of how enjoyable the consumption experience will be.

Therefore, we hypothesize that when making a sharing decision, people are more willing to share affect-rich resources with others when holding the monetary value constant. Further, although the anticipated personal enjoyment from consumption may be enhanced by either the mental simulation of others' involvement, or the pros-

pect of actual joint consumption, we predict the prospect of actual joint consumption may further amplify one's willingness to share affect-rich resources, because synchronized joint consumption has been shown to enhance enjoyment in multiple facets (Boothby et al. 2014; Ramanathan and McGill 2007; Steinmetz et al. 2016). We present four studies to examine the decision to share.

In study 1, we recruited 186 mturk participants ($M_{\text{age}} = 35$, 52% Male) to an allocation task between themselves and another mturker modeled after the Dictator Game. Participants were randomly assigned to two conditions that differed in the nominal resource for allocation (token vs. joke). The value of each token was equated with a joke. Participants either allocated tokens that they would use to redeem jokes, or allocated jokes directly. We found participants allocating jokes were more generous than those allocating tokens (giving 5.5 vs. 4.1 out of 11 to the other, $t(184) = -3.57$, $p < .001$). Subsequent measures suggest that participants allocating jokes considered each other's enjoyment from consumption (i.e., of listening to the jokes) more than those allocating tokens, whereas they similarly considered each other's satisfaction with possession (i.e., with the allocation decision). In sum, the consideration of the subsequent consumption experience may underlie the willingness to share affect-rich resources with others. A replication study with real consequences in a lab is in progress where preliminary evidence of the same pattern has been observed ($N = 45$ (target $N = 200$), Median = 6.0 vs. 4.5, non-parametric t-test $p = .07$).

In study 2, we further examine how subsequent consumption affects the sharing decision. We randomly assigned online participants ($N = 320$, $M_{\text{age}} = 35$, 56% Male) to a 2 (resource: affect-poor vs. affect-rich) \times 2 (subsequent consumption: separate vs. joint) between-subjects design. We asked participants to imagine that they had been kept hungry for a food-tasting study and were given seven mini trays of cracker chips. The experimenter ran short on chips for the next participant, so participants were asked how much they would like to share their chips, from one to six trays. The cracker chips were either described as plain or flavorful, paired with doctored images that highlighted the difference in flavors. A pretest ($N = 60$) validated that the flavored chips were rated more likely to induce positive affective reactions than the plain cracker chips, and both were rated to have a similar market price. Further, participants either read that the other participant would retrieve the allotted cracker chips and taste them in a separate room, or that they would taste the cracker chips sitting next to each other. Overall, participants were more willing to share when the cracker chips were considered affect-rich than affect-poor (2.9 vs. 2.3, non-parametric $p = .002$). Moreover, subsequent joint consumption amplified this effect ($F(1,318) = 3.3$, $p = .044$). Participants were more willing to share when the allocation decision was followed by joint consumption (3.2 vs. 2.2, $p < .001$).

In study 3, we examined a theoretical moderator, that people will be more willing to share if they considered experiential gain to be more crucial to their happiness, and less so if they considered material gain to be more crucial to their happiness. We recruited participants ($N = 194$, $M_{\text{age}} = 35$, 49% Male) online and asked them either to recall three material possessions or three experiential consumption experiences that made them happy in order to prime material or experiential goals. Manipulation checks confirmed that participants considered material possession or experiential consumption to be more crucial for their happiness depending on the condition ($p < .05$). We then asked participants to imagine that they were having a good time catching up with a specified neighbor/friend, and wanted to have a drink together. The participants were asked to choose between a generic bottle vs. a premium bottle of wine. Results revealed that the experiential goal prime increased participants' willingness to share the affect-rich premium wine (45% vs. 24%, $\chi^2 = 6.4$, $p = .012$).

Last, we explored how affective value influences the decision to share in common food consumption scenarios ($N = 266$). We found the willingness to share a food item with a friend was predicted by the anticipated affective experiences ($s = .44$, $p < .001$), but not the overall substantial benefits (e.g., nutritional or material) brought by the food item ($\beta = .02$, $p > .25$).

Getting the Most from Shared Experiences: The Undervalued Impact of Goal Clarity on Shared Consumption

EXTENDED ABSTRACT

Consumers often engage in leisure activities with others, such as visiting an art gallery or attending a baseball game. When these activities support multiple objectives, such as absorbing the consumption content and socializing with the partner, it may be unclear to consumers the degree to which an activity partner wants to absorb the consumption content versus simply to enjoy the experience and socialize. The primary goal of this research is to examine how the degree of clarity about the partner's objectives impacts a consumer's ability to balance focusing on the consumption content and socializing with the partner during shared leisure activities.

Building on previous research on teamwork suggesting that clarity about objectives facilitates coordination and reduces concerns about the partner's experience (e.g., Bang et al. 2010; Fitzsimons, Finkel and vanDellen 2015), we posit that lacking (vs. having) clarity about the partner's objectives (i.e., whether the partner prioritizes absorbing the consumption content or socializing) hinders consumers' ability to coordinate during the experience. The poorer coordination associated with low (vs. high) clarity about the partner's objective not only undermines consumers' ability to absorb the consumption content, but also their ability to socialize with the partner. This poorer coordination can also lead to downstream consequences such as lower enjoyment and higher regret about engaging in the experience accompanied. However, given people tend to underestimate the necessity of remedying a mildly harmful (vs. critical and intense) situation (Gilbert et al. 2004), we predict that in mundane leisure contexts consumers underestimate the importance of clarity and do not take simple steps to increase clarity. Five experiments tested these hypotheses.

In experiment 1, participants were asked to explore an art gallery in their campus student union either alone or with another person. We measured accompanied participants' clarity about the partner's objectives. As predicted, the higher the clarity accompanied participants had about their partner's objectives, the better they remembered information about the artwork, and the more they felt they learned ($ps < .05$). Solo consumers learned more and better than accompanied consumers with low but not high clarity. Further, enjoyment of the shared experience increased with higher clarity ($p = .03$).

Experiment 2 examined the effects of clarity when partners had incongruent (vs. congruent) objectives. We also tested the mediating role of coordination. Specifically, participants in the high-clarity condition recalled an accompanied leisure activity where they were clear that their partner had the same (congruence condition) or different (incongruence condition) objectives. Participants in the low-clarity condition recalled an experience where they were not sure whether their activity partner had the same (vs. different) objectives. Whereas objective (in)congruence had no significant effects, participants with low (vs. high) clarity were less able to focus on the consumption content ($p = .005$) and socialize with the partner ($p = .038$), effects that were mediated by the ease of coordination. Results also

revealed that low (vs. high) clarity led to lower enjoyment and higher regret about engaging in the activity accompanied ($ps < .01$).

We conducted experiment 3 in the art gallery of a hotel/conference center to further examine the effects of clarity in real consumption environments and whether consumers would take steps to increase clarity. We manipulated clarity by instructing one-third of the pairs to discuss about their objectives before entering the gallery (“high-clarity”), instructing one-third to go directly into the gallery (“low-clarity”), and allowing one-third to choose whether to discuss their objectives before entering the gallery. Additional participants were sent into the gallery solo. Consistent with results of studies 1 and 2, low-clarity participants felt less able to read brochures and absorb art, and had poorer memories of the artwork than participants in high-clarity or solo conditions ($ps < .01$). Low (vs. high) clarity participants were also less able to socialize with the partner ($p = .019$). Again, the ease of coordination mediated these effects. Despite the benefits of clarity, 24 out of 26 pairs in the choosers condition chose not to discuss about their objectives, providing evidence that consumers underestimate the benefits of having high (vs. low) clarity.

Most dyads in experiments 1-3 were friends/family. Experiment 4 manipulated the relationship (friends vs. strangers) between partners in addition to clarity to test whether the positive effects of clarity can be generalized to strangers. Participants were asked to explore five movies with another person in the lab. Whereas dyads in the “strangers” condition went directly to the movies, dyads in the “friends” condition had a Relationship-Closeness-Induction-Task (Sedikides et al. 1999) first. We manipulated clarity by having pairs disclose (vs. not disclose) their objectives to each other before starting the activity. Results showed that dyads under low (vs. high) clarity learned less about the movies ($p = .005$), enjoyed the experience less ($p = .046$), and were less interested in visiting the movie festival ($p = .058$). In a separate study, we described the procedures of this study and asked participants to predict the effects of clarity on enjoyment and learning. Only about half of the participants correctly predicted the positive effects of clarity, suggesting that people tend to underestimate the benefits of clarity.

To provide further support for the proposed mechanism of coordination, experiment 5 manipulated the level of coordination required during an activity. Clarity about the partner’s objective was measured. Specifically, participants were asked to explore photos from National-Geographic Instagram with another participant in the lab, and they were either shown the photos and the blurbs automatically (“low-need-for-coordination” condition) or they needed to navigate through the activity together (“high-need-for-coordination” condition). Results showed significant interaction effects of clarity and need-for-coordination on the ability to focus on the consumption content and enjoyment ($ps < .04$): when the activity required high coordination to navigate through, lower clarity about the partner’s objective decreased consumers’ ability to focus on the consumption content and enjoyment; however, when the activity required minimal coordination, clarity did not impact consumers’ ability to focus on the consumption content or enjoyment.

Together, our results show that clarity about the partner’s objective plays an important role in shared consumption. However, consumers don’t predict the strong effects of clarity nor do they take simple steps to increase clarity.

Celebrations and Social Support

EXTENDED ABSTRACT

Extensive research has focused on social support during times of adversity (e.g., Bolger, Zuckerman, and Kessler 2000; Cohen

1988; Kasser and Sheldon 2000; Lakey and Cohen 2008); yet, almost no empirical work has examined social support during positive life events (see Gable et al. 2004; Reis et al. 2010 for exceptions). Recently, Feeney and Collins (2014) called attention to the lack of research on social support during times of non-adversity and emphasized the importance of this type of supportive function in helping people thrive. In particular, they note that “very little theoretical or empirical work has focused on the factors that promote or hinder effective social support processes in close relationships” (Feeney and Collins, p. 18). The current research examines this understudied area and investigates how celebrations can be a relevant context for understanding the process by which individuals garner social support during positive life events.

In our first study, we explored individuals’ innate definitions of celebrations and the benefits they receive from celebrations. 204 participants from Amazon’s Mechanical Turk completed the study in exchange for financial compensation. Participants answered a series of open-ended questions and prompts designed to explore celebrations and social support (e.g., “What does a ‘celebration’ mean to you?” “Please recall and describe a recent celebration you had or participated in that was not related to a holiday” “What did you get out of the celebration?”) We then had two undergraduate RAs code the responses. Coders were highly reliable and any disagreements were resolved by a third coder. Supporting our own conceptualization, participants viewed celebrations as joint consumption highlighting at least one member’s separate, positive event. Celebrations were also viewed as largely providing social and emotional benefits. Furthermore, we found that individuals who are the focal celebrant and have a celebration organized for them report greater support than do individuals who have to organize their own celebration.

In our next set of studies, we expand upon our initial findings using experimental designs to better understand how celebrations may contribute to perceptions of social support. In Study 2, we examined whether individuals report greater perceptions of social support after recalling a celebration, experience (i.e., positive consumption) than a coping experience (i.e., negative consumption) as previous research has largely focused on social support in response to negative life events. In addition, Study 2 examines the process through which celebrations may increase perceptions of social support, namely by increasing the number of close others in one’s social network. 214 participants from Amazon’s Mturk successfully completed this study. Participants received financial compensation in exchange for participation. Participants were randomized to recall a time when something positive [negative] happened and they celebrated [coped with] this positive [negative] event by engaging in a consumption activity with others. Participants then indicated, “about how many close friends and close relatives do you have (people you feel at ease with and can talk to about what is on your mind)?” Finally, they completed the measure of perceived social support (MDSPSS, Zimet et al. 1988). An ANOVA revealed a significant difference between the conditions in terms of perceived social support ($p < .05$) with individuals in the celebration condition reporting greater social support ($M = 5.7$) than the coping condition ($M = 5.4$). Moderated mediation analyses revealed that the number of close others mediated the link between consumption experience and perceived social support.

Study 3 used a 3-cell design (celebration vs. coping vs. positive control) to further explore celebrations and social support. After indicating consent, participants were randomized to recall one of the following: a time when something positive happened and they engaged in a consumption activity with others (celebration), a time when something negative happened and they engaged in a consumption activity with others (coping), or a time when something positive

happened (positive control). Participants then completed the same measure of number of close others as in the previous study and the MDSPSS (Zimet et al. 1988). An ANOVA revealed a significant difference between the groups in terms of number of close others ($p < .05$) and planned comparisons indicated that individuals in the celebration condition reported significantly more close others than did those in the coping ($p < .02$) or the control ($p < .05$) conditions. Number of close others significantly predicted perceived social support, and moderated mediation analyses revealed that the number of close others mediated the link between consumption experience and perceived social support.

Finally, Study 4 experimentally manipulated the focal celebrant and the organizer to replicate the findings from Study 1 and to explore whether the role of the individual at a celebration may differentially contribute to perceptions of social support. Study 4 used a 2 (focal celebrant: self vs. other) \times 2 (organizer: self vs. other) design. 406 participants from Mturk completed the study in exchange for financial compensation. After consenting, participants were randomized to recall and describe a recent celebration that was for them [not for them] and that they helped [did not help] organize. They then completed a series of measures, including the measure of perceived social support (MDSPSS, Zimet et al. 1988). In line with the findings from the previous study, an ANOVA with focal celebrant condition, organizer condition, and their interaction as predictor variables revealed a significant interaction on perceived social support ($p < .02$). Planned comparisons indicated that individuals who organized a celebration for someone else reported greater perceptions of social support than did individuals who organized a celebration for themselves ($p < .05$). Conversely, individuals who did not organize a celebration reported greater perceived social support when the event was for them than when it was for someone else ($p < .05$).

Across four studies, we find evidence that celebrations as joint consumption increase perceptions of social support. Furthermore, we suggest some of the ways in which this process occurs, e.g., increasing the number of close others, and how different roles, e.g., whether one is the focal celebrant and/or organizer, in celebrations can influence perceptions of social support. The theoretical and practical implications are discussed.

Wasting Time and Money? How Consumers Evaluate Others' Resource (Mis)Management

EXTENDED ABSTRACT

Recent research demonstrates that low-income consumers receiving government assistance are seen as undeserving of ethical consumption choices (Olson et al. 2016). This group, relative to those who earn modest to high incomes, are perceived as less moral when buying organic food, renting a Prius, or making monetary donations, presumably because such options cost additional money. We build upon this research by examining decisions beyond financial expenditures. Specifically, we propose that divergence in moral attributions extends to decisions about *all* resources, including time and material goods.

This prediction is not obvious based on past research. Previous work on consumer altruism suggests that resources are not perfectly fungible. The act of giving time versus money (holding dollar value constant) is seen as more caring, moral, and heartfelt (Reed, Aquino, and Levy 2007). While favorable perceptions of altruism exist for the *act* itself, they may not extend to the *people* doing the act, especially when those people are at the lower end of the socioeconomic (SES) ladder. We propose that identical resource expenditures by low-income consumers receiving government assistance are

subject to greater scrutiny due to opportunity costs (i.e., “considering alternative uses for one’s resources when deciding whether to spend resources on a focal option”; Spiller 2011, 595). Simply put, low-income consumers receiving government assistance “should” be devoting resources toward gaining economic independence (Henry, Reyna, and Weiner 2004). From this perspective, volunteering without pay is a wasteful use of one’s time. Similarly, donating material possessions is perceived as wasteful because it implies that the giver has so many possessions that s/he can afford to give some away, making him/her appear less needy and therefore more wasteful of government assistance. Consumers have a strong aversion to waste, especially when waste is tangible (Bolton and Alba 2012). Accepting government assistance without contributing back to the economic system through hard work may be a “tangible” reminder of “their” (participants’) taxpayer dollars being misallocated. We examine these predictions in a series of experiments.

Experiment 1 examined moral judgments toward three types of equivalent resource expenditures. Participants read about a target described as either receiving \$12,000 a year in welfare benefits or earning \$12,000 a year. Participants also learned that the person had donated \$250 to a local charity, donated \$250 worth of material possessions, or volunteered for 35 hours at a local charity. These amounts were calibrated based upon the federal minimum wage of \$7.25 per hour (U.S. Department of Labor 2016), which would be a probable wage for someone earning \$12,000 a year. Thus, working 35 hours for minimum wage would be valued at approximately \$250. The key dependent variable was a morality index (used in all experiments), which was created by averaging responses from four items: unethical/ethical, cruel/kindhearted, immoral/moral, and uncaring/caring. The results revealed that across all three resource expenditures, the welfare recipient was perceived as less virtuous than the low-income earner.

Experiment 2 was designed such that the ethical choice directly benefited the target (vs. donations to others in experiment 1). Specifically, participants read about a target who has a dessert craving and decides to either buy or make an organic apple pie. The experiment followed a 3 (Income: \$12,000 in welfare benefits vs. \$12,000 earned vs. \$85,000 earned) \times 2 (Resource: Money vs. Time) between-subjects design. The results revealed that \$12,000 welfare recipients were perceived as more moral when they made an organic apple pie at home versus buying the same pie at the store. Targets earning \$12,000 or \$85,000 a year were evaluated similarly whether they chose to spend time or money.

Although welfare recipients received a boost for spending a small amount of time versus money in experiment 2, they did not receive moral credit on par with earners. Given the importance of opportunity costs (Spiller 2011), time spent baking is time *not spent* seeking paid employment. Thus, spending time that comes at the cost of gaining employment may be seen as wasteful and ultimately immoral. We tested this prediction in experiment 3 using a 3 (Income: \$12,000 in welfare benefits vs. \$12,000 earned vs. \$85,000 earned) \times 2 (Employment: Yes vs. No) between-subjects design. Participants read a scenario about an individual who was volunteering each week at a museum without pay; the position was described as either being likely or unlikely to lead to future employment. Mediation results revealed that volunteering at a position that is unlikely (vs. likely) to lead to employment is deemed wasteful for low-income consumers receiving government assistance, and being wasteful is seen as immoral. This judgment sequence did not extend to low- or higher-income earners.

Our next three experiments focused on moderators of these moral attributions. We find that spending money to purchase organic

food for children (experiment 4A) or spending time to help a child with her volunteer efforts (experiment 4B) are considered moral endeavors for everyone, regardless of income. We also find that low-income consumers receiving government assistance are judged *less* harshly than wealthier consumers when lying about the price of an organic purchase to save money (experiment 5).

Our final experiment demonstrates that these divergent moral reactions also have behavioral implications. Specifically, we manipulated the income of a volunteer (\$12,000 in welfare benefits vs. \$85,000 earned) seeking monetary donations for his organization. The results revealed that low-income consumers receiving government assistance were perceived as more wasteful of their time than relatively wealthier volunteers (i.e., “he should be working, not volunteering”), which resulted in lower donor support from participants. Donating money to his cause, however commendable it may be, may be perceived as facilitating waste and condoning his reliance on taxpayer dollars.

In conclusion, results from seven experiments demonstrate that moral attributions extend to non-financial expenditures, showing that those lowest in SES are under the greatest moral scrutiny.

SESSION OVERVIEW

By 2030, the proportion of US adults over 65 is projected to swell by 53% and top 71.5 million. A better understanding of how consumer decision making changes across the life span is therefore increasingly more relevant for the well being of the society as a whole. Yet, research on aging and consumer decision making has been relatively limited, and has yielded mixed findings. In this session, we focus on a set of studies that seek to characterize the nature of decision biases in older adults, and elucidate their underlying mechanisms. The papers, which involve tasks from different decision-making domains and use different methodologies, address two core questions: 1) How and why do older adults behave differently than younger adults, and 2) what are the implications of these differences for real-world consumer decisions involving older adults?

The first two papers examine temporal discounting in older adult population. Zaval and colleagues use an inter-temporal choice task, and focus on age-related differences in affective forecasting. Across four studies, they indicate that future anhedonia is a skill that improves across the life span. They further show that improvements in future anhedonia may underlie older adults' lower temporal discounting. Hampton and colleagues show that the degree of discounting is modulated by how the decision options are "framed". They demonstrate that younger adults discount future rewards more steeply and project collecting Social Security later, relative to older adults. Both groups discounted future rewards less in the loss-frame condition. However, older adults exhibited greater susceptibility to loss framing, providing valuable insights for the development social security claim interventions.

Strough and colleagues focused on the effects of age on preference for temporal sequences. Using hypothetical scenarios describing positive and negative hedonic and monetary contexts of enjoyable, painful, rewarding or costly activities, they show that older adults prefer taking either the best or worst event sooner when part of a sequence. In other words, older adults preferred scheduling events with 'larger' impact sooner in the sequence.

Lastly, Seaman and colleagues examined age-related differences for decisions under risk, focusing on skewness. They found that older adults were more likely to accept positively-skewed gambles, and to reject negatively-skewed gambles. These differences were also borne out in the brain: individuals who were more biased towards positively-skewed gambles showed increased activity in a network of regions, including the nucleus accumbens. These findings imply that age-related preference for skewed risks assessed in laboratory might provide an index of fraud susceptibility in everyday life, which could bolster prevention efforts before fraud occurs.

Overall, this session will appeal to researchers interested in decision making across the life span. This session brings together papers that draw on a wealth of methodologies, including laboratory experiments, large-scale field surveys, with the common goal of seeking to better understand decision biases in older adults. As such, these findings have important implications for designing choice architecture and for public policy. They additionally speak to issues regarding the welfare of individual consumers, particularly in the realm of consumer financial decision making.

Affective Forecasting Improves Across the Life Span

EXTENDED ABSTRACT

Background

Although the literature on affective forecasting is broad and wide-ranging, it has largely neglected to examine whether affective forecasting errors improve or worsen with age. The present research addresses this gap by investigating age differences in one type of affective forecasting error, and exploring what underlying processes may contribute to age-related improvements. Understanding age differences in affective forecasting ability is essential, as aging is associated with a range of critical decisions about the future in areas from retirement planning to health care. Research on age differences in time perception, affective processing, and accumulated experience suggest that older adults should exhibit greater accuracy in affective forecasting, specifically the recognition that an outcome will produce similar affective responses regardless of whether it occurs now or in the future—i.e., *future anhedonia* (FA; Kassam et al, 2008) will reduce with age. We present four studies that investigate this hypothesis.

Methods

In Studies 1 (N=645) and 2 (N=618), we tested the relationship between age and future anhedonia in domains such as financial rewards, financial losses, receipt of a utilitarian and hedonic product, free-time rewards, as well as measuring FA using a second dependent variable—willingness to pay. Participants from across the life span were surveyed online and estimated their present reaction to a present event, and their future reaction to a future event (at the time of its occurrence). Study 2 also ruled out a number of cognitive explanations of this age effect and tested the relationship between age-related differences in FA and age-related increases in crystallized intelligence, reductions in fluid intelligence, and reductions in temporal discounting. In Study 3 (N=750), we investigated several psychological factors that may account for age differences in affective forecasting, and also examined the implications of this age effect on evaluative consumer judgments, such as purchase regret. Because

prior research indicates that future self-continuity is an important determinant of inter-temporal decisions, we tested whether differences in future self-continuity underlie age differences in FA. Study 4 (N=600) extended these results by experimentally manipulating future self-continuity.

Results and Discussion

Across studies, we show that older adults are less likely than younger adults to wrongly predict that their affective response to an event will be less intense if the event occurs later in time—a reduction in FA. These findings suggest that with age comes the awareness that events will likely feel the same, regardless of whether they occur in the immediate present or at some delay in the future. This age difference occurs regardless of outcome valence and product types, highlighting the generalizability of the effect. Further, age differences in FA remained robust controlling for age differences in crystallized and fluid intelligence (Study 2). Our results also offer a new potential explanation of the trend of increasing patience in intertemporal choices over the life span, as we find that increased patience in older adults is related to age-related improvements in FA (Study 2).

We also demonstrate that this age-related improvement may occur because older adults feel a stronger sense of connection with their future selves: Among the covariates measured in the present study (including fluid and crystallized intelligence, domain-specific experience, and current affective state), future self-continuity alone explained age-related differences in affective forecasting accuracy. Older adults' enhanced connection to their future identity mediates the association between age and diminished FA (Studies 3 and 4). This work joins an emerging literature that emphasizes the importance of the mental representation of future events in understanding temporal discounting.

Discussion

These findings make theoretical contribution on several fronts. First, given age-related cognitive decline, it is critical to investigate whether other abilities may help to compensate for and mitigate declines in decision making. Taken together, the present results add to the literature on age differences in decision-making by suggesting that future anhedonia is a skill that improves across the life span. Second, our findings contribute to the growing literature demonstrating that people tend to devalue future outcomes and have a fundamental inability to project their feelings into the future. We find that increased patience in older adults is related to age-related improvements in affective forecasting for future events. Moreover, we demonstrate that age is related to diminished future anhedonia and that this may occur because older adults feel more connected with their future selves. These findings suggest that the manner in which people feel connected to their future selves influences the strength of errors in affective prediction. Investigating age-related changes in consumer decision-making is a vital, but understudied area of consumer research. With the aging consumer segment growing in purchasing power and economic significance, researchers and managers cannot afford to ignore whether other skills, such as affective forecasting, may help mitigate the impact of cognitive decline on older consumers' decision-making. Increased focus on how different consumers make these types of pervasive affective judgments may be particularly important for developing an improved understanding of ways to maintain consumer satisfaction and high decision quality across the life span.

Loss Framing Attenuates Delay Discounting in Older Adults

EXTENDED ABSTRACT

Background

By 2035, the proportion of US adults over 65 is projected to swell by 65% and top 79 million (Social Security Fact Sheet). These older adults (OA) face a myriad of life-changing decisions, such as when to begin collecting social security and how to manage their long-term health. OA, like most people, exhibit *delay discounting*, in which they devalue future rewards according to how long they must wait (Johnson et al. 2002). Despite the ubiquity of discounting behaviors, there is substantial variability in the extent to which future rewards are discounted. Discounting rates tend to decrease with age (Steinberg et al. 2009), yet OA are also more variable in their discounting behavior (Webb et al. 2014), and exhibit sharp discounting in many critical real-world situations.

Aside from being biased toward immediate smaller rewards, people are also biased in many other ways; most individuals, including OA, are also influenced by how options are framed, even if the choices are logically equivalent. Specifically, people dislike losses more than they like matched gains (e.g. losing \$100 is more painful than the joy of gaining \$100). This bias leads people to avoid choices framed as losses, i.e. they exhibit *loss aversion* (Tversky and Kahneman, 1991). Loss aversion and delay discounting have been studied at length in isolation, yet their interaction is understudied. Here we collected samples of YA and OA who (1) completed gain- and loss-framed behavioral delay discounting tasks, (2) responded to questions relating to social security collection.

Methods

We recruited 50 younger (aged 18 to 25) and 50 older (aged 60 to 75) through Temple Psychology Research Participation System, and Osher Lifelong Learning Institute, respectively. We measured financial impulsivity via two delay discounting tasks. These tasks find an individual's *indifference point*, the dollar amount at which they are indifferent between a present and future reward. This procedure is then repeated for different points in the future. Participants completed two versions the discounting task: 1) a traditional delay discounting task with choices displayed as gains, and 2) a task with logically equivalent choices, that were been modified to display choice outcomes to included both loss and gain information.

The discount rate (k) is an index of the degree to which an individual devalues delayed rewards as a function of the length of delay to receipt of the delayed reward. We used a standard equation used to compute this value is $V = A/(1 + kD)$, where V is the subjective value of the delayed reward (indifference point), A is the actual value of the delayed reward (in this case, always \$1000), D is the time delay interval, and k is the discount rate (Odum 2011). Higher discount rates indicate increased devaluation of delayed rewards in favor of immediate rewards. We also calculated a "framing susceptibility" score by subtracting each participant's loss-framed k value from his or her gain-framed k value. We then analyzed group differences between younger and older adults across our measures.

Results

Consistent with prior research, we found that both older and younger adults hyperbolically discounted delayed rewards. Younger adults discounted future rewards more steeply than OA. Younger adults also predicted they would begin collecting Social Security later than OA either predicted or actually did. When the immediate

rewards were framed as a loss, both young and older adults discounted future rewards less, i.e. both groups were susceptible to loss framing effects. However, OA had significantly higher loss- versus gain-framed discounting rates. In other words, OA were more susceptible to loss framing effects than were younger adults. Interestingly, participant's loss-framed k value, but not their gain-framed value predicted planned or actual age of collection of Social Security.

Discussion

Over a fifth of married Social Security recipients and nearly half of single recipients over the age of 65 depend on Social Security for 90% or more of their income (Social Security Fact Sheet). The decision of when to begin collecting Social Security closely mirrors a delay discounting task: OA must choose between a smaller-sooner monthly payment and a larger delayed monthly payment. In 2013, more than a third of OA claimed Social Security benefits as soon as they became eligible, at age 62 (Munnell et al. 2015). For some, this proves a serious mistake: many OA find themselves without the necessary funds to maintain their quality of life in the last years of their lives (Bohn et al. 1996). Indeed, delaying Social Security collection until age 70, results in 76% higher monthly benefit (Social Security Fact Sheet).

Delay discounting has also been connected with addictive behaviors. For instance, cigarette smoking, which is increasingly dangerous with age, involves the rapid loss of subjective value for delayed outcomes (LaCroix et al. 1993). Similarly, gambling is associated with steep discounting and is increasingly a form of recreation and entertainment for OA (McNeilly et al. 1998). Further, when gambling and substance use co-occur, the effects on discounting can be additive, and trap OA in a feedback loop (Andrade et al. 2013).

Our findings therefore have important implications for policy relating to OA decision-making. Given that OA are more susceptible to loss framing effects, this information could be applied to Social Security communication. Specifically, on Social Security documents, the choices of when to collect could be framed in terms of losses, in order to encourage older adults to wait until an older age to collect. Similar framings might be applied in other domains such as when giving older adults options regarding health management, or in consumer scenarios.

Taking the Best and Worst First: Age Differences in Preferences for Monetary and Hedonic Sequences

EXTENDED ABSTRACT

Background

People commonly face choices about scheduling free time and medical procedures, as well as about paying and receiving money. Choices about sequences of hedonic and monetary events often show a preference for 'saving the best for last' (Chapman, 2000; Loewenstein & Prelec, 1993). An example would be a preference to receive a fixed amount of salary in increasing increments instead of receiving larger amounts sooner than smaller amounts. For salaries, this preference toward improving sequences conflicts with the normative economic principle of maximizing the present value of funds (Loewenstein & Sicherman, 1991).

Few studies consider age differences in sequence preferences. Those that do show mixed results as to whether older people 'save the best for last' or 'take the best first' (e.g., Drolet et al., 2010; Loeckenhoff et al., 2012). Mixed results could reflect a dependence of age differences on the decision context (Strough et al., 2011). Positive and negative hedonic and monetary features of the decision context

could cue age-related individual differences in using emotion, experience, and reasoning skills to make decisions (Strough et al., 2015).

Emotion regulation improves with age and emotional processes have been linked to age-related improvement in decisions (e.g., Bruine de Bruin et al., 2014). Life experience increases with age (Baltes et al., 2006), and could facilitate a better appreciation for the present value of money. Self-reports of using reason to make decisions have been linked to better performance on judgment and decision making tasks (Bruine de Bruin et al., 2007) and older age is associated with a deliberate and self-controlled approach to decision making (Delaney et al., 2015). Future time perspective also may be important for understanding age differences about sequences of events over time. With age, future time perspective is shorter due to increased awareness of life's finitude (Strough et al., 2016).

Here, we first investigated age differences in sequence preferences in monetary and hedonic contexts with a positive or negative valence. Second, we considered the roles of emotion, experience, reason and future time perspective in accounting for age differences in sequence preferences.

Methods

Participants were from RAND's American Life Panel, an internet-based panel study of adults age 18 and older from across the U.S. (see <https://mmicdata.rand.org/alp/>). The sample ($n = 1296$) ranged in age from 20-91 years (Mean age=53.06, $SD=16.33$).

In two surveys, participants were shown four hypothetical decision scenarios that together formed a 2 (valence: positive, negative) X 2 (context: money, hedonic) within-subjects design. One survey contained two positively-valenced scenarios depicting decisions in monetary (receiving an unexpected inheritance) and hedonic contexts (spending weekends enjoyably). A second survey completed two weeks later contained two negatively-valenced decision scenarios that depicted a decision in monetary (paying bills) and hedonic contexts (painful dental procedures). Survey order was counterbalanced and randomly assigned.

After each scenario, participants indicated their sequence preferences on a scale that ranged from 1 to 6. For example, for the monetary scenarios, 1 was labeled "Start with larger amounts first, end with the smaller" and 6 was labeled "Start with smaller amounts first, end with the larger." For all scenarios, lower scores indicated a preference for the most impactful event sooner over later (i.e., receiving most of the money up front, paying most of the money at the beginning, starting off with the most pleasant weekend, starting off with the most painful procedure).

Each survey ended with individual-differences measures. The positively-framed survey included items from the inferential and affective subscales of the Types of Intuition (TIntS) scale (Pretz et al., 2014) and the rational subscale of Scott and Bruce's (1995) decision styles inventory to measure use of experience, emotion, and reason when making decisions, respectively. The negatively-framed survey included a twelve-item version of Carstensen and Lang's (1996) future time perspective scale. For each scale, higher scores indicated greater endorsement of the items on the scale.

Results

The significant association between age and sequence preferences indicated that older age was associated with being less likely to delay 'larger' events ($r=-.22, p<.001$). The age by valence interaction indicated that this age difference in preference was more pronounced for positive events ($r=-.21, p<.001$) than negative events ($r=-.09, p=.002$). The significant three-way interaction between age, valence and context indicated that the association between older age

and being less likely to prefer to delay the ‘largest’ event was significantly stronger for choices about receiving money ($r = -.21$, $p < .001$) compared to the other three choices: enjoyable weekends ($r = -.11$, $p < .001$), dental procedures ($r = -.07$, $p < .008$), and paying money ($r = -.06$, $p < .05$).

Correlations indicated that older age was significantly associated with greater reported use of reason and experience to make decisions, lesser reported use of emotion, and shorter future time perspective. Mediation analyses (Hayes, 2013) indicated: (1) older adults’ lesser reported use of emotion to make decisions partly explained their preferences to receive larger amounts of money sooner than smaller amounts; (2) older adults’ greater reliance on reason partly accounted for their preferences to pay larger amounts of money sooner than smaller amounts; and (3) older adults’ greater reliance on experience partly explained their preferences to get more painful procedures over with sooner than less painful procedures. Future time perspective did not account for age-related variance in sequence preferences.

Discussion

Our findings add to the emerging literature on age differences in choices about sequences of events. Understanding sequence preferences is important because the choices people make about when to receive versus pay money and when to schedule aversive health appointments and positive experiences likely have implications for their wealth, health, and psychological well-being. Older age was associated with present-oriented preferences of taking both the best and worst first, as shown in scheduling events with a ‘larger’ impact sooner in the sequence. This association characterized all the sequences we examined and was strongest for positive sequences of receiving money. Individual differences in using experience, emotion, and reason to make decisions offer a starting point for understanding why older age was associated with taking the best and worst first.

Individual Differences in Skewed Financial Risk Taking Across the Adult Life Span

EXTENDED ABSTRACT

People frequently confront risky choices, ranging from whom to interact with to what to invest in. Given an uncertain future, nearly all long-term financial choices involve some degree of risk. Although research on financial risk taking has explored the effects of expected value (mean) and risk (variance) on financial choice (e.g., Knutson & Huettel, 2015), less research has focused on how extreme or skewed outcomes influence choice. Although older adults are often targeted by fraudulent investment schemes which promise positively-skewed returns (in the form of large but unlikely financial gains; MetLife Mature Market Institute, 2011), no research has specifically focused on age differences in preferences for skewed risks.

This study thus examined adult age differences in choice and neural activity before individuals chose to accept or reject symmetric (50% chance of modest win or loss), positively-skewed (25% chance of large gain), or negatively-skewed (25% chance of large loss) gambles as they underwent fMRI scanning. Thirty-two healthy adults (Age: $M = 47.9$, Range = 18-85) completed a 72-trial variant of the skewed gambling task used by Wu, Bossaerts, & Knutson (2011). Prior to the task, participants were endowed with \$10 cash. On each trial, if the gamble was chosen, the gamble was played out and the results were added to the cumulative total. The cumulative total at the end of the experiment was added to or subtracted from this endowment plus the hourly rate of compensation.

Overall, participants were more likely to accept positively-skewed gambles but more likely to reject negatively-skewed gambles. However, this trend was more pronounced in older adults compared to younger adults. To ensure that these age effects were not driven by outliers, we compared the difference between the proportion of positively-skewed and negatively-skewed gambles chosen by each participant. This individual difference measure – skew bias – varied from 1 to -1. While young participants varied widely on this measure, with similar numbers of young individuals showing negative and positive skew biases, almost all of the older participants displayed a positive skew bias.

Whole-brain analyses comparing positively- (vs. negatively-) skewed trials revealed that relative to young, older adults showed increased anticipatory activity for negatively-skewed gambles but reduced activity for positively-skewed gambles in lateral prefrontal regions, including a large cluster in the inferior frontal gyrus and anterior insula. Individuals who were more biased towards positively-skewed gambles showed increased activity in a network of regions including the nucleus accumbens. Within older adults, individuals showed increased activity in the right inferior frontal gyrus on trials where they were more likely to accept the gamble. This association was not present in younger adults.

This study investigated individual and adult age differences in choice and neural activity during skewed financial risk taking. Controlling for age, participants showed greater acceptance of positively-skewed gambles relative to negatively-skewed gambles. Although positively- and negatively-skewed gambles were equivalent in *expected* value, many participants revealed either an increased preference for positively-skewed gambles, or a decreased preference for negatively-skewed gambles, or both. This suggests that many participants placed relatively greater *subjective* value on positively-skewed than on negatively-skewed gambles. These differences in behavioral preferences for positively- over negatively-skewed gambles increased with age and follow-up analyses confirmed that these trends were not driven by outliers or an artifact of averaging. These findings might begin to clarify some inconsistencies reported in previous studies of the effects of age on risk preferences, since prior studies have not accounted for the skewness of risky choices.

The predicted but novel age-related increase in a bias towards positively-skewed gambles is consistent with the age-related positivity effect (Mather & Carstensen, 2005). The findings suggest that an increased focus on positive incentives may bias choice and could increase susceptibility to fraudulent investments and lotteries in real life. Older adults also were less likely to accept negatively-skewed gambles. Although this result was unpredicted, it is consistent with another theory of adult development, the selection, optimization and compensation model (SOC; Baltes & Baltes, 1990) which posits that as people age, they become less focused on acquiring new resources and more focused on maintaining and avoiding the loss of current resources (Baltes & Baltes, 1990). An age-related increase in loss-avoidance could have important real-life consequences. For example, older adults may be more likely to allocate financial resources to insurance to protect against potential losses.

Many studies of aging show that older adults recruit broader neural networks in cognitive tasks (Cabeza & Dennis, 2012; Reuter-Lorenz & Park, 2014). While the left IFG was recruited by both age groups when considering skewed gambles, only older adults also engaged the right IFG. “Hyperactivation” has been interpreted as compensatory, such that older adults recruit more neural resources to counteract age-related declines in other neural circuits. Future research will need to clarify how and whether these systems interact to influence skewed risk taking differentially across adulthood.

Although little research has focused on skewed risk preferences, many major financial choices in everyday life necessarily invoke skewed risks. While some evidence suggests that older adults might not necessarily be more susceptible to fraud (Ross, Grossmann, & Schryer, 2014), the consequences of being financially defrauded in older age are much more severe, since older individuals have more to lose but limited time and marketable labor resources to recover from a major financial loss (MetLife Mature Market Institute, 2011). Both researchers and policymakers are interested in identifying and reducing susceptibility to victimization by financial fraud. These findings imply that age-related preference for skewed risks assessed in the laboratory might provide some index of fraud susceptibility in everyday life, which could bolster prevention efforts before fraud occur (Scheibe et al., 2014) and older consumers are disproportionately targeted. We conducted a field experiment to test whether forewarning could protect people who were victimized in the past. A telemarketer pitched a mock scam 2 or 4 weeks after participants were warned about the same scam or an entirely different scam. Both warnings reduced unequivocal acceptance of the mock scam although outright refusals (as opposed to expressions of skepticism).

SESSION OVERVIEW

A key conclusion from four decades of research on choice and preference construction is that preferences are highly susceptible to the manner in which they are elicited (Hsee and Leclerc 1998; Nowlis and Simonson 1997; Park, Jun, and Macinnis 2000; Simonson and Tversky 1992; Tversky, Sattath, and Slovic 1988). The current session provides novel insights into the consequences of several important preference elicitation methods, such as ranking, step-by-step choices, and shortlist creation. How do these different elicitation modes influence experienced and anticipated decision difficulty, and what are some surprising consequences of difficulty in such cases? What is the role accuracy, maximizing, and consistency motivations under different preference elicitation modes? Four papers address these and related questions as they deepen our understanding of how elicitation modes affect preferences and decision outcomes.

The first two papers investigate the effects of elicitation modes on subjective experiences of difficulty. Contrary to expectations, **Zwebner and Schrift** demonstrate that ranking options leads to lower subjective experiences of difficulty than does choosing, despite choosing being embedded within the ranking process. This happens because choice is associated with a sense of loss whereas ranking is not. The paper by **Nardini and Sela** reexamines the relationship between decision difficulty and choice deferral. It suggests that although simplifying multi-attribute decisions increases decision ease, which is associated with lower deferral, it also simultaneously activates a maximizing mindset, which decreases satisfaction with the available options and, surprisingly, increases deferral.

The next two papers focus on elicitation effects beyond difficulty. **Morvinski, Saccardo, and Amir** demonstrate that seemingly equivalent methods for eliciting willingness-to-accept have markedly different effects on preferences. Consumers who indicate their desired level of earnings up front make more money than consumers who take compensation spontaneously, without initially indicating their desired earnings. The paper by **Liu and Simonson** investigates how the anticipation of difficulty shapes consideration-set formation in the context of one particular decision method (shortlist). It shows that as the shortlist grows larger, decision-makers become increasingly concerned about future deliberation costs.

Taken together, the four papers in this session provide novel insights into the mechanisms through which different elicitation methods influence decision experiences and outcomes, including difficulty (paper 1), choice deferral (paper 2), willingness-to-accept (paper 3), and shortlist formation (paper 4). This session will appeal to a broad range of researchers, including those interested in consumer decision making and choice, elicitation methods, context effects, and choice deferral.

Choosing vs. Ranking: Elicitation Modes and Their Impact on Consumers' Subjective Experience of Difficulty

EXTENDED ABSTRACT

The degree to which consumers experience decision difficulty is an important and fundamental aspect of the decision making process. For example, previous research demonstrated that experienced difficulty may elicit negative emotional states (e.g., Luce, Payne and Bettman 1999), cause consumers to end up choosing nothing (e.g., Iyengar and Lepper 2000), delay their choice (Dhar 1997, Tversky and Shafir 1992), increase the need to justify the decision (Shafir, Simonson, and Tversky 1993), and increase the likelihood to compromise (e.g., Novemsky et al. 2007). Additionally, the subjective experience of decision difficulty has been shown to also impact consumers' tendency to engage in simplifying and complicating behaviors (e.g., Schrift, Netzer and Kivetz 2011, Schrift, Kivetz, Netzer 2016) and could even play an important role when observing others making decisions (Schrift and Amar 2015).

Indeed, as the subjective experience of difficulty impacts variety of different behaviors, understanding what factors increase or decrease it, is important from both theoretical and applied perspectives. The current work focuses on how the preference elicitation mode impacts consumers' subjective experience of difficulty. In particular, we focus on two prominent modes, namely, choice and rank-ordering.

When comparing a choice task to a ranking task, it is quite intuitive to expect that a ranking task will elicit greater experience of difficulty. That is, while choosing includes the selection of one option that offers the greatest utility, rank-ordering includes the same selection (i.e. ranked first), as well as the ordering of all the other inferior options. Thus, the operations required to make a choice are embedded in those required to complete the ranking procedure. However, in the current research we repeatedly find that consumers' subjective experience of difficulty is actually higher when asked to choose as opposed to rank-order the options. That is, even though the outcome of the ranking procedure is identical to that of the choice (i.e., consumers are fully aware that the option they rank first is the one they will eventually receive), framing the process as ranking as opposed to choosing decreases the difficulty that consumers experience. Consistent with research on option attachment (Carmon, Wertenbroch, and Zeelenberg, 2003) we find that the mere framing of the selection process as ranking as opposed

to choosing (although the outcomes are kept constant) reduces the sense of loss that consumers experience towards the forgone alternatives. This, eventually reduces consumers' subjective experience of decision difficulty. Below, due to space constraints we briefly describe a subset of 4 studies out of the 8 that were ran.

In Study 1 participants viewed five products and either chose their most preferred product, or rank-ordered the products according to their preferences. Across both conditions we informed participants that their most preferred product (chosen or top-ranked) is the one they will receive should they win a lottery that was conducted. After choosing or rank-ordering, participants rated the difficulty they experienced using five items (Cronbach $\alpha=.88$). Results confirmed that consumers experienced greater difficulty in the choice compared to ranking condition ($t(215)=4.59$; $p<.001$). Interestingly, this difference was despite the fact that participants spent more time ranking the options ($p<.001$).

In Study 2 participants received only two options and were asked to either choose or rank-order the two options (between-subjects). Because the set consisted of only 2 options, the actual task in both conditions, is virtually identical. Results confirmed that even when only two options were available, participants still felt greater degree of difficult in the choice compared to the rank condition ($t(197)=2.35$; $p=.022$). Thus, these finding suggest that the effect is driven by how people construe the task and not by the actual cognitive operations required to performing it.

If the effect is driven by the elevated sense of loss toward the forgone options in the choice condition, then the effect should persist only when participants feel that their chosen/top-ranked option is the one they will receive. However, if the same operations are meant to identify the least desirable option, that is, the option that participants prefer to avoid, then the effect should attenuate. That is, choosing which option one likes to avoid should not trigger any sense of loss toward the non-selected options. Accordingly, Study 3 employed a 2x2 between subject design in which we also manipulated the target selection goal (receive vs. avoid). In particular, in the receive condition participants were told that their chosen/top-ranked option will be the one that they will receive. However, in the avoid condition, participants were told that their chosen/bottom-ranked option is the one that they will surely not receive. Results revealed the expected interaction ($p=.007$). For those in the receive condition, again, choice was significantly more difficult than ranking ($p=.003$). However, for those assigned to the avoid condition, there was no difference in perceived difficulty between the choice and rank conditions.

Study 4 tested the mediation role of option attachment by following Carmon, Wertenbroch and Zeelenberg, 2003 and using the item they employed to measure sense of loss for the forgone options. Participants viewed two products and were asked to either choose their most preferred product or rank-order the products such that their most preferred is ranked first (in a between subject design). Participants then indicated how they felt about not choosing (rank-ordering first) the non-chosen (ranked second) option on a 1 to 10 scale (1=I feel good to 10= I feel bad). In addition to replicating the effect observed in Studies 1-3, a mediation analysis (using the macro PROCESS, model 4, Hayes, 2013) confirmed that the sense of loss mediated the effect of elicitation mode (choice vs. rank) on participants' subjective experience of difficulty ($B=.25$; $CI95\% = .007$ to $.51$).

To summarize, we find that merely framing the selection process as ranking reduces the subjective experience of difficulty. Consumers find choice to be more difficult than ranking, even though the latter typically took them longer. The results suggest that choice highlights the sense of loss related to the non-selected options and therefore, framing the selection process as a ranking process could benefit consumers as well as marketers.

When Simplified Choices Backfire: The Role of a Maximizing Mindset

EXTENDED ABSTRACT

People commonly experience difficulty when making choices among multi-attribute options, which can result in frustration (Sela and Berger 2012), weaker preferences (Chernev 2003), and choice deferral (Dhar and Nowlis 1999). One common solution is to simplify the decision in some way. For example, choices can be broken down into a series of smaller sequential steps (Tversky and Sattath 1979). Step-by-step decision formats are ubiquitous (Haskell 2004), and often reduce choice difficulty and increase satisfaction with the decision process (Dhar 1996; Valenzuela, Dhar, and Zettelmeyer 2009).

However, contrary to the notion that easier choices generally benefit decision-makers and decrease deferral (Novemsky et al. 2007; Valenzuela et al. 2009), we propose that simplified choices impact deferral through two simultaneous processes which operate in opposite directions. Although simplifying multi-attribute decisions indeed increases decision ease, which by itself decreases deferral, it also simultaneously activates a maximizing mindset (Ma and Roesch 2014), which decreases satisfaction with the available options (Betman, Luce, and Payne 1998; Levav, Reinholdt, and Lin 2012) and consequently increases deferral. Thus, simplified decision formats may sometimes paradoxically increase deferral due to the activation of a maximizing mindset. We find that the net effect of decision simplification on decision deferral, through ease (positive) and maximizing (negative), depends on consumers' chronic maximizing tendencies

Study 1 demonstrates the dual effect of decision simplification on choice deferral. Participants chose among eighteen grill options varying on three attributes (i.e. fuel type, grilling space, and maximum heat capacity). In the complex choice format condition, all eighteen options were presented simultaneously and participants chose their preferred option. In the simple choice format condition, participants saw one attribute at a time and chose whether to stay at the base level for that attribute (e.g., charcoal) or pick a different level (e.g., propane for an additional \$30). We used a standard measure of decision deferral (Novemsky et al. 2007) and also measured decision ease and maximizing tendencies (see Levav et al. 2012). We measured option visualization (i.e., how easy it was for participants to visualize the options) to rule out a possible alternative account. Consistent with our hypotheses, decision deferral was lower in the complex condition than in simplified condition. Further, both decision ease and maximizing were lower in the complex condition than in the simplified condition. No significant differences in option visualization emerged, suggesting that the effect of format on choice deferral is not due to differences in the ability to visualize the available options. Mediation analysis suggests that the effect of condition on deferral was simultaneously mediated by maximizing, which increased deferral, and by decision ease, which decreased deferral. Thus, decision simplification may affect deferral through two independent and opposing processes, ease and maximizing.

Study 2 uses two different step-by-step designs for generalizability. Participants chose among twenty-four laptop options, varying on memory, weight, and speed. They were randomly assigned to one of three conditions. In the complex condition, all twenty-four options were presented simultaneously and participants chose their preferred option. In the sequential simplified condition, participants chose their desired level of each attribute one step at a time, where each attribute decision was displayed on a separate page. In the simultaneous simplified condition, participants chose attribute levels

one at a time, but these three simple decisions were presented on the same page instead of sequentially. We used the same measures of decision deferral, decision ease, and maximizing from Study 1. Consistent with our hypotheses, decision deferral was lower in the complex condition than in each of the two simplified conditions, which were not different from each other. Further, both decision ease and maximizing were lower in the complex condition than in the two simplified conditions, which were not different from each other. Mediation analysis suggests that the effect of condition on deferral was simultaneously mediated by maximizing, which increased deferral, and by decision ease, which decreased deferral. Thus, it is not the sequential nature of the simplified decision process that is driving the effect, but rather simplification itself – breaking down the decision into a series of easier decisions – increases maximizing and decreases purchase likelihood.

In Study 3, we measured participants' chronic maximizing tendencies, which we predicted would moderate our effect. Specifically, we predicted that decision simplification would activate maximizing among people not already prone to maximizing at baseline (i.e., satisficers), but would have an attenuated effect among people who already maximize at baseline (i.e., maximizers). We also examined whether the maximizing mindset evoked in the focal decision task would carry over to an unrelated subsequent decision. Participants chose among 30 cameras varying on megapixels, optical zoom, and waterproofing in a complex or simplified sequential decision format as in Study 1. We again measured decision deferral, ease, and maximizing. Results revealed the predicted decision \times chronic maximizing tendency interaction. Whereas chronic maximizers showed high levels of deferral regardless of decision condition, chronic satisficers showed high deferral in the simplified decision condition but not in the complex condition. Decision process ease and state maximizing mediated the effect of choice format on purchase likelihood for chronic satisficers, but not chronic maximizers. Finally, the maximizing mindset appeared to have carried over to a subsequent choice task: participants in the simplified camera decision condition were later more likely to defer an apartment purchase decision in an unrelated choice task, compared with participants in the complex camera decision condition.

Three experiments, utilizing different product categories support our theoretical perspective. Our findings suggest that easier decisions do not necessarily decrease deferral, and that the net effect of simplification depends on the relative weights of two opposing mechanisms: decision ease and maximizing mindset. We extend recent findings suggesting that maximizing, in addition to being an individual disposition, can also be triggered by the decision context (Ma and Roese 2014). Our results also contribute to the ongoing attempt to understand when and why simplified decision procedures increase versus decrease deferral, purchase likelihood, and consumer satisfaction (Chernev et al. 2015; Schrift, Kivetz, and Netzer 2011; Valenzuela et al. 2009).

The Effect of Stated Preference on Subsequent Revealed Preference

EXTENDED ABSTRACT

Measuring individual's preferences is central to consumer research, although measurement instability remains a challenge for researchers and practitioners. We focus on situations characterized by full information (post-experience evaluation), and investigate the relation between an individual's stated WTA after exerting effort on a task, and the subsequent behavior that reveals said individual's preference. In four experiments involving consequential decisions, indi-

viduals are given the choice to collect their own wage for a task they had performed from a bowl of money. As expected, subjects do not behave in accordance with standard economic theories and only take a fraction of the money from the bowl. Most importantly, we find that under some conditions, the mere act of stating one's preference may significantly influence subsequent behavior and the preference that behavior reveals.

On the one hand, money has been shown to evoke greed and cause coldhearted behavior (Vohs, Mead, and Goode 2006), which predicts those who go directly to take the money without stating their preference first, to be less mindful of their decision, and take a higher compensation than those who first stated their WTA. On the other hand, hypothetical bias (preference overstatement; Murphy et al. 2005) together with consistency theory (Cialdini 1987) predict that people may rely too heavily on preference overstatement and consequently take a higher compensation after stating their preference. Our main findings suggest that consistency with previous judgments, and not greed, plays a central role in biasing observed preference. Individuals who stated their desired compensation for a task they had just performed, take a much higher compensation than those who had not done so.

Participants in Experiment 1 ($N = 82$) listened to a noisy sound for one minute, and received \$.25. This task was followed by a similar 5-minute task. Upon completing the second task, participants could take any amount of money they believed they deserved for completing the longer task from a bowl containing \$10 in quarters. Taking money from the bowl was done in private. In a between-subject design, half of the participants stated how much they believed they should be paid before moving to the experiment room to collect their payment (Write condition), while the other half did not (Baseline condition). On average, participants in the Write condition took twice the money than those who did not initially state their deserved payment ($M_{write} = \$2.59$, $M_{baseline} = \$1.28$). Additionally, participants stated they deserve a lower amount than what they eventually took ($Med_{write} = \$1.75$, $Med_{take} = \$1.25$, $p < .001$).

Experiment 2 ($N = 245$) explores the proposed mechanism that people are consistent with previous actions and therefore taking more money in the Write condition is a result of consistent behavior with a previously overstated wage. We speculate that writing an expected wage lacks realism, attenuating the psychological cost of writing a higher wage. Hence, once a (higher) wage is stated, it becomes a reference, which justifies taking a higher wage. Research suggests that visual aids help reduce stated preference biases (Bateman et al. 2009). In addition to the original conditions, Experiment 2 included a third condition (visual realization-VR) in which participants indicated their deserve wage by selecting quarters on the screen, one by one, until reaching the desired amount. We measured a list of emotions before participants completed the listening tasks as well as immediately after they collected the money. Experiment 2 replicated the previous results ($M_{write} = \$2.29$, $M_{baseline} = \$1.43$, $p < .001$). Importantly, those in the VR condition indicated they deserved less than those in the Write condition ($M_{VR} = \$1.75$, $M_{write} = \$2.20$, $p < .01$) and consequentially took less money ($M_{VR} = \$1.92$, $M_{write} = \$2.29$, $p < .01$) such that no effect was observed in the VR condition. Lastly, taking more money increased negative emotions in general, though there was no difference in emotions between conditions suggesting that once the reference wage is set (e.g. by writing), it is less costly to adhere to.

In Experiment 3 ($N = 293$) we adjusted the previous design by utilizing a slider task (Gill and Prowse 2011) and introducing four additional conditions. The main effect remains robust ($Med_{write} = \$3.00$, $Med_{baseline} = \$1.00$, $p = .028$). Experiment 3 also explored

boundary conditions and alternative accounts. The effect remains even when participants stated their deserved amount from a bounded list of numbers (up to \$10) suggesting the nature of an open-ended stated preference task (contrary to the restricted amount of money in the bowl) cannot explain the effect. However, we did not observe an effect when participants were asked to think about, but not report their WTA, suggesting cognitive construction of individuals' (unreported) preferences might not be strong enough to affect consequent behavior. Finally, manipulating temporal proximity between task performance and payment did not explain the effect and using other medium (e.g. Dollar bills) offered inconclusive results.

Finally, we explore whether people anticipate the observed behavior. Participants in Experiment 4 ($N = 90$) completed similar listening tasks but instead of earning money, they read descriptions of the two conditions (Write and Baseline, counterbalanced), and indicated the situation they would rather be in and why. Only 44 participants chose the Write situation, suggesting that subjects do not anticipate writing their deserved wage to have any differential effect. The majority rationalized their decision to be in the Write condition by saying that it would help them to be moral, honest, ethical, fair, less greedy and less tempted to take more money. Experiment 4 demonstrates that peoples' intuition is not aligned with the highest payoff condition. Further, those who prefer to state their deserved wage, do so for reasons other than merely payoff-maximization.

Given the critical role that preference estimation plays in many domains of behavioral science, our findings help consumer researchers to better understand the effect of the selected elicitation procedures on the estimation outcome, and stress that individual's preference estimation should be interpreted in the context in which it was elicited. These findings also have direct implications for theory, markets, and policy making.

Drivers of Sequential Shortlist Decisions

EXTENDED ABSTRACT

Consider a consumer shopping on Amazon for a fleece jacket. There are 200 options left after filtering for price and size. The person now needs to look at each option and decide whether to put the option into a shortlist she is keeping. Importantly, the person is not waiting until she has evaluated all 200 options to then simultaneously decide which of them go into a shortlist; instead, like in most real life shopping situations, the shortlist is kept on a running basis, where options are added (or not) sequentially as they are looked at. When looking at a particular option, how does the person decide whether or not it will go into the shortlist?

This research investigates this decision. In their seminal paper on sequential consideration set formation, Hauser and Wernerfelt (1990) proposed a theoretical model positing that when facing a particular option in the sequence and deciding whether to add it to the shortlist, the decision is driven by a cost-benefit consideration. This research tests the psychological processes proposed by H&W, and their prediction of a latecomer disadvantage.

On the benefit side, the person examines whether adding the option to the existing shortlist will increase the expected utility at final choice. This translates to a comparison between the current option and options already in the shortlist, and whether the current option offers incremental benefit to the final choice. Given this process, the serial position of the option influences this decision in two ways: first, in a manner that is not unique to shortlist decisions, serial position may influence the perceived attractiveness of the option (per a large body of previous literature on serial position effects on option ratings and choice). Second, and importantly, position may also af-

fect the shortlist decision in a way unique to sequential shortlist assembly, namely through the comparison with options already in the shortlist. Specifically, because a new option is added to the shortlist only when it can offer non-zero incremental expected benefit over existing shortlist options, then it follows that each time an option is added, the bar for incremental expected benefit raises. Consequently, the later in the sequence, the higher the bar for incremental benefit, thereby creating a disadvantage for latecomers. However, an alternative behavioral possibility is that, when deciding whether to add a particular option to the shortlist, the person only compares the option's attractiveness to some independent attractiveness threshold, but show disregard for what is already in the shortlist. We test whether the attractiveness of what are already in the shortlist is a factor driving a current decision (H1).

On the cost consideration side, H&W proposed that for each option added to the shortlist, the person recognizes that a deliberation cost will be added to the final decision. This deliberation cost consideration must be true, because if not, there will be zero cost to expanding the shortlist, and the person can maximize utility by simply choosing from the ultimate large shortlist, namely, the whole choice set. Thus for the person to engage in shortlisting behavior to begin with, this means the person perceives a cost to choosing from a larger choice set, and therefore prefers to have a shortlist that balances benefit (product utility) against deliberation cost at final choice. However, in the H&W model, the perceived incremental deliberation cost of adding the current option is constant to the option, and not influenced by the serial position of the option. However, we argue that behaviorally, it is possible that the perceived incremental deliberation cost to adding an option to the shortlist may not be constant to the option, but instead, may depend on the existing shortlist size. Specifically, people become increasingly (rather than constantly) concerned about deliberation cost as the shortlist grows larger (H2; that is, people are not too concerned about deliberation cost when adding a 3rd member to a shortlist of 2, but feel very concerned adding a 6th after there are already 5). This would be an amendment to the H&W model.

Study 1 ($N = 244$) allowed participants to keep a running shortlist when going through 20 DVD's sequentially towards the goal of selecting one DVD as a bonus prize for the study. The serial order of the DVD's was randomly generated for each participant. When we ran a logistic regression on each decision of whether to add the current option with existing shortlist size as the predictor (and other relevant covariates; and different models for robustness), we found a significant negative effect of existing shortlist size ($p < .001$). This evidence is consistent with H1 and H2 in that the existing shortlist does matter; however, it does not separate benefit vs. cost considerations. We also found a significant latecomer disadvantage, consistent with H1 and H2 and H&W.

Study 2 ($N = 295$) asked participants to rate the attractiveness of each DVD on each product screen. Thus we are able to dissociate the perceived attractiveness of sequentially presented options, the incremental benefit in attractiveness of adding an option, and the perceived incremental cost. Results showed that all three factors contributed to the shortlist decision (p 's $< .001$), and contributed to a latecomer disadvantage, supporting H1 and H2.

Study 3 ($N = 489$) directly manipulated the goal to have a small shortlist by telling participants that "most people had a shortlist of 2 [10] DVD's". We found that larger existing shortlist was even more punishing to the current option when people held a goal of a very small shortlist (interaction $p < .001$). Correspondingly, latecomer disadvantage was even greater under stringent versus relaxed shortlist size goal ($p = .01$). This study shows that indeed the perceived

incremental cost of adding is not constant to the option, but rather is a function of how “full” the shortlist already is, supporting H2.

Our research provides the first empirical evidence of the psychological processes underlying sequential shortlist decisions, and validates and modifies the H&W model.

Tailoring Elderly Patients' Identities through Healthcare Service Relationships: Toward a Guardian Conception of Vulnerable Publics' Identities

Abdelmajid Amine, Université Paris-Est, France

Audrey Bonnemaizon, Université Paris-Est, France

Margaret Josion-Portail, Université Paris-Est, France

INTRODUCTION

Population aging has become an unprecedented global phenomenon, impacting most countries across the globe; in France, seniors aged 65 and over will become the largest age group in 2050, accounting for nearly 30% of the total population (Cetelem Observatory 2016). This trend has a tremendous impact on the management of public hospitals, which are facing new challenges with the admission of elderly patients.

Patients' medical and social care can be viewed through the prism of the healthcare service relationship. It refers to the mutual implication of patients and healthcare providers, as well as to the potential mobilization of their respective resources to nurture and develop the care relationship; however, in the case of vulnerable groups, such as elderly patients, the service relationship tends to develop in an asymmetrical manner: healthcare providers can claim a legitimacy in the provision of care derived from their competences and status. As hospitalized elderly patients can be considered fragile subjects facing an alteration of their physical and/or cognitive resources, healthcare providers have a natural tendency to make decisions on their behalf and tailor their identities. The healthcare service relationship in hospitals can thus be analyzed through the prism of care providers' representations of old-patient figures, as well as through the identities they project on the elderly, which are impacting their healthcare practices.

Identity configuration does not only depend on one's personal resources but also develops through social interactions. It can be read in others' eyes and enacted in their actions (Tesser, Millar and Moore 1988). The role played by social interactions in identity configuration is even greater when an individual is old and vulnerable. To define their identities, the elderly will use their remaining personal (cognitive, physical and emotional) resources, the social resources provided by the group of people assisting them in their everyday activities, and the social and cultural imaginary at work in the representations of the elderly.

The theoretical framework of the *elderly consumption ensemble (ECE)*, defined by Barnhart and Peñaloza (2013), identifies family and paid caregivers as central members of a nuclear network within which the elderly's identities are negotiated in relation with consumption activities. In line with Drolet-Rossi, Kelleher and Peñaloza (2015), we propose to broaden the perspective to health service consumption contexts, and explore the role of healthcare providers' practices in the preservation, restoration or alteration of the elderly's identities. This paper introduces a *guardian conception* of elderly patients' identities, viewed as a process through which healthcare providers substitute them in making decisions on their behalf, and thus tailor their identities.

ELDERLY PATIENTS' VULNERABILITY AND IDENTITY CONSTRUCTION

Elderly patients are confronted with vulnerability (Baker, Gentry and Rittenburg 2005), as they experience chronic illness, pluripathology, functional decline, loss of autonomy and decline in their

social role. These combined disabilities increase the tendency to perceive them as impaired people, which potentially affects their feelings of dignity and integrity (Monod and Sautebin 2009). Perception of the elderly as vulnerable may influence healthcare providers' mental representations of senior patients. These representations will be embedded in their care practices as representations perform reality. Vulnerability can be considered as the result of several internal and external factors affecting elderly patients, health decline being a central catalyst (Mason and Pavia 2006; Pavia and Mason 2012).

Perception of their altered body and representations conveyed by others are central in elderly patients' identity construction. Physical, psychological and/or emotional vulnerability favor the alteration of their identities. Furthermore, the context in which interactions with others take place plays an important role in the definition of seniors' identities: uncomfortable situations, perceived negatively, and negative attitudes or criticism from others can alter self-esteem and even lead to a negative *self* (Banister and Hogg 2001). The inability to perform everyday tasks without help and interactions with others placing the elderly in a state of discomfort are perceived as stigmatizing as they remind them of their physical and/or cognitive impairments. These experiences exacerbate the negative perception of the *self*, and may even generate a kind of dissolution of *self* constituents (Mason and Pavia 2014).

Though social interactions can project stigmatized identities on seniors, they are neither prepared nor ready to accept them (Barnhart and Peñaloza 2013; Pavia and Mason 2012). When they have the resources to do so, they tend to deploy strategies to preserve or reconfigure their identities to counter the institutionalization of negative stereotypes, in particular when central elements of their identities are at risk. They engage in an attempt to build a resilient identity (Mason and Pavia 2014) that allows them to focus on the restoration of the positive and rewarding aspects of their *self*.

ELDERLY PATIENTS' VULNERABILITY AND THE GUARDIAN CONCEPTION OF THEIR IDENTITIES

Recent research (Mason and Pavia 2014; Pavia and Mason 2012; Stone, Brownlie and Hewer 2011) has focused on the study of the processes in action during the transformation of seniors' self, without providing a complete understanding of the mechanisms leading to the reconfiguration of their identities however. Indeed, these studies reveal the role played by seniors' personal resources in this process but do not analyze how resources deployed by members of their network (family, friends and paid caregivers) (Barnhart and Peñaloza 2013) may play a role in this identity preservation process. To the nuclear network of actors already identified in the literature, it is possible to add healthcare givers working in medical institutions as they have frequent interactions with hospitalized elderly patients and can be included in what we call the *extended elderly network*. Depending on the role they play, the legitimacy that they give themselves and the contexts in which social interactions with elderly patients take place, we propose that these actors elaborate

representations that also contribute to the identity (re)configuration of the elderly.

This research contributes to the field of service relationships with vulnerable publics. We focus on the role of healthcare givers with authority in the provision of health services, in building, preserving or altering elderly patients' identities. We reveal the existence of a *guardian conception of elderly patients' identities*, embedded and enacted in healthcare practices. This conception relates to two different visions: deficient elderly patients, dependent on others, requiring an adaptation of professional norms to their specificities; and elderly patients as individuals with remaining resources, actors of their healthcare path and needing to be preserved to respect the ideal type of autonomous patients.

METHOD

This exploratory qualitative research¹ was conducted in the geriatric ward of a French hospital group admitting elderly patients aged 75 and over in the suburbs of Paris (France). Data was collected from June to October 2016. Eighteen healthcare providers (doctors, nurses, nursing assistants, a nutritionist and a physiotherapist) were interviewed at their workplace. Informants were contacted by hospital executives and volunteered for the research. Semi-structured interviews lasted one hour on average. Interviews were registered, transcribed entirely and content-analyzed through a process consisting in going back and forth between data and existing literature (Miles and Huberman 1994). The authors double coded the data to increase the reliability of their findings. Categories emerged from the coding process – they consist of representations and figures of elderly patients' identities, perceived, elaborated and enacted by healthcare providers during service relationships.

Bricolage and Ruse as Levers to Preserve, Restore or Alter Elderly Patients' Identities

Our findings show that healthcare providers use *bricolage* and *ruse* as strategies to deliver healthcare and that these practices may shape elderly patients' identities. This tendency to (re)configure senior patients' identity is a way for hospital staff to legitimate their role in their treatment. On the one hand, it can help elderly patients recognize their own capabilities and be active in their care, and can thus contribute to rebuild or rehabilitate their desired positive *self*. On the other hand, it may convey to the elderly the image of a dependent person and thus contribute to build or confirm their negative, undesired *self*.

As a result, healthcare practices can be viewed as coping strategies developed by care providers confronted with elderly patients' various situations. These strategies reveal a *guardian conception of patients' identities*, which is two-fold; it can take the form of fragile and dependent figures to which hospital staff needs to adapt even if it requires derogating from professional norms (when the aged patient is perceived as limited in his/her resources) or take the form of enabling, resilient and autonomous figures, which favor the expression of patients' power to act (when the senior patient is seen to have relevant personal capabilities).

Bricolage as a Way to Adapt to Elderly Patients Perceived as Limited in Their Capabilities

Daily healthcare provision and the variety of interaction contexts in which they take place create interstices to which standardized processes cannot fully be applied. This creates possibilities to imagine and tinker other methods that impact elderly patients' iden-

ties directly. Hospital staff creates hybrid and modified practices; they tap into their own history and cultural values to find the resources needed to accomplish their care mission. This hybridization of practices can be viewed as "*a contribution to sociology of the in-between, sociology from the interstices. This involves merging endogenous/exogenous understandings of culture*" (Pieterse 1995, 64). Healthcare providers thus have to arbitrate between the obligation to respect patients' power to act and the perception of their physical and cognitive deficiencies. The progressive alteration of senior patients' abilities, which can occur when hospitalized or during their stay in the medical institution, leads to practical questions on the possibility to involve them in the care relationship. It raises questions about the best way to do so, by trying to articulate goals that are not always compatible: "respect the patients' will" without actually putting them in danger and "making them comfortable" without undermining their autonomy.

Bricolage practices show that elderly patients' guardian conception of identity is expressed through deficient and weak figures such as the dependent patient, patient with dementia, child patient, soiled patient, patient from the past and deviant patient (*cf.* Table 1).

Ruse as a Way to Protect or Rehabilitate the Autonomy of Senior Patients Perceived as Having Residual Resources

Besides *bricolage*, we identify *ruse* as a coping strategy deployed by caregivers confronted with patients' potential refusal of care. We borrow *ruse* from Hennion and Vidal-Naquet's (2012) ethnographic research of home care relationships. Drawing on Goffman's theoretical frameworks (in particular his usage of fiction, 1973) and those of Paul Ricoeur on narrative (1983), the authors consider home care as bearing a *fictional paradox*: "*it is precisely to preserve an autonomy whose very meaning is eroding, and to provide protection that individuals may no longer see as an opportunity, that, depending on the practical issues to be resolved, one has to encroach on autonomy, or accept some risk-taking to "save" what is essential, for instance to maintain a possible form of autonomy and protection given the situation*" (Hennion and Vidal-Naquet 2012, 329). Authors call *ruse* this risk-taking contributing to the recognition and self-worth development of individuals - *ruse* "*viewed not as a deception but as an art of making do*" (326), or even "do with". This is what we mean here: a series of tricks embedded in healthcare micro-practices allowing for the preservation of the ideal-type of autonomous patients and as such, getting them to do and cooperate.

Ruse practices allow the guardian conception of elderly patients' identities to be expressed through the projection of positive images of the self, embedded in the healthcare providers' attitudes and practices, as shown by the following figures: the person patient, wise patient, active patient and equipped patient (*cf.* Table 1).

DISCUSSION AND CONCLUDING REMARKS

A first contribution of this research consists in proposing a *guardian conception of elderly patients' identities*, which enriches the notion of senior subject positioning (Barnhart and Peñaloza 2013). Our findings suggest that, as a vulnerable public, elderly patients experience an alteration of their physical and/or cognitive resources, allowing actors belonging to their resource network to substitute for them, making decisions on their behalf and configuring their identity. This *guardian conception of identity* thus goes beyond a representation or a projection that the elderly would receive from others and try to articulate with their own vision of their self. We uncover two types of guardian identities elaborated by healthcare

¹ This research received funding from the French National Center for Scientific Research (CNRS) and the authors' university.

Table 1: Guardian conceptions of elderly patients, healthcare practices and types of related identity configurations

Guardian conception of elderly patients	Description	Bricolage practices	Types of related identity configurations
Dependent patient	Elderly patients are perceived as dependent subjects. Healthcare professionals wonder whether the dependency is real and caused by their polypathology or exaggerated by them to get more attention from hospital personnel.	Slow down the pace of care.	Elderly patients' identity alteration – portrayed as ill and dependent.
		“One day, a doctor said to me: “You see, you take two hours to round up patients”. I told him: “OK, now you come with me and you tell me where I’m being slow (...) Because taking a pill, putting it there and telling the patient: “take this” and then go away, I can do that... and it’ll save time. But at the end of the day, I don’t know whether the pill was taken.” (nurse B.L.)	
Patient with dementia	Elderly patients' dementia is frequently evoked by informants. It crystallizes individuals' own projections into old age. In its soft version, it relates to anxiety and confusion exacerbated by the hospital's sanitized environment.	Take time to reassure.	Elderly patients' identity alteration – portrayed as psychologically fragile.
		“They wander. Sometimes it creates problems but then, well, you have to go with them ...and tell them what to do and why. Always reassure them. It's a little bit like a psychological support.” (nurse E.L.)	
“Child” patient	Elderly patients are frequently compared to children with no critical judgment capacities, sometimes unable to verbalize their pain, and who are under the supervision of their parents.	Take the time to explain and reformulate.	Elderly patients' identity alteration - portrayed as not capable of thinking critically.
		“The old patient, sometimes, he does not understand you see. We explain again, we reformulate, and try to adjust.” (nurse B.L.).	
Soiled patient	Elderly patients' bodies are marked by decline, degeneration, uncontrolled soiling whose tracks must be covered by healthcare givers.	Delegate healthcare to third parties.	Elderly patients' identity alteration – portrayed as not capable of controlling their bodies.
		“Her daughter finally took over and said: “Well, I’m going to clean her. I will go with her.” It happened like this but we had to take her clothes because they were completely soaked [<i>with urine</i>]. We were running after clothes afterwards.” (nurse S.F.)	
Patient from the past	Elderly patients are locked in the past and use words and expressions and cultural references that are old-fashioned.	Avoid certain types of care to adjust to patients' old habits.	Elderly patients' identity alteration – portrayed as belonging to a bygone era.
		“There are certain types of care that...well you know, (they say)”I don’t want now...I’m tired...”. It’s not a problem. We go on. Finally, we come back. (...) there are people who do not want to wash every day. You know...they were born... before the war... and...you have to take this into account.” (nursing assistant J.M.)	
Deviant patient	Elderly patients refuse care and/or treatments, or even engage in deviant behaviors; informants evoke numerous <i>translation</i> conflicts. This figure differs from the representation of the vulnerable patient.	Physically coerce the patient to protect him / oneself.	Elderly patients' identity alteration through usage of physical coercion.
		“Well...for example, if there are violent patients (...) we constrain their lower and upper extremities, but it’s on prescription. This means that doctors decide if it needs to be done. (...) It looks... It looks a bit barbaric but...sometimes you have no choice.” (nursing assistant C.B.)	
Guardian conception of elderly patients	Description	Ruse and trick practices	Types of related identity configurations
Person patient	Elderly patients are primarily seen as persons, individuals with whom it is possible to develop a relationship of equals, to discuss, exchange and laugh.	Create a common language to establish a symmetrical relationship.	Elderly patients' identity preservation through the recognition of their identity.
		“As she did not speak French, I looked at her. I put myself at her level. I looked at her and I told her: “Don’t worry. We’re not here to harm you”. I told her this, with my words. I tried to convey this through my eyes...to try to calm down.” (nurse C.B.).	
Wise patient	Elderly patients are wise elders who share their knowledge and life experiences, which are of value to the current generation.	Use past cultural references to establish communication	Elderly patients' identity preservation through the recognition of their valuable past experience.
		“You know, sometimes, there are old, elderly people who are very interesting, they tell you their old stories and it is enriching: I would say about war, about their private life when they were young:” I was doing that. At that time (...) it was good » (nursing assistant G.M.).	
Active patient	Elderly patients are individuals with their own rights, having residual resources that they can mobilize to express their self.	Sensitize elderly patients about their rights to decide, to get them to exercise their power to act.	Elderly patients' identity restoration through the recognition of their rights.
		“It’s...the patient has the right not to know; it means that if he doesn’t want to know what disease he has, we need to respect that. We need to try to understand why he does not want to know [...]. It’s really the patient who...who is the owner...of his disease.” (doctor SK).	
Equipped patient	Elderly patients are not vulnerable, a “normal” relationship with them is possible provided that we use objects that extend their bodies or substitute for deficient physical functionalities.	Use (patients) objects as levers enabling the activation of their capabilities.	Autonomous elderly patients' identity restoration through the recognition of material resources enabling them to exercise their power to act.
		“If, for example, your patient needs glasses to read, I need to know that I will find them in the room, because if he does not have his glasses, it means that he will not be able, of course, to read the documents I will give him.” (nurse S.F.).	

providers: the first relating to a dependent and stigmatized vision of the elderly and the second, contrary to the first, conveying the image of an old patient capable of doing and resilient, and favoring the expression of the patient's power to act. In the first case, the identity projected on the patient could be destructive and act as a factor of identity dissolution (Mason and Pavia 2014), contributing to the creation or exacerbation of a negative identity. In the second case, the projected identity is rewarding and could help to create, restore or preserve a positive, desired self.

This *guardian conception of identity* has an impact that goes beyond the context of elderly patients and can apply to vulnerable populations (e.g. precarious consumers or individuals with physical or mental disabilities) more generally. It seems that when individuals experience a temporary or durable deficit of their internal abilities and become vulnerable, resource persons give themselves the right to confiscate the decision-making on their behalf and the definition of their identity. This situation can lead to the preservation or valuation of vulnerable publics' identities, or on the contrary, result in its deterioration or dissolution. This *guardian conception of identity* is based on resources mobilized by a third party having or claiming to have supervisory authority over senior, fragile or vulnerable individuals who are permeable to representations conveyed in others' discourses and practices. This *by proxy* intervention of a third party in someone else's identity configuration represents a significant theoretical contribution to the area of *self*-concept (Sirgy 1982; Belk 1988). Indeed, it challenges the view that individuals are themselves the repositories of the arrangement of internal and external resources constituent of their identity.

The second contribution of this research is to enrich the concept of the *elderly consumption ensemble* (Barnhart and Peñaloza 2013) through the proposal of the *extended elderly consumption ensemble*. We show that the network of resource persons committed to the elderly is changing depending on places and contexts where consumption or service activities take place. We thus identify the existence of an extended network in the hospital, consisting of healthcare providers whose representations of old age challenge elderly patients' own identities. In this perspective, we propose a dynamic view of the elderly network, viewed as a field of power relationships between healthcare providers and patients.

This research draws only on healthcare providers' discourses, ignoring old patients' perceptions of their own *selves* to capture the whole picture of the latter's identity reconfiguration. Moreover, the role of other members of the elderly network (family members, relatives, etc.) is also neglected whereas they may intervene in tailoring the elderly patients' *selves*. So, interesting directions for future research would be to study patients' own views about how hospitalization impacts their selves and projects for the future, as well as to explore the impact of tensions between members of the *extended ensemble* on the elderly's identity configuration. These resource members (such as family and healthcare providers) may develop different tutelary figures of the elderly and compete to tailor elderly patients' identities. Such conflicts create the risk of generating and projecting a tense and fragmented identity on the elderly.

Few and Far Between: Identifying Measures of Advertising Visuals that Correlate with Neural Engagement and Sales

Samuel B. Barnett, Northwestern University, USA

Moran Cerf, Northwestern University, USA

ABSTRACT

We present a novel approach to assess visual attention in advertisements. We find that movie trailers with fewer and larger attention-grabbing visuals generate higher collective neural engagement (i.e., Cross-Brain Correlation) among consumers in a movie theater. The number and size of attentional targets also correlate with future population-level ticket sales.

INTRODUCTION

With decreasing attention spans and increasing communication urgency, every second of an engaged mind counts even more. Content creators in every profession aim to engage their audiences in limited time, and the question of how to deliver a message quickly is especially pronounced in advertising. Advertisers and neuroscientists are constantly striving for better answers to this question, especially given the strong economic incentives to communicate efficiently. For context, a typical 30-second advertising slot during a primetime television news broadcast cost \$5,000 in 2016; when more viewers are watching, such as during contentious political debates or sporting events, airtime rates often exceed that price per second (Poggi 2015). During *Super Bowl LI*, a single second of advertising time cost over \$167,000 according to the American Marketing Association (Watters 2017). Furthermore, these costs only reflect the airtime and do not account for the cinematography and production expenses. Producing just one second of a Hollywood film or advertisement often costs over \$20,000 (\$22,109 mean budget per second for the ten highest grossing films in 2016; IMDb.com, Seattle, Washington).

Since images often convey messages more efficiently than words (Simion & Shimojo 2006; Cerf, Frady, and Koch 2009), visual attention to natural stimuli has increasingly become a focus of research. Certain commonalities in visual attention have been identified through a variety of techniques, such as eye tracking (Teixeira et al., 2010), saccade models (Itti & Koch 2001; Mackay et al. 2008), electroencephalography (EEG; Charland et al. 2013), functional magnetic resonance imaging (fMRI; Falk, Berkman, and Lieberman 2012; Poldrack 2008), and biometric measures (Ohme et al. 2011). In particular, elevated neural similarity across viewers during rich visual stimuli (e.g., videos) has been linked to heightened collective brain engagement, attention, memory, and population-level sales (Hasson et al. 2004, 2008; Barnett & Cerf 2015, 2017).

Recent research has shown that simpler advertisements with fewer words and lower visual entropy are linked to elevated neural similarity and engagement with content (Putrevu, Tan, and Lord 2004; Pieters, Wedel, and Batra 2010; Barnett et al. 2016).

By extension, we hypothesize that advertisements utilizing images with fewer attentional targets will promote greater neural similarity. However, it is not clear how the size of an attentional target will impact neural similarity. On one hand, a small visual might pinpoint collective attention (i.e., cause everyone to focus on a precise location within the image), thus increasing stimulus processing consistency. On the other hand, perceptual load theory suggests that an image with a larger attention-grabbing portion (e.g., high load) will minimize task-irrelevant attentional allocation (Lavie & Tsal 1994; Lavie 1995). Under this model, attentional targets are parsed as distinct entities (e.g., characters, faces, objects) rather than locations, so neural similarity is presumably increased if the audience simply

focuses on the same entity (even if each viewer's gaze falls on a different location within that entity).

Put simply, does an image make brains think alike if it makes everyone look at the same location (as with a smaller attentional target, which minimizes gaze variance) or pay attention to the same entity (as with a larger attentional target, which minimizes distraction by other entities in the image)? We hypothesize that the latter is true; in other words, we expect that the average size of individual attentional targets throughout an advertisement will correlate with its neural similarity.

We address these hypotheses with a combination of neural and subjective report data. In a field experiment, we measure neural similarity as Cross-Brain Correlation (CBC) of moviegoers in a theater during natural viewing of trailers for upcoming feature films. Since movie trailers are dynamic advertising stimuli that both entertain and persuade, they have been the focus of many recent studies (cf., Boksem & Smidts 2015). We also perform an online survey to assess the number and location of attentional targets for images extracted from each second of the movie trailers.

Finally, in addition to showing that fewer and larger attentional targets correlate with higher CBC, we provide evidence that these metrics predict future sales.

METHODS

A total of 611 subjects collectively participated in this research; 59 viewed movie trailers in a theater while undergoing EEG recordings, and 552 analyzed images extracted from each second of these movie trailers.

EEG Field Experiment

Subjects and Procedure

Subjects watched trailers and movies while undergoing EEG recordings at a commercial theater (AMC Theatres, Northbrook, Illinois). Subjects selected a movie that they had not previously seen and were offered free admission in exchange for participation. To minimize non-neural artifacts in these recordings, subjects refrained from all other activities (e.g., drinking, eating, talking, moving) except viewing the screen. Subjects were fitted with an electrode cap and conductive gel was placed at each electrode site. All subjects were native English speakers with normal (or corrected-to-normal) vision and hearing who provided informed consent.

Task

After the setup procedure, subjects viewed the movie trailers and feature film naturally. Following the movie, subjects responded to a written questionnaire that asked them which trailers they recalled and other questions about their preferences.

EEG Data Acquisition

Subjects' neural data were collected using 32-channel EEG systems (Brain Products, Gilching, Germany) at a rate of 250 Hz. The electrode sites were distributed across the entire scalp according to the actiCAP 64Ch Standard-2 (green holders) montage.

Computation of Neural Similarity

We computed CBC, moment-to-moment synchrony in EEG data across subjects experiencing the same audiovisual stimuli, through-

out each movie trailer. At each electrode site, we measured neural activity over time as the power (dB) of alpha oscillations (Berger 1929), which are often associated with visual attention (Klimesch 2012, Dmochowski et al. 2014). We performed a Short-Time Fourier Transform (STFT) of the EEG signal at each timestep, filtered the Power Spectral Density (PSD) matrix, and multiplied the common logarithm (base 10) of the PSD matrix by 10. Next, we assembled a time series of activity at the given electrode site that was correlated with the stimulus-matched time series of activity at the corresponding site for each subject. At each timestep and site, we averaged the correlations for every pair of subjects. Lastly, we averaged across the sites to arrive at a single value of neural similarity at each timestep, thus producing the CBC time series. CBC values were normalized to range from zero (minimum) to one (maximum).

Stimuli. Each movie was typically preceded by six or seven movie trailers. Throughout the study, a total of 13 trailers (1,775 seconds in length) were presented more than once and subsequently recalled by more than one subject. On average, the length of each trailer was 136 ± 20 seconds (*mean ± standard deviation*).

Identification of Attentional Targets

Subjects and Procedure

We recruited subjects on a crowdsourcing Internet marketplace (Amazon Mechanical Turk, Seattle, Washington) to analyze still images extracted from the first frame of each second of the 13 movie trailers (i.e., 1,775 images), and 25 unique subjects responded to each image.

Task

Each image was divided into a grid of 60 locations (six rows, ten columns) and subjects were asked to (1) identify the location that “grabbed their attention the most,” which we denote as their “primary attentional target,” and (2) report the “total number of items that drew their attention” (e.g., characters, objects, graphics). Subjects spent 13 ± 8 seconds per image. We also included control tasks to verify reasonable effort; in these randomly interspersed tasks, subjects were instructed to choose an asterisked location in the image.

Data was discarded for subjects who failed to answer any control task accurately.

Measures of Central Tendency

We calculated the mean and median numbers of attentional targets across the 25 responses per image. Across all images in a given trailer, we calculated the mean of these means (i.e., “average mean”) and mean of these medians (i.e., “average median”).

RESULTS

Movie trailer CBC averaged $.49 \pm .03$. The highest and lowest trailer CBCs corresponded with z-scores of 2.19 (*X-Men: Days of Future Past*) and -1.37 (*Mr. Peabody and Sherman*), respectively. The CBC distribution is right tailed; that is, engaging, high CBC trailers are rarer than would be expected in a symmetric normal distribution (positive skew of .59).

Most often, one attentional target was reported per image (37% of responses); the median was two (26%), and the mean was 2.12 ± 1.64 . Zero attentional targets were reported for images with no discernible visual content (5%). Responses with more than ten reported targets (2%) were discarded as outliers for all of the following analysis. Also, the plurality (as well as median and mean) of primary attentional targets were in one of the four centermost locations of the frame (rows 3/4 × columns 5/6); however, this was only observed in 30% of responses.

Neural similarity tended to be higher for movie trailers with fewer attentional targets. We observed strong negative correlations between CBC and both average median ($r = -.67, p = .01$) and average mean ($r = -.64, p = .02$) numbers of attentional targets per image. The highest CBC trailer had an average median and average mean of 1.42 and 1.84 targets, respectively, which is significantly fewer ($p < .01$, unpaired two-sample *t*-tests) than the corresponding average median (2.00) and average mean (2.29) of the lowest CBC trailer.

Additionally, we observed that CBC was correlated with spatial dispersion of primary attentional target locations (see legend in Figure 1). In other words, for a given attention-grabbing visual, CBC increased as primary attentional target locations were further apart

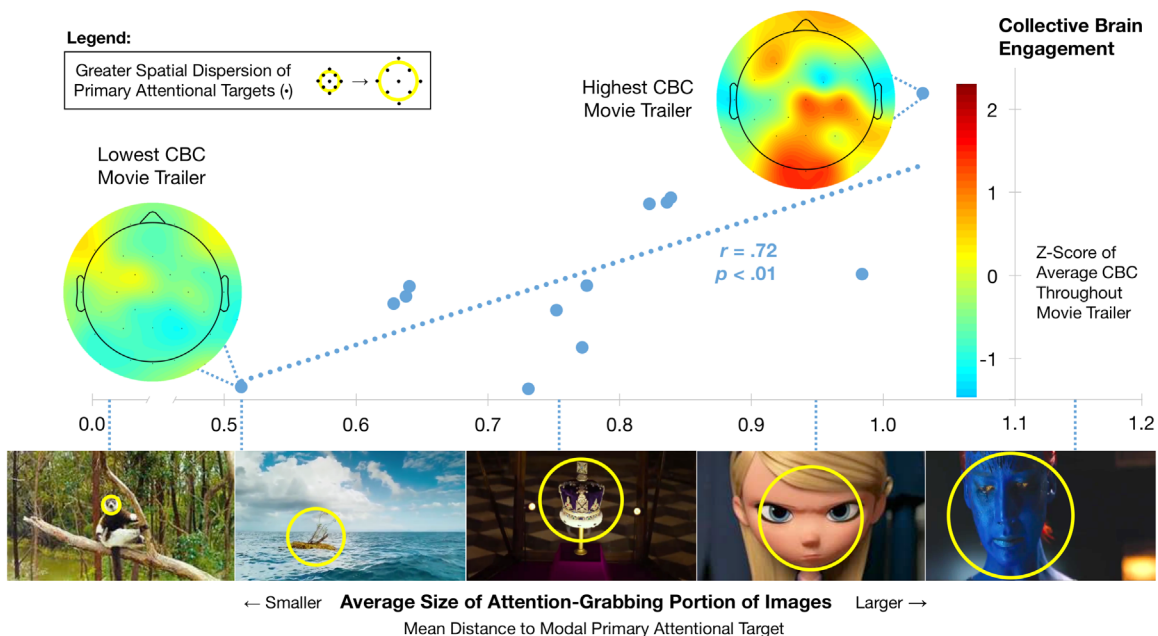

Figure 1: Size of Attention-Grabbing Visual Predicts Collective Brain Engagement During Movie Trailers.

from each other. Specifically, CBC was highly correlated with the standard deviations of primary attentional target locations along both the horizontal ($r = .80, p < .01$) and vertical ($r = .72, p < .01$) dimensions. Therefore, elevated CBC arose for attentional targets that were “few and far between”: fewer items that drew subjects’ attention, but primary targets “far between” each other.

To investigate this phenomenon further, we analyzed images with a median of one attentional target. For each image, we computed the mean distance of all subjects’ primary attentional targets to the within-image mode of these responses, approximating the size of the attention-grabbing portion of the image. These averages of mean distance across trailers ranged from .51 to 1.03 units (where the distance between horizontally or vertically adjacent locations was one unit, and the distance between diagonally adjacent locations was $\sqrt{2} = 1.41$ units). We found a strong positive correlation between CBC and average distance ($r = .72, p < .01$). That is, given a single attentional target, CBC increased with the size of the attention-grabbing area of the image (see Figure 1).

The standard deviation above/below average CBC throughout a given movie trailer (y-axis) is plotted against the average size of the attention-grabbing portion of images in that trailer (x-axis). For reference, five images are each shown with a dotted line indicating its attention-grabbing portion’s size. Additionally, superimposed yellow circles delineate the attention-grabbing regions; the legend illustrates how the circle’s size depends on the spatial dispersion of the attentional targets. Overhead EEG spatial maps (Niedermeyer & Lopes Da Silva 1993) of the regional CBC levels are shown for the lowest and highest CBC trailers (ranging from blue to red for lower and higher CBC, respectively; see gradient adjacent to vertical axis). In addition to greater average CBC, the highest CBC trailer has especially high CBC in posterior regions (represented in red) associated with visual processing areas of the brain.

Similarly, we measured the percentage of primary attentional targets that were at or adjacent to the within-image modal location (i.e., proportion of responses ≤ 1.41 units away from mode selection). These “near-mode percentages” were relatively high across trailers, ranging from 77.91% to 90.11%. Lower percentages corresponded with larger attentional areas since fewer primary attentional targets are concentrated near the modal location. Again, we found that CBC is directly related to the size of an attention-grabbing visual; CBC was negatively correlated with near-mode percentages ($r = -.71, p < .01$).

Given that CBC is positively correlated with the size of the attention-grabbing entity and negatively correlated with the number of attentional targets, we may gain additional predictive power by combining these metrics. For example, the fraction of (mean distance to within-image mode) \div (average median number of attentional targets) is more strongly correlated with CBC ($r = .79, p < .01$) than either the numerator or denominator alone.

In addition to being strongly correlated (positively or negatively) with CBC, these visual components are predictive of the eventual sales of the advertised movies (see Summary Table for statistics on each measure and its correlations with CBC and weekly sales).

The mean and standard deviation of each visual measure utilized in this work were calculated across trailers. The per-trailer averages for each measure were also compared to the average CBCs and ultimate weekly ticket sales of the full movie corresponding with each trailer, and the table displays the resulting correlations. All $|r| > .40$ were statistically significant ($p < .10$).

DISCUSSION

Fewer and larger attentional targets throughout movie trailers were significantly predictive of both higher CBC during viewing and increased sales of the advertised films. These findings agree with and extend prior literature on visual attention in advertising.

For example, lower numbers of attention-grabbing visuals have been associated with improved effectiveness of print advertisements (Book and Schick 1997; Aitchison 2012). Since consumers control the amount of time spent viewing a print advertisement, potential attentional targets are necessarily competing with each other for time and interest, so advertisers provide fewer degrees of freedom to increase focus on key items. We show this phenomenon also holds with video advertisements, despite that consumers do not control the presentation rate. In other words, competition for visual attention is continuously occurring (even frame by frame during a movie trailer).

Furthermore, when an item dominates more of the visual field, it reduces the set of other hypothetical targets for stray attentional resources. Also, when an item is larger, more visual details (e.g., colors, edges, textures) are visible, which demands greater within-item feature processing (i.e., higher perceptual load), thereby enhancing visual attention (Pieters, Wedel, and Batra 2010). Therefore, our observation that larger visuals generate higher brain engagement may be due to maximization of task-relevant (and minimization of task-irrelevant) attention according to perceptual load theory (Lavie & Tsai 1994; Lavie 1995).

Our efforts to capture natural attention in a commercial context were accompanied by many limitations. We were restricted to the theater’s available films and their corresponding trailers; our findings may not hold for other types of video advertisements. Additionally, to maximize the authenticity of the movie viewing experience, subjects did not wear eye tracking goggles, and we instead supplemented the neural data with subjective reports of attentional targets in the online survey. These limitations can be addressed in future studies with different exploratory priorities.

Nonetheless, if “a picture is worth a thousand words” (Flinders 1911), then perhaps one with a single, large attentional target is worth a million.

Summary Table: Fewer and Farther-Distributed Attentional Targets Linked to Higher Collective Brain Engagement and Sales.

Visual Component	Measure	Mean \pm Standard Deviation	Correlation with	
			CBC	Weekly Sales
Number of Attentional Targets	Average Median	1.79 \pm .22 targets	-.67	-.48
	Average Mean	2.15 \pm .19 targets	-.64	-.51
Primary Attentional Target Location	Near-Mode Proportion	84.75% \pm 3.97%	-.71	-.50
(Size of Attention-Grabbing Portion)	Standard Deviation (Horizontal)	15.94% \pm 2.48% of width (10 units)	.80	.46
	Standard Deviation (Vertical)	14.37% \pm 1.74% of height (6 units)	.72	.31
	Mean Distance to Mode	.77 \pm .14 units	.72	.39
Combined	(Mean Distance)/(Average Median)	.44 \pm .13 units/target	.79	.53

Turkish Consumers' Response to Westernised Ethical Consumption Culture: An Acculturation Theory Approach

Gaye Bebek, Coventry University, United Kingdom

ABSTRACT

We argue that marketing of Western consumption practices is practically imposing a different consumption culture upon consumers in non-Western or emerging markets. By using Berry's (1980) acculturation framework, we investigate consumer acculturation towards an imposed dominant Western marketing practice (organic products) in the multiplicity of the Turkish urban city Istanbul's context.

INTRODUCTION

Aided by increasing availability and media interest, the landscape of environmental products remains resilient (Euromonitor, 2010). Organic produce is the most pertinent in this market; the second eco-friendly product type consumers are willing to pay for more (Visser; 2010; Euromonitor, 2015). Given the promise of lucrative market, last 25 years saw considerable efforts from scholars trying to identify the psychology, norms, values of ethical consumer or the contextual factors of decision-making processes (for ex. Shaw and Clarke, 1999; Stern, 2000; Auger and Devinney, 2007; Chatzidakis, Hibbert and Smith 2007; Kihlberg and Risvik, 2007; Kilbourne and Pickett, 2008; Doran 2009; Devinney et al., 2010; Romani, Grappi and Bagozzi, 2016). Albeit insightful, efforts do not come to an agreement as to what makes an ethical consumer. Recent research suggests understanding ethical consumer may not at all be possible as change necessitates deeper conflicts to be resolved between the ideologies of consumption and protecting the environment which alludes to consuming less (Johnston 2008; Chatzidakis, Maclaran and Bradshaw, 2012; Chazidakis 2015; Carrington, Zwick and Neville, 2016). Scholars cannot exactly capture the phenomenon; but accept it as a peculiarity of Western consumption culture (Thompson and Coskuner-Balli, 2007a; Dombos, 2008; Humphery 2010; Carrington, Neville and Whitwell, 2014; Pecoraro and Uusitalo, 2014).

The premise of this paper accepts that ethical consumption is a Western cultural practice, and draws from acculturation theory to understand how and why this culture is/ is not adopted in different consumption contexts. We investigate this in the complexity and the multiplicity of an urban Turkish city: Istanbul. When change is imposed upon, rather than innate, ethical marketing efforts will be perceived as *imposed Westernised popular* culture. Added to this will be the multiplicity of the Turkish urban cities' consumption cultures. These offer a setting where fragmented cultures of immigrant rural and urban consumers co-exist (Sandikci and Ger, 2001; Sandikci, Ekici and Tari, 2006; Izberk-Bilgin 2010; 2012). Migrants may remain connected with their original culture and manifest this through their consumption patterns (Bardhi and Eckhardt, 2010); or they put in effort to fit in with the host culture (Mehta and Belk, 1991; Penaloza, 1994; Oswald, 1999). Through an emergent design study conducted in Istanbul, we explore Turkish consumers' attitudes towards the imposed dominant organic consumption culture. Focus groups and ethnographic observations stretched over 18 months identify four consumer segments that show different acculturation attitudes resembling Berry's (1980). Findings also suggest that there are two parallel marketing structures which are favoured by different consumer groups.

LITERATURE REVIEW

Consumer Acculturation of Ethical Markets

Consumers negotiate the meaning of products in different ways and may accept/ reject them as part of their consumption practices (Cross, 2000; Bardhi and Eckhardt, 2010). As Rudmin (2003) argues, humans have likelihood of adapting to new practices and consumers manifest their attitudes via consumption practices. Berry's (1980) fourfold acculturation (assimilation, rejection, integration and marginalisation) model has been applied to various contexts (Penaloza, 1989, 1994, 2000; Oswald, 1999; Penaloza and Gilly, 1999; Maldonado and Tansuhaj, 2002; Askegaard, Arnould, and Kjeldgaard, 2005; Ustuner and Holt, 2007; Hughes, 2010; Bardhi and Eckhardt, 2011; Chytkova, 2011). Postassimilationist acculturation researchers argue that acculturation is not a direct path; and show that consumers are in negotiation of their culture and do not necessarily always commit to one culture (Penaloza, 1989; Ger and Ostegaard, 1998; Oswald, 1999; Askegaard, et al 2005; Sandikci et al 2006).

Ethical consumerism as a product of the Western consumption culture (Humphery 2010; Dombos, 2008; Pecoraro and Uusitalo, 2014); is not inborn but rather *brought in* to non-Western cultures or emerging. Consumers in non-Western cultures are then faced with the new Western consumption culture, an *imposed dominant culture*, coinciding with the extant culture. Acculturation framework will shed light on whether consumers accept or reject these product types as part of their own consumption patterns. We investigate this in the context of Turkish culture, particularly in the urban city Istanbul, with added extant multiplicities and hybridised cultures of immigrant rural and urban consumers (Sandikci and Ger, 2001; Sandikci et al, 2006, Izberk-Bilgin 2010; 2012).

Turkish Consumer Acculturation towards Organic Products: Imposed Dominance vs Extant Rural

Newly affluent consumers in emerging markets are potentially the greenest consumers of the future in terms of their earnestness. As an example of this, Turkish organic packaged food shows an increase in current value by 25% in 2015 (Euromonitor, 2016). Surprisingly, Turkish demand and awareness for organic products were non-existent until the late 1990s; production was export oriented. In 1999, the Ministry of Agriculture and Rural Affairs (MARA) and NGOs started to encourage the domestic consumption, and market grew until 2005 when there were 300 sales points in the country (IF-OAM, 2009).

Consumer acceptance and awareness is growing (Akgungor, Miran and Abay, 2010; Aygen and Yagci, 2013), but Turkish consumer culture also possesses unique characteristics which influence consumers' response to marketing phenomena. Scholars noted towards different consumer groups within Turkish culture, which show different consumption styles and can induce conflicts and identity negotiations when these group coincide. These conflicts can be between rural and urban consumers (ie Sandikci et al 2006; Ustuner and Holt, 2007); upper and lower-class consumers (Ustuner and Holt, 2010); or can be ideological tensions caused by different religious beliefs (Sandikci and Ger, 2002; Izberk-Bilgin, 2012).

Sandikci et al (2006) discuss the hybridised version of Western modernity which exists in newly modernised Turkish regions. "Satellite modernities" (Ma, 2001) create an environment where the

Westernised consumer and migrant consumer from the rural regions coincide and consumption culture is negotiated (Sandikci and Ger, 2001; Sandikci et al 2006; Ustuner and Holt, 2007; Izberk-Bilgin, 2010). For Turkey, a secular country with active religious power groups, the conflict of Western and rural ideologies enhances the role of products as part of consumers' social identity construction (Oncu and Weyland, 1997), particularly status induced (Ustuner and Holt, 2007). This creates fragmented consumption practices which can align with the acculturation attitudes Berry (1980) underlines.

The satellite modernity of big Turkish cities entail more rural traditional culture carrying the traces of rural consumption patterns, and a more Westernised culture, along with various fragmented versions (Oncu and Weyland, 1997; Ustuner and Holt, 2007). A more traditional/ rural segment of consumers who shop from the rural areas and open bazaars and believe that natural products are organic in nature has been documented previously (Ozbilge, 2007; Demiryurek et al 2008; Costa et al, 2014). Given Turkish domestic organic products market is growing (Euromonitor 2016), this leads to a new consumption culture being introduced to an already fragmented market. Thus, the multiplicity of the Turkish consumer culture provides a unique context to investigate the consumer attitudes towards mainstream imposed organic products culture as opposed to their extant traditional/rural consumption practices and to what extent they have acculturated.

METHODOLOGY

The research design is adoptive and emergent and evolved as fieldwork took place. The initial tool was exploratory focus group discussions. As we acquired new knowledge, more fieldwork including ethnographic observations and photographic documentation was undertaken. All fieldwork took place in Istanbul, a highly cosmopolitan city in Turkey, attracting high level of immigration from rural areas, and a melting pot of consumption cultures. Total field work was stretched over a period of 18 months with intermittent visits.

We have followed Morgan (1996) and Tadjewski's (2016) recommendations. 10 focus groups with 7-9 participants were conducted. Participants were all residents of Istanbul with some residents of squatters and existing links with the rural regions. Each discussion took between 45 to 60 minutes over lunchtime. Transcription and translation of the scripts from Turkish to English were handled by the moderator (a native Turkish speaker). We have analysed the data through simultaneous manual coding (Auerbach and Silverstein, 2003, Saldana, 2009).

FINDINGS

From the initial focus groups, we identified two different marketing efforts in the Turkish organic markets. These were further supported by our consecutive ethnographic observations.

- a. Supermarkets and niche bazaars selling certified organic produce (Exhibit 1a, 1b, and 3a).
- b. Rural bazaars and markets selling traditional rural products with the unjustified organic assumption (Exhibit 2a, 2b, and 3b).

Aligned with the legitimacy framework (Dowling & Pfeffer 1975; Suchman 1995; Kates, 2004; Johnson et al. 2006; Humphreys 2010) our findings identify a parallel legitimacy in the organic markets in Turkey; each marketing type fitting with the consumption patterns of different consumer cultures in Turkey. The first group of products assume certificate legitimacy and is targeted towards the more Westernised modern consumer group, while the second assumes traditional legitimacy and targets more rural/traditional consumers in the satellite modernity of the cities.

Assimilation: Westernised Moderns

We identify a group of consumers who fully support the packaged organic products. Consumers in this category hold ecocentric views (Thompson and Barton, 1994; González et al, 2015), and find these products as representative of an escape from the chaos of the urban life. They actively search for certificates on products and complain of the lack of clarity of the legitimate certification processes. The supermarkets selling branded certified organic products, or on-line shopping site, similarly offering certified organic products are the main channels of shopping. The interesting point though, consumers tend to isolate themselves from the conventional consumers. In their discourse, the conventional consumers are usually referred to as "they". In this case, consumers tend to build their Westernised identities by using certified consumption as a manifestation tool. They look for certifications because that is what the aspired Western modernity dictates; they support organic products because that is what aspired Westerners do (Dombos, 2008) Therefore, this protection of their consumer group from conventional consumers suggests strong identification with the group and signals status induced consumption.

F2P6: Certificates are the only way to know what you pay for is organic. Some think they can grow organic vegetables at home! That is just ridiculous, you have to make sure the air is not polluted, the soil is not polluted...how can you make sure? Certifying bodies account for all these...

(Female, 30, White-collared worker, no links with rural regions)

F5P7: "If I may say so...I believe that I am part of the more educated consumers, I search for known brands and certificates when buying organic products. The demand must have increased in my neighbourhood [as] my local supermarket expanded their section..."

(Female, 56, Retired artist, no links with rural regions)

Rejection: Rural Consumers of the City

The rural-to-urban immigrants still have connections with their original home cultures. This group of consumers reject the imposed packaged consumption and retain their original consumption patterns. For this group, packaged certified products sold from in supermarkets have no legitimacy, what constitutes as legitimate is traditional and rural cues:

F7P5: "My friend brought some [organic] tomatoes for me from Canakkale"

(Male, 46, white collared worker, links with rural regions)

F7P3: "I know organic means chemical-free, but no one I know is actually uses the term for that, everyone thinks organic equals natural".

(Female, 36, housewife, links with rural regions)

We also identify the contrast between the rejecters' and assimilates' discourse. Whilst assimilates' isolate their "selves" from the conventional consumers, the rejecters' refer to a social grouping when discussing their consumption styles, ie "everybody". Similar to Bardhi et al (2011; 2012) and Oswald's (1999) arguments, this group of consumers want to feel attached to their original culture and manifest this by building their identity around this consumption

style. There are several ways to manifest this consumption pattern. Nearly every neighbourhood in Istanbul has weekly bazaars where produce from rural regions are sold. The first way of manifesting the rejection of packaged consumption is shopping from such outlets. Yet, rural-to-urban immigrants will not have access to every aspect of rural consumption styles. Immigrant life demands certain level of effort if they want to retain original cultures. This effort is seen in growing number of consumers making agreements with farms out of Istanbul.

F7P7: “We do not trust the ones that are sold in the supermarkets, but we have agreements with some farms out of Istanbul, we phone them and they send us via post”

(Male, 43, self-employed, links with rural regions)

Integration: Altered shopping methods for the same products

The multiplicity of Istanbul makes leeway for hybridised version for Westernised ethical consumption and traditional consumption patterns. A most pertinent way is to shop from ecological bazaars. These bazaars offer certified organic produce in a traditional/rural setting (Exhibit 3a). The consumers who shop from these ecological bazaars manifest traces of both cultures: acceptance of certified organic produce as the norm, and maintenance of the traditional rural shopping styles.

F6P2: “If I will shop for organic, I shop from [these] bazaars. I want to touch and smell [laughs] what I am buying...I enjoy the ambiance and the banter of the sellers! Thanks to those bazaars I learnt how a strawberry should taste like!”

(Female, 34, white-collared worker, links with rural regions)

We see a similar pattern for the traditional rural consumption culture learning to accept the certain demands of the urban life. We identify a marketing practice for branded products, which do not claim to be organic, but marketed for their rural origins. These products are sold in supermarkets and they are branded aptly as “extra geleneksel” (extra traditional, Exhibit 3b).

F6P4: “When I was a child, we used to grow fruits and vegetables in our farm. I can never forget the taste of those...and this is the closest I get to it. Yes, it is a little bit more expensive, but it is worth it”

(Male, 32, white-collared worker, links with rural regions)

We note this as an effort to integrate the urban consumption culture into the original traditional consumption culture and resemble consumers’ reactions towards Protected Destination of Origin (PDO) (Grunert and Aachmann, 2016). Another consumption practice that embodies elements of rural/traditional consumption whilst also adapting to the organic consumption is growing organic produce at home. This retains the element of rural farming culture but also accepts the idea and the benefits of the organic consumption. This resembles a co-optation of the dominant culture (Thompson and Coskuner-Balli, 2007b; Exhibit 3c).

Marginals: Anthropocentric Sceptics

A final group of Turkish consumers seem to reject both the traditional rural culture as well as the imposed Westernised organic culture. They adhere to consumption as usual and reject both marketing efforts and focus on other priorities; such as price, convenience, quality, or value for money. As ethical and organic products have price premiums (Gifford and Nilsson, 2014; Davies and Guts-

che, 2016) they do not find their place in the marginals’ shopping basket. In-between the imposed Westernised organic consumption culture and traditional/rural culture, these consumers have moved away from both. Within the marginals there is a group of sceptical consumers who believe certified organic consumption is another marketing whim.

F5P3: “People object to nuclear stations’ being built but they don’t mind buying a giant LED TV for their own pleasure. They are “protecting” the nature, but they don’t mind turning the air conditioner on.”

(Male, 29, white-collared worker, no links with rural regions)

Noted is a group of consumers who hold anthropocentric views (Thompson and Barton, 1994; González et al, 2015); believing this is the way the earth is evolving, and human kind can adapt to this. This is akin to the developmental realist justification (Devinney et al, 2010); and act of neutralising the inaction to buy socially responsible products by supporting with the argument that “this is the way we evolve”, and is usually seen in emerging markets (Devinney et al, 2010).

F6P3: “If this is the natural way we are evolving, how natural can ‘organic’ products be? Technological advancement does bring the demands of the modern life with it, along with the convenience.”

(Male, 59, retired, links with rural regions)

CONCLUSION

This study aims to contribute to the ethical consumption literature by offering a novel lens to understand the impact of imposed ethical consumption practices over existing consumption patterns. Accepting ethical consumerism as a product of the Western culture, we use acculturation framework to explore consumers’ response in a non-Western emerging market: Turkey. Consumption is a vehicle to communicate identities but more importantly it provides a more fluid context in which consumers can more easily switch codes as and when required (Oswald, 1999), which makes consumption a necessary competence to cohabit in a global culture. The contemporary urban culture in Turkey further necessitates this culture swapping to be a competence of consumers (Sandikci and Ger, 2001). As Sandikci et al (2006) outline in Turkey there is no one immigrant culture and no one fixed host culture to adapt.

Our findings show that through the lens of acculturation, Turkish consumers’ responses towards Westernised ethical consumerism can be captured via Berry’s (1980) framework: Turkish consumers get assimilated, reject or integrate the ethical consumption culture, or they marginalise. We identify an extant organic consumption culture which resembles that of rural consumer culture, and an imposed dominant organic culture which is more institutionalised and being surged by the policy makers. These two cultures coincide in the urban cities. Both cultures are represented via different marketing structures and assume different legitimacy frames.

Findings suggest acculturation is a promising concept to further shed light on consumers’ acceptance of outsider products and consumption styles, particularly for the case of emerging and non-Western cultural contexts given the dominance of the Western consumption style in general. Although promising, our study takes place in the context of Turkey, which bears its own complexities, especially for products that are potentially used as part of status induced consumption practices and signal consumers’ social identities (Ustuner and

Table 1: Summary of results

Imposed Dominant Organic Consumption Culture: Certificate Legitimacy				
	Assimilation (Y/N)	Exemplary Quotes	Rejection (N/Y)	Exemplary Quotes
	Extant Organic Consumption Culture: Rural/traditional legitimacy	Consumers accept imposed culture of organic product consumption. Certified organic products have legitimacy. Traditional cues do not possess legitimacy. Examples of consumption practices include buying packaged certified organic products from mainstream supermarkets and websites (ekoorganik.com)	F2P6: <i>Certificates are the only way to know what you pay for is organic. Some think they can grow organic vegetables at home! That is just ridiculous, you have to make sure the air is not polluted, the soil is not polluted...how can you make sure? Certifying bodies account for all these...</i> F5P7: <i>"If I may say so...I believe that I am part of the more educated consumers, I search for known brands and certificates when buying organic products. The demand must have increased in my neighbourhood [as] my local supermarket expanded their section..."</i>	Consumer reject imposed culture. Retain traditional consumption patterns. Rural or traditional products have legitimacy and destination of origin have legitimacy. Certificates have no legitimacy. Examples of consumption practices include shopping form bazaars for authentic rural products, or shopping online from farms (memlekettengelsin, koydenyayladan, kars bali).
Integration (Y/Y)		Exemplary Quotes	Marginalisation (N/N)	Exemplary Quotes
	Consumers accept partially the imposed culture practices while retaining the rural, traditional patterns. Both certificates and rural/traditional cues have legitimacy. Examples of consumption practices include buying certified organic products from bazaars (shopping from bazaars retains the rural/traditional consumption practice), or shopping from markets for rural products branded as "extra traditional". Consumers also co-opt organic consumption by growing at home themselves (pink tomatoes network)	F6P2: <i>"If I will shop for organic, I shop from [these] bazaars. I want to touch and smell [laughs] what I am buying...I enjoy the ambiance and the banter of the sellers! Thanks to those bazaars I learnt how a strawberry should taste like!"</i> F6P4: <i>"When I was a child, we used to grow fruits and vegetables in our farm. I can never forget the taste of those...and this is the closest I get to it. Yes, it is a little bit more expensive, but it is worth it"</i>	Consumers reject imposed culture practices as well as rural/traditional patterns. Neither certificates nor rural/traditional cues have legitimacy. Skeptics and Consumers as Usual Examples of consumption practices can be defined as "consumption as usual". Other priorities (bargains, taste, convenience, accessibility) take precedence. Consumers are skeptics and do not "buy-into" organic produce or rural/traditional cues (ie extra traditional" products).	F5P3: <i>"People object to nuclear stations' being built but they don't mind buying a giant LED TV for their own pleasure. They are "protecting" the nature, but they don't mind turning the air conditioner on."</i> F6P3: <i>"If this is the natural way we are evolving, how natural can 'organic' products be? Technological advancement does bring the demands of the modern life with it, along with the convenience."</i>

Holt, 2010). Thus our results are not generalisable. Further studies should look into cross-cultural comparisons for more generalisable results or investigate the role of these products on social identity construction processes.

Ephemeral Consumerism: Crossing Territories of the Indian Female Body

Anoop Bhogal-Nair, De Montfort University, United Kingdom

Andrew. M. Lindridge, Newcastle University, United Kingdom

INTRODUCTION

The delicate, ephemeral boundaries that permeate everyday life in complex marketplaces presents consumers with both opportunity and threat. The understanding of 'movement' in this paper is not akin to the notion of migration, but looks to understand how the body, as an active, territorial agent (Smith et al, 2016) and carrier of cultural meaning, challenges the social structures embedded in patriarchal morality. Indeed, Smith et al. (2016) view the body's mundane and extraordinary practices and experiences as simultaneously shoring up and tearing down territories and borders. However, it is important to remember social and economic histories imbued in places can be welcoming and embracing or alienating and exclusionary (Phillips and Robinson, 2015). In this vein, spaces and places serve to provide opportunity or threat – and at times, both. As the product of intersecting discourses, borders and territories serve to both limit and expand an individual's epistemological vision (Agnew, 2008).

India's relationship with women's identity, their bodies and even their ownership is a complex one, varying from religious representations and embodiment through to sexual glorification offered through Bollywood films. Such relationships exist within a society undergoing rapid modernisation producing conflicting opinions about what constitutes a woman. It is within this contrasting relationships that we explore both rural and urban Indian women's engagement with their bodies through adoption of western clothing and freedom to choose alternative forms of identity, within a wider context of a patriarchal society. Identities that may both be temporal or permanent created in one space or in multiple spaces but all within the constraints of a modernising society where patriarchal values dominate. Yet female engagement with western- or stigmatic-forms of consumption as ephemeral experiences, serve to temper bodily territoriality have been rarely discussed within the marketing literature.

CONCEPTUAL FRAMEWORK

In societies where the female body is held to be sacred (Agnew, 1997), engaging with the 'modernity project' through acts of consumption presents women with contrasting cultural values of tradition and modernity. Chatterjee (1989) argues that in societies like India, the female body is consumed through a material/spiritual dichotomy that manifests in the discourses of nationalistic modernity. Womanhood, then, is positioned through a prism of patriarchal moralities where the structures surrounding female conduct not only become embodied but also reconstituted through consumptive behaviour.

As noted by McClintock (1992) women in the social sphere are still deemed the atavistic and authentic 'body' of national traditions, simultaneously functioning as the living archive of the national archaic (Reuben, 1994). Effectively Indian women are juxtaposed between contrasting and opposing forces; revered and subjugated, worshiped and molested, free to express themselves in different domains, and yet voiceless (Olivelle, 1999, 2004). Within this ambivalence, modernity has created a sphere of empowerment through consumer culture, providing opportunities to challenge, subvert or re-negotiate societal patriarchy in a material world once reserved for men. Women become active agents and look to construct their own individual 'body projects' in light of the opportunities provided to them through the market. Within the fissure of self as individual and self as collective, women negotiate their physical and bodily territories through

a complex interplay of differing cultural contrasts between the old, traditional (rural areas) and the new, modern (urban areas).

As both a cultural and social project (Delanty, 1999), modernity is not merely bound to a departure from tradition and faith to logic and scientific fact, but one which resides in the fluid, ouroboric state of society in being able to ingest and absorb those elements which serve to temper, challenge or contradict the status quo. Consumption choices account for new sociocultural patterns that have come to dominate urban lifestyles in emerging markets, highlighting how the "epistemological styles" (Appadurai, 1990) of life have shifted to incorporate the new and alien. This phenomenon highlights one of Giddens' (1991) central critiques; societies with a social order based firmly in tradition would provide individuals with clearly defined roles, the post-traditional society requires individuals to carve out their roles and identities. In modern social life, the notion of lifestyle takes on significance and it is now tradition, identity and society that consumption becomes a tool to showcase individual's participation in the modernity project. Yet it is within these very roles that women challenge, perpetuate and reinforce on a daily basis whether it be cultural, religious or social. An enforcement that may be as voluntarily as it is involuntary.

Population movements from the rural to the urban offer many opportunities to engage with modernity, consumption symbolic of the urban modernity and adapting who we are. Within this Delanty (1999) notes the dualism of modernity as being both a cultural and social project, where the former focuses upon the autonomy of the subject (the self-assertion of the self, reflexivity), and the latter as a process of fragmentation (destruction of cultural foundations).

In sum, traditional forms supply support for, as well as against, change. It is within these forms, we argue, which prop up the properties of what is now deemed as a modernity unique and specific to those who are central to this research.

METHOD

Multi-method interpretive research data was collected over a three-month period at Bharati College, an all- female college in New Delhi, India. The college was selected due to its diverse student body (both urban and rural students) and access was negotiated through communication with the principal of the college and staff members of the English department. 23 young urban and rural women were selected, interviewed and observed. Observations facilitated the production of written ethnographic accounts and descriptions, where notes on the college site, city and the female researcher's own experiences of navigating through the city were all documented. A mixture of focus groups and one-to-one interviews formed one source of data. Each interview lasted up to ninety minutes and interviews were conducted in both Hindi and English. Transcribed interviews were analyzed using Spiggle's (1994) seven analytical stages. Reading and then re-reading the transcripts produced preliminary codes, with coded sheets annotated to identify comparisons, metaphors, and tropes (Meamber and Venkatesh, 2000). This produced several emergent themes, including 'perceived superiority', 'discrimination and ridicule' and 'liberation' and 'morality'.

Through a projection technique, participants created posters and took photographs of their consumer experiences of a 'modernising India'. Respondents were invited to talk through their photographs and posters and explain to the researcher the motivations for the im-

ages taken and the explanations and rationale for the posters that were created.

Finally, the findings were considered with the literature providing a more informed understanding, whilst subjecting the findings to further empirical scrutiny.

DISCUSSION

The findings showed how participants considered the role of the body as central to negotiating both consumption activities and notions of modernity. Conclusions were drawn about the centrality of consumption for the young women in being able to forge alternative identities which have not been socially scripted. However, the attempts made at constructing this alternative (through rebellion, seeking loopholes and testing boundaries) was constrained through forms of control and surveillance from the familial and social spheres respectively, presenting an ongoing tug-of-war between traditional, social narratives of the conduct of women, and an individually ascribed notion. Women, as noted by Liddle and Joshi (1986) have been seen to be given new sets of possibilities which enable them to survive outside of the confines of a patriarchal structure, yet considering our findings, seems much less optimistic. The college became a site for territorial interactions that brought to the fore a form of superficial emancipation. It was the complex dialogical process through which bodily territories interacted that failed to present a clear binary between self and society, but further perpetuated patriarchal moralities as ascribed by the surrounding social structures. The findings support Lury's (2001) notion that images and products follow a trajectory which encompasses the processes of undoing, destruction and construction. The opportunities and choices presented to the young women, particularly urban, of television programming, lifestyles, clothing, education and professions were ones which they were pleased to have access to, yet the adoption, appropriation and negotiation of these elements were still, to some degree, conducted within their respective territorialities mediated by the familial and social. Young urban women were relatively unperturbed by consuming elements of Western culture, yet their rural counterparts were comparatively sceptical and presented on numerous occasions a fear of loss.

The body was a site of risk and the girls were more than aware of this aspect and had tailored, where appropriate, not only their choice in clothing purchases but also their behaviour. There were numerous examples of where purchasing behaviour had come under scrutiny, however, at times much of this criticism had been self-imposed and demonstrated a deep-set understanding of territorial bargaining: Shivangini's potential purchase of shorts, Deepika's resistance to her father's rule of not wearing jeans, Anya's experience with the researcher in purchasing undergarments and jewellery, Baby's discomfort in wearing jeans and make-up in a rural setting and Swati's explanation of the rural bus journey to college and how dress deems one as 'good' or 'bad'.

Swati, a rural participant, provides an apt example both fearing rejection from her village community for transcending the norms and expectations of her village and her fear of rejection from her urban peers in her college. This example raises many deep-set concerns. The threat of 'transformation' through ephemeral movements into new territories – the city and college. It is important to note that in light of this idea, the young women constructed identities through 'structural realities' (Derné, 2005) which were specifically embedded into the social and cultural fabric of India. Additionally, what the body could potentially be exposed to through engaging in the act of consumption at various sites had prompted an increased level of surveillance and control by parents, society and rural peer groups over

the young women. This notion of the body is constructed heavily in the social realm, where the "significance of the body is determined ultimately by social structures which exist beyond the reach of individuals" (Shilling, 2006: 63), or in Goffman's (1963) words, the meanings attributed to the body are "determined by shared vocabularies of the body idiom which are not under the immediate control of individuals" (p.35). Ultimately, what the young women become are territorial agents, where the dynamic of place and space serve to temper a multi-faceted bodily territoriality that becomes negotiated through ephemeral boundary-crossing.

Despite this, it would be false to assume that resistance to these social dictates did not exist in the village setting nor amongst rural girls. There were elements of resistance where stories of rural girls changing into jeans whilst on the college campus were numerous. The college campus became a haven for consumption of the unfamiliar, immoral and Western, in addition to being a place where the body could be showcased.

Several commentators have noted that the increasing influence of consumer cultures have imposed an individualising effect on citizens-turned-consumers (Bauman, 2005; Du Gay, 1996). Binkley (2009:25) asserts that "consumer cultures impose an individualising, reflexive or narcissistic orientation on individuals who become self-enterprising, self-governing and disembedded from collective, shared contexts". What seems to be apparent from this definition of consumer culture is that it is an inherently Western notion of the term. There seems to be little acknowledgement for the term 'culture' within the assessment and it pushes to turn a complex phenomenon into a distinct binary where consumer and culture are placed at opposite ends. Although there may be some element of truth in Bauman's (2005:30) assertion that "there is no such thing as collective consumption", the findings present consumption as a social process in that it relates to a continuous expression of territories through a continuous cycle of negotiation and re-negotiation which is prompted by a collective form of moral policing.

Through the urban girls' rejection of their college and its associated 'backward' connotations, the college environment had significantly restricted their ability to fully explore their lifestyles/tastes and meant that much of their frustration fell upon the shoulders of the majority, rural student body. This group was subsequently sidelined and at times mocked by the urban crowd for their 'backward' dress, lack of fluency in English, body language, lack of exposure to the 'foreign' and overall lack of drive and professional ambition. In other words, the girls were seen to lack in all attributes associated with a modern, cosmopolitan notion of an Indian woman, as defined by the young women themselves.

The 'self' emerged as an ontological dilemma where the preoccupation with the 'self' was looked down upon by rural respondents who felt that the loss of collectivity would result in a loss of tradition. The self in terms of grooming and maintaining trends was a project of necessity for the urban respondents; the rural girls on the other hand critiqued this expression of self-indulgence as unnecessary, especially before marriage. Control and surveillance were of particular importance as they operated as mechanisms to curb and control not only women as their physical selves, but formed to protect the 'morality' of the nation. Ultimately, as material and discursive sites where tradition is performed (Oza, 2001), the body posed many complex and often contradictory negotiations for the young women in light of their constructions of identity.

CONCLUSION

Our paper explored the often conflict issues surrounding territorial bodies and how they are constructed, presented, and displayed

within an all-female territory. Somers (1994) explanation of stories and narrative as an 'ontological condition' provides an apt conclusion here. Somers places authority back into the hands of the respondents; being able to develop an intricate understanding of the ways in which this group of consumers are able to construct a multiplicity of identities, through skilful cultural navigation, was at the heart of this study. The process of 'making sense' and the ways in which the young women were guided through 'social, public and cultural narratives' whilst negotiating their own sense of selves are of central importance in developing a rich understanding of consumption behaviour amongst this group of respondents. Above all, this paper, simply put, is about experiences and not solutions; it is about presenting to the reader the sorts of questions that force a renegotiation of Western theoretical perspectives and where some theoretical assumptions could not lie further from the realities of lived consumer experiences in the East.

Is Sweaty Betty a Hollister Follower? Parsing the Poetics of Branding

Stephen Brown, Ulster University, Northern Ireland

Pauline Maclaran, University of London, UK

Sharon Ponsonby-McCabe, Ulster University, Northern Ireland

Lorna Stevens, University of Westminster, UK

Roel Wijland, Otago University, New Zealand

INTRODUCTION

According to Alain Badiou (2014), a fashionable French philosopher, the “age of the poets” is over. For the best part of one hundred years high modernist poetry was the touchstone of western thought. But those days are gone, he says, never to return. *The Washington Post* agrees. Despite valiant efforts to revive the art form, such as National Poetry Month, the patient is either dead (Zomparelli 2010) or terminally ill (Petri 2013), depending on who’s asking.

The business community begs to differ, however. Numerous corporations, Meredith (2000) reports, refuse to let poetry go gently into that good night. American Airlines hands out complimentary anthologies, as do Amtrak, Safeway and Lancôme. DaimlerChrysler and Bertelsmann sponsor poetry performances, readings, slams, and recitation contests like Poetry Out Loud (*Economist* 2014). Blue-chip consultancies invite esteemed poets to mentor top management teams (Morgan, Lange, and Buswick 2010). The BBC, British Airlines, Marks & Spencer and other elite Anglophone organizations routinely appoint poets-in-residence (Walton 2014). Business schools, too, are coming to terms with the poetic imperative (Coleman 2012); ditto individual academic disciplines (Ramsey 2006), marketing and consumer research among them (Belk, Fischer, and Kozinets 2013).

Impressive as these developments are, more needs to be done if poetry is to fulfil its full potential (Downey 2016). This paper, therefore, contends that poetry is an apt metaphor for branding in our increasingly abbreviated age. We begin with a brief review of poetry’s place in the consumer research firmament. This is followed by a potted history of branding and its poetic components. Our brands-are-poems metaphor is outlined thereafter and demonstrated with an empirical study of Hollister Inc, an iconic American brand. A brand of trope and poetry...

PUTTING POETRY IN ITS PLACE

A decade or so ago, poetry was described as a looming presence over our discipline (Arnould and Thompson 2005). Twelve years on, it’s no longer looming but loitering with intent. Annual anthologies are being published; special sessions at conferences are commonplace; freestanding poems are appearing in prominent journals and edited volumes alike (e.g. Dholakia 2005; Kozinets 2002; Schouten 2009; Sherry 2008). These works, what is more, come in a wide range of forms, from haiku, sonnets and elegies to light verse, free verse and, as often as not, “concrete” or “pattern” poetry, where the words are set out in striking geometrical arrangements (Fry 2005). Prose poems, such as Holbrook’s (1994) lyrical paean to New York City, also form part of marketing’s literary tradition, alongside short stories, screenplays, novels, and dramatizations of diverse stripe (Schroeder 2014).

In addition to individual artworks, a light sprinkling of learned articles about poetry is evident. Some seek to make the case for the art form, arguing that it is well established in other academic disciplines, the hard and life sciences among them (Sherry and Schouten 2002). Others point to the palliative benefits poetry bestows on its readers and writers, not least solace to scholars in their demanding day jobs (Downey 2016). Yet others contend that verse is more than

an important source of empirical inspiration (Belk 1986) but a valuable means of conveying information in a cogent, compact, compelling manner (Canniford 2012). It is a condensed mode of communication that is becoming ever more appropriate in an aphoristic world of short-form social media messages like likes, tweets, tags and texts (Johnson 2011).

Another important element in marketing’s poetic ecosystem is literary criticism. Thanks, more than anyone else, to the endeavors of Barbara B. Stern (1989), a diverse array of literary theories has been brought to bear on marketing matters. Alongside Scott (1994), Hirschman (1989), McQuarrie and Mick (1996), Stern showed that poetics – the formal study of poetry – deserves a place in marketing’s methodological and theoretical pantheon. Indeed she even performed, in accordance with best critical practice, a cogent close reading of several lengthy poems by leading consumer researchers (Stern 1998), concluding that poetry is a superior way of representing truth than the standard academic article. It is a way, we believe, that can be adapted to the study of branding.

THE HISTORY AND POETICS OF BRANDING

Brands, Moore and Reid (2008) remind us, have been around for thousands of years, ever since makers’ marks made an appearance on ancient Roman pottery. However, as Blackett (1998) makes clear, there is an important qualitative difference between trade-related marks and 21st century brands. The former are part of a corporation’s intellectual property, valuable assets that demand constant vigilance. The latter include intangible attributes, such as personality and identity, which are predicated on uncontrollable consumer perceptions.

Although the history of branding, Blackett (1998) contends, is less venerable than many imagine, it has made up in alacrity what it lacks in antiquity. From a standing start in fast-moving consumer goods, when mass production, mass consumption, mass marketing and distribution emerged in the administrative and industrialized centers of the western world (Bastos and Levy 2012), branding’s imperium has spread to every conceivable product and service category, from cities and celebrities to charitable organizations and university colleges (Bengtsson and Ostberg 2006; Muñiz and Schau 2005). Even the once unassailable fine arts are falling under branding’s dominion. In a domain where a “shift from art to marketing” is discernible (Alvarez 2006, p. 107), “each artist, regardless of temperament, must become his or her own producer, promoter and publicist” (Timberg 2015, p. 7). And brand for that matter. If branding is about being different, attracting attention and standing out from the crowd, then it’s as important as artistry itself when building a career in the brutally competitive cultural industries.

The arts, to be sure, have not been immune to branding’s blandishments. When Stern (1998) waxed lyrical about the poetics of commerce, for example, she was reiterating H.G. Wells who wrote about the poetry of patent medicine promotions in 1909; she was seconding William Stead’s (1899, p. 62) announcement that “ordinary persons cannot write advertising any more than they can write poetry;” she was echoing T.S. Eliot, who inserted brand names into his earliest experiments in verse and named his breakthrough poem after a brand (Crawford 2015); she was on a direct line of descent

from the peerless Claude Hopkins, the doyen of scientific marketing, who made his name with a rhyming slogan for Schlitz (Poor Beer vs. Pure Beer) and later articulated his credo for advertising copy in the imperishable iambic tetrameter *The More You Yell, The More You Sell* (Feldwick 2015).

Poetry, in point of fact, has been part and parcel of commerce since the birth of the brand. Mellifluous brand names like Hubba Bubba, Sweaty Betty, Coca-Cola and “Zanozan” are more impactful than less euphonious alternatives (Argo, Popa, and Smith 2010). Rhyming tag lines, such as *A Mars a Day/Helps You Work Rest and Play*, rarely fail to resonate with consumers (Sedivy and Carlson 2011; Schouten 1998). Jingles similar to “Pepsi Cola Hits the Spot,” rank among the most insidious earworms imaginable, thanks to their often unforgettable combination of rhyme, rhythm, refrain (Cone 2008). Alliteration, assonance, onomatopoeia, and every other trick in the poetaster’s book have been pressed into marketing service, not least among academicians, whose introductory textbooks are interspersed with acronyms, mnemonics, and wordplay (Brown 2002). Social media are equally partial to rhythmic tweets, rhyming texts, honeyed hashtags and dulcet postings (Johnson 2011). Oreo’s much-admired instant response to the power outage during Superbowl XLVII – “you can still dunk when it’s dark” – is retweet testament to poetry’s profile-raising prowess.

From a scholarly perspective, nevertheless, perhaps the most important connection between poetry and branding is metaphor. The very word is a figure of speech (Twitchell 2003) and those who have sought to formally define, or encapsulate, the concept unfailingly resort to figurative language (Brown 2016). A brand, we are reliably informed, is a relationship, a rainbow, a prism, a pyramid, an umbrella, an onion, an amoeba, an iceberg, a doppelgänger, a gestalt, a promise, a conversation, an idea to live by (see de Chernatony 2009; Jakob 2015). A brand, others sagaciously observe, is nothing less than “an opus, a complex design, a mosaic, a symphony, an evolving cultural construct” (Bastos and Levy 2012, p. 360). We likewise talk about brand image, identity, personality, aura, essence, love and lifecycles, metaphors one and all (Kitchen 2008). Perhaps the only thing that brands haven’t been likened to, oddly enough, is poetry...

REASONS WHY

Yet strange as the comparison initially appears, a moment’s reflection reveals at least eight pertinent parallels between poems and brands. First and foremost, poems are very distinctive. They stand out on the page like tropical islands in a wide blue ocean of prose (Baker 2009). If being different is one of the routes to branding success, poetry is a toll-free turnpike. Poems, secondly, are more than mere “verbal icons” (Wimsatt 1954). Like brands, they are profoundly visual thanks to their striking imagery, which captures and commandeers the mind’s eye (Sutherland 2010). The most powerful poems induce synesthesia (Richards 1924), activating many senses simultaneously, much like iconic experiential brands (Thompson, Rindfleisch, and Arsel 2006). Dynamism, thirdly, is a trait many poems possess. Powered by driving rhythms and chiming rhyme schemes (“Rhymes the rudders are of verses/By which, like ships, they steer their courses”), poetry parallels the zest, pizzazz, and irrepressible energy that the best brands are blessed with (Kotler 2003). Voice or tone, fourthly, refers to the uniqueness, the singularity, the inimitable stylistic flourishes that make outstanding poets stand out (Alvarez 2006). Uniqueness, likewise, is something that charismatic brands enjoy (Apple, Nike, IKEA, for example), and copycats strive to emulate. They are endowed with an unmistakable tone of voice which speaks volumes even when whispered (Wijland 2011, 2015; Wijland and Fell 2009).

The fifth parallel pertains to constraints. Poems in traditional meters – unfree verse, as it were – are constrained by the requirements of the form, be it seventeen-syllable haiku, fourteen-line sonnets or the rigid rules of the villanelle (Morner and Rausch 1995). Brands too are unfree for the most part. They face all sorts of restrictions: Resource shortages, financial controls, competitive pressures, historical baggage, which can in fact be beneficial, because branding breakthroughs often involve “beautiful constraints” (Morgan and Barden 2015). More beautiful still – and the sixth salient feature – is the simple fact that poetry is comparatively compact. Poems typically pack a lot into a little (Eagleton 2007). Their power is predicated on compression. They are thus well suited to today’s ferociously frugal, do-more-with-less forms of marketing communication (Polman 2015).

Legal aspects comprise the seventh concordance. Both poems and brands are legally protected – the former through copyright, the latter via trademarks – and as anyone who has ever sought permission to reproduce a line or two of poetry is well aware, versifiers are just as protective of their intellectual property as brand owners (Davis 2008). The eighth obvious similarity is that brands-are-poems complements prior tropes, particularly the increasingly popular proposition that brands are narratives, stories and, not least, myths (Cayla and Arnould 2013). Many of the latter, remember, began life in poetic form when they were passed down orally by the lyricists of pre-literate societies (Fenton 2003). Poetry, in sum, is a pocket-sized mode of storytelling, something that can be artfully employed by culturally inclined consumer researchers. It provides a compact method of presenting findings in today’s short-form-favoring world of texts-tags-tweets.

CONSIDER HOLLISTER

According to its official brand biography, the Hollister Company (HCo) is the retail store scion of an inveterate adventurer, John Hollister, Jr., who travelled far and wide throughout the Dutch East Indies during the early days of the 20th century. On his return to the United States, Hollister settled in California where, in the year of our Lord 1922, he established the emporium that not only bears his name but commemorates the great man’s far eastern adventures in aspects of its in-store décor.

Not a word of this pre-post-colonial farrago is true, however, not even remotely. Hollister’s back-story is cut from the whole cloth. It’s as fabulously fantastic as several other literary masterpieces from 1922, including Joyce’s *Ulysses*, Wittgenstein’s *Tractatus*, Eliot’s *Waste Land* and Malinowski’s *Argonauts of the Western Pacific* (Jackson 2013). If Nobel Prizes were awarded for the noble art of brand narrative, Hollister’s shaggy dog story would surely be in with a shout. Or on the shortlist at least.

The reality is rather more mundane. Hollister is a subsidiary of Abercrombie & Fitch, the upscale fashion brand. Headquartered in Columbus, Ohio, its first retail outlet opened in July 2000 – to popular acclaim – and a program of national and international expansion soon transpired (Foster and McClelland 2015). As of 2016, HCo comprises some 600 stores in nineteen different countries, from Germany (19 stores) via Canada (12 stores) to Japan (4 stores) and the UAE (3 stores). More competitively priced and targeted at a slightly younger market segment than A&F, Hollister sells an idealized version of the Southern California lifestyle (surf, sand, sunshine, seductive sexuality) to would-be way-cool high school students. With its striking beach-hut exterior, disorientating dimly-lit interior, pounding indie soundtrack, buff ‘n’ beautiful sales associates, vast video screens featuring live feeds from the Pier at Huntington Beach, CA, and a select range of fashionable casualwear, with seagull logo much

to the fore, Hollister exudes a synthetic So-Cal surf shop vibe for *Baywatch* wannabes worldwide. When it comes to theming and retail theater (Kozinets, et al 2002), HCo is the acme of atmospheric.

Our Hollister dataset consists of 105 autobiographical accounts by consumers in the brand's youthful target market. Their introspective essays averaged 2,000 words, supplemented with photographs, videos, clipart and, in one case, a flashlight (to symbolize the store's Stygian interior). When analyzed in accordance with the precepts of Consumer Culture Theory (Arnould and Thompson 2005), the reflections reveal a multiplicity of conflicting feelings about the brand: love/hate, disgust/delight, disdain/desire and, more often than not, delirious discombobulation. But from a poetic perspective, the experiential accounts are especially intriguing because the majority of essayists intuitively employ an archetypal narrative structure. Namely, that of the classical quest, the epic journey, the thrills and spills-filled adventure, where trials and tribulations are overcome and the author-hero ultimately triumphs (Hirschman 2000).

Although manifold forms of poetry are associated with questing – the Homeric epic in dactylic hexameter, Dante's *Divine Comedy* in terza rima, Milton's *Paradise Lost* in blank verse – one of the most common is the ballad, both in its demotic (folk ballad) and artistic (literary ballad) variants. Often quite lengthy and characterized by a rollicking rhythm of alternate four- and three-beat lines (usually in quatrains, rhyming abcb), ballads rank among the foremost learn-by-heart literary works in the western tradition (Fry 2005). Seminal examples include Coleridge's *Ancient Mariner*, Longfellow's *Evangeline*, Yeats' *Fiddler of Dooney*, Kipling's *Barrack Room Ballads*, Moore's *Night Before Christmas*, and Thayer's much-loved *Casey at the Bat*. *Rime of the Hollister Follower* accords with that tradition (Figure 1). Sweaty Beatty swears by it:

Extensions, Intensities and the Convergent Advertisement

Hélène de Burgh-Woodman, University of Notre Dame, Australia

ABSTRACT

Convergence media disrupts how advertising is constructed, disseminated and used by consumers. This paper asks whether assemblage thinking can be mobilized to apprehend this new advertising/consumer landscape. If viewed as complex assemblages, rather than as texts or persuasive devices, a more reflexive theoretical frame for convergent advertising may evolve.

INTRODUCTION

The current era of technological innovation has enabled the development of new media forms (Jenkins 2006), new consumer identities (Shau and Gilly 2003) and access to ever-evolving visual-affective worlds. The impact on advertising has been profound, suggesting “a disappearance of the advertisement in its traditional form... and its intensification and hybridization in oblique ways and through new media” (Campbell 2013,142). In effect, this transformation from static persuasive mechanism to integrated entertainment form (Campbell 2013) fundamentally challenges how advertising is constructed, disseminated and ultimately used by consumers (de Burgh-Woodman and Payne 2013). However, as different media channels continue to shape advertising consumption, equally traditional approaches to *understanding* both the dissemination and uses of advertising content come under increasing scrutiny as their capacity to adequately interpret and capitalize upon new consumer engagements with advertising is questioned (Taylor 2006).

The essential question posed in this conceptual paper is whether assemblage thinking, as imagined by Deleuze and Guattari (1980), can be fruitfully mobilized to better apprehend this new advertising/consumer landscape? While consumer engagement with the marketplace has radically changed through the advent of digital media, the theoretical evolution to understand these changes has lagged. As researchers grapple with the reality of the digital world, they are confronted with the need for theoretical resources for interpreting this landscape. In response to repeated calls for more nuanced theoretical perspectives that can deal with a rapidly transforming media landscape (Duguet 1981; Kuntzel 1980; Schroeder 2006; Speilman 2008; Taylor 2006), the present paper aims to show how assemblage thinking (Deleuze and Guattari 1980) as perhaps distinct from assemblage theory (De Landa 2015, 2006) enables a more reflexive perspective on how both the construction, dissemination and uses of advertising can be understood. To date, assemblage thinking has been applied in various contexts such as brands (Lury 2009), consumer communities (Parmentier and Fischer 2014) and the public sphere (Campbell 2013). However, assemblage thinking has not been applied extensively to advertising. In this paper, we focus specifically on how the advertisements by noted film directors blur cinema/art/advertising lines to form multi-faceted assemblages composed of filmic, artistic and persuasive components.

CONVERGENCE AND ASSEMBLAGE

Convergence

Based on Levy (2001), the term convergence was coined by Jenkins (2006) to explain the flow of content across multiple media platforms, the cooperation between multiple media industries, the search for new structures of media financing that fall at the interstices between old and new media, and the migratory behavior of media audiences” (p.3). The emergence of convergence catalyzes the

shift from static advertising forms to the “re-appearance” (Campbell 2013) of advertising as a sophisticated entertainment form akin to a film, documentary or video game. The effect of convergence is that advertising becomes constructed for multiple media platforms, engages disparate audiences and utilizes creative modalities such as film, documentary and photographic production to generate content (Dena 2004). Convergence extends advertising aesthetics (Brown, and Patterson 2001; Joy and Sherry 2003; Schroeder 2006; Venkatesh and Meamber 2006) and provides a platform for diverse, enriched new forms of advertising production. These forms give rise to consumers engaging in ‘spreading’ (Jenkins et al. 2015) activities, whereby ads become shared cultural resources. Equally, the advent of embedded marketing “reflects the merging interests and priorities of the entertainment, communication, advertising and brand marketing industries” (Hackley 2005). This evolution has given rise to the “mini-film” (Copping 2010; Chen 2015) ad genre that consciously hybridizes advertising and traditional cinematic forms. The spreadable nature of convergence media potentially prompts the same self-extension, symbolic meaning and personal reflexivity we attribute to the object-possession (Belk 1988) transposed into a digital context (Belk 2013). It becomes important, then, to view advertising potentially as part of these kinds of culturally mediated collections.

Assemblage

Assemblage theory has attracted attention from consumer researchers seeking to understand diverse contexts such as individual consumption experiences (Canniford and Shankar 2013), consumer communities (Scaraboto and Fischer 2016; Thomas, Price, and Schau 2013) and families (Epp, Schau, and Price 2014; Epp and Velagelati 2014). As mentioned, assemblage theory has also been used to understand brands (Enwistle and Slater 2012 2013; Lury 2009). Assemblage theory allows us to excavate how ideas are composed to create new interactions between artistic, market and media platforms. Assemblage thinking was originally flagged by Deleuze and Guattari (1980) and elaborated as theory by DeLanda (2006, 2015). DeLanda describes assemblages as “agentic systems of diverse components that interact with one another in ways that can either stabilize or destabilize an assemblage’s identity” (DeLanda 2006, 12). Assemblages “draw attention to the material and expressive “capacities” of components: capacities are defined as what components have the potential to do when they interact with other entities” (Parmentier and Fischer 2015 p.1229). Material components have a function or presence, others have an expressive or symbolic function that organize the assemblage. Equally, assemblages are characterized by extensions (the evolving inclusion of new components via expansion) and intensities (the greater or lesser power of individual components within the assemblage) (DeLanda 2015). Finally, assemblages are not fixed in time or space. They are able to adapt and shift over time (DeLanda 2006). In the same way that research has suggested brands can hold together or dissipate as assemblages (Lury 2009; Parmentier and Fischer 2015), advertisements can also be regarded as assemblages in that they collate diverse components that interact to produce a tangible, stabilized (yet open to destabilization or deterritorialization) entity – the ad or campaign itself. Embedded within the ad or ads are an amalgam of components that acquire expressive capacities as they interact with other entities.

METHOD

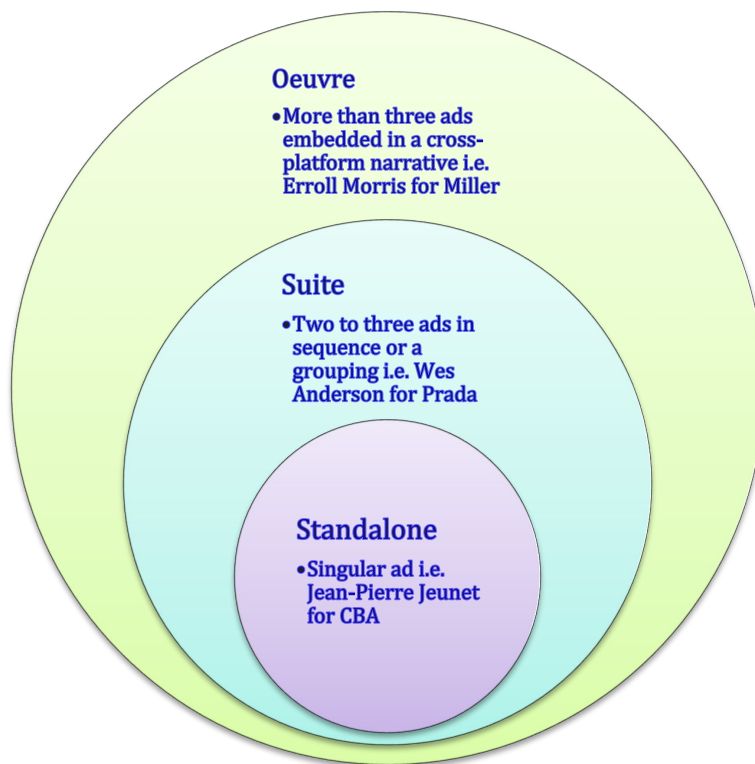

In this research, a two-step method was utilized. The first step was to undertake an analysis of the assemblage’s intensities. To achieve this, critical visual analysis (Schroeder 2002; Schroeder and Borgerson 1998) was used. Following the operations of *description*, *interpretation*, *contextualization* and finally *comparison*, Schroeder’s visual analysis method was adapted to take in diverse elements of the moving image such as its complex intertextual and technological qualities (Conomos 2007), spatio-temporal structures, perceptual and affective dimensions (Deleuze 1989) and audio-visual relationships (Chion 2009). The data used included 69 campaigns (sets of ads - some of which comprised multiple/numerous ads for the one campaign but captured here as one campaign count) directed by Wes Anderson, Darren Aronofksy, Michael Bay, Sofia Coppola, David Fincher, Jean-Pierre Jeunet, Spike Jonz, Ang Lee, Baz Luhrmann, David Lynch, Errol Morris, Martin Scorsese, Ridley Scott, and Joe Wright.

The second step was to map a classificatory typology of certain advertising forms. This classificatory typology reflects assemblage extension. Assemblages can be understood as accumulative to the extent that an assemblage can exist microcosmically (i.e. an individual ad), extend to a larger level (i.e. a suite of connected ads that

extend the same set of structures and can be read as one large assemblage) or sit within an overarching assemblage (i.e. form a component of an entire oeuvre of inter-related transmedia communications for a particular brand). Therefore, the first step involved isolating a specific data set of ads made by film directors (described below), classifying said data set into one of three types i.e. 1. *Singular* 2. *Suite* or 3. *Oeuvre*. Once the data had been organized into one of these three types, the nature of the typology was elaborated, tracing the accumulation of visual, rhetorical and symbolic force.

DISCUSSION

Deleuze and Guattari (1980) emphasize the rhizomic nature of assemblages as entities with ‘multiple roots’ that spring up across time and space. This inherent quality is reflected in convergence media itself and, by extension, convergent advertising as it moves across multiple platforms, springing ‘new roots’. Advertising created by film directors further augments this rhizomic nature as the ads can be viewed as rhizomic ‘lines of flight’ (Deleuze and Guattari 1980) connecting to greater cinematic, narrational, authorial and stylistic multiplicities that render our view of rhizomic advertising as ‘always in the middle, between things, inter-being, intermezzo...the rhizome is alliance, uniquely alliance’ (pg. 26). Viewing advertising in this

- Extension of stylistic elements
- Extension of narrative
- Extension of product based brand name
- Extension of film director brand
- Extension to other media/marketing platforms
- Extension of cultural forms/memories
- Extension of consumer spreadability

- Extension of stylistic elements
- Extension of narrative
- Reinforcement of affect
- Extension of spatio-temporal parameters
- Extension of cultural forms/references or memories
- Extension of consumer spreadability

- Advertising intent
- Narrative intent
- Stylistic intent
- Stylistic extension of cinematic content
- Extension of film director identity
- Extension of filmic references
- Representation of other cultural forms/references or memories
- Consumer spreadability

- Narrative
- Visual-narrative affect
- Stylistic audio-visual effect
- Stylistic character (often replication of film maker’s cinematic stylistics)
- Microcosmic storyworld
- Consumer transportation
- Authorial stamp
- Reflexivity
- Consumer affect and memory
- Media platform

Figure 1: Key Extensions and Intensities

way also requires us to see its extensions and intensities as perpetually engaged, shifting and changing the nature of the assemblage. The following figure (Figure 1) captures some of the dominant components at work in an advertising assemblage, thus representing the core of the typology evolved from the classification of the data along the axes of extension and intensity. The figure presented here is not exhaustive but rather designed to demonstrate some of the core relationships between components and how the nature of the assemblage either alters or preserves certain core components depending on whether it is a standalone ad, a suite or an oeuvre. The relationship between extensions and intensities is symbiotic as the affective, narrative, stylistic and referent intensities of the ad enable both de-territorialization in the form of larger, emergent assemblages and re-territorialization of key assemblage components. Like certain forms of cinema itself (Brown and Fleming, 2011), the simultaneous capacity for de-territorialization and re-territorialization through extension and intensification of affective, stylistic, narrative and referent intensities is shown to characterize the data presented here.

Intensities

DeLanda (2015) emphasizes intensities that interact within the assemblage. As the valence of different intensities morph and realign within the assemblage, so too does the assemblage itself. Thus, we should bear in mind these intensities are not static but always in an iterative dialogue of becoming with one another. In the case of convergent advertising, seemingly the most powerful intensity that affects all others within the assemblage is narrative. In its shift from persuasive spectacle to entertainment (Gurevitch 2010), convergent advertising is marked by a return to strong narratives (i.e. Lee's mini-film for BMW, Anderson's set of ads for Prada) that galvanize the other assemblage components. Chen (2015) also notes that narrative facilitates consumer transportation and fantasy processes, both of which appear as necessary intensities in the convergent assemblage as they drive consumer affect (in the Deleuzian sense) and the desire to seek extensions across platforms.

Drawing from narrative, particularly in the context of film directors who make ads, visual-narrative affect (or the synergy between the storyline, its visual realization and the emotional affect on the consumer) and the stylistic visual effects intensify the narrative through aesthetic and audio cues (Chion 2009). Linked to stylistic character, the style and effect of the ad is often a replication of the film director's cinematic signature (Wes Anderson for H&M, David Lynch for Calvin Klein), intensified by similar visual styling, use of the same cast (Lara Flynn Boyle for David Lynch's Calvin Klein Obsession, Adrien Brody as train conductor in a similar role to his Grand Budapest character for Wes Anderson for H&M, Nicole Kidman referencing her *Moulin Rouge* 'Satine' character for Baz Luhrmann for Chanel) and a replication of similar cinematic techniques and strategies to create a rich storyworld that harkens to other similarly rich storyworlds (Jean-Pierre Jeunet for Chanel referencing *Amélie*). Further intensities include the authorial presence or stamp of the director (Gerstner and Staiger 2003) whose distinctive stylistics and filmic techniques inhabit and frame the viewing experience. Finally, convergent ads embody an inherent reflexivity, moving somewhere between ad and art, low and high culture, disposable snippet and cinematic experience. These multiple intensities thus work within the ad itself but also affect consumer perception, engagement and use.

Extensions

The convergent nature of these ads, many of which are part of a set (in some cases like Errol Morris' Miller ads, the set runs to 80

ads and each extends the 'world' of the Miller Man as he moves from home, to diners, to lakes and open roads. Here one territorialized space spills into the next, i.e. de-territorializes, only to be recuperated or re-territorialized by the constant narrative thread), opens up what Deleuze and Guattari (1980) call 'lines of flight', reflecting, again, a rhizomic multiplicity that can 'turn up' at any time. Extensions in the convergent ad assemblage enable core intensities such as narrative, stylistics, spatio-temporal parameters and authorial stamp to spill over either into other ads to compose a suite i.e. a larger assemblage that at once extends and intensifies core components. David Lynch's *Calvin Klein Obsession* ads represent this suite approach where each one of the four ads draws from a great writer (D.H. Lawrence, F. Scott Fitzgerald, Ernest Hemingway, Gustave Flaubert), utilize black and white photography and evoke a similar brooding mood with tell-tale Lynchian close-ups and abstractions of bodily forms. While each ad is complete (or territorialized) in its own right, there is nonetheless a larger narrative, stylistic and interpretative becoming that spills across the four ads. Where these components are further extended into larger assemblages again, an oeuvre is composed. Unlike a suite, which essentially replicates the intensities of the singular ad across a further two or three ads, an oeuvre further intensifies its original components but embeds within a much larger brand, marketing and cultural assemblage where the original assemblage potentially faces de-territorialization as its components moves across a greater diversity of platforms, confronts additional, more complex branding/marketing/ cultural components and offers maximum opportunity for consumer spreadability – which, in turn, replicates further de-territorialization as components find new, possibility de-commodified, assemblages with which to interact. One such example of an oeuvre is David Lynch's four ads for *Georgia Coffee*. The four ads make no sense unless they are viewed in sequence. However, the entire aesthetic, narrative and symbolic composition of the ads rely on the consumer's thorough knowledge of the *Twin Peaks* series. The ads' *mise en scènes* such as the Red Room in the Black Lodge, Ghostwood Forest and the local diner harken back to the symbolic spaces of *Twin Peaks* with the return of Agent Cooper and his love of coffee introducing the customary comedic relief. More broadly, the ad provokes troubling questions in the context of oeuvre as the *Twin Peaks* season 2 cliffhanger (1990) left Agent Cooper imprisoned in the Red Room with his body/soul taken over by the omnipotent evil of "Bob". While the fate of Agent Cooper was resolved in the series 3 return (2017), these ads' airing between seasons posed questions around where and who Agent Cooper was. Was he still trapped in the Red Room with his imposter doppelgänger promoting Georgia Coffee? Read against the overwhelming cult following, the copious textual extensions (such as *Laura Palmer's Diary* and the *Guide to Twin Peaks*) and the larger cinematic opus of Lynch himself, these ads take on monumental symbolic and narrative intensity within a highly extended assemblage.

CONCLUSION

The question posed in this paper is whether assemblage thinking can be mobilized to apprehend a rapidly evolving advertising/consumer landscape. The analysis of 69 ad campaigns by noted film directors demonstrates how assemblage thinking enables us to reconceptualize convergent advertising as a rhizomic intersection of intensities (within the assemblage) and extensions that implicate diverse components from media, filmic, cultural and persuasive influences. From the consumer perspective, new terrains of engagement, sharing and spreadability (to borrow Jenkins' term) are made possible if advertising as static 'genre' is exploded, challenged by a

conceptualization of advertising as a liminal entity, working at once within and across its territories or planes.

This paper is an early step towards considering how assemblage thinking may account for the fluid nature of convergent advertising as it shifts and morphs into new forms. As such, further research is needed to see how this thinking might work as a sustainable framework. However, assemblage thinking animates the necessity to consider the intersectional, embedded nature of convergent advertisements, seeing them not as snippets of media 'content' or grabs of persuasive rhetoric but rather emergent forces, driven by the authorial, narrational, stylistic and cultural components that propel them across platforms, linking rich terrains of cultural referents, filmic influences and fantastical possibilities. At once de-territorialized so as to surge across platforms and re-territorialized back into the storyworld at the heart of the assemblage, this way of conceptualizing convergent advertising in the contemporary media environment opens up new possibilities for consumers and scholars alike.

Global Local Dialectical Relationship in a Mediterranean Context

Amina Djedidi, Université Paris-Est, France

Nacima Ourahmoune, KEDGE Business School, France

Daniele Dalli, Università di Pisa, Italy

ABSTRACT

We study the sources of brand iconicity in a Southern Mediterranean Non-Western context where the leader is the local brand versus the giant *Coca-Cola* (epitome of a global brand). We reveal how local cultural macro-social and micro discourses are intertwined to sustain this situation of inversed brand leadership in Algeria.

INTRODUCTION

CCT Research and cultural branding approaches have often neglected Non-Western contexts ('the invisible half', Jafari et al. 2012). Although iconic brands like l'Occitane, Fiat, Camper, Prada, Dolce and Gabbana brands have been investigated through Mediterranean conceptualizations (Cova and Cova 2001; Rinallo 2007; Visconti 2010; Dalli and Romani 2012; Carù, Cova and Dalli 2014; Visconti and Di Giuli 2014) all these brands emerged from Northern Mediterranean contexts (France and Italy). The present research addresses the Southern Mediterranean side through the case study of Algerian number one soda, Hamoud Boualem (HB).

Previous research showed local or regional cultures can be leveraged by local brands to secure a distinctive and motivating positioning against global players (Ger 1999; Steenkamp, Batra, and Alden 2003; Özsomer 2012) and the ability of local brands to tap into cultural values and imaginaries shared in common with local consumers as a competitive advantage vs. global brands (Bhardwaj, Kumar, and Kim 2010; Dalli and Romani 2012; Riefler 2012). Indeed, Béji-Bécheur, Ourahmoune, and Özçağlar-Toulouse (2014) portray the way Mediterranean people are tied to their culinary inheritance, either real or collectively imagined.

We study the sources of brand iconicity in a Southern Mediterranean Non-Western context where the leader is the local brand versus the giant *Coca-Cola* (epitome of a global brand). We reveal how local cultural macro-social and micro discourses are intertwined to sustain this situation of inversed brand leadership in Algeria.

METHOD

The case study method adopted in this research allows to investigate the interplay between local and global dynamics and is relevant for studying cultural branding and marketing (Dalli and Romani 2012; Holt 2006). From 2013 to 2016, we used multiple data sources including: company interviews (4HB managers, 2stakeholders, and 2 firm owners' family member); 29consumers with a varied sample in terms of gender, age (19 to79), occupation, education and location (North, South, and Abroad). Verbal and visual data also included participant observation in the company and in consumption contexts (home, family events), archival documents, and company website in order to cross-validate the complex dimensions of the topic. The research team includes three Mediterranean researchers. The first author is Algerian and has collected the data providing a point of entry in the field and ability to speak Algerian. The two other researchers have experience investigating Mediterranean contexts including Algeria, and being French-Algerian and Italian provided analytical distance in terms of interpretation. The results are the negotiated understanding of the themes that emerged from the extensive varied data collected.

FINDINGS AND DISCUSSION

The name Hamoud Boualem (HB) comes from Youcef Hamoud, the founder, a flavorist who produced aroma in Algiers and started producing artisanal lemonade with lemon taste end of 19th century. We discovered that HB is not a "me too" sort of brand grown up in the shadow of a multinational brand as it has appeared in 1876 few years before *Coca-Cola* was invented. The brand won the golden medal at Paris Universal Exposition in 1889 (Algeria was a French colony at that time).

Currently HB is a beloved brand in Algeria: it was elected the best product/brand in 2010 Algerian Food National Fair and the most beloved brand to Algerian consumers compared to all brands in any product categories in 2011. HB developed partnerships at the national and international scale. It holds the leader position followed by *Coca-Cola* in many coastal towns.

Therefore, HB Managers present HB as a public property that belongs to all Algerians: it is not an Algerian firm, it is the Algerians' firm.

To uncover the sources of brand iconicity of HB as a Non-Western, Southern Mediterranean brand we articulate our findings around three prominent themes that emerged from data analysis: food, embeddedness and myth.

Food

HB as a milestone for local food-drink know-how

Through HB consumption, Algerian consumers emphasize the way they become specialists of taste. Consumers highlight skills and know-how regarding proper combinations to adopt for health sake, gustative pleasure, and social conformity to normative taste. Even young generations extensively mention the importance of Social taste constellation of food and drinks "*When you eat something greasy and heavy, like M'hajeb –coastal tomato and onion stuffed crepe-, I ask my family to purchase white HB, it helps digesting, it tastes lemon, and I like lemon. ... For other kind of dishes, it goes with Selecto, the black HB*" (Farah, F, Coast, 27y). These constellations of food-drink combinations can also be related to special occasion meals versus ordinary meals "*During Eid el Edha -Islamic celebration involving a sheep sacrifice-, white HB goes with barbecue, and for other (dishes), it is Selecto*" (Zohra, F, Desert_Coast, 65y). HB is lived as an incorporated culinary heritage, having M'hajeb with HB is natural even when living abroad: "*Now that you are here, I'd like to prepare M'hajeb; I need to go downtown to buy Selecto*" (Kahina, F, Coast_Luxembourg, 34y).

For multi-domestic industries, demand is heterogeneous across countries and regions and it is difficult to standardize products and market offerings in general. In these conditions, local firms can build their competitiveness at home as they are considered as more authentic as food and drink are culture-bound categories for which it is easier to establish local and cultural associations (Özsomer 2012). Then, through rituals and hedonic attitudes toward food consumers integrate local brands in their self-representations, often in terms of know-how. Béji-Bécheur et al. (2014) demonstrate the way a typical South Mediterranean food (couscous) helps in building such self-representations. This latter goes through all the social codes that either translate personal preferences or local culinary know-how.

HB as celebration drink

Till the 1990's, soda consumption habits were different and linked to special occasions. Now that soda is consumed on a daily basis. Yet HB still is an icon of Algerian feasting decor which paradoxically reinforces its status as a high-end product despite being present on a daily basis. As alcoholic beverage is a minor practice, HB's meaning is displaced like Champagne in other contexts: « *HB is served also in marriage ceremonies, when you celebrate your middle school graduation, your baccalaureate. You would not serve Coca or Juice, you would serve Hamoud in the yellow crates (for glass bottles), and so we share joy through HB.* » (Soumia, F, Coast, 30y). Then, categorizing is not only horizontal and cognitive, it is vertically connected and associated with particular socio-cultural practices (Delmestri and Greenwood 2016). These reflects status games and habitus that forms specific local taste regimes (Bourdieu 1979; Ourahmoune and Özçağlar-Toulouse 2012). When global iconic brands might sound fascinating or like 'a luxury' in emerging markets, our data suggest consumers' tastes may consider the global brands as a less relevant alternative in satisfying social, cultural, and traditional needs as well as gustative, hedonistic motives.

Embeddedness

Company rootedness in Algeria's modern history

HB history is strongly intertwined with Algerian modern history. It is the oldest Algerian company that is still active and it has been through good and bad times, just like Algeria did. During Algerian war for independence (1954-1962), HB was the first contributor of the Front of National Liberation. Consequently, two of HB's managers were imprisoned. Consuming HB drinks at that time was a form of support for the "*firm bravery*" (HB family member, M, 94y). Algerian economy became increasingly dependent on oil, leading to hardship when the price collapsed during the 1980's oil glut. HB, then, faced budget deficit for years. The Algerians' riot in 1988 led Government to open the market and gave a new impetus to HB.

Product category as Mediterranean rooted drink

Tracing the culture of citrus and of lemonade shows that it is widespread across the Mediterranean. Algeria had witnessed the birth of citrus fruits, like Clementine. The now global citrus based soda Orangina has also started close to Algiers in 1930's. Other citrus derived products like lemonade are well known and widespread across the Mediterranean cultures just as olive oil and bread: they are called Cherbet in Algeria. Algerian citrus based sorbet, Creponné, is a close version of Italian Limoncello alcohol free ice cream. This engrained citrus based consumption is reinforced by the absence of culturally accepted consumption of alcoholic beverages. Then, consumers are socialized in a Mediterranean culture of lemonade and sparkling nonalcoholic beverages. Their expectations, knowledge, and specific tastes are imbued by HB recipes. Eckhardt (2005) highlighted that a product category foreignness overshadows the perception of brand localness. Through unfolding elements of the history of citrus and citrus based drinks, sodas are less likely to be the American way of life, but a deeply rooted Mediterranean product and life style. In this sense, the story of sodas and the role of HB in Algeria are not antagonist or dependent on the positioning of multinational, usually US brands: these seems to be two parallel stories in which the local and the global lived together in the same market without ruling out the other.

Coast-bound local food-drink constellation

HB is rooted in the coastal area of Algeria rooted in the 1600km Mediterranean coastal area.

Moving south, *i.e.* getting farther from the sea, regional dishes are still related to HB for those who were in touch with the coast culture. Mastering codes of social know-how can also be illustrated through regional dish-drink combinations for Rachid who spent his childhood in the desert, then moved for 20 years to Algiers, and then established again in desert: "*(about food and drink) You have great and big Matabig -southern tomato and onion stuffed crepe- or Batout -typical southern dish made of local bread mixed with tomato and pepper- then you sip a glass of HB*" (Rachid, M, Desert Coast, 57y). The same combination (regional dish-HB) was noticed with Zohra who was raised in the south, then moved to Algiers in the 1970'.

For southerners who have always lived in desert with no connection with the coast, more laxity is tolerated towards global brands consumption that happens to intrude regional traditional dish-drink combinations. HB and *Coca-Cola* can be substitutable options to accompany occasion related dishes: "*In Eid el Edha, barbecue can only be enjoyed with HB or Coca-Cola, with barbecue it is white or black HB, a very fresh one, yes, and we add pressed citrus to it, whether it is black or white, and we drink it a lot in Eid el Edha*" (Seif, M, Desert, 48y).

Food-drink constellations can also show boundaries between personal and collective tastes and, then, creating legitimacy regarding being a connoisseur with culinary know-how, like illustrated in the discussion between household informants: "*We only purchase Coca-Cola when we cook Matabig or Pizza or Coca -Stuffed turnover- (Amira, F, Desert, 42y) or Seffa -typical southern couscous-*" (Lamia, F, Desert, 50y). Then Amira interrupts: "*No, Seffa goes with milk, my son only eats it with milk.*" Researcher: "*who, amongst you, would purchase Coca-Cola when cooking Matabig, Pizza or Seffa?*" (In chorus) "*Yes Coca-Cola!*" Researcher: "*and who, amongst you, would purchase HB when cooking them?*" "*Yes, we also purchase HB (in a less convincing way) yes, we consume Coca-Cola and N'gaoues -inland local brand- (Amira) and we consume N'gaoues for Ramadan (Samira, F, Desert, 60y)*".

Myth

HB and sodas as a curative "magic potion"

Sodas being one of the targeted categories for health related awareness campaigns, some informants highlighted the fact that their occasional consumption of sodas is a way of enhancing their well-being. Surprisingly, the same objective, *i.e.*, well-being, has been related by other informants using different arguments. Indeed, soda becomes a "*magic potion*" to enhance traditional dishes digestion of, to reduce belly located fat and to fight throat infection.

HB as blessed firm

HB tries to be authentically close to the Algerian consumer by donating to the Ministry of Solidarity, providing free meals, offering free air conditioner to Sahara people. HB managers and stakeholders strongly believe that HB owners are noble people who have their ancestors' benediction, hence HB success. Their nobleness is translated, according to local culture, in their actions of donating and spreading joy amongst disadvantaged people.

Their benediction is partially explained through being true to principles "*(interests), they never use them and they give them to poor people. HB formally rejects bribery and bank interest. These are educated people who have value and who do not change their principles whatever the circumstances are*" (TM, M, Retired HB banker). Sticking to local values tends also to explain how circumstances helped "*blessed*" HB to overcome difficulties that turned to be beneficial because. For instance, in the 1980', Government set a

unique controlled system for imported ingredients. Some HB competitors used lobbying to have the best ingredients and leave the worst for HB. Since HB priority is quality, it had to reduce product outcome to maintain quality. As HB drinks became rare on the market, it was associated with luxury: “When you go at someone’s place and HB was served, that was ‘La Classe!’” (TM, M). Later on, HB won the trial at court and all these constraints disappeared.

CONCLUDING CONTRIBUTIONS

Our research contributes an understanding of the drivers of brand iconicity -a prominent research topic (Holt 2004) - displaced in a Southern Mediterranean non-Western context. We address recent calls for more diverse and inclusive research and more meta-regional approaches to add depth to cultural branding and consumer behavior constructs (Jafari et al. 2012, Carù et al. 2014).

Specifically, systematically locating the discourses at the micro-level of analysis (e.g. the lived experiences of the brand from various actors) in the macro-socio-historical context (secondary data analysis) allows to shed light on the sources of brand legitimacy that secure HB an iconic position in Algeria despite global competition marked by *Coca-Cola* as the epitome of the modern global brand.

In this process, we offer a captivating account on how consumers actively work at reversing the narrative of the giant global *Coca-Cola* as first. The hegemonic local brand Hamoud is fueled with consumers’ energy to safeguard space for their specific status games, pleasures and traditions reflecting their habitus. Furthermore, we show Hamoud’s osmosis with key moments of the national Algerian narrative to weave a unique relationship with consumers coupled with a mystique of magic and blessing. Yet, our findings suggest Hamoud is given central role of a positive catalyzer in the scripts related to food in Algeria rather than acts of explicit ideological resistance toward *Coca-Cola* that coexists and is consumed with other foods.

Moreover, results advocate that these consumption dynamics are explained by: 1/ the long historical expertise of the Mediterranean context as per the category of product and 2/ the history of Hamoud as it appeared a few years before *Coca-Cola* - which reflects Mediterranean expertise, 3/ The expertise of consumers socialized in drinking soda and their invaluable ability to reconfigure and elevate HB status as a mediator of refined local norms of good taste when it comes to food protecting the brand iconicity despite *Coca-Cola*’s impressive marketing and communication resources.

Table 1: Results Summary

Themes	Sub-themes
Food as a category products that mediates consumers cultures and traditions emerges at a site where consumers express complex meanings associated with HB	<ul style="list-style-type: none"> • HB as central to experiences of specific foods • Consumers work on setting subtle boundaries of good taste (some foods are more suitable for Hamoud other for Coca, some foods will be accompanied by white lemonade versus black one) • Food/beverage associations: Dos and Don’ts to secure position of connoisseurship. • Extensive and lively conversations witnessed during ethnography around the topic and the interviews signal the pleasure of speaking about food and demonstrate knowledge, skills, refinement or creativity • Habitus: incorporated norms of socialization as per local food constantly reworked and validated through self-pleasure and social validation • As celebration drink: festive versus ordinary foods, festive versus ordinary occasions: the brand adapts consumers’ routines and events (weddings, family events, Muslim celebration like Eid el Edha and Ramadhan, A-level celebration). • As a sparkling drink in a context where alcohol is not a major social practice, HB is elevated to the status of a special drink and even a status symbol –glass bottles for weddings consider as chic (informant use the French word – <i>classe!</i>).
Embeddedness characterized the very intimate relationship the history of Hamoud with modern Algerian history as well as the intricate link of the product category with the long Mediterranean history of soda	<ul style="list-style-type: none"> • Brand rootedness in Algeria’s modern history • Brand as a reflection of ruptures and national narrative drama increases consumer intimacy and passion toward the brand • Product category as Mediterranean rooted drink: old skill regional competence, presence of various products of similar inspirations across the Mediterranean space (lemonades and ice creams based on citrus) • Innovations in the Algerian context related to lemonade, citrus and shared recipes with other locations in the Mediterranean space • Coast-bound local food-drink constellation extensively expressed by consumers. • Differences emerge among consumer preferences and practices as per location within Algeria (North-Mediterranean/ South-Desert). • Results reinforce the legitimacy of the category of product as a Mediterranean cultural heritage when one thinks of soda as a marker of American way of life
Myth. The brand builds its iconicity beyond expertise, time and space on spiritual elements.	<ul style="list-style-type: none"> • HB and sodas as a curative “magic potion”. HB as pourvoyeur of well-being for consumers. • Blessed firm as described by the management as rhetoric of key factor success of the brand • Brand imbued with a mystique, an aura from a consumer perspective • Brand shows attention to ethics (not corrupted in a country where political and economic elites are subject to suspicion of corruption and nepotism) • Solidarity and social responsibility actions toward vulnerable populations expressed as conformed to dogma of Islamic inspiration and of caritas

Gender as a Softly Assembled Performance: Interrogating the Tenuous Possession-Self Link When Women Don't Want Pink and Men Don't Want Blue

Carly Drake, University of Calgary, Canada

Scott Radford, University of Calgary, Canada

ABSTRACT

The extant product gender literature uses experimental designs in arguing that consumers' [static] gender identities match their product choice. Conversely, interview data from the present study illustrate that decisions regarding product gender are not always a reflection of the [fluid] gendered self. These findings complicate theory on this possession-self link.

INTRODUCTION

In 2012, the 'Cristal for Her' pens, introduced by Bic, received a dose of negative publicity and ridicule in both media (e.g., West 2012) and product reviews. On Amazon, over 2,000 people shared their opinions about Bic's assumption, based on gender stereotypes, that women need slim, pastel-colored pens. Some women joked that the pens would be useful for completing feminine tasks, such as writing recipe cards, while others wondered how they could get a man's permission to write with the pens. While most of the reviews were negative, a small minority provided more positive feedback. One customer wrote: "Serious review here . . . They are really nice pens and I'm glad I got them" (Amazon 2014). This example highlights the potential challenges that a firm faces if it relies on gender stereotypes to alter an otherwise gender-neutral product to be "for her" or "for him."

Referencing traditional gender roles by employing gender stereotypes in product design may be an effective way of appealing to men and women in a sex-based market segmentation strategy (Alreck 1994). In contrast, there is also evidence that showing men and women in non-traditional gender roles can also be successful (Zawisza et al. 2006), in part because it appeals to consumers seeking more realistic representations of femininity and masculinity (Barry 2013). However, as the Bic example illustrates, since such research has largely focused on stereotypes in advertising, attention must be paid to gender stereotypes in product design and the role they play in consumers' lives as part of the extended self (Belk 1988).

Bic's sex-based marketing segmentation strategy is premised on a correlation between gender identity and product preference. Yet, recent research on gender performativity (e.g., Corbett 2008) suggests that consumers' gender identities are more fluid than identity-based segmentation strategies consider. In juxtaposing sex-based market segmentation strategies with the increasing scholarly acknowledgment of gender's fluidity, the present study asks: How do consumers understand and navigate gender identity when selecting products? Further, how do they evaluate gender cues from products targeting the stereotypical man or woman? The resulting analysis extends theory on the possession-self link in relation to gender identity, and offers a critical voice to conversations surrounding the use of gender in guiding product design.

GENDER IN PRODUCT DESIGN AND CONSUMER BEHAVIOR

Products have sex-typed identities in that consumers can readily and consistently identify them as "male" or "female" and, correspondingly, "masculine" and "feminine" (Milner and Fodness 1996; Fugate and Phillips 2010). Product gender is inherent in many designs, such as the feminine curve of a wine glass or the masculine angularity of an off-road vehicle. While these designs may elicit a

perception of gender, gendered products have the same basic characteristics, but the design, packaging, or advertising is intentionally modified to appeal to the stereotypical man or woman (Alreck 1994). These design decisions are linked to traditional sex roles rooted in sex-trait stereotypes (e.g., masculine strength and feminine gentleness; Williams and Best 1990).

The present study considers consumer responses to both product gender and gendered products as part of consumer identity projects (i.e., consumption that both constructs and bolsters the self). Since consumers use products as signals to express their self-concept to themselves and others (Berger and Heath 2007) they prefer products congruent with their self-concept (Van den Hende and Mugge 2014). Studies on the possession-self link have explored many elements of the self-concept, including those surrounding sex and gender. One stream of this research (e.g., Alreck et al. 1982; Van den Hende and Mugge 2014) argues that individuals respond to stimuli that reflect an identity tied to their biological sex (i.e., their physical maleness or femaleness; West and Zimmerman 1987). Here, a woman would be feminine-identified and seek feminine products. A second stream (e.g., Fry 1971; Feiereisen et al. 2009) posits that individuals respond to stimuli that reflect their gender identity (i.e., their self-perceived endorsement of stereotypically masculine or feminine traits; Palan et al. 1999). Here, masculinity and femininity are not confined to the physical realms of maleness and femaleness, respectively, and a feminine-identified person would seek feminine products.

GENDER AS A SOFTLY ASSEMBLED PERFORMANCE

While the aforementioned consumer research assumes gender identity is static, elsewhere scholarship argues that the identities individuals construct around gender are stable, but never fixed (Fausto-Sterling 2012). Here, gender is considered a "softly assembled" collection of behavioural attractors that vary in form and stability depending on an individual's life history and the context and task at hand (Harris 2000). Gender-related causal chains are elusive since consumers' enactments of gender are complex and personalized. Indeed, "norms do not exist without variance; the repetition of patterns or averages is never exact" (Corbett 2008, p. 839).

Poststructuralist feminist theory on gender performativity understands gender not as something one is, but something one does (West and Zimmerman 1987). A person who (un)intentionally succeeds at doing gender meets society's expectations of how men and women look and act. Alternatively, a person who does not meet society's gender-related expectations is *undoing* gender, or deconstructing it (Deutsch 2007). Decisions regarding product gender and gendered products can be considered performances that make statements about the gendered self and influence its ongoing development (Schultze 2014).

This theoretical framework is adopted to explore product gender because consumer goods can represent the kinds of social values and norms that exacerbate gender stereotypes that limit men and women in their self-expression (Caldas-Coulthard and van Leeuwen 2002). Feminist theory and methods offer the resources needed to critically engage with these goods and their consumption. Since there is little consumer research on product gender from this perspective, the pres-

ent study asserts that critical engagement is necessary for researchers to understand how these products are evaluated and used.

METHOD AND STUDY DESIGN

Twenty consumers (6 men and 14 women) living in a large city in western Canada and ranging in age and social location participated in the study. Because of the personal nature of the interview topics and the need for a diverse array of perspectives, participants were recruited using convenience, snowball, and purposive sampling (Creswell 2014). Between July 2015 and February 2016, the first author met with participants for 60- to 90-minute semi-structured interviews (McCracken 1988) focused around the act of shopping, identity, and social influence in a retail context. Participants were also shown a series of seven photographs of gendered products (e.g., bread, tea) and asked questions about the products and their packaging (see figure 1). Most participants chose a pseudonym.

The interview transcripts were reviewed using a feminist critical discourse analysis (CDA) approach. CDA views discourse as a countable noun that is not only the language of individual communication, but the larger systems of thought within a particular historical location (Foucault 1971). Feminist CDA, specifically, examines discourses that promote and reproduce androcentric perspectives that, for example, define appropriate behavior and attributes for women

(Sunderland and Litosseliti 2002). This approach can advance analyses of the way power and ideology work in discourse to sustain patriarchal social structures (Lazar 2007).

Adopting Fairclough's (1992) framework, interview transcripts were first reviewed for their internal mechanisms (e.g., grammar and vocabulary) by reading each text in its entirety, noting differences and commonalities between them. Second, patterns and themes were grouped together as discourses to be read and analyzed as cohesive wholes. In doing so, what participants deemed "thinkable" and "sayable" (Foucault 1971) from the perspective of their respective social locations could emerge. Third, the discourses were explained from a macro perspective by positioning the groupings within broader conversations regarding gender.

IDENTIFYING AND INTERPRETING PRODUCTS' GENDER CUES

By interpreting products' gender cues, participants engage in four discourses, which will now be discussed in turn (and are summarized in the attached table). Consistent with the understanding of gender as a softly assembled performance, assigning participants to a single discourse is an unfruitful task, and one not undertaken here, as participants do not consume one type of products (e.g., masculine or feminine) exclusively.

Figure 1: Gendered Products

Discourse 1: Complying with Social Norms by Doing Gender

The first discourse surrounds participants' doing gender in relation to the gendered products they were shown as well as through their daily consumption habits. Individuals who most consistently participate in this discourse have gender identities that "match" their biological sex. As these participants navigate gendered products and product gender, their purchases correspond with the possession-self link and they may abide by strict rules in selecting products. Ben, 57, cites his requirements in a bicycle: "You don't want to look like your mom put you on it. You don't want to look like a geek out there."

To Ben, not looking like a geek means avoiding feminine pastel colours in favour of darker ones, like the grey of his current bicycle. His rule revolves around image – looking like you rely on your mom is forbidden if one is to do gender correctly, especially in a social context like a bike trail where one's ability to do gender is presented for judgment (West and Zimmerman 1987). For this reason, a product's gendered positioning influences its evaluation. For those who most consistently engage in this discourse, the idea of a product being meant for the opposite sex is a powerful influence that threatens their self-concept and perceived social standing.

Discourse 2: Defying Expectations by Undoing Gender

The second discourse follows participants' undoing gender both in their reactions to the gendered products they were shown and their daily consumption habits. Those who most consistently participate in this discourse are feminine-identified women, but they break the possession-self link according to guidelines they set for themselves. Chiefly, they do not want to be "put in a box" in terms of their consumption, because they consider their lives as women as being more nuanced than the stereotypes employed in gendered products. For example, Karen, 48, speaks of a desire to "rebel" against what is expected of her as a woman. This opinion corresponds with research that notes the failure of identity appeals in marketing when consumers' agency in expressing an identity is restricted (Bhattacharjee et al. 2014).

These women criticize companies that rely on a sex-based market segmentation strategy. Responding to a photo of gendered tea, Jennifer, 30, says, "It's just so offensive. It's upsetting. . . I do want to try the tea but I'm not going to buy it." This quote reveals a clear boundary condition to the possession-self link. That is, taking offense to a product – even one with appealing qualities – is grounds for dismissing that product. In response to a set of earplugs showcasing hyper-masculinity and hyper-femininity, Deloris, 26, she says, "I think generally when things are like this I try to buy gender neutral . . . Just something in the middle." Participants may also avoid products altogether or buy products meant for the opposite sex.

Discourse 3: Muting Gender as a Daily Performative Choice

In some cases, gender and its related norms and values are muted in participants' consumption habits. Those who most consistently participate in this discourse do not use gender as a heuristic in their consumption habits. They may argue gender identity is unimportant to them and/or lament the arbitrariness of "masculine" and "feminine" labels. Products' gendered positioning or use of stereotypes holds little sway, and these participants select what appeals to them with no agenda to conform or rebel. As the co-owner of an art gallery, Greg, 30, values creativity and risk-taking. Despite his masculine gender identity, he purchases products that have an aesthetic he enjoys. A pink suit and a women's coat are among the most feminine items in his closet that deviate from his typically masculine taste.

Moreover, Lorian (who identifies as masculine) and Stephanie (who did not provide a gender identity) articulate a frustration with the array of outdoor-gear options available to them as women. Lorian, 30, says pink and purple pastels are impractical because "when I'm on a glacier or on the side of a mountain, I want something vibrant that's gonna be seen from a helicopter if there's an incident." Pragmatism is a powerful heuristic in these participants' consumption decisions when they mute gender. This discourse's muting of gender aligns with the notion that gender varies in salience across different situations (Ridgeway and Correll 2004) to the point that at some times it may be completely irrelevant (Deutsch 2007).

Discourse 4: Muting Gender as an Incidental Performative Option

Muting gender is not solely the realm of consumers who participate in that discourse on a daily basis. For example, individuals who most consistently do or undo gender through consumption may list consumption contexts (e.g., at home – away from social gaze) and purchases that do not implicate gender (e.g., for price-conscious consumers: products that might be on sale). For all participants, there is also cause to mute gender as an incidental performative option when the product is seen as "illegitimately" gendered. Participants question marketers' urge to gender a product. Their skepticism may stem from annoyance, confusion, or amusement.

In turn, they offer what they perceive as more legitimate grounds on which marketers can gender a product: (1) ergonomics; and (2) biology (i.e., differences that may *actually* exist between men and women, beyond perceived aesthetic preferences). Responding to a photo of gendered earplugs, feminine-identified Valerie, 34, says that earplugs typically do not fit her ears, so if there were something designed for a woman's ear, "I might consider buying it on that attribute alone." Similarly, she says she considered buying a tea that promised to help menstrual cramps, and that the function of such a product meant she might overlook its aesthetic "pinkness." That this observation is separate from participants' doing and undoing of gender again shows that gender can be silenced (or less salient) in some consumer contexts.

DISCUSSION

The extant product gender literature uses experimental designs to argue that consumers' static sex- and gender-based identities match their product choice. By contrast, the present study argues that decisions regarding product gender and gendered products can be considered performances that reflect and shape the softly assembled gendered self (Schultze 2014). Decisions regarding product gender and gendered products are not always a reflection of this gendered self. This finding complicates theory on this possession-self link by highlighting cases in which the link is broken, illustrating – in keeping with the idea of gender as a softly assembled performance – that no one develops as a simple mechanical reiteration of social norms (Butler 2004). Even participants content to regularly do or undo gender have exceptions to their habits.

Regardless of their identities and habits, participants question the separation of gender-

neutral products into their masculine and feminine counterparts. As such, moving beyond gendered products based on men and women's perceived aesthetic preferences to products that cater to men and women's respective biological and ergonomic needs may draw support. Future research must monitor these opinions against the backdrop of ever-evolving structures in terms of gender and related identities. By understanding how identities are formed and act-

Table 1: Summary of Findings

Discourse	Illustrative Quotes	Analysis
<p>Complying with gender norms and “doing gender” regarding gendered products and daily consumption habits. Participants’ gender identities “match” their biological sex and purchasing habits.</p>	<p>“If I ever heard someone say about a vehicle that I was interested in, ‘Oh, that’s a girly car’ or one of those kinds of comments, it would probably turn me off of that car.” (Robert, 52, masculine-identified)</p> <p>“I don’t want to accidentally wear something that’s for women . . . Like practicality-wise I know [women’s lip balm] does the same thing [as men’s lip balm] but I guess it’s just that identity aspect of it. I would not want someone else to see me using a pink lip balm.” (Ernie, age 21, masculine-identified)</p>	<p>The idea of a product being meant for the opposite sex is a powerful influence that threatens these participants’ self-concept and perceived social standing.</p> <p>Females discuss choosing and enjoying products that reflect their gender identity. Males more eager to discount products meant for the opposite sex. These findings correspond with research that shows women may face backlash if they violate feminine norms (Rudman and Phelan 2008), but men are generally held to stricter standards (Williams 1985) and are rewarded socially for adhering to masculine norms (Connell 2005).</p>
<p>Defying expectations and “undoing gender” regarding gendered products and daily consumption habits. Participants’ gender identities may “match” their biological sex, but not necessarily their purchases. Their breaking the possession-self link with purchases is an act of rebellion.</p>	<p>“I would say that I am typically, I know ‘repulsed’ is a strong word but I’m typically repulsed by things that are overly femininely presented.” (Valerie, age 34, feminine-identified)</p> <p>“No, [I wouldn’t buy the toolkit] because it would annoy me because it’s pink. I would buy a real one. Obviously it’s not strong enough because it’s pink. Yeah, I wouldn’t buy it.” (Catherine, 40s, feminine-identified)</p>	<p>These participants do not want to be “put in a box” in terms of their consumption, because they consider their lives as women as being more nuanced than the stereotypes employed in gendered products.</p> <p>Findings from this discourse correspond with research that notes the failure of identity appeals in marketing when consumers’ agency in expressing an identity is restricted (Bhattacharjee et al. 2014), and extends these findings to the context of product design.</p>
<p>Muting gender as a daily performative choice. Gender is “muted” regarding attitudes towards gendered products and daily consumption habits.</p> <p>Participants’ gender identities may “match” their biological sex, but these identities are unimportant in consumption. Products’ gendered positioning holds little sway over these participants compared to other attributes (i.e., practicality).</p>	<p>“It wouldn’t matter to me which [tea] to buy . . . Because I’d be the one drinking it so I’d want to buy what I like.” (Martin, age 45, feminine-identified)</p> <p>“I would say [I’m] feminine but not very typical feminine. Um, not super tomboy-y, but I do enjoy playing sports, for example, or I don’t really relate with typical girl things. I don’t like pink. Anything very typical of girl things I’m very <i>laissez-faire</i> about.” (Coral, age 26, feminine-identified)</p>	<p>This discourse aligns with research that shows that gender can be silenced or less salient (Ridgeway and Correll 2004 to the point that at some times it may be completely irrelevant (Deutsch 2007). For these participants, gender is consistently unimportant in their consumption habits.</p>
<p>Muting gender as an incidental performative option. Participants’ purchases may typically conform with or defy social norms, but there are specific instances in which they elect to mute gender.</p> <p>A situation in which all participants mute gender in this manner is when they criticize products they see as “illegitimately” gendered (i.e., they are gendered based on perceived aesthetic tastes that are rooted in stereotypes).</p>	<p>“Why do men need protein and why do women get calcium, you know? Men can have calcium and Vitamin D . . . I don’t like products that would separate stuff like that.” (Catherine, 40s, feminine-identified, in response to a photo of gendered bread)</p> <p>“I thought they were kind of funny because I was like, ‘What determines that these are men’s flavours and what determines that these are women’s flavours?’” (Walter, 28, masculine-identified, in response to photos of gendered tea and bread)</p>	<p>These observations are separate from participants’ doing and undoing of gender in the sense that even participants who typically conform with or rebel against social norms will opt to mute gender when they find it to be unimportant.</p> <p>As with the third discourse, this finding shows that gender can be silenced (or less salient) in some consumer contexts (Ridgeway and Correll 2004) to the point that at some times it may be completely irrelevant (Deutsch 2007). Different from the discourse regarding muting gender as a daily performative choice, this discourse emerges in specific contexts or in relation to specific purchases.</p>

ed upon through consumption practices, researchers can better understand the broader norms and values that guide consumers' lives.

Web 2.0: Online Communities or Bla-Bla Land?

Natalia Drozdova, Norwegian School of Economics, Norway

Denis Utochkin, Norwegian School of Economics, Norway

Ingeborg A. Kleppe, Norwegian School of Economics, Norway

ABSTRACT

This paper explores users' interactions on Twitter and Kickstarter. Not only do users interact with each other significantly more often on Kickstarter than on Twitter, they also express a stronger community feeling. This paper contributes to the understanding of the variations of possible interactions across different online platforms.

INTRODUCTION

The brand community framework (Kozinets 1999; Muniz and O'Guinn 2001) has been extremely fertile in studying the eruption of consumer-generated online content that followed the launch of Web 2.0 in 2004. In online conversations, a brand can work as a shorthand signifier (Holt, 2004) connecting consumers to aggregates of other consumers in a nongeographically bound online space (Belk, 2013). Cova (1997) suggests that the linking value of a brand can be more important than the consumption of the brand product or service. The early years of Web 2.0 have inspired an abundance of brand community insights, such as the concept of collective creativity in online crowds (Kozinets, Hemtsberger, and Schau 2008); consumer-to-consumer co-creation of word-of-mouth-marketing (Kozinets, Valck, Wojnick, Wilner 2010); how marginalized consumers use online communities to quest after greater inclusion in mainstream markets (Scaraboto and Fischer 2013); and how ordinary consumers can earn online leadership to an audience (McQuarrie, Miller, and Phillips 2013).

A recent study challenges the strong hold of the consumer community concept (Arvidsson and Caliendo, 2015). They claim that people's online activity is not driven by communicative interaction around a shared identity with a brand. Instead, they claim that it is the platform – or the mediation – that drives individual postings that might be inspired by ongoing affective trends or sentiments. Contrary to communities, a public is not about consumer-to-consumer communication. Arvidsson and Caliendo (2015) claim that online posting is mostly about publicity, not community.

Arvidsson and Caliendo (2015) study the #LouisVuitton on Twitter, and based on a quantitative content analysis their research suggests that people do not address each other in their tweets. The #LouisVuitton case confines to a larger group of studies that uses the field of fashion as their online study context (Dolbec and Fisher 2015; McQuarrie, Miller, and Phillips 2013; Scaraboto and Fisher 2013). The combination of Twitter as a mediating platform and the field of fashion constitutes a specific study context that might tint the conclusions regarding community versus public online content. The motivation for this research comes from this assumption, as we suggest that fields outside fashion in combination with other platforms need to be studied in order to make reliable conclusions regarding the types of interactions online.

In this study, we follow up on Arvidsson and Caliendo's (2015) research and take their findings to a different context. As Web 2.0 has evolved, social media migrates to other sectors of the economy. In particular, the finance and banking sectors are blooming with new online platforms. Kickstarter, a reward-based crowdfunding platform, is the finance counterpart to pure social media platforms such as Twitter and Facebook. Crowdfunding is defined as an open call, essentially through the Internet, for the provision of financial resources either in the form of donation or in exchange for some

form of reward and/or voting rights in order to support initiatives for specific purposes (Schwienbacher & Larralde, 2010). Reward-based crowdfunding is one type of crowdfunding where funders get various non-financial benefits in exchange for their contribution such as a token souvenir or a promise of a future customer privilege such as early access to a product. Kickstarter attracts entrepreneurs who call for backers wanting to buy into new ideas at an early stage. Founders can inform about the development of the project and backers can post and have conversations on the project site.

We study the case of Obsidian Entertainment, a video game developer that has a large following both on Twitter and on Kickstarter. Our research question explores to what degree consumers interact with each other in conversations on these two very different online platforms.

THEORY

We use the conceptual dichotomy between publics and communities proposed by Arvidsson and Caliendo (2015). A community is based on, and supported by, interaction between its members, while publics are largely non-interactive and are instead sustained by a mediation device such as a specific topic of interest, brand, celebrity, hashtag, etc. Moreover, consumers participate in a community by engaging, communicating, and interacting with other community members. Participation in a public only requires sharing one's sentiment or perspective on a topic that ties the public together, without engaging in a conversation or expecting a reaction from other members of the public. Finally, members of communities develop and maintain a shared identity, while members of a public use publicity to reinforce their individual identities.

METHOD

Case

In order to avoid a bias stemming from potential differences between consumers communication around long-established brands and brands that first emerged through crowdfunding campaigns, we chose to analyze a brand that had a sufficiently large following before its Kickstarter success. Game developer Obsidian Entertainment fits this criterion. The studio had been founded by game designers well-known for their 1990s projects and released five major titles by 2012, accumulating a considerable fan base. In 2012, the developer turned to Kickstarter to seek funding for their new game. Obsidian Entertainment received nearly USD 4 million from more than 73,000 backers in 60 days. The game, named Pillars of Eternity, was released in 2015, enjoying critical acclaim and commercial success. Project's comments section spawned a massive discussion with more than 63,000 postings, making it a fertile ground for content analysis.

Measurement

We compare Twitter and Kickstarter on the two dimensions suggested by Arvidsson and Caliendo (2015). In doing so we build on qualitative and quantitative data using three algorithms written in Python, two for collecting Kickstarter comments and fetching tweets with specific keywords, respectively, and one for conducting computer-assisted text analysis on collected data. We collected and analyzed a total of 13,942 tweets and 60,882 Kickstarter comments.

Since we are interested in investigating consumers' communication patterns, we exclude all postings by the brand representatives.

Interaction dimension. We define 'interactive communication' as postings in which users address one another. Both on Kickstarter and Twitter, users type @USERNAME when addressing other members. By counting the number of comments or tweets containing the @ symbol and excluding instances where it is followed by an email domain name, we find the number of times users have reached out to other members of the online platform. We also analyze how features of the platform can facilitate/discourage users' interaction.

Identity dimension. We conduct a qualitative analysis to identify the core values of the collective and also employ quantitative techniques to estimate the number of postings that contain personal pronouns that point towards a sense of shared identity ('we', 'our', 'us') and individual identity ('I', 'my', 'me').

Arvidsson and Caliandro (2015) identify communicative dimension as the third measure of communities and publics. It is rooted in the interaction dimension and the identity dimensions. Therefore, we will not measure it separately in this paper.

FINDINGS

The analysis reveals significantly higher interaction between the users of the Kickstarter platform in comparison with Twitter. On the Kickstarter commentary, in 48 % (29026 comments) of the comments backers were addressing other backers. On Twitter, only 8 % (435 tweets) of the tweets that mentioned Obsidian Entertainment were addressed to a Twitter account other than the ones affiliated with the brand. Twitter provides an easier way to address other users (users can be tagged to create an interactive link to their profile), while Kickstarter does not provide this option. On the other hand, the 'newsfeed' on Kickstarter presents a flow of the comments in chronological order. This news feed appears the same for all users. Twitter, however, lacks a centralized discussion thread.

In order to analyze the identity dimension, we first conducted a qualitative analysis of the Kickstarter commentary and Twitter feed. We followed the Corley and Gioia (2004) data-analyzing template. First, we meticulously managed our data by organizing postings chronologically in a collated data file. Second, we read the data file and searched for emerging patterns and systematic variation. We were particularly looking for shared consciousness, rituals and traditions, and a sense of moral responsibility (in accordance with Muniz & O'Guinn, 2001).

Analysis of the Kickstarter commentary revealed a rather strong *we*-feeling, with many funders expressing a group sentiment instead of an individual one – 'So, are we getting any details on...', 'We want Linux support!', 'We love your work more than you think =>', 'Everyone here is rooting for you!', 'We are all counting on you!'. Even though first person singular pronouns are prevalent, the share of comments that refer to 'we-ness' is substantial: mentions of individual self appears in 42% of backers' comments, while 13% of the postings by funders appeal to the shared communal identity. The ratio of 'we-comments' to 'I-comments' was therefore estimated at 0.29 (the higher the value, the larger the share of 'we'-postings compared to comments referring to one's individual identity).

Funders also express excitement of being one of the people behind a project and are looking forward to sharing this experience with others – 'Hey Guys, im happy to collaborate in funding this project. I'm a developer too ...', 'Looking forward to belong to your party and go on this adventure together'. It seems that on Kickstarter there is a natural *we*-feeling, as only the ones who pledged funds to the project can leave comments on comment feed. Therefore, there is a natural border between the 'we-who-funded-the-project' and the 'outsiders'.

Kickstarter gives backers a common goal which unites people and makes them willing to work together towards its achievement ('Hey everyone ! Next is going to look fantastic! Let's work together to make Project Eternity a reality!', 'I'm i,n – hope that we get enough money for a MAC version'). Many funders also monitor the progress in achieving this common goal, and share their observations with others - 'We're so close to hitting the half-way point. It's just unbelievable!! This game is SO happening!', 'Half way there!!'

Shared rituals and traditions is another important element of a community, whose function is to maintain the culture of the community. The analysis of Kickstarter community revealed the use of slang by many funders. Probably the most popular is 'Shut up and take my money', which was used at least 175 times. The frequent usage of the phrase was noticed by the commenters, with one of them actually admitting: 'I think this project warrants a "Shut up and take my money!" meme!' Also, many creative variations of this phrase were used, such as 'Please cease your vocalizations and accept my gold coins!'

Another important element of the brand community is moral responsibility. Moral responsibility is a sense of duty to the community as a whole, and to individual members of the community. The existence of moral responsibility implies that the communities formally and informally recognize the bounds of what is right and wrong, appropriate and inappropriate (Muniz & O'Guinn, 2001). Analysis of the Kickstarter commentary reveals the existence of certain ideological preferences, which motivate funders to back the project. Users point out the differences between 'soulless games' produced by publishers and Obsidian – 'Obsidian entertainment going to make a game without a publisher telling them what to do and how to do???? F*** YEAH!', 'we're sick and tired of consolized games and this will be a breath of fresh air!', 'The publisher model is broken, Kickstarter let's us bypass the retardation of the publisher model and go straight to giving the gamers what they want', 'They want freedom from stupid publishers, let's give it to them.'. There is an ideology behind the project, which lets users distinguish between the 'bad publishing model', and the independent project that they are funding.

We also read thoroughly through the tweets mentioning Obsidian Entertainment or Pillars of Eternity. From our initial sample of 13,942 tweets, we excluded tweets containing links (as the majority of them are promo tweets linking to news websites), tweets in languages other than English, as well as postings by official company's account and accounts of its founders. That limited our sample to 2,243 tweets. Content analysis of the tweets revealed three main topics:

Tweets containing various technical inquiries ('Someone needs to talk to the MTG people and convince them to team up with Obsidian Enter.')

Tweets containing announcements ('Just announced! Tyranny, the epic new RPG from Paradox Interactive and Obsidian Entertainment ! #whatifevilwon'), or discussion of potential news events ('I hope Obsidian Entertainment gets the rights to Fall-out and they make a game (with enough time and resources this time) that outsells FO4.')

Tweets containing personal experiences ('Today is my 1 year anniversary of working at Obsidian Entertainment! It's been a great year! Time definitely flies when you're having fun.', 'Took some time to escape into Obsidian Entertainment's "Tyranny" rpg. It's awesome. (steam)')

While the share of postings appealing to individual identity was nearly equal for Kickstarter and Twitter communication (47% and 48% respectively), the ‘we’-feeling is considerably weaker on Twitter: ‘we-ness’ was expressed in mere three per cent of the tweets in our sample, resulting in a ratio of ‘we’-tweets to ‘I’-tweets of 0.095. In addition, we were not able to identify any shared traditions or rituals. The emotional modality of the tweets is very diverse. Some users express strong positive emotions - ‘*obsidian entertainment BEST F***ING DEVS IN THE WHOLE WORLD*’, while others share very negative experiences - ‘*Obsidian Entertainment has to be the poorest excuse for a game development company ever. Every game they’ve released has been trash.*’. While Kickstarter limits the possibility to comment only to the ones who funded the project, Twitter does not impose any limitations of such type, therefore it seems natural that emotional modality of the comments on Twitter is significantly wider than on Kickstarter.

DISCUSSION

This paper reveals significant differences between the users’ interactions on Twitter and Kickstarter. Not only do users interact with each other significantly more on Kickstarter than on Twitter, they also express a stronger community feeling. The common goal (funding the project) and the feeling of belonging to the same project seem to unify Kickstarter users. We find indication of all three dimensions of community (Muniz & O’Guinn, 2001) such as consciousness of kind, shared slang, and moral responsibility (expressed via ideological preferences towards independent game development) on Kickstarter. On Twitter, on the other hand, users seem to lack communal feeling and strong unifying factors, which is in line with the findings by Arvidson and Caliandro (2015).

Based on our analysis, we suggest that brand communities and brand publics co-exist on the Internet. Indeed, it is possible that communities and publics are but two points on a continuum of consumer collectives.

The important contribution of our analysis is the variations of possible interactions across different online platforms. Some plat-

forms may in fact be a ‘bla-bla land’, but others may facilitate strong community feelings among users. Further research is needed in order to fill in the gaps on the public-community continuum of consumer interactions online as well as observe consumer behavior in other study contexts.

Table 1: Summary of Results

Obsidian Entertainment, Project Eternity	Kickstarter	Twitter
Interaction dimension	- Share of backer-to-backer (consumer-to-consumer) comments: 48%	- Share of tweets addressing someone other than official Obsidian account (consumer-to-consumer postings): 28%
	Generally, Twitter users interact with each other significantly less than Kickstarter users.	
Identity dimension	- Existence of We-feeling ‘We’-postings to ‘I’-postings ratio: 0.322 47 % of all posts used first person singular pronouns 15 % of all posts used first person plural pronouns - observable usage of common slang (‘Shut up and take my money’ used more than 175 times) - moral responsibility (expressed via ideological preferences towards independent game developing)	- Lack of we-feeling ‘We’-postings to ‘I’-postings ratio: 0.072 48 % of all posts used first person singular pronouns 3 % of all posts used first person plural pronouns - no common slang or shared rituals - no shared understanding of moral responsibility expressed
	Kickstarter users seem to be unified by the existence of common goal (funding the project). They use significantly more we-postings than Twitter users, share common slang and express shared ideological preferences. Tweets, on the other hand, do not merge into a coherent discussion.

Sustaining Behavioural Change: The Power of Positive Emotions

H.P. Samantha Gallage, Nottingham University, UK

Teresa Heath, Nottingham University, UK

Caroline Tynan, Nottingham University, UK

INTRODUCTION

This study explores emotions experienced by consumers who give up excessive drinking and considers how these emotions help consumers to sustain their healthy consumption behaviours. Current studies mostly focus on *changing* risky consumption behaviours (excessive drinking, smoking and gambling), rather than *sustaining* the positive behavioural change, which is a key challenge for consumers (Peattie and Peattie 2009; Scammon et al. 2011). Negative emotional appeals such as guilt and fear have been widely used to discourage these unhealthy consumption behaviours (Antonetti, Baines, and Walker 2015; De Hoog, Stroebe, and de Wit 2007). However, negative emotional appeals can encourage maladaptive responses that could be damaging for healthy behaviour (Hastings, Stead, and Webb 2004) and some authors urge the use of positive emotions such as hope, love, and excitement to *sustain* a behavioural change (Peter and Honea 2012). Yet, we know little about positive emotions experienced by consumers who transit from a risky behaviour to a less risky behaviour (Fry 2014) and how these emotions may help them to sustain this change. As this study demonstrates, these emotions can be fundamental in the process of achieving and sustaining responsible drinking behaviour.

THEORETICAL BACKGROUND

Alcohol has consistently been promoted through fun and excitement (Smith and Foxcroft 2009), which has made excessive drinking common amongst young people in the UK (Hackley et al. 2013; Measham and Brain 2005). Thus, alcohol is embedded in the culture of the UK (Piacentini and Banister 2006) and thereby young people are “invited to binge” (Haydock 2015, 1057). Countering this dominant practice is challenging for individuals because it can lead to their stigmatisation (Piacentini and Banister 2006) or exclusion (Cherrier and Gurrieri 2013). While this was found to cause negative emotions such as tension, shame (Piacentini, Chatzidakis, and Banister 2012), stress and agony (Fry 2014), the positive emotions that emerge while opposing dominant consumption practices have been neglected. Nevertheless, resisting overconsumption can lead to happiness (Cherrier 2009) and life satisfaction (Boujbel and D’Astous 2012). Peter and Honea (2012) also suggested that positive emotions associated with optimism are a key driver for sustaining a pro-social behaviour.

Alcohol consumption as a symbolic act (Szmigin et al. 2011) helps define young drinkers’ self- and social identities, and their behaviour (Fry 2010; Piacentini et al. 2012). In these circumstances, for individuals to alter and sustain responsible alcohol consuming practices they need to change their social roles and social groups (Piacentini et al. 2012) and develop a new identity contrary to the dominant culture (Fry 2014). According to theories of social identity (Tajfel and Turner 1986) and self-identity (Stryker 1968) these new identities require recognition and validation from others. Success or failure in enacting a new identity may cause strong emotional reactions (Stets and Burke 2014). Thus, gaining validation for an identity or meeting one’s identity expectations produces positive emotions and failure to do so produces negative emotions (Turner and Stets 2005). Therefore, in this situation positive emotions emerge when individuals are able to validate their *sober self* (Cast and Burke 2002) or/and when individuals are able to achieve a match between an *ideal*

sober self with the *actual performance of the self* (Turner and Stets 2005). Positive emotions linked to the sober identity strengthens the commitment towards that identity (Stryker 1980), which will aid in sustaining the behavioural change.

METHODOLOGY

We adapted a narrative methodology which is suited to deep exploration of: context-specific consumption (Shankar, Elliott, and Goulding 2001), such as drinking alcohol; turning points in life (Barrios, Piacentini, and Salciuviene 2012); and identity-related concepts (Ricoeur 2002). Data was collected using narrative interviews (Fry 2010; Szmigin et al. 2008) with 25 self-reported ex-binge drinkers who had given up excessive drinking for 6 months or more (Peter and Honea 2012). Taking the view that reality is socially constructed (Hudson and Ozanne 1988), we let participants elaborate on the construction of their emotions (Shankar et al. 2001) when countering the UK heavy-drinking culture. Participants were aged 19-35 and interviews lasted 90-150 minutes. In order to enrich narratives and obtain insights about emotional changes (Tennen, Suls, and Affleck 1991), an event-based online diary was also used. The 25 interviewees were asked to note their alcohol-related experiences and associated emotions, over a period of 8 weeks (Burton and Nesbit 2015). We conducted a thematic analysis of the data (Davis and Francis 2014). After gaining a grasp of the overall shape of the data (Riessman 2008), we coded it using NVivo 11 (Ryan and Bernard 2003; Spiggle 1994). Codes were guided by identity theories, and the emotions literature (Miles and Huberman 1994). Some categories emerged from the data itself (Miles and Huberman 1994). Finally, the themes were discussed and modified by the three researchers until reaching a consensus (Price, Arnould, and Curasi 2000).

ANALYSIS AND DISCUSSION

This section explains emotions experienced by individuals who give up excessive drinking. Participants experienced emotions that are complex and sometimes “bittersweet” (Price et al. 2000, 186). In most cases, happiness and pride were prominent. These emotions were described as enduring or self-fulfilling and enabled participants to overcome negative emotions such as sadness, loneliness and nostalgia. Equally, feelings of hope and relief about their “new”, “better” selves were intertwined with embarrassment, shame and guilt about their past drinking selves. As our participants indicate, the positive emotions experienced helped them to maintain their new sober, or responsible drinking, behaviour.

Self-Fulfilling Happiness as Opposed to Temporary Enjoyment

Most of our participants reported experiencing happiness as a result of quitting excessive alcohol consumption. Mogilner, Aaker, and Kamvar (2012) suggested that happiness can be twofold: on the one hand associated with excitement, elation and enthusiasm; and on the other with calmness, peacefulness and serenity. Our participants’ experiences seem to be of the latter type; for example, Jacob says:

I think I am definitely happy now. Hmmm I feel that I am wasting less time because of being hungover. (...) I guess if you see on social media you see pictures of people that post when they

are on night outs. Then you might think that “ohh my God they are having fun”. But I know that if I really want to, then I could organise something like that easily. So I would say **that looking forward to different things and looking forward to spending time with people you love is better**. Also, whenever I am trying to be **mindful**, try and do some **meditation or something like that** I try and focus on **how my body is feeling** and I know if I drink alcohol my body doesn't **feel healthier** and it **doesn't feel good** as it does.

(Jacob, 22 years old, responsible drinker, *Interview data*)

Jacob's experience of happiness is one of contentment and tranquillity rather than excitement and fun. He compares his current “healthier”, more responsible and mindful self favourably with his previous “hangover” self. This agrees with identity theorists who describe happiness as an outcome of evaluating one's current state in relation to an earlier state or to some reference group (Stets and Trettevik 2016). Although he may feel loss for the fun he is missing with others, Jacob is focused on enjoying new things and the company of loved ones. Jacob's new reflective and mindful persona makes him feel better and more in control, which is instrumental in sustaining his new self, as this diary entry also indicates:

*Day out to socialise with friends and attend a **football match**. Alcohol was involved as **drinking was a social thing** to do before the match began (...) I was part of a large crowd of people who were drinking. I made sure I did not drink ‘too much’ alcohol and stayed within my limits. **I felt calm, happy and in control for the whole situation**.*

(Jacob, 22 years old, responsible drinker, *Diary data 7th week*)

Becoming a responsible drinker is challenging and like Jacob, other participants experienced negative emotions when confronted with what they were missing. However, participants' contentment about their new lives and selves acts as a powerful driver to maintain their behaviour (Peter and Honea 2012) and cope with these negative emotions:

*I have my friends and I see them on **Facebook**, my friends were **going out and having great fun** when I was at home eating lettuce so that made me feel **really, really sad**. I wasn't being sociable. (...) But (...) on the other hand **I see it as better**. I feel a lot **healthier** and a lot **happy**. It's a different feeling.*

(Kim, 23 years old, responsible drinker, *Interview data*)

Similarly, many other participants experienced this self-fulfilling happiness associated with being able to spend time with people they loved (Benjamin 30, Jeremy 28, Gerard, 23), being in control (Alicia 23, Charles 30, Lizzie, 25), saving money and time (Bella 25), not making situations unpleasant (Jeremy 28, Max 35) and living more healthily (Andrew 27, Jeremy 28, Kim 23).

I am Proud because I am a Better Person

Participants' happiness with their new selves was linked to pride, a positive emotion associated with a sense of achievement and self-esteem (Brown and Marshall 2001). According to self-identity theory, validation of an identity produces feelings of competence and increased self-esteem (Cast and Burke 2002). As our participants achieved and confirmed their “responsible drinker” or “sober” identity goals, they experienced pride. This confirmation comes partly from their self-evaluation wherein they compared their drinking-self (and behaviour) with their sober-self (Tracy and Robins 2004). Im-

portantly, however, this confirmation also arises from the responses from significant others, as Kim's account illustrates:

*I think actually everybody now sees me as a **pillar of society** (laughs) if you know what I mean. I know my **grandparents, my parents are so proud of me**. (...) I would say I am a healthy 23 year old who **isn't alcoholic and nobody abuses**. I think they see me now as “**well done**”. I think even my **friends look up to me**. I think my friends are still at the university and I think they think like “Oh wow she is doing well and **she is an adult!**” “Doesn't drink much” (...) sometimes when they are laying in the floor. I am like “it's ok. They will grow up” (laughs) so I think they **see me not as equal anymore***

(Kim, 23 years old, responsible drinker, *Interview data*)

Kim's new, sober self is a “superior” and “successful adult” whom “no one abuses” as opposed to her friends “who are laying in the floor” and need to “grow up”. Similarly, many participants were proud because they have “matured” (Lisa 20, Gerard 23, Miriam 19, Yara 23), have “will-power” (Bella 25, Jacob 22, Susan 25, Yara 23, Jeremy 28), are “confident” (Alicia 23) and “successful” (Carmel 25, Lilly 25).

While feeling proud of their current selves, several participants also felt guilt and regret for their former excessive drinking selves. Interestingly, some were able to find a silver lining (Gilovich and Medvec 1995), resulting from having grown-up with the experience:

*I wouldn't be **the same character and like resilient personality** if I haven't been into so much shit on myself. It definitely made me I think like more of a like **confident and like vocal person**.*

(Carmel, 25 years old, responsible drinker, *Interview data*)

In this way participants can find valuable meaning in their experiences, which helps them to overcome negative emotions associated with their previous drinking selves. Similarly, many participants said they were hopeful about the future because of the life lessons they learnt. These and other participants' enhanced feelings of self-worth or pride seem to be a determinant in sustaining their responsible drinking behaviour even when they could have been tempted to do otherwise:

*[I] went to a wedding of two friends. I felt **comfortable**. People around me were drinking more than I was. **But it didn't bother me**. The glass of wine felt right to toast ...**I felt proud of myself for sticking to the one glass**. (...) They were surprised. I would not abuse the alcohol and nor did I feel that I would want more after drinking just the glass. I felt like I was a **stronger person and a brave person** (...) I have a **healthy life style now unlike others***

(Alicia, 23 years old, responsible drinker, *diary data 3rd week*)

Alicia constructs herself as “heroic” because of her ability to oppose widely shared consumption practices and as “different” due to the healthy lifestyle. Her pride helps her foster “good” behaviour while hindering “wrong” behaviour (Gregory-Smith, Smith, and Winklhofer 2013). Similarly, many participants who were unable to get validation of their new, sober identities from dominant, drinking groups, developed a sense of self-worth and pride through lifestyle and behavioural changes and sustained their responsible consumption.

GENERAL DISCUSSION AND IMPLICATIONS

“Sober identity” validation in the UK can be challenging because individuals are countering a dominant consumption practice i.e. excessive drinking (Fry 2014; Piacentini and Banister 2006). Literature on identity tells us that in such a situation negative emotions could emerge (Stets 2004). In the process of becoming abstainers or responsible drinkers, participants experienced ambivalent emotions about their sober decision (Otnes, Lowrey, and Shrum 1997). However, for most of them positive emotions such as happiness, pride and hope worked as a “repairing strategy” to overcome negative feelings (Zeelenberg and Pieters 2007) emerging from the perceived losses of fun, company or excitement in participants’ lives. That is, participants felt content with their more mature, wiser, respected and healthier selves. Importantly, these positive emotions emerged as a result of individuals’ perceived “superiority” over their previous selves and drinking friends. These positive emotions worked as a defence mechanism to sustain their sobriety or responsible drinking. This supports the argument of Peter and Honea (2012) that positive emotions are key to maintaining pro-social behaviours.

Theoretically, this paper elaborates on the power of positive emotions to *sustain* healthy consumption choices, especially when the choices are contrary to dominant practices. Secondly, explaining emotions in light of identity theories provides a new perspective for consumer researchers to understand the intertwined nature of identity and emotions. This study also provides implications for social marketing practitioners and policy makers interested in maintaining a positive behavioural change. Specifically, we suggest that social marketing campaigns using positive emotions associated with “achiever” or “heroic” sober selves, who are able to defeat the dominant drinking culture, could more effectively maintain healthy behaviours than merely using negative emotions such as fear, fear and sadness.

LIMITATIONS AND FUTURE RESEARCH

These findings can be used to inform future studies examining the sustainability of other healthy consumption choices, such as healthy eating, non-smoking, weight loss, and physical activities. Equally, future studies could explore in greater depth the identity negotiations associated with the emotions that individuals experience while adopting healthy consumption practices. This study was limited to a particular age group in the UK and we relied on self-reported accounts of participants. Further research into a broader population, employing a quantitative approach could provide an interesting extension of evidence.

“Mirror Mirror on the Wall, Who is Real of Them All?” – The Role of Augmented Self, Expertise and Personalisation in the Experience with Augmented Reality Mirror

Ana Javornik, Newcastle University, UK

Marta Pizzetti, Università della Svizzera italiana, Switzerland

INTRODUCTION

Augmented reality (AR) sets itself apart from other interactive technologies in that it overlays physical environment with virtual annotations in real-time, meaning that they react to the user's movements as if really existing in the physical environment. In the heterogeneous class of AR devices and applications (Scholz and Smith 2016), AR mirrors with front-facing cameras are especially on the rise as they represent the most advanced version of virtual try-on in terms of real-time fit. As if seeing herself in the mirror, the user views her image on the screen, which appears modified with virtual representations of products (Javornik 2016). Such technology represents an elegant solution for trying on more products in comparison to physical testers or products. Due to the immediacy of how the virtual products appear and disappear from one's image, the consumer can explore more choices with minimum effort (Kim and Forsythe 2008). Given that the AR try-on directly modifies one's image in the mirror, it is important to understand how consumers perceive such augmented images, how they relate to the products that constitute such augmentation and, finally, what the resulting behavioural intentions are.

The present research aims to fill this knowledge gap by investigating the effect of AR try-on on the level of self, the product and the behavioural intentions. Two experimental designs compare different forms of AR in order to investigate the effects of such technology on the different levels of the experience (i.e. the self, the product and the intentions), but also to shed light on the most effective way of using AR.

THEORETICAL FRAMEWORK

Digital and virtual technologies were shown to have an effect on the self (Schau and Gilly 2003; Siddiqui and Turley 2006; Sheth and Solomon 2014). Following the idea of “extended self” (Belk 1988; Belk 2013) and “malleable self” (Aaker 1999), Jin (2012, 2161) proposed the concept “virtual self” which refers to “the technology-mediated self simulated in virtual environments”. When creating virtual avatars, users in her study felt a stronger self-connection with those avatars that represented their ideal self than with the avatars that represented their actual self (Jin 2012). What happens when the users see such an enhanced version of the self not only on the screen, but superimposed on their own image in a mirror? Does the consumer create a closer connection to the augmented image when she feels that such augmentation represents an enhanced or improved self?

Unlike in virtual reality, in AR augmentation happens in real-time; the virtual annotations are overlaid directly onto the face; and the fusion of the self and the image is much more realistic (Azuma et al. 2001). With virtual try-on mirrors, the virtual elements are embedded seamlessly as part of the mirrored image and thus appear as a realistic part of the self. Given such superimposition, we expect that the *virtual augmentation of the self in the AR mirror* and the *perception of such virtual augmentation* allow for an emergence of an *augmented self* that we define as *a modified perception of the self that is based on an augmented representation*.

However, we expect that the augmented self can appear only under specific conditions. First, following the line of research that examines the relationship part-whole in consumer behavior literature (Labroo, Dahr and Schwarz 2008), it should be easier for consumers to appreciate the virtual products when they appear in the context

of a holistic augmented image (where multiple virtual annotations appear in unison) in contrast to seeing a partial augmentation (where only one part of the image is overlaid with virtual augmentation). Both Gestalt theory (Schiffman 2001) and conceptual fluency (Lee and Labroo 2004) underline the importance of the additional cues and context that allow a user to process and relate to a particular part. In the context of AR, a product would be perceived more as a part of the “augmented self” when additional augmentation cues are offered. It would mean that a holistic augmentation, which superimposes elements on the whole image, has a stronger effect on the perception of the self, compared to a tool that superimposes virtual annotations only over a small part of the image. More formally:

Hypothesis 1: Holistic (vs. partial) augmentation of the self significantly impacts the perception of the self.

The second condition for such enhanced self-perception relates to the personalization of the augmentation. The literature on personalization established that creating a product increases the perception of uniqueness, but also allows the consumer to better express her desires compared to standardized, mass-produced products (Franke et al. 2009). We can then expect that, when a consumer can personalize the augmentation, meaning that she can modify the elements superimposed on the mirrored image, she can find a look that better matches the desired image, resulting in a greater perception of augmented self. However, the level of subjective knowledge or expertise is crucial in the process: previous studies have shown that those with higher level of expertise prefer to have more options to customize the look (Randall et al. 2007; Moreau et al. 2011; Javornik et al. 2017). Thus, we might expect that AR would be more impactful in terms of increasing self-perceptions when the users are able to personalise it.

Hypothesis 2: Personalising holistic augmentation (vs. not personalising) leads to a more positive perception of self when the consumers are knowledgeable about the products that constitute the augmentation.

Another important issue is how the real products are perceived in this process. As the virtual enhancement is a visual representation of actual products, we hypothesize that when a positive perception of the enhanced self is established, this perception will relate not only to the mirrored augmented image of the self, but would also transfer to the products, as the augmentation is effectively a result of the virtual products. The augmented self is an outcome of virtual simulation of products and thus the self-perception that results from viewing the (holistic) augmented self would be associated with those products. Peck and Shu (2009) show that mental imagery can generate a sense of ownership over a product even if the product is not available to touch. Moreover, literature on psychological ownership suggests a positive relation between psychological ownership and behavioural intentions (Jussila et al. 2015).

We thus postulate that when an AR mirror displays a simulation of how such products would look on one's face and when such a simulation increases one's self-perception, this would lead to greater psychological ownership of the products, which would further impact the purchase intentions.

Hypothesis 3: Effects of holistic (vs. partial) augmentation on the intentions to purchase the visualized products are mediated by self-perception and then psychological ownership (H3a), especially when the augmentation is personalized (H3b).

METHODOLOGY

We conducted two experimental lab studies with a make-up virtual try-on. The application was created especially for the aim of this research in collaboration with an agency specializing in AR. As make-up is predominantly a female product category, the participants were female only. They were under- and post-graduate students recruited from a British university pool, between 18 and 29 years old and they received a small monetary incentive.

In both experiments, respondents completed a questionnaire, answering questions before and after the task. Their task was to find a lipstick (Study 1) or a full make-up look (Study 2) that they liked best and they thought fitted them the most. After the task, the self-perception, psychological ownership (6 items from Fuchs et al. (2010)) and purchase intention (2 items from Li and Meshkova (2013)) were assessed. Self-esteem was used as a proxy for self-perception, given that self-esteem is conceptualized as one of the main dimensions of the self concept (Sirgy 1982). Self-esteem was measured with 6 items from Heatherton and Polivy (1991) and assessed before (T1) and after (T2) the task in order to verify potential differences between groups prior to the experiment (T1) and its variation after. All the measurement items were on a 7-Likert scale and Cronbach alphas are reported in Table 1.

STUDY 1

Study 1 tested H1 and H3a in a single factor between-subject design (AR: holistic vs. partial) that involved 51 participants, randomly assigned to the conditions.

AR was manipulated by simulating more (vs. less) superimposed objects on the face of the participant. Specifically, in the holistic condition a complete AR make-up look (set in advance with mascara, foundation, eyeshadow, blush and eyeliner) was virtually overlaid on participants' face while choosing the lipstick, which was also virtually overlaid. Participants in the partial condition had their faces overlaid only with virtual lipstick with no other virtual make-up available.

Findings

The participants in the two groups did not have different self-esteem at T1, but a significant difference was found at T2 with participants reporting higher self-esteem for holistic AR. Moreover, in the holistic augmentation the participants experienced greater psychological ownership compared to those who tried only the lipstick, although purchase intentions did not differ. Means, standard deviations and ANOVA indexes are reported in Table 1.

In order to maintain the same condition, the participants in the holistic augmentation group needed to be exposed to the same look. We tried to design the look to be neutral (i.e. avoiding excessive features). Nevertheless, the suitability of a full make-up can still vary depending on the facial features and personal taste (e.g. the foundation could appear more or less fitting depending on the skin tone). We accounted for the different attitudes towards the make-up look superimposed by asking users to rate the make-up look (without the lipstick) on a Likert scale from 1 (do not like at all) to 7 (like very much). As 6% of the participants did not like the look, we excluded them from the analyses, as the dislike could have potentially affect their experience.

Within this subset of participants (N=48), the analyses revealed significantly higher self-esteem (T2), psychological ownership and purchase intention for the holistic condition. Moreover, a bootstrapping mediation analysis with 5,000 resamples (Model 6; Hayes, 2012) showed that self-esteem at T2 and psychological ownership mediated the relationship between AR and intention to purchase.

The results provided preliminary evidence for the effect of AR on the perception of the self. Specifically, they suggest that a holistic augmentation provides a more powerful experience in terms of positive self-perception in comparison to a partial augmentation. The higher self-esteem is associated with psychological ownership, which mediates the effects on the intention to purchase. The mediation showed significant indirect effects, indicating a fully mediated relationship (Hayes 2009; Zhao et al. 2010).

We now further explored if the augmented self differed across various types of holistic augmentation, also because the suitability of the full make-up appeared crucial for the experience.

STUDY 2

A 2 (holistic AR: personalised vs. not-personalised) x 2 (make-up expertise: high vs. low) between-subjects design was conducted involving 97 participants. In all the conditions, AR was holistic, meaning that a complete look was superimposed (i.e. the look included mascara, foundation, eyeshadow, blush and eyeliner), but the holistic AR experience differed between conditions to allow greater (vs. lower) look personalisation. Specifically, in the personalised condition, the participants created their own looks by deciding within a wide range of available virtual lipstick, foundation, eyeshadow, eyeliner, mascara and blush. In the non-personalised condition, the participants could select among 13 pre-designed looks that were set in advances by the researchers. They included make-up from the same categories that were available in the personalised condition. These pre-defined looks were composed in a manner that they offered a variety of colours, strength of effect (subtle vs. strong look) and a combination of products. Make-up artists and brands like Charlotte Tilbury and Rimmel offer virtual try-on of signature looks, thus we deemed the approach reflected a realistic practice. We also measured participants' subjective knowledge in order to take into account how much they perceived themselves to be experts about this product category. It was assessed with 9 items on a 7-point Likert scale (adapted from Flynn and Goldsmith (1999)). The participants were divided into the groups of high and low subjective knowledge by median split (median = 4.44).

Findings

Self-esteem at T1 did not differ across the four conditions, while a significant interaction effect was found at T2: expert participants in the personalised condition reported the highest scores of self-esteem ($F = 5.696, p < .05$). However, we did not find a significant effect of the two factors on psychological ownership and purchase intentions.

We now examined only the experts' responses (N=50). Although we did not find a variation in terms of psychological ownership and purchase intention across the two holistic AR conditions, we found that the relationship between AR and purchase intention is fully mediated by self-esteem (T2) and psychological ownership as in Study 1.

The results of Study 2 thus offer an additional support to the findings of Study 1, confirming the mediating role of self-esteem and psychological ownership between AR and intention to purchase - when the AR user possessed a high expertise (supporting H3b). Moreover, the self-esteem is higher for expert users when they personalised the make-up as opposed to those expert users that didn't (supporting H2).

	Main effect AR F=1.061 p >.05; Main effect expertise F=3.038 p >.05; Interaction F = 1.254 p >.05								

GENERAL DISCUSSION

The two experiments provide evidence that when the AR tool superimposes a holistic, instead of partial, augmentation and consequently creates an impression of a more complete simulation, this strongly affects how consumers perceive themselves (their self-esteem increases) and the product (they experience a stronger psychological ownership of a product). Such a change in the self perception offers a preliminary support for the idea that using AR allows for the emergence of the augmented self. Consequently, a relationship is established also with the products that were visualized as part of such

augmented self. Positive appreciation of such augmented representation is, importantly, indispensable to this phenomenon. In Study 1 the effects were significant only if consumers liked the holistic look.

Furthermore, Study 2 showed that a holistic augmentation was particularly effective for the emergence of the augmented self when it allowed the consumer to personalise the experience. Such personalisation increased self-esteem compared to the holistic AR where the looks were pre-defined. However, the role of expertise in personalisation of AR looks appeared crucial for understanding the effects of augmented self on psychological ownership and purchase inten-

Figure 1: Participants from the two studies:

- 1) trying only the lipstick in partial augmentation condition in Study 1 (extreme left),
- 2) trying the lipstick while generic holistic make-up is also visualized on the face in holistic augmentation condition in Study 1 (middle left);
- 3) choosing between 13 pre-designed looks in Study 2 (middle right);
- 4) customizing a complete look in Study 2 (extreme right)

tions. Study 2 reveals that the augmented self emerges only when customers are already knowledgeable about make-up, but is hindered by low expertise. Customizing a complete AR make-up look might appear too challenging for someone who knows little about this product category. Non-expert customers do not experience the emergence of the augmented self and consequently personalized AR does not increase their intentions to purchase.

CONCLUSION

This study contributes to the understanding of the "self" in virtual try-on with AR, highlighting the relevance of providing a holistic experience for augmented self. This offers useful insights for marketers into consumer experience with AR mirrors. However, extensive further research is required. Would a recommendation system integrated as part of the mirror (or advice by shop assistant) overcome the barrier that a lack of expertise represents? Also, going beyond this product category, what are further characteristics of augmented self in other contexts where augmentation is related to the whole body, a personality trait or a specific skill? Consumer research should follow up the technological developments with a clearer understanding of "augmented self".

Acknowledgements

This research received UCL Knowledge Exchange and Enterprise Funding from EPSRC Impact Acceleration Account (EP/K503745/1) and funding from KITE centre at Newcastle University Business School. The authors would like to thank Prof Anthony Steed and Prof Yvonne Rogers from UCL for their support of the project and Dr Ana Moutinho, Maria Jose Garcia Sopo, Dr Russell Freeman and Jonathan Chippindale from company Holition Ltd for their invaluable help with the design of AR apps.

Not Every Talk Follows A Walk: The Importance of Considering SR Investors Over General Population When Analyzing SRI Behavior.

Fatima Yaqub Khan, Minerva School at KGI, USA
Sadia Yaqub Khan, The College of Saint Rose, USA

ABSTRACT

This study develops and validates segments of SR-investors of building-society based on varying SRI-selection motives. Additionally, it explores if similar segments appear when general-population is segmented on same basis. Findings support heterogeneity among SR-investors and highlight the significance of studying actual SR-investors over general population when exploring SRI.

INTRODUCTION

According to early investment theories, investment has always been linked with making money and yet the concept of socially responsible investment (SRI), investment that offers both financial and social returns, has been on the rise. One main difference between conventional investment and SRI is that in conventional investment the main return is financial return, whereas in SRI financial return is complemented by non-financial (Social, Environmental and Ethical-SEE) returns (Heimann et al., 2013; Brill and Reder 1993; Nilsson, 2009). Though, early investment theories identified SRI as an investment behavior practiced by only a small number of immature investors (Sampson, 2000), the past 10-15 years have witnessed a significant growth in SRI (Adam and Shauki, 2014; Glac, 2009; Heimann et al., 2013; Hofmann et al., 2008; Nilsson, 2009; Renneboog et al., 2008; Social Investment Forum, 2014), highlighting the emergence and progression of a new breed of investors; the socially responsible investors (SR-investor) (Cheah et al., 2011; Hallerbach et al., 2004; Hofmann et al., 2008; Khan and Khan, 2015; Nilsson, 2008; Nilsson, 2009; Rivoli, 1995; Sandberg and Nilsson, 2015).

Though it is widely acknowledged by academics and practitioners that SRI is an investment with dual motives, except for a few studies (e.g. Barreda-Tarrazona et al, 2011; Khan and Khan, 2015; Mackenzie and Lewis, 1999; Nilsson, 2009; Nilsson et al, 2014; Sandberg and Nilsson, 2015) majority of the past research has treated SR investors as a homogeneous group of investors preoccupied with only SEE issues, thereby largely neglecting the financial-motivation aspect of SRI (Cheah et al., 2011; Nilsson, 2009). Interestingly, research indicates that companies performing well on the environmental aspects also show better financial returns in comparison to the ones having comparatively worse environmental records (US-SIF, 2014; Derwall et al., 2005). It is also argued that “the better performing ethical funds attract not just ethical-investors but more general or conventional investors as well” (Michelson et al., 2004, p. 2). This understanding highlights the fact that both financial and non-financial motives are important when exploring SRI (Lewis and Mackenzie, 2000; Nilsson, 2008; Woodward, 2000; Pérez-Gladish et al., 2012). Scholars like Cheah (2011) and Nilsson (2009) argue that the two different aspects of SRI offerings – financial return and/or social return- are expected to motivate each SR investor differently. However, as mentioned above, except for only a few studies (such as Derwall et al., 2011; Barreda-Tarrazona et al, 2011; Khan and Khan, 2015; Mackenzie and Lewis, 1999; Nilsson, 2009; Nilsson et al, 2014; Sandberg and Nilsson, 2015), the literature largely neglected this difference in investors’ motivations, viewing all SR-investors as a homogeneous group. Also, the results of studies analyzing the interplay between SR-investors’ social (SEE) and financial motivations (such as, Barreda-Tarrazona et al, 2011; Mackenzie and Lewis, 1999; Nilsson, 2009; Nilsson et al, 2014), and classifying them in

terms of the balance between these two motives, have mixed findings (Derwall et al., 2011) and it remains unclear as to what degree the SR-investors are ready to give-up financial returns for a social payoff (Sandberg and Nilsson, 2015). Additionally, the studies that have attempted to classify SR investors in terms of the balance each SR investor seeks or accepts between financial return and social return motives (Mackenzie and Lewis, 1999; Lewis and Mackenzie, 2000; Nilsson, 2009; Sandberg and Nilsson, 2015; Dorfleitner and Utz, 2014; Wins and Zwegel, 2015), has mainly explored SR investors of mutual funds and/or used data from general public. Given that the motivational diversity among SR-investors is important to understand SRI fully (Nilsson, 2009), it is reasonable to argue that an examination of SR investors who choose other forms of financial institutions besides mutual funds, could bring more insight into the SRI literature and reduce the ambiguity regarding heterogeneity/homogeneity among SR investors. Additionally, given that the past research has used general public when exploring SRI, it is important to understand if the general public can present SR investors.

To address the first knowledge gap, it is necessary to empirically explore if SR investors (other than the ones choosing mutual funds) are a homogeneous group or if they can be classified into diverse groups based on the differing level of significance these investors place on social-return and financial-return aspects of SRI. Therefore, the first research goal of this study is to empirically explore heterogeneity/homogeneity among SR-investors of a building society. Building societies are financial institutions that are “partly or wholly exempt from bank license requirements, and therefore regulated under separate rules.” (Satyanarayana, et al., 2015. Pp. 337), thus making them unique, yet important in the UK financial market. Therefore, an understanding of homogeneity/heterogeneity among SR-investors of building societies, in terms of the balance they pursue between financial and non-financial motives, could help to better understand SR-investors, and help to resolve some of the uncertainty created by the mixed findings provided by similar studies in the past.

The following question is then addressed so as to fill the second gap: can general population be used when studying SRI? Most of the past research has used general population when exploring SRI (for example see Adam and Shauki, 2014; Nilsson, 2008, Nilsson, 2009, Pérez-Gladish et al., 2012). Although SRI has gained much acceptance, it is still seen as niche (Nilsson, 2009). Therefore, it is reasonable to argue that using the general population who would self-report as to whether one is involved in SRI or not, carries a high risk of a social desirability bias (SDB). Consequently, the second research goal of this paper addresses this issue by exploring if the general population when classified, in terms of the financial and the social return aspects of SRI (if they were to choose SRI), result in similar groups as those of SR-investors of building society. This is done to see if similar segmentation, as that of SR investors of building society, is generated when using data from general public or not, so as to understand if the general public is a good representative of SR investors or not.

METHODS

The findings within this paper are part of a larger project concerning an in depth analysis of SR investors. To fully understand SR investors, and to address the two research gaps presented earlier

in this manuscript, two data sets were collected; one from Ecology Building Society (EBS) (n=298) investors (SR investors), and other from general Cardiff population (N=100). Data was collected regarding attitudes, values and beliefs, along with the significance of financial return and social return when opting for SRI. Items measuring these variables were used from past research. For the first dataset (SR-investors of EBS) multistage sampling was adopted. Multi-stage sampling is a probability sampling technique where one uses a combination of different sampling technique so as to identify the technique that suits the study the best. At this stage, both stratified sampling and simple random sampling technique was combined. First EBS customers were divided into two groups (strata): the active member group and the non-active member group. The active member group comprised of individuals who were active online [EBS had their active emails and these customers were also participating in EBS activities virtually]. The second stratum was that of non-active members [these members were not active virtually/online]. Given that the questionnaire used in this study was online, SR investor sample, through simple random sampling, was generated only from one stratum: the active member group. The survey link was sent out to the entire online database of Ecological Building Society (n=1250). The survey link was kept active for 8 week during which a total of 298 investors completed the survey, giving a response rate of 24%. For the second dataset non-probability convenience sampling technique was used. The data was collected via paper based questionnaires, using self-administer method, from the general public. The questionnaire included questions regarding importance of financial return and importance of social return. However as the data was gathered from the general population, it was assumed, based on past research (Nilsson,

2009; Nilsson et al., 2014), that not everyone would be a SR investor, hence the questions were reworded slightly to say “if you invest in an SR organization...” rather than having a more affirmative statement about SR investment (Nilsson 2009, Sandberg and Nilsson, 2015). A total of 100 questionnaires were filled over a period of 4 weeks.

To assess the heterogeneity/homogeneity among the investors, two-step cluster analyses were performed on each set of data separately with significance of financial return and social return as being the clustering variable. All the segments that emerged through the two-step cluster analysis, from both the data sets, were further analyzed using analysis of variance.

RESULTS

The two-step cluster analysis, using Bayesian Information Criterion (BIC) and log-likelihood distances, revealed heterogeneity among SR investors as well as indicating the fact that the general population is not a good representative of SR investors.

Uncovering the Investor Clusters

Figure 1 Displays the results of two-step cluster analysis for the two datasets.

First Dataset (SR-Investors)

For the first dataset a three cluster solution was obtained through the two-step cluster method. The results were validated by split sampling technique as recommended by Hair et al., (2008) and Malhotra et al., (2012).

The three clusters of SR investors identified are:

1. *Financial Return Driven Investors [FR Driven] (smallest cluster)*

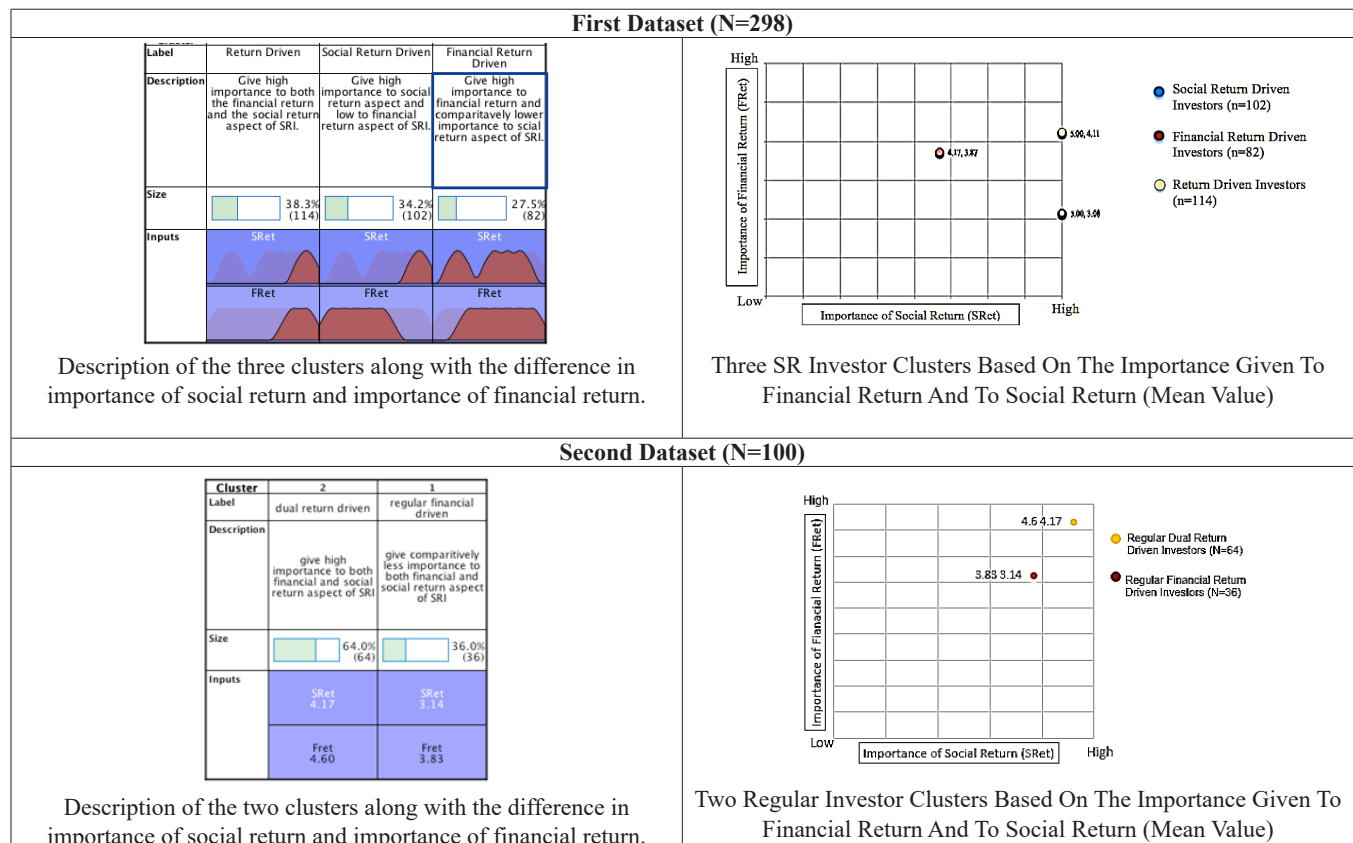

Figure 1: Results of Two-Step Cluster Analysis

Representing 28% of the sample (n = 82), this cluster scored lowest on importance of social return (mean = 4.03, SD = .505) and gave relatively high importance to the financial return (mean= 3.77, SD = .528).

2. *Social Return Driven Investors [SR Driven] (second largest cluster)*

Representing 34% of sample (N = 102), this cluster gave least importance to financial return (mean = 2.88, SD = .523) and the most to social return (mean = 4.97, SD = .127) when investing. Thus, justifying the name Social Return Driven (SR Driven) Investors.

3. *Dual Return Driven Investors [DR driven] (largest cluster)*

The third cluster comprised of 38% of the first dataset (N = 114). This cluster gave high importance to both social return (mean = 4.99, SD = .066) and financial return (mean = 4.09, SD = .260) when investing in SRI.

Second Dataset (Regular Investors)

For the second dataset, a two cluster solution was obtained through the two-step cluster method. The results were validated by split sampling technique as recommended by Hair et al., (2008) and Malhotra et al., (2012).

These two clusters are:

1. *Regular Financial Return Driven Investors [Regular FR Driven] (smallest cluster)*

This cluster comprised of 36% of sample (N = 36). Investors in this cluster gave more importance to financial return (mean = 3.83, SD = .359) as compared to social return (mean = 3.14, SD = .529) when investing.

2. *Regular Dual Return Driven Investors [Regular DR Driven] (largest cluster)*

The second cluster that appeared represented 64% (N=64) of the regular investor. If this cluster was to invest in SRI, they would value both social return (mean = 4.17, SD = .473) and financial return (mean = 4.60, SD = .41) aspect of SRI, similar to dual return driven cluster of SR-investors.

Variation among the Five Clusters

The fact that two instead of three clusters appeared when regular investors were classified with respect to the importance they place on financial return and social return aspects of SRI, if they were to invest in SRI, highlights the difference between SR investors and regular investors. To further examine the differences between and among these five clusters (SR driven investors, FR driven investors and DR driven investors, regular FR driven investors and regular DR driven investors) one-way ANOVA was performed. Results indicate that the five clusters differ significantly with respect to both the financial return [F (4,393) = 183.664, p = 0.000] and the social return [F (4,393) = 297.059, p = 0.000] aspects of SRI. Table 1 presents the pairwise difference among the clusters obtained through Tukey's HSD.

Variation among the Clusters in Terms of the Importance of Financial Return

From table 1 it can be seen that among the SR investor groups, the FR driven cluster (mean=3.77, SE=.528) gave more importance to the financial return aspect of SRI as compared to the SR driven cluster (mean= 2.88, SD=.523). Whereas the DR driven cluster (mean= 4.09, SD=.260) valued the financial return aspect of SRI more than both the SR driven and the FR driven clusters. Furthermore, among the SR investor and regular investor clusters, the DR

Table 1: Multiple Comparison for Clustering Variables

Clusters	Mean	Standard Error	Sig.
Importance of Financial Return			
Financial Return Driven > Social Return Driven	.886**	.066	.000

Regular Dual return Driven > Regular FR-Driven	1.033**	.072	.000

**Significant at the 0.001 level

*significant at the 0.05 level

driven cluster valued financial return aspect of SRI more than the regular FR driven cluster (mean=3.83, SD=.359). Also, the regular FR driven cluster valued financial return aspect more than the SR driven cluster. Whereas for the regular DR driven cluster (mean= 4.60, SD=.410) the financial return aspect of SRI was more important than it was for any of the three of the SR investors clusters: FR driven, SR driven and DR driven investors.

Differences among the Clusters in Terms of the Importance of Social Return

As displayed in table 1, among the SR investor clusters, both the SR driven (mean= 4.97, SD=.127) and the DR driven clusters (mean=4.99, SD=.066) valued the social return aspect of SRI more than the investors making up the FR driven cluster (mean=4.03, SD=.505). Additionally, both the SR driven cluster and the DR driven cluster valued the social return aspect of SRI more than both the regular FR driven cluster (mean=4.17, SD=.473) and the regular DR driven cluster (mean=4.17, SD=.473). Whereas, for the FR driven

cluster, social return aspect of SRI was more important as compared to how important it was for the regular FR driven cluster. This difference is important, as although the financial driven cluster of regular investors looked similar to FR driven cluster of SR investors, these two are significantly different from each other. Lastly, the regular DR driven investor cluster valued the social return aspect of SRI more than the regular FR driven cluster.

FINDINGS

There are two main findings of this study. Firstly, within the SR investors three unique clusters emerged, thus echoing heterogeneity among SR investors. Though the results from past research, majority of which explored investors of mutual funds, had mixed findings, this study, while exploring SR-investors of building society, supports the understanding that individuals who chose SRI are not all the same, rather SR investors could be classified into three unique segments each acquiring different combination of financial return and social return aspects of SRI. Thereby supporting and validating past research (e.g. Nilsson, 2009; Sandberg and Nilsson, 2015).

Secondly, the fact that similar groups, as that of SR investors, did not appear when regular investors were segmented, based on the same clustering variable used for clustering SR investors, indicates the uniqueness of studying SR investors. Though the two clusters of regular investors (regular DR driven and regular FR driven investors) seemed similar to two clusters of SR investors (DR driven and FR driven investors), results of ANOVA revealed significant differences among these clusters. Results from one-way ANOVA also show substantial difference between the three SR investor clusters and two regular investor clusters, with respect to importance given to the financial return and the social return aspects of SRI. This understanding of the difference between clusters of SR investors and the clusters of regular investors highlights the importance of studying SR investors as a unique class of investors. One reason for this difference could be due to the fact that general population still place financial return at the heart of investment and that SRI being a niche cannot be represented by studying the general public (Nilsson, 2009). Additionally, the fact that regular DR driven cluster valued the financial return aspect of SRI more than any of the three SR investors clusters, indicates that though the regular investors claim to value social return aspect of SRI if they are to become SR investors, yet they value the financial return aspect of their investment the most. These findings reflect the effect of SDB as the individuals in this segment state that they value social return aspect of SRI, yet the high significance of financial return aspect speaks otherwise. These regular Dual Return driven investors value financial return even more than the regular FR driven investors, thus echoing the high significance of financial gain these individuals desire from their investment.

In a nutshell, this study not only indicates heterogeneity among SR investors, but also highlights the significance of studying actual SR investors rather than the general public. Thus, augmenting the uniqueness of the first dataset used in this study (SR-investors of EBS) and strengthens the argument that SR investors are different from regular investors.

CONCLUSIONS

This paper focuses on understanding and exploring SRI. We contribute towards a more comprehensive understanding of SRI by producing and validating three unique clusters of SR investors of a building society. Thereby, not only giving clarity to past SRI research, which has mainly explored mutual fund investors, but also by exploring SR investors of a yet to be explored investment platform:

that of a building society. SR investment firms can utilize these findings to develop customized strategies focused on catering to segment specific needs so as to achieve higher customer loyalty and satisfaction. Additionally, policy-makers pursuing sustainability can benefit from these findings by determining which motivations to promote in order to sway people towards sustainable investment. We further contribute by exploring SRI behavior of the general population and highlighting the significance of studying actual SR investors over the general public. It is important to highlight that for majority investors financial return is important part of their investment decision, thus SR investment firms should promote their financial position along with social position so as to attract more investors.

Though, this paper brings more understanding of investment behavior, the following limitations must be kept in mind: firstly, the analysis uses only one building society and in that only investors who were active online. Further research should seek to broaden the approach by involving both active online and inactive online investors and possibly from more than one building society. Second, the study only uses qualitative approach. Future research could also interview SR investors in order to understand them fully. Despite these limitations this study with its novel findings is a step towards fully understanding the interesting phenomenon of SRI. Future research can explore these SR segments by exploring, for example, difference in value orientations for each segment.

Why Don't Parents Walk Their Talk?

Exploring Parental Deviant Food Socialization Behaviors within the Family

Tanyatip Kharuhayothin, University of Manchester, UK

Ben Kerrane, Lancaster University, UK

ABSTRACT

This study, drawing on neutralization theory, explores how parents neutralize their feelings of guilt when performing deviant food socialization practices (e.g. offering unhealthy food to their children). The findings highlight how neutralization techniques help lessen parents' self-blame through performing negative displays of parenthood.

INTRODUCTION

Why do parents socialize their children in ways that they know they shouldn't be doing? Parents sometimes find it difficult to behave in accordance with the ideals of *good parenting*, particularly in the context of food socialization. Parents are considered to be the most powerful socialization agents for children (Dotson and Hyatt 2005; Hunter-Jones 2014; Moschis and Churchill 1978) with parents playing a pervasive role in shaping children's consumption patterns (Kerrane, Bettany, and Hogg 2014), especially food consumption habits (Nicklas et al. 2001). Given the global concern surrounding childhood obesity¹ (WHO 2017) and recent calls for research to explore the role parents play in forming healthy family food socialization practices (Grier and Moore 2012), it is timely to explore parental food socialization behaviors that may, eventually, contribute to obesity amongst children (Ayadi and Bree 2010).

In this paper, we explore the *deviant* food socialization behaviors of a sample of parents, as food preparers, in the United Kingdom from October 2015 to June 2016, using multiple stages of qualitative data collection - existential phenomenological interviews, photo-elicitation exercises, and accompanied grocery shopping trips. We draw on the theoretical tenants of neutralization theory and the techniques of neutralization to gain a better understanding of *how parents 'neutralize' their deviant food behaviors*, and show *how such deviant food behaviors can work to develop food habits*.

The findings, thus, extend our understanding of the attitude-behavior gap through exploring the performance of deviant behaviours of parents within the context of food socialization/consumption, as called for in previous studies (Grier and Moore 2012; Hoy and Childers 2012; Moschis and Cox 1989) and the implications of such parental deviance (offering unhealthy food to their children) are discussed, with parents violating the norms of 'good' parenting. This is one of the first studies to apply neutralization theory to family food consumption. Our potential contribution responds to the call for extending the use of neutralization theory to other deviant consumption behaviors, rather than ethical consumption alone (Chatzidakis, Hibbert, and Smith 2007; Harris and Daunt 2011; Strutton, Vitell, and Pelton 1994).

Attitude-behavior gap, deviant consumer behavior, and neutralization literature

The 'attitude-behavior' gap has been extensively studied in consumer behavior, particularly in relation to ethical consumption (Carrigan and Attalla 2001; Elliot and Jankel-Elliot 2003; Harrison et al. 2005). It is proposed that the attitudes of individuals are determined by personal values, moral norms, and internal ethics (Carrington, Neville, and Whitwell 2010; Shaw and Shui 2002). Thus,

the attitude-behavior gap may occur in behavior that deviates from social norms. It is noted that such gaps remain poorly understood and are under-researched, especially in the field of consumption (Belk et al. 2005; Connolly and Shaw 2006; Carrington et al. 2010).

The majority of studies in the consumption literature often link the attitude-behavior gap with organic or fair-trade products (Brunner 2014; Hempel and Hamm 2016) their food purchase behaviour and their personal characteristics. The purpose is to investigate the differences in attitudes and willingness-to-pay values between consumers who consider the organic production of food (very or those associated with environmental concern (Atkinson and Kim 2014). Prior studies exploring the attitude-behavior gap among parents have shown the existence of attitude-behavior inconsistencies among parents in providing food to their children (Hughner and Maher 2006; Gram 2014). However, what is yet known is how parents alleviate their feelings of guilt associated with such discrepancies or 'paradoxical' behavior (Hoy and Childers 2012, 569).

Behavior is considered to be 'deviant' when it deviates or does not adhere to social norms (Moschis and Cox 1989). Although socially acceptable behaviors are considered norms, such behaviors may not be formally administered by law within society (Dootson et al. 2016). Thus, consumers often see deviant consumer behavior as logical from their own perspectives (Harris and Daunt 2011). Studies in consumer behavior suggest that much less is known about the rationalizations associated with performing deviant acts of consumption, despite the fact that such behavior is thought to be common (Fullerton and Punj 1993, 2004; Harris and Daunt 2011).

Neutralization theory is commonly used in the sociology of deviance (Maruna and Copes 2005; Minor 1981) with Sykes and Matza (1957) outlining a range of neutralization techniques in their seminal study of juvenile delinquency. Five neutralization techniques are identified; (1) denial of responsibility, (2) denial of injury, (3) denial of victim, (4) condemning the condemners and (5) appeal to higher loyalties (see Sykes and Matza (1957) for a comprehensive review of each technique).

Existing consumer studies have applied neutralization theory contexts including *shoplifting* (Strutton et al. 1994), *consumer fraud* (Rosenbaum and Kuntze 2003), *ethical consumption* (Chatzidakis et al. 2007; Strutton et al. 1997), *alcohol and cigarette consumption*, and *cannabis use* (Peretti-Watel et al. 2003; Piacentini, Chatzidakis, and Banister 2012). However, neutralization theory has not been adequately studied, remains under-theorised, and has received limited attention in consumer behavior research (Brunner 2014; Chatzidakis et al. 2007; Piacentini et al. 2012; Strutton et al. 1994). It is also noted that the studies of wider forms of deviant consumer behaviors are lacking and the understanding of consumers for justifying their norm-contradicting behaviors should be extended to a range of consumer activities (Chatzidakis et al. 2007; Harris and Daunt 2011). Moschis and Cox (1989) highlight that *adopting a socialization approach in the study of deviant consumer behavior is imminently sensible* given that the acquisition of deviant behaviors (such as unhealthy eating practices) could be as a direct result of the consumer socialization process.

¹ The WHO acknowledges childhood obesity as today's greatest health concern with over 42 million children worldwide under the age of five classified as obese (WHO 2017).

METHOD

Thirty parents, who self-identified as the primary food preparer in their family, participated in this study. Informants were recruited through social media, nurseries and primary schools (places where children were present). Parents of younger children were recruited because they exert the greatest influence on children when they were born up until adolescence (Moore and Moschis 1980). Multiple stages of data collection occurred, drawing on a photo-elicitation task, an existential-phenomenological interview, and an accompanied grocery-shopping trip. First, participants were asked to take photos of the food inside their kitchen cabinets, refrigerator, and the meals they prepared for their children during a one-week period. Such an approach to data collection has been employed within studies of consumption (Fournier 1998; Harman and Cappellini 2014, 2015). Next, participants were asked to talk about the photos they took at the beginning of an in-depth interview². The descriptive information from the photos was used to identify any attitude-behavior gaps among the parents (Elliott and Jankel-Elliott 2003). Each interview lasted between one and two hours, with the interview exploring topics such as how the food preparers make sure that their children eat healthy food and in what situations (if any) they allowed their children treats, capturing the justifications behind such actions. The interviews were conducted at the home of each participant, or at a convenient location of their choice. Participants then took part in an accompanied grocery-shopping trip or an observational interview (Belk et al. 2012), which lasted between thirty minutes to one hour. Multiple methods of qualitative data collection were utilized to shed greater light on how consumers perform deviant acts and, in turn, to understand how they rationalize such actions (Gruber and Schlegelmilch 2014). The interviews were audio recorded, and procedures taken to ensure the ethical credibility of the research project. Transcripts were transcribed verbatim, coded, and analyzed using Interpretative Phenomenological Analysis (IPA).

FINDINGS

The findings offer an in-depth understanding of 'deviant' behavior practiced by parents and show how techniques of neutralization can be successfully applied to food socialization practices within the family, as called for by earlier research (Chatzidakis et al. 2007; Harris and Daunt 2011). Five neutralization techniques were found within our data, although, as reported by others (Brunner 2014; Chatzidakis et al. 2007; Piacentini et al. 2012), certain techniques were more prominent. We find that 'denial of responsibility' and 'denial of injury' have been employed the most, while 'denial of victim' has been employed the least. Thus, the elicited family stories associated with four dominant neutralization techniques (denial of responsibility, denial of injury, condemning the condemners, and appeal to higher loyalty) will be discussed in turn. Illustrative quotes from the participants are offered in table 1.

Parents Feel They Have Limited Control Over Their Deviant Food Consumption Practices

Parents *denied their responsibility* because they felt that there were many forces beyond their control in terms of their children's food intake, resulting in their children consuming unhealthy food (Sykes and Matza 1957) ("*It's not my fault, I had no other choice*"). Most parents mentioned that when their children attends a friend's party or house, or even when they are at school, children would be given sweets and other 'unhealthy' food products. These are situa-

tions in which parents feel that they "can't avoid" unhealthy food practices/consumption, and where they "don't know what is given and have no control over it".

Many participants identified themselves as being time-poor parents. Time-pressure is another constraint contemporary parents face in raising their family (Copelton 2007), especially given the rise in dual-income families. Participants often employed this technique when providing ready meals for their children. As such, they often denied that there was anything wrong in giving ready meals to their children, justifying such practices on the basis of being time poor.

Parents feel that giving children some 'treats' does not do any real harm

With *denial of injury* parents did not deny their deviant behaviors (i.e. they recognised that they did offer unhealthy food to children *at times*), but they felt that their behavior did not really cause any great harm to their children (Sykes and Matza 1957) ("*what's the big deal?*"). Parents reported that their children would get some treats for special occasions, such as birthdays or on designated treat days. Although acknowledging their actions, the participants felt that this was in no way harmful because they were only engaging in such deviant behaviors *occasionally* (i.e. on designated treat days alone). Participants mentioned that their children would have their treat days every week, most often at the weekend.

Kate, for example, mentioned that 'finger food' at birthday parties was not healthy. But, she is fine with her children eating such food (as (a) this is not a frequent occurrence; and (b) such food consumption occasionally falls outside her control, noting the relationship with the earlier neutralization technique). This signifies that she tends to identify herself as a 'good' parent through providing more healthy food than unhealthy foods for her daughter. Such a notion is considered a way to display good parenting as parents are judged by the way that they follow social norms in providing healthy food for the family (Harman and Cappellini, 2014).

Other Parents and Other Children are Performing the Same Deviant Food Behaviors

For *condemning the condemners* ("*everyone else does it*"), parents attempt to shift attention away from their deviant acts towards the acts of those who condemn their deviant behaviors (e.g. other parents or other children) (Sykes and Matza 1957). Individuals rationalize their actions by asserting that others are doing worse and yet they are not caught (De Bock and Van Kenhove 2011). Parents mentioned that other parents would allow children to have sweets on special occasions. For example, Isabella remarked that giving children treats is what "other parents always do". In addition, Joy's opinion (see table 1) provides a good example of how parents condemn other parents (i.e. those other parents have done worse). Moreover, parents also highlight that other children are eating food, which is considerably worse (healthy eating wise) than they provide.

Children follow their Friends and Parents Allow them To

With *appeal to higher loyalty* parents neutralize their deviant behaviors by signaling that what they did was for the good of their family, prioritizing their bond to the subculture or inner social group rather than to society as a whole (Chatzidakis et al. 2007; Sykes and Matza 1957). Parents consider consuming finger food, sweets, and sugary drinks at parties or at social gatherings as normal and socially expected among other parents and other children within their personal networks.

Parents commented that it would be difficult to tell their children what to eat at such gatherings because their children see other children eating such unhealthy foods. Here, parents justify such un-

² The photographs from the photo diaries were used to helping stimulate discussion during the in-depth interviews, as utilised by others (Elliott and Jankel-Elliott 2003; Harman and Cappellini 2014, 2015).

Table 1: Neutralization techniques in the context of parental deviant food socialization behavior

Technique of neutralization	Illustrative quote(s)
<p>1. Denial of Responsibility: <i>Parents feel they have limited control over deviant food consumption practices</i></p>	<p>IAN: You know there are always <i>little slips and things</i> where they get treats and they have chocolate biscuits or they go to their friend’s house and then they <i>eat rubbish</i> when they are round at their friend’s house. <i>You can’t stop all of it from happening.</i></p> <p>JANE: <i>That’s the worst thing ever. It’s very difficult to stop your children having sweets.</i> Yesterday my son went to a party, so he was given sweets. That’s really difficult. How can I say you can’t have that? So my daughter also got sweets from another party. So if somebody has a birthday at school often they [sweets] get given out when they come out of school.</p> <p>NATASHA: I use those <i>pre-cooked food once or twice a week</i>. Because it’s convenient. So, at the moment I’m especially busy because my daughter is about to go to secondary school. So, as well as after school’s activities, we are looking at senior schools. So, <i>we have no time in the evening. So, when I’m time pressured, it helps.</i></p>
<p>2. Denial of Injury: <i>Parents feel that giving children some ‘treats’ does not do any real harm</i></p>	<p>JANE: Yesterday was my son’s sweet day, so we go to the shops after school. He gets 70p and he can go and select some sweets and he knows that is once a week treat. And then occasionally he gets pocket money at the weekend. He might go and buy a chocolate bar or something like that. So <i>it’s fine occasionally.</i></p> <p>REBECCA: When the <i>Advent Calendar last Christmas</i>, they get lots of biscuits and chocolate and things at all these Christmas events and he’s kind of, every day, “Where’s chocolate?” And you would be like no not now. And then he’d throw a tantrum. So <i>special occasions</i>, so like there was <i>Halloween</i> the other day and he had some chocolate because he went Trick or Treating with his cousins and <i>that’s fine</i>. But just <i>save it for a party.</i></p> <p>WENDY: When we are out, I just <i>turn blind and let her enjoy her life and have whatever she wants</i>. When we are out, she sometimes drinks coke or lemonade or eats cakes. Of course, she doesn’t have cake all the time. So, <i>occasionally I’d say that’s okay.</i></p>
<p>3. Condemning the Condemners: <i>Other parents and other children are performing the same deviant food behaviors</i></p>	<p>JOY: How I do it is quite highly rationed. But <i>my sister-in-law, she is worse than me</i>. She lets them have sweets twice a week. And for Halloween this year, she got this tiny little glow sticks that you can buy online. It’s very tiny like cocktail sticks. So, apparently, it’s really popular. She’s also gotten Haribo for them. <i>You see when everybody does it.</i></p> <p>IZABELLA: For the birthday parties, all parents are thinking that they should prepare something very sophisticated. Often than not, the treats would be cakes and they are full of sugar on the top of them. <i>Everybody is doing this.</i></p> <p>KATE: We try to encourage her. <i>She probably could eat more fruits and veg than she does I think all the kids could ((Laughs)).</i> So, she seems to understand and <i>she’s not too bad eater neither comparing to some kids.</i></p>
<p>4. Appeal to Higher Loyalty: <i>Children follows their friends and parents allow them to</i></p>	<p>NATASHA: Going somewhere like McDonald’s is not unheard of. And he’s a small child and his friends do. So, it adds a social element to it. <i>He shouldn’t feel that he couldn’t go there.</i> I would go there because <i>he should be able to experience it and chat with his friends about it, like it’s a normal thing to do.</i></p> <p>FRAN: I don’t want to be a Victorian parent but I also don’t – if I go a bit kind of, you must have this, that and the other. <i>Sometimes their friends come and oh, I’m not allowed this and that. I don’t want them to have that sort of feeling associated with food.</i></p> <p>SANDRA: It’s ok because sometimes <i>they will see other kids eat something else that they might want to try.</i> We used to live close to McDonald and they saw other kids went. So, they asked ‘Can we go to McDonald?’</p>

healthy food consumption as they want their children to ‘fit in’, and not to be ostracized by their peers should they be denied unhealthy foods. Parents also commented that the reason their children want to go to McDonald’s is because they have seen other children going, and the parents did not want their children to feel like ‘the odd one out’ in denying them such visits.

DISCUSSION

Stories of ‘deviant’ parental food socialization practices demonstrate a clear gap between parents’ attitudes of *performing good parenting* (adhering to the social norm of providing healthy food to their children) and the actual performance of ‘deviant’ parental acts. Parents tend to identify themselves as ‘good parents’ by adhering to norms of society in providing healthy food to their children, with parents feeling ‘on display’ through the food they provide to their children (Harman and Cappellini 2014, 2015). However, because of a range of factors (e.g. limited income, perceptions of being time ‘poor’) parents engage in ‘deviant’ food socialization behaviors in providing less than healthy food to their children, and draw on neutralization techniques to justify doing so to protect their negative self-image (Chatzidakis et al. 2007; Copelton 2007). The findings, yet, suggest that parents sometimes perform deviant acts as they are in the best interests of their children (i.e. I allow unhealthy food because my children likes that food; my children will be socially excluded by their friends if I do not allow them to eat such food). Techniques of neutralization provide insight into how parents neutralize

their feelings of guilt when undertaking ‘deviant’ food socialization practices *without changing their intended attitude.*

Although this study used a relatively homogenous sample, it contributes to our understanding of parental deviant food behaviors and shows that the theory of neutralization can be applied to various perspectives of deviant consumer behavior as previously calls for research encourage (Chatzidakis et al. 2007; Harris and Daunt 2011). To the best of our knowledge, this is the first study that explores parental deviant acts in the context of food-socialization. It extends our knowledge of parental attitude-behavior gaps, as also called for by existing research (Grier and Moore 2012; Hoy and Childers 2012).

This paper offers opportunities for policymakers to counter the possibility of repeated parental deviant food behaviors (i.e. having *treat* days every week), such as encouraging parents to provide fruits to children as *normal* weekly treat. Also, marketers could use such knowledge to implement strategies to tackle childhood obesity or to promote products/services that could prevent parents from situations where deviant food behavior is likely to occur.

Guilt and Loathing in the Kitchen. Why Sustainable Consumers Waste Food

Karolina Kraus, Bauhaus-University of Weimar, Germany

Julie Emontspool, University of Southern Denmark, Denmark

INTRODUCTION

Sustainable consumption has developed into a rich yet complex research theme. Existing research has debated over the gap existing between consumers' attitude towards sustainability and their behavior (Eckhardt, Belk, and Devinney 2010), over the relative importance of individual or communal actions (Papaoikonomou and Alarcón 2015, Gollnhofer 2017), as well as concerning the plural articulations of sustainable consumption (Pecoraro and Uusitalo 2014).

Yet our understanding of sustainable consumption remains incomplete when it comes to consumers' critical evaluation of sustainability and the realism of its applicability, specifically when it comes to the lowering or avoidance of food waste. Such knowledge is important from an academic angle to better understand consumers' reluctance to lower food waste when it is a central feature of sustainability (Connolly and Prothero 2003). From a public policy angle, understanding why consumers who support sustainability in other domains of their life fail to lower food waste allows to develop communication strategies addressing this specific side of consumer behavior.

This paper therefore asks how and why consumers justify failure to lower their food waste, with a special focus on their critical reflections relative to the role of the individual in addressing sustainability issues. To investigate this question, we focus on consumers' practice of buying and cooking, with special attention given to their practices of food waste disposal (also called disposition), one of the key elements of the "squander sequence", food waste occurring during the consumer decision-making process (Block et al 2016). Such a perspective involves paying close attention to consumers' practices, "a routinized type of behavior" (Reckwitz 2002) that provide insights into the way in which consumers approach issues of food waste in their everyday consumption behavior. A qualitative research design combining observations, diaries and in-depth interviews allows for recording such practices as well as understanding consumers' rationales.

The findings of this study, which identify three types of consumer responses (apathetic, overwhelmed and pragmatist), advance current knowledge relative to the gap existing between consumers' attitude towards sustainability and their behavior (Eckhardt et al. 2010). They further provide indications as to the ways in which consumers' apathy, their feeling of being overwhelmed and pragmatism can be countered by promoting hope for individual agency in sustainability measures.

LITERATURE REVIEW

Consumers' ability to express moral preferences through consumption has been widely studied (Hilton 2004; Hilton and Daunton 2001). Yet while consumers view the adoption of sustainable consumption practices as desirable, many fail to do so in practice (Eckhardt et al. 2010; White, MacDonnell, and Ellard 2012). Among the factors explaining this gap between attitudes and behaviors are consumers' economical rationalization about the excessive cost of ethical consumption, a focus on the institutional dependency of sustainability that limits individual actions, and developmental realism, which claims that unethical practices are unavoidable in successful economies (Eckhardt et al. 2010). Furthermore, individual desire for ethical consumption is hindered by doubts and insecurities (Connolly and Prothero 2008) as well as a licensing effect where consumers allow for non-ethical behavior if they behave ethically in other domains of their life (Khan and Dhar 2006). Furthermore, if consumers

believe in the existence of a fair world order, they are more enthusiastic to consume ethically than when they are disillusioned about the fairness of the world (Luchs et al. 2010; White et al. 2012).

The role of social groups and communities has been promoted, advertising connectedness as solution to difficulties in adopting ethical consumption behaviors (Casey, Lichrou, and O'Malley 2016; Papaoikonomou and Alarcón 2015; Rokka and Moisander 2009). Attempts at encouraging ethical consumption behavior further focus on considering ethical consumption as a tool for positive image-building (Connolly and Prothero 2003; Naderi and Strutton 2013). Communication focused on self-accountability is for instance promoted over the generation of feelings of guilt (Pelozo, White, and Jingzhi 2013). Yet aside from individual factors, existing research increasingly addresses the role of macro-economic and -social structures in shaping consumption behavior (Dolan 2002). Individual agency increasingly becomes seen as a myth aimed at discharging public and private organizations of their responsibilities (Carrington, Zwick, and Neville 2015; Giesler and Veresiu 2014; Holt 2012). While this critical perspective gains traction in marketing research, consumers' viewpoints on this seemingly misguided focus on the individual has not been investigated. Specifically when it comes to the increasing plurality of ethical consumption behaviors, how consumers manage these different trends becomes challenging. Existing studies demonstrate that consumers combine different ethical consumption practices (Pecoraro and Uusitalo 2014), where some behaviors, such as buying local products are preferred to reducing meat consumption (Niva et al. 2014). Further understanding is needed about consumers' criticality towards and potential dismissal of specific ethical consumption practices despite their beliefs in the need for ethical consumption.

The case of product disposal is particularly understudied despite the centrality of recycling and waste problems in sustainability (Connolly and Prothero 2003; Guillard and Roux 2014). Existing research has shown that while reduction and reuse link to individual-level environmental values and knowledge, recycling is more closely linked to adherence to societal norms (Barr 2007). Further, different logistics co-exist for recycling household waste, which means that sustainability is not solely a question of motivation, but also of logistics (Monnot, Reniou, and Rouquet 2014). We study these logistics specifically when it comes to the case of food waste. Awareness about issues of food waste has been shown to lower wasteful behavior (Principato, Secondi, and Pratesi 2015; Whitehair, Shanklin, and Brannon 2013), yet the role of criticality towards individual action and responsibility requires additional research, which the following sections detail.

METHODOLOGY

This paper relies on qualitative interpretive data, emerging from the combination of three data collection methods: in-depth interviews, observations and diaries. Firstly, food disposal diaries were kept for one month by the respondents to record their habits in discarding food (Hackley 2003; Smith-Sullivan 2008). In order to facilitate data collection, the respondents were encouraged to take pictures of the discarded food using their mobile phones. They then sent the pictures, along with information relative to the reason for discarding the product to the first author, who registered the data. Secondly, the first author collected observational data during joint shopping and cooking with the respondents. These observations took place in the respondents' usual shops and their kitchens, in order to remain as

close as possible to their habitual context (Marvasti 2014). Thirdly, the insights from the diaries and the observations were discussed during in-depth interviews, to understand consumers' discourses about food waste. Semi-structured interview guides with open-ended questions served as basis for interviewing (Ayres 2008).

In order to favor depth of insights over population representativeness, we chose to concentrate in depth on a small sample of respondents (Carfagna et al. 2014; de Ruyter and Scholl 1998). 10 consumers participated in the study, aged 20-29 years, which is appropriate as young consumers represent the highest shares of food wasters (Principato et al. 2015; Rosenbauer 2011). Purposive sampling allowed to reach an equilibrated distribution in terms of gender and age within the segment (Hackley 2003). All respondents possessed high educational level, which reflects the usual customer type aware of and sensitive to sustainability issues (Olli, Grendstad, and Wollebaek 2001). Data collection took place in Germany, a country

where sustainable food consumption has been actively promoted and supported (Thøgersen 2010). All respondents were therefore knowledgeable about sustainable consumption and had the possibility of adopting it. The interviews were fully recorded and transcribed. Hermeneutical comparison between data and literature allowed for data interpretation (Thompson 1997), which involved both individual and comparative analysis of the respondents' statement (Maxwell and Chmiel 2014).

FINDINGS

Data analysis generated three types of responses to food waste and its avoidance. These responses differ on the basis of the level of relative activity, the former (apathetic) response reflecting a lower self-drive than the two following responses. In the following, we highlight specific expressions and words from the interviews that support the response type. Full excerpts are gathered in table 1.

Table 1 – Rationalizing food waste

Type of “wasting” response	Illustrative quotes
<p>Apathetic</p>	<p>Refusal to think about sustainability “sustainability, it’s nothing I am occupying myself with every day or often. It’s an important topic, but nothing I am confronting myself with extremely” (Lukas) “I didn’t really think that much about this topic so far.” (Jan)</p> <p>Avoiding conscious effort “when it works that it all comes from this region, then this is nice, but I think you don’t need to force it at all cost” (Jan)</p> <p>Resistance to fashionability “Climate change? Well I think that actually everyone is right now joining this trend [...] everyone is suddenly green and offers vegan and green products [...] I think you can also exaggerate it” (Jan)</p> <p>Fatalism “when it’s expired, then it would be for sure food waste for me, because if I would have taken care about the date and it wouldn’t have expired if I would have eaten it.” (Daniel)</p>
<p>Overwhelmed</p>	<p>Information overload “you are literally overloaded, you – I mean us in the industrial countries – hardly can protect yourself from all this information” (Tobias) “when you know too much then you worry too much about different things and I think in some cases this is not very good” (Laura) “There is so much to question that I am not able to question everything and I cannot know everything and I think that’s stupid” (Anna)</p> <p>Guilt management “For example I threw away my cheese, even though I knew: ‘oh now you have to eat it, because it gets dry, and then you leave and don’t eat it’ and then after a week you check it and think: ‘oh now it molds, hm what a pity, now I throw it away’. [...] That’s actually a bit of a fraud, so you don’t have to have a bad conscience.” (Katharina) “you start to kind of suppress this, that’s what I do I think. Because the moment you occupy yourself a lot with this, you recognize that there is so much and then you just behave like ‘ok I don’t know anything” (Anna)</p> <p>Feeling insignificant “In my opinion, all this is not avoidable. The whole climate change, I don’t think you can still save this. [...] I just think this is unstoppable in any kind of way.” (Laura) “you feel like a mini ant in a huge mass. [...] You just feel so small in our industry and the whole. [...] There is so much wasted that you just feel very small. You have the feeling that you could do something right, but you cannot really change something” (Katharina)</p>
<p>Pragmatic</p>	<p>Individual responsibility “you’re not interested in what you’re eating, you also do not appreciate food and then it doesn’t hurt, when you throw something away.” (Julia) “you can just make sure for yourself that you to some extent live in the right way and that you can arrange this with your conscience.” (Julia) “you do not only feel better personally, but you also do your bit for society.” (Christian)</p> <p>The impossibility of perfection “I maybe also already give a nudge towards this, by talking to others about it, maybe not that someone directly changes the next day, but that he takes a bit more care” (Christian) “you can’t be 100% consequent...only if you try, the way towards this or at least 60-70% I think is awesome” (Christian)</p>

Apathetic: Rejecting Sustainability Efforts Through Indifference

The first type of response reflects apathy, customers being aware of sustainability questions as well as appropriate behaviors but not engaging in it. The respondents refer to sustainability as something they “do not confront themselves with” (Lukas), they do not “think that much about the topic” (Jan). As a consequence, apathetic consumers consider food waste as an unfortunate outcome of their lack of attention, but not something that could have been avoided consciously: “when it’s expired then it would be for sure food waste for me, because if I would have taken care about the date and it wouldn’t have expired I could have eaten it.” (Daniel). By refusing to let sustainability questionings come to the fore, customers diminish the importance of this trend, banalising it through the expressions such as “everyone is joining this trend right now” (Jan). While the respondents at times reflect about their wasteful consumption, they do not want to “exaggerate it” (Jan). Apathetic customer responses thereby focus on resisting the “trendy” or fashionable factor of ethical consumption more than its underlying principles. The focus lies on signaling indifference, by diminishing the relevance of adopting sustainable consumption practices.

When sustainability and reduction of food waste becomes a standard discourse, customers are thus saturated, they approach sustainability as one trend among others, which they want to remain indifferent to, in order to not exaggerate.

Overwhelmed: Consciously Allowing for Food Waste to Reduce Guilt

The second type of response reflects customers’ awareness of sustainability’s importance, but also their feeling of being overwhelmed by the task. The respondents refer to information “overload” (Tobias), the fact that they “cannot know everything” (Anna), which curbs their initiatives in reducing food waste, paralyzing them: “when you know too much then you worry too much” (Laura). They highlight the small effect that their individual actions would accomplish, displaying fatalism in claiming that “this (climate change) is unstoppable anyway” (Laura). They admit that at times, they commit “fraud” (Anna), knowingly letting products perish in order to have an excuse for throwing them away instead of eating them. Customers suppress their feeling of guilt in this type of response and choose to waste food at times in order to be relieved of the perceived pressure. Their perception of lacking importance and power to address climate change hinders them from accepting the extent of their individual contribution, resulting in maintenance of wasteful practices.

This second type of customer response highlights the sense of incapacity resulting from information overload concerning sustainable consumption behavior. This perceived incapacity leads to conscious food waste of a type where customers wait for products to perish to a level where throwing away remains the only option. They thereby try to suppress their sense of guilt, minimizing their own influence.

Pragmatist: Maintaining Idealism While Limiting Initiatives

The third type of response refers to customers’ pragmatism, where idealism is tempered by fact-checking concerning the relative efficiency of sustainable behavior as well as the realities of everyday life. The respondents profess rationality, highlighting their numerous actions for reducing food waste, to “do your bit for society” (Christian). They support maintaining high food prices, as otherwise “it doesn’t hurt when you throw something away” (Julia). Despite a relatively low income, these respondents display a strong support for

a responsible way of consuming, such as buying organic, seasonal or local products. Yet simultaneously, they limit their initiatives for lowering food waste, acknowledging that “you can’t be 100% consequent” (Christian). While they hope to convince others, they concentrate on their own behavior, in order to “arrange this with your conscience” (Julia). By focusing on pragmatism, customers thereby moderate their idealism in reducing food waste, supporting small individual steps in order to eventually attain a sustainable lifestyle.

The third type of customer response reflects the balance customers aim to strike between idealism and the practicalities of everyday life, acknowledging the time-consuming character of consciously avoiding food waste.

CONCLUDING DISCUSSION

This study contributes to existing research by providing insights into consumers’ rationales relative to food waste, more specifically their considerations when it comes to their failure to avoid such waste. It demonstrates that even consumers who are aware and concerned about sustainability, as illustrated in the overwhelmed and pragmatist types of responses, develop rationales that for them justify wasting food. Among others, consumers exonerate themselves from wasteful behavior by acknowledging the difficulty of behaving sustainably on all fronts, as illustrated in pragmatist types of responses.

These additional insights contribute to existing research about sustainability and consumption by providing further information concerning the gap between consumers’ attitudes towards sustainability and behavior. In contrast to the rather rational argument found in previous studies (Eckhardt et al. 2010), the present findings paint a picture of young consumer abandoning efforts, explaining this decision by relativization, pragmatism and lost hope. While reducing food waste should be one of the most central practices in sustainable consumption behavior (Connolly and Prothero 2003), the studied consumers fail specifically to reduce food waste. These insights also add to existing research differentiating between deliberate and unintentional food waste behavior (Block et al 2016) by showing that while consumers may be aware of their wasteful behavior, they feel unable to address it, a state of mind going beyond the previously described licensing effect where consumers balance virtuous and less virtuous behaviors (Khan and Dhar 2006, Block et al 2016).

The paper provides practical insights concerning strategies for supporting sustainable consumption that goes against some existing findings. While existing research has repeatedly argued that raising also young consumers’ awareness to the food waste problematic can lower food waste (Principato et al. 2015; Whitehair et al. 2013), our findings point to the limits of such a strategy. The respondents feel conversely paralyzed by the excess information. Knowing precisely how to behave sustainably inhibits them from reducing food waste.

Such a finding is in line with existing research highlighting that consumers’ pessimism regarding their future well-being facilitates sustainability (Kaida and Kaida 2016). However, this doesn’t seem to be the case regarding food waste reduction. The respondents’ responses, such as feeling apathy, disbelief, guilt and being overwhelmed reflect a rather negative outlook on environmental matters. The outcomes therefore support existing assumptions that younger people tend to numb when they are confronted with information about environmental problems too unpreparedly and too extensively (Hicks and Bord 2001). In addition to experiencing doubts and insecurities (Connolly and Prothero 2008), consumers feel less empowered, they lose hope. The only improvement of wasteful food consumption practices seems to be connected with the generation of hope. Existing research about the role of hope in connection to

consumer agency is brought to a new level through our contribution (Courville and Piper 2004). The pragmatist consumer response indeed allows for potential reductions in food waste through supporting hope. Apathetic consumers in contrast may remain less responsive to messages of hope. The hope of overwhelmed responders could in contrast be rekindled, highlighting that individual action does play a role. Therefore, food consumption practices seem to be rather changed by influencers like hope than information about environmental problems, hence increased knowledge.

Limitations

Given that the methodological choice for this study was to investigate a limited number of participants in depth, the study could benefit from a broader, if less deep, exploration of consumers' discourses about food waste that includes a larger number of participants. Also, the data point to a small predominance of male customers adopting the apathetic response rather than the two other types of responses. Given the potential gender differences in sustainable consumption attitudes (Brough et al. 2016), it would be relevant to quantitatively assess this issue, in order to identify potential correlations between food wasting behavior and gender.

The Art of Solo Dining: A Rhythmanalysis of Restaurant Spaces

Ai-Ling Lai, University of Leicester, UK

Ming Lim, University of Liverpool, UK

INTRODUCTION

All urban spaces are informed by specific rhythms related to the activities, practices and rituals of residents and inhabitants. Commercial eating establishments such as restaurants and cafes are no exception: they are replete with multifarious and divergent rhythms (Edensor 2010, Finkelstein 2013) that reveal an uneven social playing field (May and Thrift 2007). In this paper, we demonstrate how restaurants are inscribed with 'heteronormative rhythms' that privilege the dining experience of couples and families (see Valentine 1993, Browne 2007) while marginalizing that of the solo diner.

Commercial dining establishments are performatively constituted (Browne 2007, Valentine 1993; Finkelstein 1989): that is, they are spatially, temporally and culturally laid out to endorse, promote and sustain certain sets of heterosexual practices (e.g. dating, courting rituals, family outings) as normative. While these studies reveal the anguish and fear associated with the dining experiences of lesbian couples, the experience of *dining alone* in an overtly heteronormative environment is little understood. According to Ratner and Hamilton (2015), dining out is considered to be a hedonic social pursuit, the pleasure of which is derived from being in the company of another (Warde and Martens 2000, Finkelstein 2013). Solo diners are not only 'out of place' (Bell and Valentine 1997; Johnson and Ekstrom 2009); they are considerably 'out of sync'. The lack of a dining partner conjures a pitiful note, an arrhythmia in an otherwise convivial ensemble.

Drawing on Henri Lefebvre's theory and method of rhythmanalysis (2004), we consider how heteronormative rhythms shape the spatio-temporal experiences of solo diners and the strategies employed by these consumers to manage commercial protocols. The questions that drive our study are, therefore, first: to what extent do solo diners synchronise, resist and/or recalibrate their 'deviant rhythms' in relation to the 'dominant rhythm(s)' of a society where coupledom and families are still overwhelmingly normalized? Second (and more generally for our aim to advance consumer research, theory and culture), what room is there, if any, for creative improvisation in the consumption of space and time in the act of solo dining?

RHYTHMANALYSING COMMERCIALISED DINING SPACES

While rhythmanalysis has recently received considerable attention among geographers and sociologists interested in the rhythms of the market (e.g. Borch et al 2015, Cronin 2008, Kärrholm 2009), it remains largely overlooked in consumer research and marketing. With the exception of McEachern et al (2012) and Warnaby (2013), consumer researchers have instead concentrated on developing an 'understanding of consumption *in* and *of* place' (Chatzidakis et al 2013, Goode and Anderson 2015, de Burgh-Woodman 2012, Maclaran and Brown 2005) culminating in what O'Guinn et al (2015) has called the topological turn in consumer research. The privileging of space in consumer research echoes May and Thrift's (2007: 2) concern that 'social theory is moving towards a creeping and just as debilitating spatial imperialism,' which perpetuates a dualistic thinking about

time and space. As Edensor (2010) suggests, rhythmanalysis has the potential to bridge the dualism between time and space by considering the mutual entanglement of spatio-temporal practices as one that are folded through embodied rhythms. As Lefebvre famously proclaimed, 'every rhythm implies the relation of time with a space, a localised time, or if one wishes, a temporalized space' (1996: 230).

Theoretical Framing

Lefebvre's theory of rhythmanalysis has been extensively studied in diverse fields for its insights into urban life, space and time. He envisaged nothing less than the founding of a new form of knowledge through the study of bodily, natural, urban and spatial rhythms (Elden 2004, Lefebvre 2004). Crucially, Lefebvre (2004) emphasises the centrality of the body as a metronome, which allows the rhythm-analyst to 'grasp' and 'be grasped' by the rhythms of everyday life. By listening to the body, the rhythm-analyst is able to appreciate external rhythms (Borch et al 2015) and thus becomes attuned to the social pulses that animate everyday spaces. Key notions of Lefebvrian analysis are eurythmia, arrhythmia and isorhythmia (Lefebvre 2004). Eurythmia occurs when one's body is healthfully in tune with the natural rhythms of sleep, rest, play and work. Isorhythmia refers to the adjustment and adaptation of one's inner rhythms with those of public/private spaces. Arrhythmia is the often jarring collusion of mechanical, capitalistic time with the cosmic rhythms that govern our planet.

According to Kärrholm (2009), urban spaces are polyrhythmic: they are pervaded through and through by heterogeneous temporalities and rhythms where *linear time* (i.e. a product of modern capitalism that institutionalise clock time with working time, school time etc.) intersect with *cyclical time* (i.e. cosmic time such as day, night, the seasons). Kärrholm observes how market rhythms achieve synchronicity by turning polyrhythmic urbanscapes into isorhythmic retailscapes. In other words, urban rhythms are isolated and redirected to coincide with the rhythms of shopping (e.g. retail opening time, scheduled mealtimes etc.). Urban eating establishments thus play a crucial role in perpetuating this isorhythmic landscape. This fact is evidenced in Finkelstein's (2013) observation of the service encounter in restaurants, where patrons are funnelled into occupying specific 'territories' that befit their social importance:

'The power of the waiter has also been described in terms of choreography and space management (Erickson 2007); at their discretion, they allocate territory and prescribe the amount of movement of individuals inside the restaurant. The diner is directed to a table by the waiter, and not all tables provide the same experience; some are noisier than others, they are nearer to the kitchen, or toilets, or front door and passageways, and this can impinge on the dining experience. The waiter's body language frame their diner's experience and create a sense of intimacy as when the waiter introduces themselves and offers to help... Alternatively, the waiter can be remote, formal, or even distracted, and this conveys the message that the diner is not very important' (p.103)

While Finkelstein does not allude to the sorting of patrons along heterogendered lines, she does make special note of how the experience of dining out is organised to reflect heterosocial companionableness and structures of what constitutes conviviality (Finkelstein

1 The notion of heteronormative rhythm is derived from Rich's (1980) concept of '*compulsory heteronormativity*', an ideological framework that institutionalises heterosexuality as a 'natural' sexual preference. Such a framework legitimises the heterosexual couples and families as a 'normative' and ideal form of intimacy.

1989). Dining establishments are spatially (e.g. table-for-two/large table, candlelight, set meals for two/more) and temporally (e.g. the sequencing of a three course meal) co-ordinated to encourage sociability.

Lefebvre and Dining Out

For those with company, dining out can be an experience of eurythmia, where the bodies of patrons harmonise with the rhythms of the (restaurant) space. For the solitary patron, however, this happy state of affairs is often disrupted. Dining out alone is an act of social transgression that brings about *arrhythmia* - a pathological situation where there is a disruption to normative rhythms (Lefebvre 2004). Dining etiquette, dress code and gestures are perpetually enacted to police diners into a moral order in line with the heteronormative framework (Valentine 1993). After all, dining out is a mannered event (Finkelstein 1989), where there is an embodied knowing of how one should behave, how one should conduct oneself publically etc. Such embodied knowing is taken as 'natural', which according to Lefebvre (2004) is cultivated through repeated rhythms that over time 'break into' habits. He calls this dressage. However, Lefebvre is careful to assert that an analysis of the rhythm of dressage does not preclude the possibility of an improvised rhythm.

METHOD

The findings presented in this paper are derived from a larger project exploring single consumer's experience of the marketplace. Using referral sampling, 19 participants were recruited to participate in an in-depth interview exploring their experience of singleness and solo dining. Despite obvious advantages, interviews privilege 'talk' and textual data that disengage the researchers and the participants from their spatio-temporal contexts. We therefore supplement our interview data with 'walking' observation (Middleton 2011), a method that engages the body as a metronome (Lefebvre 2004). Through 'walking', we are able to establish an 'embodied engagement' with the participants by sharing in their 'rhythm of movement', 'multi-sensorial experiences' and 'visual field' (Lee and Ingold 2006: 80). Using a combination of observation, photography, offsite and in-situ interviews, we captured the intricacies of spatial practices and social interactions. Of the 19 participants, 8 agreed to participate in the 'walk', generating a wealth of data which include 57 hours of observation, 309 photographs and approximately 300 pages of transcribed in-situ interviews.

FINDINGS

In this paper, we discuss two prominent time-space tactics our participants employ when dining out alone: (1) negotiating mobility and (2) managing visibility.

Negotiating Mobility

Our participants consistently express a feeling of awkwardness when requesting a 'table for one'. Their expressions speak to an unwritten code that construes solo dining as a transgressive act (Finkelstein 1989; Johnson and Ekstrom 2009). One of them, Arjun, explains:

"The table is designed for two, minimum. There's no such thing as a table for one, really. Restaurateurs want you to be in a couple. It's all marketing isn't it? It's like an unwritten rule. When I go into a restaurant by myself I am always very apologetic about it. I'd be, 'I'm sorry, but it's going to have to be a table for one, I was due to meet somebody who's cancelled.' I'd be constantly trying to explain myself. I shouldn't really need to

do that. I should be able to say, 'table for one' - no questions." (Arjun, Off Site Interview)

For Arjun, dining establishments are spatially co-ordinated to reflect a 'social norm' that privileges the heterosexual couple (Valentine 1993, Browne 2007). To cope with this rhythm of heteronormativity, Arjun employs an 'apologetic tactic' as a pre-emptive gesture. Such a gesture is rooted in his embodied knowing - or dressage (Lefebvre 2004) - of having trespassed into a heteronormative domain. By feigning a cancellation of a fictitious partner, Arjun is able to calibrate his 'awkward' presence and reposition himself as a 'legitimate' diner.

In a similar vein, another participant, Will, reflects on how his experience of negotiating an entry into an Italian chain of restaurants (Zizzi) makes him feel 'out of place':

"People don't come to Zizzi to eat. They come here to socialize... It is a sleek operation. I wouldn't really feel I have the freedom to move about. In a place like this, I would just have some lunch and go. I feel a bit out of place. It's not a single friendly place. It has an air of formality about it. It's got very straight lines. You have to fit into a strict protocol or else you stand out. You have got to wait to be seated. You can't just wander in and sit down anywhere." (Will, In-Situ Interview)

Zizzi falls into Finkelstein's (1989) category of a parodic restaurant, a space engineered to prioritise 'socializing' over gastronomical experiences. For Will, Zizzi is a highly regulated operation, which is reflected in its spatial linearity. This organisation of space into 'straight lines' reflects the spatialisation of 'linear time' (Lefebvre 2004), in which patrons' mobility are regulated in accordance to a routinised set of protocol. In this context, the waiting staff assumes an authoritative position as a 'gatekeeper' who is capable of manipulating the patron's occupation of 'space' and 'time' (ibid. 2004). This generates an asymmetrical power relation that renders Zizzi an isorhythmic (sleek) space (Finkelstein 2013; Lefebvre 2004).

For Will, Zizzi's regimented protocol does not only 'fix' him to his place (seat), it paces his dining experience into a sequential tempo - where he is expected to 'wait to be seated', and be 'waited on' -throughout his three course meals. In an attempt to manoeuvre such a strict regime, Will resorts to speed up his dining time ('lunch and go'). For Will, 'waiting' constitutes a rhythm of subordination (Adam 1990), which exposes him to the heteronormative gaze. For our participants, managing visibility within the spaces of restaurants is paramount.

The interview took place at an off-peak period for the restaurant. It was nearly empty when we entered. When we asked if we could choose our seats, the waitress politely brushed aside our request, saying: 'you can sit anywhere *other than the larger tables*'.

Managing Visibility

Solo dining conjures a heightened sense of visibility, which our participants consider to be alienating (Browne 2007). As such, they attempt to calibrate their bodily rhythms in a way that does not disrupt the heteronormative rhythm. In particular, they negotiate spatial positioning (where to sit) and temporal pacing (duration of stay) to manage their conspicuousness. As Arjun explained:

My preference would be to sit around the edges at the back (Café Rouge). Where we are now is the prime seat because you get a view of the whole restaurant. You get a view of the people coming in; you can catch the eye of the waiter. You get a sense of the space. You don't feel confined or crowded. I can just

Table 1: Findings

Themes	Descriptions	Participant Data
Negotiating Mobility	From negotiating entry to negotiating exit, our participants find themselves having to assert their mobility. In particular, we observe the extent to which participants are (1) free/inhibited to come and go (2) made to stop (wait) and (3) able to control the pace of their dining experience.	
	Freedom/Inhibition to Come and Go	I think there's a likelihood of being turned away at San Carlos. I can see San Carlos just reluctantly giving you a table, but on a Friday or Saturday night, I can see them saying, "We're full," even though there's, like, actual tables there. "Oh, they're booked." So I can see them do that, but I think I would find San Carlo more intimidating than Bistro Pierre. In comparison I think San Carlos would be more difficult, because the tables are even bigger as well. You know, it's a little bit, ugh, no. But it just seems like a real, kind of, snobby place, where it's just couples only. (Arjun, In Depth Interview) I think the fact that it's a fast food place means that it's—I don't know. Somehow it makes it simpler to just come in and just—it's like the whole concept of YO! Sushi. You're going in there and the food's readily available, so you're not hanging around. I think it's just a different dining experience. I don't know. It somehow feels more acceptable (of solo dining)...it is a quick eating establishment (Priya, In situ interview)
	Made to Wait	I think in city centre Leicester there's pretty much the same format. The emphasis is going in, sitting down, being waited on. Er, there's not many places where you go in and you can stand up and eat at a bar where there's a flow of people. City centre Leicester or even city centre Nottingham I'd feel a little bit odd going into a restaurant on my own. Um, I don't know, I, I do honestly think (pause) it's so, I think it must be so unusual and I think I'd, I think I'd feel I was a bit too conspicuous (Ingrid, In Depth Interview)
	Freedom to Pace One's Dining Experience	Wagamama have this seating in the middle where they tend to sit single people. But they primarily, and you can see that other single people are sat around the table. I requested to be sat on the edge near the window. . It's just I wanted to be near the window so I could view other things. I think the tables around the window were catered for more than one person. But they seem to frown upon my request. I felt like I needed to rush and hurry up and leave. I feel like I'm different because I'm being treated differently just because I'm there as a single person rather than (someone with company). I feel like maybe if there was a couple that went in there or maybe it was a group of people they wouldn't have been questioned. I could've been in and out of there within 15 minutes and there could be a couple sat in front of me for about an hour, but yet I was still frowned upon. I think it's like I just want to be treated equally. So if you walk in a couple, you walk in as a group, you're asked where you want to sit. I think a single person should have the same rights (Priya, In Depth Interview).
		I think this place (Yo! Sushi) kind of promotes people coming alone and eating, because especially the conveyer belt idea, it's more like a bar where you can definitely come alone. Or do something yourself and just stand at the bar while finishing your drink. So, under no pressure to please someone or look at someone, you can just eat and mind your own business. So it's an activity that you indulge in, but also you don't need anybody else. (Ela, In Situ Interview)
Managing Visibility	All the participants in this study express concerns over the heightened visibility associated with solo dining, which renders them exposed and vulnerable. Participants devise a myriad of spatial and temporal tactics to manage their visibility in restaurant spaces. Most notably, the managing of visibility involves (1) choosing a strategic location and (2) evading or confronting the heteronormative gaze	I think it would be like 'oh look she is a single woman. Has she been ditched? Is she desperate? Is she looking?' When you walk in on your own people do stop and stare and it is that whole, why don't you just leave me alone to read my book and have my glass of wine and let me be instead of staring. You can feel that, and they might not even be looking but you are paranoid (Javinder, In depth Interview)
	Choosing a Strategic Location	I will sit along the back wall on the nice long seat. I would quite like to sit by the window and look out the window and just see the world go by. Obviously if I am here by myself I need some distraction and something to look at. It's quite a nice street place. Here, I can look at the entire restaurant, look at all the decoration and everyone else here, look at all the staffs. I want to be the person who is looking out at everyone else rather than having them looking at me. I think if I was by myself, I would probably sit either side of the corners (by the wall or by the window). I wouldn't sit in the middle, it's very conspicuous. I will look a bit out of place. By the side wall, it's better because it's kind of like I merge into the wall. (Will, In Situ Interview)
	Evading the Heteronormative Look	I do like people watching though and another thing I've just thought as well if I was on my own I'd probably bring something. A book... not a book, a magazine or look on your phone or something so it looks like you're doing something else so you're not just sat here like this. You've got something else, a paper or a magazine or something to occupy yourself a bit so you're not catching people's eyes. It looks like... you know avoiding eye contact. Say if I don't have a book or a phone I'd still be looking at the menu, I'd be like this (<i>head down, facing away from the crowd, avoiding body language</i>), I'd still be reading (Aisha, In Situ Interview)
	Confronting the Heteronormative Look: Gameplay	I would generally prefer sitting outside. It really depends. Sometimes I will purposely do it just to make others feel uncomfortable. (Laughter) I'm like, "Feel like that. You should," whatever. Yes, that's just pure pleasure that I will get out of making somebody else uncomfortable. (Ela, In Situ Interview)

blend into the corners. I suppose I've got the control... It would be my worst nightmare because then I could have like a million eyes behind me. (Arjun, In-Situ Interview)

On arrival at Café Rouge, Arjun and I were greeted by a waitress who invited us to 'sit wherever we want(ed)'. Without hesitation, Arjun headed directly to the rear of the restaurant, occupying a corner-seat, facing the front and away from the window. Arjun considered this to be a 'prime seat' (See Figure 1) as it enables him to take command of his visual field (which encompasses the entire restaurant). For Arjun, the corner allows him to 'blend into' the spatial recesses (Bachelard 1994), thus concealing his presence. By occupying an interstitial space, Arjun can assume the role of an observer and 'lose himself in the crowd' without compromising his position. Ironically, it is within the confined space of the corner that Arjun gains a 'sense of space' since he is not 'crowded' by the invasive 'look' of others. He is highly attuned to the ebb and flow of patrons entering/leaving the restaurant and this sensitises him to orient his bodily gestures (e.g. eye contact, posture) in accordance to the level of exposure he feels comfortable with (Lefebvre 2004). For example, he can 'catch the eye of the waiter' should he wish to be attended to (Finkelstein 2013). Or retreat into the corner when he desires privacy.

However, being seated in the middle or occupying a seat that faces away from the crowd constitutes a 'nightmarish' experience

for Arjun. His exposure conjures a vulnerable sense of arrhythmia (Lefebvre 2004) that is corporeally felt ('millions of eyes' closing in on him).

While most participants tend to evade and/or manage this heteronormative gaze, yet another participant, Simon, chooses to engage in a creative game play that signifies an improvisation of routine:

I'd be happy to go anywhere on my own. I think there're once or twice when I've gone to a place and ask for a "Table for one?" The truth is table for one means it's those grotty little ones by the window. I've got this thing where I can flip negatives into positives and I often play to them. I often play the game, which is looking at who is the most attractive waitress. (Simon, Off-site Interview)

Unlike most of our other participants, Simon is accustomed to patronising a restaurant on his own. While he is conversant with the unpleasantness of the 'grotty little table by the window', Simon possesses an embodied competence that is adept at improvising on an undesirable situation (Lefebvre 2004). In a subversive game of 'spotting the most attractive waitress', Simon reverses the heteronormative gaze that shift the power dynamics between him and the waitress (see Crang 1994). By subjecting the waitress to a 'male gaze' (Mulvey 1975), Simon simultaneously exposes the hypocrisy and 'constructedness' of the heteronormative gaze.

Top Left: The corner seat identified by Arjun as the 'prime seat'

Bottom Left and Top Right: The expansive visual field encompassing the entire restaurant, as viewed from the 'Prime Seat' (Top Left). This vantage point safeguards the 'invisibility' of the observer while exposing the visibility of other patrons/staff.

Bottom Right: Aisha 'shrinks into' the seat occupying a tiny corner on a long bench.

Figure 1: Corner as a prime location

CONCLUSION

Our stated aims for this study were to gain insight into how solo diners mitigate marketplace exclusion and social arrhythmia (Lefebvre 2004) and to probe the ways in which these consumers negotiate mainstream rhythms of the marketplace. Our findings show that solo dining consumers exercise considerable ingenuity and a certain technical skill in both aligning with, yet subtly subverting, the rhythms of the marketplace. Using rhythmanalysis, our paper demonstrates that a spatio-temporal analysis opens up new knowledge into how solo diners negotiate heteronormative rhythms in eating establishments that, to date, continue to privilege couples and families.

Remarkably, our participants are highly attuned to their 'transgressions' into heteronormative spaces. Their feelings of what Lefebvre calls 'arrhythmia' is grounded in an embodied knowing, of being 'out of sync' with the rhythms of heteronormativity they encounter in dining establishments. As reported by our participants, their occupation of a table intended for two/more is often considered by restaurateurs as 'wasting space'— so much so that they are often isolated by being moved away to the periphery of the main space, away from the conviviality of crowds (Valentine 1993, Finkelstein 1989). One could say that such orchestration is deeply symbolic: solo diners are simply not 'part of the action'.

Even more interesting is our finding that our participants are seemingly complicit in the established isorhythmic practices (Kärholm, 2009) of restaurants they dine at. They actively employ spatial positioning strategies (negotiating strategic seating) and temporal pacing (eating quickly/slowly) to help them circumvent and 'blend into' the heteronormative environment. Contrary to what one might expect, however, we argue that such tactics are far from disempowering. Rather, our participants are enacting what De Certeau (1998: 37) calls the practical 'making do' of everyday life. Occupying a marginalised position, solo diners found themselves making use of interstitial spaces and improvising with both physical objects (chairs, tables) as well as with their eyes, bodies and space itself. The corner (Bachelard 1994), for example, provides a temporary refuge that allows them to 'manoeuvre' within the field of vision of those in a position of power (De Certeau 1998). In this way, solo diners are capable of improvising on the heteronormative rhythms that are imposed on them; while subverting these rhythms, however, our participants show a keen awareness of how they can simultaneously protect and exploit their visibility.

Future research may well question what restaurants can do to optimize the solo diner's consumption experience, to elevate it from 'normal' or 'merely satisfying' to 'delightful' and beyond. While the number of restaurants for solo diners has recently shown signs of increasing, more research is needed to explore how the culture of urban dining can evolve beyond the heteronormative model that privileges the dining experience of couples, groups and families. In line with socio-demographic trends across the globe and the continued increase in the number, mobility and purchasing power of solo travellers and single professionals, it seems only logical that their consumption experiences should be radically thought through by restaurants. In the meantime, we hope our research has extended knowledge of the extent to which the solo diner has to accommodate the spatio-temporal (rhythmic) protocols within restaurants – and, indeed, the social order itself - in order to have the consumption experience she/he desires.

Repositioning via Abstraction

Jonathan Lee, University of La Verne, USA

Heungsun Hwang, McGill University, Canada

An Tran, University of La Verne, USA

INTRODUCTION

A brand's *position*, represents the key attribute, benefit, or "image" that it stands for in the minds of consumers, relative to competition (Shimp 2010). Many advertising practitioners regard positioning as the most important factor in establishing a brand in the marketplace (Belch and Belch 2015). When a brand's current position is weak or not deemed ideal relative to competitors, it requires repositioning and we refer to it as *the strategic process that is motivated by a perceived discrepancy between a brand's current and intended position*. While the cumulative knowledge in positioning strategy and perceptual mapping is rich, theory-based repositioning principles received little attention. We extend Pham and Muthukrishnan (2002) and present an abstraction-based conceptual and empirical framework that argues that, depending on the diagnosis at different levels of abstraction, repositioning strategy can be easily guided by determining the optimal level of abstraction. In this study, we (1) present a framework of abstraction-based repositioning strategy grounded in construal level theory, (2) adopt a simultaneous two-way clustering method based on multiple correspondence analysis that enables managers to account for the heterogeneity in consumer perceptions, and (3) illustrate our approach using online automobile consumer panel data.

CONCEPTUAL FRAMEWORK

Construal Levels and their Influence on Consumers' Judgment

Academics and practitioners recognize a number of positioning/repositioning strategies and tactics that are grounded in attitude theory/models and their associated attitude change approaches. These traditional approaches to the repositioning problem tend to focus on brand attributes/features (e.g., warranty, price). Applying a multi-attribute model perspective, there are three general ways to change consumer attitudes: change beliefs (attributes), change attribute importance, or change ideal points (Blackwell, Miniard, and Engel 2001; Lutz 1975). This strategy is most effective when there is no other clear identity or image for the brand in consumers' minds, assuming that the strong attribute matters to consumers. When, however, the attribute-based approach fails, we may consider repositioning based on the higher levels of abstraction at which consumers perceive the offering differently. Considerable research has established that consumers construe objects and events at different levels of abstraction. These differential levels of abstraction in construal has significant influence on how consumers evaluate objects, and consequently, on consumers' behavior (Trope and Liberman 2003).

Research on construal level theory (CLT) demonstrates that people's mental representations of psychologically distant objects and events are more high-level, simple and abstract, while mental representations of the same objects and events when they are psychologically closer are more low-level, detailed and concrete (e.g. Trope and Liberman 2003; Trope, Liberman and Wakslak 2007; Forster, Friedman and Liberman 2004; Forster 2009). For example, "grocery shopping" will be represented as "walking to the local grocery store to buy milk" when it is construed on a low-level. High-level construals are schematic, decontextualized, abstract representations that include superordinate, central, desirability features, or the *reason* for

which events happen. For example, "taking a class" is represented as "gaining knowledge" on a high level of construal. On the other hand, low-level construals are more concrete, unstructured, contextualized representations that include subordinate, peripheral, feasibility features, or the *means* by which events occur (Lieberman and Trope 1998). In our context, repositioning based on abstraction means that a brand's position in consumers' minds varies on the abstraction spectrum, from the high abstraction position that communicates the *values/goals* that consumers deem important by buying a brand's offering, to the low level, concrete position that communicates the physical features or attributes that consumers get from an offering. Consistent with findings from the CLT literature, brand's positions at differential levels of construal or abstraction could result in diverging evaluations of the same object/event. This leads to changing preference as abstraction in thinking increases. Individuals in an abstract mindset assign more weight to central, primary factors when evaluating a brand, while individuals in a concrete mindset to peripheral, secondary ones. Judgments resulting from high-level, abstract construals, relative to ones from low level, concrete construals, have been shown, among others, to focus more on the positive attributes of objects and events (Eyal et al. 2004; Herzog, Hansen and Wänke 2007), to be more stable across situations (Wakslak et al. 2008; Nussbaum, Trope and Liberman 2003), to be more aligned with long-term goals (Freitas, Gollwitzer and Trope 2004; Fujita et al. 2006).

Besides leading to diverging evaluations of the same object or event, levels of construal have also been shown to influence the way individuals think and behave in general. For example, abstract, high-level construals, relative to concrete, low-level construals, have been shown to increase dispositional (vs. situational) attributions (Henderson et al. 2006), to increase promotion-focused (vs. prevention-focused) concerns (Pennington and Roese 2003), and to enhance self-control (Fujita et al. 2006). The differences in the effects of high versus low levels of construal are partly because abstract, high-level construals are based on the gist of events and on the values of the perceiver, while concrete, low-level construals are based on secondary features of events and the judgment context (Wakslak and Trope 2009). As high-level construals, relative to low-level construals, are based on the gist of events and the values of the perceiver, they are more likely to remain unchanged as psychological distance increases (Lieberman and Forster 2009), and across different judgment contexts. This body of work suggests that abstract positioning that communicates the values/goals that consumers deem important by using a brand rather than the attributes of the brand's offering could be more effective because, among other benefits, consumers' perception of a brand is more likely to be stable.

METHOD

Model Estimation by Simultaneous Two-way Clustering of MCA

The main objective of our empirical model is to obtain a positioning map that also accounts for the heterogeneity in consumer perceptions by identifying *joint* clusters, each consisting of a distinct subset of consumers and variable categories. A comprehensive view of repositioning through a joint mapping of consumers and attribute categories at each abstraction level adds row-dimension projections.

Thus, repositioning strategy can be evaluated based on consumer demographic/psychographic characteristics in addition to attribute-level changes. This can be achieved via a simultaneous two-way clustering of MCA (multiple correspondence analysis) that combines MCA and k -means into a single framework (DeSarbo, Grewal and Scott 2008; Hwang and Dillon 2010). In the next section, we present the estimation results based on the methods in Hwang and Dillon (2010).

Once we obtain a heterogeneous positioning of brands at different levels of abstraction for a distinct subset of consumers and attribute categories, a summary statistic that measures the strength of association with those attributes within a specific cluster is required to diagnose the desirability of a brand's current position. For brand i and attribute j belonging to cluster k , the strength of association between brands and attributes in a d -dimensional map, defined here as *Association Index* (AI), is calculated based on the Euclidian distance:

$$(1) \quad AI(i, j) = 1 - \frac{D(i, j)}{\sum_{j'=1}^j D(i, j')}, \quad \text{where } D(i, j) = \sqrt{\sum_{u=1}^d (f_{i_k}(u^i) - f_{j_k}(u^j))^2},$$

where $f_{i_k}(u^i)$ denotes the d -dimensional coordinates of i in cluster k . As shown in Table 1, for any brand i , the row indices across attributes sum to 1. To facilitate the comparison among brands, we standardize the AIs across all brands in cluster k by subtracting the average column index and dividing by the standard deviation. This standardized measure is hereafter referred to as the *Relative Association Index* (RAI). The RAIs computed at each level of abstraction not

only provide a measure of brand-attribute association strength, but they also help determine the ideal level of abstraction.

Empirical Illustration

We illustrate the proposed repositioning approach by abstraction using family sedan automobile online panel data. A national sample ($n=732$) from an online consumer panel completed the survey dealing with preferences and attitudes towards mid-sized sedans. The proposed model is estimated using pick j/N choice data, where N is the number of alternatives considering that rank order and ratings data in the present setting may have some limitations. Most notable to our context, positivity bias is common when all items in a single instrument are perceived to be desirable and important (Beatty et al. 1985). The survey asked participants to select the three ($j=3$) sedan models that they most prefer, the three product features that they consider most important in their purchase decision for a new sedan, and the three most important personal values. The 13 brands are chosen to reflect the middle of the sedan market, which exclude luxury and small economy models. The 12 product features are chosen to be consistent with reports published by *Consumer Reports* and *J.D. Power and Associates* and the 10 values items are adapted from *The List of Values* (Kahle 1983) and other established measures (Mitchell 1983; Rokeach 1973). As previously defined, the *Relative Association Indices* (RAI) can be evaluated by column (i.e., how strongly consumers perceive that each model reflects a particular feature/value relative to other models – a relative comparison across brands) or by row (how strongly consumers perceive that each feature/benefit/value fits a particular model – a relative comparison of features/values for one specific model). Once the current positioning

Table 1: Relative Association Indices from the 2-Way Clustering of MCA

Segment 1 (42.49%)	Safety Features	Fuel Efficiency	Reliability	Social Recognition	Sense of Accomplishment	Healthy Lifestyle	Self-Fulfillment	
Subaru Legacy	1.743	-1.495	-1.680	-1.648	-1.043	1.154	1.754	
Toyota Camry	-.566	.440	.636	.543	1.365	-1.207	-.490

Segment 2 (23.36%)	GPS	Interior Design	Luxury Features	Exterior Design	Sound System	Warranty	Fun & Excitement	Good Relationships
Mitsubishi Galant	-1.045	1.135	1.098	.362	-.026	-1.056	-.328	.328
Hyundai Sonata	.948	-.381	-.239	-1.131	-.987	.933	-.795	.795
Mazda 6	.097	-.753	-.859	.769	1.013	.123	1.123	-1.123
Standard Deviation	.045	.035	.031	.007	.039	.027	.019	.019
Segment 3 (34.15%)	Performance	Price	Roominess	Security	Self-Respect	Comfortable Life	Sense of Belonging	
Buick LaCross	.174	-.215	.323	1.376	-1.061	1.062	-.794	
Chevrolet Malibu	-.738	.738	-.702	-1.234	-.304	-1.187	1.246	
Chrysler Sebring	-.072	.212	-.588	.238	-.517	.196	-.039	
Mercury Grand Marquis	-.369	.449	-.645	-.278	-.537	-.321	.466	
Ford Taurus	-.872	.723	-.275	-.900	.821	-.946	.613	
Standard Deviation	.098	.131	.035	.066	.052	.083	.156	

map and RAIs are diagnosed, managers can determine the most appropriate repositioning level.

Low vs. High Abstraction Positioning

Figure 1 shows the association of key product attributes and preferred models (e.g., warranty with the *Hyundai Sonata*) and the competitive relationship between brands (e.g., *Chevrolet Malibu* and *Ford Taurus*). Based on the estimation of a simultaneous two-way clustering of MCA model, we obtain three segments with the centroids denoted as S1-S3. The individual object scores are plotted in small dots to show the final classification outcome. For S1, it is no surprise that the *Honda Accord*, *Nissan Altima*, and *Toyota Camry* are rated comparable in terms of specific features, most notably reliability. The association with safety and fuel efficiency support manufacturers’ long-standing product claims and promotional campaigns. We find a bit fuzzy classification of *Subaru Legacy* but with strong association to performance and *Volkswagen Passat* also joins this group of vehicles, possibly suggesting that *Volkswagen’s* recent efforts to associate their *Passat* with these market leaders may be working. Recent reviews of the *Passat* by Edmunds.com report significant improvement and movement towards the Japanese brands.

A few model-specific findings in Table 1 include that (i) safety is the strong feature associated with the *Subaru Legacy* compared to other models (RAI=1.743), (ii) three models (*Camry*, *Altima*, *Passat*) are comparable in terms of reliability, and (iii) the *Honda Ac-*

cord is the most fuel efficient model in Segment 1 (RAI=1.199). The latter finding is consistent with *Honda’s* environmental efforts (use of recycled materials in car production, popular hybrid models) and recent TV commercials (“*Honda* has been a fuel economy leader for the past 30 years”). These brands are highly competitive and comparable that it will be a challenge for any one brand to rise above the others in the pack.

Value positions are layered over the low-abstraction positioning map in Figure 1. It is clear that most of the models in Segment 1 have stronger association with high abstraction values such as social recognition, a sense of accomplishment, healthy lifestyle, and self-fulfillment. It is easy to see how self-fulfillment and a sense of accomplishment which reflect high life satisfaction and self-esteem, a success-directed orientation, and psychological well-being (Gurel-Atay et al. 2010; Kahle 1983) are associated with these reliable and high image brands. Specific distinctions include: (i) driving a *Camry* affords “a sense of accomplishment” (RAI =1.365); and (ii) the *Altima* and *Passat* are strongly associated with social recognition. It suggests that those models are better off by implementing an alternative positioning strategy based on values instead of product features.

Segment 2 is the smallest segment with only three models: *Hyundai Sonata*, *Mazda 6*, and *Mitsubishi Galant*. Interestingly, this segment is linked with 6 brand features. It was not expected to find the associations in terms of luxury and design, however, it

Figure 1: Low vs. High Abstraction Positioning by Segment

suggests that recent “luxury and design at a value price” campaigns are effective. In recent years, *Hyundai* is perhaps most known for its extended warranties. In addition, *J.D. Power*’s rankings now put *Hyundai* above *Nissan*, and consumers’ quality perceptions are starting to catch up with reality (Hirsch 2010). Examination of the RAIs indicates: (i) the *Galant* is most linked with luxury (RAI=1.098) and interior design (RAI=1.135), (ii) the *Sonata* is most closely attached to warranty and GPS, and (iii) the *Mazda 6*’s strongest traits are exterior design and sound system (RAI=.735).

Not all models are suited for high-abstraction positioning. We can clearly see that the *Sonata* and *Galant* are uniquely positioned with a number of specific product features. In fact, the results emphasize the need for recognizing the optimal level of abstraction in positioning. The *Mazda 6*, however, is well positioned very close to “fun and excitement” (RAI=1.123), which they pursued consistently with “Zoom, Zoom” and other fun-related themes.

In Segment 3, the major U.S. models (*Buick LaCross*, *Chevrolet Malibu*, *Chrysler Sebring*, and *Ford Taurus*) are weakly associated with performance, roominess, and price. American car brands are traditionally known for their interior roominess, and their positions also confirm that these manufacturers provide large/powerful engines, typically at a lower price than foreign imports. Note that results for price may in part reflect our decision to sample only models within a limited price range, and the aggressive price incentives offered by the American brands to lure drivers into their showrooms.

As was the case in Segment 1, the American brands of Segment 3 show the stronger connection to high abstraction values. This may explain the moderate level of success from many of their campaigns and promotional efforts, which are feature-driven (e.g., *Chrysler/Dodge*’s long-running *Hemi* engine campaign) with little attempt to connect vehicles to higher order benefits or values. These American models have relatively high average RAIs for self-respect, a comfortable life, and a sense of belonging. When brands are examined separately (by row), the *Buick LaCross* (RAI=1.062) is strongly attached to “security” and “a comfortable life”. Three brands lean towards “a sense of belonging”, reflective of a strong family-orientation with more dependency tendencies. The *Taurus* reflects self-respect (RAI=.821) more than the other models, which is encouraging since self-respect is the most “popular” value in America, and those who rate it as most important are diverse, sharing few distinguishable characteristics (Gurel-Atay et al. 2010; Kahle 1983).

DISCUSSION

We present and illustrate an abstraction-based positioning framework that allows managers to treat repositioning strategy not only at the product attribute level, but also at higher abstraction levels. We explain that, consistent with the findings from construal level theory, brand’s positions at differential levels of abstraction will affect consumers’ evaluation and choice of the brand’s offering. While the concept of *abstract positioning* may not be new, we try to incorporate abstraction in a comprehensive conceptual and empirical framework that managers can use to diagnose and develop a brand’s repositioning strategy. Marketers need to be aware that just as desired features may change over time, so do benefits and values. The proposed approach offers a simple but flexible guide for managers to achieve the most ideal position by prioritizing features and/or values to properly appeal to target market consumers.

In Pursuit of Happiness: Phenomenological Study of The KonMari Decluttering Method

Hsin-Hsuan Meg Lee, ESCP Europe, UK

ABSTRACT

Examining the phenomenon of KonMari decluttering method, this study explores how objects move through the journey from “possession,” and “organization,” to “dispossession” and the role of happiness in the process. The results suggest personal symbolic classification serves as the primary anchor for consumer happiness rather than the physical objects.

INTRODUCTION

How do consumed objects move through the journey from possession to dispossession? Where do consumers find happiness in this process? Prior research seems to center around the two extreme ends. On one end, happiness can be found in consumption, both in the form of materials and experiences, albeit to a different extent (Nicolao, Irwin, & Goodman, 2009). On the other end, conscious dispossession such as anti-consumption has also proven to influence consumer happiness (Cherrier, 2009). This type of mindful consumer behavior is often thought to be aspired by the reflection of societal overconsumption (Sheth, Sethia, & Srinivas, 2011). The notion of overflowing items in possession has inspired another stream of research on the household organization and the need for tidiness (e.g., Löfgren, 2016). While the process of tidying things up is considered mundane, the domestic order is often linked to consumer tranquility. However, little is known about how these three stages ‘possession,’ ‘organization,’ and ‘dispossession’ work together and how happiness is perceived and influences the decisions during the practices. Focusing on a decluttering approach, KonMari Method (Kondo, 2014), this research aims to yield insights on object-subject relationships beyond what is currently available in the literature. While the prime focus of the method is to organize the domestic mess, it emphasizes on finding the joy sparked by items as the standard to decide whether to possess or discard. This sets a proper context to explore how consumers define happiness in their decision making.

LITERATURE REVIEW

Consumption, Anti-consumption, and Happiness

Materialism is thought to be the primary social drive for modern consumption. In the context, happiness is defined by the abundance and the capability of acquisition (Richins and Dawson, 1992). Investigating the view of “money can buy happiness,” prior studies illustrate that consumption does lead to contentment. It is common for consumers to use object ownership as a mean to satisfy their psychological (Yu, Jing, Su, Zhou & Nguyen, 2016) and functional needs (Bhardwaj, Park & Kim, 2011), reward oneself (Godey et al., 2012), signal social status (Rege, 2008), reduce negative emotions (Kemp and Kopp, 2011), and consequently, increase happiness. However, many have argued that experiential purchase, in fact, induces more happiness than material purchase (Carter & Gilovich, 2010; Dunn, Gilbert & Wilson, 2011; Nicolao, Irwin, Goodman, 2009). In particular, extraordinary experiences tend to result in a higher level of happiness than those ordinary ones (Bhattacharjee & Cassie, 2014). Though the direct relationship between money and happiness is weak, consumption does seem to influence one’s wellbeing.

Parallel to this development, in the past decades, there are several consumer movements against over-consumption. Starting with the notion that excessive consumption makes people unhappy (Lee & Ahn, 2016), consumers may express their resistance toward the

marketplace in various forms, ranging from complaining, boycotting, voluntary simplicity to anti-consumption (Cherrier, 2009). They may engage in these activities driven by intrinsic or extrinsic motivations. Movements such as mindful consumption (Sheth et al., 2011) and collaborative consumption (Albinsson & Perera, 2012) are motivated by concerns for the well-being of the environment. Consumers may find happiness in thinking they are contributing to the greater good. It may also come from the feeling of regaining control of oneself and reduced stress level that is related to the variety and the number of choices offered in the marketplace (Lee & Ahn, 2016).

Symbolic Classification System and Pollution

Owning too many objects and the need to organize have become central in modern consumer life (Cwerner and Metcalfe, 2003). Decluttering has become a widespread practice. It may seem straightforward to remove the items from a collection when an object is losing its value, functional or hedonic. However, consumers often attribute the cause of having “too much” to the overall volume rather than specific objects, which makes it hard to choose what to discard. Also, because of the meaning that the items represent, one may be reluctant to do so. Materiality studies suggest that while objects are non-human entities, consumers may have a psychological and emotional attachment to their possessions. Object-centered thinking views things as having a life and an identity which plays a significant role in the narratives of belonging (e.g., Zwick and Nikhilesh, 2006). This subject-object relation motivates and sustains the ongoing commitment to the labor of possession (Ekerdt & Baker, 2014).

The increasing number of items tends to result in a domestic mess, which is defined as a form of symbolic pollution, that is, items that are misplaced based on a self-identified system. Taking from Douglas (1967) definition of symbolic classification system where everything has its own place, Dion and her colleagues (2014) studied how people manage the mess at home. They found people have their systems defining the proper places and boundaries for objects. Those that are “out of place” are considered untidiness. While messiness is related to positive outcomes such as creativity (Löfgren, 2016), the disorder can create stress and anxiety. It is not the object itself that results in such negative feelings, but rather a disruption in the classification system that the person has created (Dion, Sabri & Guillard, 2014). According to this, knowing where to place an object at home can be both satisfying and endangering consumers’ well-being. While decluttering aims at clearing out the mess, it is also promoted as an act of restoring happiness in the household (Cherrier & Belk, 2015).

KonMari Methods

Marie Kondo, a Japanese organizing consultant, and her best-selling book titled “The Life Changing Magic of Tidying up” (Kondo, 2014) has led a movement of decluttering one’s possessions in pursuit of happiness. It has attracted millions of worldwide followers who consider themselves as KonMari converts (Yourgrau, 2015). There are some unique features to this method that may explain its popularity. Kondo advertises her method as a once in a lifetime experience that by completion, people will never have clutter in the house again. The most critical step is to touch each item and ask oneself if it “sparks joy.” Whether an object induces happiness serves as the sole principle whether one should own the item. Specific organizing tips are followed to help find places for every single object at

home. In her view, items are not just objects but things with their arcs and narratives. For all the items that do not spark joy, Kondo suggests the readers to thank it for having served its purpose before throwing it away. When an item ends its journey, no one else should own it. Thus, the items are not for reselling or recycle, as this would indicate the continued attached (monetary) value from the owner. Studying how consumers applied KonMari methods to organize their possessions, this study investigates how people find happiness in the process of moving objects through possession, organization, and dispossession.

METHODOLOGY

To analyze the role and the definition of happiness in the trajectory of objects, the study follows the descriptive phenomenology research approach to describe the reality of the phenomenon of KonMari. This method allows a substantial representation of the subjective experience of the participants (Mick & Demoss, 1990). In-depth interviews were conducted with 11 female adults between the age of 26 and 47 who self-identified as practicing some forms of KonMari methods. The participants were recruited through convenience and snowball sampling strategies. One critical selection criterion of the participants is that they must have documented their decluttering attempts with pictures, blog articles, diaries or videos. These materials were used to prompt answers and recall their processes. Their experience with the KonMari method ranges from 2 months to 5 years, as the book was first published in Japanese in 2011 and only later translated into different languages around the world. Six of the participants considered themselves as pure KonMari converts who faithfully followed all steps in the method. The rest have given up at a various stage or adjusted it to their preferences. The interview transcripts, the verbal and visual content of the documentaries are analyzed. An initial coding scheme was developed based on the steps identified in the KonMari method as well as the three key stages of possession, organization, and dispossession in the literature. The analysis built on continual comparisons between the data collected from different participants.

ANALYSIS AND INTERPRETATION

It is an interactive process to redefine the place of an object in one's heart and one's house. While the KonMari steps are linear with a rigid procedure, depending on participants' symbolic classification and how flexible it can be, they may experience a different level of challenges.

Personified Objects

In understanding one's true feelings toward an object, Kondo recommends followers to treat it as a person, to thank it for its service, and to feel the intangible bond with the item. Many, even the converts, found it challenging to comprehend. Many participants rejected the idea of attaching narratives to the items, albeit understanding the logic behind it. Some were more familiar with the exercise because it's natural to them: *"I guess it's a cultural thing. My parents always told me to respect the stuff I have, to take care of them and to appreciate their beings. Granted, I don't normally talk to them... or maybe sometimes I do. It's not that weird"* (Mai, 5 years with KonMari). The attached meanings and personalities do not seem to influence the process of dispossession as anticipated. In some cases, it supports the notion of discarding items: *"Well, I said thank you, and that's that. It's a bit sad, but hey, everything has it's time, right? Every story must come to an end. You can't hold on to things forever. I guess I just spent longer time to say goodbye."* (Mari, 5 years with KonMari).

Joy-Sparking Items

Everyone seemed to have their own interpretation and understanding of joy-sparking. Some were clearly struggling in defining happiness or hedonic value in items: *"I just don't get it, I'm sorry, Only God can spark joy, not stuff!"* (Boudoir, 2 months with KonMari). Even without the religious view, this is still challenging for some when concerning functional items, while others can easily justify happiness provided by the objects as it makes their life easier anyhow. On the other hand, happiness has been interpreted by the participants sometimes purely by the appearance, as in how they are pleasing to look at and that makes them happy. In general, happiness often is tied to their places in the symbolic system. As a participant described: *"I found it hard to feel if something sparks joy, because they are just stuff. So I just judge by if I can imagine their place in the house, or a place in my mind, if I will think about it in the future and put a smile on my face, I think then that's it."* (Karlie, 2 years with KonMari).

Possession or Dispossession

The KonMari method suggests participants to only keep an item if it makes them happy. Few participants who are possession-oriented believe this is a positive mindset that helps the process. They argued that the method eliminates the guilt feeling and force them to focus on what to keep. However, most participants found it easier to think about what to discard. Many believed the best part of the practice is to throw away items, even though they felt guilty to toss away usable objects. Many described the process as uplifting and refreshing. Some even suggested it being the "best part" or the "happiest moment" in the whole exercise. Depending on ones' symbolic classification and the ideal volume of items that they wish to have, participants would have their preferred approach in thinking about what to possess or what to abandon. People who have a more definite feeling in deciding what makes them happy were also more comfortable with thinking about what to keep. It seemed that the positive feelings and actions are linked together.

Act of Decluttering and Organizing

The method promises the participants that they would only need to do it once and they would be forever freed from the household mess. Only one participant agreed to the notion entirely. It seemed to be a more common idea that the participants experienced frustration once the system has been established. They appeared to restrict themselves to the classification they had created. The objects themselves became less important, but rather their place in the system was of paramount importance. Most participants had difficulties in keeping up with the restored order, and they consistently found themselves decluttering with the same or other methods, after the first practice. The most noticeable impressions from all participants, however, is the change in their perception about tidying up. It transcended from being a mundane activity to an almost enjoyable experience and triggered happiness in the process. The one-off promise seemed to have created happiness by being an "extraordinary" event in the participants' life. The ones who were self-proclaimed organizing enthusiasts experienced the joy in a different way. They thought getting decluttered is their passion and their way of life, where KonMari is just one of the methods used. It is doing what is part of them made them happy.

CONCLUSION

This research examines how consumers declutter their households and explore the role of happiness in the process. While most consumer research focuses on the two extreme ends of consumption

TABLE 1: Results Summary Table

THEMES	CATEGORIES	DATA INSTANCES
Personified Objects	Non-Personified	“I must confess, I have never thank my payslips or my t-shirt for a job well done. I know she said that we should treat all items as if they have feelings and personalities, but I just can’t resonate with that, why would payslip have feelings? I understand that we need to show appreciation, but I just can’t go that far”
	Personified	“I guess it’s a cultural thing. My parents always told me to respect the stuff I have, to take care of them and to appreciate their beings. Granted, I don’t normally talk to them...or maybe sometimes I do. It’s not that weird”
Joy-Sparking Items	Happiness can’t be found in objects	“I just don’t get it, I’m sorry, Only God can spark joy, not stuff!”
	Happiness found in objects	“Things that are useful and that you use, whether they look lovely or not, they do spark joy. Because they serve a very useful function and help you do things easier/faster/better, that’s a kind of joy isn’t it?”
	Happiness found in symbolic system	“I found it hard to feel if something sparks joy, because they are just stuff. So I just judge by if I can imagine their place in the house, or a place on my mind, if I will think about it in the future and put a smile on my face, I think then that’s it.”
Possession or Dispossession	Possession-oriented	“because it releases you from the guilt of getting rid of things. Plus you’re deciding what to keep, not what to get rid of, and I think this will help you declutter more thoroughly.”
	Dispossession-oriented	“I just really need a fresh, clean start. I do feel guilty throwing things out, but then it also teaches me that I should stop buying craps. I mean it’s not like I’m a hoarder, I just apparently had a tendency of buying random stuff that doesn’t make me happy. Not anymore! So I guess like she [Marie Kondo] said they still serve a purpose, even though I threw them away, they taught me a lesson”
Act of Decluttering and Organizing	Creating experience	“I dreaded to start, though I have heard about it for so long. But the week that I finally put myself through it, I was just so happy. I feel like I’ve done something for myself and now I’m living a happier, less stressful life because of that.”

and anti-consumption, consumers’ daily life constitutes of constant negotiations where they establish boundaries and make choices. In line with the prior study, our results suggest that the object-subject relations seem to be an essential element in defining consumer happiness (Dion, Sabri & Guillard, 2014). The symbolic classification system serves as the primary anchor for consumers’ decision in possession and dispossession, along with the organization of objects. In some cases, material consumption and the objects themselves do bring happiness, especially for those consumers who personify the objects and attach a hedonic value to items. However, this alone is not enough to sustain the object-subject relations. The things must be organized into the symbolic classification system. Only when an item has a place, it is considered serving a purpose and fulfilling its role in enriching the subjects’ life. Consumers are often bounded by the system, and once the objects are in the system, the cause of happiness and unhappiness is attributed to the system rather than the objects themselves. This highlights the importance of maintaining the order of the system. Contrary to the previous belief that organizing can be daunting and tedious, the setup of the KonMari method creates an extraordinary experience that often results in a high level of happiness (Bhattacharjee & Mogilner, 2014). This suggests that the dynamic process of establishing a symbolic system is also critical to the consumer happiness. Other than gaining control and feeling relieved, a sudden shock in the object-subject relation also seems to generate new feelings and revitalize the relationships which move objects through the cycle of possession, origination, and dispossession. This process, to a larger extent, is beneficial for consumer well-being.

ABSTRACT

We examine how the interplay of partners' interpersonal orientations in a decision-making dyad impacts the joint decision quality. Using both subjective (satisfaction) and objective (deviation of joint decision from partners' individual preferences) measures of decision quality, we show that altruistic/altruistic dyads make worse joint decisions than altruistic/selfish dyads.

STUDY 1

The purpose of Study 1 was to examine how the interplay of decision-making partners' interpersonal orientations impact the quality of their joint decision. In this study, we used (1) post-consumption satisfaction as a measure of perceived decision quality and (2) gender as a proxy for participants' interpersonal orientation. Past research robustly demonstrates gender differences in interpersonal orientations, such that women are more communal and are thus more likely to exhibit an altruistic orientation and incorporate others' preferences in their decision-making. However, men's agentic nature leads them to typically embrace a more selfish orientation, placing greater importance on the self and one's own preferences and goals (e.g., Balkan 1966; Eckel and Grossman 1998).

Method

We recruited 168 undergraduate students from a large southeastern university to participate in Study 1 in exchange for course credit. We paired each participant with a partner, making an effort to ensure we had approximately equal sample sizes across the three dyad types - male/female dyads, male/male dyads, and female/female dyads, which, according to previous literature should serve as a simple but robust proxy for selfish/altruistic, selfish/selfish, and altruistic/altruistic-oriented dyads, respectively.

To ensure ecological validity of the decision-making process, we first asked participants to complete the relationship closeness induction task (RCIT) together in order to familiarize themselves with each other and establish relationship closeness (Sedikides et al. 1999). Next, we presented the dyads with the focal joint decision. Specifically, we gave each dyad 10 movie posters and descriptions taken from IMDB.com of upcoming unreleased films. We asked the dyads to jointly choose which movie trailer they would like to watch together later in the study session.

Once participants made their decision, we asked them to answer several questions about their decision process individually on the paper questionnaire. Specifically, we asked participants to rate how "happy," "satisfied," and "disappointed" they were with the decision-making process on a nine-point scale (1=Not at All, 9=Very). We averaged these items to create an index measure of decision process satisfaction ($\alpha = .68$). Participants also individually rated their agreement on nine-point Likert scales with three statements intended to capture decision regret: "I think there is a better movie trailer on that list that we should have picked," "I feel sorry that we made this movie trailer choice," and "I regret the movie trailer choice we made" ($\alpha=.71$).

Next, participants watched their selected movie trailer together on the iPad. Then they responded to the same three satisfaction items

and feelings of regret that followed the decision task. However, we adapted these items to measure their satisfaction with the consumption experience ($\alpha=.95$) and feelings of regret with the consumption experience ($\alpha=.84$). We refer to these measures as post-consumption satisfaction and regret and their represent our focal measures of joint decision optimality in this study. Additionally, we asked participants to individually respond to items regarding the "ownership" of the decision making process. Specifically, we asked participants which partner in the dyad was most "responsible" for the movie decision, who "contributed" more to the decision, and whose "preferences" were more reflected in the movie choice using nine-point scales (1=definitely my partner, 9=definitely myself; $\alpha = .85$). The study concluded with demographic questions.

Analysis and Results

We excluded two dyads who failed to indicate their gender, and one dyad which included an individual who was a clear outlier in age (42 years old, $M=20.5$). Thus, the final usable sample consisted of 81 dyads, or 162 individuals.

Manipulation check

First, we note that in line with prior research, gender was a statistically significant proxy for selfish/altruistic orientation, as males reported significantly higher ownership of the decision ($M_{males}=5.38$) than females ($M_{females}=4.85$; $F(1, 158)=6.53, p=.012$). Partner's gender was also a significant predictor of ownership, such that having a male partner reduced one's ownership of the decision ($M_{male\ partner}=4.88$ vs. $M_{female\ partner}=5.35$; $F(1, 158)=5.00, p=.027$). The interaction, however, was not significant ($F(1, 161) = .091, p=.76$). Given the success of this manipulation we refer to dyads by their interpersonal orientation - selfish/selfish, selfish/altruistic, altruistic/altruistic.

Joint decision optimality

In this study, we measured decision optimality using post-consumption satisfaction and regret. Using a one-way ANOVA we found a significant effect of dyad type on post-consumption satisfaction ($F(2, 161)=4.94, p=.008$). This effect is primarily driven by the fact that altruistic/altruistic dyads had significantly lower post-consumption satisfaction ($M_{altruistic/altruistic} = 6.80$) compared to both selfish/altruistic dyads ($M_{selfish/altruistic}=7.79$; $p=.005$) and selfish/selfish dyads ($M_{selfish/selfish}=7.71$; $p=.01$). There was no difference between selfish/altruistic and selfish/selfish dyads ($p = .83$). Importantly, there was no difference in the satisfaction of the altruistic and selfish partners in a mixed-orientation dyad ($M_{altruistic}=7.77, M_{selfish}=7.81$; $F(1,55)=.016, p=.90$).

Similarly, the effect of dyad type on post-consumption regret was also significant ($F(2, 161)=5.00, p=.008$) and also driven by significantly higher regret among altruistic/altruistic dyads ($M_{altruistic/altruistic}=2.76$) relative to selfish/altruistic dyads ($M_{selfish/altruistic}=2.12$; $p=.030$) and selfish/selfish dyads ($M_{selfish/selfish}=1.85$; $p=.002$).

Additional analysis

We first found that there was no effect of dyad composition on decision process satisfaction ($F(2, 161)=1.32, p=.27$) and only a marginal difference in regret prior to consumption ($F(2, 161)=2.55,$

$p=.081$). Participants felt relatively positive about their decisions prior to consumption, regardless of dyad type ($M_{\text{altruistic/altruistic}}=7.50$, $M_{\text{selfish/altruistic}}=7.29$, $M_{\text{selfish/selfish}}=7.83$), suggesting that the joint consumption experience (rather than the decision-making process) drives the differences among the three types of dyads on post-consumption satisfaction and regret.

Discussion

Study 1 demonstrates that the interpersonal orientations composition of dyads alters the quality of the joint dyadic decision (captured by post-consumption satisfaction and regret in this study). When deciding together altruistic/altruistic dyads were less satisfied and reported higher regret post-consumption than either selfish/altruistic dyads or selfish/selfish dyads.

While our manipulation check results are in line with prior research that suggests that women are generally more altruistic than men (Eckel and Grossman 1998), a limitation of this study is that the indirect assessments of consumers' selfish or altruistic motivations leaves open the possibility of a variety of alternative explanations based on gender. To account for these alternative explanations, we manipulate participants' interpersonal orientations in study 2.

Another limitation of study 1 is that our measure of decision quality—post-consumption satisfaction and regret—was subjective. Therefore, in study 2, we objectively measure the quality of the joint decision by collecting individual preferences information prior to the study and comparing the deviation of the final joint decision to the individual preferences of the two decision-making partners.

STUDY 2

Method

Pre-study preferences

We recruited 384 participants at a large northwestern university to participate in study 2. Several weeks prior to the study we asked participants to rank and rate seven music videos. This allowed us to establish participants' true, independent preferences prior to any manipulations or meeting their partner.

Procedure

When participants arrived for the study, we randomly paired them with a partner in a small room. Each participant had their own iPad—where the manipulation took place and where they responded to individual measures—and in each room there was a computer for participants to make a joint decision and watch the music video together.

To manipulate the selfish vs. altruistic interpersonal orientation, participants were randomly assigned to read a news article about new research which suggested either (1) that people who make a decision with their own interests in mind are happier (selfish motivation) or (2) that people who make a decision with a partner's best interests in mind are happier (altruistic motivation). Thus, there were three possible dyad combinations: selfish/selfish, selfish/altruistic, altruistic/altruistic.

Next the dyads jointly choose a music video to watch later in the session. They were presented with the seven options they had rated and ranked individually several weeks prior. After making their joint choice, participants watched the music video together.

Finally, participants responded to a manipulation check measure of interpersonal orientation ("In the joint music video decision that you made, whose preferences did you look out for?" to which participants responded using a 7-point Likert scale (1 = My preferences, 9 = My partner's preferences) and demographic questions.

Analysis and Results

Manipulation check

Participants in the selfish condition reported looking out for their own preferences during the decision significantly more than those in the altruistic condition ($M_{\text{selfish}}=4.57$ vs. $M_{\text{altruistic}}=5.07$; $F(1, 377)=7.41$, $p=.007$). The partner's interpersonal orientation condition and the interaction of the two conditions did not significantly predict the selfishness of the participant, providing further evidence that our manipulation was successful. Gender had no main effect on the manipulation check and did not interact with the manipulation.

Joint decision optimality

First, we examine pre-study *rankings* of the music video chosen by the dyad as an objective measure of decision quality. Thus, lower numbers indicated greater pre-study preference and an objectively more optimal joint decision. In a one-way ANOVA, we found a significant effect of dyad type on the quality of the dyad's decision ($F(2, 383)=3.02$, $p=.05$). Specifically, altruistic/altruistic dyads ended up with lower-ranked (worse) options ($M_{\text{altruistic/altruistic}}=3.76$) compared to a mixed-orientation dyad ($M_{\text{altruistic/selfish}}=3.15$; $p=.02$). There was no difference in the decision quality between selfish/selfish dyads and mixed dyads ($M_{\text{selfish/selfish}}=3.53$; $p=.19$) nor any difference between altruistic/altruistic dyads and selfish/selfish dyads ($p=.51$).

Next, we examined participant's pre-study *ratings* of the jointly chosen music video as another objective measure of decision quality. Higher numbers indicate greater pre-study preference and hence a better decision. Using a similar one-way ANOVA, the effect of dyad type was marginal ($F(1, 381)=2.71$, $p=.07$). The contrast between the altruistic/altruistic dyad ($M_{\text{altruistic/altruistic}}=4.28$) and mixed dyad ($M_{\text{altruistic/selfish}}=4.86$) was significant ($p=.03$), however, the contrasts between the selfish/selfish and the altruistic/altruistic dyads ($M_{\text{selfish/altruistic}}=4.45$, $p=.63$) and the selfish/selfish and mixed dyads were not significant ($p=.17$).

Discussion

Study 2 replicates the findings of Study 1 and demonstrates that when both members of a dyad are altruistic, worse decisions are made, measured objectively, compared to when one member is selfish and one member is altruistic.

CONCLUSION

The results of our studies suggest that dyads in which both partners have an altruistic orientation and seek to make decisions that benefit their partner make less optimal decisions than dyads in which one partner has an altruistic orientation while the other one has a selfish orientation. Decision optimality was captured by both subjective and objective measures, that is post-consumption satisfaction (Study 1) and deviation of the joint decision from the partners' personal preferences (Study 2). In other words, in a dyad there needs to be a "driver" of a decision and a "passenger" to get the most optimal outcome. Two "passengers" and two "drivers" leads to less optimal decisions.

Our work makes important theoretical contributions to the joint decision-making literature by being the first to examine how the interplay of interpersonal orientations (altruistic vs. selfish) within a decision-making dyad impacts the quality of the joint decision. Importantly, our research also provides clear recommendations for joint consumer decisions. First, partners in a decision-making dyad should attempt to sense the interpersonal orientation of their partner. If both partners are looking out for each other's interests (i.e. both partners are being altruistic), one partner should take the lead and state their individual preferences since this will lead to a more optimal decision

for both partners. Second, our research implies that partners within a couple should find different areas of expertise where they can lead and their partner can follow. This would result in a natural altruistic/selfish orientation within the couple which should lead to better joint decisions.

Tra il Dire e il Fare c'è di mezzo il Mare*: An Investigation into the Ethical Purchasing Gap

*Italian Proverb: Between Saying and Doing is half a Sea

Andreas Plank, University of Innsbruck, Austria

INTRODUCTION

Ethical consumption practices such as purchasing Fair Trade (FT) products are common at the turn of the 21st century (Andorfer and Liebe 2015). Just as the consumption of FT products is increasing (Krier 2008) so is research on ethical consumption in general and FT consumption in particular increasing (see Andorfer and Liebe 2012, Papaioikonomou et al. 2011 for reviews). Prior research has investigated the discrepancy between individuals' self-reported attitudes, intentions or purchasing and actual purchasing behavior under the notions of attitude-behavior gap (e.g., Kim et al. 1997), intention-behavior gap (e.g., Hassan et al. 2016), and ethical purchasing gap (e.g., Bray et al. 2011; Nicholls and Lee 2006). The theory of planned behavior (TPB; Ajzen 1985, 1991) has been the theoretical framework for many studies on ethical consumption. However, many studies on ethical consumption applying this theoretical framework, end up investigating individuals' buying intentions as the final outcome variable rather than individuals' actual buying behavior and thus these studies do not fully reflect the TPB (Andorfer and Liebe 2012). To date no study that builds on the TPB has compared the effects of driver and barrier variables on FT purchasing intentions and observed FT purchasing behavior. This study seeks to close this gap by combining observation in the field with a survey in the context of FT coffee consumption.

THEORETICAL BACKGROUND AND HYPOTHESES

In a nutshell, the TPB postulates that attitude, subjective norm, and perceived behavioral control impact behavioral intention which in turn impacts behavior in a specific situation (see Ajzen 1985; 1991). In the context of FT consumption several studies build on and extend the TPB (e.g., Chatzidakis et al. 2007; De Pelsmacker and Janssens 2007; Ozcalgar-Toulouse et al. 2006). However, the most prevalent methodological shortcoming of FT studies building on the TPB is that studies investigate consumers' purchasing intentions but not consumers' actual purchasing behavior (Andorfer and Liebe 2012). As a consequence, socially desirable responding might lead to an overestimation of FT consumption, which might result in a gap between stated and observed preferences due to unconstrained survey response methods (Auger and Devinney 2007). While research on ethical consumption grounded in the theoretical tradition of economics employs more incentive-compatible methods for data collection (e.g., choice experiments, Auger et al. 2003; conjoint experiments, De Pelsmacker et al. 2005; field experiments Arnot et al. 2006) these types of studies typically provide willingness to pay estimates but do not investigate consumers' motivations for their respective willingness to pay (Andorfer and Liebe 2012). In this respect prior research suggests that a combination of research methods could further improve our understanding of ethical consumption and the ethical purchasing gap (e.g., Andorfer and Liebe 2012; Auger and Devinney 2007). This study seeks to contribute to the extant literature on FT consumption by combining observation in the field with a survey and answering the following research questions (RQs):

RQ 1: Which factors differentially drive and impede FT purchasing intentions and FT purchasing behavior?

RQ 2: How do consumers who are inconsistent in terms of their FT purchasing intentions and FT purchasing behavior differ from

consumers who are consistent in their FT purchasing intentions and FT purchasing behavior?

In line with prior research on FT consumption building on the TPB (e.g., De Pelsmacker and Janssens 2007; Ozcalgar-Toulouse et al. 2006; Shaw et al. 2000; Shaw and Shiu 2003) this study hypothesizes that attitude has a positive effect on consumers' FT purchasing intentions and FT purchasing behavior:

Hypothesis 1: Attitude positively affects consumers' FT purchasing intentions (H1a) and consumers' observed FT purchasing behavior (H1b).

Building on Shaw et al. (2000), and in line with De Pelsmacker and Janssens (2007) this study disregards the construct subjective norm in its conceptual model. However, this study expects positive effects of both, ethical obligation and self-identity on consumers' FT purchasing intentions and behavior:

Hypothesis 2: Ethical obligation positively affects consumers' FT purchasing intentions (H2a) and consumers' observed FT purchasing behavior (H2b).

Hypothesis 3: Self-identity positively affects consumers' FT purchasing intentions (H3a) and consumers' observed FT purchasing behavior (H3b).

Building on Bray (2011) this study investigates the effect of perceived locus of control (Rotter 1966) instead of perceived behavioral control (Ajzen 1991) on FT purchasing intentions and behavior. More specifically, locus of control captures individuals' beliefs about their control over ethical dilemmas, with an external locus of control indicating an individual believes the ethical dilemma is beyond his control whereas an internal locus of control indicating an individual makes ethical decisions in defiance of conflicting social or situational pressures (Singhapakdi and Vitell 1991).

Hypothesis 4: Locus of control positively affects consumers' FT purchasing intentions (H4a) and consumers' observed FT purchasing behavior (H4b).

Typically, FT products sell at a price premium to conventional products in the respective categories. Several studies indicate that price and consumers' price sensitivities are among the most important barriers to FT consumption (e.g., Bray et al. 2011; Cailleba and Casteran 2010; De Pelsmacker et al. 2005).

Hypothesis 5: Price sensitivity negatively affects consumers' FT purchasing intentions (H5a) and consumers' observed FT purchasing behavior (H5b).

In a focus group study on barriers to ethical consumption Bray et al. (2011) find that inertia in purchasing behavior is a substantial barrier to purchasing ethical products. Likewise, De Pelsmacker and Janssens (2007) find that price, the effort to find FT products, as well as informants' lack of interest in FT products and breaking their habits of buying their usual brands are barriers to FT consumption.

Hypothesis 6: Inertia in purchasing behavior negatively affects consumers' FT purchasing intentions (H6a) and consumers' observed FT purchasing behavior (H6b).

Results on the effects of socio-demographic variables such as gender or age on ethical consumption remain inconclusive (e.g., Bray et al. 2011; De Pelsmacker et al. 2005). Given these inconsistent results, this study does not formulate formal hypotheses on the influences of socio-demographics on FT purchasing intentions and behavior but includes gender, age, and income as control variables. Figure 1 depicts this study's conceptual model.

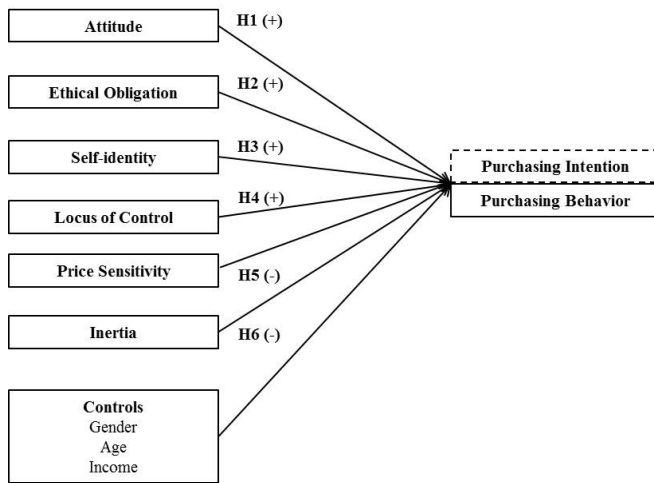

Figure 1: Conceptual Model

METHOD

This study combined observation in the field with a survey to test its hypotheses. Coffee vending machines at two campuses of a European university offered a unique data collection opportunity: The vending machines carry both, unlabeled and FT-labeled coffees. More specifically, all sorts of coffee (e.g., Cappuccino) are available both, as an unlabeled and a FT-labeled version. The unlabeled coffees sell at € 0.50 for 180 ml while the FT-labeled coffees sell at € 1.00 for 300 ml. That is, the price premium for FT-labeled coffees is 20.00%. Data were collected by first observing an individual's coffee choice (unlabeled vs. FT-labeled) and subsequently administering a questionnaire to willing consumers. Coffee choice was recorded first, to avoid that the questionnaire induces possible demand effects (Orne 1962). To incentivize participation in the survey, participants had the chance to win one of three shopping coupons (€ 25 each) for a major online retailer upon provision of their e-mail address at the end of the questionnaire. Data were collected on different weekdays, different times of the day, and two different campuses during 6 weeks in spring 2016. In the end the convenience sampling strategy yielded a total of 199 questionnaires.

To measure the drivers of- and barriers to FT purchasing this study either adapted prior studies' measures or derived measures from prior literature. More specifically, this study used three items to measure attitude (e.g., "In general, my attitude towards purchasing a Fair Trade product is favorable.", Shaw et al. 2000), two items to measure ethical obligation (e.g., "I feel that I have an ethical obligation to purchase Fair Trade grocery products.", Shaw et al. 2000), four items to measure self-identity (e.g., "I think of myself as some-

one who is concerned about ethical issues.", Shaw et al. 2000), two items to measure locus of control (e.g., "My life is determined by my own actions.", Halpert et al. 2011), three items to measure price sensitivity (e.g., "Fair Trade products should not be more expensive than ordinary products.", De Pelsmacker and Janssens 2007), and three items to measure inertia in purchasing (e.g., "I am not interested in fair trade products because I prefer my usual brands.", De Pelsmacker and Janssens 2007). All driver and barrier variables were measured using 7-point Likert-type scales. The questionnaire captured the socio-demographic variables gender, age, and income. As the cup size between regular and FT coffees differed (i.e. 180 ml vs. 300 ml) the questionnaire included an item (i.e. "How important was the cup size for your beverage choice?") to control for this potential confound in the analysis. The dependent behavioral variable was coffee choice (regular coffee = 0 vs. FT coffee = 1). To compare FT purchasing behavior with FT purchasing intentions the questionnaire additionally included an item to measure FT purchasing intentions (i.e. "The next time you go grocery shopping, how likely are you to purchase a Fairtrade product?", Shaw et al. 2000).

RESULTS

Multiple hierarchical regressions were used to test the hypothesized effects. First, only the demographic controls, then the hypothesized drivers, and finally, the hypothesized barriers were added to the regression model. With the addition of driver and barrier variables, the explained variance improved significantly from model 1 to model 2 (R -square change of .439 $F(4, 191) = 41.653, p = .000$) and from model 2 to model 3 (R -square change of .036 $F(2, 189) = 7.218, p = .001$) respectively. The results show significant positive effects of attitude, ethical obligation, and self-identity on FT purchasing intentions. Additionally, age has a significant positive effect whereas inertia in purchasing behavior has a significant negative effect on FT purchasing intentions (see Table 1, Panel A). Consequently, the analysis supports H1a, H2a, H3a, and H6a but rejects H4a and H5a.

In a second analysis this study investigated the effects of the potential drivers and potential barriers on observed FT purchasing behavior, controlling for socio-demographic variables. Furthermore, the control variable for cup-size was included in the hierarchical logistic regression model. First, only the demographic controls, next the control for cup-size, then the hypothesized drivers, and finally, the hypothesized barriers were added to model. With the addition of the control for cup-size as well as driver and barrier variables, the model fit improved significantly from model 1 to model 2 ($\chi^2(1) = 12.199, p = .000$), from model 2 to model 3 ($\chi^2(4) = 16.609, p = .002$), and from model 3 to model 4 ($\chi^2(2) = 10.880, p = .004$) respectively. The results show that the inclusion of the control for cup-size was adequate given its significant effect on observed purchasing behavior. Despite controlling for the effect of cup-size, the results of this analysis show that price sensitivity and inertia are significant barriers to FT purchasing behavior. Furthermore, attitude, ethical obligation, self-identity, and locus of control have no significant effects on FT purchasing behavior (see Table 1, Panel B). Consequently, the analysis supports H5b and H6b but rejects H1b, H2b, H3b, and H4b.

To further elaborate on the ethical purchasing gap this study compared consumers who exhibit consistent FT purchasing intentions and behavior with consumers who exhibit inconsistent FT purchasing intentions and behavior. First the variable purchasing intention was split at its median into a group high in FT purchasing intentions and a group low in FT purchasing intentions (i.e. observations at the median were excluded from this analysis, $n = 47$). Then, based on the newly calculated binary purchasing intention variable and observed purchasing behavior two groups were com-

pared applying multiple T-Tests with Bonferroni-Holm correction. The respective groups were (1) consumers who bought FT coffee and intended to buy FT products (i.e. consistent consumers, *n* = 69) and (2) consumers who did not buy FT coffee but intended to buy FT products (i.e. inconsistent consumers *n* = 41). The dependent variables were the drivers and barriers to FT consumption as well as the socio-demographic variables age and income. The results show that

inconsistent consumers are significantly more price sensitive ($M_{incon} = 4.35$; $M_{con} = 3.43$, $p = .001$), exhibit a higher level of inertia in purchasing behavior ($M_{incon} = 2.97$; $M_{con} = 2.31$, $p = .010$) and have a significantly lower income ($M_{incon} = 2.31$; $M_{con} = 2.91$, $p = .018$) than consistent consumers.

DISCUSSION

This study contributes to our understanding of FT consumption by showing that drivers of- and barriers to FT purchasing intentions and FT purchasing behavior differ substantially. This study shows that constructs based on the TPB have no effect on actual FT purchasing behavior, supporting prior research suggesting substantial gaps exist between consumers', self-reported ethical purchasing attitudes, intentions or behavior and actual ethical purchasing behavior (e.g., Auger and Devinney 2007; Bray et al. 2011; Carrigan and Attalla 2001; Hassan et al. 2016). Furthermore, the explained variance of consumers' FT purchasing behavior was satisfactory, lending support to the adequacy of a model of FT purchasing that takes into account driver as well as barrier variables and controls for sociodemographic variables. Additionally, this study sheds some more light on the ethical purchasing gap by showing that consumers who are inconsistent in their FT purchasing intentions and behavior differ in terms of price sensitivity, inertia in purchasing behavior, and income from consumers who show aligned FT purchasing intentions and behavior. That is, the FT price premium along with consumers' price sensitivities and income situation is a major obstacle to FT purchasing. Consequently, this study confirms prior research findings showing price and/or price sensitivity are important factors in the context of FT consumption (e.g., Andorfer and Liebe 2015; Bray et al. 2011; Hainmueller et al. 2014) and argues that TPB-based ethical consumption studies should include at least some attitudinal measure that accounts for the FT price premium (e.g., price sensitivity). As suggested by Bray et al. (2011) this study found that inertia is a significant barrier to FT purchasing that should be considered in future studies. This study shows that in the context of FT purchasing, consumers seem to be reluctant to change their usual purchasing and consumption habits. Overall, this study contributes to the literature on FT consumption by combining drivers of- and barriers to FT purchasing in an integrated model, building on the most commonly applied theoretical framework (i.e. TPB), controlling for socio-demographics, and comparing drivers' and barriers' effects on both, consumers' purchasing intentions and consumers' observed purchasing behavior. Prior research on ethical consumption calls for studies that capture actual behavior (Andorfer and Liebe 2012; Hassan et al. 2016) and this study's findings support such demands because predictors' effects differ substantially for purchasing intentions and behavior.

Furthermore, this study provides an implication for practitioners: While organizations promoting FT might not be able to reduce prices or consumers' price sensitivities, inertia in purchasing behavior is a barrier to FT consumption that could be more amenable to change. In this respect classical measures to raise awareness and motivate consumers to try something new (e.g., short term price promotions, advertising) might be effective in decreasing inertia in purchasing behavior.

Men will be Men, Women will be Women: The Case of Cross-Gender Brand Extensions

Aravind Reghunathan, Indian Institute of Management Kozhikode, India

Joshy Joseph, Indian Institute of Management Kozhikode, India

ABSTRACT

The paper examines the current popularity of cross-gender brand extensions, based on its theoretical foundations in branding and gender differences in information processing strategies. We argue that consumers experience a situation of gender-salience in the case of cross-gender brand extensions, resulting in gender-differential responses towards the practice.

INTRODUCTION

“Definitely male!” said the tagline of Bajaj Pulsar motorcycle in one of their most popular advertisements. Extant literature in marketing has found that many of the brands in the marketplace possess gender identities (Grohmann 2009; Avery 2012). Consumers tend to place brands such as Davidoff, Marlboro, Lego in masculine category and Lancôme, Barbie, Chanel in feminine category (Jung and Lee 2006). At the same time, a recent phenomenon shows certain brands, usually associated with any one particular gender, extending into the opposite gender category using the same brand name. ‘Pond’s’, which has traditionally been perceived as a feminine brand, extending to the men’s segment with ‘Pond’s Men’ is a case in point. This practice, called cross-gender brand extensions, is a clear departure from the conventional branding practices of companies employing two different brands to target the two different gender segments or having a single brand that does not have a clear gender identity. This paper examines the current popularity of cross-gender brand extensions, based on its theoretical foundations in branding and gender differences in information processing strategies. We argue that the gender-differential responses to this practice can be explained by a situation of gender salience, stimulated in the consumer’s self-concept when the original brand gender associations are changed to target the opposite sex. Adding a novel perspective using gender differences in information processing, the paper advances the current understanding of cross-gender brand extensions.

THEORETICAL FOUNDATIONS

Brand Personality

Extant literature in marketing recognizes brand personality perceptions in consumer psyche, developed by consumers themselves or created as a result of specific strategies employed by brands. Aaker (1997) has given a commonly accepted definition of brand personality as “the set of human characteristics associated with a brand.”

Consumers tend to associate brands with human personality characteristics, as a result of the strategies used by advertisers (e.g. Coke projected as cool and all-American). Popular among these advertising strategies include anthropomorphization, personification, and the use of user imagery (Aaker 1997). McCracken (1989) argues that the transfer of personality traits to a brand is directly possible through the people associated with it. Consumers tend to form associations about the brand thinking about the brand’s user imagery, the company’s employees or CEO (e.g.: consumers may perceive the brand Virgin to be different based on the traits of its founder-CEO Richard Branson), or celebrity endorsers. The transfer of human personality traits can also happen in indirect ways such as consumers imbibing them through product-related attributes, forming associations about the particular product category, brand name, advertising style, logo, and other variables in the marketing mix (Batra, Lehm-

ann and Singh 1993). Fournier (1998) argued for the validity of relationships in brand-consumer context and added that consumers see brands as active relationship partners when they can connect with their own self with the brand, thus gender being a major dimension. The final purchase decision is shown to be influenced by this “one-to-one correspondence” between brand personality and the personality of the consumer (Mathews 2015).

Adding on to the personality characteristics, researchers including Levy (1959) suggest the addition of demographic features such as age, gender (“Usually it is hard to evade thinking of inanimate things as male or female”), and class to the symbolic language of different objects. Subsequently, Aaker’s definition (1997) also has encompassed demographic descriptions (i.e. age, gender, and socioeconomic status), human personality traits, and lifestyle characteristics as part of brand personality (Hayes, Alford, and Capella 2008). Taking cue from this stream of arguments, we explore the gender characteristic of a brand as the base for a brand’s gender crossing.

Brand Gender

Companies convey masculine or feminine characteristics to brands in order to differentiate products and to attract gender segments into their customer basket (Fugate and Philips 2010). Strong masculine and feminine brands are considered high on one of the two gender traits (that is, masculinity would be high for masculine brands, but they have low femininity, and vice versa). This intensity of brand gender makes their positioning in the market easily recognizable, contributes to brand equity and helps the consumers to categorize the brands with high degree of certainty into one of the gender segments (Lieven et al 2014).

Till and Priluck (2001) have observed that in many product categories such as jeans, cologne, and cigarettes, brands utilize masculine or feminine images in their advertisements to project their brand as more appealing to the target audience. Thus, marketers use classical conditioning as a mechanism for transferring gender perception in consumers’ minds. A common strategy is making use of celebrities or affixing a celebrity name to the brand (e.g.: Beyonce’s Heat perfumes or Someday by Justin Bieber, Michael Jordan shoes). McCracken (1986) argued that consumers exercise the appealing meanings out of products to categorize themselves into appropriate gender, age, and social class groups. Based on an individual’s self-perception, gender meaning can be a salient brand attribute that enhances the likelihood of purchase. In addition, the degree of masculinity or femininity influences purchase behaviour and people tend to favour products associated with their own gender (Alreck, Settle, and Belch 1982). Specifically, men prefer brands with masculine positioning and women prefer ones with feminine positioning (Till and Priluck 2001). Hence, a brand with an established gender positioning crossing over to the opposite gender category makes for interesting research.

Consumer Evaluations of Brand Extensions

Investigations about the various factors in consumer evaluations that influence success of brand extensions have figured prominently in extant branding literature (Morein 1975; Chernatony and McDonald 1998; Ahluwalia 2008; Loken, Ahluwalia, and Houston 2010). The extension’s perceived fit with the parent brand is considered to be a crucial factor leading to favourable consumer evaluations (Ahlu-

walia 2008; Kim and Yoon 2013). Generally, fit can be considered as the “extension’s perceived similarity to the parent brand” (Ahluwalia 2008). This is in terms of product category and attributes (e.g., product features, image, benefit, user imagery, usage situations) that can be classified as product or non-product-attribute-related associations (Bridges, Keller, and Sood 2000). Categorisation theories also (e.g. Lee and Sternthal 1999; Cowley and Mitchell 2003) suggest that if consumers observe connection or ‘fit’ between the parent brand and the extension, they tend to transfer the positive affect associated with the brand to the latter (Aaker and Keller 1990). A brand extension is more likely to be accepted when consumers sense commitment, trust, and/or liking for the parent brand or have had experience using the parent brand, when the extension is consistent with the core brand image or brand associations of the parent brand, and when the focus of the information about the brand extension includes favourable relevant information (Loken, Ahluwalia, and Houston 2010).

Several product development strategies, such as increasing brand breadth (Dacin and Smith 1994; Wu and Yen 2007), maintaining quality consistency (Dacin and Smith 1994), and generating brand extension synergies (Shine, Park, and Wyer 2007) also influence consumer perceptions, thereby leading to success or failure of the extension strategy. Research also points to the importance of retail environments in which brand extensions are exposed to consumers. Firms carefully choose retail locations that best reinforce their brand’s image (Joachimsthaler and Aaker 1997; Smith and Burns 2013) and that maintain consistency between a brand’s image and the retailer. In summary, it is clear that the factors in consumer evaluations of a conventional brand extension are generic to any brand extension strategy. However, the inherent nature of disturbing the gender status-quo would result in consumers being influenced by an additional set of factors in the case of cross-gender brand extensions.

Cross-Gender Brand Extensions

Gender stereotyping in consumption

Individuals often attempt to “create, enhance, and accomplish gender identities through consumption and, thus, our possessions function as symbolic gender identity markers” (Avery 2012). Penaloza (1994) argues that existing consumer cultures in a society dictate what is proper (and improper) to acquire or consume for each gender. Extant research in marketing has indicated brands as one of the markers we use to express our gender (Stern 1988; Palan 2001). Consequently, men and women have a preference towards brands, possessions, and practices that goes in tandem with their gender identity. Azar (2015) distinguishes three types of sexual attributions to brands within brand-as-a-person metaphor: brand sex as a demographic characteristic; brand gender as a personality characteristic; and brand sexual orientation as a behavioral characteristic. In this study, we consider brand gender as a personality characteristic, which is also in line with Levy’s argument (1959) that personality includes gender as a characteristic.

Cross-Gender Brand Extensions

Men and women, both, engage in ‘gender-bending consumption’, which is, adopting the consumption practices and products of the opposite sex to partake in redrawing the definitions of gender and give rise to novel ideologies (Avery 2012). Appropriating men’s consumption symbols to stand for gender fairness in the wave of feminism was the starting point of this paradigm shift (McCracken 1988; Hollows 2000). This was characterised by women patronizing cigarette smoking, short haircuts, and masculine fashion styles. On the other side, the metrosexual ideology emerged as an alternative to the prevailing concepts of masculinity and gave men the confidence

to choose products that had traditionally been linked with female or homosexual consumption (Crane 1999). These movements can be seen as attempts to redefine the boundaries of gender-based consumption and questioned the conservatives consciously or unconsciously dictating what is appropriate to consume for each gender category.

However, gender still occupies a prominent position in marketing. Brands usually associated with any one particular gender are often seen to target the opposite gender group by employing altogether different brand names. Philip Morris, which has the brand ‘Marlboro’ for men employs ‘Virginia Slims’ to cater to the women-folk (Alreck et. al 1982). At the same time, certain recent examples indicate gender-bending of brands by marketers, whereby products that had traditionally been focused at one sex are made appealing to the opposite gender without changing the brand name (Jung and Lee 2006; Ulrich 2013). The growing number of examples include Estee Lauder extending their ‘Pleasures’ perfume brand to men’s segment and Gillette targeting women with the same brand name offering. Considering the fact that cross-gender brand extensions are becoming popular even when gender identities of brands are not yet erased, how consumers evaluate and form attitudes about the same would influence the success of the practice.

Consumer Evaluation of Cross-Gender Brand Extensions

Gender studies have observed that in modern societies, masculine traits are likely to be placed higher than traditional feminine traits (Bem 1993; Kramer 2005). Consequently, the superior social appeal for masculine characteristics would be reflected in the consumer behaviour towards products as well as brands by consumers. This view is in line with past research which suggested that men will mostly reject feminine brands while women will most likely accept masculine brands (Alreck et. al 1982; Wolin 2003). According to this school of thought, using feminine brands carries a greater stigma for men than using masculine brands does for women (Borgerson and Schroeder 2004; Rinallo 2007; Avery 2012). Penaloza (1994) argues that the tendency for women crossing into the male domain by altering their dressing styles are viewed rational because of the higher number of men with money and power, when compared to women. Subsequently, for a man to cross into the feminine realm by trying clothes associated with women is to keenly follow its stigma. The phenomenon is referred to as “opposite sex rejection” (Alreck 1994), and is evident in our daily lives. Extant research in cross-gender brand extensions also points towards the impact of biological sex of consumers on the extension’s acceptance. Specifically, women are found to be more receptive when a typically masculine brand crosses over to the feminine category, than men when a feminine brand attempts to cross over to their category (Jung and Lee 2006). This essentially implies that the direction of the cross-gender extension also affects the success of the strategy.

Grohmann (2009) contended that consumers’ sex role identity and their brand personality-self-concept congruence in terms of masculine and feminine brand personality would influence their affective, attitudinal, and behavioral brand-related responses. This essentially recognizes gender as a multifactorial construct and maintains that gender, of the brand and of the consumer, influences the consumer attitude towards cross-gender extensions. The success factors of gender-based brand extensions are in line with the conventional extension literature and in addition, factors arising due to the characteristics associated with extending to the opposite gender category also play a significant role. Jung and Lee (2006) have established that the gender of a brand, gender of consumers, and product type influence the evaluation of cross-gender brand extensions.

Gender differences in information processing strategies

Consumers differ, according to gender, in evaluating products and services, decision processes, information searches, and attitudes towards marketing mix strategies (Gunay and Baker 2011). Men are said to be “selective processors” who depend on heuristics or overall themes for their decisions, whereas women are characterized as “comprehensive processors” who focus on integrating detailed information (Meyers-Levy and Maheswaran 1991; Meyers-Levy and Sternthal 1991).

In this paper, we propose that a gender-salience situation arises when a gendered brand crosses over to the opposite gender category. Psychologists have recognized situations of gender salience, where human behaviour can be affected by stimulations in gender-related elements of the self-concept (Deaux and Major 1987; Spence 1993). Specifically, they suggest that gender assumes salience when immediate situational cues prompt, such as the proportion of men and women in our environment; through the actions of another person in a specific context (e.g. when a man asks the opinion of a woman about something and she feels important); when the gender-related aspects in the self-concept are frequently stimulated (e.g. materials strongly associated with one gender, such as cooking utensils with women as opposed to mechanical tools); or the individual has the gender component central to his/her self-concept (e.g. school children who came from households where their sex is a minority are likely to mention gender in self-attributes (McGuire, McGuire, and Winton, 1979). The situational cues arising out of a change in the original brand associations due to a cross-gender brand extension may stimulate the gender-related elements of the consumer's self-concept (Ulrich 2013). Extant research in marketing has shown that the congruency between the consumer's gender and the brand gender leads to favourable evaluations for the brand (Grohmann 2009). We argue that a cross-gender brand extension shakes the consumers' original gender perceptions about the brand. This effect, in turn, would reflect in the consumer evaluations of both the parent brand and the extension. Several researchers have observed that significant results tend to be obtained from studies showing men and women differ in decision making and purchase behaviour in situations where gender was salient (e.g.: Ulrich 2013; Palan 2001). Thus, the paper contributes to strengthening the case for considering gender-salience in marketing research.

MANAGERIAL IMPLICATIONS

In case of a cross-gender brand extension strategy, practitioners may build favourable evaluations for the brand by positive gender associations related to the target consumers. They may also take care not to stimulate situations of negative gender salience. As an illustration, promotional activities featuring a celebrity who has a strong gender identity same as that of the target group may be employed to differentiate the extension from the gender identity of the parent brand. Another practical implication is in choosing the retail environments in which brand extensions are exposed to consumers. For example, a cross-gender extension targeting men may use retail props projecting several heuristics or overall themes to differentiate the brand from its parent brand gender. On the other hand, targeting women for the extension may require retail settings focusing on integrating detailed information about the extension's brand gender.

A Cultural View on Healthcare Access: Considering the Hispanic Perspective

Sharon Schembri, University of Texas Rio Grande Valley, USA

Suad Ghaddar,, University of Texas Rio Grande Valley, USA

ABSTRACT

This research provides a cultural perspective on healthcare access with a specific focus on Hispanic consumers. The research question of how Hispanics experience healthcare access is addressed with 24 phenomenological interviews. The findings are presented as emergent themes: affordability, access and resistance, and consequences of a lack of healthcare access.

Keywords: Healthcare, Hispanic consumer, consumer culture, phenomenology

INTRODUCTION

This research addresses the question of how Hispanics experience healthcare access. Access to healthcare was proposed by the United Nations (UN) in 1948 and again in 2012 as a human right (UN 2012), which is a policy position supported by the United States of America (USA). Similarly, a key policy objective in the Organization for Economic Co-operation and Development (OECD) is to reduce health inequalities and to achieve adequate and equitable healthcare access (Devaux 2015). Accordingly, most OECD nations provide universal healthcare coverage (Pearson et al. 2016), with the exception of the USA (Davis et al. 2014). Ranked as the most expensive healthcare system globally (Lorenzoni, Belloni, and Sassi 2014; Mahon and Fox 2014), the USA ranks last on measures of quality of care, access, and equity (Brubaker et al. 2011; Davis et al. 2014; Mossialos et al. 2016).

Rather than universal coverage, USA employer-sponsored private insurance arrangements spread widely during 1940-1950 (Oberlander 2012), linking insurance to employment (Schembri and Ghaddar 2017). The 1965 establishment of Medicare and Medicaid was designed to accommodate the healthcare needs of the elderly and low-income households (Iglehart and Sommers 2015). More recently, the enactment of the Patient Protection and Affordable Care Act in 2010 enabled a significant decrease in the number of uninsured Americans with some 20 million adults gaining insurance and the greatest impact evident in African American and Hispanic minority groups (Office of the Assistant Secretary for Planning and Evaluation (ASPE) 2016). Yet, despite this progress, millions of American consumers remain uninsured with low-income (Milligan 2015) and minority consumers overly represented (Mitchell 2015). More specifically, across the USA and also in Texas, Hispanics show the highest rate of uninsurance (Marks, Ho, and Balihe 2015). Indeed, the negative social and economic impact of health inequalities is well documented (Brummer et al. 2016; LaVeist, Gaskin, and Richard 2011; Magge et al. 2013) and especially so amongst ethnic and racial minorities (Hunt and Whitman 2014; VanderWielen et al. 2015). Therefore, investigating the perspective of lower-income, minority, specifically Hispanic, consumers in terms of healthcare access is a timely and worthy question. To that end, this phenomenological investigation focuses on Hispanics and their experience of healthcare access.

CONSIDERING THE HISPANIC CONSUMER PERSPECTIVE

As the largest and fastest growing ethnic/racial minority in the USA (Ennis 2010) and representing 17% of the US population (US Census 2014), the Hispanic segment purchasing power is reported between \$1.2 and 1.5 trillion (Gonzalez and Monistere 2014; Nielsen

2012, 2015). However, rather than an identifiably homogenous group, there is much diversity within the 54 million Hispanic demographic (US Census 2014) with, for example, 63% of Mexican origin (63%), 9.6% from Puerto Rico, and 5.3% from Cuba (US Census 2010). As a predominantly collectivist culture, cultural values include familial relationships with primary reference groups including friends and family (Alvarez, Dickson, and Hunter 2014). Accordingly, overcompensation to children is high with documented higher spending in baby goods, hair care, and toiletries (Nielsen 2012). Hispanic brand loyalty is also reported as high because Hispanics are fear driven and risk-averse consumers (Korzenny and Korzenny 2012).

The challenge in engaging the Hispanic consumer with regards to healthcare is related to the documented disparities (Bleich et al. 2012; Ramirez, Thompson, and Vela 2013). Hispanics have significantly higher rates of diabetes (Brunk et al. 2015), obesity (Isasi et al. 2015), cancer (Shoemaker and White 2016), HIV and AIDS (Bonacci and Holtgrave 2016), and myriad other conditions (Martinez, Ward, and Adams 2015). Yet, the healthcare system is not necessarily designed to accommodate Hispanic needs. Compounding evident health disparities, proactive patient activation is low for Hispanics relative to non-Hispanics (Cunningham, Hibbard, and Gibbons 2011). As well, those without health insurance are less likely to seek health services and when they eventually do seek help, their health conditions tend to be more advanced (Cawley, Moriya, and Simon 2015). Little or no access to healthcare adversely affects health outcomes, increases morbidity and mortality, and increases healthcare costs, especially for minority groups (Reininger et al. 2012). While lack of health insurance and finances constitute formidable barriers for Hispanics to access healthcare, individual, interpersonal, and systemic influences are also substantial barriers (Reininger et al. 2012); personal influences include fear, denial, embarrassment, and unaffordability, interpersonal influences include culturally interpreted concepts of respect and effective communication, and systematic influences including healthcare access considered easier in Mexico than USA. Therefore, Hispanics are reluctant to access, likely choosing to delay care and prefer to access healthcare in Mexico (Su et al. 2011). Accordingly, there is a double jeopardy situation for Hispanics, where being uninsured as well as in poorer health means being at higher risk of needing medical care (Bruhn 2014).

METHOD

This research was conducted across two counties in South Texas, along the US-Mexico border. The population exceeds one million, is predominantly Hispanic (91%), with a median income less than \$35,000, 31+% living in poverty (US Census 2015), 39% uninsured (Smith and Medalia 2015), and with a high prevalence of obesity, diabetes, cancer, and heart disease (Ramirez et al. 2013). Existing at the periphery of the USA economy, the US-Mexico border community is distinct geographically, economically, culturally, and socially, and is subject to systematic economic, social, and health injustices (Lusk et al. 2012). As such, there is much need for access to healthcare and a phenomenological research design has been used to investigate the question of how Hispanics experience healthcare access.

For phenomenologists (Heidegger, 1962/1927; Husserl 1970/1900-1; Merleau-Ponty 1962/1945), the world is considered an experiential world where reality is assumed to be socially construct-

ed and meaning is based on the context. Generalizability therefore is not the goal but rather a depth of understanding (Hudson and Ozanne 1988; Schembri and Sandberg, 2002, 2011; Thompson, Locander, and Polio 1989, 1990). In this study, the research focus was to provide a contextually dependent depth of insight as to how Hispanic consumers access healthcare, which has been documented with 24 phenomenological interviews. Treating the interview transcripts as legitimate accounts of how Hispanics experience healthcare access, interpretation proceeded as a part to whole analysis of participant experience, as per Thompson et al. (1989, 1990). This analytical process began with repeatedly reading each of the transcripts in full to gain an initial understanding of the situation for each participant. From there, the set of interviews were considered more broadly and holistically and then segments and fragments were identified and contextually considered in relation to the whole. This part of whole analytical process continued to the point where recurrent meaningful themes began to emerge and stabilized. Then, significant statements were specifically identified as illustrative quotes of emergent themes. Note, the English grammar has not been corrected in the illustrative quotes presented to demonstrate the Hispanic linguistic context of these participants. As summarized in table 1, the emergent themes reported here are affordability, access and resistance, and the experiential consequences of the lack of healthcare access.

FINDINGS

This research addresses the question of how Hispanics experience healthcare access. From a series of phenomenological interviews and an interpretive analytical process, the emergent themes identified are affordability, access and resistance, and consequences of a lack of healthcare access. These findings are summarized in table 1.

Affordability

Given this research was conducted in one of the poorest areas of America, with almost a third of families living below the poverty level and nearly 40% uninsured (US Census Bureau 2015), cost constraints and affordability were a primary concern with regards healthcare access. Giving context to the financial consideration, Catalina (22 years) explains how very expensive her \$40 co-pay is. But Catalina is lucky because she has health insurance. Unlike Catalina, Matias (26 years) and his family do not and he explains how his mom was in hospital for nine days and will be paying that bill for the rest of her life. Like Matias, Ivanna (21 years) does not have insurance and neither does her younger sister. So when Ivanna’s sister had a kidney stone, they had to go to Mexico because *“we can’t really go to the hospital here [USA] because we know is really expensive.”* Similarly, 19 year old Elisa visited Mexico to go to the doctor on the weekend. She tells the story as a journey where the danger element is mentioned but largely dismissed.

“I’m so close to the border I can get very cheap medical assistance in Mexico. We drive over usually just in the mornings ‘cause you know it’s kind of a bit dangerous still. We have breakfast, pick up ice, and groceries, then we go to the doctor. We get our medicines and then we just come back. Usually we spend maybe two three hours.”

Access and Resistance

Beyond the lack of financial resources and health insurance, another constraint on healthcare access for Hispanics is the cultural orientation. Karen is 36 years old and works as an administrative

Table 1: Summary of findings on how Hispanics experience healthcare access

Theme	Summary	Illustrative quote
Affordability	In this low-income Hispanic context, affordability is given meaning with Catalina’s <i>“very expensive”</i> \$40 co-pay; without health insurance, Matias’ mother will be paying the bill for her 9-day hospital stay for the rest of her life; Ivanna’s younger sister went to Mexico to treat a kidney stone	<i>“We can’t really go to the hospital here [US] because we know is really expensive.”</i> (Ivanna, 21 years)
Access and resistance	Karen explains the Hispanic cultural orientation as a barrier to healthcare access; Elisa highlights the relational trust she experiences with Mexican healthcare service providers	<i>“...in the Hispanic community if we don’t have to go to the doctor we don’t go unless it is an absolute emergency. We are talking about bleeding and severe pain that you can’t control with a pill, [otherwise] we are not going to utilize ...I mean because anyone and everyone knows that whenever something is broken we [Hispanics] go to Mexico to fix it!”</i> (Karen, 36 years)
Consequences to lack of access	Jose is overweight with a thyroid problem and no health but explains he does not need healthcare access; even though Mateo had cancer as a child yet he too does not need healthcare access; Andrea explains the stress of not having healthcare access on her mother; Vanessa explains how working sick perpetuates illness; Daniela has never seen a doctor and is overwhelmed with not knowing the process; and Elisa’s parents are anti-doctor meaning the whole family lacks healthcare access	<i>“I just have colds and stuff it’s not a big deal.”</i> (Mateo, 24 years)

assistant in a dental office. She explains how the context of the Hispanic culture is a barrier to healthcare.

“...in the Hispanic community if we don’t have to go to the doctor we don’t go unless it is an absolute emergency. We are talking about bleeding and severe pain that you can’t control with a pill, [otherwise] we are not going to utilize”

Karen goes on to explain the Hispanic inclination to exit the USA in order to access healthcare.

“I mean because anyone and everyone knows that whenever something is broken we [Hispanics] go to Mexico to fix it!”

Multiple other participants discussed this cultural constraint and resistance to accessing healthcare even when it is available. In the following comment, Elisa highlights the quality of healthcare services she experiences in Mexico relative to the USA and the relational trust she experiences with her Mexican healthcare service provider.

“Here [USA] it’s a longer wait but there [Mexico] I just walk [in] and its empty so I just go in and sometimes I wait like thirty minutes if it’s busy. Here I use to go to the doctor and he [doctor] was like very busy, it was just a five minute thing [visit] and then he leave. I didn’t feel comfortable talking all my concerns and questions [but] over there like I guess since you trust a person [doctor] you know for a really long time you feel better over there in Mexico”

Consequences to Lack of Access

Given the financial, systemic, and cultural constraints on accessing healthcare, participants also brought to light consequences to a lack of healthcare access. Jose (33 years) for example is overweight with a history of thyroid problems and no health insurance. He explains that he does not need healthcare access because he does not get sick. This response from Jose mirrors the Hispanic cultural attitude towards healthcare access.

Manageable conditions left unattended may escalate unnecessarily, consequently requiring more resources when they are finally attended to. Other examples of this cultural orientation to healthcare access and the potential consequences are further demonstrated with Mateo’s situation. As a young child he suffered from cancer with healthcare access enabled through the Medicaid program. However, at 24 years of age, many years have passed since his last check up and he does not think he needs access. He says, “*I just have colds and stuff it’s not a big deal.*”

When there are complex medical needs, this non-attendance to manageable conditions is problematic not only for the individuals but also the immediate family in terms of worry and stress as well as the broader community in terms of financial burden. Andrea (20 years) highlights the stress of the situation when adequate healthcare access is not available.

“My mom is been I guess stressful and you know thinking ‘what about my kids get sick?’ ‘what about if they get in an accident?’ we have no way to be able pay the hospitals if we ever have to land at the hospital so it’s been very stressful, and then her work. It’s like work, us, the insurance. My grandma who is old and we have to take care of her I guess like is very stressful for my mom and you can tell by her face that she is stressed!”

Similarly, Vanessa (19 years) explains in the following comment the distress she feels in the face of not having health insurance and healthcare access. She explains that the fear of being unemployed, means working sick, possibly spreading the germs, and perpetuating the illness.

“If something happens to you or you feel sick you can’t go to the doctor and if you hate a job you can’t stop going to your job because you need the money and you’re just working sick and then people other people get sick ‘cause you’re sick and it’s like a little chain.”

At 23 years, Daniela explains that she has never seen a doctor and the consequence for her is that “*I don’t know the process, what to*

do, or what they accept in order to get checkups.” Not knowing the process seems overwhelming for Daniela to visit the doctor for the very first time. Elisa brings the point home in stating that “*my mom and dad, well my dad mostly, they’re like anti-doctor kind of thing.*” If mom and dad are anti-doctor then the family will lack access too.

CONTRIBUTION AND LIMITATIONS

This research has investigated the question of how Hispanics experience healthcare access. As such, the contribution of this work is a depth of insight on Hispanic healthcare access where the emergent themes of affordability, access and resistance, and the consequences of a lack of healthcare access have been documented. In line with the findings of Cunningham et al. (2011), Hispanic proactive health management is not evident. The findings presented here also confirm the findings of Reininger et al. (2012) that barriers to healthcare access for Hispanics include personal influences such as fear and unaffordability, interpersonal influences such as cultural interpretations, and systemic influences such as healthcare access considered easier in Mexico than USA. More than that, this work confirms the double jeopardy situation highlighted by Bruhn (2014), where uninsured Hispanics with complex healthcare needs are either delaying care or not accessing healthcare services. While this work confirms the work of Cunningham et al (2011), Reininger et al. (2012) and Bruhn (2014) from health, minority health, and health disparities literature, the contribution of this work is focused on a consumer behavior perspective.

This contribution is useful to policy makers and social marketers in the design of future policy and communications seeking to achieve an improved outcome for minorities. Policy makers are informed in terms of the challenges and barriers that Hispanic healthcare consumers are facing. Social marketers are informed in terms of Hispanic consumer needs and considered alternatives with regards to healthcare service utilization.

Beyond this contribution, a limitation of this work is the focus on consumers alone. Consumers are only one of many stakeholder perspectives that might inform the question of how Hispanics experience healthcare access. Other stakeholder perspectives that might be investigated include the myriad healthcare service providers and para-professionals. Focusing specifically on the Hispanic consumer perspective, however, has enabled documentation of the consumer views of this increasingly significant segment. More than that, the phenomenological research design has achieved a depth of insight not achievable with other research methods.

ACKNOWLEDGEMENT

The authors would like to thank the Public Health Action Support team at the University of Michigan, School of Public Health for their assistance with data collection. We would also like to thank Matthew Benavides, Patricia Garcia, Alyssa Garza, and Ruth Juarez for their invaluable assistance with recruitment and interview transcriptions.

This research was supported in part by the South Texas Border Health Disparities Center (STBHDC) at The University of Texas-Pan American (UTPA), now The University of Texas Rio Grande Valley (UTRGV). The contents of this manuscript are solely the responsibility of the authors and do not necessarily represent the official views of UTPA, UTRGV or STBHDC.

Brand-Mediated Ideological Edgework: Negotiating the Aestheticized Human Body on Instagram - The Case of American Apparel

Jonathan D. Schöps, University of Innsbruck, Austria
Philipp K. Wegerer, University of Innsbruck, Austria
Andrea Hemetsberger, University of Innsbruck, Austria

INTRODUCTION

Brands make vast use of social media platforms such as Instagram to connect with “cultural intermediaries” and engage consumers (Carah and Shaul 2016, 69). Recent research finds that consumers – on new sites such as Twitter or Instagram – rather use brands in an instrumental manner for self-presentation, publicity, self-branding or bragging (Arvidsson and Caliandro 2016; Marwick 2015; Presi, Maehle, and Kleppe 2016; Rokka and Canniford 2016). So, how can brands engage consumers? Contrary to these findings, the Instagram account of American Apparel (AA) – a fashion brand that is well known for its controversial visual ads – provokes considerable consumer reaction and gender-ideological discourse on Instagram. How do brands use visual rhetoric to initiate ideological discourse on otherwise quite self-centered social networking platforms? And how do these brand visuals mediate what Thompson and Üstüner (2015) denominate as consumer ideological edgework?

Ideological edgework refers to marketplace performances of consumers that “challenge orthodox gender boundaries, without losing sociocultural legitimacy” (Thompson and Üstüner 2015, 1). Thompson and Üstüner (2015) describe ideological edgework as a form of gender work, but focus on the consumer as primary actor. However, brands also play a significant role in the (de-)construction of social reality, and market morality. Prior research describes the active role of brands as facilitators of networked brand performativity (von Wallpach, Hemetsberger, and Espersen 2017), and as catalysts of moral coalition formation (Stoeckl 2014). Research on the facilitating and catalyst role of brands in ideological discourse is scant.

This study aims to investigate into the role of brands as mediators of ideological edgework on social networking sites. Our analysis focuses on the visual and textual discourse that enfolds on the Instagram account of American Apparel. We analyze the visual performances of the brand, as well as brand-mediated consumer practices, and how these practices co-construct (body) ideologies in the digital marketplace. Findings reveal three brand, and three consumer practices. The brand authenticates, sets agendas and sensitizes through provocative visual performances of the body. Consumers textually applaud, moralize, and negotiate. We introduce and discuss the notion of brand-mediated ideological edgework, point out limitations of this study, and offer future research possibilities.

THEORY

Brands and Consumers on Social Media

In the age of digitalization, social media became an indispensable medium for brands to connect, communicate, and interact with consumers. Scholars find that consumers do interact with brands on social media, but use brands merely as a mediation device to gain publicity, and self-promotion (Arvidsson and Caliandro 2016; Marwick 2015; Presi et al. 2016; Rokka and Canniford 2016). These consumer practices do not lead to the development of a collective identity around the brand of interest (Arvidsson and Caliandro 2016), but rather to a multitude of identities that can destabilize the “spatial, temporal, symbolic and material properties of brand assemblages” (Rokka and Canniford 2016, 1). Closely related to this phenomenon is the notion of the microcelebrity (Marwick 2015). Microcele-

brities mimic celebrity culture by “using the familiar trappings of thin but buxom bodies, sports cars and designer clothes” (Marwick 2015, 157). These studies rely on the concept of the “demiotic turn,” which describes the possibility to acquire mass audiences through the display of “a set of physical and aesthetic criteria” (Marwick 2015, 157). The relationship between brands and consumers can be described as unidirectional, where consumers use brands as means to gain publicity in social networks. On the other hand, studies point out micro-practices of consumers that aggregate and eventually change social institutions, such as fashion (Dolbec and Fischer 2015; McQuarrie, Miller, and Phillips 2013; Scaraboto and Fischer 2013).

Our aim is to extend this stream of research by studying how consumers and brands co-construct and challenge dominant ideological formations around idealized body and gender norms. Performativity theory offers a theoretical lens that allows investigating the co-construction of social norms through brands and consumers.

Performativity Theory

This study draws on performativity theory (Austin 1975; Butler 1993, 2010; Callon 1998; Lash 2015) in order to investigate how a brand visually performs the human body on Instagram. The central idea of performativity theory is that social reality, in our case the human body, is constructed through repetitive performances by brands and consumers. Performativity is constituted through the three elements of actors (brand and consumers), performances (the body), and socio-materiality (visuals) (Lucarelli and Hallin 2014). Performativity theory is based upon the idea that linguistic acts, practices, and visuals form a (perlocutionary) force that shapes reality (Austin 1975; Butler 2010). In the context of this study, this implies that a brand’s visual performances combined with consumers’ linguistic acts provide a discursive space, in which these two actors negotiate conceptions of the human body. A performance of the body is a “stylized repetition of acts” by multiple actors (Butler 1990, 140), that is, the hegemonic body ideal is itself a constant and repeated effort to imitate its own idealizations. The representation of the body by fashion brands can be subversive to the extent that it reflects on the imitative structures of hegemonic body representations. Thus, fashion brands can produce and dispute body ideals and claims for naturalness and originality.

This study focuses on a brand’s visual performances of the human body, and how this perlocutionary act is re-constructed by the brand’s audience. We study socio-material (Instagram brand images), as well as linguistic acts (comments of consumers) (Callon 1998). Applying this performative view onto the co-construction of human body aesthetics in the context of Instagram provides a more nuanced understanding of how brands and consumers contribute to the performance of the human body in the digital marketplace.

METHODOLOGY

Our study uses a netnographic approach to investigate how a brand mediates ideological consumer discourse in the digital marketplace (Bartl, Kannan, and Stockinger 2016; Kozinets 2015). Our primary source of data was the Instagram account of American Apparel (@americanapparelusa) as a prime example of a brand that induces ideological discourse through controversial visual body performanc-

es on Instagram. We collected 2528 posts from a total of 4842, covering a time frame from 2012 to 2017. We browsed through all Instagram posts of AA and selected all posts with an extensive comment section. The final sample comprised 37 Instagram posts with slightly more than 8000 comments in total. Data analysis encompassed an iterative process of inductive categorization (Kreiner, Hollensbe, and Sheep 2006; Spiggle 1994) and abstraction to derive major themes related to the visual performances of AA and the textual discourse of the consumers. An interpretive group of three authors coded independently, and reached final consensus and intercoder reliability in extensive rounds of discussion (Arnold and Fischer 1994; Kreiner et al. 2006).

FINDINGS

The majority of brand accounts on Instagram show little to no interaction among consumers in the comment section, or between consumers and brands (Arvidsson and Caliendo 2016). In contrast, we found an extensive discourse among consumers, reacting to non-conventional brand-mediated portrayals of the human body, for instance to a portrayal of an elderly model, a gay couple or other body forms and performances that deviate from prevalent fashion market ideologies (Dolbec and Fischer 2015). Consumers draw on the visual performances of the AA brand and address previous comments of other consumers in their attempt to (re-)construct ideologies of the human body. In the following we provide a detailed description of the discursive practices of the brand and the consumers (Table 1).

Visual Brand Performances: Authenticating, Agenda-Setting and Sensitizing

We find that the posts that trigger extensive consumer discourse employ a number of **authenticating performances** (Arnould and Price 2000) that embrace the natural and imperfect nature of the human body. Performances include featuring employees as brand models. The brand intentionally uses the hashtags #AAmodel or #AAemployee to emphasize whether the model is a professional or an employee. Sometimes the brand links the Instagram username of the model or the employee in the caption. AA also commonly adds personal interests of the models in the caption; that is, personalizing the ads to diminish the objectification of the depicted female bodies. Diversity is emphasized by depicting all body sizes and shapes, as well as all ethnicities and age groups in their ads. The posts are neither photo-shopped, nor retouch the depicted bodies. Various posts exhibit natural features of the human body, i.e. armpit hair on women, nipples or women with visible stretch marks, practices that aim to subvert the normalized social body, authenticating naturalness instead.

Agenda-setting contrasts the socialized body with 'out of the norm' visuals thus setting a mental agenda for public discourse (Ragas and Roberts 2009; Sutherland and Galloway 1981). AA, for instance, supports minorities, i.e. the LGBTQA+ community. For example, an ad depicting two black gay men featured the caption: "*American Apparel celebrates sexuality! #LegalizeGay.*" AA further cooperates with activist movements, i.e. the Human Rights Campaign, and challenges ideologies of youth by portraying Jacky O'Shaughnessy, a 64-year-old model, for their campaign "*Sexy has no expiration date.*" Agenda-setting performances question aestheticized body ideologies that go beyond the institution of fashion, addressing the social body. AA's agenda-setting addresses consumers to follow the brand's effort to challenge societal issues.

A third performance of brand-mediated ideological edgework is **sensitizing** through visuals (Hirschman and Thompson 1997). The edgy and provocative ads differ from mainstream ads pursu-

ing contemporary norms of human body shape, health, or hygiene. AA regularly depicts bodies that deviate from aesthetic ideologies, i.e. pregnant or hairy women. Sensitizing refers to practices of repetitively introducing visuals that raise awareness of the implicit persuasiveness of the normalized social body. That is, AA's visual performances can be interpreted as an attempt to problematize taste regimes and management of corporeality in contemporary society (Bauman 2005; Dolbec and Fischer 2015).

Brand-Mediated Consumer Practices: Applauding, Moralizing and Negotiating

How does the brand's audience react to brand performances? First, we find that consumers **applaud the brand**. They do so textually, i.e. "*Love it!*" but also sign-based, using emojis. We find that consumers embrace the visual performances of the brand on Instagram to express visions of a different human body ideology. For example, one consumer commented on an ad depicting model Jacky O'Shaughnessy: "*I am so fucking proud to have a company like this based in America. #gousa #AALove.*"

Moreover, consumers embrace the idea of "*real human beings*" that defy "*the made up concept of beauty*" in our society. Consumers further defend the brand against negative comments and brand-attacks of other consumers. They bond with the brand to "*shatter the delusions [...] of youth obsessed culture,*" emphasizing the collaborative character of ideological edgework (Fournier 1998).

Second, in response to AA's brand performances we find **moralizing** consumer discourse (Luedicke, Thompson, and Giesler 2010). Consumers regularly attack the depicted human bodies. Human bodies that deviate from beauty conventions are targeted with negative comments in an attempt to (re-)stabilize current social norms of beauty and social order. Consumers do not only attack the depicted human bodies, but also the LGBTQA+ community as such, religious beliefs of other consumers, and AA itself for their attempt to break institutionalized norms of beauty, sexuality, and religion. For example, one consumer commented: "*American Apparel goes too far to break the boundaries of 'beauty' sometimes.*"

In contrast, counter-ideological moralizations defend brand-mediated edgework and argue for freedom of speech and belief. We find that these consumers verbally defend the brand's visual rhetoric. As one consumer put it: "*I love how you all are shattering standard societal beauty norms.*" Moralizing consumer discourse addresses the brand or other consumers directly, mostly by the use of the affordance "@[username]". Consumers and the brand form a moral coalition and destabilizing force to break the rigidity of social conventions and beliefs in normalized body aesthetics.

Third, we also find that consumers **negotiate body-related ideologies** initiated by the brand's visual performances (Rokka and Moisander 2009; Thompson and Hirschman 1995; Thompson, Rindfleisch, and Arsel 2006). Negotiations comprise gender-related ideologies, i.e. what does it mean to be a woman or a man in our society; where does beauty start and where does it end. For instance, consumers discuss the role of body hair and shaving practices. An ad of AA featuring a young woman showing her armpit hair initiated negotiations of women's liberation, and why men do not have to shave off armpit hair, but women do. In defense of armpit hair, a consumer comments: "*YES. Just a huge yes to promoting females loving their body even they don't match standards for women these days.*"

Similarly, consumers negotiate body sizes and shapes (Scaraboto and Fischer 2013), or argue for more ethnic diversity and sexual freedom. Consumer negotiations comprise discourse of liberation and empowerment and include consumers as well as the brand. In contrast to moralizing, negotiating practices articulate consumers'

Table 1: Findings

Visual Brand Performances	Examples of Visual Brand Performances
<p>Authenticating</p> <ul style="list-style-type: none"> Naturalizing the human body Displaying the imperfect human body, i.e. stretch marks Displaying diversity, i.e. body shapes, sizes, ages, ethnicities Personalizing the ad, i.e. “Meet Jacky” 	
<p>Agenda-setting</p> <ul style="list-style-type: none"> Expressing solidarity with minorities through the use of hashtags, i.e. “#LoveConquersHate” or by producing products that express solidarity, i.e. “This month purchase a shirt or tote and proceeds will support the Equality Act and the fight to end #LGBTQA discrimination” Adding agenda-setting captions and hashtags to the IG posts, i.e. “#LegalizeGay” or “#MakeAmericaGayAgain” 	
<p>Sensitizing</p> <ul style="list-style-type: none"> Edgy and provocative visual performances Display of ideology-deviant human bodies in an aestheticized fashion Provocative captions and hashtags, i.e. “Sexy has no expiration date” 	
Brand-Mediated Consumer Practices	Examples of Consumer Data
<p>Applauding</p> <ul style="list-style-type: none"> Expression of positive feelings towards the depicted human body, i.e. through comments, likes and emojis Embracing the brand’s visual performances Embracing the marketing style of AA 	<p>“This is beautiful, she is beautiful and the commentators on the AA Instagram are always so disappointing. This is a great ad and those who think a human body past a certain age is gross are just ignorant. This deserves more positive comments and I applaud AA for not letting comments like these stop the use of models of all shapes, sizes, ages and colors”</p> <p>“Beautiful! Let’s shatter the delusions we’ve created in this youth obsessed culture! I hate to tell you guys, but just as she was a young woman once, so shall each of us age. Let’s accept that and not judge people based on their age. How is that any better than judging based on ethnicity or gender?”</p>
<p>Moralizing</p> <ul style="list-style-type: none"> Attacking <ul style="list-style-type: none"> the depicted human body the brand minorities, i.e. LGBTQQA+ community religions Defending <ul style="list-style-type: none"> the depicted human body minorities freedom of speech freedom of belief 	<p>“Shame on your company @americanapparelusa! Maybe you should just try to make quality clothing to sell your product instead of using porn to draw attention. On a side note your clothing is boring and monochromatic”</p> <p>“Everyone has their own beliefs no matter what religion is. We need to stop those who want to cause harm to innocent people. No matter what religion, race, gender or sexual orientation we cannot let people die cause of what they are. Humans are all born equally and we need to join together and share peace and love with the world! Violence isn’t the answer. LOVE IS!”</p>
<p>Negotiating</p> <ul style="list-style-type: none"> Gender ideologies Female objectification vs. liberation and empowerment Freedom of the feminine body Ethnic diversity Freedom of sexuality 	<p>“[...] because for decades now women have been molded to fit a certain image and if you don’t meet up to this image you aren’t worthy, beautiful, etc so with her not giving a fuck about the natural hair she has and that we were ALL born with and sharing her confidence with the world, can uplift and encourage a way bigger movement than just you and I and everyone else commenting on this damn thing. Not sure why this needs to be explained to so many women it’s frightening and the only gross thing about this fucking post”</p> <p>“[...] Anyway. Only us women argue about body hair. I, myself, don’t like hairy armpits, vagina, upper lip, or nothing that looks ungroomed. No hair on those parts of my body make me feel clean and feminine. I don’t even like too much hair on men. So it’s not a “I’m a sheep who follows society’s rules about women.” But I guess didn’t do my research enough to know that nothing screams out “I am a rebel” or “f*** you, society rules!!” like hairy women. #VivaLaBush (tree-emoji) I’m out.”</p>

opinions towards societal ideologies per se. Brand-mediated ideological edgework is applauded as liberating and at the same time contested for simply abusing human bodies for marketization.

DISCUSSION

This paper introduces the notion of brand-mediated ideological edgework to illustrate how brands induce consumer discourse that challenges societal ideologies and norms. Interestingly, in the case of AA, we find that a commonly monologue oriented social media platform provides a discursive space enabling powerful visual rhetoric for brand-mediated ideological edgework. Our notion of brand-mediated ideological edgework extends Thompson and Üstüner's (2015) perspective by showing how a brand becomes a central actor in ideological edgework. We define brand-mediated ideological edgework as a brand's effort to mediate consumer ideological discourse that destabilizes and (re-)stabilizes social convention and order. Ideological edgework thus becomes collaborative work of diverse market actors, embracing brand performances that exert an intentional (illocutionary) force (Austin 1975; Butler 2010) followed by a perlocutionary act visible in consumer discourse (Schechner 2006).

Our study shows that social formations around a brand within a digital environment are more multifaceted than the notion of brand public implies (Arvidsson and Caliandro 2016). Our findings suggest that social media based consumer culture may very well be structured by discourse, and not only by affects, intended to generate publicity and fame (Arvidsson and Caliandro 2016; Marwick 2015; Presi et al. 2016; Rokka and Canniford 2016). The case of American Apparel demonstrates that brands mediate consumer discourse in that consumers use brand rhetoric to express their concern and form coalitions with brands to engage in ideological edgework about beauty ideals, body, and gender norms.

This study has two main limitations. First, our study focuses on one brand and one digital platform. Second, findings are still exploratory. Further research should therefore investigate ads in detail, i.e. using a critical visual analysis (Rokka and Canniford 2016), and adopt a processual perspective in order to capture the dramaturgy of brand-mediated ideological edgework. Social network analysis could further illuminate central themes and key players that manifest the public negotiation of the human body in the social network of a brand.

Impact of Numerosity on Allocation Behavior

EXTENDED ABSTRACT

We often decide how to allocate resources between ourselves and others, or, between our needs and other causes we support. The traditional Dictator game is probably the most frequently used tool to study allocation behavior. In the standard Dictator game, an individual referred to as the ‘dictator’ is allotted an initial sum of money (initial endowment) and is asked to allocate a portion of it to another individual who must accept the allocated amount (Forsythe, Horowitz, Savin & Sefton 1994). Ideally, the dictator should take all the money for herself and allocate nothing to the recipient. However, past research has demonstrated that many allocate a substantial share of their initial endowment to the recipient. Recent research has sought to understand several factors that influence the level of allocation (See Engel 2011 for a review). Despite the considerable research in this area, there is little work on how the ‘numerosity’ of the resource itself impacts the decision-maker’s allocation to the recipient.

To this end, we find that the form of the numerical value representing the quantity of the resource (e.g., 5 Kg vs 5000 grams; \$20 vs 2000 cents) systematically biases the decision-maker to perceive the quantity she is thinking of allocating as being ‘less than adequate’ or ‘more than adequate’ - consequently influencing her final allocation decision. We attribute this systematic bias to ‘numerosity’ bias.

Numerosity Bias

“Make six slices of the pizza, I can’t eat eight” - ‘not so hungry’
Yogi Berra

As the classic pizza slices joke depicts, we may perceive a resource, such as a pie of pizza in the above case, to be greater in quantity if it’s represented in terms of the more-numerous eight slices than the less-numerous six slices. This is Numerosity “bias” (Pelham, Sumarta & Myaskovsky 1994), because the size of the resource (i.e., the pie) remains the same. The numerosity bias explains that individuals over-infer quantity when it’s represented with higher numeric values or bigger numbers (Pelham et al 1994).

Recently, numerosity has been shown to impact judgments across consumer domains (Bagchi & Davis 2016) such as points in loyalty/reward programs (Bagchi & Li 2011; Nejad & Onay 2014), quality perceptions (Burson, Larrick & Lynch 2009) and pricing (Coulter, Choi & Monroe 2012; Coulter & Coulter 2010). However, how numerosity can impact pro-social behavior, is under-studied (Bagchi & Davis 2016). We look to fill this gap as our work has implications for charity behavior. Across four experiments, we show that numerical values representing the quantity of a resource systematically bias decision-makers’ perception of the quantity to be less than, adequate, or more than adequate. As we demonstrate, this bias significantly impacts decision-makers’ allocations.

In our studies, we manipulate the decision-maker’s perception of quantity of resources (which is money in this case) by describing the initial endowment using objectively equivalent amounts expressed in either dollars or cents. Essentially, we posit that when a decision-maker contemplates how much to allocate to the recipient in ‘cents’, the numerosity bias will occur. By that we mean, a

certain amount in cents such as 300 cents, will be perceived to be greater in quantity or more abundant than an objectively equivalent amount expressed as 3 dollars, as the numerical representation of 300 is much bigger than 3. Consequently, under this ‘Cents’ condition, any amount in cents that the decision-maker is thinking about allocating to the other person (e.g., 300 cents) will be perceived to be greater than an objectively equivalent amount that a counterpart decision-maker may be thinking of giving in the ‘Dollar’ condition (e.g., 3 dollars). Because the decision-maker tends to over-infer the amount when represented in cents, and thus perceives it to be more than adequate, she will adjust her contemplated allocation in cents to a lower value (for e.g. 270 cents), when compared to an allocation decided by the counterpart decision-maker in dollars. Accordingly, as a direct result of the numerosity bias, we expect to see that the final allocation made to the recipient in the ‘Cents’ condition will be lesser in absolute value when compared to the allocation made in the ‘Dollar’ condition. We check this intuition in study 1 and find that the other individual’s share was substantially (more than 10%) lower in the more numerous Cents condition when compared to that in the Dollar condition.

To provide further insight into the manner in which numerosity drives allocation, we manipulate the decision-maker’s focus by framing the decision as “giving to the other” versus “keeping for oneself” (study 2a), and, manipulate the decision-maker’s relative attention by bolding either the numerical value or the denomination (study 2b). Finally, we use a hypothetical currency to validate our process account and show that numerosity biases the decision-maker’s perception of ‘adequacy’ with respect to quantity of the allocated resource (study 3).

Past research has often used dictator games to study charity behavior (e.g., Bekkers 2007; Engel & Grosman 1996). In the context of charitable giving, the Dictator is in the role of the benefactor and the recipient takes the role of the charity. Thus the present work, which demonstrates the impact of numerosity on allocation behavior in dictator games, can have implications for charity behavior as well. In this vein, our paper paves the way for further research on how numerosity affects pro-social behavior, which is currently understudied (Bagchi & Davis 2016). In this way, our work contributes to the numerosity bias literature as well as adds to research studying determinants of allocation behavior.

The Effect of Temporal Distance on Self-Presentation by Brand

Teck Ming Tan, University of Oulu, Finland

Jari Salo, University of Helsinki, Finland

Jouni Juntunen, University of Oulu, Finland

Ashish Kumar, Aalto University, Finland

INTRODUCTION

In this paper, we examine how consumers' self-presentation of self-brand connections is affected by the temporal distance. Although the research on self-brand connections and consumer-brand relationship have been well documented (MacInnis and Folkes 2017), the effect of temporal distance on self-brand connections is less well understood. We are particularly interested in the extent to which the temporal distance influences the brand's ability to serve as a means of consumers' self-presentation.

Consumers make choices based on their self-construal via the attitude object, which is influenced by their judgment of how far into the future the event will happen (Trope and Liberman 2010). Further, consumers assess the value of a symbolic brand depending on how they construe themselves with the brand hypothetically (Sung and Tinkham 2005). Thus, the interesting question is—does people's temporal distance determine his or her self-presentation?

The current paper suggests that the way the consumer perceives, comprehends, and interprets a brand's ability to serve as a means of *self-presentation by brand* (SPB) is dependent on whether the brand is to be used in a near-future event or in a distant-future event—in other words, it depends on temporal distance. As such, our research contributes to the self-brand connections literature, which emphasizes the effect of temporal distance on consumers' self-construal via the brand as a means of presenting their actual self or ideal self.

CONCEPTUAL FRAMEWORK

SPB

Self-presentation relates to impression management with interactions involving close relationships, those of the same-sex, those of the opposite-sex, and strangers (Leary et al. 1994; Tice et al. 1995). Apart from verbal presentation, non-verbal expression, and purposive behaviors, people use artifactual displays for self-presentational tactics (Schneider 1981). To illustrate this point, people tend to project their desired images on cues for physical appearance (Schneider, Hastorf, and Ellsworth 1979), clothing and jewelry (O'Guinn, Tanner, and Maeng 2015), and conspicuous and inconspicuous consumption (Berger and Ward 2010).

SPB is defined as the connection of the self with a brand—the self-brand connections—in which the consumer utilizes the brand as a means of self-presentation to create a positive impression in the social world (Escalas and Bettman 2009). SPB engages the consumer's self with a brand by involving the signifying and connecting processes (Schmitt 2012). Thus, SPB enables consumers managing their self-presentation by associating with a symbolic brand, which serves as a means of presenting their actual self and ideal self (Cialdini and De Nicholas 1989).

Effect of Temporal Distance on SPB

We adopt temporal distance because it has a significant effect on the use and effectiveness of self-presentational strategy (Carter and Sanna 2008). Temporal distance refers to the judgment of an upcoming event in terms of how far into the future the event will happen (Trope, Liberman, and Wakslak 2007). It has a significant influence on people's evaluations, predictions, and choices (Trope

and Liberman 2003). Wakslak et al. (2008) state that people perceive self-concept more abstractly in the temporally distant condition than in the temporally proximal condition and tend to perceive a wider form of self-concept due to broader self-reflection.

When construing near-future events, people tend to think more concretely as they are currently engaged with low-level construals and are inclined to utilize all the rich and contextualized details (Trope et al. 2007). Therefore, their psychological distance from the direct experience of reality should be closer when compared to people who are considering a distant-future event. Consequently, people in the temporally proximal condition are motivated to engage with an actual self because the event is closer to the "here and now" and therefore at a smaller psychological distance (Malär et al. 2011).

People tend to conceptualize objects more abstractly while they think about distant-future events (Trope et al. 2007). Thus, people in the temporally distant condition are likely to engage with an ideal self because they are motivated toward involvement in self-enhancement activities (Malär et al. 2011). Furthermore, self-enhancement involves moving toward one's ideal self by promoting self-presentation and exaggeration of one's strength (Alicke and Sedikides 2011). Therefore, we hypothesize:

When considering events in the near future (vs. distant future), people exhibit more favorable attitudes and choices towards a brand that serves as a means of presenting their actual self (vs. ideal self) rather than a brand that serves as a means of presenting their ideal self (vs. actual self).

STUDY 1A AND STUDY 1B

The goal of Study 1a was to examine whether considering a near-future (vs. distant-future) event; people tended to exhibit more favorable attitudes towards a brand that served as a means of presenting their actual self (vs. ideal self). The objective of Study 1b was to examine the effect of temporal distance on the choices of familiar brands that served as a means of presenting consumer's self.

Study 1a

One hundred twenty adults from across the US (63 men; age 18–69, $M_{\text{age}} = 32$) were recruited from an online panel to participate in this study in exchange for a fee. The study was a 2 (temporal distance: near vs. distant) \times 2 (consumer's self: actual vs. ideal) between-subjects design. The participants were randomly assigned to a near-future or a distant-future event (Appendix). They were then asked to indicate three items on a temporal thought index (TTI, $\alpha = .91$; adapted from Spassova and Lee 2013). Next, the participants were told to imagine they were currently inside in a shopping complex to search for clothing for the event. A sales assistant approached them by showing four clothing items (i.e., Tommy Hilfiger, Gant, Clarks, and Esprit) that could serve as a means of presenting their actual self or ideal self. The participants were then asked to rate a manipulation check item. We assessed brand attitude as dependent measure by asking the participants to evaluate the fashion brands using a three-item, 7-point scale ($\alpha = .88$; adapted from Spassova

and Lee 2013). All the measurement items were listed in the methodological details appendix.

Results

The results revealed successful manipulations of temporal distance ($t = 14.33, p < .001$) and consumer’s self ($t = 5.44, p < .001$). Table 1 showed that the participants in the temporally proximal condition evaluated the brands more favorably when they were offered the brands that served as a means of presenting their actual self ($M_{actual} = 1.75$ vs. $M_{ideal} = 1.04; t(58) = 2.57, p < .05$), whereas the participants in the temporally distant condition evaluated the brands more favorably when they were offered the brands that served as a means of presenting their ideal self ($M_{actual} = .87$ vs. $M_{ideal} = 1.49; t(58) = -2.53, p < .05$).

Study 1b

One hundred adults from across the US (52 men; age 18–62, $M_{age} = 34$) were recruited from an online panel to participate in this study in exchange for a fee. The participants first were told to choose three brands that could serve as a means of presenting their actual self and three brands that could serve as a means of presenting their ideal self from a pool of fifteen familiar brands (i.e., Nike, Adidas, Levi’s, Calvin Klein, Michael Kors, GAP, Coach, Armani, Forever21, Gucci, Old Navy, H&M, Ralph Lauren, Zara, and Puma). They were then randomly assigned near- or distant-future travel prizes (Appendix) and were asked to indicate their TTI ($\alpha = .93$). Next, the participants were informed that they had bought the selected six

brands and they wanted to use the clothes of the brands during the trip. We assessed brand choices as dependent measure by asking the participants to allocate a percentage of how much time they would spend wearing the clothes for the trip, and the total percentage had to add up to 100%. The participants then answered a brand-checking question.

Results and Discussion

The result revealed successful manipulation of temporal distance ($t = 11.54, p < .001$). All the participants scored at least 50% correct answers for the brand-checking section and the average percentage of correct answers was significantly above the 50% ($t = 26.53, p < .001$). The participants in the temporally proximal condition allocated a significantly higher percentage to the brands that served as a means of presenting their actual self ($M_{actual} = 54.78\%$ vs. $M_{ideal} = 45.22\%; t(49) = 1.98, p < .05$). In contrast, the participants in the temporally distant condition allocated a significantly higher percentage to the brands that served as a means of presenting their ideal self ($M_{ideal} = 55.16\%$ vs. $M_{actual} = 44.84\%; t(49) = 2.35, p < .05$).

Study 1 provides empirical evidence that the participants construed themselves via the brands to present their actual and ideal self, which then influences brand attitude and choices. However, there is no evidence whether temporal distance shifts the way people construe a brand’s ability to serve as a means of self-presentation. Further, Study 1 did not cover such effect reflected on a comparison with a brand that might not relate to self-presentation. Thus, we addressed these issues in the next study.

Table 1: Key findings from studies 1–2

Studies & Dependent Variables	Near future				Distant future			
	Actual self <i>M (SD)</i>		Ideal self <i>M (SD)</i>		Actual self <i>M (SD)</i>		Ideal self <i>M (SD)</i>	
Study 1a	1.75 (.96)		1.04 (1.16)		0.87 (1.02)		1.49 (.89)	
Brand attitude	$t(58) = 2.57^*$				$t(58) = -2.53^*$			
Study 1b	54.78% (17.11)		45.22% (17.11)		44.84% (15.53)		55.16% (15.53)	
Brand choices	$t(49) = 1.98^*$				$t(49) = -2.35^*$			
Study 2	2.29 (.64)		1.57 (1.35)		1.97 (.83)		2.53 (.51)	
Brand attitude	$t(38) = 2.17^*$				$t(38) = -2.58^*$			
SPB	5.99 (.89)		5.38 (.91)		5.58 (1.13)		6.28 (.72)	
	$t(38) = 2.12^*$				$t(38) = -2.34^*$			
Study 2	Actual self <i>M (SD)</i>	Listed brand <i>M (SD)</i>	Ideal self <i>M (SD)</i>	Listed brand <i>M (SD)</i>	Actual self <i>M (SD)</i>	Listed brand <i>M (SD)</i>	Ideal self <i>M (SD)</i>	Listed brand <i>M (SD)</i>
Brand choices	61.94% (21.71)	38.06% (21.71)	60.64% (26.02)	39.37% (26.02)	58.84% (21.97)	41.16% (21.97)	69.04% (18.57)	30.96% (18.57)
	$t(19) = 2.46^*$		$t(19) = 1.83$		$t(19) = 1.80$		$t(19) = 4.59^{**}$	

Note: $*p < .05, **p < .001$

STUDY 2

To minimize potential confounding effects, we used a fictitious brand to prompt the SPB. A self-customization procedure was adopted because this method enables consumers to construct a customized offer for each of the brand's attributes that best fits their preference (Valenzuela, Dhar, and Zettelmeyer 2009).

Method

Eighty adults from across the US (46 men; age 18–64, $M_{\text{age}} = 30$) were recruited from an online panel to participate in this study in exchange for a fee. The study was a 2 (consumer's self: actual vs. ideal) \times 2 (temporal distance: near vs. distant) between-subjects design. The participants were first asked to list three fashion brands that they preferred. They have subsequently invited to an imaginary near- or distant-future event and have been asked to indicate their TTI ($\alpha = .93$). The participants have been asked to imagine they had entered a new fashion outlet called Zeemiata. Next, they were randomly assigned to customizing Zeemiata clothing that could serve as a means of presenting their actual self or ideal self (Appendix). The participants were first asked to report on their brand attitude ($\alpha = .94$) and three items on SPB for Zeemiata ($\alpha = .90$; "I believe that Zeemiata could help me to present myself effectively in front of my friends," "I believe that Zeemiata could help me to present myself effectively in front of strangers," "I believe that Zeemiata could help me to give a positive impression of myself in front of the public"; ranging from 1 = strongly disagree to 7 = strongly agree), they were then informed that they had finalized two clothing options for the event: a customized Zeemiata clothing and clothing item produced by the first fashion brand listed by the participants. The participants were asked to allocate a percentage of their choices to both Zeemiata and the listed brands, ranging from 0% to 100%. This was followed by answering one manipulations item of consumer's self.

Results and Discussion

The results revealed successful manipulations of temporal distance ($t = 14.11, p < .001$) and consumer's self ($t = 12.16, p < .001$). As predicted, Table 1 showed that the participants in the temporally proximal (vs. distant) condition evaluated Zeemiata more favorably and had significantly higher levels of SPB when it served as a means of presenting their actual self (vs. ideal self). Participants in the temporally near condition chose Zeemiata that served as a means of presenting their actual self ($M_{\text{actual}} = 61.94\%$ vs. $M_{\text{listed}} = 38.06\%$; $t(19) = 2.46, p < .05$), but there was an insignificant difference in the participants' choice of Zeemiata that served as a means of presenting their ideal self ($M_{\text{ideal}} = 60.64\%$ vs. $M_{\text{listed}} = 39.37\%$; $t(19) = 1.83, ns$). In contrast, the participants in the temporally distant condition chose Zeemiata that served as a means of presenting their ideal self ($M_{\text{ideal}} = 69.04\%$ vs. $M_{\text{listed}} = 30.96\%$; $t(19) = 4.59, p < .001$), but there was an insignificant difference in the participants' choice of Zeemiata that served as a means of presenting their actual self ($M_{\text{actual}} = 58.84\%$ vs. $M_{\text{listed}} = 41.16\%$; $t(19) = 1.80, ns$).

Study 2 provides convergent evidence for our proposed effects, people in the temporally proximal (vs. distant) condition are more likely to have favorable attitude and make choices that concur with a brand that serves as a means of presenting the consumer's actual self (vs. ideal self). We conclude that this effect has strong evidence of causality because it shows a high degree of internal validity.

GENERAL DISCUSSION

Our work contributes to the self-brand connections literature (Escalas and Bettman 2009), which addresses the consumer's self-construal via a brand as a means of presenting their actual self and

ideal self. Current research moves the examination of self-brand connections beyond an association of brand personality and brand image (Aaker 1999; Malär et al. 2011) toward an understanding of how the symbolic attributes of a brand could be further enhanced by tapping the psychological distance that results from the shift in the temporal distance. We demonstrate fine-grained insight into how the consumers' self-construal via the brand as a means of self-presentation is affected by their thoughts about events in the near or distant future, which results in a more favorable attitude toward a symbolic brand and influences the choices consumers make.

An important remark is that we found that the consumers' choice of near- and distant-future events is not influenced by the brand's ability to serve as a means of presenting their actual self or ideal self (Appendix for an additional study). This is because consumers are more likely to wear a purchased product of a brand to a near-future event once they have received positive comments about using the brand.

This research is relevant to the practical implication of authentic branding strategy (i.e., a strategy that targets on the fit of the perception of consumer's actual self with the brand's personality) and aspirational branding strategy (i.e., a strategy that focuses on consumer's ideal self-congruence). To enhance SPB, marketing managers should consider individuals' construals of future events while emphasizing a brand personality related to actual self or aspirations, especially on product self-customization, remarketing, and retargeting.

The samples of this research were recruited from the US. Thus, it limits the universality of SPB in Eastern cultures. In the third study by Ryder, Alden, and Paulhus (2000), the results show an unrelated independent self-concept for Chinese and East Asian samples, and this could be due to the self-criticism found in Eastern cultures, wherein people are vigilant about their self-presentation and try to fulfill their roles in the eyes of their parents, family, relatives, and friends rather than trying to be self-sufficient and autonomous (Heine 2001). Further, Eastern consumers may heavily emphasize status consumption, which is significantly influenced by the power distance belief (Gao, Winterich, and Zhang 2016). Future research is needed to generalize the findings to different cultures.

A SUMMARY OF AN ADDITIONAL STUDY

Our framework proposes that consumers tend to evaluate a brand that serves as a means of presenting their actual self (vs. ideal self) more favorably when they are thinking about events in the near future (vs. the distant future), but it does not rule out an alternative explanation for this effect. We argue that consumers are excited to wear or use purchased products in the near future once they have received positive comments from others, regardless of whether the brand serves as a means of presenting their actual or ideal self. Thus, this study set out to test the effect of a brand's ability to serve as a means of presenting the consumer's self on a choice regarding a near-future event versus a distant-future event. One hundred twenty adults from across the United States (62 men; age 18–69, $M_{\text{age}} = 33$) were recruited to participate in this study in exchange for a fee. The participants were randomly assigned to imagine that they had bought a dark suit or gown that highly recommended by their friends and family members, which was also served as a means of presenting their actual self, their ideal self, or no specific self-concept. The participants then were required to make a decision about wearing the dark suit or gown for either a near- or distant-future event and were asked to provide a brief description of their choices.

Results and Discussion

The results showed that the participants wished to wear the purchased black suit or gown for a near-future event; either it served as a means for presenting their actual self (83%), their ideal self (75%), or they were in the control condition (85%; $\chi^2 (1.40), p > .10$). We crosschecked the written explanations with the event choice, and the given reasons were reasonable because the dark suit or gown was perfect and the participants were excited to wear it to a near-future event. In contrast, the participants who wished to keep the dark suit or gown for a distant-future event had provided various reasons that were not related to the consumer's self.

METHODOLOGICAL DETAILS APPENDIX

Temporal Distance Scenarios

Study 1a and 2	Imagine that you have been invited to a significant annual event that will be held <i>on next Friday (after six months)</i> . Assume that you have accepted the invitation and that there is no particular dress code for the event.
Study 1b	Imagine that you have won a trip for five days and four nights to Barcelona from American Airlines, and the travel prize includes two flight tickets, accommodation, and other packages such as two nights' fine-dining and tickets to various attractions and shows. Assume that you have accepted the travel prize and have found a person to go with you <i>on next Friday (after six months)</i> .

Manipulation of Self-customization

Study 2	Imagine that you are currently in a new fashion brand store called Zeemiata; a sales assistant approach you by introducing a mobile application that can customize offerings to your preferences. Kindly use the online clothing design studio to customize a Zeemiata clothing style that best fits your <i>actual self (ideal self)</i> by tailoring it to a particular size, color, clothing material, and by adding personalized texts to the clothing.
----------------	---

Measurements

Study 1a, 1b, and 2	Temporal Thought Index (Spassova and Lee 2013)	This event is going to happen (1 = <i>soon</i> , 7 = <i>not so soon</i>) I will be going to this event (1 = <i>in a few days</i> , 7 = <i>in a few months</i>) I have (1 = <i>limited time</i> , 7 = <i>a lot of time</i>) to plan for this event
Study 1a and 2	Brand Attitude (Spassova and Lee 2013)	bad (-3) versus good (+3) unpleasant (-3) versus pleasant (+3) unfavorable (-3) versus favorable (+3)
Study 1a	Manipulation Check of Consumer's Self	Just now, the sales assistant was trying to present me with fashion brands that could serve as a means of presenting my (-3 = <i>actual self</i> , 3 = <i>ideal self</i>)
Study 2	Manipulation Check of Consumer's Self by Self-Customization	Generally, Zeemiata could serve as a means of presenting my (-3 = <i>actual self</i> , 3 = <i>ideal self</i>)

Constructing a Narrative Identity of Los Angeles Through a Gastronomic Adventure

Mine Üçok Hughes, California State University Los Angeles, USA

Tony Stovall, Towson University, USA

Rossen Ventzislavov, Woodbury University, USA

INTRODUCTION

O’Henry famously quipped that New York would have made a great city if they finished it. This observation is meant as an exaggeration but it also registers an important truth—cities are works-in-progress. The question of a city’s identity is ultimately one about people—the locals who shape the outlook of a place and the visitors who try to decipher or contest this outlook. In terms of the human factor, however, cities present a modern paradox—they facilitate both quiet anonymity and stark individuality. Ever since the Parisian *flâneur* of the nineteenth century this paradox has driven our perception of our cities and of our own selves. The study of residents’ relation to, valuation of, and identity with the city tends to be rooted in the disciplines of environmental psychology (i.e. Twigger-Ross and Uzzell 1996; Lewicka 2008) and geography (i.e. Molotch 1976; Harvey 1989), while the field of marketing tends to approach the consumption of the city from an overly-general, value-based perspective exercise in place (Rainisto 2003) or destination marketing (Goss 1993) or from a very specific perspective such as an examination of public goods like street art (Visconti, et. al. 2010). Because the various types of value – product value (Sweeney and Soutter 2001), service value (Vargo, Maglio and Akaka 2008), and experiential value (Holbrook and Hirschman 1982) – can all apply to varying degrees to the city, we situate our study in the realm of consumer culture and propose, that the city, itself, is an object to be consumed.

In this interdisciplinary study drawing from philosophy, geography, environmental psychology, anthropology, and consumer research, we explore the various narratives which make social, cultural, economic and political change intelligible to us, that account for the dynamic personality of a city. The city is not a person, but it lends itself to articulations of personhood similar to those that apply to any urban dweller. Our life stories are thus not merely responsive to the city’s symbolic identity but are also in equal measure constitutive of it.

We look at the relationship between two types of narratives which we label as dominant and emergent and explore the tensions that underpin the confluence of these narratives for city dwellers. Cities invariably give rise to dominant narratives, which include the historical records, urban legends and major branding campaigns. Conversely, cities also inspire and facilitate emergent narratives—stories that capture the personal, the particular and the idiosyncratic, but find resonance beyond the private individual.

In this brief treatment of our thesis we structure our paper as follows: We first introduce the concepts of dominant and emergent narratives and how they clash within the context of the city as a consumed entity. We chose to examine the ways in which food is used as a system of communication to expound on the way narrative modes of thinking and expression contribute to the identity of the city. Los Angeles serves as the context to understand how dominant narratives and emergent ones shape our conceptual understanding of the city. We focus on a particular form of cultural engagement - a series of thematic dining events titled *Los Angeles Eats Itself* (LAEI). LAEI, in particular, is a pertinent example of the productive tension between dominant narratives and emergent ones. We explore this tension through the dinner series that recreates and re-consumes notorious events that shape the narratives of Los Angeles. The real Los Angeles is a notion whose validity hangs in the balance between the two

extremes -- a negotiation between competing narratives, in which the dominant and the emergent narratives conspire to respond to the dynamic nature of the city.

DOMINANT AND EMERGENT NARRATIVES

It is our desire to grasp the city in its totality that accounts for what we have identified as dominant narratives. The city’s identity is, on Certeau’s (1984) reading, not the sum total of such dominant stories. Instead, it is a function of the interplay between them and what we have identified as emergent narratives. We understand the latter as stories of real human lives that implicate the city as a character.

The dominant narrative is defined as a top-down imposition of city branding from historians, politicians, corporations, advertising and marketing professionals. We suggest examples of qualifiers meant to elucidate both the origin of this type of narrative (marketing, branding) and its essential character (overarching, organized, homogenous, dogmatic, totalizing). While the emergent identity represents the unregulated agglomeration of micro-narratives that find resonance upon the symbolic urban fabric. The following qualifying terms are examples that capture how emergent narratives are formed (individually, spontaneously, arbitrarily, authentically) and what challenges they present for the dominant narrative of the city (irreverence, subversiveness, fluidity).

In the case of Los Angeles, branding labels such as “The City of Angels,” “Tinseltown” and “La La Land” represent aspects of so-called dominant narratives. The reason Los Angeles makes a perfect study subject is that it does not cater to dominant narratives as readily as the average global metropolis. While cities like New York and Paris have built strong brands that lend themselves to immediate articulation and recognition, Los Angeles challenges its visitors by defying the preconceptions they seek to confirm. But this challenge is equally present for Los Angeles residents because they often mythologize the parts of the city they do not frequent. In this sense everyone in Los Angeles is a visitor. The effect this has is that the city amplifies the two contradictory conditions that the nineteenth century *flâneur* was trying to enjoy at the same time—it oscillates between the extreme existential anonymity of the sprawl and the radical individualization of the spotlight. The middle ground that exists between the two is the narrative function of identity. We approach Los Angeles as a city-making toolkit—a story each one of us, visitor and resident alike, pieces together to ever more idiosyncratic specifications.

The convergence of these two types of narratives creates what we term *negotiated identity*. This occupies the shared space of the previous two—a contested ground whose boundaries are perpetually redrawn. In the tension between artificial order (dominant narrative) and organic chaos (emergent narratives) there exists a conceptual space, which we qualify as liminal, collaborative, dynamic, transitional, mediated, and relational. And while both extremes--the dominant and the emergent--are real and ever present in our reading of the city, it is this middle negotiated ground that represents the urban reality that informs our judgments and actions.

CONSUMING THE CITY THROUGH CULINARY ADVENTURES

The physical aspect of cities is just as inconstant as that of humans. When we think of cities it is not of statistics or infrastructural

agglomerations that supply our operational concepts. Instead, it is certain events, people and places that command disproportionately important status in the urban imagination. The sanction of what is remembered and what is conscripted to oblivion is a function of the city's narrative arc. For Baudelaire, the city is a spectral accumulation of "glorious perspectives, only increased by the thought of all the drama they contain" (as cited in Benjamin 1999, 231). This is in agreement with Hughes' (1964) insistence on the vital role partially arbitrary abstractions play in the composition of historical narratives. Each event, place and person that lends itself to such arbitrary abstraction, to the multiple perspectives of multiple beholders and storytellers, gains entry into the symbolic identity of the city. The unique trajectories we travel along—commutes, diversions, explorations—are not derived from the city's identity but are, rather, constitutive of it.

The construct of place encompasses three components: geography, available activities, and the cultivated meanings its residents give to the city (Gustafson 2001). The identity of each place/city is unique, and is created in consort with both official narratives (originating with government entities and marketing firms) and communal ones, both of which are separate from the influence of any one group of residents (Lewicka 2008). Much of the literature on place argues that the way people understand cities is similar to the way they understand brands (Ashworth and Kavaratzis 2009), which suggests that the branding of a city can be similar to that of other goods and services (Freire 2005). Each year, billions of dollars is spent marketing places (cities) as "commodities to be consumed" (Rainisto 2003), and as invigorating, entrepreneurial, alluring and fun, yet safe and distinct (Prytherch 2002). Still, Ashworth and Kavaratzis (2009) have argued that a city is more than simply a product to be marketed—it is also an object to be consumed. Hence, our focus here is not city/place branding/marketing.

Understanding a particular location allows for deeper insights into the specific consumptive behavior of its inhabitants. Freire (2005) argued that a city's residents consume the goods, services, and experiences in and of the city, and these acts of consumption serve as the foundation of belongingness and identification with that city, which ultimately drives its continued consumption. Invariably, place plays a pivotal role in the formation of any negotiated identity (Twigger-Ross and Uzzell 1996). In an urban environment, the highly differentiated consumption spaces often leave residents negotiating multiple identities.

The critical components of a brand—equity, essence and authenticity—are all reliant on the relevant modes of consumption. This is why those who live in and consume the city co-create its identity and culture. Living in a particular city impacts each resident's identity constructions including values and culturally-influenced customs (Aitken and Campelo 2011). Cities inherently create a binary engagement which suggests not only a sense of one's individual place in society, but also of others' place in it (Bourdieu 1984). The extent to which values and customs are disseminated by residents drives the collective understanding of the city's brand for both residents and non-residents (Aitken and Campelo 2011). Although people consume a city through a variety of means -- transit, geographic layout, entertainment choices/venues, festivals, to name but a few, -- food is perhaps the most quotidian. In its many shapes and forms, and cultural/ethnic/racial affiliations, food shapes our relationship to a city. It is a system of communication (Barthes (1961) 1997; Douglas, 1991) in which the relations between the members of a social group are reflected. When treated as a code, the message food encodes can be "found in the pattern of social relations being expressed" (Douglas 1991, 249). When treated as a narrative device,

culinary adventure becomes a metaphor for cultural consumption writ large.

Los Angeles Eats Itself is "a dinner series where cuisine and LA noir merge like freeway onramps in a savory digestible history." (<http://losangeleseatsitself.com/about/>). The themes for each dinner "event" are notorious LA moments that "border on the tragic, catastrophic and macabre" (<http://losangeleseatsitself.com/about/>). Our taste of and for Los Angeles is in part a function of these adventures which are centered around some of Los Angeles' most notorious events, like the Black Dahlia murder and the Heidi Fleiss (Hollywood Madam) scandal, and the salacious stories that drive them. "If the narrative of Los Angeles is one of an industry that makes narratives but has no singular story, *Los Angeles Eats Itself* is an effort to present a range of narratives in a unique and tangible way" (<http://losangeleseatsitself.com/about/>).

The *Los Angeles Eats Itself* project affords a contextualized understanding of the city's negotiated identities. Since the stories around which the dinner series is built are sealed in the formaldehyde of urban legend, their deconstruction through the clash of culinary and artistic visions is truly transformative. All relevant parties—the creators, the artistic and culinary luminaries, and even the intrepid diners—are given the opportunity to reread history from a highly personal viewpoint. The dominant narratives of exploitation, inequality and disaster are confronted by the idiosyncratic personalities and remembrances of everyone involved. It is a scripted clash, but the resultant mythologies are impossible to predict. So are also the new identities Los Angeles assumes as it consumes itself.

CONCLUSION

In exploring the way cities are understood and consumed, scholars operate on a reductive picture of the formation and structure of the city's identity. With the help of philosophy and critical theory we explore a series of unresolved dichotomies that frame our understanding of the city as a disjunction of two types of narrative identity--the dominant and the emergent. Dominant narrative is the centralized top-down image of the city produced over time through marketing, branding, etc. Emergent narrative is the idiosyncratic fabric of individual, bottom-up storytelling that links to and challenges the dominant narrative. While the extant literature accommodates both sides of the dichotomy, the relationship between the two is left unexplored. We propose a third kind--*negotiated identity*--which not only furnishes a novel ground for conceptual analysis, but also captures the realities of how the identity of the city is constructed and, consequently, how the city is consumed. We show that narrativity is as helpful in understanding our consumption of the city as it is in articulating our phenomenological and semiotic engagements with it.

Between the dominance of urban legend and the emergence of personal association we are able to apprehend a middle ground--*negotiated narrative identity* at its most palpable. Further discussions on the dominant and emergent narrative construct could explore the mechanisms through which negotiated identities enable emergent narratives to become dominant narratives over time, and examine whether dominant narratives are fixed, or dissolve over time through negotiated identities?

While our study has its limitations, one of which is the specific context of Los Angeles and the food theme, we propose that the scope of our thesis reaches far beyond the example of this series of culinary adventures. Our notion of negotiated identity could benefit from intentional application to other cultural contexts such as art, education, sports, or politics.

Corporate Branding as a Source for Employees' Moral Identity Work

Philipp Wegerer, University of Innsbruck, Austria

INTRODUCTION

There is a growing interest on the moral dimension of consumption (Luedicke, Thompson and Giesler 2010, Belk 1988; Arnold and Thompson 2005; Holt, 2002, 2006, Caruana and Crane 2008) and the ethical dimension of branding (Palazzo and Basu 2007, Land and Taylor 2010, Jeanes 2013, Arvidsson 2005). The present study engages in this discussion and sets the focus of inquiry onto how brands effect the 'self' of employees. It studies how the ethical branding of a chocolate company becomes a key resource for employee identity work.

The ethical dimension of consumption and the ambivalent moral nature of brands gained increasing attention over the past years. There is an extensive critical literature that has highlighted the role of branding in the manipulation of consumers (Klein 2000, Curana and Crane 2008), and the role of brands in various consumption practices such as 'brand avoidance' (Lee and Conroy 2009) and 'anti-brand activism' (Palazzo and Basu 2007), free labour (Arvidsson 2005, 2015, Cova and Dall'Aglio 2009, Curana and Crane 2008, Land and Taylor 2010), and in terms of managerial control and organizational culture (Jeanes 2013, Klein 2000, Willmott 2010). The question how branding conceptually relates to employee identity still a matter of discussion.

The study draws on social identity theory (Giddens 1991, Watson 2008) and organization theory (Alvesson and Willmott 2002) in order to link the concept of self-identity with the concept of corporate brands. This perspective highlights how corporate brands can transform discourses in society into coherent brand-stories, which can be understood as meaningful social identities used by employees in their identity work. The paper then presents a case study which illuminates the various ways by which a corporate brand informs and affects employee identity work. The findings show the crucial importance of moral stories in the branding process and furthermore their significance in framing the moral superiority of employees who draw upon these stories in their identity work.

THEORETICAL FRAMEWORK: BRANDING AND IDENTITY WORK

There is a growing body of research examining the relationship of brands and consumer ethics (Luedicke, Thompson and Giesler 2010, Belk 1988; Arnold and Thompson 2005; Holt, 2002, 2006; Muniz and O'Guinn 2001), and the interplay of brands and other stakeholders (Vallaster and vonWallpach, 2013), such as employees (Kärreman and Rylander 2008, Land and Taylor 2010, Jeanes 2013, Miles and Mangold 2007). This study engages in this growing stream of research by shifting the attention onto how employees consume brands. Thus, it seeks to highlight the complex, yet ambivalent relationship of brands, ethics and employee identity work.

The reflexive self and the process of branding share a common mechanism in their creation on the grounds that both rely heavily upon storytelling and narrative construction in their enactment. Following Belk (1988), this paper argues that consumers and employees alike draw on brand stories in shaping their own self-identities. Where Belk (1988) emphasised the role of possessions for consumer identity work Watson (2008) has pointed the role of non-material stories and discourses for identity work. Watson (2008) argues that social identities are personalized elements of a discourse "in a way which makes them [the discourses] meaningful, accessible, and appealing or unappealing to the individual" (Watson 2008, p. 129).

The analytical category of 'social identities' allows us to understand 'identity work' as "a coming together of inward/internal self-reflection and outward/external engagement – through talk and action – with various discursively available social identities" (Watson 2008 p. 130). How does the concept of 'social identities' relate to brands?

Brands draw on, reflect and re-interpret discourses in society by crafting meaningful stories that provide narratives that overcome personal struggles with contradictions in society (Holt and Camerun 2010). Thus, successful brands provide meaningful 'social identities' for consumers and employees to position themselves in the discursive landscape. We can understand brands as carefully narrated 'social identities' (Watson 2008) based on the absorption, reflection and play with contradictions, discourses and cultural shifts within society. Following Watson (2008), I argue that the brands have become an important element of 'social identities' that consumers and employees draw on in the shaping of their own personal self-identities. According to this line of argument, brands do not merely offer one story amongst other possible accounts of ourselves and our world, but provide "an idealized image that one strives to become" (Kornberger, 2010, p. 92).

METHODOLOGY

Data gathering was based upon a set of qualitative methods including a number of visits to the organization, interviews, participant observations, informal conversations, field notes and document analysis. In sum 15 semi-structured interviews including the marketing director, the director of distribution and retail staff employed in the three retail shops located beyond the headquarter were conducted. In addition, the researcher analysed company branding documents including the company website, advertising materials, social media platform activities, and employee training documents. The analysis followed an inductive approach to research in order to identify emerging patterns within the data related to the branding process (Miles and Huberman 1994; Flyvbjerg 2006).

FINDINGS

The data indicates that the brands communicational efforts, although directed towards consumers, has a major effect on its employees. The theory driven analysis revealed that 3 modes of identity work predominate the branding process: i) moral self-definition by differentiation, ii) explicating morals and values as moral superiority, and iii) categorization and affiliation into a common sense of mission. Check the table for illustrative interview data.

Moral self-definition by differentiation

Differentiation is the primary strategy for defining what Chukka is and, logically, what it is not. Differentiation was a pattern that appeared in talking about their customers, competitors, products, and their way of doing business. The emphasis was not so much on what Chukka actually does or on what makes Chukka unique, but what Chukka does (and of course does not do) as compared to others. The others, be it competitors, customers or society at large, are framed as being average, amoral, normal or mainstream.

One instance of differentiation occurred when we talked about the business policy of Chukka. Questions about topics such as fair trade and organic production were regularly answered in a negative, excluding way. Interviewees explained what the others believe, think, and do wrong. However, questions about what the company actually

Table 1: Illustrative data

Moral self-definition by differentiation	
<i>Sentiments against competitors</i>	"There are chocolates [on the market] I doubt if they have cacao in them, they look like they are only painted brown, they just taste like sugar, some of them have this white milk inside them, probably they don't have milk in them, so [they consist] only of sugar, basically they are sugar bombs." (Shop assistant)
<i>Using brand vocabulary for differentiation</i>	"(...) I used to eat Milky before, but since I know the difference, since I know what is the difference between standard chocolate and 'bean to bar'; I don't eat that anymore (...) I don't know (...) this Milky thing, that is something completely different, it is chocolate but it is a product I would not buy." (Shop assistant)
<i>Critique against customers</i>	"For sure, something stays in the employees' minds. But when a customer was in our manufactory five or six years ago, what stays in his mind is that he could eat as much chocolate as he wanted to, and not that the beans have to be harvested by hand. And I doubt that the people are really more sensitive for this topic after their visit." (Shop assistant)
<i>Constructing employees as true believers</i>	"... they [the costumers] have the impression of a prestige organization. I don't think that all people see the Fair Trade, organic, sustainability concept that Chukka wants to be seen and associated with, I don't believe that. I believe that people basically think that it is expensive chocolate." (Shop assistant)
<i>Constructing employees as true believers</i>	"There are customers who are well informed [about Chukka business approach], others have basic information and got in touch with the topic of sustainability recently, and there are customers who ask directly in the shop what we are about. But there is definitely a tendency among the customers towards the insight that they are doing something good if they consume [our products] (...) but basically I have the impression that the customers have less of an idea on the topic [of sustainability and fair trade] than they believe." (Shop assistant)
Explicating moral and values as moral superiority	
Ethical conception of work	„Humm (...) to live up to Chukkas' philosophy, Yes I think I feel a kind of pressure, because Chukka has for me (...) if I look at the label, they are so damn good that I really want to try hard to do better [in following a sustainable lifestyle]. (Shop assistant)
The myth of the charismatic leader	"There is a name and a face which stands for his values. There is a personality, a character that is transformed into our products. This is what most products do not have anymore."
Voluntary constrain of consumption	Hmm, I think it is much better to pay a bit more for fair-trade chocolate. Personally, I would spend more for one bar of fair-trade chocolate than for three bars of Milky chocolate, because one chocolate bar a week is enough, just because there is no reason to eat three bars of chocolate a week if I cannot afford it right now." (Shop assistant)
Vagueness of organic and fair trade	Organic? There are these standards from the European Union. What organic means? It focuses on the use of pesticides." (Shop assistant) That means that these products should be healthier than products produced with pesticides, and that (the farmers) have certain requirements for the environment and they way of production which they have to follow." (Shop assistant)
Job as an ethical practice	"I only stand here [as a shop assistant] this I really have to say, because it is for Chukka and because it is this product. If it would not be this brand I would not work in here, that is clear, I have to say that".
Job as an ethical practice	„Humm (...) to live up to Chukkas' philosophy, Yes I think I feel a kind of pressure, because Chukka has for me (...) if I look at the label, they are so damn good that I really want to try hard to do better [in following a sustainable lifestyle]. (Retail assistant)
Categorization and affiliation into a common sense of mission	
Conversion of competitors	Market participants, no we don't talk about them in any evil or aggressive way, (...) [our CEO] talked to one of these guys from Jupiter [an industry leader], it was at a trade fair, he said you could rebuild your business, you could work sustainably, you could work in a fair way. So he appealed to his conscience (...) but I think in those companies the will for change is missing (...). And I think that's the difference between [them and] Chukka, which is a stable family business that does not want to grow above a specific size within a given time period."
Conversion of customers	"(...) we have certain customers which show a strong awareness [for fair trade and sustainability], and who have an awareness that they are buying organic and fair trade products [at Chukka] (...) but of course that's not everybody. That's why we try to bring it close to everybody. Because it is us who represent the company's philosophy and it is our duty to create and maintain this awareness (among the customers)."
Expansion as ethical education	"[With the expansion to Shanghai] Chukka can teach the Chinese people, whose economy is based mainly on the exploitation of resources, how to conduct business in a sustainable way (...), that is really cool, this social-pedagogical approach, this market education approach, that's really cool shit!" (Shop assistant)
Social transformation	"So you would say that Chukka has some effects?" (Interviewer) "Yes definitely, that [the customers] start at least to think, or if they don't start to think that they are at least offended, and that somebody else starts to think for them." (Shop assistant)
The high price as moral	"Our price is not something that we calculate arbitrarily like a stock price, or that we check the market for what we can get, or how much we can get out of the customer for our product. It is actually very simple: it is the raw material plus working hours, then we get a price X, and then of course we want to earn something, so that the company can be successful. In sum this is the retail price. It is very simple; we all want a fair wage and a safe place to work. We cannot work or give something away for free. We can only produce more cheaply if we buy cheaper raw materials, but this would change the character of our product." (Shop assistant)

does were answered vaguely or by using common statements such as "Chukka is fair trade". If asked what fair trade, organic or sustainability actually meant, or what the terms meant for Chukka, the answers remained vague, or differed significantly from each other.

The interviewees explained Chukka's strategy by highlighting how their competitors exploited native farmers and the environment and that Chukka avoided this by sticking to fair-trade or organic pro-

duction. The interview respondents did not show in-depth knowledge of Chukka actual business practices. Some competitors were seen as so inferior that they were described as having a different product, serving a different market and having a different manner of production and distribution.

The brand created a strong division between 'them' vs. 'us', where the employees clearly distinguish themselves as being brand

believers in contrast to both their competitors and even their own customers. Competitors were seen as exploiting nature and native societies, customers were perceived as naive and ignorant, society is framed as blind and based on exploitation. This negative framing of others is used as a source of differentiation. Employees framed Chukka as a responsible producer and themselves as experts in the chocolate business and as responsible members of society.

Explicating Moral and Values as Moral Superiority

In addition to the tendency to define Chukka by differentiating it from others, the organization was also positioned as being morally superior. The two labels 'fair trade' and 'organic' in particular played a key role in this realm; both were regularly subsumed under the term 'sustainability' and used to define Chukka directly as a morally outstanding organization. The position of Chukka was framed as "against profit maximization", "authentic" and "driven by its own values". Phrases used by interviewees included "we do not outsource sustainability" and "we stand behind what we say", and Chukka is a "credible", "authentic" and "reliable" organization.

Interviewees also saw and presented themselves as morally outstanding individuals. They expressed doubts about topics such as endless growth, profit maximization and reservations towards capitalism and globalization in general. Western capitalism was seen as being an exploitative, destructive force. Their job as shop assistants was seen as an ethical practice in which these negative tendencies of capitalism are addressed. Working for Chukka is thus an expression of a different, responsible way of life.

The dimension of moral superiority can also be found in the pricing policy. Chukka is situated in the premium sector. Today a 70-gramme bar of chocolate is sold about three to four times the price of a regular bar of chocolate. This high price was legitimized by the employees on a moral level. The rationales given included: the complex production process, the high quality of the raw materials, and the fair prices paid for raw materials. Additionally, the price is seen as being calculated in a reasonable, and thus an ethically correct way. The price is 'credible' and 'authentic'; it is seen as the 'real' expression of the production costs.

The high price becomes an expression of the company's ethical brand; it is justified as being the result of a morally superior purchasing policy and production techniques. It cannot be questioned as being illegitimate because it is the proof of the high quality of the raw materials, the sustainable production methods, and the fair prices paid to farmers for these materials. The chocolate is framed as a luxury product which must be consumed in an ethically conscious way.

Based on Chukkas branding efforts the employees developed a clear understanding of the production reality in the mainstream chocolate production sector. This includes the exploitation of the chocolate farmers, market inequalities and environmental issues. Chukka is seen as being in opposition to those practices, as producing in a responsible ('organic') and fair ('fair trade') way and is therefore in a morally superior position. When we asked in detail about Chukka practices and what the terms 'fair trade' and 'organic' implied, the answers remained vague and differed significantly between interviewees. Questions such as "What does it mean to be organic?" or "What does it mean to be fair trade, what is that exactly?" were answered in a vague way.

The employees used the moral vocabulary provided by the brand messages in giving moral justifications. Employees used the brands vocabulary to portray Chukka as being morally superior in terms of the company's business practices (fair trade and organic) and the production techniques (bean to bar). The brand image of the

organization has also become a key element of the employees' identity work. Employees explicitly draw on the images, the vocabulary and discourses of the brand for defining themselves as morally superior to others.

Categorization and Affiliation into a Common Sense of Mission

'Categorization and affiliation' is a key mode of identity work, which engenders a sense of community and a common sense of purpose. In the present study, this was apparent both from the respondents' feelings of being morally superior to their competitors, but also in terms of their missionary zeal. The interviewees had a desire to spread their worldview and convert the whole world (including me as a researcher) to a new form of business. This included a strong belief in the notions of 'organic production', 'fair trade' and 'sustainability'. Employees talked about converting their competitors to "better business practices".

Employees expressed a sense of mission to transfer Chukka business practices to other organizations in order to create a sustainable society. Some shop assistants described Chukka expansion plans to China not as a new business opportunity, but as a way of disseminating Chukka sustainability concept to other countries.

The missionary zeal of Chukka is also apparent in their relationship with the customers. For instance, the visitors centre (an important tourist attraction with more than 200.00 visitors a year) was not seen as a marketing tool, but as a way of ethically educating the consumers and of changing their minds in thinking about fair trade, sustainability and the condition of our society in general. The shop assistants understood their job as containing a sense of mission that goes far beyond selling chocolate. Their part-time job as a shop assistant is understood as containing an ethical duty of educating the customers in responsible consumption practices.

CONCLUSIONS

The main empirical finding of this study is that quite specific modes of identity work are engaged by the brand in its effects on employee identity formation. The company's brand-story is largely built on the incorporation and modification of available social discourses, such as 'organic production', 'fair trade' and 'sustainability' into meaningful 'social identities'. The employees draw upon these ready-made 'social identities' as meaningful narratives in the construction of their own self-narratives. The choice of these particular discourses is significant because they all tend to focus on the moral qualities of the product and the way in which it is being produced. The moral values and stories that have been drawn upon in the development of the brand directly mimic the brand-stories found in successful social movement organizations. In fact, the social discourses that the brand taps into are themselves brands associated with social movement organizations such as the Fairtrade movement and the organic farming movement, and the organizations whose work is involved in supporting these social movements.

The theoretical contribution extends existing research on ethical branding and consumption (Luedicke, Thompson and Giesler 2010, Arnold and Thompson 2005; Holt, 2002, 2006, Caruana and Crane 2008) by identifying the specific 'modes of identity work' (Alvesson and Willmott 2002) that are mediated by company branding processes. This research shows that in the case of branding, specific modes of identity work appear to be far more influential than others, and offers a theoretical refinement of the existing work on identity work for understanding the effects of the branding process on employee identity. The brand is largely built around the three modes of identity

work: i) 'self-definition by differentiation, ii) 'explicating moral and values' as moral superiority, and iii) 'categorization and affiliation'.

In the case of Chukka the brand not only communicates a moral position, but also positions the organization's actions within a wider meaning system as a contribution to a vision of a 'better world' situated beyond endless growth and capitalist exploitation. The brand enables employees to make sense of their job in a way that goes far beyond earning money. The work identity of the individual is shifted from being a low paid shop assistant towards experiencing the job as being part of wider ethical and social movements within society. The brand connects the employees with desirable lifestyles in society and thus helps the individual to address their struggle to choose between the different competing discourses in work and life.

When Doing Healthy is Scary: The Case of Detection versus Prevention Health Messages

Chethana Achar, University of Washington, USA

Meng-Hua Hsieh, Pennsylvania State University-Harrisburg, USA

Nidhi Agrawal, University of Washington, USA

EXTENDED ABSTRACT

Engaging in a healthy behavior is often seen as a self-control issue and conceptualized as a tension between goal-oriented self-regulation and temptation-driven indulgences (Trope & Fishbach, 2000, 2005). As a result, much of literature on health consumption has identified that higher-level, goal-focused thinking increases healthy behavior (Agrawal & Wan 2009, Fujita & Han, 2009; Zhang et al. 2010). The intuition behind this is that higher-level thought (operationalized either as the construal or the mindset with which an action is considered) increases focus on the goal, while reducing focus on lower-level thoughts of indulgences, efficacy and resource concerns (Fujita et al. 2006).

The premise here is that the higher-level outcome (e.g., losing weight) is *more desirable* than the lower-level process (e.g., exercising everyday, avoiding high-calorie foods) and therefore higher (vs. lower)-level focus is more likely to lead to healthy behavior. We ask: does this premise hold true to all health consumption contexts? What if a healthy action was not a pleasant one? In the current research, we identify healthcare actions with outcomes that - while healthy - may be dreadful and therefore, undesirable. Specifically, we consider the case of messages that suggest illness detection health actions.

Consider a health message about mammograms claiming that “early detection saves lives” and encouraging women with risk of breast cancer to take the screening test. This is a *detection message*, which promotes actions that help early detection of health problems. *Prevention messages*, in contrast, suggest actions that prevent a health problem from developing in the future. An example is a sunscreen ad suggesting “shield yourself with sunscreen & prevent skin cancer.” In this way, health messages can be classified as two types with a clear demarcation between preventive and detective actions (Detweiler et al. 1999; Fielding 1978).

In current research, we demonstrate that detection (vs. prevention) health actions are associated with the scary outcome of finding out that one is ill. Next, we show that as a result of this dread, a higher (vs. lower)-level thought about the action reduces the persuasiveness of a detection (vs. prevention) health message. This is a reversal of past predictions. On the other hand, a lower (vs. higher)-level thought focuses on efficacy concerns and reduces the persuasiveness of prevention (vs. detection) messages. This replicates predictions from past research. We provide converging evidence for this phenomenon through a dual mediation process.

This work makes two major theoretical contributions to consumer behavior. First, we explore the understudied psychology of detection health messages (Keller and Lehmann 2008) and show that the unique dread associated with illness detection (vs. prevention) drives their persuasiveness. Second, we contribute to the literature on construal level & persuasion (White, MacDonnell, & Dahl, 2011) by showing when the predictions of the past literature about high (vs. low)-level thought hold, and when they reverse.

Theoretical Development

While both prevention and detection advocacies are types of messages that advocate healthy behaviors, they differ in how consumers might conceptualize these actions. Complying with a detection message might lead to discovery of an illness. On the other hand, complying with a prevention message might lead to maintenance of or improvement over the current state of health. Given this, is the outcome of, say, *detecting* skin cancer as desirable or pleasant as preventing skin cancer?

Detection Actions Have Scary Outcomes. Research has shown that individuals perceive detection behaviors as riskier than prevention behaviors because detection behaviors involve the risk of finding out whether they are ill (Kirscht 1983; Rothman et al. 1999). For example, complying with a health message promoting mammography can be construed as a gamble because getting a mammography involves the chance that one might get a positive test result for breast cancer. On the other hand, prevention behaviors can maintain one’s current health state and have little, if any, shortcomings. For example, complying with a health message promoting sunscreen use does not present a gamble; rather, sunscreen use is considered protection from future risks.

In the context of illness-detection, health actions have the dreaded outcome of finding out that one is ill. For example, the outcome of getting a mammogram is the possible detection of breast cancer. In contrast, outcome of engaging in an illness-prevention action is desirable. For example, the use of regular sunscreen leads to prevention of cancer. As a result of this difference, consumers are likely to view detection (vs. prevention) actions as taking a gamble (Rothman, Salovey, Antone, Keough, & Martin, 1993).

Message Types and High (vs. Low)-level Thought. The important behavioral implication of viewing detection behaviors as scary is that focusing on the goal or outcome of the behaviors may *reduce* the likelihood of performing the goal-oriented action since individuals are reluctant to pursue that goal. This is counterintuitive to the extant literature which conceptualizes that higher level thought leads to focus on the outcome of a healthy behavior and is therefore more effective in comparison to lower-level thought which leads to focus on resources and efficacy (Agrawal & Wan 2009).

We posit that there is a message type and construal level match such that a) detection messages are more persuasive when combined with lower-level thought, and this is driven by reduced scariness of the behavior and b) prevention messages are more persuasive when combined with higher-level thought, and this is driven by goal focus.

Four experiments that systematically test this theory are reported below. In study 1, we demonstrate that participants anticipated that using a skin lotion would be scarier when they were told that it detects (vs. prevents) skin cancer. In study 2, we show that the scariness is reduced when individuals are made to elaborate on low (vs. high) level thought about a detection (vs. prevention) product and that this is moderated by disease severity. Participants were more likely to use a detection skin lotion when elaborating on how (vs. why; study 3) and use a detection dental rinse when in the process

(vs. outcome) mindset (study4). These findings reverse for prevention messages. Study 3 also presents a dual mediation test to demonstrate that lowered scariness drives the effectiveness of detection messages whereas lowered efficacy concerns drive the effectiveness of prevention messages.

Study 1: Detection (Prevention) Actions are Scary

In Study 1a, our objective was to empirically verify the premise that the outcomes associated with detection (vs. prevention) actions are scary. For this purpose, we developed stimuli about a skin lotion (adapted from Mathur et al. 2013), which is presented as either designed to detection skin cancer (detection condition) or prevent skin cancer (prevention condition).

105 undergraduate lab participants ($M_{\text{age}}=21.20$ years, 46 females) were assigned to a one-way (detection vs. prevention) between-subjects design. Each participant saw one of two health messages about a skin lotion. They were then asked to rate “how scary would it be to use this lotion (not scary at all =1, very scary=9)”, how much would you dread using this lotion “ and “how scared would someone be to use this lotion”(not at all=1, very much=9)”. Participants anticipated that using the lotion would be scarier under the detection condition ($M=4.20$) than the prevention condition ($M=2.48$; $t(103)=3.20, p=.002$).

This study conceptually replicates past literature that detection (vs. prevention) actions are perceived to be riskier (Rothman and Salovey 1997). This also empirically confirms the premise for the following studies. In study 2, we test if the scariness associated with detection (vs prevention) actions is changed based on high (vs. low)-level thought.

Study 2: ‘How’ (vs. Why) makes Detection (vs. Prevention) Actions less Scary

In Study 2, we tested the prediction that lower (vs. higher) construal thinking about the outcome of an action reducing the scariness associated with the outcome. Further, we used disease severity moderator as test of process. We reasoned that the scariness of engaging in detection (vs. prevention) actions would hold for high (vs. low) severity diseases. Study 2 ($N=230$) had a 2 (advocacy: detection vs. prevention) X 2 (disease severity: high vs. low) X 2 (elaboration: how vs. why) design. Participants were presented with a health message about an oral rinse that either helped detecting or preventing a disease. The target disease was called dental plaque (low severity) or dental cancer (high severity). Participants were then instructed to write about how (vs. why) they would use the rinse (adapted from White, MacDonnell, & Dahl, 2011). A three-way ANOVA ($F(7,218)=4.73, p<.001$) using an index of scariness (used in study 1) as the DV revealed that participants anticipated that they would be more scared using the oral rinse when it was framed as detecting (vs. preventing) and under high disease severity ($b=6.12, p=.007$). Interestingly, thinking about why (vs. how) increased how scared they expected to be while using this rinse ($b=2.91, p=.004$).

Study 2 provides evidence that low (vs. high)-level thinking about detection actions reduces the dread associated with them. This finding sets foundation for the following studies in which we test the thought-level and message type matching effect.

Study 3: ‘How’ Enhances Detection Message and ‘Why’ Enhances Prevention Message for Skin Cancer

Study 3 tested that high (vs. low) construal thinking enhances healthy behaviors as response to prevention advocacies (as predicted by Fujita & Roberts, 2010), but reverses for detection advocacies (as predicted by current theory).

A panel of 205 participants were randomly assigned to one condition in a 2 (advocacy: detection vs. prevention) X 2 (elaboration: how vs. why) design. The primary dependent variable was their intentions to use the lotion by indicating their answers to “how likely are you to use this lotion”, “how interested are you in using this lotion” on a scale of 1 to 10 such that higher numbers are higher intentions.

Health Intentions. ANOVA results showed that participants in the detection condition were more likely to use the lotion when they thought about how (vs. why) ($M_{\text{det-how}}=7.89$; $M_{\text{det-why}}=7.29$), while those in prevention condition were more likely to use the lotion when they thought about why (vs. how) ($M_{\text{prev-how}}=6.89$; $M_{\text{prev-why}}=7.67$; $F(1, 200)=4.17, p=.042$).

Dual Mediation. We had theorized that a thinking about how (vs. why) enhances the effectiveness of detection advocacies by reducing the scariness of the action, thinking about why (vs. how) enhances the effectiveness of the prevention advocacies by reducing the perceived difficulty of the action. Scariness and efficacy concerns were measured and used as two mediators in analysis (PROCESS Model 4; Hayes 2013). In case of detection advocacies, elaboration on why (vs. how) increased how scary using the lotion was and this mediated persuasion such that higher index of scariness reduced attitudes toward the ad ($b=-.13$; 95% CI $-.39, -.07$). Conversely, in the case of prevention advocacies, elaboration on why (vs. how) reduced the felt difficulty of prevention actions, acting as a mediator, such that reduced difficulty improved persuasion ($b=-.64$; 95% CI $.09, 1.26$).

These results show that different processes drive the effectiveness of detection (vs. prevention) health messages under high (vs. low) –level elaboration. Detection health messages are more effective when associated with lower (vs. higher)-level elaboration - in contrast to findings in the past literature – and this is driven by scariness of detection. However, in case of prevention messages, we replicated the findings from past literature that high (vs. low) level thought is more effective and is driven by lowered efficacy concerns. In study 4, we present another test of process through moderation.

Study 4: Outcome vs. Process Mindset Influences Detection (vs. Prevention) of Dental Cancer

In study 4, we used another operationalization of high (vs. low) level thinking by inducing the participants with an outcome (high-level) or process (low-level) mindset. Further, to test that the underlying process in the effect is that of dread, we used relevance as a moderator, pre-measured as ratings of their perceived dental health while recruiting participants.

Relevance as test of process. Among individuals with poor dental health, detection is more likely to lead to discovery of dental cancer, therefore they are scared and more likely to use the product when thinking about the process (vs. outcome). However, among individuals with good dental health, detection is very low likelihood; therefore they are not threatened by it and are indifferent to outcome vs. process. Similarly, among individuals with poor dental health, prevention is a salient goal but are deterred by efficacy concerns (Fujita & Roberts 2010, Agrawal & Wan 2009). Therefore, they more likely to use the product when thinking about the outcome (vs. process). However, to individuals with good dental health, prevention is not a salient goal, therefore they are indifferent to outcome vs. process.

Procedure. In a 2 (mindset: outcome vs. process) x 2 (advocacy: detection vs. prevention) x 2 (relevance: high vs. low; continuous) design, 408 online participants ($M_{\text{age}}=34.43$ years, 189 females) were asked to evaluate a ‘dental rinse’ and focus on the outcome

(vs. process) of using the product. They were then presented health messages that framed the product as being a dental cancer detection or dental cancer prevention rinse. The 3-way model using product use intentions as dependent variable (adapted from study 3) was significant (PROCESS Model 3; Hayes 2013; $F(7,400)=2.34, p=.023$). The three-way interaction among independent variables was significant ($b=.54, p=.04$). Among participants who thought their dental health was bad (-1 SD on dental health; high relevance) were more likely to use the detection rinse when they were in the outcome mindset ($b=1.31, p=.019$), while they were more likely to use the prevention rinse when they were in the process mindset ($b=-1.75, p=.002$). Participants who thought they had good dental health (+1 SD on dental health; low relevance) were indifferent to mindset and message type ($b=.02, p>.50$) in forming their intentions.

Note. Means are provided as data labels. Under low relevance, means are not significantly different between message type and mindset conditions. Under high relevance, contrasts are significant ($p<.05$) between mindset conditions in both detection and prevention message types.

General Discussion

Using five experiments, this paper demonstrates that a) detection (vs. prevention) actions, are perceived to be scary, b) a lower (higher) level elaboration enhances the effectiveness of detection (prevention) advocacies, and c) two different processes jointly mediate this effect. This research presents implications to consumer behavior theory by identifying that a lower-level, 'how' construal might lead to healthier behavior when the outcome of the healthy action is scary.

One limitation of the set of studies reported here is that the thought level was manipulated as mindset or elaboration *outside* the health message. Future studies can test if framing the health messages at a high versus low level will replicate this effect.

Findings presented here offer insights to health marketers about the thought-level matching effect to promote the effectiveness of detection versus prevention advocacies.

Consumer-Brand Relationships in Conspiratorial Narratives

Mathieu Alemany-Oliver, Toulouse Business School, France

EXTENDED ABSTRACT

To summarize this research, I show that conspiracy theories infuse marketplaces, leading to specific conspiratorial relationships between consumers and brands. Discourse analysis of 30 consumption-related conspiracy narratives available on the Internet --in English and in French, underlines that consumers and brands can play the integrative roles of the culprit and the victim.

In the realm of consumer research, a conspiracy theory can be defined as an alternative, explanatory, non-refutable, and logical narrative about a brand-related event which is rooted in consumer's belief that nothing happens by accident, and that there must be a secret and powerful group of people pulling the strings behind the scene. It therefore differs from rumors, (urban) legends, hoaxes, and gossip. Marketers are particularly interested in understanding and anticipating conspiracy theories in that these conspiratorial narratives happen outside of marketing channels of communication and therefore out of marketers' control. Moreover it is difficult to persuade conspiracists that their theory is unfounded once they start to believe in it (Nyhan, Reifler, and Ubel 2013; Sunstein and Vermeule 2009). Reasons for such hardly debunkable narratives might be, among others, that some theories revealed to be true (Keeley 1999). To Aupers (2012) and Jane and Fleming (2014), conspiracy thinking carries a cultural logic of modernity that is taken to its extreme through the accumulation of proofs in a methodological and rational way, finally leading to a manifestation of distrust and "fashionable conspiracism" (Aaronovitch 2010, 3). Recent increase of conspiracy thinking might be understood as a consequence of new technologies of information, and more particularly the advent of the Internet (Barkun 2003). The abundant flows of online information would decentralize all forms of discourses and favor echo chambers in which ideas and theories are no longer challenged, but only strengthen (Pariser 2011; Sunstein 2009).

Several convincing reasons might lead consumers to develop conspiracy thinking. For example, some business traditions such as special-interest lobbying that are characteristic of the late 20th and early 21st centuries can only feed conspiracy thinking since on many occasions particular industries -- especially the tobacco industry -- have been accused and found guilty of conspiring against the law (Brandt 2009). Another plausible reason for the belief in conspiracy is to be found in the Goliath effect (Fine 1985). Like the too big to fail theory in economics, there might be a too big to be honest consumer theory developed regarding the size of major companies such as Nestlé, Google, Amazon, Procter & Gamble, Monsanto, Walmart, ExxonMobil, or Toyota. When one of these giants is involved in a scandal, such as the recent Volkswagen emissions scandal, consumers might give more credit to conspiracy theorists and to the possibility of hegemonic entities that try to deceive and control them.

In order to better understand conspiratorial relationships between consumers and brands, 30 consumption-related conspiracy narratives, available online, were analyzed through a poststructuralist perspective (Moisander, Valtonen, and Hirsto 2009; Thompson and Hirschman 1995). Analysis was also structured around the idea that characters and storylines structure texts and semiotic relationships (Hirschman 2000). We have therefore used Greimas' (1966) concepts of *acteur* and *actant*. Results underline the different roles that consumers and brands can play, and more particularly two integrative roles that gather all the other roles: the victim and the culprit. Most conspiracy narratives in the field of consumption involve a cul-

prit/victim relationship between consumers and brands/companies. From the analysis, we find that a majority of conspiracy theories make consumers the victims, while brands, companies, or industries are considered the guilty party (e.g., McDonald's ice cream machine conspiracy). We also find narratives in which the company is a victim of consumers' conspiracy. These narratives often appear as official counter-narratives to answer conspiracy theories that directly attack the company (e.g., Phil Schiller from Apple about the removal of the audio jack). Two other kinds of consumer/brand relationships are the culprit/culprit and victim/victim situations. In these cases, events are interpreted either as the consequence of collaboration between consumers and brands/companies/industries (e.g., black market of Hollywood movies in Iran organized by consumers themselves and the USA to pervert Islam, local culture, and Americanize the whole world) or as the unfortunate cause of both consumer and brand misfortune (e.g., Malaysia Airlines flights 370 and 17 in 2014, allegedly shot down for secret political reasons). Finally, the brand can sometimes benefit from conspiracy theories and even feed them. For example, the Newton community considers Microsoft to be a conspirator (Muniz and Schau 2005). Drawing on this narrative in which Microsoft is the villain, Apple takes the roles of both the victim and the hero fighting the suppressor of superior technology. These conspiracy narratives are even more plausible to the audience when the media announces that Microsoft shares consumers' information with the NSA whereas Apple refuses to collaborate with the FBI in order to protect its consumers' privacy.

Unsustainable Luxury and Negative Word-Of-Mouth: The Role of Shame and Consumers' Cultural Orientation

Cesare Amatulli, University of Bari, Italy
Matteo De Angelis, LUISS Guido Carli University, Italy
Giovanni Pino, University of Salento, Italy
Gianluigi Guido, University of Salento, Italy

EXTENDED ABSTRACT

Sustainability is often treated as an unimportant driver of luxury consumption (Davies et al. 2012), if not simply deleterious to their perceptions about the quality of luxury items (Achabou and Dekhili 2013). Although most studies have focused on the link between luxury and positive emotions such as pride, prior research neglected to explore the association between luxury and negative emotions. To supplement this growing literature, first, we investigate how negative emotions—shame in particular—affect unsustainable luxury consumption. We propose that messages highlighting the unsustainable (vs. sustainable) nature of luxury products may trigger a sense of shame in consumers, which will then affect their subsequent behavioral intentions, in particular their intention to share negative word-of-mouth (hereafter, NWOM). We also study the moderating role of culture (Hofstede et al. 2010) by focusing on *individualism* (the tendency to seek personal rewards) versus *collectivism* (the tendency to prize collective wellbeing). These orientations are relevant to sustainability research, inasmuch as sustainability is linked to people's concern about making a positive (or at least non-negative) contribution to the well-being of society.

In this research, we specifically examine NWOM as a type of pro-social behavior that follows consumers' exposure to messages emphasizing the unsustainable (versus sustainable) nature of luxury goods. Because shame leads individuals to engage in coping behaviors aimed at restoring their self-worth (Duhachek et al. 2012), we expect, first of all, that ashamed consumers would strive to restore a positive view of themselves by engaging in NWOM. Existing research shows indeed that people engage in WOM behavior to re-establish a positive self-image in social contexts (De Angelis et al. 2012). Second, we consider consumers' cultural orientation as a moderator of the effect of unsustainable-luxury driven shame on NWOM and predict that shame will increase (decrease) the tendency to share NWOM about a company selling an unsustainable luxury product when consumers have a collectivistic (individualistic) cultural orientation. We expect indeed that individualistic consumers will be more concerned with preserving their social image than others' welfare.

METHOD AND FINDINGS

We tested our predictions with 104 consumers ($M_{Age} = 35$, $SD_{Age} = 11.77$; 50% females) who participated in a 2 (type of message: sustainable product vs. unsustainable luxury product) x 2 (cultural orientation: collectivistic vs. individualistic) between-subject experiment. We manipulated cultural orientation through participants' nationality—American vs. Russian—following Hofstede's classification of U.S. and Russia in terms of the individualism versus collectivism. Thus, we administered the questionnaire to a random sample of U.S. ($M_{Age} = 35$, $SD = 9.75$, 64% males) and Russian consumers ($M_{Age} = 34$, $SD = 13.51$; 36% males), who were both extracted from national consumer panels and invited to fill in an electronic questionnaire that assigned them to one of the two experimental conditions.

The questionnaire instructed participants in the sustainable product condition to imagine they were about to purchase a luxury

car able to reduce pollutants drastically and thus to contribute to environmental protection. In contrast, participants in the unsustainable product condition read a message about a luxury car producing more emissions than similar cars and thus contributing to increase environmental pollution. Then, participants answered seven items drawn from Lindsay-Hartz (1984) that measured their sense of (anticipated) shame (e.g. "I feel a sense of blame,"; $\alpha = .88$) and three items that assessed their willingness to share NWOM about the company selling the car (e.g. "I will say negative things about this company to other people"; $\alpha = .95$), all measured on 7-point scales (1 = completely disagree, 7 = completely agree), and provided socio-demographic data.

Participants assigned to the unsustainable scenario (coded as +1) felt a more intense feeling of shame ($M = 3.60$, $SD = 1.68$) than those assigned to the sustainable scenario (coded as -1; $M = 2.66$, $SD = 1.32$, $F(1, 102) = 10.08$, $p < .05$). We regressed willingness to share NWOM on sustainability, shame, and participants' cultural orientation (coded as +1 for Russian consumers and -1 for American consumers), and the interaction between shame and cultural orientation. This analysis returned a significant index of moderated mediation ($b = .49$, 95% CI: .15, 1.02), indicating that cultural orientation moderates the effect of shame on willingness to share NWOM. In particular, type of message had a significant and positive effect on anticipated shame ($b = .47$, $p < .001$). Controlling for type of message and cultural orientation, we found that shame had a significant negative effect on NWOM intentions ($b = -.37$, $p < .05$); controlling for type of message and shame, cultural orientation had a significant negative effect on NWOM intentions ($b = -.423$, $p < .001$). The analysis revealed a positive and significant effect of the interaction between shame and cultural orientation ($b = 1.05$, $p < .001$) on NWOM intentions. The effect of type of message on willingness to share NWOM was negative for American consumers ($b = -.17$, 95% CI: -.43, -.01) and positive for Russian consumers ($b = .32$, 95% CI: .10, .61), thus showing that collectivistic consumers expressed increased NWOM intentions in response to their feelings of anticipated shame. Meanwhile, NWOM intentions decreased among individualistic consumers.

Our study contributes to the research on luxury and sustainability which still lacks an examination of how negative emotions aroused by unsustainable luxury products can shape consumers' responses. By assessing how shame affects WOM intentions, this research also extends the literature on the emotional antecedents of WOM intentions. Moreover, our research investigates the previously unexplored role of consumers' cultural orientation in the relationship between luxury and sustainability. Operationally, our results suggest that managers could deliver messages that emphasize the differences between their firm's sustainable products and their competitors' less-sustainable ones, thus fostering negative buzz around competitors' products. Not-for-profit organizations may use our results to design and diffuse messages aimed at warning consumers against deleterious unsustainable products especially in collectivistic cultures. Finally, for luxury managers interested to introduce their products in international markets, our research points to the need to consider the cultural aspects when designing their communication actions.

The Belonging Process: Elements and Enactment within a Consumption Context

Robert Arias, University of Illinois at Urbana-Champaign, USA

Cele Otnes, University of Illinois at Urbana-Champaign, USA

EXTENDED ABSTRACT

Given the centrality belonging is to daily life, it is not surprising that the phenomenon attracts scholars' attention from many disciplines (Maslow 1943). Yet what is notable is that while consumer researchers allude to concepts related to belonging (Schouten and McAlexander 1995), research on the actual construct, and how belonging relates to consumption activities (Mead et al. 2011), remains undertheorized. We believe focused attention to belonging in our discipline is crucial, especially considering it may provide further enlightenment on related and entrenched topics such as power and self-esteem (Rucker, Galinsky, and Dubois 2012).

Most belonging consumer research examines how people fulfill needs to belong after being excluded. Yet this does not account for how people actively *leverage* consumption practices to construct, maintain, or enhance belongingness. Consequently, our overall goal in this paper is to leverage empirical research to delineate a broader conceptualization of belonging than dominant definitions currently reflect, and to offer evidence for a new understanding of belonging, one we term the *belonging process* (referred to as "BP"). This conceptualization reflects the relatively recent assertion that belonging is best understood as a process rather than a state-based construct (Yoval-Davis 2006). Importantly, delineating the process first required us to identify previously unarticulated but focal elements within it. Our overall contribution, therefore, is that we develop and illuminate a broader and more refined lens to facilitate scholars' examination of the role belongingness plays in consumption. More specifically, we shed light on how people engage with various focal elements during the BP, and how that process unfolds, in their attempt to fulfill goals pertaining to social inclusion.

The Need to Belong Construct

Baumeister and Leary (1995) are the first to compile empirical evidence to support the existence of the NTB. They propose the NTB possesses two distinct features: 1) frequent personal contacts or (non-negative, ideally pleasant) interactions with others, and 2) perceptions of "an interpersonal bond or relationship marked by stability, affective concern, and continuation into the foreseeable future" (500). These features distinguish the NTB from other social needs; e.g., the need for attachment or social connection. For example, one's need for attachment can be met by maintaining a stable relationship filled with negative interactions, falling short of the NTB's requirement of pleasant personal contact. Or one may fulfill the need for social connection via brief stranger encounters, but never form a stable relationship, thus eschewing the second feature.

Consumer Behavior and Belonging

We assert that much extant consumer research relates to belonging, although belongingness-related theoretical constructs are often left unarticulated or undeveloped.

Social Exclusion. Consumer research often approaches belonging experimentally, treating social exclusion as an implicit proxy for a heightened NTB. Research finds consumers spend strategically after being excluded, demonstrating increased desires for goods and experiences that aspirational social groups valorize (Dommer et al. 2013). Extant findings suggest people are willing to sacrifice "personal and financial well-being for the sake of social well-being" (Mead et al. 2011, 902). The authors find such sacrifices include tailoring spending preferences to an interaction partner's preferences,

spending money on unappealing food favored by peers, and even an increased willingness to try cocaine, when doing so increases chances of social connections.

Brand Communities. One of the most relevant contexts linking belonging with consumption is the brand community, defined as a "specialized, non-geographically bound [and] based on a structured set of social relations among admirers of a brand" (Muniz and O'Guinn 2001, 412). This research acknowledges the importance of belonging – at least indirectly. McAlexander and colleagues (2002) suggest that one potential barrier to brand community participation is the fear of not belonging. Importantly, newer members' fears are partially alleviated when experienced members initiate interactions with newcomers (McAlexander et al. 2002, 46-7).

Context

Belonging is frequently studied in education-based contexts. In university contexts, research finds students' identities may change, depending on the specific groups, times, and places in which they interact, demonstrating the enacted nature of belonging (Bhopal 2008). Such relocation implies students' social relationships are disrupted, especially for freshmen, transfer students, and international students. Consequently, we follow precedents from social psychology and sociology and consider the university campus a conducive context for examining belonging.

Our context is a large Midwestern university serving over 45,000 students (30,000 undergraduates). Tuition averages approximately \$27,000/year in-state and \$41,000/year out-of-state. Though 73% of undergraduates are in-state, about half come from a large city over 120 miles away. In two phases, we study general college students and then a specific honors program.

Methodology

We employed qualitative methods to understand how students use consumption to pursue belongingness. Two researchers acquired a dataset composed of written narratives pertaining to consumption and belonging by eighty-three undergraduate business students. Narratives require participants to organize experiences in temporally meaningful episodes, framing experiences as "'part' of a whole... and that something is a 'cause' of something else" (Polkinghorne 1988, 6). We recruited these students from two classes, offering extra credit for voluntary participation.

While our initial narrative sample provided breadth, the first author engaged in a longitudinal exploration of a second specific cohort in the college. Specifically, he conducted an ethnography in a college honors program to study how the students selected for this community establish and maintain belongingness. These honor students must enroll in four courses restricted to the cohort during their freshman and sophomore years, and are strongly encouraged to participate in an international immersion experience at the end of their freshman year.

Refined Research Questions

We began with one broad research question: "How do people proactively leverage consumption to enhance their sense of belonging?" We found our analysis demonstrated that consumers' belonging experiences involve constructs previously unidentified in either the NTB or sense of belonging conceptualizations. Furthermore, our longitudinal phase provided deep insights not only into how these

constructs intersect, but how belonging unfolds as a process, and how consumption practices foster and fit into this process. Thus, our analysis necessitated refining our original research question, and breaking it into two, as follows: 1) What elements structure the BP? and 2) How do these elements relate to each other and contribute to the BP?

Findings

Elements and their Enactment in the Belonging Process

Cultural Context. All belonging processes are embedded in a specific cultural context. Ours is a North American university campus in the Midwest, which encourages a broad range of extracurricular activities. It is also embedded within a first-world consumer culture, containing aspirational middle and high income consumption patterns. These characteristics are important as they shape the cultural norms and behaviors, which may be very distinct from a university in a different country or even from different colleges accommodating lower or higher-income consumers. Darryl, a university administrator, articulates how these broad cultural forces may influence the students, "...students don't like to brag about [being] in the honors program because I think we have a little bit of a Midwest value set.... That's a different context than I see in other schools, but they're very supportive of each other..."

Belonging Targets. Belonging targets (hereafter; targets) are the social entities within which one aims to belong. Consistent with prior research on the level of analysis of belonging, targets emerge on three distinct structural levels: macro, meso, and micro (Christenson 2009). Utilizing Christenson's (2009) framework, we describe macro targets as "imagined communities," resembling a concept broader than a specific collective of people (such as national, kinship, religious, or cultural groups). We employ the term meso to describe social entities in which a consumer may interact with other members, but still does not know everyone within the target. Finally, we reserve the term micro targets for social entities in which a consumer knows and interact with everyone in the group; this is usually limited to a small number of individuals. One informant provides an example of how she conceptualizes her university as a macro-level target, and how she belongs in it:

Belonging in a group so vast and diverse happens more in terms of values than relationships. My sense of being a student is similar to the sense of citizenship one feels for their country; there are some shared priorities and behaviors,...but little direct connection with the many subcultures that exist (NARR, WF, 21).

Belonging Conduits. Belonging conduits are the resources both from the marketplace and other sources consumers leverage to facilitate belongingness pursuits. One informant notes that once he bought his Sperry Topsiders, "I felt like I belonged to a group, community, and culture. The group was my fraternity...the community was all of Greek life on campus, and the culture was...Greek culture [as a whole]." (NARR, WM, 21) The plethora of consistent research noting linkages between branded clothing and a strong sense of self, and affiliation with a group supports the salience of this finding (e.g., Chaplin and John 2004; Fernandez 2009). Significantly, we observe that technology products like smartphones and gaming gear can act as both functional and symbolic conduits, while apparel, accessories and jewelry are primarily symbolic. Similar to how a consumer may rely on a symbolic product to reinforce family identity, our consumers leverage these conduits to enhance belongingness within their targets (Epp and Price 2008). One gamer notes he needed an Xbox "to interact with my friends the way I wanted to...[it] helped me

become even closer to [them] and eliminated our distance barrier." (NARR, WM, 21) As such, consumers rely on conduits to transcend limitations rooted in time and space, barriers that otherwise could contribute to the weakening of social ties (Otnes et al. 2014).

Belonging Cues. Alternatively, consumers' selection of conduits may also depend on perceived cues, defined as the signals informants perceive as helping them track their progress toward the ultimate goal of belonging within the target. Extant research finds people often monitor others' actions to assess evidence of their own exclusion (Leary et al. 1995; Loveland et al. 2010). In like fashion, we find evidence of informants monitoring others (and themselves) as they proactively pursue belonging and acceptance. The data suggest two types of cues exist: external and internal. External cues derive from consumers' observations of others' behaviors, while internal cues originate from their own self-realizations.

Belonging Barriers. Lee and Shrum (2012) identify two types of belonging threats: being rejected and being ignored. However, our data support a broader interpretation of hindrances to belonging that extend beyond mere ostracism. We find evidence of belonging barriers, defined as enduring forces that hinder people from achieving belongingness within a target. A participant explicitly indicates how he did not achieve belongingness within the program due to demographic variables:

Our class is primarily White females. And guess what demographic I've had the least contact with? White females.... Asian guys and White girls don't mix. I don't mind, but other people do....I just noticed that they're [students in honors cohort] mostly women."

Zack clearly identifies gender and race as two sociological factors he believes impact his ability to belong in his honors program.

Belonging Outcomes. We use this term to capture the various belonging-related goals consumers desire and proactively pursue. These outcomes relate to their general perceptions and feelings of belonging, and manifest across a broad spectrum, from engaging in simple interactions or establishing strong, stable relationships within a target. In fact, while extant research links positive social interactions to belonging and acceptance (Baumeister and Leary 1995), consumers even express just having non-negative interactions as desirable outcomes. For example, a young African-American woman compares the negative reactions that White people sometimes express toward her natural-state hairstyles, to post-purchase experiences after she undergoes professional hair-straightening:

Although many are unconscious of it, straight hair is more accepted, and less threatening to others in this society; and I would prefer to be unnoticed but accepted than to be ostracized. However, when unnoticed, there are not many affirmations that you are accepted. (NARR, AAF, 21)

As this young woman frequently straightens her hair, she knows the type of reactions she will garner after purchasing a relaxant. More importantly, she understands the (negative) reactions she will avoid. She relies on this particular consumption activity to manage the stigma of "natural" hair (Crosby 2012) and explains how even the absence of negative reactions can serve as a reflection of acceptance.

Importantly, these quotes evidence desired outcomes beyond simply fulfilling the NTB or establishing a sense of belonging. Our data demonstrates consumers may simply aim to belong functionally, or "fit in just enough" to go unnoticed, or, to be accepted (NARR, AAF, 21).

The Belonging Process

This section demarcates the interrelationships among the various elements of the belonging process. The cultural context shapes and influences all of the elements, as it encompasses the entire process. Importantly, this impact includes the social context of a consumer's intended belonging target. Within a target, a consumer may live through a variety of experiences that lead to specific outcomes, and we emphasize those pertaining to consumers' conscious pursuit of belonging outcomes.

The nature of the target will shape how consumers evaluate potential marketplace resources (i.e. conduits) to achieve particular outcomes. Targets can influence the selection of conduits explicitly, directing a consumer's attention toward specific consumption opportunities (e.g., branded shirts of a student club, the honors program strongly encouraging students to participate in the international trip) that can enhance belonging. Conversely, the influence of a target on conduits can be less overt, as a target can merely act as an information source that communicates to the consumer what consumption activities the target (de)values.

Discussion

Our findings demarcate key theoretical constructs to help illuminate the process of consumers' efforts to belong. The identification of these constructs allows scholars to be more precise when designing research studies. More importantly, we theorize how the constructs operate in relation to one another, forming the belonging process. The process we theorize reveals important belonging/consumption issues beyond the scope of NTB and sense of belonging conceptualizations. Thus, we move beyond the compensatory perspective of restoring belonging needs and illuminate a previously overlooked area in consumer/belonging research, that is, consumers' proactive pursuit of belonging. Here, we highlight a variety of marketplace resources that may facilitate belonging, the role targets may play in shaping consumers' preferences, and alternative belonging-laden outcomes beyond attaining a sense of belonging and fulfillment of the NTB.

Conclusion

We find support for emergent constructs and classifications that pertain to consumers' belongingness desires. We discuss five elements essential to the BP: cultural context, targets, conduits, cues, barriers, and outcomes. We offer preliminary theorization of how these emergent constructs relate to each other. Our research contributes to work on identity, belonging, and consumption by advancing understanding on the processual nature of consumers' proactive pursuit of belonging, heretofore unexamined in consumer behavior. The belonging process we propose provides scholars with a theoretical foundation to build upon and advance the nascent research link between belonging and consumption.

Catching the Health Wagon: Consumers' Strategies of Control in Healthy Food Consumption

S. Sinem Atakan, Ozyegin University, Turkey
Meltem Ture, Université de Lille, France

EXTENDED ABSTRACT

Debates about healthy food have once again come to the fore as obesity rates increase in most parts of the world and more people suffer from diet-related illnesses. In the contemporary consumption-scape where meanings assigned to food items and practices of cooking and eating are fluid and ever-changing, it is becoming more and more challenging for consumers to practice healthy food consumption. The current research focuses on this issue and investigates how consumers, in interaction with other actors, establish the practices related to healthy food consumption.

In order to explore the topic, a two-step research methodology was used. First, a multi-sited netnography (Kozinets, 2010), on four websites (discusscooking, cookingbites, SparkPeople, eggheadforum) consisting a total of 4000 consumer posts, was conducted. The sites were chosen due to their high circulation rate and diversity of the posts related to food preparation and consumption. Then, semi-structured in-depth interviews with six consumers and 10 dieticians provided further insights. The consumer informants were chosen among consumers who declared an interest in healthy eating and/or cooking. The interviews with consumers started with general questions about daily eating and meal preparation routines and moved onto more specific inquiries about healthy food, healthy eating, and food preparation. The interviews with dieticians depicted multiple discourses around healthy food consumption and processes of behavioural change.

The data set was coded and analysed with research goals in mind; first separately, then altogether by comparing and contrasting within and between the texts from interviews and netnography. Data analysis followed an iterative process and was in constant dialogue with the literature. Analyses revealed four strategies that consumers use to eat healthily and, ultimately, gain control over their bodies and lives: 1) relocating the locus of control to external actors, 2) shifting the focus away from food, 3) planning in advance, and 4) cooking.

Relocating the locus of control: In a world where people occasionally feel out of control of their own body, well-being, and even their future, some consumers paradoxically find it necessary to temporarily relinquish control in order to regain some power over their life in the long-term. Control is transferred to external parties such as dieticians and renowned experts or even to sports and diet applications. External agency keeps consumers in check by provoking feelings of fear, anticipation, and anxiety:

Pauline: It (seeing a dietician) motivates you, well, you know, when you do not have the willpower. Someone to continuously watch over you, follow you...and you pay, you know, it motivates... cause the fear of not showing any improvements in the next appointment, I mean, it makes you, you know, go...

The interaction with the external agency (e.g., dietician) is not one without any problems. The educative process fails when consumers resist submitting to the authority of the dieticians in the first place. Such resistance is specifically prominent among children and teenage patients as well as when the individual goes to the dietician without her own will.

Shifting the focus away from food: Another strategy through which consumers regain some control over their diet is by forming a more functional relation with food:

Alice: Before, food was priority, a culture. Now the logic is to eat as little as possible. ...I don't eat unless hungry, I avoid occasions to eat...

In some cases, consumers replace eating with activities that further destroy their self-control (e.g., smoking, extreme shopping). However, many find healthier alternatives such as exercising.

Planning in advance: Healthy eating and cooking are associated with a great deal of planning in advance. Planning involves projecting on activities of what to cook and therefore what to buy, cooking ahead in batches and freezing in single-serve portions, as well as daily planning of the ideal balancing of the food intake. Such planning and cooking ahead affects healthy consumption through four positive (availability of healthy food, portion control, efficiency, sense of control/confidence) and two negative (overconsumption due to availability, frustration due to over-planning) routes.

Cooking as a form of control: Cooking provides higher control over the ingredients and the process. However, a complementary explanation that emerges from our dataset is that the effort one invests into preparing a meal make the consumers more committed to the food produced and, consequently, to a dietary regime based on health concerns. Cooking also leads to a healthier diet by enhancing consumers' awareness of what goes into a meal and, consequently, appreciation of the activity. Consumers describe this as a form of education, during which they not only enhance their cooking skills but also "train their taste buds to appreciate healthy food".

This study extends the discussion that consumers try to establish a sense of control by moderating their food consumption when they feel powerless in other domains of life (Rezek and Leary, 1991). We found the pursuit of health to be perpetual, full of uncertainties, and a source of anxiety for consumers. The strategies of control we delineated above help consumers navigate those dynamic discourses. Hence, while the pursuit of healthy eating can add to the feelings of stress, distrust, and confusion – trademarks of postmodern times – it can, at the same time, provide consumers with a sense of control over their lives and hope for their future wellbeing.

Our findings have significant implications for researchers, managers, and policy makers. We observed that high levels of planning may have negative consequences and should be done in moderation to prevent cognitive overload. Furthermore, when consumers give up unhealthy food or try to shift their focus from eating, they usually need other activities to broaden their horizons. Moreover, our analyses hint at tensions between dieticians and consumers as the latter tries to form a balance between submission and autonomy. Future research could focus on such tensions as well as their resolutions to reveal new forms of value co-creation in service environments.

1. Introduction

As obesity rates increase and more people suffer from diet-related illnesses (e.g., diabetes, cancer), food consumption has again become the centre of attention. Consumers, marketers, policy-makers as well as governmental and civil organizations have been debating

over the definition of healthy food and its standards. Considering that people may consume more food when it is presented as healthy (Finkelstein and Fishbach, 2010), these debates are timely and understandable. The current research explores how consumers, in interaction with other actors, establish the practices related to healthy food preparation and consumption.

We draw from a data set collected through a multi-sited netnography (4000 consumer posts) and 16 interviews with dieticians as well as consumers. The findings highlight a constant use of control strategies that involve food, the self, and external agents. Specifically, we find four strategies through which consumers pursue health, regulate their diet, and gain a sense of control over their well-being.

2. Food Consumption and Health

Research from the marketing field mostly focuses on food choice, amount of food intake, and how food consumption is influenced by contextual factors such as plate size, ads, packaging, ambiance in the restaurant (e.g., colour, music), and meal companions (Chandon and Wansink, 2007; Wansink and Cheney, 2005). Other research explores the relation between participation in meal preparation processes and perception of food. These studies find that consumers positively evaluate a meal whose preparation they participated (Troye and Supphellen, 2012). On a more negative note, adults (Dohle, Rall, and Siegrist, 2014) and children (Van der Host, Ferrage, and Rytz, 2014) can eat more when they prepare the meals themselves. This argument is supported by other researchers who have shown that people perceive home-made meals (whether prepared by them or not) as healthier (Costa et al., 2007) and, therefore, likely to consume more of it (Finkelstein and Fishbach, 2010).

From a socio-cultural perspective, symbolic meanings of food have been the centre of attention for researchers. Food items and food preparation and consumption practices help consumers manifest and affirm their commitment to ancestral roots and group identities or facilitate their integration into a new culture (Beagan, Ristovski-Slijepcevic, and Chapman, 2010; Kniازهva and Venkatesh, 2007; Wallendorf and Arnould, 1991). Food preparation techniques (e.g., boiling, fondue) and ability to appreciate and consume specific food items may distinguish consumers and social groups (Levi-Strauss, 1966). Particularly, eating out is a sign of taste and status, a form of entertainment (Warde and Martens, 2000), and a stage to perform social roles (Finkelstein, 1989). From this perspective, health concerns constitute one of the many constraints consumers face in their daily food consumption. That is, consumers negotiate multiple meanings of preparing food at home, buying processed food, or eating out in trying to regain control over their families' and their own well-being and social as well as financial needs.

Food consumption has also been studied more critically. Choices related to food or food preparation practices can be ways for consumers to contest negative aspects of consumerism or broad political issues (Beagan et al., 2010; Press and Arnould, 2011; Sasatelli, 2006). For instance, Beagan et al. (2010) show that for most consumers, who define themselves as committed to eating healthily, this practice is part of a broader concern for ethical consumption. Similarly, abstinence from specific food items helps consumers achieve a healthier lifestyle as well as resist consumer myths and authorities they don't trust (Kristensen, Boye, and Askegaard, 2011). Natural food is viewed as more authentic than fast food and processed alternatives (Levy, 1981). In addition, food preparation practices, especially cooking "from scratch," is defined as a form of craft through which consumers resist the impersonalizing and standardizing effects of the marketplace (Moisio, Arnould, and Price, 2004; Ulver-Sneistrup, Askegaard, and Kristensen, 2011).

Thus consumers, through various food consumption practices, restore their autonomy on others' and their own lives amidst the issues that are normally out of their control. Our research aims to further explore this topic by focusing on consumers' practices of cooking and eating healthily.

3. Methods

This study uses a two-step research methodology. First, a multi-sited netnography (Kozinets, 2010), on four websites (discusscooking, cookingbites, SparkPeople, eggheadforum) consisting a total of 4000 consumer posts, was conducted. These sites were chosen due to their high circulation rate and diversity of the posts on the topic. Then, semi-structured in-depth interviews were conducted with 10 dieticians and six consumers, who declared an interest in healthy eating and/or cooking. Some informants had, at one point of their lives, sought help from dieticians in order to regulate their eating habits. The interviews with consumers started with general questions about daily eating and meal preparation routines and moved onto more specific inquiries about healthy food, healthy eating, and food preparation. The interviews with dieticians revealed multiple discourses around healthy food consumption and processes of behavioural change. They also highlighted the tensions between "the official" notions of healthy food, and consumers' perceptions and actual practices of food preparation and eating.

The data set was coded and analysed with research goals in mind; first separately, then altogether by comparing and contrasting within and between the texts from interviews and netnography. Data analysis followed an iterative process and was in constant dialogue with the literature. The initial data interpretation revealed emerging themes and new questions that guided further data collection and analysis until the saturation.

4. Findings

Our analyses revealed four strategies through which consumers eat healthily and, ultimately, gain control over their bodies and lives: 1) relocating the locus of control to external actors (e.g., dietician, application), 2) shifting the focus away from food, 3) planning in advance, and 4) cooking to control food intake and content.

4.1. Relocating the locus of control

In a world where people occasionally feel out of control of their own body, well-being, and even their future, some consumers paradoxically find it necessary to temporarily relinquish control to regain autonomy over their life in the long term. Control is transferred to external parties such as dieticians and renowned experts or even to diet applications.

Going to a dietician, where consumers regularly write or talk about food, brings subconscious thought and behaviours to the surface, helping consumers to reflect on these. It forms a type of control first by creating a fear for "...what will the doctor say when s/he sees what I have eaten?" Then, it makes consumers think about what or how much to eat and, as such, helps them control their urges in daily life or in social gatherings.

The idea of a dietician frequently activates a control mechanism that keeps consumers in check by provoking feelings of fear, anticipation, and anxiety:

Pauline: It (seeing a dietician) motivates you, well, you know, when you do not have the willpower. Someone to continuously watch over you, follow you...and you pay, you know, it motivates... cause the fear of not showing any improvements in the next appointment, I mean, it makes you, you know, go...

Pauline's narrative illustrates how some consumers willingly submit to a regimen of discipline and punishment (e.g., reducing the amount of some food items) to compensate for their lack of internal control. Yet, dieticians' main goal is to gradually re-establish, in the long term, consumers' autonomy and positive perceptions over their diet, body, and health.

As dietician Haley explains "our aim is to teach them the ways to a healthy life, healthy food...make sure they can maintain this throughout their lives...it's really not about dieting." Yet, this educative process fails when consumers resist dieticians' authority. Such resistance is specifically prominent among children and teenage patients as well as when the person goes to the dietician without her own will.

4.2. *Shifting the focus from eating*

Consumers can also regain some control over their diet - hence their health and well-being - by forming a more functional relation with food:

Alice: Before, food was priority, a culture. Now the logic is to eat as little as possible. ...I don't eat unless hungry, I avoid occasions to eat...

While keeping food out of the focus of their lives comes naturally to some consumers, others may need external motivation and more time. As dietician Haley highlights, food is dangerous when people use it as a crutch to deal with their problems or as a goal to reach. Dieticians can help patients to keep food at bay and, as such, to exert more control on their consumption.

When consumers give up unhealthy food or try to shift their focus from eating, they usually need other activities to broaden their horizons and branch out into other aspects of life. In some cases, consumers replace eating with activities that further destroy their self-control such as smoking or extreme shopping. However, many find healthier alternatives such as exercising:

Amy: I can feel an ornery streak coming my way today. I am already thinking about Oreos. I gotta get outside and do more walking.

4.3. *Planning in advance*

Healthy eating and cooking are associated with a great deal of planning in advance. Especially when dieting, consumers, usually with the help of their dieticians or applications, calculate the necessary daily food intake and plan what to eat in each meal. We observe different types of planning activities such as preparing and taking healthy snacks to business meetings so as not to miss meal times or developing strategic menu alternatives for vacations. Thus, planning activities "re-contextualize" eating in specific consumption situations like vacations (Ostberg, 2003) and help consumers negotiate their urges and requirements of their diet.

Planning is not limited to consumers who are following a strict diet but a part of a daily routine for those who want to eat healthy. For instance, Bella, a housewife responsible for preparing meals at home, synchronizes her shopping and cooking activities:

Bella: I go to farmer's market and walk around a few times to find good stuff, you know...if I bought spinach I would cook it first, potatoes, cabbage, they can wait... Cabbage, like, changes its taste if you keep it long because of sulphur...according to the vegetable and their expiration time, I plan what to cook, buy...

Consumers also cook in advance to increase the availability of healthy meals. This way, when consumers are exhausted and tired, rather than ordering unhealthy meals, they can eat home-made food. Planning and cooking in advance also enables portion control. When consumers cook, they divide the large batch into smaller portion sizes and store in single-serving containers. This enables self-control over consumption later on.

Planning meals in advance and/or cooking in batches enhance efficiency and, hence, leaves more "me" time as Nathalie states: "once you cook it its good for 3 months so you can send more ME time." The extra time can be used to attend to one's own needs and indirectly exercise more autonomy on other aspects of life.

Furthermore, cooking in large batches and freezing in single-use portions creates a sense of readiness and control (or an illusion of it) for what's to come. Through food preparation, one is able to deal with the hardships of daily life - the challenges that the environment or oneself has created. From such readiness and knowledge of being prepared in the best possible way emerges a sense of self-confidence, control, and security:

Oddman: Most of the time I also try to make some dinners ahead that I can freeze and reheat. It's just nice to come home and know that I don't have to start from scratch.

Stacy: I find the more organized my food is (and how clean my house is, for some reason!) the better I do with weight loss!

Paradoxically, for some consumers, existence of food in the fridge creates an adverse effect, tempting them to consume food in large quantities. Such loss of control can be frustrating and lead consumers to invent new tactics such as preparing only specific things in advance for convenience:

Amanda: I don't find that cooking larger portions of meat ahead works for me, because I tend to go back and grab another portion if it's there. The only proteins I keep readily available are boiled eggs, small cheese portions, and nuts.

4.4 *Cooking as a form of control*

As previous research indicates, our data also reveals that cooking provides higher control over the ingredients and the process. However, a complementary explanation that emerges from our dataset is that the effort one invests into preparing a meal make the consumers more committed to the food produced and, consequently, to a dietary regime based on health concerns. The dietician interviews also indicate that among their patients, those who cook and prepare their meals at home have a higher success rate and are better at adapting to their diet for longer terms:

Dietician Marvin: ..those who prepare their meals are more committed to their diets...it's controlling what you eat.... they regard it (their diet) as "my own labor, like hardwork."

Cooking can also lead to a healthier diet by enhancing consumers' awareness of what goes into a meal and, consequently, their appreciation of the activity. Consumers describe this as a form of education, during which they not only enhance their cooking skills but also "train their taste buds to appreciate healthy food".

5. Discussion and Implications

Food items and practices associated with it can become focal to our lives by strengthening our relation with our environment and contextualizing our experiences (Borgmann, 2000). Building on this

view, this study extends the debates that consumers try to establish a sense of control by moderating their food consumption when they feel powerless in other domains of life (Rezek and Leary, 1991). Indeed, attesting to Bauman (2012), we found the pursuit of health – in our case, healthy eating – to be full of uncertainties and a source of anxiety for consumers. Such uncertainty and anxiety is nurtured both by the simultaneous existence of multiple views – and choosing which to follow, integrate or ignore – and by the quick changes in the discourses surrounding health and food. While these emotions may lead some consumers to reject the official notions of health, the strategies of control delineated above help consumers navigate those dynamic discourses. Hence, while the pursuit of healthy eating can add to the feelings of stress, distrust, and confusion it can also enhance consumers' sense of control over their lives and hope for their future wellbeing.

Our findings have significant implications for researchers, managers, and policy makers. We observed that high levels of planning may have negative consequences and should be done in moderation to prevent cognitive overload. Furthermore, when consumers give up unhealthy food or try to shift their focus from eating, they usually need other activities to broaden their horizons. Moreover, our analyses hint at tensions between dieticians and consumers as the latter tries to form a balance between submission and autonomy. Future research could focus on such tensions as well as their resolutions to reveal new forms of value co-creation in service environments.

It Happens Because I'm Watching It: The Effect of Observing an Uncertain Event on Probability Estimation

Amin Attari, University of Kansas, USA
Promothes Chatterjee, University of Kansas, USA
Frank Cabano, University of Kansas, USA

EXTENDED ABSTRACT

Many of decisions that people make deal with assessing the probabilities of uncertain events. For example, people estimate the chance of rain, the odds of their favorite team winning the Super Bowl, or the chances of a company's stock price increasing. Subsequently, people form preferences and make decisions based on their judgments of subjective probabilities. Because of the prevalence and importance of probability estimation, a large body of research has investigated different factors that can influence probability judgments. The findings show that people have biases in estimating the subjective probabilities of uncertain events. These biases can lead individuals to either overestimate or underestimate the subjective probabilities. Examples of these biases include anchoring, availability, and representativeness (Tversky and Kahneman 1974). Moreover, it has been shown that illusion of control is a bias that can lead individuals to overestimate the subjective probabilities (Langer 1975; Hamerman and Johar 2013). For instance, as a result of an illusory sense of control, people make larger bets when they roll the dice themselves (Langer 1975), are less likely to trade their lottery ticket when they choose (vs. are given) the ticket numbers (Langer 1975), and prefer higher speeds as a driver versus a passenger (McKenna 1993).

In this research, we investigate whether observing the occurrence of an uncertain event affects probability estimation of that event. We hypothesize that people overestimate the likelihood of a positive outcome happening when they observe (vs. do not observe) the uncertain event unfolding in front of them. For a similar reason, we expect that individuals underestimate the chances of a negative outcome happening when they observe the occurrence of the event. We rule out alternative explanations (such as involvement and wishful thinking) and show that the results are attributed to individuals' illusion of control. That is, when people observe (vs. do not observe) the occurrence of an event, they have the illusion that they can control the outcome of the event in their own favor. This illusory sense of control leads to a biased estimate of subjective probabilities. We provide support for our hypotheses in four studies.

Study 1 tested the hypothesis that consumers overestimate the likelihood of a positive outcome happening (and similarly, underestimate the chances of a negative outcome occurring) when they observe the uncertain event unfolding in front of them. One hundred and thirty two students participated in the study for course credit. Participants were randomly assigned to a condition in a 2 (valence: positive vs. negative) \times 2 (watching: yes vs. no) between subjects design. Participants were instructed to imagine a scenario in which they had made a bet with a friend that their favorite football team would win (not lose) the upcoming game. The scenario added that the game would start in a few hours. Participants in the watching condition imagined that at the time of the game, they would be at home and would watch the game live on TV. Participants in the not watching condition imagined that at the time of the game, they would not be at home and would not watch the game live on TV. Participants indicated the likelihood that their team would win (lose) the game and therefore they would win (lose) the bet (1 = extremely unlikely; 7 = extremely likely), as well as the chances that their team would win the game (on a 0-100 probability scale). Four participants were

excluded from the analysis since they failed to answer an attention check question.

An ANOVA on the likelihood of winning the game as the dependent variable and valence and watching as factors revealed a main effect of valence ($F(1, 124) = 10.09, p < .001$). Participants indicated higher likelihoods for the occurrence of the outcome when we asked them about chances of winning ($M = 5.02$) versus chances of losing ($M = 3.63$). This finding is in line with prior research on optimistic bias, which argues that people are optimistic in making probability judgments of future events (Chambers, Windschitl, & Suls 2003; Weinstein 1989). More importantly, the main effect of valence was qualified by a significant interaction between watching and valence ($F(1,124) = 10.09, p = .002$). Simple contrasts show that there was an effect of watching for the positive valence ($M_{\text{watching live}} = 5.32$ vs. $M_{\text{not watching live}} = 4.70, t(59) = 2.35, p = 0.02$), as well as an effect of watching for the negative valence ($M_{\text{watching live}} = 3.30$ vs. $M_{\text{not watching live}} = 3.94, t(59) = 2.185, p = .03$). Similarly, an ANOVA on the chances of winning the game (on a 0-100 probability scale) as the dependent variable, and watching and valence as factors revealed a main effect of valence ($F(1, 124) = 51.57, p < .001$). Participants indicated that the likelihood of the occurrence of the outcome was higher when we asked them about the chances of their team winning ($M = 60.36$) versus chances of their team losing ($M = 42.31$). More importantly, there was a significant interaction between watching and valence ($F(1,124) = 5.63, p = .02$). Simple contrasts reveal that there was a directional (although not statistically significant) effect of watching for the positive valence ($M_{\text{watching live}} = 62.00$ vs. $M_{\text{not watching live}} = 58.67, t(59) = .97, p = .34$), and a significant effect of watching for the negative valence ($M_{\text{watching live}} = 37.94$ vs. $M_{\text{not watching live}} = 46.56, t(59) = 2.37, p = .02$). These findings provide support for the hypothesis that individuals who observe (vs. do not observe) the occurrence of an event make biased estimates regarding the likelihood of the occurrence of an outcome in their own favor.

Experiment 2 was designed to rule out a semantic anchoring explanation (related to the use of words "will" or "will not" in the first experiment). Seventy two (42 men) participants recruited from MTurk were randomly assigned to one of the two conditions: watching vs. not watching. A scenario similar to study 1 was used. Participants in both conditions were asked to imagine that their favorite football team was going to play in an important game the next night at 6pm. The description told participants in the watching (not watching) condition that they were going to watch the game live on TV (do some pre-planned activities). To prevent semantic anchoring, no positive or negative words (will or won't) were used. At the end, we asked participants to indicate their opinions on the chances of their team winning the game on a 0-100 scale. Six participants were excluded from the analysis since they failed to imagine the scenario correctly according to an attention check question. As expected, participants assigned significantly higher probabilities to their team winning the game in the watching condition ($M=60.42, SD=15.11$) compared to the not watching condition ($M = 52.31, SD = 21.13, t(64) = 1.72, \text{one-tailed } p < 0.05$).

The objectives of experiment 3 were two-fold: (1) to demonstrate the robustness of our effect with a behavioral manipulation, and (2) to rule out some alternative explanations. The study used a

single factor (watching: live vs. recorded) between participants design. Eighty six students from a major Midwestern university participated in the study for course credit. Participants in both conditions participated in a card game in which the researcher had ten random cards from the deck. The ten cards consisted of different numbers and suits. The participants were told that the researcher would randomly select one of the cards. If the researcher selected a heart, the participant would win and if the researcher selected a card with another suit, the participant would lose the game. Participants in the live condition were told that they would be watching the game unfold in front of their eyes, while participants in the recorded condition were told that they would watch a previously recorded video of the game. After watching the demonstration of the game, participants were asked about the likelihood that they thought they would win the game (1 = extremely unlikely, 7 = extremely likely).

Results show that participants in the live condition indicated higher likelihood to win compared to participants in the recorded condition ($M_1 = 3.24$ vs. $M_2 = 2.71$, $t(84) = 1.69$, one-tailed $p < .05$). Moreover, results indicated that there was no significant difference in the level of wishful thinking ($M_1 = 2.89$ vs. $M_2 = 3.08$; $t(84) = -.79$; $p = .43$), involvement ($M_1 = 3.30$ vs. $M_2 = 3.39$; $t(84) = -.27$; $p = .79$), interest ($M_1 = 3.24$ vs. $M_2 = 2.92$, $t(84) = .91$; $p = .37$), positive affect ($M_1 = 2.45$ vs. $M_2 = 2.57$, $t(84) = -.59$; $p = .56$), and negative affect ($M_1 = 1.34$ vs. $M_2 = 1.49$, $t(84) = -1.26$, $p = .21$) across the two conditions.

In experiment 4, we sought to gain process evidence for the effect of watching on individual's estimation of the likelihood of an event's outcome. One hundred and twenty participants (72 men, $M_{age} = 34.2$) recruited from MTurk were randomly assigned to one of two conditions: watching vs. not watching. In both conditions, participants were instructed to imagine that they would be playing in a game in which winning entailed choosing a blue ball from an urn that contained some blue and some red balls. The scenario added that the game was going to be held in an auditorium and an independent, trustworthy person would pick a ball for each participant. All participants for whom a blue ball was chosen would win and all participants for whom a red ball was chosen would lose. In the watching (not watching) condition, participants were told that they would see (would not be present to see) the game in the auditorium. Next, participants indicated their probability estimate of winning the game on a 1 (very low probability) to 7 (very high probability) scale. Then they responded to a 3-item illusion of control measure (adapted wording from Langens 2007), and the 20-item Desirability of Control Scale (Burger and Cooper 1979). Finally, to rule out an alternative explanation, participants indicated their level of wishful thinking ("To what extent do you wish to win this game?") on a 1 (not at all) to 5 (extremely) scale.

One-way ANOVA revealed that participants in the watching (vs. not watching) condition reported higher expectations of winning the game ($M_1 = 4.03$ vs. $M_2 = 3.53$; $F(1, 118) = 6.33$, $p = .01$) as well as higher levels of illusion of control ($M_1 = 2.95$ vs. $M_2 = 2.24$; $F(1, 118) = 4.72$, $p < .05$). Importantly, a bootstrapping analysis (with 10,000 samples) indicated that the illusion of control emerged as a significant mediator in the relationship between watching and probability estimate (illusion of control: indirect effect = .21, 95% CI: .04 to .46). As expected, the effect of watching on wishful thinking did not reach the conventional level of significance ($M = 4.13$ vs. $M = 3.86$; $F(1, 118) = 2.80$, $p = .10$). When entering wishful thinking as the mediator in a bootstrap analysis (10,000 samples), the results indicated no significant indirect effect of watching through wishful thinking upon expectations of winning the game (wishful thinking: indirect effect = .04, 95% CI: -.01 to .19). In addition, when enter-

ing both the illusion of control and wishful thinking as simultaneous mediators with 10,000 bootstrap samples (model 4; Hayes 2013), only the illusion of control emerged as a significant mediator in the relationship between watching and probability estimate (illusion of control: indirect effect = .20, 95% CI: .04 to .46; wishful thinking: indirect effect = .02, 95% CI: -.03 to .13). Finally, a moderated mediation analysis with 10,000 bootstrap samples (model 8; Hayes 2013) revealed that the illusion of control significantly mediates the relationship between watching and probability estimate at moderate (indirect effect = .19, 95% CI: .03 to .44) and high (indirect effect = .34, 95% CI: .08 to .71), but not low (indirect effect = .04, 95% CI: -.19 to .28) levels of desire for control. The same pattern of results remained when we included wishful thinking as a covariate in the model. Thus, watching the game unfold significantly increased the expectation of winning due to a heightened illusion of control, but only for those individuals who have a moderate or high need to possess a sense of control in their lives.

Taken together, the findings of this paper suggest that the mere observation of an uncertain event increases the subjective probability of the occurrence of a desirable outcome. In addition, the illusion of control emerges as the psychological process underlying this effect. This research adds to the two streams of research on subjective probability judgements and illusion of control by identifying a novel situational variable (the mere observation of an event) that increases the illusory perception of control and leads to a biased subjective probability estimate. Marketers can use the findings of this research by providing consumers with the opportunity to observe the occurrence of uncertain events (for example gambling or stock market). This would lead individuals to overestimate the probability of a desirable outcome and therefore engage in more risk taking behavior. Public policy officials can inform individuals about the downstream consequences of watching uncertain events (such as gambling) on overestimating the likelihood of a desirable outcome and consequently engaging in excessive risky behavior.

Authenticity Under Threat: When Social Media Influencers Need To Go Beyond Passion

Alice Audrezet, Institut Supérieur de Gestion, Paris, France
Gwarlann Caffier de Kerviler, Lille Catholic University, France
Julie Guidry Moulard, Louisiana Tech University, USA

EXTENDED ABSTRACT

Recent research has pointed out the emergence of new online actors, “social media influencers” or SMIs (Etter et al. forthcoming). SMIs are defined as “people who possess greater than average potential to influence others due to such attributes as frequency of communication, personal persuasiveness or size of—and centrality to—a social network.” With the growing success of many SMIs, companies are intensifying their investment in “word-of-mouth marketing” or WOMM (Kozinets et al. 2010). One of the reasons brands partner with SMIs is that they are considered trustworthy and “one of the few forms of real, authentic communication” (Scott 2015, 295). However, sometimes collaborating with brands may question this authenticity as SMIs’ inner desires to focus on products they are passionate about are challenged by commercial opportunities to showcase brands that they would not ordinary like. Despite growing research on influencers and acknowledged pressure of pursuing financial gains, past research has overlooked the challenges to remain authentic when collaborating with brands. As such, this research focuses on the question: What are the strategies of SMIs to maintain authenticity while they are under commercial pressure?

SMIs often start as non-professional contributors who share their daily life and respond to fan comments (Colliander and Erlandsson 2015). However, over time SMIs become professionals with a mass audience of followers and gain competence in generating sophisticated content such as creation of stories, videos, visuals, etc. (McQuarrie, Miller, and Phillips 2013). In turn, SMIs leverage their online influence to partner with brands and negotiate with sponsors. Their credibility might then be questioned as the persuasive effect of their messages is often attributed to their perceived noncommercial nature contrasting with branded advertisements. Recent research started to investigate bloggers’ authenticity under commercial pressure (Savignac, Parmentier, and Marcoux 2012), but the analysis considered solely online self-presentation without considering how influencers communicate about brands, products, and collaborations.

Authenticity is recognized in the marketing literature as an important attribute, as prior research suggests that consumers increasingly desire authenticity in the products and brands they consume (Chronis and Hampton 2008). One particular notion of authenticity has been gaining acceptance, which revolves on whether an individual or brand expresses their true self (Guidry Moulard, Raggio, and Folse 2016). In this body of research, authenticity is linked to the distinction between intrinsic motivations and extrinsic motivations. Holt (2002, 83) notes, “to be authentic, brands must be disinterested; they must be perceived as invented and disseminated by parties without an instrumental economic agenda, by people who are intrinsically motivated by their inherent value”.

We chose the context of fashion, beauty and lifestyle, as it is one of the most successful and visible domains of digital production (Duffy and Hund 2015). We analyze posts from 49 influencers participating in 9 brand campaigns that employed multiple SMIs simultaneously. These observations are complemented with 27 interviews with SMIs varying in audience size to understand “behind the scene” goals pursued to project this authenticity.

From the posts about the campaign, we identified main topics, perspective towards the campaign and rapport with ones’ experience. The analysis allowed for identification of 2 distinct patterns for expressing authenticity under commercial pressure: 1) expressing inner self and be-

ing passionate even when involved in a collaboration; 2) proving what is said, reflects the truth about the partnership, the influencer or the products promoted.

Interviews confirm that SMIs manage authenticity both through communicating passion and giving a true report of reality. We label these two potentially complementary strategies as: passionate authenticity and/or informational authenticity.

The notion of passionate authenticity has been established in the previous literature (Guidry Moulard et al. 2016) but we identify a new form of authenticity, which is about being consistent with the facts and not lying, that we name informational authenticity. It refers to the degree to which what is claimed is consistent with reality about the commercial partnership with the brand, the SMI and the products. These two strategies are sometimes considered as an optimal goal, rather than a systematic rule of conduct. Also, SMI often seem to use them sequentially. SMIs start out of genuine passion but, with growing recognition, they are tempted to accept partnership with brands they are not passionate about. Reflecting on the tension between their inner passions and financial gains, SMIs then implement a strategy of informational authenticity and communicate more transparent information to their audience.

Informational authenticity may have links to Grayson and Martinec indexical authenticity “when an object is believed to be ‘the original’ or ‘the real thing’” (2004, 297) and “it has the spatio-temporal link that is claimed” (2004, 298). However, authors focus on objects as indexically authentic while we show how it applies to individuals. Informational authenticity can be also associated with the notions of having integrity and being professionally ethical. Mohart et al. (2015) suggest that one component of brand authenticity is integrity. We complement their research by adding the notion of sincerity in what is claimed. Napoli et al. (2014) identify a related notion of sincerity, as one component of brand authenticity, but do not offer a definition of their sincerity concept.

Our findings should also help SMIs manage their authenticity under threat as it suggest that they can either use Passion or Information. SMIs should be cautious to report the reality of the partnership and the product in their WOMM contents. Similarly, they should keep producing noncommercial messages about brands they are really passionate about. In the same vein, managers should be attentive to let SMIs selects products in order to increase enthusiasm for the brand and minimize constraints to give room for personalized communication aligned with SMI’s style and opinions.

WeChat Brands: Communal Interaction and Brand Publicity in Chinese Social Media

Yuxin Bai, Lancaster University, UK
Xin Zhao, Lancaster University, UK
Hayley Cocker, Lancaster University, UK

EXTENDED ABSTRACT

Extant research on communal consumption has previously focused on how brands facilitate communal interaction and the expression of collective identity (Cova, Kozinets, and Shankar 2007; Muñiz and O'Guinn 2001; Schau, Muñiz, and Arnould 2009) to recently how brands also enhance publicity, visibility, and other forms of sociality (e.g., Arvidsson and Caliendo 2016; Kozinets et al. 2010; McQuarrie, Miller and Phillips 2013). This stream of work suggests a changing focus from a brand's "linking value" to its "publicity value", and argues that consumer assemblies are motivated not only by the desire for interaction but also by the desire for visibility and publicity. The essential issue is how varied communication forms shape communication content and communal practices (Kozinets et al. 2010). In this paper, we examine a hybrid form of sociality that conceptually lies between communal interaction and brand publicity.

The context of our study is China's dominant social media platform, WeChat. With more than 846 million monthly active users, WeChat has dominated Chinese social media space since its launch on January 21st 2011. It successfully integrates a variety of social media functions offered only separately by other Western platforms, most of which are not available for Chinese consumers (e.g., Twitter/Facebook/Instagram). WeChat allows users to do instant message, make video-calls, share experiences, pay bills, play games, shop, blog, book hotels and flights, and even to call a taxi. This integrated social media hybrid provides a unique opportunity to examine how technology shapes consumption and how social media form shapes its content (see Kozinets, Patterson, and Ashman 2017).

In this study, we focused on a particular function, WeChat Blog or Public Account. WeChat bloggers create various content including food, health, fashion, travel etc. WeChat blogs often have a large devoted audience, whose comments are routinely integrated by bloggers to create more engaging commercial content. Although everyone can leave a comment, only comments selected by the blogger will be publicly displayed. Filtered comments and the original blog become integrated and contribute to the development of a personal brand but not necessarily a community.

We used netnography (Kozinets 2015) and in-depth interviews (McCracken 1988) to collect data. Online fieldwork focused on WeChat blogs and reader comments. As a WeChat blogger with over 20,000 followers and several brand collaborations to date, the first author also kept notes of her experiences and interactions on WeChat. 30 in-depth interviews were conducted with 20 popular bloggers from various fields and 10 marketers who used WeChat public account for promotions in China. Our analysis took an iterative approach moving between data and theory (Spiggle 1994; Kozinets 2015).

Our findings suggest that WeChat brands represent a markedly different form of sociality to the brand community or brand public discussed in previous studies. WeChat blogs discourage interaction among users and attention is carefully directed toward the communication content. Participants' comments are not immediately displayed but are carefully filtered by bloggers. Promotion is an iterative process, in which the blogger generates a blog entry, elicit comments, then select and use the comments to construe new meanings that are consistent with the blog.

Previous research has noted consumers' dislike of commercial messages on social media (Pashkevich et al. 2012) and has highlighted

the commercial-communal tensions (e.g., Kozinets et al. 2010). However, we found that Chinese users appear more receptive toward commercial content. Although consumers may not necessarily reject or disdain commercial messages on blogs (McQuarrie, Miller, and Phillips 2013), motivations for positive responses are culturally embedded and may go beyond the notions of authenticity that has been offered as an explanation in extant research.

Within this "semi-closed" social media platform, utilizing reader comments is important in sustaining a successful WeChat brand. Four types of comments that illustrate the engagement of devoted readers are identified: loyalty and devotion, blog content extension, inquiries about promoted brands, and opposition to bloggers' views. WeChat bloggers do not change their narrative style or blogger communicative character in their word-of-mouth marketing (WOMM) promotions. Key bloggers strategically select and use comments to build credibility and authenticity, to express connection, to provide empathetic understanding, and to remove unwanted audience and guard their WeChat brand. All these differ from the previous notion of WOMM, in which bloggers adopt varied narrative strategies (e.g., evaluation, explanation, embracing, and endorsement) to justify their promotion of marketing message (Kozinets et al. 2010). We discuss the theoretical implications of our study for our understanding of communal consumption and brand publicity.

What You Are Getting and What You Will Be Getting: Testing Whether Verb Tense Affects Intertemporal Choices

Akshina Banerjee, University of Minnesota, USA
Oleg Urminsky, University of Chicago, USA

EXTENDED ABSTRACT

Since the 19th century, philosophers, linguists and psychologists have wondered about the causal role of language on thought. Perhaps the best known version of this idea, often called the Whorfian hypothesis, is that differences in languages determine or at least influence differences in thought. In this view, the structure of a given language can facilitate some ways of thinking and impede others, leading some cognitions to be more accessible and therefore more prevalent among speakers of that language, in ways that are empirically testable (Hunt and Agnoli 1991). For example, differences in the way languages frame time in spatial terms (horizontally in English vs. vertically in Mandarin) would then lead to differences in how speakers of each language process visual demonstrations of time. This idea, while highly intuitive, has been quite controversial, and seemingly promising empirical demonstrations (Boroditsky 2001) have sometimes failed to prove robust (January and Kako 2006).

This paper tests the effect of linguistic form on decision making, specifically intertemporal choices. We build on Chen (2013), which distinguishes between languages that have strong vs. weak Future Time Reference (FTR) in their verb tense. Weak FTR languages are those which have the same verb forms for present and future events. For example, Finnish uses the same linguistic form (*on kylmä*) to express present and future cold and merely changes the time term to convey “it is cold today” and “it will be cold tomorrow”. In contrast, English uses different verb tenses (is vs. will be) to convey this difference. Chen (2013) relates these linguistic differences to financial behaviors, and finds that speakers of weak FTR languages tend to have higher savings rates and are more likely to report a range of other far-sighted behaviors. This has been widely debated, with some studies finding additional evidence through other means (e.g., experiments with bilingual participants, Perez & Tavits 2017), while others have questioned the robustness of the finding.

In this paper, we investigate one way in which language might influence choice. We test whether in-context linguistic differences (i.e. the wording of choice options) shape intertemporal preferences, either due to priming or inferences.

We leverage an inherent ambiguity in verb use in some strong FTR languages, especially in English. While separate verb tenses do exist for present and future events, English speakers have the option of using the present form when describing a future event. For example, consider a person who is being informed that he or she will receive an amount of money in the future. This can be conveyed in multiple ways:

1. You get \$5 in a week.
2. You are getting \$5 in a week.
3. You would get \$5 in a week.
4. You will get \$5 in a week.
5. You will be getting \$5 in a week.

The above sentences have the same meaning – the only difference is that (1) and (2) use the same form as if discussing the present, (3) uses a neutral form that does not imply a timing, while (4) and (5) use a form reserved for discussing the future.

Across six studies, we test the effect of verb tense framing of choice options on intertemporal preferences, varying the degree to which diagnostic cues are present in the decision context.

Study 1: Direct Inferences from Verb Tense

Online participants (N=222) read 10 scenarios in which two people were getting money, described using different tenses, and chose which person would be getting the money sooner. The verb tense had a substantial effect. For example, 85% of participants thought that “Bob gets \$20” would happen earlier than “John would get \$20”. Of the 10 comparisons, participants were significantly more likely to indicate that one of the options would be earlier than the other in all cases but one.

Based on a combined regression analysis, “gets” was the verb tense seen as occurring the earliest. Compared to the “gets” formulation, all the other verb tenses were seen as occurring later, to varying degrees: “is getting”, $\beta = +.131$; “will get”, $\beta = +.310$; “is going to get”, $\beta = +.408$; “would get”, $\beta = +.501$; all $ps < .001$.

Study 2: Within-Choice Verb Tense Framing

In the next study, we administered intertemporal choices to 112 participants. The survey flow was designed in a way such that every participant first got one set of four initial questions, using the “would get” verb tense.

Then every participant made a series of choices between sooner-smaller, later-larger options, specifying the (randomly determined) amount and time of delay. The verb tense of both the sooner-smaller and later-larger option were independently and systematically varied across questions. The final set of four final questions used the “would get” tense.

Choices of the later-larger option significantly depended only on the sooner smaller ($\beta = -.04$, $p = .043$) and later-larger amounts ($\beta = .05$, $p = .017$). Choices were not affected by the verb tense (all $ps > .11$). Controlling for income, order, interacting with education, gender and age did not change any of the results.

Study 3: Between-Subjects Verb Tense Framing

In the next study (N=259), we varied the tense of both choice options (present, neutral or future) between subjects in an initial round of eight choices. Participants chose between a sooner-smaller and later-larger option (with timing and amounts randomized). After the initial choices, each participant made eight more choices between options presented with neutral tense.

Choices of the later-larger option in the first set (with tense manipulated between subjects) were significantly dependent on only the sooner-smaller amount ($\beta = -.07$, $p < .001$), later-larger amount ($\beta = .07$, $p < .001$), and delay ($\beta = -.03$, $p = .003$), but not verb tense (all $ps > .24$). Furthermore, choices in the second set (same in all conditions) were not affected by the verb tense used in the first set. Controlling for income, interacting with education, gender, age and collapsing across type did not change any of the results significantly.

Study 4: Benchmarking Verb Tense Framing

Thus far, we find no effect of verb tense framing. This is surprising, not only in light of the findings of Chen (2013), but in light of the strong inferences people drew from verb tense alone in Study 1. In this study (N=1460), we test whether this lack of a verb tense effect was explained by inattention or depended on question framing.

Each person made two intertemporal choices (present vs. future, and near future vs. distant future). We independently varied the tense

of each choice option, across subjects (present, future or no tense). We also varied whether the timing was presented as a date or delay (e.g., in 6 weeks vs. on September 2d), which has been found to affect choices in prior research (Read et al 2005; LeBoeuf 2006). Lastly, we varied whether the choice options specified the non-payments (e.g, \$30 today vs. \$30 today and \$0 in six weeks), which has also been shown to shift choice (the “hidden zero effect”; Magen, Dweck & Gross 2008; Read, Olivola & Hardisty 2016). In all, the study included 20 conditions in a 5(verb tense) x 2(date/delay) x 2(hidden zero) design.

Consistent with the prior literature on the date-delay effect, people were less patient when the delays were presented as weeks rather than dates ($\beta = -.15, < .001$). Likewise, we replicated the hidden zero effect, with more patience when the hidden zeros were shown ($\beta = .17, p < .001$). Despite the strong sensitivity of the participants to these aspects of how choice options were communicated, we found no effects of verb tense ($ps > .57$). Furthermore, the null effect of verb tense was robust across the different ways of presenting the options tested (date vs. delay and hidden-zero present vs. absent).

Study 5: Vague Temporal Information

In all the studies thus far, we have used specific monetary amounts and specific delays. The lack of a verb tense effect could be due to redundancy – once people know the exact timing differences between the sooner-smaller and later-larger options, they are not sensitive to verb tense. In the next study (N=246), we test this possibility by using vague temporal cues (“soon”, “later”, “at some point after”) instead of specific timing information. Participants made a series of intertemporal choices, varying the timing words and verb tenses of the options.

While participants were sensitive to the vague temporal cues used to describe the options (all $ps < .001$), there were no significant effects of verb tense ($ps > .14$). Thus, even when participants had scope to make inferences about the timing, because they did not have precise information, the verb tense did not impact their choices.

Study 6: Vague Temporal Information

In the last study (N=184), we test the effect of verb tense in the most extreme case – the complete absence of *any* timing cues. Participants made a series of choices between two options, each specifying a dollar amount and varying in the verb tense. For example, a person might be asked to choose between “You get \$19” and “You are going to get \$21”. The amounts varied randomly between \$19 and \$21, and we tested all five verb tenses.

As in Study 1, the verb tense had a substantial effect when timing cues were entirely absent. For example, 71% of participants preferred an option framed as “You get” rather than an option framed as “You are going to get”, averaging across tested amounts. Of the 10 comparisons, participants’ choices revealed a significant preference for one framing over the other for all but one.

Based on a combined regression analysis, “You get” was the verb tense that made the option most likely to be chosen. Compared to the “You get” formulation, all the other verb tenses were less likely to be the chosen option, to varying degrees: “You are getting”, $\beta = +.09$; “You will get”, $\beta = +.122$; “You are going to get”, $\beta = +.225$; “You would get”, $\beta = +.382$; all $ps < .001$.

Discussion

Across six studies, we tested people’s inferences from verb tense and the effects of verb tense on different kinds of intertemporal choices. We find that people can make consistent inferences from verb tense, seeing events described in present as occurring sooner than events described in future tense or a neutral tense. However, when information about timing is present, we find no effect of verb tense on intertemporal choices. This lack of an effect of verb tense is estimated with high confidence, as the studies use large samples and we do find a strong and highly significant impact of other option framing effects identified in the prior literature. Furthermore, the lack of an effect of verb tense persists even when the available timing cues are vague and only convey incomplete information. We only find an effect of verb tense in the complete absence of *any* timing cues whatsoever.

Overall, we conclude that the underlying psychology of verb tense inference is right – people can and do use verb tense in a consistent manner as a cue for timing. However, in practice, the verb tense of the options is highly unlikely to shape preferences, contrary to at least some interpretations of the Whorfian hypothesis motivating Chen (2013), as some timing information is typically present in choice options.

Pain of Payment and the Moral Tax: the Neural Basis of the Credit Card Effect

Sachin Banker, University of Utah, USA

Derek Dunfield, Massachusetts Institute of Technology, USA

Alex Huang, Massachusetts Institute of Technology, USA

Drazen Prelec, Massachusetts Institute of Technology, USA

EXTENDED ABSTRACT

When people shop while using credit cards, they generally tend to loosen their restraints on spending relative to using cash. One reason as to why people may spend more when using credit cards is that the payment method may blunt the negative subjective feeling people experience when giving up hard earned dollars. In other words, credit cards may diminish the *pain of payment* relative to using cash.

Yet, little evidence has been offered in support of this mechanism, in part due to methodological limitations. Only a few attempts to measure differences in the pain of payment between payment methods have been reported in the literature (Shah et al. 2015; Thomas, Desai, and Seenivasan 2011). While results from these experimental studies are consistent with the pain of paying hypothesis, the self-reported measures of pain of payment pose interpretive challenges. Because previous research has established that paying with credit card leads people to place less attention on cost attributes (Chatterjee and Rose 2012) and that paying with credit impairs recall of cost information (Soman 2001), higher self-reported displeasure of paying in cash conditions may simply reflect the relative ease with which negative cost information came to mind rather than the actual pain of paying associated with the transaction. We applied fMRI methods to directly observe changes in neural activity during the purchase decision and thus overcome the many limitations inherent in self-report measurements.

To investigate how payment methods influence these neural mechanisms involved in making purchase decisions, we scanned human subjects ($n = 27$) using fMRI while they viewed products and made shopping decisions. The shopping task was designed to simulate a retail shopping experience where participants browsed through different products. We first collected a database of over 22,000 top selling products on Amazon.com, hierarchically organized into categories. Prior to entering the scanner participants indicated the departments they were most interested in shopping within. For each participant, half of the products shown were randomly determined to be available with credit card only while half were available with cash only. Participants browsed products in sequence, and for each item they were asked whether they were interested in purchasing it. If so, the product was added to the participant's shopping basket, and if not, no additions were made to the basket. After participants indicated whether or not they wanted to buy, they were shown a confirmation page and then signed off on their decision. At the end of the study, participants were asked to pay out-of-pocket using the specified payment method for one randomly selected trial.

We examined how neural activation in each *a priori* determined region of interest (ROI) differed between purchase and non-purchase decisions. ROI anatomical coordinates were chosen using meta-analytical studies (Bartra, McGuire, and Kable 2013; Kelly et al. 2012). When participants were shopping with credit, we observed that their purchase decisions were distinguished from non-purchase decisions by activity in reward networks, including the striatum and ventromedial prefrontal cortex (VMPFC). When participants were making purchase decisions using cash, we observed a price-dependent pattern of activity distinguishing purchase trials from non-purchase trials. Under low prices, purchase decisions were associated with heightened activity in the striatum and VMPFC. Purchases of high-

price items when using cash were more strongly associated with lowered right anterior insula cortex (rAIC) activity.

These findings imply that credit cards change the evaluative criteria consumers use when making a purchase decision. Consumers may be asking simply "do I like it?" rather than stopping to question "is it worth it?" when they decide whether or not to buy (Karmarkar, Shiv, and Knutson 2015). In addition, we found that shopping with credit did not lead to exaggerated deactivation in the rAIC, inconsistent with the idea that credit cards lower the pain experienced during a transaction. Instead, credit cards appeared to generally facilitate greater reward sensitivity, rendering consumers less sensitive to price information. Overall, our findings advance theoretical accounts of the mechanisms by which payment methods influence spending behavior.

I Don't Care if You're Committed, But "We" Do: How Group Brand Connections Affect Access-Based Brand Extension Evaluations

Aaron J. Barnes, University of Illinois at Urbana-Champaign, USA
Tiffany White, University of Illinois at Urbana-Champaign, USA

EXTENDED ABSTRACT

Analysts expect the sharing economy's revenue potential to reach \$300B by 2025 (Geron 2013; Price Waterhouse Cooper 2015). To leverage this growing trend, many firms have begun to extend their brands into sharing spaces by introducing brand extensions that offer consumers access to, but not complete ownership of, their goods and services (i.e., access-based brand extensions). Examples include manufacturer-based car-sharing offerings (e.g., Ford2go; Baumeister, Scherer, and Wangenheim 2015) and online degree programs from physical universities (e.g., online MBA).

Among other factors (most notably, the perceived fit or similarity between the parent and the extended brand; Aaker and Keller 1990; Park, Milberg, and Lawson 1991), the success of brand extensions also depends on the nature of the consumer brand relationship. Not surprisingly, brand attachment has been linked to more favorable reactions to brand extensions (Fedorikhin, Park, and Thomson 2008; Kirmani, Sood, and Bridges 1999; Park and Kim 2001), even when the extension is unsuccessful (Cheng, White and Chaplin 2012, Swaminathan, Page and Gurhan-Canli 2007).

This research builds upon prior research, but offers two important points of departure. First, we theoretically differentiate access-based brand extensions (hereafter ABE) from traditional brand extensions (TBE) and, in so doing, highlight why the nature of consumers' prior brand connections may differentially influence (and, specifically, lower) their evaluations of ABEs versus TBEs. Second, we examine the impact of group-brand connections (hereafter GBC). In so doing, we acknowledge that brands can be instrumental in helping consumers shape and reflect who they are as individuals (e.g., a savvy Apple owner), but also as members of important groups (e.g., a fiercely loyal member of the Chicago Cubs fan club). Indeed, a person's group identities reflect a fundamental need to affiliate with others and are equally important to their self-concept as their individual identity (Kleine, Kleine and Allen 1995, Tajfel and Turner 1979). Yet, whereas much of the extant research focuses on consumer-brand attachments that are based on a brand's perceived ability to shape and reflect consumers' individual identities (e.g., self-brand connections (SBC); Escalas and Bettman 2005, Fournier 1988), relatively less is known about group-brand connections (GBC), those that are based on a brand's perceived ability to facilitate and reflect a consumer's identity as a member of a group (e.g., brand country-of-origin connections; Gurhan-Canli and Maheswaran 2000, Swaminathan, Page and Gurhan-Canli 2007).

Using the sharing economy as our context, we theorize and find that when consumers believe that a brand is instrumental in reflecting or facilitating their connection with an important group (i.e., high GBC consumers), they are more likely to: a) negatively evaluate those who use that brand's ABEs (hereafter "accessors") based on commitment perceptions and b) rate ABEs less favorably than TBEs.

Theoretical Framework

We define an ABE as a type of brand extension in which a firm offers modified goods or services that limit the user's ownership. Our conceptualization of ABEs includes offerings that either limit consumers' ownership of the good entirely (e.g., short-term car rentals; Baumeister et al. 2015) or limit ownership of some integral product attribute (e.g., forgoing the on-campus experience when earning an

online degree). Thus, whereas TBEs typically involve stretching the parent brand by introducing an innovation or extending into a new product category, ABEs extend the brand into a new business model in which consumers have access to, but not complete ownership of, their branded products or services. We argue that this distinction is associated with fundamental differences in user imagery (Keller 1993), or consumers' beliefs about the typical user, of ABEs vs TBEs and, therefore, their evaluations of these extensions.

We propose that perceived commitment is the critical element of user imagery comparison between owners versus accessors. Commitment is commonly defined as the degree to which an individual views a relationship from a long-term perspective even when things are difficult (Ahluwalia, Burnkrant, and Unnava 2000; Drigotas and Rusbult 1992). Prior research has associated ownership with commitment to the owned object (Bardhi and Eckhardt 2012; Palamar, Le, and Friedman 2012). Additional work found that consumers use perceived differences in commitment among other users to make overall evaluations (Love, Staton, and Rotman 2015; Schouten and McAlexander 1995). Moreover, accessors in the sharing economy have acknowledged lower personal commitment toward objects that they access versus those that they own (Bardhi and Eckhardt 2012). Taken together, these findings suggest that commitment perceptions may comprise an unexplored, but important part of user imagery in brand extensions. Next, we discuss for whom commitment perceptions are most likely to matter.

From social identity theory, we know that the self can be conceptualized as composed of personal and group identities (Tajfel and Turner 1979). Just as material possessions can help owners express group identity (Kleine, Kleine, and Allen 1995; Wallendorf and Arnould 1988), brands can also facilitate this expression. Thus, group-brand connection (GBC) is the extent to which a brand is used to express one's social identity. Prior work suggests that GBC may influence attitudes when there is greater focus on relationships with others. For example, when others were made salient in participants' construal of self (Markus and Kitayama 1991), Swaminathan and colleagues (2007) found that attitude change depended on GBC (e.g., brand country-of-origin), not SBC. According to Markus and Kitayama (1991), people are more attentive and sensitive to the norms and expectations of the in-group when others are salient. In the current work, we suggest that the fundamental differences in user imagery make others more salient when evaluating ABEs and TBEs. Building on these findings, we expect observers' GBC to determine the extent to which evaluations differ between ABEs and TBEs. Specifically, we expect high (vs. low) GBC consumers' attitudes to reflect a concern with others' adherence to group norms and expectations when a brand extension (i.e., an ABE) allows users to access the brand without commitment.

In summary, our prior arguments imply that attitudes toward accessors and owners should vary based on consumers' GBC, such that high GBC consumers evaluate accessors (vs. owners) less favorably because of lower commitment perceptions. In contrast, low GBC consumers should be less sensitive to accessors' commitment-norm violation and evaluate them similarly to owners. Prior work has found that user imagery influences extension evaluations (Desai and Keller 2002; Ferraro, Kirmani, and Matherly 2013; Keller 2003),

hence we expect commitment perceptions to mediate high GBC consumers' ABE (vs. TBE) evaluations.

Study 1

204 adults (51% male, $M_{age} = 36$) were recruited from MTurk to participate in a brand extension type (TBE vs. ABE) \times group-brand connection (measured) experiment for money. Participants indicated their GBC on three items ($\alpha = .88$; Swaminathan et al. 2007) and their self-concept connection on two items ($r = .86$; Fournier 1994; Kleine et al. 1995). After the short survey, participants saw descriptions of one of two Chevrolet brand extensions. The ABE was a car-sharing program called Chevy2go and the TBE was a Chevrolet Bike. Participants evaluated the extension, the users' perceived commitment, and general user imagery on 3-item, 7-point scales. Participants then completed a manipulation check measure, indicated their perceived similarity with the users (single item), and whether they currently owned a Chevrolet vehicle. We analyzed the data from the 172 non-owners to rule out ownership effects (Kirmani et al. 1999). Note: We measure and control for perceived user similarity in this and all subsequent studies and manipulation checks were successful in all studies.

Results

A regression model that included brand extension type (dummy coded), GBC (mean-centered) and their interaction revealed a main effect of GBC that was qualified by the predicted extension type \times GBC interaction ($\beta = .26$, $se = .12$, $p = .03$). Spotlight analysis revealed that when GBC to Chevy was 1SD above the mean, participants evaluated the ABE ($M = 5.1$) less favorably than the TBE ($M = 5.7$; $\beta = -.61$, $se = .24$, $p = .01$). In contrast, evaluations did not differ when GBC to Chevy was 1SD below the mean ($M_{ABE} = 5.2$, $M_{TBE} = 5.1$, $p = .62$). Notably, there were no significant effects when we used self-concept connection instead of GBC ($t < 1$, $p = .35$).

Mediation analyses. We tested whether commitment perceptions mediated evaluations when GBC was high (vs. low) using bias-corrected moderated mediation analysis (model 7, Hayes 2013). The results confirmed our predictions, revealing a significant indirect effect of commitment perceptions when GBC was high ($\beta = -.21$, Boot SE = .14, 95% CI: -.59, -.0092), but not when it was low ($\beta = -.11$, Boot SE = .10, 95% CI: -.30, .08). We also conducted a serial mediation analysis to confirm our expectation that commitment perceptions influence overall user imagery and ultimately extension evaluations. In support of our hypothesized process, this serial mediation was significant ($\beta = -.09$, Boot SE = .05, 95% CI: -.23, -.01). These results suggest that commitment perceptions are the critical aspect of general user imagery that mediates the accessor effect.

Study 2: Priming Group Connection

203 adults ($M_{age} = 36$) participated in a 2 (extension type: TBE vs. ABE) \times 2 (GBC: high vs. low) between-subjects factorial design. Group connection was manipulated by adapting a procedure from prior brand country-of-origin and self-construal research (Brewer and Gardner 1996; Swaminathan et al. 2007). Participants in the high (low) GBC condition were asked to write about how they were similar to (different from) Chevrolet owners. A separate pretest with 50 adults confirmed the success of our manipulation ($M_{high} = 4.0$, $M_{low} = 2.6$, $M_{control} = 2.7$; $F(2, 47) = 3.9$, $p < .05$). After the priming procedure, the study continued as in Study 1.

Results and Discussion

We analyzed the data using a two-way ANCOVA. We found the predicted brand extension type \times GBC interaction ($F(1, 198) = 3.5$, $p = .06$). Specifically, participants in the high GBC condition evalu-

ated the ABE ($M = 5.0$) less favorably than the TBE ($M = 5.5$, $p < .05$). However, no differences emerged among participants in the low GBC condition ($M_{ABE} = 5.5$, $M_{TBE} = 5.4$, $F < 1$, ns).

The results from moderated mediation analysis again confirmed our predictions, revealing a significant indirect effect of commitment perceptions in the high GBC condition ($\beta = -.13$, Boot SE = .07, 95% CI: -.30, -.03), but not in the low condition ($\beta = -.09$, Boot SE = .07, 95% CI: -.29, .02). The serial mediation analysis also replicated prior results such that commitment perceptions influenced overall user imagery and ultimately extension evaluations ($\beta = -.11$, Boot SE = .05, 95% CI: -.21, -.03). Using a priming paradigm, this study replicated the findings obtained with the Chevrolet extensions in Study 1.

Study 3: Ruling Out Fit Perceptions

Study 3 was designed to replicate the accessor effect and examine the extent to which user imagery affects extension evaluations over and above fit perceptions. We operationalized GBC via brand country-of-origin, by sampling participants who owned two brands: Ford and Toyota. Pretest results confirmed that Ford (vs. Toyota) owners felt a higher brand country-of-origin connection.

114 Ford and Toyota owners completed the online survey for monetary compensation ($M_{age} = 35$). Participants were randomly assigned to an ABE or TBE condition. Participants in the ABE (TBE) conditions read about Ford2go (Ford Flex eBike) or Toyota2go (Toyota Prius Bike). Extensions and the users were evaluated as in Studies 1 & 2. Respondents also rated perceived fit between the extension and parent brand.

Results

We analyzed an extension type \times GBC ANCOVA. Moreover, a significant effect of extension type was qualified by a group connection \times extension type interaction ($p < .01$). Ford owners' evaluations in for the ABE ($M = 4.0$) than the TBE ($M = 6.2$, $p < .001$). In contrast, Toyota owners' responses were statistically similar in both conditions ($M_s = 5.7$).

Mediation analyses. To reveal the unique effects of perceived commitment over fit, we simultaneously tested both potential mediators in a single model. Using the procedure developed by Preacher and Hayes (2008), we bootstrapped the indirect effects of brand extension type on evaluation through both mediators. Taken together as a set, fit and commitment perception did mediate the link between extension type and evaluations ($\beta = -.41$, 95% CI: -.76, -.07). However, the specific indirect effects indicated that only perceived commitment was a unique mediator ($\beta = -.48$, 95% CI: -.76, -.24); fit with the parent brand did not contribute to the indirect effect above and beyond perceived commitment ($\beta = .07$, 95% CI: -.04, .24). The results from moderated mediation analysis again confirmed our predictions, revealing a significant indirect effect of commitment perceptions when group connection was high (Ford owners; $\beta = -1.0$, 95% CI: -1.5, -.56), but not low (Toyota owners; $\beta = -.28$, 95% CI: -.65, .08). Finally, results from the serial mediation analysis were again significant ($\beta = -.22$, Boot SE = .10, 95% CI: -.47, -.08), supporting our conceptualization.

Study 4: Ruling Out Self-Implications

Prior work has found that out-groups influence consumer behavior through self-presentation concerns (Escalas and Bettman 2005; White and Dahl 2006, 2007). However, we proposed that when consumers have a GBC, relatively less focus is placed on preserving self-identity. Thus, we expect the accessor effect to persist even when consumers have the opportunity to repair their self-concept (e.g., self-affirm). We tested this proposition in Study 4. We used university affiliation to manipulate GBC. 193 undergradu-

ates (42% female) participated in a 2 (brand extension type: ABE vs. TBE) x 2 (GBC: high vs. low) x 2 (self-affirmation: present vs. absent) between-subjects experiment. We found a significant brand extension type x GBC interaction that was not further moderated by self-affirmation ($F < 1, p > .65$). These findings demonstrate the robustness of the accessor effect and rule out self-identity threat as alternative mechanism for the accessor effect.

Summary

This research provides a framework for understanding when and which consumers' brand evaluations will be differentially sensitive to (and adversely affected by) the perceived commitment of other brand users. Compared to TBE users, ABE users are perceived to be less committed to the brands they access, and this lack of commitment is associated with lower user and brand extension evaluations for consumers with a high (vs. low) GBC. These effects occur over and above those associated with brand extension fit or self-identity threat. Results provide insights into important boundary conditions of consumers' brand attachments.

When Words Hurt – Emotional Contagion in a Company’s Facebook Apology

Madeline Barth, University of Mannheim, Germany
Elisa Konya-Baumbach, University of Mannheim, Germany

EXTENDED ABSTRACT

Corporate crises constitute a severe threat to a company’s reputation and performance by causing negative customer emotions and reactions (Coombs 2007; McDonald, Sparks, and Glendon 2010). Hence, a major goal of corporate crisis communication is to protect an organization’s reputation and avert financial damage (Utz, Schultz, and Glocka 2013). Corporate apologies have been identified as an effective strategy to mitigate the negative consequences of a crisis (Coombs and Holladay 2008; Robbenolt 2003). Interestingly, the expression of negative emotions like sadness appears to be an injunctive norm for apologies (Cialdini 2003). However, it is unclear how consumers process and react to such negative emotions. The socio-psychological process of emotional contagion (EC) supposes that individuals can “catch” the emotions of others (Hatfield, Cacioppo, and Rapson 1994). Based on the notions of the feelings-as-information theory (Schwarz 1990), consumers might rely on transferred negative emotions as information causing them to make valence-congruent evaluations. To date, there is a deficiency in literature on the possible consequences of EC, particularly with regard to negative emotions. The present study addresses this research gap by investigating EC in corporate apologies in a social media context. In doing so, we additionally consider the role of potential influencing factors (i.e., the authenticity of displayed emotions and susceptibility to EC). To this end, we conduct an online experiment and an eye tracking experiment.

Experiment one examines the effects of (authentic) negative emotions expressed in corporate apologies on consumers’ sadness and willingness to forgive. Overall, 194 participants (59% female, $M_{age} = 27.1$) were randomly assigned to a 2 (extent of negative emotion: low, high) \times 2 (extent of authenticity: low, high) between-subjects design. We manipulated the extent of negative emotion by the number of affective cues such as the word “saddened” (one vs. seven negative affective cues) and the authenticity of negative emotions by the use of emoticons (none vs. two emoticons). Participants first viewed a newspaper report on a fictive corporate crisis that was identified via a pretest. Consumers’ sadness was measured at three points in time: T0 (before corporate crisis), T1 (after corporate crisis), and T2 (after corporate apology). Additionally, participants were asked to indicate their willingness to forgive the company and answered manipulation checks. Overall, consumers’ sadness increased after reading about the crisis (T1). The analysis revealed a significant change in participants’ sadness from T1 to T2. The extent of emotion, authenticity, and susceptibility show significant effects on the change in sadness from T1 to T2. The results of a mediation analysis further indicate that the effect of the extent of expressed negative emotions on consumers’ willingness to forgive is fully mediated by customer sadness after reading the apology (T2). The extent of negative emotions in the apology positively affected participants’ sadness, which in turn, negatively influenced their willingness to forgive the company. In contrast to susceptibility, authenticity did not significantly moderate the contagion of negative emotions.

Experiment two uses physiological measures (i.e., pupillometry) to investigate negative EC in a company’s Facebook apology. Pupil size is endogenously affected by emotion and cognition (e.g., Bradley et al. 2008, Fox 2015). Specifically, the pupil diameter is assumed to vary depending on the extent of (negative) emotions (i.e., the number of affective cues). Cognitive processing was manipulated

by syntactic complexity which causes the disruption of smooth processing (Gordon, Hendrick and Johnson 2001; Davison et al. 1980) and higher processing costs (Gibson 1998). Overall, 30 participants (70% male, $M_{age} = 22.4$) were randomly assigned to a 3 (extent of negative emotion: low, medium, high) \times 2 (syntactic complexity: low, high) experimental within-subjects design. Participants first saw a newspaper cover illustrating the crisis for nine seconds followed by a fixation cross. They were then presented with the corresponding Facebook apology which varied in the extent of negative emotions and syntactic complexity. The timeline analysis of the pupil size data indicates a similar pattern for most apologies. There is an initial increase in pupil size, followed by a pupil constriction, followed by a steep pupil dilation. The final dilation initiates later for apologies with a higher complexity and higher extent of emotions. This is in line with participants’ dwell time, the time participants’ eyes spend on the Facebook apology, which increased with complexity and partly with emotion. The final pupil dilation seems to be in accordance with a proposed delayed pupillary response to emotions. For further analyses, we considered three points in time: 1) data in second two as here the initial peak occurred, 2) data in second 13 as here the final dilation for low complexity apologies and the lowest point for high complexity apologies occurred, 3) data in second 20 as here the final peak had already been reached in all groups. At second two, there was a significant interaction effect for emotion and complexity on pupil size change. Similarly, at second 13, the analysis revealed a significant interaction of emotion and complexity. At second 20, pupil change did not significantly differ across the apologies.

The present research shows that negative emotions expressed in corporate apologies in a social media setting can be contagious. While apologies largely reduce sadness triggered by the crisis, this reduction varies depending on the extent of negative emotions communicated and consumers’ susceptibility to EC. Interestingly, the effect of the extent of negative emotion on consumers’ willingness to forgive is fully mediated by participants’ sadness. Authenticity did not significantly moderate the contagion process. Using physiological measures of emotions, the second experiment provides an innovative approach to investigate EC and validate the findings of experiment one. This research illustrates that affective cues suffice for companies to transfer emotions to consumers online and to thereby influence consumers’ willingness to forgive. While a corporate apology can mitigate the negative emotions of consumers in a social media environment, managers must pay attention to the extent of negative emotions communicated in a corporate apology since the contagion of negative emotions can attenuate consumers’ willingness to forgive the company.

Are Dark and Frightening Story Worlds Inspirational?

An Analysis of the Narrative Persuasion Process

Kerstin Barth-Strieder, Johannes Gutenberg University, Germany

Frank Huber, Johannes Gutenberg University, Germany

EXTENDED ABSTRACT

The rising tide of media broadcasts, misinformation, public persuasion knowledge and the extreme polarization of opinions, as challenges of the information age, heighten the need for an effective social marketing. Against the background of the striving for entertainment (Singhal & Rogers, 2002), narratives become increasingly important to open human eyes and minds across various areas of social and health problems (Slater, 2002; Hinyard & Kreuter, 2012). Narratives are “(...) a way of organizing spatial and temporal data into a cause-effect chain of events with a beginning, middle, and end that embodies a judgement about the nature of the events as well as demonstrates how it is possible to know, and hence to narrate, the events” (Branigan, 1992) and meet higher audience acceptance than overtly persuasive argument-based messages (Dal Cin et al., 2004). Scholars increasingly try to explain the mysterious background of narrative persuasion by using the phenomenon of perceptual illusion that a mediated experience is not mediated (nonmediation, Lombard & Ditton, 1997). Transportation, as a central element of nonmediation, is defined by Green and Brock as “a convergent process, where all of the person’s mental systems and capacities become focused on the events occurring in the narrative” (Green et al., 2003). It seems to be particularly crucial, since this mental process regulates the subsequent phase of the narrative persuasion procedure, capturing the readers’ discovery of the deeper story message and its projection into their individual future (e.g., Moyer-Gusé & Nabi, 2010). The most important subsequent intermediary, in this context, can be summarized as reflection, which involves cognitions and emotions evoked by the narrative, as well as reflections about the reader and the world external to the reader (Hamby, 2014). Nevertheless, there are only a limited number of studies available analyzing the driving forces that increase transportation, reflection and set the narrative persuasion procedure in motion (Appel & Malečkar, 2012; Hamby, 2014).

In this respect, research suggests the power of threatening and creepy content in narratives. Findings in the field of fear appeals, traditional persuasion (e.g., Dillard & Anderson, 2004; Cauberghe et al., 2009) and narratives (e.g., McQueen et al., 2011; Nabi, 2015; Bartsch et al., 2014) particularly provide evidence for the power of dark stimulating emotions, which may lead to the journey into a narrative world, representing the secret key to the inspiration mechanism of narratives, which has never been analyzed before. Therefore, we attempt to uncover the capability and the workflow of fear-inducing stories to arouse story-related reflections. Thereby, we contribute to the existing findings by addressing four important issues. First, we reassess the debate towards the relevance of fear in relation to a) fear appeals (Tannenbaum et al., 2015) and in relation to b) reflective cognitions (Bartsch et al., 2014). Second, the paper furthers the effort of Green and Brock (Green et al., 2003) to understand the emergence of transportation. Third, we broaden the knowledge regarding the steps in the narrative persuasion process (Appel & Malečkar, 2012) and recover transportation as an intermediate process between story reception and reflection (Hamby et al., 2014). Finally, we add to the discussion regarding the role of personality traits in the persuasion process (Weibel et al., 2010; Bartsch et al., 2010; Zwarun & Hall, 2012; Green et al., 2008).

Narrative Persuasion Process

In comparison to argument and data-based evidence, narratives are completely different communication vehicles. This implies distinct ways of mental processing, including distinct moderators and mediators (Slater & Rouner, 2002).

While dual-process models, normally applied in the context of traditional argument-based messages, deal with the elaboration likelihood, narratives concentrate on image sequences. Moreover, there is no need to separate between a central and a peripheral route of mental processing, since the cognitive and affective stimuli of narratives are simultaneously processed (Slater & Rouner, 2002). If a compelling story succeeds to completely absorb the individual’s cognitive resources, the audience immerses into the story and feels present in the imagined world. Thus, no capacity for counterarguments is available (Hofer, 2013). In this matter, considerable attention has been paid to the concept of transportation, which is very similar to *presence* (Lombard & Ditton, 1997) but includes also the engaging “journey” into the story world (Kim & Biocca, 1997). Green and Brock (Green et al., 2003) argue in the Transportation-Imagery-Model that distance to the real world increases by being mentally drawn into a narrative world such that story claims are no longer called into question. Thus, after the immersion into the story world, the audience is more prone to support the story-consistent beliefs due to the emotional experience and the missing cognitive resources. In this respect, far-reaching effects on emotions, self or other-centered cognitions (Dunlop et al., 2010; Escalas, 2007; Banerjee & Greene, 2012, Green & Brock, 2000) and behavior (van Laer et al., 2012) were identified.

Overall, there is evidence that transportation is a promising precondition of narrative persuasion. However, little is known on how the transition between reception and persuasion proceeds and which key determinants beside transportation join in the process (Appel & Malečkar, 2012). Cognitive and emotional post-story-message evaluations, which can be described as upstream processes of change in attitude and behavior (Dunlop et al., 2010; Moyer-Gusé & Nabi, 2010) are important intermediaries. They can also be summarized as the phenomenon of reflection, resembling Oatley’s (1999) idea of the reader’s and storyteller’s meeting of minds. Hamby (2014) similarly defines reflection as “...a process related to integrating elements encountered in the story world into one’s understanding of the real world“. Whereas transportation corresponds to the immersion into and the presence in the story world, the secondary process of reflection covers the “return trip to the real world“. As Hamby (2014) suggests, reflection involves three types of successive opinion-forming evaluations, including cognitive, emotional responding and reflections about the reader’s self and the reader’s social surrounding.

Overall, reflection was found to be a very central mechanism in the persuasion process, subsequent to the experience of transportation (Hamby, 2014). It is, however, still an open issue regarding how the causal chain of transportation and reflection is activated. Recent research in this context explored the power of emotionally charged media experiences to stimulate reflective thoughts directly (Bartsch et al., 2014). But research also reflects signs of an indirect pathway, since scary story contents were uncovered to be incredibly absorbing (Hoffner & Levine, 2005), fascinate the audience through the sensation of fear (Sparks & Sparks, 2000) paired with inspiration

(Merchant et al., 2010). As the following discoveries of fear appeals and associated works demonstrate, fear is a very effective device in provoking deep message processing and message acceptance - potentially in terms of narrative persuasion.

Fear Appeal Research

Initial research on fear appeals primarily shed light on the role of fear for persuasion (Janis, 1967; Mc Guire, 1968). In contrast to anxiety, fear represents a short-term reaction towards an identifiable stimulus (Sutton, 1982) and is explained as "(...) a negatively valenced emotion, accompanied by a high level of arousal" (Witte & Allen, 2000).

In contrast to the previous models (Janis, 1967; McGuire, 1968), the central role of fear dwindled in successive models and was gradually replaced by danger and fear control appraisals (Witte, 1992). But the decisiveness of fear in terms of the effectivity of fear appeals on persuasion outcomes is still an ongoing debate (Dillard et al., 2016). Inspired by drive theories, recent research highlights the major importance of fear in the persuasion process (Dillard et al., 2016) and supports the direct and linear link between fear and persuasion-related outcomes (Dillard & Anderson, 2004; Roskos-Ewoldsen et al., 2004). Besides the direct impact channel, there is also evidence for an indirect mechanism (Cauberghe et al., 2009), running through elements mirroring the phenomenon of transportation recovered in narrative persuasion research (e.g. Keller & Block, 1996; LaTour & Rotfeld, 1997; Tanner et al., 1991; LaTour & Rotfeld, 1997; Panić et al., 2011).

Packaged in an entertaining tale, fear-inducing storytelling seems to be a suitable stage to transfer compelling visions in terms of educational work and social marketing. Therefore, we suggest that the identified indirect and direct power of fear identified by persuasion research might be recovered and applied in the field of narrative communication, especially in the area of transportation and subsequent evaluations like reflection.

Direct and Indirect Pathways to Reflection

For two reasons stories are very favorable to set the receivers into an absorbing reflection mode. Stories firstly provide a high entertainment value for the receiver (Green et al., 2004). Secondly, narratives are unconsciously educationally valuable (Hoffner & Levine, 2005; Kniveton, 1978). Both characteristics of narratives, which demonstrate important preconditions of narrative persuasion in terms of transportation and reflection, are especially valid for fear-inducing stories. Since frightening stories include unforeseeable, new, surprising, sensational and destructive contents (Allen & Greenberger, 1978), which address life beyond social rules (McCaulley, 1998) they are very arousing and suspenseful for us, as long as we feel safe (Nell, 2002). Thereby, these contents are very entertaining. Alongside their role regarding entertainment, emotional arousal and pleasurable suspense represent core components of transportation, as research has disclosed, and increase the receiver's emotional engagement to follow the storyline (McQueen et al., 2011). These insights reveal more strongly the direct impact of fear-inducing content on transportation as well as reflection.

Second, threatening stories offer the opportunity to address controversial issues that are avoided in everyday life (Moyer-Gusé, 2008; Sparks & Sparks, 2000). This explains the educational value of that kind of story influencing the audience to become transported, resulting in reflection (Hamby, 2014; Hamby et al., 2014). Therefore, we suspect that fear, which can be enjoyable in terms of the experience of a frightening narrative, while feeling safe (Nell, 2002), might be a vitalizing avenue to enhance entertainment-educational effects

(Nabi, 2015; Bartsch et al., 2014) by increasing transportation and reflection. Thus, we predict that:

Hypothesis 1: Higher levels of fear evoked by a narrative will result in a higher level of transportation.

Hypothesis 2: Higher levels of transportation will result in a higher level of reflection.

Literature reviews alert that negative emotions like fear may affect information processing negatively, which occur particularly at higher levels of arousal (Lang, 2000; Sanbonmatsu, 1988). But this observation also suggests that arousing stories provoke the receiver to become "lost in the story", weakening the processing of real world information but strengthening the focus on the narrative. Due to the equivalence to transportation, we conclude that this subsequent process makes the aroused receiver enter the phase of reflection (Hamby et al., 2014). Hence, we assume:

Hypothesis 3: Transportation mediates the impact of fear on reflection.

According to the aforementioned findings of persuasion research, we additionally suppose that activating fear might be an important immediate driver of reflection and narrative persuasion. Therefore, we hypothesize:

Hypothesis 4: Higher levels of fear evoked by the narrative will result in a higher level of reflection.

Previous research has shown the link between specific personality traits and transportation, as well as persuasive outcomes (Weibel et al., 2010; Bartsch et al., 2010; Zwarun & Hall, 2012; Green et al., 2008). Hence, we also controlled for extroversion, neuroticism, openness for experiences, conscientiousness, agreeableness and need for cognition.

Study 1

Particularly in the field of the meat industry and the heightened consumption of food produced by factory farming, consumer education in adulthood regarding the dangerous consequences for human health and animal welfare is needed (Chemnitz & Becheva, 2014; Stehfest et al., 2009; Hughner et al. 2007). Thus, our study concentrates on the capability and the procedure of fear-inducing narratives to make consumers reflect on those issues to promote better consumption decisions.

180 respondents (132 females; mean age: 30.44 years, SD: 10.574) participated in the online and paper-based quasi-experimental survey voluntarily, anonymously and individually. After the participants were shortly briefed about the topic of factory farming, the participants were invited to carefully read a narrative and to answer some questions regarding their feelings (fear) and their mental processes during and after story reception (transportation and reflection). In our survey, we utilized an adapted translation of the experimental text material *Murder at the Mall* (provided by Appel & Richter, 2010, originally used in Green & Brock, 2000). Modelled after selected episodes of a well-known German TV crime series (*Tatort, 2014*), we inserted the issue of the consumption of meat produced by factory farming in the initial version of the scary narrative (due to the German speaking sample, this method seems to be reasonable). In conjunction with this issue, we embedded argumentation lines towards the environmental and personal threats of factory farming (animal welfare and personal health status), as well as educational

handling recommendations. An online-performed Delphi-interview (12 experts) served to correct misleading and disturbing story passages (c.f. narrative description in the appendix).

Multi-item measures extracted from peer-reviewed studies were used for the operationalization of the variables (cf. appendix).

Results

This study aims to analyze whether transportation fully or partially mediates the relationship between fear and reflection. To validate the effects, we include the covariates of *need for cognition*, *extroversion*, *agreeableness*, *conscientiousness*, *emotional stability* and *openness to experience* (Hayes, 2013). The results of the analysis of linear regression revealed that fear significantly provokes transportation ($\beta = 0.351$, $SE = 0.039$, $p < 0.01$), providing support for H 1. Additionally, we find a significant impact of the covariate *extroversion* on transportation ($\beta = 0.094$, $SE = 0.037$, $p < 0.05$). In line with our expectations, we observe that a higher level of transportation results in significantly higher levels of reflection ($\beta = 0.589$, $SE = 0.097$, $p < 0.01$) (H 2). Moreover, we find significant positive effects of the covariates *emotional stability* ($\beta = 0.099$, $SE = 0.047$, $p < 0.05$) and *openness to experience* ($\beta = 0.116$, $SE = 0.068$, $p < 0.1$), as well as negative effects of *agreeableness* ($\beta = -0.169$, $SE = 0.079$, $p < 0.05$) and *conscientiousness* ($\beta = -0.104$, $SE = 0.059$, $p < 0.01$). We applied the bootstrapping method proposed by Preacher & Hayes (2004) using Hayes's PROCESS macro (2012) in order to analyze the mediation effect. The computation of the bias corrected 95% confidence intervals for the indirect effects was based on 10,000 bootstrap samples (Hayes, 2013). The results disclosed that the impact of narratively induced fear on reflection is mediated by transportation ($\beta = 0.207$, $SE = 0.048$, 95% CI = .122 to 0.310) (H3). Beyond the indirect effect, we observe fear as a significant direct predictor of reflection ($\beta = 0.220$, $SE = 0.061$, $p < 0.01$) (H4), providing evidence for a partial mediation. The results of the total effect model revealed a total impact of fear on reflection ($\beta = 0.428$, $SE = 0.055$, $p < 0.01$) (c.f. appendix).

Study 2

In order to validate the findings of Study 1, Study 2 aims to analyze the proposed effects in the context of a narrative dealing with a more serious fear (e.g. the consequences of a life-threatening disease) solely on human-based reflections. More precisely, in Study 2, we explore the effects on reflections associated with blood cancer prevention and social motivations to donate to leukemia patients. 186 respondents (131 females; mean age: 27.90 years, SD: 9.066) attended the online and paper-based survey. Except for the contextual changes into a health-related narrative addressing the issue of leukemia prevention and support (similar to an episode of *Tatort*, 2013), we applied the same procedure as in Study 1 (c.f. appendix).

Results

The linear regression analysis reveals our first hypothesis that fear affects transportation ($\beta = 0.321$, $SE = 0.038$, $p < 0.01$). A positive effect of extroversion ($\beta = 0.099$, $SE = 0.0359$, $p < 0.01$) and a negative effect of emotional stability ($\beta = -0.064$, $SE = 0.037$, $p < 0.1$) on transportation is also found. Moreover, transportation is a significant predictor for reflection ($\beta = 0.403$, $SE = 0.091$, $p < .01$) (H 2). Negative effects of emotional stability are also again obtained ($\beta = -0.078$, $SE = 0.045$, $p < 0.1$). Mediation analysis again suggests a significant indirect effect of fear on reflection, providing support for the mediating role of transportation ($\beta = 0.123$, $SE = 0.031$, 95% CI = .077 to 0.199) (H 3). Beside the indirect effect, we also find the direct effect of fear on reflection, suggesting a partial mediation as proposed in H4 ($\beta = 0.251$, $SE = 0.055$, $p < 0.01$). In summary, we

find a significant total effect of fear on reflection ($\beta = 0.380$, $SE = 0.048$, $p < 0.01$).

General Discussion

As in Study 1, the supposed steps in the narrative persuasion process reemerge: half of the fear effect operates through transportation, which is again identified to be an important upstream process of reflection. Besides these factors, a minor part of the narrative effect might be attributed to specific personality characteristics (Weibel et al., 2010; Bartsch et al., 2010; Zwarun & Hall, 2012; Green et al. 2008), as both studies reflect. These findings, implying the power of fear-provoking narratives to vitalize the persuasion process, show that insights of fear appeal research (Dillard et al. 2016; Dillard & Anderson, 2004; Roskos-Ewoldsen et al., 2004) and related study fields assuming an indirect relationship (Cauberghe et al., 2009; Keller & Block, 1996; LaTour & Rotfeld, 1997) might also be valid in the field of narrative persuasion. Furthermore, we find that fear-inducing stories provoke transportation, which contributes to the understanding of the emergence of transportation. Consistent with the literature, we again demonstrate the significance of transportation toward evoking persuasion-related outcomes (e.g., Green et al., 2003; Murphy et al., 2011).

Furthermore, our study could respond to the recent call to research (Appel & Malečkar, 2012; Hamby, 2014). Both studies provide evidence for the supposed and partially uncovered sequence of elements in the persuasion process. As previously supposed (Nabi, 2015; Bartsch et al., 2014; McQueen et al., 2011; Moyer-Gusé, 2008; Sparks & Sparks, 2000), fear is identified to be a crucial emotional arousal, which directly initiates transportation and successively evokes reflection. We therefore strongly recommend practitioners to predominately use fear as a stimuli in narratives, which directly or subsequent to the compelling process of transportation promises that readers transform the narratively simulated experience into cognitions and emotions, which may have suggestive impact on their own lives.

Overall, the outcomes also demonstrate that further work needs to be done in order to identify relevant emotional factors introducing transportation, as well as reflection, and in particular the causal-chain of transportation and reflection as well as other valuable upstream mechanisms of narrative persuasion outcomes (e.g., reception of stories transmitted by other media channels, purely experimental setting, and measurement of covariates).

\$100 a month or \$1,200 a year: Impact of Regulatory Focus on the Evaluation of Temporally Framed Attributes

Shankha Basu, University of Leeds, UK
Sharon Ng, Nanyang Technological University, Singapore

EXTENDED ABSTRACT

Consumers often encounter benefits and costs which recur over time framed at different levels of aggregation. For example, a weight loss program may advertise either in an aggregate (“Lose 10 pounds in 10 weeks”) or a disaggregate (“Lose 1 pound per week over 10 weeks”) frame. In using this strategy, marketers hope that consumers will utilize the largeness of the numeric expression as a heuristic for making magnitude judgments. Indeed, some research suggests that this may be the case. An aggregate frame makes the consumers perceive the benefit or cost to be higher in magnitude leading to a greater weightage being assigned during evaluation and choice (Burson, Larrick, and Lynch, 2009; Goldstein, Hershfield, and Benartzi, 2016; Gourville 1998). However, not much is known about the way in which consumer characteristics may impact the evaluation of such frames. Further, research is needed on means to reduce consumers’ reliance on this erroneous heuristic. In this research, we aim to accomplish these objectives by examining how consumers’ goal pursuit strategies affect the evaluation of such frames.

In any decision process, one of the two primary goals of a human being, the need for advancement and that for security (Bowlby, 1969), may be salient. Regulatory focus theory (Higgins, 1997) posits that these goals lead to two distinct motivational states in a consumer – a promotion and a prevention focus, respectively. We contend that temporal framing of attributes will affect the evaluation of only promotion focused (but not prevention focused) consumers. We base our predictions on the distinct information processing strategies elicited by these regulatory goals (Forster and Higgins, 2005; Lee, Aaker, and Gardner, 2010; Pham and Chang, 2010). Promotion focused consumers, who pay greater attention to the most salient aspect of any information, may be easily swayed by the largeness of the numeric expression in an aggregate frame. However, prevention focused consumers, who pay attention to all aspects of any information, may be immune to the effect of temporal reframing.

In Study 1 (N = 152), we primed regulatory focus using an anagram task (Jain et al., 2007). Next, participants in the aggregate (disaggregate) condition, read that their salary post graduation was “\$36,000 a year” (“\$3,000 a month”). A two-way ANOVA revealed a significant interaction effect, $F(1,148)=7.0, p=.01$. Promotion focused participants evaluated the salary more positively in the aggregate condition ($M_{\text{aggregate}}=4.84, M_{\text{disaggregate}}=4.29, F(1,148)=5.39, p=.02$). No such difference emerged for prevention focused participants ($M_{\text{aggregate}}=4.40, M_{\text{disaggregate}}=4.73, F(1,148)=2.02, p=.16$).

Study 2 (N = 148) examined a downstream effect. We primed regulatory focus using a goals task (Li et al, 2011). Next, in the aggregate (disaggregate) condition, participants read that they had a job offer which paid \$42,000 a year (\$3,500 a month). Participants intention to join a retirement saving plan offered by their employer serves as the dependent measure. A two-way ANOVA revealed a significant interaction effect ($F(1, 144)=4.00, p=.047$). Promotion focused participants were more likely to save in the disaggregate condition ($M_{\text{disaggregate}}=6.95, M_{\text{aggregate}}=5.51, F(1,144)=7.92, p=.005$). No difference emerged for prevention focused participants ($M_{\text{disaggregate}}=6.49, M_{\text{aggregate}}=6.51, F(1,144) < 1$).

In Study 3, female participants (N=121) indicated their evaluation of a weight loss program where the calorie loss was expressed as 6,400 Calories (800 Calories per week) over 8 weeks in the ag-

gregate (disaggregate) condition. Regulatory focus was measured (Lockwood, Jordan, & Kunda, 2002). Interaction between regulatory focus and frame was significant ($B=.38, t(116)=2.01, p<.05$). Promotion focused participants evaluated the program more positively in the aggregate ($M_{\text{Aggregate}}=4.91$) as compared the disaggregate ($M_{\text{Disaggregate}}=3.49, t(116)=2.37, p=.02$) condition. However, no such difference emerged for prevention focused participants ($M_{\text{Aggregate}}=4.88, M_{\text{Disaggregate}}=5.16, t(116)=-.49, p=.62$).

Study 4 provided evidence for the underlying process. After a priming task similar to Study 1, participants (102) evaluated a lottery which was expressed as \$4,500 (\$160 a month) over 2 years and 4 months in the aggregate (disaggregate) frame. They also indicate their perception of magnitude for the reward. Both measured followed similar patters as previous studies. More interestingly, A moderated mediation analysis revealed that frame affected the magnitude perception of the reward amount only for promotion focused participants and led to different evaluation of the lottery based on frame ($B=-1.35, SE=.38, 95\% CI [-2.18, -.69]$). However, the frame did not affect the magnitude evaluation of amount for prevention focused participants ($B=0, SE=.38, 95\% CI [-.79, .74]$).

Finally, in Study 5, we examined costs. After a priming task similar to Study 2, female participants (N = 182) indicated their intention to join a health club where the cost was framed as \$1,560 (\$65 a month) for a 2 year membership. They also indicated their magnitude perception of the cost. Promotion focused participants indicated a greater intention to join when they viewed the price in disaggregate ($M_{\text{disaggregate}}=3.81$) as compared to the aggregate frame ($M_{\text{aggregate}}=2.04, F(1,177)=23.55, p<.0001$). This effect was only marginally significant for prevention focused participants ($M_{\text{aggregate}}=2.70, M_{\text{disaggregate}}=3.5, F(1,177)=3.64, p=.06$). More importantly, as in the previous study, moderated mediation analysis revealed an indirect effect of magnitude perception. This indirect effect was significant only in the promotion focus condition ($B=-1.02, SE=.30, 95\% CI [-1.61, -.43]$) and not significant in the prevention focus condition ($B=-.22, SE=.30, 95\% CI [-.80, .37]$).

Across five studies, spanning multiple domains and different operationalization of regulatory focus, we show that promotion focused consumers evaluate an aggregate frame more extremely as compared to a disaggregate frame. However, no such difference in evaluation based on frame emerged for prevention focused consumers. This research contributes to the area of temporal framing and numerosity heuristic by introducing an important moderator, the decision makers’ regulatory focus. Future research may explore other factors which may affect the perception of such frames such as processing styles and cross cultural differences.

I've Got the Power: Investigating Dynamic Brand Logos

Stacey Baxter, University of Newcastle, Australia

Jasmina Ilicic, Monash University, Australia

EXTENDED ABSTRACT

Henderson and Cote (1998) highlight the importance of active brand logo designs (those that give the impression of motion) for increasing consumer interest. One approach to creating an active brand logo is through the inclusion of a human figure in motion, for example, *Johnnie Walker* (walking figure), *Interflora* (running figure), or *Air Jordan* (jumping figure). Drawing on Newtonian principles in physics, we employ a 'dynamics' in classical human mechanics lens to examine active brand logo effects through the *causes* of motion in human movement (i.e., force). Scientific research has demonstrated that when a force is applied in the opposite direction of a human figure in motion (e.g., gravitational force when running up a hill) the figure is exerting greater work (e.g., Zatsiorsky 2002). Cues to hard work align with perceptions of brand competence (Aaker 1997), which increases brand attitude and behavioral intentions (Eisend and Stokburger-Sauer 2013). As such, we propose that a *dynamic* brand logo featuring human work (motion along with a force), results in more positive brand-based attitudes and behavioral judgments than a *kinematic* logo featuring less work (motion without a force applied).

Study 1 demonstrates that a dynamic brand logo (i.e., greater work exerted due to the inclusion of force) results in more positive brand attitude and purchase intention than a kinematic brand logo (i.e., less work exerted in a logo with only motion and no force applied). In Study 2, we demonstrate that the indirect effect of brand dynamism on brand attitude is explained through our developed brand energy construct, not by brand engagement, which previous research suggests. We also empirically reveal the bounds of our brand work-energy effect in Study 3. Specifically, the results provide evidence to suggest that the effectiveness of brand logo dynamism (work exerted through applied force) on perceptions of brand energy is attenuated when positive work is undertaken (thrust force in the direction of motion).

Active Dynamic Brand Logos

Active brand logo designs are those that "give the impression of motion" (Henderson and Cote 1998, p. 17). To date, only one study has examined active brand logos and their effects on brand engagement and attitude (Cian et al. 2014). Cian's et al. (2014) study focuses only on the use of motion in brand logos, which they term dynamic. However, we argue that their study examines brand logos from a kinematic perspective. Kinematics is the study of motion without regard for the cause (Beggs 1983). We, on the other hand, take the physics perspective of dynamics, which is the study of forces that produce motion (Beggs 1983).

When force is applied to a human in motion, both the force and the human are doing work (Zatsiorsky 2002). A human moving against a force expends greater work (negative force; Zatsiorsky 2002). For example, when walking uphill the increasing incline and negative gravitational push force results in positive work on behalf of the body in motion (as they must compensate by doing the work themselves; Margaria 1968). We argue that a dynamic brand logo (depicting a human figure in motion), with a force applied in the opposite direction to the human figure in motion (negative force), creates the perception of greater work, whereas a kinematic brand logo, with no force applied, creates less perceived work. Based on research that finds evidence to suggest that hard working brands are perceived to be reliable and competent (Aaker 1997), and result in

positive attitude towards the brand and willingness to buy the brand (Aaker, Vohs, and McGilner 2010; Eisend and Stokburger-Sauer 2013), we suggest that dynamic brand logos (negative force) will enhance consumer attitudinal and behavioral judgments. Formally, our hypothesis is:

Hypothesis 1: Dynamic (kinematic) brand logos will result in heightened (reduced) a) brand attitude and b) purchase intention.

Brand Work-Energy

According to the work-energy principle, the work done by a force on a particle equals the change in the particle's kinetic energy (Young and Freedman 2008). When walking uphill, the negative gravitational push force results in the body undertaking greater work, which results in an increase in the energy level of the body in order to accomplish the work (Margaria 1968). As such, we argue that the dynamic brand logo phenomenon manifests due to a brand work-energy effect, whereby dynamic brand logos influence attitudinal and behavioral judgments via perceptions of brand energy.

Brand Energy and Brand Engagement

Research demonstrates that active brand logos result in more positive brand attitudes due to brand engagement, whereby motion in the logo encourages consumers to play with the image in their minds (Cian et al. 2014). We argue, however, that the differential effect of kinematic versus dynamic brand logos on attitudinal and behavioral judgments is not driven by brand engagement. Both kinematic and dynamic brand logos include movement and should both equally result in brand engagement. Conversely, we propose a brand work-energy effect, whereby perceptions of brand energy result from active dynamic brand logos, which include force and, as a result, greater work, resulting in more positive brand attitudes and purchase intentions. We expect that the effect of dynamic brand logos on attitudinal and behavioral judgments will manifest through brand energy not via brand engagement. As such, the following hypothesis is proposed:

Hypothesis 2: The indirect effect of dynamic brand logos on a) brand attitude and b) purchase intention will manifest via brand energy not brand engagement.

Brand Dynamism and Force

Whilst a force applied in the opposite direction of motion results in positive work and, subsequently, greater energy exerted, a force applied in the direction of motion results in negative work and less energy expended (Margaria 1968). For example, when a thrust force (e.g., air propulsion) is applied in the direction of motion, the force assists human motion and, therefore, results in less work exerted by the human. We argue that a brand logo depicting a thrust force (air propulsion) and drag force (air resistance) will have differential effects on consumer attitudinal and behavioral judgments. We expect that a thrust force, which signifies less work, will result in attenuation of the brand work-energy effect, reducing perceptions of the brand's energy, and subsequently diluting brand attitudes and purchase intentions. We, therefore, propose:

Hypothesis 3: Thrust (drag) dynamic brand logos will result in reduced (heightened) brand energy and subsequent a) brand attitude and b) purchase intention.

Study 1

A sample of two hundred members of the Australian general public (90 male, 110 female; $M_{Age} = 42.88$, $SD_{Age} = 16.07$) were recruited through an Australian research panel company. A between subjects design was employed, with participants randomly allocated to one of the two experimental conditions: kinematic logo (less gravitational force, $n = 100$) or dynamic logo (greater gravitational force, $n = 100$).

First, participants were shown a logo for the fictitious brand, *Onik*. The logo was presented either horizontally (kinematic; 0° inclination) or inclined (dynamic; 45° inclination). Next, employing measures drawn from Mitchell and Olsen (1981), participants were asked to rate their attitude towards the brand (Cronbach $\alpha = .937$) and their intention to purchase the brand (Cronbach $\alpha = .861$). Finally, participants were asked to report the degree of work ("How much work is shown in the logo for this company?" none at all/a lot) and motion ("How much motion is shown in the logo for this company?" none at all/a lot) depicted in the logo, and report simple demographic information.

Manipulation Check

A significant main effect was observed for brand logo work ($F(1, 198) = 31.00$, $p < .001$, $\eta^2 = .135$), however, not brand logo motion ($F(1, 198) = 2.19$, $p = .140$, $\eta^2 = .011$). The inclined brand logo was perceived as depicting significantly more work ($M_{work} = 4.80$, $SD_{work} = 1.44$) when compared to the horizontally presented brand logo ($M_{work} = 3.82$, $SD_{work} = 1.02$), with no difference in perceived motion observed (incline: $M_{motion} = 4.80$, $SD_{motion} = 1.44$; horizontal: $M_{motion} = 4.80$, $SD_{motion} = 1.44$).

Results

Effect of Brand Logo Dynamism on Attitude towards the Brand and Purchase Intention.

An ANOVA model was estimated with attitude towards the brand and purchase intention included separately as dependent variables. Results showed that brand logo dynamism has a significant effect on both brand attitude ($F(1, 198) = 23.95$, $p < .001$, $\eta^2 = .108$) and purchase intention ($F(1, 198) = 12.25$, $p < .001$, $\eta^2 = .061$). Participants who viewed the dynamic brand logo reported a more positive attitude towards the brand and greater purchase intention ($M_{Abrand} = 4.89$, $SD_{Abrand} = .89$; $M_{Purchase} = 4.47$, $SD_{Purchase} = .88$) when compared to those who viewed the kinematic brand logo ($M_{Abrand} = 4.27$, $SD_{Abrand} = .90$; $M_{Purchase} = 3.97$, $SD_{Purchase} = 1.07$), supporting Hypothesis 1.

Study 2

A sample of two hundred and four members of the Australian general public (100 male, 104 female; $M_{Age} = 46.67$, $SD_{Age} = 17.03$) were recruited through an Australian research panel company. A between subjects design was employed, with participants randomly allocated to one of the two experimental conditions: kinematic logo (no tension force, $n = 102$) or dynamic logo (tension force, $n = 102$).

First, participants were shown a logo for the fictitious brand, *Fipple*. The brand logo included a figure that was depicted either with, or without tension force. Participants then rated their attitude towards the brand (Cronbach $\alpha = .957$) and purchase intention (Cronbach $\alpha = .933$). Next, participants reported how engaging the brand logo was (Cian et al 2014; Cronbach $\alpha = .947$) and rated brand energy, using our developed scale (*energy, power, drive, momentum*;

Cronbach $\alpha = .954$). Finally, participants were asked to report the degree of work and motion depicted in the logo, and report simple demographic information.

Manipulation Check

A significant main effect was observed for brand logo work ($F(1, 202) = 22.86$, $p < .001$, $\eta^2 = .102$), however, not brand logo motion ($F(1, 202) = 1.26$, $p = .264$, $\eta^2 = .006$). As intended, the brand logo depicting tension force was perceived as portraying significantly more work ($M_{work} = 4.68$, $SD_{work} = 1.51$) when compared to the no tension force brand logo ($M_{work} = 3.68$, $SD_{work} = 1.48$), with no difference in perceived motion observed (tension force: $M_{motion} = 4.12$, $SD_{motion} = 1.42$; no tension force: $M_{motion} = 4.40$, $SD_{motion} = 1.13$).

Results

Mediating Role of Brand Engagement and Brand Energy on Attitude towards the Brand and Purchase Intention.

Results ($n = 10000$, Model 4, Preacher et al. 200) show that brand logo dynamism is a positive and significant predictor of brand energy, yet not brand engagement. Results demonstrate that exposure to a dynamic (kinematic) brand logo results in stronger (weaker) perceptions of brand energy. Further, both brand energy and brand engagement are positive predictors of attitude towards the brand and purchase intention. The 95% bootstrapped confidence interval for the indirect effect of brand logo dynamism on both attitude towards the brand ($\beta = .19$, 95% CI = .07 to .39) and purchase intention ($\beta = .12$, 95% CI = .01 to .30) through brand energy did not include zero, demonstrating a significant mediating effect. A significant indirect effect was not observed via brand engagement (brand attitude: $\beta = .09$, 95% CI = -.06 to .28; purchase intention: $\beta = .08$, 95% CI = -.05 to .25), supporting Hypothesis 2.

Study 3

A sample of two hundred and fifteen members of the Australian general public (101 male, 114 female; $M_{Age} = 42.27$, $SD_{Age} = 15.18$) were recruited through an Australian research panel company. A between subjects design was employed, with participants randomly allocated to one of the two experimental conditions: dynamic thrust logo (propulsion air force, $n = 107$) or dynamic drag logo (air resistance force, $n = 108$).

First, participants were shown a dynamic logo for the fictitious brand, *Videx*. The brand logos included a figure and the depiction of air blowing either behind the figure (thrust force) or towards the figure (drag force). Participants then rated their attitude towards the brand (Cronbach $\alpha = .955$), their intention to purchase the brand (Cronbach $\alpha = .916$) and the perceived energy of the brand (Cronbach $\alpha = .917$). Finally, participants were asked to report the degree of motion and work depicted in the logo, and report simple demographic information.

Manipulation Check

A significant main effect was not observed for brand logo motion ($F(1, 213) = 2.00$, $p = .158$, $\eta^2 = .009$; thrust: $M_{motion} = 4.93$, $SD_{motion} = 1.45$; drag: $M_{motion} = 4.69$, $SD_{motion} = 1.00$). As intended, a significant main effect was observed for brand logo work ($F(1, 213) = 41.17$, $p < .001$, $\eta^2 = .162$). Results show that the dynamic drag logo was perceived as portraying significantly more work ($M_{work} = 4.63$, $SD_{work} = 1.17$) when compared to the dynamic thrust brand logo ($M_{work} = 3.50$, $SD_{work} = 1.40$).

Results

Mediating Role of Brand Engagement and Brand Energy on Attitude towards the Brand and Purchase Intention

Results ($n = 10000$, Model 4, Preacher et al. 2007) show that brand logo dynamism is a positive and significant predictor of brand energy and brand energy is positive and significant predictor of attitude towards the brand and purchase intention. Results demonstrate that exposure to a dynamic drag force (dynamic thrust force) brand logo results in stronger (weaker) perceptions of brand energy, with heightened brand energy increasing attitude towards the brand and purchase intention. As the 95% bootstrapped confidence interval for the indirect effect of brand logo dynamism on both brand attitude ($\beta = .52$, 95% CI = .36 to .73) and purchase intention ($\beta = .50$, 95% CI = .33 to .72) did not include zero, a significant mediating effect is demonstrated, supporting Hypothesis 3.

General Discussion

We introduce brand energy, a construct distinguishable from brand engagement and one that can be influenced by work depicted through force and motion in an active brand logo (i.e., gravitational force, tension force, and air resistance force). The results of our studies provide evidence to suggest that force and motion in a dynamic brand logo heightens perceptions of brand energy by increasing perceived work, which we term the brand work-energy effect. We also propose and demonstrate that dynamic brand logos enhance brand attitudes and behavioral judgments. We show that the indirect effect of dynamic brand logos on brand attitudinal and behavioral judgments are significant via perceived brand energy not via brand engagement (as proposed as tested by Cian et al. 2014). We postulate that the motion in a kinematic brand logo results in more work and, therefore, more perceived brand energy when compared to a static brand logo with no motion. It is, therefore, possible that the effects observed by Cian et al. (2014) can be explained by our brand work-energy effect. Future research is needed in order to test this assertion.

This research is not without limitations. Our stimuli comprise of unknown brands. While we would expect the observed effect to hold within a real brand context, a comparison of the effect of work in brand logos for known brands (e.g., Wella (air resistance force), or *Coach* (tension force)) is needed to assess the rigor of the brand work-energy effect.

Special Memories Require Special Protection

Kara Bentley, Chapman University, USA

Priyali Rajagopal, University of South Carolina, USA

EXTENDED ABSTRACT

Research has found that memories of special experiences (e.g. vacations, weddings) can be viewed as assets because of their importance for self-definition (Elster and Loewenstein 1992), and consumers often protect such memories in order to safeguard them from contamination by avoiding repetitions of the experience (Zauberman, Ratner, and Kim 2009). For example, it was found that following a special resort vacation with friends, participants did not want to return the resort for a work conference.

Our research aims to expand the memory protection literature in three specific ways. One, we suggest that consumers do not avoid all repetitions of special experiences, but only avoid *non-special* repetitions. We argue that consumers avoid repeating a special experience under ordinary, but not special circumstances (e.g. will not return to the resort for a work trip but will return for an anniversary trip). In other words, the type of interference cue (special versus non-special) moderates memory protection such that only non-special cues trigger memory protection.

Two, we explore the process underlying memory protection and find contamination of a special memory by a non-special cue is perceived as a self-concept threat, leading consumers to avoid this type of contamination. Memories of special experiences are more important for self-definition than are memories of non-special experiences, thus special memories are strongly linked to the self-concept (Belk 1988). We suggest that contaminating a special memory with a non-special cue devalues the memory (by making it seem less special), and consequently also devalues the self, by making the individual feel as though they are less special. This threat to the self-concept triggers the desire to protect the memory and results in avoidance of repeating the experience.

Third, we expand current theorizing on how memories can be contaminated by documenting that marketing communications can be perceived as non-special cues, and make the advertised brand seem less special, thereby making an individual consumer's own personal experience seem less special. This reduction in the specialness has significant negative downstream implications for brand attitudes (less special = less favorable attitudes). These are especially intriguing findings since they suggest that memory contamination and protection may be far more pervasive than originally envisioned, and also because they point to a specialness-contamination tradeoff for marketers.

Study 1 was conducted with 28 participants recruited via an online sample. Participants described a special dinner they had experienced and then rated their likelihood of going back to the same restaurant for another special versus ordinary occasion and likelihood of going back with a different person if it was for a special versus ordinary occasion.

A repeated measures analysis revealed that participants were more likely to return to the restaurant when the follow-up experience was special ($M_{special}=6.00$) than when it was ordinary ($M_{ordinary}=4.82$; $F(1,27)=12.49$, $p<.01$). Further, even when going back with a different person, participants were more likely to return when the follow-up experience was special ($M_{special}=5.29$) than when it was ordinary ($M_{ordinary}=4.54$; $F(1,27)=6.72$, $p<.05$).

Study 2 utilized a 2(initial: special vs. non-special) x 2(follow-up: special versus non-special) mixed design in which the initial (follow up) experience was a between (within) subjects factor. 141

undergraduates imagined going to dinner for a special or ordinary occasion and then rated their likelihood of going back to the restaurant for another special versus ordinary dinner.

An ANOVA revealed a significant interaction between the specialness of the initial and follow-up experiences on willingness to return to the restaurant ($F(1,139)=56.84$, $p<.001$). Following a special experience, participants were more likely to return when the follow-up experience was special ($M_{special}=6.52$) than when it was ordinary ($M_{ordinary}=5.68$; $F(1,70)=66.60$, $p<.001$).

Study 3 utilized a 2(initial: special versus non-special) x 2(experience: special versus non-special) between-subjects design. 192 undergraduate students imagined going out to dinner for either a special or ordinary occasion and were told they had worn a new item of clothing that was described to them. Participants then imagined a follow-up scenario (special vs. non-special) at which they again wore the clothing item and then reported attitudes towards the item.

An ANOVA revealed a significant interaction between the initial and follow-up conditions ($F(1,111)=6.71$; $p=.01$). Following a special experience, attitudes were more positive when subsequently worn to another special event ($M_{initial_special_followup_special}=6.11$) than an ordinary ($M_{initial_special_followup_ordinary}=5.18$; $F(1,113)=9.36$; $p<.01$).

Study 4 used an online sample of 192 participants and utilized a 2(initial: special vs. non-special) x 2(follow-up: special vs. non-special) between-subjects design. The initial and follow-up scenarios were similar to those used in study 3. In order to explore the underlying process, participants reported perceptions of a self-concept threat after reading the follow-up scenario.

An ANOVA revealed a significant interaction between the initial condition and the follow-up condition on perceptions of self-concept threat ($F(1,188)=4.38$; $p<.05$) and on evaluations of the restaurant ($F(1,188)=2.74$; $p=.10$). Participants in the non-special follow-up condition felt more threatened ($M_{initial_special_followup_nonspecial}=4.59$) than those in the special follow-up condition ($M_{initial_special_followup_special}=5.15$; $F(1,188)=4.16$; $p<.05$) and evaluated Firefly more positively ($M_{initial_special_followup_special}=5.83$) than those in the non-special follow-up condition ($M_{initial_special_followup_nonspecial}=5.19$; $F(1,188)=10.17$; $p<.01$). Mediation analysis using the PROCESS SPSS macro (Model 7; Preacher and Hayes 2004) with specialness of the follow-up as the IV, of the initial condition as the moderator, threat as the mediator, and satisfaction as the DV provided support for moderated mediation (95% CI=.0123 to .2830).

Study 5 utilized a 2(initial: special vs. non-special) x 2(control vs. ad) between subjects design. 135 undergraduates imagined either a special or ordinary dinner, and were then either shown an ad for the restaurant before filling out the dependent measures or taken directly to the dependent measures (control condition). The main dependent measures were perceptions of how special the dinner was and evaluations of the restaurant.

An ANOVA revealed a significant interaction between the initial experience and marketing communication on specialness perceptions ($F(1,131)=3.82$; $p=.05$) and attitudes ($F(1,131)=4.41$; $p<.05$). Following a special experience, participants in the control condition perceived their experience as more special ($M_{control}=6.28$) than those who had viewed an ad ($M_{ad}=5.63$; $F(1,131)=6.52$; $p<.05$), and had more positive attitudes ($M_{control}=6.36$) than those who viewed the ad ($M_{ad}=5.74$; $F(1,131)=7.49$; $p<.01$).

The Implications of Self-regulation Difference Between Heavy Versus Light Media Multitaskers For Advertising Effectiveness

Emma Beuckels, Ghent University, Belgium

EXTENDED ABSTRACT

Media multitasking, is broadly defined as the act of consuming two or more media simultaneously, using a single or multiple media device(s) (Yeykelis, Cummings, & Reeves, 2014). Consistent to previous media multitasking research the first study of this paper predicts that engaging in multitasking behavior would deplete ones self-regulatory resources. Furthermore, recent studies have shown that people differ in how often they engage in media multitasking, distinguishing heavy (HMMs) from light (LMMs) media multitaskers. Although it seems counterintuitive that people who often engage in media multitasking are more distracted by their environment and less efficient at navigating it, research suggest that HMMs have a deficit in self-regulation (Cardoso-Leite et al., 2016; Ophir, Nass, & Wagner, 2009). Based on dual processing theories, the present paper explores whether the difference in self-regulatory resources between HMMs and LMMs is due to a lower *ability* (i.e., capacity to perform a task) or a lower *motivation* (i.e., willingness to perform a task) to optimally control their attention. The allocation of one's attention may be driven by both external and internal factors. In some contexts, the opportunity to freely allocate one's attention is high. Media multitasking contexts fit well into this category. In situations where perceived autonomy is high, attention allocation is not only driven by ability but also by internal factors such as goals or motivation. If attention allocation is driven by external factors, however, the free allocation of attention is limited and no longer driven by motivation. Manipulating the level of autonomy over one's attention allocation would, therefore, allow us to determine the role of motivation to exert attentional control in driving the observed performance differences between HMMs and LMMs. If an inherently lower motivation to self-regulate indeed drives the different approach of attention allocation, HMMs would not be as motivated as LMMs to apply cognitive control over how they allocate their attention when given high autonomy over their attention allocation. Instead, they would allow distracting stimuli to interfere more. Ralph, Thomson, Cheyne, and Smilek, (2014), however, found no correlation with actual cognitive errors (long-term memory failures) in support of the premise that HMMs' deficits does not stem from problems of inability. Therefore study one hypothesized the following:

Hypothesis 1: Engaging in a multitasking compared to a non-multitasking context will deplete self-regulatory resources.

Hypothesis 2: Media multitasking frequency will have a negative effect on self-regulatory resources after engaging in multitasking with high autonomy over attention allocation. This difference will be less apparent after multitasking with low autonomy over attention allocation.

Consequently, the second study of this paper investigated whether HMMs (vs. LMMs) respond differently to advertising in a media multitasking context, due to these self-regulatory differences.

People with low self-regulatory resources have been shown to be more likely to yield to temptation and to buy impulsively (e.g. Vohs & Faber, 2007). Hence, we expect that their purchase intentions towards products advertised within the media content will be higher. Therefore, we expect the following:

Hypothesis 3: High levels of autonomy when media multitasking will lead to lower self-regulatory resources when media multitasking frequency is higher (versus lower) and consequently to higher purchase intentions for the advertised brand.

To investigate the role of motivation versus ability, the autonomy with which respondents could allocate their attention between two media tasks was manipulated in our two studies. In one condition they could freely switch their attention (as internally motivated) across two media streams (television and internet), whereas in the other condition respondents were forced to switch their attention guided by the sign of the researcher (motivation to switch no longer plays a role). If a motivational aspect is indeed at play, then HMMs should experience stronger cognitive deficits compared to LMMs when attention switching is internally driven.

For the first study (N= 85, 69% women, Mage = 21.93), we conducted a between subjects factorial design with three conditions (sequential, multitasking under low autonomy over attention allocation and multitasking under high autonomy over attention allocation). This study tested the moderating impact of autonomy over attention allocation on the effect of media multitasking frequency on self-regulatory resources in a very controlled multitasking setting. The moderation was tested by model 1 of the process macro of Hayes (2013 ; 5,000 bootstraps; 95% bias-corrected confidence intervals). The interaction term was statistically significant indicating that the effect of media multitasking frequency on self-regulatory resources changes across different levels of autonomy, $B = 14.29$, $SE = 5.94$, $t(48) = 2.41$, $p = .02$. This analysis shows us that *only* under conditions of high autonomy, thus when motivation is at play, HMMs needed more time to complete the Stroop Task compared to LMMs. Under low autonomy conditions, so when only ability is expected to be at play, no significant difference between HMMs and LMMs in Stroop performance and thus self-regulatory resources could be found.

The aim of study II study (N = 91, 56% women, Mage = 22.64) was to replicate the findings of study I in a more naturalistic media multitasking environment and to test the implications of self-regulatory differences for advertising effectiveness. Therefore, the same between subjects factorial design as in study I was conducted. The results of study II reveal that the interaction term stays statistically significant within a more naturalistic media multitasking setting, $B = 1.36$, $SE = .44$, $t(5) = 3.09$, $p = .003$. A thereafter conducted spotlight analysis, confirmed the findings of study I, showing that the effect of media multitasking frequency on self-regulatory resources was only significant under conditions of high autonomy, thus when motivation was at play. Further on, a moderated mediation analysis (Hayes,

2013, Model 8, 5,000 bootstraps; 95% bias-corrected confidence intervals), $ab = .266$, $SE = .18$, 95% LLCI = .013, 95% ULCI = .752, revealed that the effect of media multitasking frequency on purchase intentions was mediated by self-regulatory resources depending on the level of autonomy. When autonomy was high, we found a significant positive indirect effect of media multitasking frequency on purchase intentions through self-regulatory resources. On the contrary, when autonomy was low, this indirect effect was eliminated.

Summarized, our data suggests that HMMs are more depleted than LMMs under conditions of high autonomy over attention allocation, most likely because of lower motivation to exert attentional control. This proposition is further supported by the finding that, under conditions of low autonomy of attention allocation, HMMs were *equally depleted* compared to LMMs. The results also supported the assumption that the fewer self-regulatory resources for HMMs under conditions of high autonomy impaired their ability to resist persuasive attempts.

Can Concern for the Disadvantaged Promote Disadvantage? Neglecting the Benefits of Exploitation

Amit Bhattacharjee, Erasmus University Rotterdam, The Netherlands
Gabriele Paolacci, Erasmus University Rotterdam, The Netherlands

EXTENDED ABSTRACT

In 2013, hundreds died when a clothing factory in Bangladesh collapsed, provoking an international outcry over unsafe working conditions and meager wages in the developing world. Companies like Nike, H&M, Gap, and Disney have been heavily criticized for employing low-wage labor, and have often abandoned these factories in response. For instance, Nike “decided to reduce [their] Bangladesh footprint” as a result of these concerns (Powell 2014). But does banning these labor practices actually help disadvantaged workers?

People in the developing world often elect to work under conditions that are morally outrageous to those in the developed world, such as low wages, long hours, and poor safety conditions. The increasing prevalence of outsourced production has spurred varied forms of resistance from ethically minded consumers, including boycotts of exploitative companies and petitions to improve wages and standards in labor exchanges. Though the desire to improve the lives of disadvantaged people in developing countries is nearly universal, many advocates warn that anti-sweatshop initiatives might harm the very people they mean to help by threatening the existence of their best or only available opportunities, leaving them with even worse alternatives (Kristof 2009; Powell and Skarbek 2006). In other words, “bad jobs at bad wages are better than no jobs at all” (Krugman 1997).

This article investigates how consumers in the developed world react to exploitative labor practices that are beneficial to the disadvantaged. We suggest that the moral outrage provoked by exploitation can divert consumers’ attention away from the benefits of exploitative practices for disadvantaged workers. This has downstream consequences for consumer behavior in the first world (e.g., intentions to engage with exploitative companies) and the persistence of disadvantage in third world (e.g., support for policies that might eliminate opportunities to earn).

Moral Outrage and Beneficial Exploitation

An exchange can be called *exploitative* when one party takes advantage of its position to obtain most of the value created through the exchange. However, the imbalance between the benefits obtained by the two parties is unrelated to whether the exchange is *harmful* or *mutually beneficial* (Wertheimer and Zwolinski 2016). In other words, the consequences for the disadvantaged party are crucial: are they worse off or better off than they were before the exchange? When parties are not coerced but voluntarily opt into a labor exchange, this signals that the relatively disadvantaged party still finds it better than the available alternatives. Disadvantaged workers often find earning by working under exploitative conditions far better than the other alternatives they face: either unemployment or working under even worse conditions. Because restricting the range of opportunities for a labor exchange (e.g., by demanding that companies pay higher wages) can impair the very existence of the exchange (e.g., by inducing companies to relocate), consumer resistance to exploitative practices can ultimately harm the disadvantaged (Powell and Zwolinski 2012, Zwolinski 2007). Because workers in the developing world lack better alternatives (Powell and Skarbek 2006), human rights campaigns in countries like Indonesia have resulted in massive unemployment and harmed disadvantaged workers (Harrison and Scorse 2010).

People’s attitudes towards sweatshops may not account for these consequences to the disadvantaged. Moral outrage over unfair or exploitative work conditions may drive consumers to reinstate fairness by punishing advantaged exploiters through boycotts or petitions to improve labor conditions through legislation (Garret 1987, Kozinets and Handelman 2004), but these actions may not actually promote the welfare of exploited workers (Darley and Pittman 2003). In other words, consumers’ moral outrage may lead them to neglect how exploited workers benefit from exploitative exchanges and thereby neglect their voluntary, mutually beneficial nature (cf., Baron, Bazerman and Shonk 2006; Bazerman, Magliozzi and Neale 1985; Caplan 2007). This paper examines whether moral concern for the disadvantaged can make consumers insensitive to the benefits of exploitation for the disadvantaged.

Six studies investigate how consumers in the developed world react to exploitative labor practices that benefit the disadvantaged. We show that consumers do not consistently view low-wage employment as a means to benefit those most in need (Study 1A-1B). Providing materially irrelevant information about the wages of more privileged workers (Study 2A) or executives (Study 2B) provokes moral outrage and greater resistance to exploitative labor that benefits disadvantaged workers. On the contrary, directing consumers’ attention to the alternatives faced by disadvantaged workers reduces resistance (Study 3A-3B). Our studies were conducted with US residents through Amazon Mechanical Turk, using between-subjects designs with a target sample size of 100 participants per condition. All study materials are available here: <https://tinyurl.com/sweatshopsappendix>.

Study 1A: Employment Decisions are Less Need-Based Than Donations

Study 1A (N = 201) tested whether consumers view employment as a means of helping the disadvantaged by comparing this decision to an otherwise equivalent donation decision. Respondents read about a wealthy businessman planning to allocate resources to either a developed country (the US) or a fictional developing country (Sangala), where the same amount could have 20 times more impact due to a lower cost of living. We manipulated whether the resources to allocate were monetary donations or employment opportunities. Participants indicated whether the businessman should allocate resources to people in the US or Sangala.

When allocation was framed as a donation, 71% of participants felt it was appropriate to allocate resources to Sangala, but this percentage decreased to 48% when the decision was framed as employment ($\chi^2(1) = 11.11, p < .001$). Participants were thus less prone to allocate employment opportunities to those most in need, indicating that many do not view employment as a means to create social welfare.

For participants in this study, choosing not to allocate resources to a third-world country entailed benefiting their home country. We conducted Study 1B to examine whether these results depend on participants’ preferences for allocating resources to their home country.

Study 1B: Insensitivity to Need is Robust to Home-Country Preferences

Study 1B ($N = 202$) compared donation and employment decisions using the same scenario and cost-of-living information as Study 1A but used a fictional developed country, Norland, in place of the US. To disentangle participants' own preferences for allocation from beliefs about what would strategically benefit the businessman, we reworded our dependent variable question as "How would you like the businessman to allocate his money?"

When framed as a donation decision, 94% of respondents favored allocating resources to Sangala, indicating a nearly unanimous desire to help the most disadvantaged. However, only 78% wanted the businessman to employ Sangalians, a significant difference ($\chi^2(1) = 10.99, p < .001$). The shift in allocations relative to Study 1A indicates the presence of home-country effects in both conditions in Study 1A. However, these effects cannot explain the difference between conditions.

These two studies suggest that consumers do not consistently view employment opportunities as resources to benefit those most in need. Studies 2A and 2B investigated how the salience of workers' disadvantage relative to others affects consumers' resistance to exploitation and appreciation of its benefits.

Study 2A: Salient Worker Disadvantage Increases Resistance

Study 2A ($N = 202$) used a sweatshop scenario in which a clothing company from Norland opened a factory in Sangala and improved its financial performance through reduced labor costs. We tested whether consumer resistance to exploitative labor conditions depends on their disadvantage relative to workers in first-world countries. Participants in the control condition only learned that workers in the Sangalian factory "make the equivalent of \$1200 per year, on average." In the disadvantageous comparison condition, participants also read about the company's Norlandian factory where workers "make the equivalent of \$24,000, on average."

We measured consumer resistance using seven items to capture purchase avoidance intentions (e.g., "I would rather buy from a Domino's competitor than from Domino's"; "I would support a boycott of Domino's products") and policy judgments ("Domino's factory in Sangala should be closed"). In accordance with our conceptualization of beneficial exploitation, we also measured moral outrage towards the company and perceived benefits for disadvantaged workers (i.e., whether the factory leaves them worse off or better off) to explain these effects.

Making this wage disparity salient made participants significantly more resistant ($M = 4.54$ vs. $3.97, p = .005$). This effect was explained by both increased moral outrage at the company's practices (indirect effect = $0.59, SE = .14, 95\% CI [0.33, 0.88]$) and though decreased perceptions that the factory benefited Sangalian workers (indirect effect = $0.10, SE = .06, 95\% CI [0.02, 0.23]$). Study 2B sought to conceptually replicate these findings by providing a comparison that was arguably even less relevant: the salary gap between exploited workers and the company CEO.

Study 2B: Salient Ceo-Worker Disparity Increases Resistance

Study 2B ($N = 204$) used the same scenario, design, and measures as Study 2A. In the disparity condition, however, participants read that thanks to the company's performance, the CEO's income "increased to \$12,000,000 from \$6,000,000 in the previous year."

Conceptually replicating Study 2A, considering the disparity between parties significantly increased consumer resistance ($M =$

4.33 vs. $3.73, p = .007$). This effect was mediated by moral outrage (indirect effect = $0.35, SE = .15, 95\% CI [0.08, 0.68]$) and by decreased perceptions of benefits for disadvantaged Sangalians (indirect effect = $0.10, SE = .05, 95\% CI [0.01, 0.23]$).

Though the salaries of workers in Norland or the company CEO are irrelevant to judgments about whether exploitative labor opportunities leave Sangalians better off than the alternatives, these findings show that highlighting the relative disadvantage of Sangalians can reduce consideration of their welfare. Since the benefits of exploitative exchange depend on its superiority to available alternatives, Study 3A examined if prompting this alternate comparison could reduce resistance.

Study 3A: Prompting Consideration of Alternatives Reduces Consumer Resistance

In Study 3A ($N = 205$), we examined whether resistance to exploitation is attenuated when consumers are prompted to consider the alternatives faced by disadvantaged workers. We used the same scenario and measures as in Study 2A-2B. Across two conditions, we noted that although conditions and wages in the factory were much worse than those in the company's Norlandian factories, these jobs were in great demand among the Sangalians. In the treatment condition we prompted respondents to consider the alternatives to factory labor available to Sangalians, including unemployment or employment under even worse conditions.

Relative to the control condition, considering Sangalians' alternatives reduced resistance ($M = 4.87$ vs. $4.34, t(203) = 2.36, p = .019$). Though participants were outraged at the company across conditions, the prompt reduced consumer resistance by increasing participants' appreciation of the benefits for Sangalians (indirect effect = $-.195, SE = .069, 95\% CI [-.343, -.068]$).

These findings further support the notion that people naturally neglect to consider how disadvantaged workers can benefit from exploitative practices. But is it really the case that people neglect to consider disadvantaged workers in particular, rather than counterfactual scenarios in general? Study 3B tested this possibility.

Study 3B: Consumers Focus on Advantaged Parties and Neglect the Disadvantaged

To assess whether consumers neglect to consider disadvantaged parties in particular, Study 3B ($N = 307$) included a third condition with a separate prompt. In particular, we prompted respondents to consider the alternatives faced by either the disadvantaged parties (Sangalian workers) or an advantaged party (the clothing company CEO, who would earn less without operating the factory). We also directly asked people how much they focused on the advantaged versus disadvantaged party when reporting their resistance to the company.

These prompts significantly affected consumer resistance ($F(2, 304) = 8.97, p < .001$). Compared to the control condition, considering the alternatives faced by the Sangalians significantly reduced resistance ($M = 5.02$ vs. $4.21, p < .001$), an effect that was mediated by greater perceived benefits for Sangalians (indirect effect = $.40, SE = .140, 95\% CI [.11, .66]$) and reduced outrage at the company (indirect effect = $.15, SE = .051, 95\% CI [.07, .29]$). In contrast, considering the alternatives faced by the CEO had no effect on consumer resistance ($M = 5.02$ vs. $4.79, p = .245$).

Compared to the control condition, considering Sangalian workers also reduced focus on Domino's CEO ($M = 3.56$ vs. $2.88, p = .009$), while prompting consideration of the CEO had no effect ($M = 3.56$ vs. $3.44, p = .647$). Together, these findings indicate that consumers may naturally focus on punishing advantaged parties when

evaluating unfair labor practices, but focus less on the welfare of disadvantaged parties.

General Discussion

We live in a world of limited and imperfectly distributed resources. Despite the unprecedented prosperity enjoyed by many in the developed world, about a tenth of the world's population still lives in extreme poverty. Though sympathy and moral concern for the disadvantaged is nearly universal, prosocial efforts are often misguided. For instance, people fail to allocate donations to the most effective charities (Berman et al. 2015), and humanitarian aid in response to natural disasters depends more on the number of fatalities than on the number of people in need (Evangelidis and Van den Bergh 2013).

Our results show that people might fail to benefit the disadvantaged *because* of their moral concerns. By the standards of the developed world, work conditions and wages in the developing world are outrageously poor. In light of the advantages of other parties (e.g., workers in developed countries and company executives), consumers are right to label these labor practices as unfair and exploitative. However, unfair or not, banning these exchanges may eliminate workers' only means of remedying their disadvantage. Just as sympathy for those in need may lead to suboptimal allocations of charitable resources (Loewenstein and Small 2007; Small 2010), moral outrage over the poor conditions and inequities faced by disadvantaged populations may thus harm them more.

These findings join recent warnings that moral concerns often restrict the acceptability of the solutions we consider to create social welfare (Bloom 2016). People often view profit-seeking as fundamentally incompatible with societal good, regarding those who personally benefit from charitable behaviors as worse than those who do nothing to help others (Newman and Cain 2014). Restrictions on these exchanges may have steep societal costs. For instance, moral objections to exchanging organs may be costing hundreds of lives every day (Roth 2007), and keeping for-profit firms from participating in charitable enterprises may dramatically reduce charitable funds available to those in need (Pallotta 2008). However, our findings suggest that the costs of moral outrage can be mitigated. Considering workers' (lack of) alternatives increases consumers' support for employment in the developing countries and increases their appreciation of the benefits of these exploitative exchanges despite their persistent moral concerns (cf., Newman and Cain 2014).

Though helping the disadvantaged is an admirable goal, doing so effectively may require confronting realities that are shocking to first-world consumers yet obvious to third-world workers themselves. Hence, workers' own choices, and the enormous unmet demand for more sweatshop jobs (Kristof 2009; Powell and Zwolinski 2012), may reflect better awareness of these realities. Where no perfect solutions are likely to appear, even deeply flawed, imperfect solutions may merit consideration. Solving persistent social problems like global poverty may require us to use all the tools at our disposal.

Consuming the Streets: Story of a Street Peddler

Ayşe Binay Kurultay, Kadir Has University, Turkey

EXTENDED ABSTRACT

Informal retailers are described as “dealers whose shops consist solely of portable stalls or modified vehicles, whose cachement areas are determined by whatever market circuits the vendor chooses to travel, whose income may or may not be reported accurately to tax authorities” (Sherry, 2001). Street vendors contribute to the overall economic activity, to sustaining themselves as well as their dependents, to the expansion of the range of places and times where goods and services are provided. They are also seen as manifestations of a peaceful and informal revolution of hard-working poor people against a regulatory state promoting the interests of big businesses. Informal commerce has become a lifesaving income opportunity for the unemployed in many countries. As an alternative consumption space in informal commerce, street peddlers provide an immediate service to passers by either using creative product presentations or social performances such as street cries or demonstrations. Individual accounts of street vendors have been a neglected area in consumption research and this study will try to invite the reader to take a glimpse into the life of a street vendor to introduce the reader to the behind-the-scenes of the informal market retailing, consumption. The article aims to make a contribution to the marketplaces cultures domain (Arnould and Thompson, 2005) and provides a case study of a vendor in Istanbul to demonstrate the interactions between the buyers and seller as well as map his consumption space in terms of human interaction, space allocation and advertising practices.

Literature suggests that peddling has developed in Turkey as a result of internal migration from rural areas especially in the last 30 years (Akgeyik, Yavuz, Ersoz, Ozdemir, & Senocak, 2004). As internal rural-urban migrants are unable to find formal employment in urban settings, they are inclined to work informally as street peddlers. Peddling has turned into a social reality characterizing the income dimension of a certain lifestyle (p.20). One of the most striking qualities of informal commerce jobs is the fact that these jobs are found hastily and as means of income, not as a career step. People who are involved in informal sector jobs in Istanbul are mainly interested in finding a source of income for themselves and their families. Without the fixed costs of taxes, store rent, electricity or water bills, street peddlers are able to offer lower priced yet lower quality products or services compared to their formal settled competitors. In the Turkish context, lower priced products satisfy the demands of many low-income consumers. As the internal migration continues from rural to urban areas resulting in low-income consumer masses, demand for street peddling sector increases. Thus, street peddling and informal commerce are guaranteed to be long lasting (Baştaymaz, 1999, p.3) in Istanbul. Another factor supporting street peddling in urban areas is the fact that establishing a formal business is a costly and a long procedural process. Starting a business by completing the legal procedures creates significant limitations for low-income people and it becomes a discouraging construct for individual entrepreneurs. As a result, those who want to be producers or sellers with their individual initiative opt for the easiest way, namely street peddling (Akgeyik, Yavuz, Ersoz, Ozdemir, & Senocak, 2004, p.52). In times of economic crises, major businesses and stores opt for using peddlers as subcontractors in order to ride out fiscal crises with minimal loss. The peddlers involved in such an alliance either share the profits with businesses or are used as wholesale buyers (Yildiz, 2008). The customer-seller relationship has become an important factor in peddling. The hundreds of thousands of people working as

street peddlers virtually create a new employment culture (Akgeyik, Yavuz, Ersoz, Ozdemir, & Senocak, 2004, p.50). This study utilizes qualitative methods of participant observation, semi-structured and unstructured interviews with the peddler, introducing the reader to behind the scenes. The study focuses on a single peddler, Xalo, in Istanbul, Turkey to whom I had access to, thus developing this research into a case study mapping his consumption space in terms of human interaction, space allocation and advertising practices.

Findings include fluidity of the consumption place, competitive yet cooperative behavior between sellers and lack of social performance in advertising practices. Nakanishi's (1990) argument on segmentation based on mutually beneficial interpersonal relationships and uncompetitive markets in the informal sector finds support in this study. As Price and Arnould (1999) suggest, friendships among competitors are characterized by intimacy, loyalty and social support. As a retail service, peddling depends highly on product presentation. Without the formal marketing developments such as packaging, advertising or promotion, peddlers in the informal sector are forced to find creative solutions for presentation of products they sell through street shows (Akbulut, 2009) in Istanbul. Thus, it is possible to see peddlers who do not use performances or other means of unsophisticated advertising solutions to sell their products. Similar to the young man selling flashlight batteries in Ankara mentioned in Uysal's (1968) research, Xalo does not use street cries or performances when he sells his products. None of the peddlers on the street use street cries, street shows or other means of social performance contrary to what Akbulut (2009) suggests. The findings support Varman and Costa (2009) that vendors do not try to steal each others' customers by “calling out”.

As important yet neglected actors of commerce in many developing and developed countries, peddlers create an innovative and convenient new geography of consumption. Street cars that peddlers sell their products on can be thought of as a fluid yet enduring consumption space where consumers can find items of interest. In this context, space should be thought of as socially produced as Lefebvre's space involving the production of social relations and new forms of spatialities (Mansvelt, 2005). As creators of such fluid consumption spaces, this study intended to invite the reader to take a glimpse into the life of a street vendor and introduce the reader to the behind-the-scenes of the informal market retailing and consumption.

Sneakers Made of Used Plastic? How Consumers' Implicit Theories Affect Buying Recycled Products

Alessandro Biraglia, University of Leeds, UK

J Joško Brakus, University of Leeds, UK

Ambra Brizi, Sapienza University of Rome, Italy

Lucia Mannetti, Sapienza University of Rome, Italy

EXTENDED ABSTRACT

In recent times, the reduction of waste and the practice of recycling have become two major topics in the societal debate. While the issue of garbage disposal has been affecting the Western World for the past decades, the global scenario has recently exacerbated due to the increased consumption volume (and related waste) of developing nations. In the past, scholars and policy makers have tried to educate as well as incentivize practices like recycling to avoid reduce land-fill stocks and create new objects from past used materials (Reid, 1990). Such products have been commercialized more and more by big brands (i.e. Adidas and Levi's) and by famous fashion designers (i.e. Stella McCartney).

While more academic literature has focused on drivers for consumers motivations to engage in recycling activities (Trudel, Argo, and Medel 2016), there has been little research investigating consumers' underlying psychological factors to favour recycled products over standard ones (Mobley, Painter, Untch, and Unnava 1998). In this study we address this issue by experimentally testing consumer evaluation and intention to adopt recycled products through an implicit theory – or mind-sets- framework on.

Implicit theories are beliefs individuals have about the human characteristics (Dweck, 1999). Some individuals maintain a fixed mind-set (or entity theory), believing that human traits—such as intelligence, personality, and morality—are relatively fixed. According to this mind-set, characteristics are stable and there is not much that can be changed about them (Dweck, 1999). Conversely, people with a growth mind-set (or incremental theory), believe that people can substantially modify their characteristics and that these characteristics are malleable. Learning and experience can in fact foster development and change even basic traits of a person together with its behaviour. In other words, incremental theorists suggest that those who strive to change an aspect of their nature can do so. Implicit theories also shape the way people think about effort (Grant and Dweck, 2003). As entity theorists believe traits are innate and unchangeable, they also tend to minimize role of effort. Achievements are in fact based on traits rather than experience and learning. In contrast, incremental theorists view effort as an important element of human nature as it allows to improve and develop, realizing their greater potential. Indeed, if things come too easily, it means they are staying in their comfort zone and not realizing their full potential. Transferring these views in the domain of recycled products, these kind of items are usually manufactured through a sometimes complicated and highly effortful process, bringing for example a plastic water bottle to become fabric for a t-shirt or a pair of trousers. We therefore believe that individuals beholding an incremental theory will be showing a higher intention to purchase a recycled (vs. non-recycled) product when they perceive the manufacturer to have put a high amount of effort to create the object. Hence, we hypothesize that perceived effort in creating the product mediates the relationship between product type and purchase intention, and that this effect is stronger when an individual is an incremental theorists.

In a set of three experiments we test the effect of implicit theories to consumers' intention to adopt recycled products. In the first experiment we asked participants to evaluate their intention to pur-

chase a standard product or one made from recycled plastic, measuring their implicit theory type. The results showed a significant higher purchase intention for incremental theorists, (i.e. individuals who believe traits are malleable and can change) than for entity theorists (who instead believe traits are fixed and unchangeable). In a second laboratory experiment we manipulated implicit theories product type (recycled vs. non-recycled) measuring individuals' level of appreciation through a single category implicit association test. We found out that incremental theorists preferred the recycled product more than entity theorists. In our third experiment we found how this effect is mediated by consumers' perception of the effort invested by the company to create the product. Specifically, the role played by the effort invested by the company in creating the recycled product mediated the effect on the type of product (recycled vs. non-recycled) on consumers' intention to purchase it. This result was stronger in the case on individuals in the incremental condition than in the entity condition.

Taken together, the results of these studies contribute to the literature on implicit theory by investigating another area in consumer psychology (intention to adopt recycled products) so far unexplored, responding to the call for more research made by John and Park (2016). On a managerial point of view, this study suggests how highlighting the effort spent by a company in creating the product (for example by mentioning the hard work done by their R&D department before the official launch) can attract consumer (especially incremental theorists) to intend to buy the product. Some limitations of this study (i.e. testing the effect on more product categories or ways to make recycled products more appealing to entity theorists) can be investigated by future research.

Putting on a Show or Showing My True Self? Exploring Consumers' Desire to Signal Accurate versus Enhanced Identities

Daniel Brannon, University of Northern Colorado, USA

Naomi Mandel, Arizona State University, USA

EXTENDED ABSTRACT

Research has shown that consumers use self-enhancing products to compensate for negative self-views, especially in the domain of public consumption (e.g. Berger and Heath 2007; Rucker and Galinsky 2008; Escalas and Bettman 2005; White and Dahl 2006). For instance, Rucker and Galinsky found that powerless individuals are more likely to consume status-related products than those who feel powerful (Rucker and Galinsky 2008). However, anecdotal evidence suggests that consumers are also concerned with signaling accurate self-view information to others, even when these self-views are negative. For instance, the *People of Walmart* website features low socioeconomic status individuals who seem to intentionally wear unflattering clothes, hairdos, and makeup.

Our research attempts to reconcile prior findings that consumers acquire and display products to be seen favorably with the notion that consumers sometimes want products that accurately signal how they see themselves. We posit that competing motives of self-verification and self-enhancement drive differing consumption responses. In particular, while self-enhancement theory asserts that people are primarily motivated to be seen favorably (Sedikides 1993), self-verification theory argues that people are motivated to be known and understood by others, even in the domain of negative self-views. Drawing on recent research showing that self-verification versus self-enhancement motives can be situationally activated (Kraus and Chen 2009), we demonstrate that an active self-verification motive leads consumers to prefer public products that accurately reflect an underlying self-view. In contrast, activating a self-enhancement motive dampens this effect, as negative self-view consumers no longer desire accurate identity products.

In study 1, we sought evidence that situational activation of a self-verification (vs. self-enhancement) motive could influence consumers' preferences for a negative identity product. We conducted a 2 (motive: self-verification vs. self-enhancement, between) \times (appearance-esteem, continuous) design. Based on findings that people are motivated to self-verify (vs. self-enhance) when around socially close (vs. socially distant) others (Kraus and Chen 2009; Swann, De La Ronde, and Hixon 1994), we asked participants in the self-verification condition to write about a significant other (e.g. close friend or family member) and participants in the self-enhancement condition to write about a loose acquaintance. Next, in a supposedly unrelated study, we asked participants to rate their likelihood of purchasing a graphic t-shirt with the tagline "Too Ugly for L.A." We found a significant motive \times appearance-esteem interaction ($b = -.38, t(245) = -2.02, p = .04$). Importantly, when people wrote about a close other, activating a self-verification motive, lower appearance-esteem increased preference for the "ugly" t-shirt ($b = -.28, t(245) = -2.06, p = .04$). In contrast, when people wrote about a distant other, activating a self-enhancement motive, this effect was dampened (*ns*). An additional spotlight contrast showed that low appearance-esteem participants were marginally less likely to purchase the shirt in the self-enhancement (vs. self-verification condition ($b = .54, t(245) = 1.91, p < .06$).

In study 2, we replicated this basic finding, but in a different self-view domain and a different product class. We conducted a 2 (motive) \times (chronic power, continuous) design. Participants completed the social distance manipulation from study 1 and indicated

their preference between a Lexus (high status) and a Kia (low status) branded car. We found a significant motive \times power interaction ($b = -4.47, t(339) = -2.61, p < .01$). Among participants who wrote about a close other (self-verification condition), lower power increased preference for the Kia over the Lexus ($b = -4.55, t(339) = -3.71, p < .001$). In contrast, among participants who wrote about a distant other (self-enhancement condition), lower power did not increase preference for the Kia (*ns*). An additional spotlight contrast showed that this dampening was driven by low power participants decreased preference for the Kia in the self-enhancement condition ($b = 23.13, t(339) = 2.92, p < .01$).

In study 3, we sought to replicate our prior findings using a different situational activation of motive. We ran a 2 (motive) \times (power) design. We asked participants read a Forbes Magazine article entitled "Should You Be Yourself in a Job Interview?" In the self-verification condition, the article argued that interviewees should share accurate information about themselves during the job interview ("...candidates should do all they can to emphasize their true selves, even if means acknowledging their weaknesses..."). In the self-enhancement condition, the article argued that interviewees should only share highly positive information about themselves during the job interview ("...candidates should do all they can to emphasize the positive aspects of themselves, while downplaying the negatives..."). Afterwards, participants again indicated their preference between Lexus and Kia. The motive \times power interaction was significant ($b = -4.68, t(352) = -2.00, p < .05$). When we activated a self-verification motive, lower power increase preference for Kia over Lexus ($b = -4.37, t(352) = -2.79, p < .01$). In contrast, when we activated a self-enhancement motive, power did not affect preference (*ns*). Further, a spotlight contrast showed that low power participants exhibited a decreased preference for Kia in the self-enhancement (vs. self-verification) condition (stats).

In study 4, we sought a boundary condition regarding when situational activation of a self-verification motive (via a social distance manipulation) would *not* increase preference for product signaling an accurate self-view. We predicted that participants with high (vs. low) fear-of-negative-feedback (Watson and Friend 1969) would be less likely to prefer products that signaled an accurate self-view because negative self-view participants with high fear-of-negative-feedback would exhibit a decreased preference of the Kia over the Lexus. We ran a 2 (motive) \times (fear of negative evaluation) \times (power) design. There was a significant motive \times fear of negative evaluation \times power interaction ($b = 8.02, t(180) = 2.25, p < .03$). Consistent with predictions, among participants with a low fear of negative evaluation, when we activated a self-verification motive, the power coefficient was negative and significant, such that lower (vs. higher) power increased points allocated to Kia over Lexus ($b = -10.27, t(180) = -3.07, p = .003$). Among participants with a high fear of negative evaluation, the effect of a self-verification motive on preference was fully attenuated ($b = -3.29, t(180) = -.89, ns$).

Introduction

“Dressed like this, in the ugliest clothes I could muster, I set off for the estate where Anne Lisbet lived... [The] filthy, ugly clothes I was wearing, the drooping head, all of this was for her benefit, so that she would understand.” (Knausgaard 2009)

In the above passage, the character who has been feeling sorry for himself for some time, responds to his girlfriend’s apparent obliviousness by wearing the most unattractive clothing he can find. Indeed, it often appears that consumers acquire and display products to accurately signal something about themselves to others, even if that signal is negative. For instance, people who suffer from depression or low self-esteem may accurately signal how they feel about themselves by wearing clothes and listening to music associated with negative subcultural identities (Sedgwick 2013). However, it also contradicts the popular notion that consumers primarily purchase products in order signal positive information about themselves to others (e.g. Berger and Heath 2007; Rucker and Galinsky 2008; Escalas and Bettman 2005; White and Dahl 2006). What accounts for this behavior?

Our research investigates this question by building on the theory of self-verification (Swann 1983). According to self-verification theory, people seek to be known and understood by others in a manner that is consistent with their self-views, even when these views are negative. We demonstrate that situational activation of a self-verification (vs. self-enhancement) motive lead consumers to prefer public consumption that signals accurate (vs. enhanced) self-view information to others.

We make several contributions to the literature. First, we provide a more nuanced understanding of consumer signaling behavior by focusing on a counterintuitive implication of self-verification theory: that consumers sometimes want to publically signal accurate, and even negative self-views, rather than only positive self-views. Furthermore, we contribute to the self-verification literature itself. While studies in this area have largely focused on how self-verification motives drive feedback preferences and partner selection behavior (Swann, Rentfrow, and Guinn 2003), little research to date has explored whether these motives influence how people signal information about themselves to others, for example through their consumption choices. Finally, we demonstrate two boundary conditions of self-verification by showing that the effects of these motives disappear when consumers consider using a product privately (vs. publicly), as well as when consumers have a high (vs. low) fear of negative social evaluation.

Competing Motives: Self-Enhancement Versus Self-Verification

According to self-enhancement theory, people strive to create to maintain a positive self-view (Sedikides 1993). The motive to self-enhance often leads people to misrepresent their actual traits and abilities. For example, people tend to have exaggerated perceptions of their control over outcomes (Taylor and Brown 1988). Based on the plethora of evidence that people want to achieve a positive self-image, several scholars have argued that self-enhancement is a universal human motivation (e.g. Taylor and Brown 1988; Sedikides 1993). Self-enhancement motives can increase consumer preferences for products that signal highly positive information about the self (Belk 1988; Berger and Heath 2007; 2008; Escalas and Bettman 2005). For instance, people engage in conspicuous consumption of luxury products in order to signal social status and power (Rucker and Galinsky 2008; 2009; Veblen 1899), attract mates and deter ri-

vals (Griskevicius et al. 2007), and maintain or enhance self-esteem (Sivanathan and Pettit 2010). Not only do self-enhancement motives lead consumers to choose products that signal positive information about themselves, they also lead them to avoid products associated with negative or undesirable information. For instance, men eschew products that signal feminine traits (White and Dahl 2006). Consumers also strive to use products that signal unique and differentiated social identities in order to avoid being seen as “conformists” (Berger and Heath 2007).

In contrast, proponents of self-verification theory (Swann 1983) have argued that people are not singularly motivated by self-enhancement motives. Instead, people also have a fundamental desire to be known and understood by others, even in domains of self-perceived flaws and shortcomings. For instance, people prefer interaction partners who give them accurate, as opposed to overly favorable, evaluations of their skills and abilities in several domains (e.g. physical attractiveness, intelligence, and athletic ability), even when these self-views are negative (Hixon and Swann 1993; Robinson and Smith-Lovin 1992; Swann, Pelham, and Krull 1989; Swann et al. 1990; Swann et al. 1992). Furthermore, people who view themselves negatively prefer feedback that validates negative feelings, as opposed to feedback that positively reframes what they are experiencing (Marigold et al. 2014).

Previous research exploring why people sometimes prioritize self-verification over self-enhancement lends insight into how this motive can affect consumer signaling behavior. People self-verify because receiving social confirmation of a self-view provides them with a sense of coherence about their world and themselves (Swann et al. 2003). Even negative self-views may serve as important sources of self-knowledge that must be maintained, not enhanced. Based on this notion, using products that signal accurate self-view information should be a particularly effective method for maintaining self-coherence, as these products provide consumers with an increased sense of assurance that others see them in the same way that they see themselves, without having to explicitly engage in social interactions or elicit direct interpersonal feedback (Oyserman 2009). Based on these ideas, we propose that the situational activation of a self-verification (vs. self-enhancement) motive will cause consumers to prefer products that signal accurate (vs. enhanced) self-view information, even when these views are negative.

For comparison purposes we consider the relevant baseline condition to be one where consumers have a self-enhancement motive (Baumeister 1989; Kraus and Chen 2009; Sedikides 1993), as prior research has found that people are more practiced at making positive social impressions (Farrow et al. 2015; Swann et al. 1990). We expect that among consumers with an active self-enhancement motive, underlying self-views will not influence product preferences, because all individuals in these conditions will be more concerned with acquiring a product that signals positive (vs. accurate) information about themselves.

Hypothesis 1: There will be an interactive effect of self-view and motive on product preference. Consumers with a self-verification motive will prefer products that are consistent with their self-view, such that consumers with a more negative self-view will exhibit higher evaluations and preference for products that signal negative (vs. positive) information. Among participants with an active self-enhancement motive, no such relationship will exist.

Of note, we do not predict a pattern that is entirely consistent with *compensatory* self-enhancement, which occurs when individuals with a negative self-view are more motivated to self-enhance than individuals with a positive self-view (see Mandel et al. forthcoming for a review). In the current research, we investigate how self-verification versus self-enhancement motives influence consumption responses to chronic self-views, which are stable views developed over an individual's lifetime (Ehrlinger and Dunning 2003). As a result, in our studies, participants do not experience the type of self-threat that creates a temporary self-discrepancy, which can in turn lead to compensatory consumption.

Fear-of-Negative-Evaluation as a Boundary Condition

How might this signaling behavior change among consumers who are averse to negative social evaluations? Individuals with high social anxiety are particularly sensitive to the social evaluations of others (Clark and Wells 1995; Rapee and Heimberg 1997). As a result, socially anxious individuals tend to exaggerate the importance of even mildly negative social feedback (Stopa and Clark 2001), leading them to try to avoid negative social evaluations (Wells 1995). Drawing on these findings, we predict that fear of negative social evaluation will dampen the effect of a self-verification motive on the product preference. More specifically, among consumers with a higher fear of negative social evaluation, we expect that fear to outweigh any concerns for self-verification, leading those with both positive and negative self-views to prefer products that signal enhanced self-view information. In contrast, we expect to replicate our effect of self-verification motives predicted in H1 among individuals with low fear of negative social evaluation.

Hypothesis 2: Among consumers with low fear of negative evaluation, activating a self-verification motive will lead consumers to prefer products that are consistent with their self-view. Among consumers with a high fear of negative evaluation, activating a self-verification motive will not lead consumers to prefer products that are consistent with a self-view.

We tested our hypotheses across four studies. In studies 1 – 3, we examined whether different situational activations of a self-verification motive led consumers with negative self-views to prefer products that signaled accurate information about this view. In study 4, we explored a fear-of-negative evaluation as a boundary condition of this effect.

Study 1 – This was a 2 (motive: self-verification vs. self-enhancement, between) \times (appearance-esteem, continuous) design. Participants completed a 6-item appearance-esteem scale (Heatherton and Polivy 1991). Next, based on past research finding that people are motivated to self-verify among socially close (vs. socially distant) others (Swann et al. 1994), we situationally activated a self-verification motive by asking participants to write 3-4 sentences about a socially other: ““Please write 3-4 sentences about a person whom you have known for a long time...”” In the self-enhancement, condition participants wrote about a loose acquaintance: “Please write 3-4 sentences about a person whom you have not known for a long time and do not currently know well...”” Afterwards, we gave participants a supposedly unrelated study asking them to evaluate a graphic t-shirt. We asked participants to rate their likelihood of purchasing a t-shirt with the tagline “Too Ugly for L.A.” written on the front. We found a significant motive \times appearance-esteem interaction ($b = -.38, t(245) = -2.02, p = .04$) (see figure 1). Importantly, when people wrote about a close other, activating a self-verification mo-

tive, lower appearance-esteem increased preference for the “ugly” t-shirt ($b = -.28, t(245) = -2.06, p = .04$). In contrast, when people wrote about a distant other, activating a self-enhancement motive, this effect was dampened (*ns*). An additional spotlight contrast showed that low appearance-esteem participants were less likely to purchase the shirt in the self-enhancement (vs. self-verification) condition ($b = .54, t(245) = 1.91, p < .06$).

Study 2 – This was a 2 (motive, between) \times (self-esteem, continuous) design. Participants completed an 10-item scale of self-esteem (Rosenberg 1965). Next, we asked participants to write about a socially close (vs. distant) other, similar to study 1. Afterwards, participants completed a supposedly unrelated study where they viewed an advertisement featuring a picture of a Kia (low status) and a Lexus (high status) brand car (Mandel et al. 2006). Afterwards, we asked participants to indicate their preference by allocating a total of 100 points between the two cars, with a higher number indicating a stronger preference for the Kia. The motive \times power interaction coefficient was significant ($b = -4.47, t(339) = -2.61, p < .01$). When participants wrote about a close other, activating a self-verification motive, lower power increased preference for the Kia over the Lexus ($b = -4.55, t(339) = -3.71, p < .001$). In contrast, when participants wrote about a distant other, activating a self-enhancement motive), lower power did not increase preference for the Kia (*ns*). An additional spotlight contrast showed that low power participants had a decreased preference for the Kia in the self-enhancement (vs. self-verification) condition ($b = 23.13, t(339) = 2.92, p < .01$).

Study 3 – We ran a 2 (motive, between) \times (power, continuous) design. Participants completed the 8-item scale of chronic power. Next, we activated motive using a different situational manipulation. Specifically, we asked participants to read a Forbes Magazine article entitled “Should You Be Yourself in a Job Interview?” In the self-verification condition, the article argued that interviewees should share accurate information about themselves during the job interview (“...candidates should do all they can to emphasize their true selves, even if means acknowledging their weaknesses...”). In the self-enhancement condition, the article argued that interviewees should only share highly positive information about themselves during the job interview (“...candidates should do all they can to emphasize the positive aspects of themselves, while downplaying the negatives...”). Afterwards, participants allocated 100 points to indicate their preference between Kia and Lexus, similar to study 2. The motive \times power interaction coefficient was significant ($b = -4.68, t(352) = -2.00, p < .05$). When we situationally activated a self-verification motive, the power coefficient was negative and significant, such that lower (vs. higher) power increased the number of points allocated Kia over Lexus ($b = -4.37, t(352) = -2.79, p < .01$), indicating a desire for the product that accurately signaled participants' power self-view. In contrast, when we activated a self-enhancement motive, the power did not affect the points allocation ($b = .31, t(352) = .18, ns$).

Study 4 – This study was a 2 (motive: self-verification vs. control) \times continuous (fear of negative evaluation) \times (power) design meant to test H3. Participants completed the power scale and Watson and Friend's (1969) Brief Fear-of-Negative-Evaluation Scale. Next, we activated a self-verification motive by asking participants to write about a close other (Kraus and Chen 2009). Participants in the control condition wrote about a neutral topic. We then asked participants to indicate their preference between Kia and Lexus using the point allocation task, similar to study 1. Replicating our previous findings, there was a significant two-way motive \times power interaction coefficient ($b = -7.18, t(180) = -1.95, p = .05$) (H1). More important, and consistent with hypothesis 2, this effect was qualified by a

significant motive \times fear of negative evaluation \times power interaction ($b = 8.02$, $t(180) = 2.25$, $p < .03$). We further examined the motive \times power interaction at one standard deviation above and below mean fear of negative evaluation. Consistent with predictions, among participants with a low fear of negative evaluation, when we activated a self-verification motive, the power coefficient was negative and significant, such that lower (vs. higher) power increased points allocated to Kia over Lexus ($b = -10.27$, $t(180) = -3.07$, $p = .003$). In contrast, in the control condition power did not affect points allocation ($b = 4.93$, $t(180) = 1.34$, $p = .18$). Also consistent with predictions, among participants with a high fear of negative evaluation, the effect of a self-verification motive on preference was fully attenuated, such that power did not affect points allocation ($b = -3.29$, $t(180) = -.89$, ns).

In sum, our research offers one possible explanation for reconciling when consumers prefer products that signal something accurate about themselves versus products that signal something favorable. Specifically, we find that situational activation of a self-verification (vs. self-enhancement) motive (such as when people think about a socially close other) can increase preference for products accurately reflect a self-view, even when that view is negative.

Trendy or Timeless? The Effect of Need for Uniqueness and Pressure on Choice

Susan Calderon, IE University, Spain

Antonios Stamatogiannakis, IE University, Spain

Dilney Gonçalves, IE University, Spain

EXTENDED ABSTRACT

Consumers seeking uniqueness prefer unique, scarce (Snyder and Fromkin 1980), and innovative products (Lynn and Harris 1997) over common ones. However, these consumers frequently choose between products that provide equal degrees of uniqueness, for either longer (*timeless* products), or shorter (*trendy* products) time. Moreover, unique products (either *timeless* or *trendy*) are often available for limited time or quantity (Cialdini and Garde 1987; Lynn 1991), potentially putting consumers under some pressure when choosing them. *How do need for uniqueness (NFU) and pressure interact to affect the choice between timeless and trendy products?*

With the exception of extreme pressure (Baumeister 1984), *motivated* individuals that decide under high pressure focus more on evaluating its most relevant dimensions (Wright 1974). High-NFU consumers are motivated when choosing unique products (Snyder 1977), and duration of uniqueness is an important dimension in such choices (Tian, Bearden, and Hunter 2001). Thus, when unique product choices only differ in their duration benefits, high-NFU consumers under pressure may focus on the duration of uniqueness, being more likely to choose timeless products, which provide greater duration benefits.

However, when motivated individuals decide under low pressure, they neglect relevant dimensions of decisions (Ben Zur & Breznitz 1981; Latham & Locke 1975). Instead, they might make intuitive inferences (Chaiken 1980; Kahneman & Frederick 2002; Slovic 1996). Trendy products might appear as more unique (Thompson and Haytko 1997; Simmel 1957) than timeless ones. Thus, although trendy products do not necessarily differ in their degree of uniqueness from timeless ones, they may still be perceived as more unique in direct comparisons (Epley and Gilovich 2006). This “trendy is unique” inference, developed when trendy and timeless products are directly compared, might be used by high-NFU consumers under low pressure. Thus, high-NFU consumers under low pressure could be more likely to choose trendy products.

The pilot field-study involved 31 unique products sales professionals, and 56 members of a business school’s luxury-club. Participants predicted the choice of a high-NFU consumer that should decide “immediately” (high pressure) or “now or later” (low pressure), between a timeless and a trendy product. Neither professionals, nor luxury-club members predicted different choice shares between the high and low pressure conditions, showing that our results are novel to unique product professionals and consumers

In Study 1, participants had to choose between two pre-tested dress-shirts. The timeless shirt was intentionally superior in several dimensions, including uniqueness duration. Two hundred eighteen participants were assigned to either the high (vs. low) pressure condition, had 40 (vs. 60) seconds to choose, and were told that this time was “just enough” (vs. “enough”). In reality, both times were enough, based on the pre-test. Participants completed the NFU scale (Snyder 1977).

Results revealed significant effects of NFU, pressure, and their interaction on choice. Specifically, high-NFU (but not low-NFU) participants tended to choose the timeless (vs. trendy) product under high (vs. low) pressure. These results suggest that high-NFU participants under low pressure might be guided by inferences made when comparing both products, neglecting the duration benefits of time-

less products. Choices of low-NFU participants were not affected by pressure. This study suggests that even with a superior timeless product, high-NFU consumers might rely on “trendy is unique” inferences under low pressure, and choose the trendy product.

Study 2 confirmed our predictions in a consequential choice, using a different product category, and operationalizations of NFU and pressure. We pre-tested two bags in individual and comparative evaluation settings. When evaluated individually, the only difference was that the timeless bag had higher perceived duration of uniqueness. When evaluated comparatively, this advantage persisted, but the trendy bag was perceived as more unique.

One hundred sixty-seven female participants were assigned to either the low or high pressure condition. Everyone had 80 seconds to choose. However, participants in the high (vs. low) time pressure condition were told that “most people take about 120 (vs. 80) seconds” to decide (Briley and Aaker 2006). Participants completed the Consumer’s NFU scale (CNFU; Tian et al. 2001).

Results showed significant effects of CNFU, and of the interaction between CNFU and pressure on choice. High-CNFU participants were more likely to choose the timeless (vs. trendy) product under high (vs. low) pressure. Low-CNFU participants’ choice was unaffected by pressure. Thus, choices of high-CNFU individuals under high pressure comply with the uniqueness duration advantage of timeless products, but under low pressure choices seem to be influenced by “trendy is unique” inferences.

Study 3 supports our theoretical mechanism using different operationalizations of NFU and pressure, and directly measuring participants’ evaluation thoughts. 312 female participants were assigned to a 2 (uniqueness vs. homogeneity prime; Maimaran and Wheeler 2008) x 2 pressure (high vs. low product availability) between-participants design. Participants made the same choice as in study 2, being primed with uniqueness or homogeneity, and considering *both* products under high or low availability. Then, they wrote the thoughts they had while choosing. Two independent coders coded the first two thoughts of each participant (Higgins 1996; Petty and Cacioppo 1981) as duration vs. non-duration related. As predicted, mediation analyses showed a significant interaction of pressure and uniqueness on the number of duration-related thoughts, and a significant effect of the number of duration-related thoughts on choice. Conditional indirect effects for the uniqueness priming (but not for homogeneity priming) was significant. Participants primed with uniqueness listed more duration-related thoughts under high (vs. low) pressure. Subsequently, these thoughts made more likely the choice of timeless products.

We demonstrated that NFU and pressure jointly affect the choice of timeless versus trendy products, through reliance on different information. Theoretically, we establish uniqueness as a multidimensional construct, with its duration as one important dimension. We also find that pressure during choices may lead to beneficial effects, depending on its degree and on individuals’ motivations. Managerially, companies should carefully use pressure depending on whether they want to promote timeless or trendy products. Finally, timeless products satisfy consumers’ uniqueness needs for longer, and thus save resources. Therefore, shoppers seeking uniqueness may want to shop under pressure (e.g., right before shops close) to gear choices towards timeless products.

The Mortgage Illusion

Nelson Camanho, Católica-Lisbon School of Business and Economics, Portugal

Daniel Fernandes, Católica-Lisbon School of Business and Economics, Portugal

EXTENDED ABSTRACT

Buying a house is perhaps the most important financial decision that households face. For most American homeowners, housing is the most valuable asset in their balance sheet. Many factors influence the housing decision, making it a complex and difficult task to many potential homebuyers. In addition, there are limited opportunities to learn from taking a mortgage. As a result, households are often uncertain about their housing decisions. When people are uncertain about a choice, they draw upon cues to help them arrive at a decision (Slovic 1995; Payne et al. 1999). These cues that people use are sometimes difficult to justify normatively. Previous research has shown that indeed housing decisions might be based in market inefficiencies (Brunnermeier and Julliard 2008; Case and Shiller 1988; Genesove and Mayer 2001; Simonsohn and Loewenstein 2006).

In this paper, we show that potential homebuyers compare the monthly rental payment (R) and the monthly installment of a mortgage at a fixed rate (M) on two equivalent houses when deciding to buy a house. Consumers are more likely to buy a house if the mortgage monthly installment is lower than the monthly rental payment.

In the first study, we manipulate the size of the difference between the monthly installment and the monthly rental payment by changing the maturity of the mortgage. We observe that people are more likely to buy the house in the longer maturity condition such that the monthly installment is lower than the monthly rental payment.

In the second study, participants answer eight scenarios, four in which the monthly mortgage installment is lower than the monthly rental payment and another four in which the opposite holds. The order of the questions is randomly assigned. Results are consistent with the mortgage illusion effect and they cannot be explained by monthly budget constraints. Participants become more likely to buy only when the mortgage installment becomes lower than the rental payment and not in the other conditions. This indicates that the effect is not caused by a desire to pay less but by a desire to pay less than rent.

We run another four experiments that aim to check the robustness of our results. In experiment 3, we narrow the gap between the monthly rental payment and the monthly mortgage installment to 5 dollars and yet find that people are more likely to buy when the monthly mortgage installment is lower than the monthly rental payment. Experiment 4 adds a condition in which the monthly rental payment is the same as the monthly mortgage installment in order to elicit the baseline preference of participants. We observe that people are indeed more likely to switch from buying to renting around the threshold, when the monthly mortgage installment M is equal to the monthly rental payment R. Experiment 5 measures several potential individual biases that could be related to the mortgage illusion. Only the immediacy bias and the long-term discount factor significantly correlate with the mortgage illusion, i.e., more impatient individuals are more likely to incur the mortgage illusion. We also observe that the mortgage illusion is lower among stock investors, full-time students, and married individuals. Experiment 6 shows that a financial education intervention is not effective at reducing the mortgage illusion effect.

We also observe the mortgage illusion in the field using the data from the Panel Study of Income Dynamics (PSID). The PSID provides on the dollar amount panelists pay monthly for rent or for

their mortgage between 1993 and 2013. We identified 2,943 panelists that bought a house in the period of the panel (i.e., between 1993 and 2013) and used to rent before the house purchase. M-R, the difference between the first monthly mortgage installment and the last monthly rental payment. Panelists' M-R concentrates around zero, which is consistent with the mortgage illusion effect. These results suggest that panelists seem to use a threshold for the monthly mortgage installment that is around the monthly rental payment they used to pay. Of course, there are many confounding factors in the PSID analysis, which preclude us to identify the mortgage illusion effect. One of the contributions of our paper is to identify it by running experiments in a controlled environment.

Decisions depend on a comparison of potential outcomes with a reference point, which are constructed narrowly (Kahneman and Tversky 1979). Reference points can be based on past outcomes or some aspiration level. For instance, people betting on horses would really like to break even for a given day and end up making longer shots at the end of the day (McGlothlin 1956). Similarly, cab drivers are highly motivated to achieve a targeted daily income and end up going home too early in a particularly profitable day (Camerer, Babcock, Loewenstein, and Thaler 1997). Along the same vein, home buyers use the monthly rental payment as a reference point to decide whether to buy a house – and fail to consider that these expenses are part of a longer stream of payments.

The mortgage illusion is also consistent with anchoring, i.e., the fact that people's estimates can be affected by a highly accessible number. For instance, when uncertain about the price of a product, people anchor to a certain reference number and adjust very little from that initial number. The adjustment is often insufficient because people stop when they are no longer certain that they should adjust further. Movers arriving from a more expensive city end up renting pricier apartments than those arriving from cheaper cities (Simonsohn and Loewenstein 2006), which is consistent with anchoring to their original city's house prices.

These biases arise because of cognitive limitations. When individuals struggle to find an answer to a decision problem and substitute the solution to a related simple problem (Kahneman and Frederick 2002). Rather than employing a discounted cash flow analysis, homebuyers resort to the simpler mortgage illusion when deciding whether to buy a house. Households who follow the mortgage illusion might end up defaulting on mortgages, worsening their balance sheets and their employment prospects.

Rightist Resistance To The Market

Marine Cambefort, Université de Strasbourg, France

Fabien Pecot, University of York, UK

EXTENDED ABSTRACT

In comparison with most social sciences (Blee and Creasap 2010; Diamond 1995; Lo 1982; Warnick 1982), there is little to no marketing scholarship about rightist resistance (Izberk-Bilgin 2010; Peñaloza and Price 1993; Roux 2007). This paper presents three potential conflicts between rightist ideologies and the market. It then discusses four avenues for future research.

The consumer research on resistance articulates two main paradigms (Izberk-Bilgin 2010). The Critical Theory based on the critique of social structures founded on capitalist ideology (Hetric and Lozada 1994; Murray and Ozanne 1991). Building on Marxism, it understands resistance to the market within a general framework of mass revolution aiming to the destruction of capitalism and its substitution by socialism. The postmodernist perspective considers that it is not possible to escape from the market (Kozinets 2002). It understands resistance at an individual level, using the codes of the market and re-interprets its symbols (De Certau 1990; Holt 2002; Roux 2007). While they differ in their theoretical and political approach, both share the same emancipatory perspective and overlooks those behaviors resisting the market in order to exclude, perpetuate or increase inequalities (Lo, 1982). A body of research looks at nationalism and religiosity (Izberk-Bilgin 2008; Russel, Russel, and Neijens 2011; Sandıkçı and Ekici 2009; Varman and Belk 2009) but it does not question the resistance to the market as a liberal institution, and overlooks Western countries. The tacit assumption that consumers sharing rightist values are unlikely to engage in resistance against the market overlooks the diversity of rightist thoughts, and the current right-wing criticism of mainstream conservative parties in Europe and in the United States (Hawley 2016).

While one branch of conservatism accepts liberal economic doctrine against socialism, another remains opposed to both social and economic liberalism (Meyer 1964). The former are also labelled conservative and the latter right-wing (Blee and Creasap 2010). Three common characteristics oppose the market and the consumer culture. First, rightist individuals tend to be patriotic and nationalistic (Femia 2012; Huntington 1957) while the market is global (Levitt 1983) and consumer culture promotes a global consumption ethos (Ger and Belk 1996). Second, conservative favor traditions and are skeptical towards modernity and progress (Femia 2012) while the market builds on novelty (Fiske 1989; Twitchell 2000). Finally, rightists tend to put the social order before the individual rights (Scruton, 1980) while the market and the consumer culture emphasize individualism (Behr 2010). In short, there are potential conflicts between rightist beliefs in the national ethos, traditions and limited individual freedom; and the market's institutions of a global consumer, search for continuous novelty, and promotion of individualism.

In order to facilitate further research on rightist resistance to the market, we integrate conservative and right-wing values with the existing paradigms. We distinguish four approaches varying in term of intensity (radical or moderate) and ideological orientation (restoration or emancipation). The critical and postmodernist approaches detailed above share an emancipatory orientation, whereas the new approaches are based on restoration of tradition. The right-wing approach is the radical form of conservative consumer resistance to the market aiming to replace capitalism by a traditional economic system. They conceive market resistance as a part of a wider political project aiming at changing society. The conservative approach is a

moderated rightist resistance to the market. Through their consumption choices, consumers express their conservative values: resistance to innovations, alien or immoral brands characterizes their consumption.

We identify four main avenues for future research. The first direction relates to the rightist groups and their targets. Social scientists point to several existing rightist movements, some of them inviting to boycott companies (eg. The Tea Party, the Alt-right...). Sociologists mention but overlook their opposition and mobilizations against alcohol, pornography, gambling, condoms and other birth control (Blee and Creasap 2010; Lo 1982). Consumer researchers could contribute to these efforts by focusing on their discourses and actions towards consumption practices and their influence on other consumers. The second direction relates to the individuals, either members of rightist groups, or performing individual conservative resistance. A first line of inquiry could look at the negotiation between their beliefs and interests. It would be interesting to investigate which particular brands or products they oppose and focus on the motivations (religious, xenophobic...). As more extreme right-wing wish to replace the liberal capitalist society by another system (Hawley, 2016), how would be the market in their ideal alternative social structure in comparison from Murray and Ozanne's (1991)? A third direction is methodological. Rightist movements are usually less visible because they directly target decision makers (Diamond 1995; Lo 1982). They are sometimes skeptical about academics' intentions (Blee and Creasap 2010). Sociologists suggest using secondary sources and discuss the possibility of covert research (Blee and Creasap 2010). Are consumer research's methods compatible with such constraints? A fourth and last direction is theoretical. Rightist movements are usually considered countermovement as they define themselves in opposition with another movement (Gross, Medvetz, and Russel 2011; Warnick 1982). The theoretical framework of movement-countermovement interactions (C-MC, Meyer and Staggenborg 1996) offers promising research perspective in resistance to the market. While much existing research focuses on the actions of the resistant movement against the market as an institution, this framework looks at the interactions between: a resistant movement, a countermovement, a regulator, and market actors.

In sum, this article contributes to social sciences' research on the influence of the new right in Western societies. It also invites reconsidering the emancipatory potential of the market. Existing research widely discusses the alienating power of the capitalist market, in line with the ideological panorama of the late 1980s and 1990s. However, in comparison with recent right-wing cultural and electoral offensives, the market appears as an institution promoting openness, progress, and individual freedom.

Non-Participants and Brands' Communication of Co-Creational Efforts: A Matter of Trust

Fanny Cambier, Université catholique de Louvain (UCL), Belgium
Ingrid Poncin, Université catholique de Louvain (UCL), Belgium

EXTENDED ABSTRACT

Today, more and more firms develop customer empowerment strategies (CES) to empower their customers in ideation or selection of new product developments (Fuchs and Schreier 2011). Research in that field has mostly focused so far on customers actively participating to CES. Another influential and bigger group might be studied: the brand audience as a whole, not participating to the initiatives. Labelling innovation as being designed/selected by consumers may have a positive impact on brand evaluations (Fuchs and Schreier 2011). Yet, marketers must know that communicating their co-creational efforts is not always positive. There might be only one step for the audience to interpret the message as another brand marketing means aiming at improving, overly and unduly, perceived customer orientation.

With this research, we examine effectiveness conditions of CES-communication to the non-participants. More specifically, we highlight reasons for non-participants to be sceptical. We here suggest that brand trust is a central concept after exposure to CES-communication, especially in the current context of greater suspicion toward brands. If the ultimate objective of marketing is to create and nurture a long-term relationship between consumers and companies, trust constitutes the main ingredient of this relationship (Morgan and Hunt 1994).

First, we empirically show the importance for non-participants to publicly see the brand feedback on participant' submitted ideas and to be transparent in the process, which is counterintuitive. Second, our study enhances understanding of how trust influences non-participants' brand relationship. We examine that influence on both fictive and well-known brands.

Our first hypothesis postulates that a message highlighting that a brand gave feedback and was transparent all along the process will improve non-participants' perceived empowerment (H1). We first draw on the vicarious empowerment non-participants can feel when they see other customers participating in innovation challenges, even if they did not participate themselves (Dahl, Fuchs, and Schreier 2014). Then, the co-creation literature reports participants' need to feel that the brand listens to their ideas; transparency and feedback are the key elements they request. If the organization fails to be transparent about the rules, to listen and to give feedback, participants quickly become irritated (Ind, Iglesias, and Schultz 2013).

Perceived empowerment helps foster brand trust (Füller et al. 2009), if participants are simultaneously provided with the needed resources (Tzafrir, Baruch, and Dolan 2004). Fostering trust may be hard in case of information asymmetry. Decreasing information asymmetry may result in increased trust. Thus, one way brands can make their customers trust them is to give them the necessary information (Gefen, Karahanna, and Straub 2003), namely here feedback and transparency. If non-participants may vicariously feel empowerment (Dahl et al. 2014), we hypothesize (H2) that feedback and transparency in CES-communication will foster non-participants' trust in the empowering brand through the indirect and positive influence of perceived empowerment.

Trust is reassessed over time, through assessment of previous encounters (Mayer and Davis 1999). Therefore, in case of low initial brand trust, non-participants might also perceive lower empowerment from the brand (H3).

We find support for our hypotheses H1 and H2 in Study 1. Participants (n=213) were randomly shown three new product development scenarios for a fictive brand: empowerment with feedback/transparency, empowerment without feedback/transparency, no empowerment. Perceived empowerment ($\alpha=0.941$) and brand trust ($\alpha=0.910$) were measured on seven-item existing scales. Results support H1: non-participants significantly perceive higher empowerment in the condition with empowerment and feedback/transparency ($M_{\text{feedback}}=4.99$) than in both other conditions ($M_{\text{no_feedback}}=3.96$, $p_{\text{feedback}}<0.001$ and $M_{\text{CONTROL}}=3.68$, $p_{\text{feedback}}<0.001$). Yet, there is no difference in perceived empowerment between the control condition and the empowerment condition with no feedback/transparency ($p=0.52$). Regarding H2 and using Hayes macro (2013, PROCESS Model 4), with 5000 bootstrap and percentile confidence interval estimates, we confirm the mediating role of perceived empowerment in the relation between CES and brand trust. Yet, only when comparing the empowerment with feedback/transparency condition to control condition. Non-participants start developing brand trust via the stronger empowerment perceived only when a brand publicly gives feedback and cues transparency.

In a second study, we manipulate brand perceived reliability, using well-known high-rotation food brands: famous with low reliability expected (BLoR), famous with higher reliability intended (BHiR) and existing but unknown brand, with neutral perceived reliability intended (BNeR). First, each randomly allocated respondent saw one of the three brand logos. After a few questions about it, he/she receives the treatment. We used identical online press lay-outs for all groups, with brand name and brand picture as sole differences. Content informed about a brand's customer empowerment strategy and included feedback and transparency cues. Initial brand trust ($\alpha=0.883$) and perceived empowerment ($\alpha=0.915$) and were again measured on 7-item existing scales.

Main effects on perceived empowerment are significant: $F(2,2374)=17.87$ ($p<0.001$). BLoR mean is significantly lower than each other two means ($p<0.001$); there is no significant differences between BHiR and BNeR ($p=1.00$). After finding a significant interaction between brand and initial trust on perceived empowerment, we run a floodlight analysis using Johnson-Neyman technique. For individuals with initial brand trust inferior to 4.03 ($\beta=-0.11$; $s.e.=0.06$; $p=0.05$), the effect of the brand on perceived empowerment is significant and negative: individuals perceive lower empowerment from the famous food brand with low reliability than for the famous brand with higher reliability. This effect is not significant for individuals with a brand trust greater than 4.03. 70.8% of the respondents have moderator value below that significance threshold and 29.2% of respondents above. These results support H3.

This research offers noteworthy theoretical insights and practical implications. First, we contribute to a still scarce literature and show the importance of non-participants' trust toward the empowering brands. We imply that initiating and communicating customer empowerment may help foster brand trust, if the brand publicly shows they gave feedback and observed transparency all along the process. Our last result, suggesting that initial brand trust modulates empowerment, allow us alert managers that communicating CES to non-participants may not be a good strategy if they suspect issues with their brand audience's trust in their integrity. These empirical

findings are limited in several ways though that delineate promising areas for future research though.

Consumer Underestimation of Energy Use and Greenhouse Gas Emissions Associated with Food

Adrian R. Camilleri, RMIT University, Australia

Richard P. Larrick, Duke University, USA

Shajuti Hossain, Duke University, USA

Dalia Patino-Echeverri, Duke University, USA

EXTENDED ABSTRACT

There is widespread scientific consensus regarding the need to urgently reduce greenhouse gas (GHG) emissions (Cook et al. 2016), and investigate interventions to do so. Attempts to modify behavior typically presume that consumers recognize the connection between their behaviors and the consequences for energy use and GHG emissions. However, there is a growing body of research demonstrating that consumers are often unaware or misinformed (Larrick and Soll 2008). For example, Attari et al. (2010) found that people had a rudimentary understanding of the relative energy use of different appliances and activities. Across four studies, we investigated people's understanding of energy consumption and GHG emissions for another important domain of daily activity: Food. Research suggests that the food system accounts for 19%–29% of global GHG emissions (Vermeulen, Campbell, and Ingram 2012). Therefore, diet change through carbon labels may be an effective strategy to help combat climate change. Encouragingly, research that has looked into carbon labelling of food has shown modest impacts (Vanclay et al. 2011). However, these labels have been criticised as being difficult to quickly interpret (Gadema and Oglethorpe 2011). Therefore, the design of an effective carbon label remains an important public policy goal.

We predicted that consumers are generally unaware of the energy required to produce food, and also the greenhouse emissions produced by food. Urbanites and suburbanites lack direct awareness of all the elements in the modern agricultural system. To the extent that they hold images of the system, the images are likely relatively simple and incomplete. As a result, we expect that many consumers may be unaware of much relevant information; for example, that cattle released methane, a gas that is 28-to-36 times more potent than CO₂.

In Study 1a, 514 participants were sampled to be broadly representative of the US population. Each participant estimated the GHG emissions from producing and transporting a serving of 19 foods and from the one hour use of 18 appliances. In Study 1b, we conducted a similar survey with another 518 participants who estimated energy use for all of the items. In both studies participants were provided with reference information for a 100-W incandescent bulb used for one hour. We found, for both foods and appliances, that estimates increased with actual levels, but remained significantly lower than the true values. Supporting these observations were the results of a number of mixed-effect regression models for foods and appliances in which we regressed logged estimated onto actual values testing for both linear and quadratic relationships. Importantly, the lines of best fit for GHG emissions and energy consumed were shifted downward for foods compared to appliances. In other words, the average estimate was lower – and hence, relatively less accurate – for foods.

In Study 2, we tested the role of knowledge and information processing as an underlying cause for underestimation. In this study, we manipulated the degree to which 606 American participants thought about the food production system before estimating the amount of energy consumed in the production and transport of a serving of different foods. Compared to two control groups (no instructions, or “think carefully”), those who either generated their own intuitive description of the food production process or examined a diagram of

the food production process gave more accurate estimates of energy use. Although all foods were underestimated in all groups, the results suggested that a lack of knowledge and salience of production process at the time of judgment and choice were key contributors to the underestimation effect observed in Study 1.

In Study 3, we designed a carbon label to address the knowledge and salience issues revealed in Study 2, and tested whether it nudged consumers to prefer lower carbon footprint foods. We asked 215 American participants to choose a hypothetical lunch, including one main, two sides, one drink, and two snacks, from a menu. Menu items varied in terms of their carbon footprint. Compared to controls, participants presented with a menu featuring carbon labels chose meals with significantly lower carbon footprints. Environmental attitudes moderated this effect such that when carbon labels were displayed, those with stronger pro-environmental attitudes tended to select meals with lower carbon footprints.

In sum, and consistent with prior research, we found that people tend to underestimate the energy consumed by the use of a range of common appliances (Gadema and Oglethorpe 2011). Similarly, people underestimate the GHG emissions from the use of those common appliances. Our primary contribution is to show that the same is true for food: people tend to underestimate the energy consumed and the GHG emissions associated with the production of a range of foods. Importantly, this ignorance can be reduced using a basic informational intervention.

Importantly, the reduction in average carbon footprint came almost entirely from those who held pro-environmental attitudes. Therefore, it appears that, when making food choices, pro-environmental consumers often fail to take their own values into account, or are unable to do so without additional information. A carbon label may therefore serve as a decision signpost: reminding consumers of their values and then directing them to options most consistent with those values (Ungemach et al. 2017).

The current research has key implications for public policy aimed at nudging people toward more pro-environmental behavior. Some companies have already trialed carbon footprint labels, namely Tesco in the UK. This initial attempt failed – in a large part because customers found the labelling difficult to understand (Lucas and Clark 2012). We suggest that governments should support the development of an optional comparative carbon label for food that translates carbon footprint information into an easy-to-understand unit, such as “light bulb equivalent”. Governments could also devise public education campaigns designed to increase awareness of the most carbon footprint heavy foods, namely beef and lamb.

The Unexpected Consequences of Beautiful Products: Sacredness, Awe and Forgiveness

Ludovica Cesareo, University of Pennsylvania, USA

Patti Williams, University of Pennsylvania, USA

Eugenia Wu, University of Pittsburgh, USA

Keisha Cutright, Duke University, USA

EXTENDED ABSTRACT

We extend the literature on beauty in consumer behavior by examining the degree to which ordinary, but beautiful, products can evoke perceptions of sacredness and feelings of awe relative to functional alternatives. Importantly, we find that such perceptions of sacredness and awe increase consumers' propensity to forgive a company transgression.

Past literature on aesthetically pleasing, beautiful products has demonstrated that they lead to more favorable attitudes, higher purchase intentions and increased willingness to pay (Bloch et al., 2003); they can reaffirm a consumer's sense of self, core values and qualities (Townsend and Sood, 2012); and when chosen for their hedonic rather than functional benefits, can lead to downstream emotional responses of either cheerfulness and excitement, or guilt and anxiety (Chitturi et al., 2007). We extend existing research by examining how beautiful products (versus ordinary exemplars of the same product category) evoke perceptions of sacredness and the discrete emotion of awe, while also identifying a novel downstream consequence associated with those feelings, specifically the heightened willingness to forgive a company transgression.

Beautiful products can create appraisals of sacredness, being perceived as inherently non-ordinary, special and unique (Clark, 1986; Mick and Demoss, 1990; Belk et al., 1989), even if they are humble, everyday objects (Morris, 1948). Prior literature has demonstrated that products deemed to be sacred are revered (Eliade, 1959), spark an emotional attachment (Mol, 1976), and are believed to possess infinite or transcendental significance (Tetlock et al, 2000; Samper and Schwartz, 2013). These perceptions of transcendence in turn lead to feelings of awe.

Awe is a positive, self-transcendent emotion associated with feelings of wonder, astonishment and surprise, elicited by experiences such as exceptional beauty and exemplary human actions or abilities (Haidt, 2003; Shiota et al. 2007). Feelings of awe produce a sense of a "diminished self," wherein one perceives the world as vaster than oneself and one's usual frame of reference, and facilitate religiosity and a propensity for spiritual behaviors (Keltner and Haidt, 2003; Schneider, 2009; Van Cappellen and Saroglu, 2012). Awe seems to evoke one's best self, with individuals who feel awe being more likely to donate time (Rudd et al, 2012), engage in ethical decision making and act according to prosocial values (Piff et al., 2015). Consistent with this diminishment of the self and this orientation toward generosity, we expect that when consumers feel awe in response to beautiful products, they will be more likely to forgive any transgressions or flaws associated with the products.

Past literature on brand transgressions has examined factors that influence a consumer's willingness to forgive a company following a transgression. These include consumer-brand relationships in terms of attachment (Fedorikhin et al., 2008), commitment (Ahluwalia et al., 2000), self-relevance (Johnson et al., 2011) and the strength of the relationship (Aaker et al., 2004), such that the more attached, self-relevant and strong the consumer-brand relationship, the less likely are consumers to forgive a company transgression; trust in the company (Chung and Beverland, 2006; Xie and Peng, 2009); customer expectations about the firm's capability to manage the transgression (Dawar and Pillutla, 2000; Chandrashekar et al., 2007);

individual's self-construal (Sinha and Lu, 2016) and transgression type (higher forgiveness for product, but not ethical, transgressions; Trump, 2014).

In four studies, we find that beautiful products are perceived as sacred, unique, special and divinely influenced, and that these perceptions evoke feelings of awe. Importantly, we find that these perceptions of sacredness and feelings of awe lead consumers to be more forgiving of transgressions associated with beautiful products.

Study 1: Beautiful Products lead to Perceptions of Sacredness and Feelings of Awe

In study 1, lab participants (N=192) were randomly assigned to describe a recent experience with a product that was extraordinarily beautiful or functional. Then, participants reported which emotions (e.g., awe, amazement, astonishment, love, excitement) described how they felt about the product. To ensure that awe was the central emotion evoked by the beautiful product, we had participants complete the Perceptions of Vastness scale (Shiota et al., 2007) (e.g., "I felt in the presence of something greater than myself", $\alpha=.75$). Finally, participants evaluated the extent to which they perceived the product as being sacred, special, unique, and divinely influenced (which we collapsed into a Sacredness index, $\alpha=.71$). Results show that participants in the "beautiful" condition felt more awe ($M_B = 4.72$; $M_F = 3.85$; $F(1, 290) = 11.53$, $p = .001$) and perceived more vastness ($M_B = 2.77$; $M_F = 2.27$; $F(1, 190) = 8.34$, $p = .004$) than participants in the functional condition. In addition, participants who described a "beautiful" product saw it as more Sacred ($M_B = 3.41$; $M_F = 2.78$; $F(1, 190) = 11.427$, $p = .001$). A mediation analysis (Preacher and Hayes, 2004, 2008; Process Model 4, 10,000 bootstrap samples) found that beautiful products increased perceptions of awe via sacredness (95% bias-corrected confidence interval did not include zero; .157- .689).

Study 2: Ruling Out the Effect of Other Positive Experiences on Sacredness and Awe

In study 2, we sought to replicate the findings from Study 1 with a more controlled stimulus, while also ruling out the possibility that any positive experience related to the product (such as receiving a surprise coupon) could be responsible for evoking feelings of sacredness and awe. Given that participants in Study 1 mostly recalled beautiful food and beverage products (cappuccinos, cakes, cupcakes and chocolates), in Study 2, we chose cappuccinos as the stimuli. Participants (N=202) from Amazon's Mechanical Turk were randomly assigned to one of three conditions (beautiful, regular and surprise) where they were shown photos and asked to imagine consuming either a beautiful or ordinary cappuccino; participants in the surprise condition saw the same ordinary cappuccino but were told they received a surprise \$1 coupon for their next visit. Participants then reported which emotions they felt when they received the cappuccino (e.g., awe), how sacred they believed it to be (four-item index) and how much they were willing to pay for it. Results show that participants in the beautiful cappuccino condition felt more awe ($M_B = 4.52$; $M_R = 2.50$, $M_S = 3.23$, $F(2, 199) = 20.460$, $p < .001$) than consumers receiving either a regular or surprise-coupon cappuccino, and that they perceived it as more sacred ($M_B = 2.74$; $M_R = 1.83$, M_S

= 2.19, $F(2, 199) = 10.753, p < .001$). Furthermore, participants were more willing to pay for the beautiful cappuccino relative to both regular and surprise-coupon cappuccinos ($M_B = \$4.54; M_R = \$3.52; M_S = \$3.08; F(2, 199) = 12.621, p < .001$). This second study not only confirms our prediction of the effects of beauty on sacredness and awe, but also offers support that it is indeed the beauty of the product, and not any positive experience related with a product, driving these effects.

Study 3: Beautiful Products lead to a Higher Willingness to Forgive

Study 3 examines how perceptions of awe and sacredness affect consumers' propensity to forgive beautiful products following a transgression. Participants from Amazon's Mechanical Turk ($N=182$) viewed either the beautiful or regular cappuccino scenario from Study 2. They then responded to the same DVs before learning their cappuccino contained a flaw: it was either a decaf (when they asked for a regular), or it contained whole milk (when skim milk was requested). Participants again evaluated the cappuccino and indicated their willingness to forgive the company, operationalized as (consistent with previous failure recovery research: Grewal et al., 2008) their likelihood to repurchase from the café and recommend it to others. Results show that participants in the beautiful cappuccino condition felt more awe ($M_B = 5.16; M_R = 2.84, F(1, 180) = 87.250, p < .001$) than consumers receiving the regular cappuccino, and they perceived it to be more sacred ($M_B = 3.77; M_R = 2.29, F(1, 180) = 52.642, p < .001$). In addition, participants in the beautiful condition were more likely to forgive the café (repurchase and recommend) after the flaw occurred, compared to participants in the regular condition ($M_B = 5.53; M_R = 4.67; F(1, 180) = 16.245, p < .001$). A serial mediation analysis (Preacher and Hayes, 2004, 2008) tested whether the beautiful products increased consumers' intention to forgive the café via sacredness and awe. Results (Process Model 6, 10,000 bootstrap samples) demonstrate this was the case, as the 95% bias-corrected confidence interval did not include zero [.187; .612]. These findings provide initial evidence for our proposed conceptual model, demonstrating that beautiful products evoke a sense of sacredness and feelings of awe, which lead to greater likelihood to forgive.

Study 4: Ruling Out Effort as a Potential Alternative Explanation

In Study 4, we sought to replicate this finding on forgiveness while ruling out effort as a potential alternative explanation to our effects. Effort is often linked to reduced culpability and rewarded with higher forgiveness following a transgression, and thus we wanted to make sure that it was the beauty, and not the perceived effort in creating the product, that was driving our effects (Morales, 2005). Participants ($N=205$) from Amazon's Mechanical Turk were randomly assigned to one of three conditions: beautiful high effort, beautiful low effort or regular high effort. They were shown photos and asked to imagine consuming either a beautiful or ordinary cupcake. They also received a card that described the process necessary to craft their cupcake as either effortful (the pastry chef took 4 hours to prepare it) or effortless (the pastry chef only took 45 minutes). They then responded to the same DVs (emotions, sacredness and willingness to pay) before discovering that their cupcake had a flaw: it had mistakenly been baked with salt instead of sugar. They then indicated how likely they were to forgive the company. To rule out the possibility that beauty simply causes a flaw to be perceived as less consequential, they also indicated how severe they thought the mistake was and how much they cared about the mistake. Results show that participants who received the beautiful high effort cupcake felt more awe

than participants who received the regular high effort cupcake ($M_{BHE} = 5.24; M_{BLE} = 4.63; M_{RHE} = 4.08; F(2, 202) = 7.590, p < .001$). They also believed the beautiful cupcake, both high and low effort, to be more sacred than the regular high effort cupcake ($M_{BHE} = 3.40; M_{BLE} = 3.56; M_{RHE} = 2.31; F(2, 202) = 12.927, p < .001$), and they were willing to pay more for it ($M_{BHE} = \$4.21; M_{BLE} = \$3.83; M_{RHE} = \$2.25; F(2, 202) = 13.920; p < .001$). In terms of forgiveness, participants who received the beautiful cupcake, both high and low effort, were more willing to forgive the transgression relative to participants who received the regular high effort cupcake ($M_{BHE} = 4.01; M_{BLE} = 4.13; M_{RHE} = 3.35; F(2, 202) = 3.344, p = .034$). These findings help rule out effort as a potential alternative explanation of the effect, while reinforcing the effect of beauty on forgiveness. There were no differences across conditions in how 'severe' participants thought the mistake was ($M_{BHE} = 4.27; M_{BLE} = 4.51; M_{RHE} = 4.41; F(2, 202) = .304, p = .738$), nor in how much they cared about the mistake ($M_{BHE} = 4.33; M_{BLE} = 4.54; M_{RHE} = 4.73; F(2, 202) = .885, p = .414$), suggesting that beauty enhances the likelihood of forgiveness after a flaw, but does not change the perceived severity of the flaw. Finally, we performed a mediation analysis to test whether the beautiful cupcake, both high and low effort, relative to the regular cupcake, increased consumers' willingness to forgive via sacredness and awe. Results (Process Model 6, 10,000 bootstrap samples) demonstrated that indeed it is the beauty that leads to a higher willingness to forgive via perceptions of sacredness and feelings of awe, as the 95% bias-corrected confidence intervals for both high and low effort beautiful cupcakes relative to the high effort regular cupcake did not include zero (BHE vs RHE: [.004; .119]; BLE vs RHE: [.052; .402]).

Discussion

Previous literature has identified perceptions of sacredness and feelings of awe as responses to exceptional beauty. Sacredness and awe, in turn, engender prosocial behavior and a willingness to forgive. Across four studies, we extend this literature, demonstrating that mundane, everyday products can be beautiful, and that such beauty leads consumers to judge those goods as sacred and to feel a sense of awe in response to them. These perceptions of sacredness and feelings of awe lead consumers to be more forgiving of flaws and errors associated with the products. Future research should expand the effect of beauty on sacredness, awe and forgiveness by: testing it across different, non-food product categories (watches, fitness trackers, vases, etc.), and perhaps by testing whether where the flaw occurs matters. Perhaps consumers are differentially forgiving of flaws that occur in the aesthetics or beauty of the products versus in their functionality. Finally, future research will examine real consumer behavior in a field study.

Together, this work contributes to the literature on beauty, linking perceptions of product beauty to a unique emotional response that is associated with specific positive downstream behavioral consequences. We also contribute to the literature on transgressions and forgiveness, identifying a new factor and process, whereby beautiful products evoke sacredness and feelings of awe, which enhance the likelihood that consumers forgive a product transgression. In addition, we contribute to the literature on emotions in consumer behavior. Awe is a relatively under-researched emotion in consumer behavior. Here we find that consumers feel awe in response to beautiful products, even when those products are in mundane categories such as cupcakes and cappuccinos, and show that these evoked feelings of awe have important downstream consequences for consumer-firm relationships.

I Am a Fashionista and I (think) I Know It: The Role of Fashion Knowledge in Preferences for Counterfeits

Ludovica Cesareo, University of Pennsylvania, USA

Silvia Bellezza, Columbia University, USA

EXTENDED ABSTRACT

Is counterfeiting good or bad for the imitated brand? Luxury counterfeiting is overwhelmingly believed to have a negative effect on the original brand, decreasing its perceived prestige and exclusivity (e.g., Commuri, 2009; Dubois and Paternault, 1995). Yet, potential positive effects of counterfeiting have also emerged, demonstrating that the status of the original brand may actually be enhanced by the availability of luxury counterfeits (Nia and Zaickowsky, 2000; Romani, Gistri and Pace, 2012). In a pilot study we conducted at the lab ($N = 58$) we asked participants if they had ever seen a product they owned in a counterfeit version and, if yes, how that made them feel. Interestingly, the sample was pretty split – while negative emotions were still predominant (65.5%, describing feelings like anger, frustration, annoyance and being upset), 35.5% of participants actually felt positively about it, with predominant feelings being flattery, excitement, interest and humor. In this article, we contribute to this debate by looking at consumers' level of fashion knowledge, both objective and subjective, as a factor influencing reactions to counterfeiting in a systematic way. In addition, we also demonstrate the mediating role of flattery and the moderating role of ownership of the real brand.

The impact of prior knowledge on consumers' information processing and product evaluations has been widely established in the literature. Whether referred to as knowledge, familiarity, expertise, or experience (Alba and Hutchinson, 1987), prior knowledge has been defined as what an individual knows and remembers about a product. Prior knowledge influences consumers' perceptions of product quality (Rao and Monroe, 1988) and price (Monroe, 1973); brand extension evaluations (Keller and Aaker, 1992); it differentiates responses to hedonic vs. functional products (Park and Moon, 2003); and, it interacts with advertising effectiveness (Chandy et al., 2001).

In this research, we specifically look at the influence of consumer's fashion knowledge, both subjective and objective, on preference for counterfeits. The former, which we refer to as *Stated Fashion Knowledge* (SFK), is a subjective level of knowledge expressing consumers' self-perceptions as savvy in fashion and luxury goods; the latter, which we refer to as *Revealed Fashion Knowledge* (RFK), is an objective level of knowledge expressing how much a consumer actually knows about fashion and luxury goods. Moving forward, we will refer to fashion knowledge as being either stated or revealed.

Across four studies, we demonstrate how consumers' knowledge of fashion and luxury goods, whether stated or revealed, is predictive of different reactions to counterfeit goods. Specifically, we find that when consumers have low fashion-knowledge, they will be the most favorable towards product counterfeiting. In addition, and in line with prior research highlighting the role of mimicry and pride in consumption (White and Argo, 2011; Bellezza and Keinan, 2014), we demonstrate that the positive reactions to counterfeiting by low fashion-knowledge consumers are mediated by feelings of flattery for being imitated. Interestingly, the effect of knowledge on favorable predispositions towards counterfeits is moderated by ownership, such that owners of the real product whose fashion knowledge is low are the most favorable towards counterfeits. Presumably, owners who do not know much about fashion feel flattered by others wanting to imitate them. This finding is consistent with prior research on the

upsides of mimicry and non-core users seen as brand tourists (White and Argo, 2011; Bellezza and Keinan, 2014).

In the studies that follow, we either measured consumers' stated fashion knowledge, that is self-perceptions as savvy in fashion and luxury goods ("How knowledgeable do you feel about fashion and high end luxury goods?"), or we measured consumers' revealed fashion knowledge. To develop a reliable measure for this second construct, we followed prior knowledge measure developments and manipulations from the literature (Wood and Lynch, 2002; Hong and Sternthal, 2010). We used four existing multiple choice questions regarding the luxury and fashion goods industry (Bellezza and Berger, 2017) and created a battery of 12 others ranging from very easy (e.g., Q: "What do the letters CK stand for on a bottle of perfume?" A: Calvin Klein) to very hard (e.g., Q: "Which brand is known for its *intrecciato* technique?" A: Bottega Veneta). Lab participants ($N = 203$) answered all 16 questions in random order. Based on the results, we selected the four hardest questions and used them as a measure of revealed fashion and luxury goods knowledge in the subsequent studies.

In Study 1, we wanted to establish the link between knowledge and differential reactions to counterfeit goods. Participants in the lab ($N = 353$) first completed the 1-item stated fashion knowledge measure. Next, they read a description of either Louis Vuitton (females) or Rolex (males), while looking at a picture of a signature product from the brand (*Speedy* Louis Vuitton handbag or *Oyster Perpetual* Rolex watch) and writing their thoughts as they imagined owning it. All participants then saw an image of a stand with various counterfeit handbags/watches of different brands, among which was their handbag/watch. Finally, we asked their overall reaction (like/dislike) to the counterfeit handbag/watch (Bellezza and Keinan, 2014), and their intention to spread positive word-of-mouth regarding the counterfeit product (Cheema and Kaikati, 2010). Results demonstrated that low fashion-knowledge participants had a more positive reaction to the counterfeit product ($F(1, 351) = 17.10, p < .001$) and were more likely to spread positive word-of-mouth about the counterfeit product ($F(1, 351) = 5.70, p = .017$) relative to participants whose fashion knowledge was high.

In Study 2, we sought to replicate the effects from Study 1 but this time manipulating consumers' stated fashion knowledge while also examining two other dependent variables.

Pretest. We wrote and pretested six articles, two about the fashion industry that would serve as our fashion-knowledge manipulation (history of the Louis Vuitton brand and history of the Rolex brand) and four about other topics, unrelated to fashion, to identify the best controls (history of Eataly, the gourmet Italian food shop; history of Banksy, the British unknown street artist; history of Tesla, the innovative motor company; and, history of Birchbox, the innovative make-up delivery company). Participants from Mechanical Turk ($N = 59$) read a short excerpt from each article and told us how appealing they thought the topic was, how interesting they thought it was alongside their intention to read the article in its entirety. Results confirmed our choice for the fashion manipulations, as Louis Vuitton and Rolex had the highest and most similar appeal (Appealing: $M_{LV} = 4.85$ vs. $M_{Rolex} = 4.79, t(57) = -.16, NS$; Intention to Read Entire Article: $M_{LV} = 5.12$ vs. $M_{Rolex} = 4.73, t(57) = -.90, NS$; Interesting: $M_{LV} = 4.96$ vs. $M_{Rolex} = 4.33, t(57) = -1.53, NS$). In terms of the control

conditions, the Eataly and Banksy articles ranked highest for females and males respectively, and were not significantly different from the Louis Vuitton and Rolex articles, so we chose them for the main study (Appealing: $M_{Eataly} = 4.96$ vs. $M_{Banksy} = 4.45$; Intention to Read Entire Article: $M_{Eataly} = 5.08$ vs. $M_{Banksy} = 4.45$; Interesting: $M_{Eataly} = 5.15$ vs. $M_{Banksy} = 4.48$).

Main Study. Participants in the lab ($N = 160$) were randomly assigned to one of two conditions, fashion-knowledge vs. control. Based on their gender (female/male), respondents read the article either about Louis Vuitton/Rolex (fashion-knowledge condition), or about Eataly/Banksy (control condition). They then completed a manipulation check in which they reported how knowledgeable they felt about the topic covered in the article they had just read and our stated fashion knowledge measure. Afterwards, they saw the same handbag/watch scenario as in Study 1 and the same counterfeit products' stand before reporting their reaction to their brand being counterfeited and assessing the impact of the counterfeit on the reputation of the original brand. As expected, results showed how, across genders and conditions, there were no differences in terms of topic knowledge ($M_{LV/Rolex} = 4.55$ vs. $M_{Eataly/Banksy} = 4.51$, $F(1, 158) = .06$, NS), while participants who read the LV/Rolex articles perceived themselves as more knowledgeable about fashion than participants who read the Eataly/Banksy articles ($M_{LV/Rolex} = 3.14$ vs. $M_{Eataly/Banksy} = 2.31$, $F(1, 158) = 20.18$, $p < .001$). Given that the fashion knowledge manipulation and measure were highly correlated ($r = .337$, $p < .001$), we used the Z-score of the fashion knowledge measure for the subsequent analyses as in Study 1. Replicating the results from Study 1, again we found that participants whose fashion knowledge was low had a more positive reaction to the counterfeit ($F(1, 158) = 8.82$, $p = .003$) and believed the counterfeit will have a more positive impact on the brand reputation ($F(1, 158) = 6.00$, $p = .015$) relative to participants whose fashion knowledge was high.

These first two studies put forth evidence that indeed consumers' stated fashion knowledge, whether self-reported or manipulated, influences how consumers perceive and react to counterfeit goods. In Study 3, we sought to replicate these findings on preference for counterfeits with a measure of revealed fashion knowledge, while also looking at the moderating role of ownership of the original brand. To ensure we would recruit a sufficient number of real owners of luxury goods, we recruited 197 wealthy participants from Qualtrics (80% female; all very high income). First, respondents completed the self-reported fashion knowledge measure. They then responded to the four hard fashion knowledge questions (tallied as a continuous variable 0-4, which we Z-scored) to measure revealed fashion knowledge. Next, participants who were luxury owners were asked to describe an owned luxury product (either a luxury leather good, luxury sunglasses, or a luxury watch) and subsequently read a counterfeiting scenario about the specific product and brand they previously mentioned. Non-owners simply read a general counterfeiting scenario about either counterfeit leather goods, sunglasses, or watches. Finally, we asked participants about their overall reaction (like/dislike) to the counterfeit product, whether their own or a generic. Results again showed how participants whose revealed fashion knowledge was low liked the counterfeit more ($F(1, 195) = 25.53$, $p < .001$) relative to individuals whose revealed fashion knowledge was high. Interestingly, we found a significant interaction between revealed knowledge and ownership on liking/disliking the counterfeit ($F(1, 193) = 4.87$, $p = .028$; Johnson-Neyman point: $-.494$, area of significance is below), such that owners whose revealed fashion knowledge was low liked counterfeit products more relative not only to high knowledge owners, but also relative to low knowledge non-owners.

Finally, in Study 4 we sought to replicate the moderating effect of ownership while also establishing process evidence. Participants from Mechanical Turk ($N = 421$) first completed the four hard fashion knowledge questions (tallied as a continuous variable 0-4, which we Z-scored) to measure revealed fashion knowledge. They then saw the same Louis Vuitton handbag/Rolex watch scenario as in studies 1 and 2, and the same counterfeit products stand before reporting their overall reaction (like/dislike) to the counterfeit product, their reaction to the brand being counterfeited, the impact of the counterfeit on the original brand and their likelihood of spreading positive word-of-mouth regarding the counterfeit. In addition, we also measured their reaction when seeing the counterfeit version of their product by having them complete a battery of emotions (e.g., guilty, proud, ashamed, embarrassed) among which was our target emotion of "flattery" which we measured through five items (flattered, admired, worshipped, glorified, inspired) and collapsed into a Flattery Index ($\alpha = .90$). Through a full factorial model with fashion knowledge and ownership we found the predicted significant interactions between objective knowledge and ownership on liking/disliking the counterfeit ($F(1, 417) = 6.46$, $p = .011$), reaction to the counterfeit ($F(1, 417) = 6.34$, $p = .012$), the impact of the counterfeit on the original brand's reputation ($F(1, 417) = 8.12$, $p = .005$), their likelihood of spreading positive word-of-mouth ($F(1, 417) = 13.65$, $p < .001$), and how flattered they felt by the counterfeit ($F(1, 417) = 4.52$, $p = .034$), such that low knowledge owners always felt more positively about and more flattered by the counterfeit relative to both high knowledge owners and low knowledge non-owners. A moderated mediation analysis (Preacher and Hayes, 2008) tested whether low knowledge individuals liked the counterfeits more via flattery, and whether ownership played a moderating role. Results (Process Model 8, 10,000 bootstrap samples) demonstrated how flattery mediated the effect of revealed fashion knowledge on all the dependent variables. Specifically, low fashion knowledge individuals liked the counterfeits more, but only when they owned the original (on like/dislike -Index of Moderated Mediation: $[-.272; -.014]$; Indirect effect for owners: $[-.979; -.192]$).

Previous literature has identified the negative and sometimes positive effects of counterfeit luxury goods on originals. We extend this work by demonstrating how knowledge of fashion and luxury goods plays a key role in consumers' preference for counterfeits. Specifically, the lower consumers' knowledge, the higher consumers' liking and predispositions towards counterfeits, even more so if they are owners of the original, because they feel flattered. In addition to contributing to the literature on luxury and counterfeit goods, this research also has interesting managerial implications, suggesting how counterfeiting may not be as detrimental as both researchers and practitioners believe. While low fashion-knowledge consumers have a more positive reaction to counterfeits, high fashion-knowledge consumers, who are the primary target for luxury brands, know the value of the original and are overall less prone to counterfeit goods.

The Price is Right: Perceptions of Control Influence How Consumers Use Price In Judging Product Quality

Boyoun (Grace) Chae, Temple University, USA
JoAndrea Hoegg, University of British Columbia, Canada
Keisha Cutright, Duke University, USA

EXTENDED ABSTRACT

In the current research, we investigate whether feelings of control—the sense that one can make positive things happen in one’s life and avoid negative things—influences how much individuals rely on price to judge product quality. More specifically, we reason that price will have a greater impact on quality judgments when individuals’ personal control is threatened. A set of four studies offers convergent evidence for this central thesis. Further, we demonstrate an underlying psychological mechanism of the effect. Specifically, we find that in a state of low control, people become more susceptible to normative social influence. Given that price-quality judgments are often deemed to be normative, people in low control are more likely to increase their reliance on price in judging quality.

As a first step, we argue that when individuals’ feelings of control are low, they become more susceptible to normative social influence. While no existing research offers direct empirical evidence for this claim, related research points to its plausibility. For example, Terror Management Theory (TMT; Greenberg, Pyszczynski, and Solomon 1986) has shown that individuals who were reminded of death—which is perhaps the most fundamental obstacle to one’s ability to control the environment (Becker, 1973)—are more likely to endorse socially approved standards in judgment and decision making (Norenzayan, 2006). Research on social exclusion also provides support for the idea that low control should increase the susceptibility to normative social influence. For instance, Williams, Cheung, and Choi (2000) found that social exclusion in an online ball tossing game leads people to be more likely to follow the majority’s wrong opinion on a simple perception question than those socially included.

We further propose that this elevated susceptibility to normative social influence will result in greater reliance on price when judging product quality. We argue that this happens because people perceive that using price in judging quality is a social norm that is popularly practiced by other people. Consumer researchers have documented that people interpret high price as a cue for high quality (Broniarczyk and Alba 1994; Cronley et al. 2005). People who are susceptible to social influence tend to rely on others’ opinions in judging quality (Martin, Wentzel, and Tomczak 2008). In sum, this research suggests that in the absence of other signals or information, a reliance on price in the judgment of quality is what consumers have learned to be a socially accepted, normative approach to decision-making.

Taken together, we propose that low control heightens susceptibility to normative social influence, which in turn, increases reliance on price when making quality judgments. Four studies support our propositions.

Study 1 investigated the role of feelings of control on price-quality inferences. The study employed a 3 (control: low vs. high vs. neutral) x 2 (price: expensive vs. cheap) between subjects design. Participants in the high (low) control condition were asked to recall something positive that happened (not) because of something they did (Kay et al. 2008). The use of a positive memory enabled us to manipulate control while holding mood constant. Those in the neutral condition wrote about “a movie or television show that you saw and enjoyed in the past few months”. Next, participants judged a burger whose price was presented as either \$18 for the expensive condition or \$5 for the cheap condition. As predicted, the results

showed that lowering control indeed increased the reliance of price in quality judgments (as opposed to high feelings of control dampening reliance on price).

Study 2 supported the proposed process by showing that merely describing the use of price in judging product quality as normative or not moderates the effect. The results revealed that low control enhanced reliance on price when reliance on price was described as popular and socially acceptable. Communicating the non-normative aspect of using price, however, decreased individuals’ reliance on price.

Study 3 examined whether uncertainty, lack of confidence in judgment, or desire for clarity could explain the effect. None of the variables was significant as a mediator.

Lastly, Study 4 documented that control moderates the downstream effect of price on actual quality experience. People in a low state of control rated an indulging food product as better when it was presented as expensive rather than as cheap. Such difference was not found among people in the high control condition.

In demonstrating the basic relationship between control and price reliance, this research makes several theoretical contributions. First, it extends the price literature by identifying a unique motivational driver for consumers’ reliance on price in judging product quality. In addition, this research offers a new perspective on why consumers rely on price. We suggest that the social aspects of price have been understudied and propose that relying on price-quality inferences can feel like the popular, socially accepted course of action.

This research also contributes to the personal control literature. Our research offers new insight into this area by providing the first investigation into how control influences perceptions around pricing. Further, our documentation of the underlying mechanism of susceptibility to normative social influence is novel; no systematic investigation has addressed the impact of personal control on susceptibility to social influence. By providing empirical evidence of the impact of control on the susceptibility to social influence, this research creates an opportunity to explore various implications of control on consumers’ social behaviors.

Can Sexy Images Drag You Down? How Gender and Self-construal Impact Subsequent Indulgent Consumption

Chun-Tuan Chang, National Sun Yat-sen University, Taiwan

Xing-Yu Chu, National Sun Yat-sen University, Taiwan

Shr-Chi Wang, National Sun Yat-sen University, Taiwan

Dickson Tok, National Sun Yat-sen University, Taiwan

EXTENDED ABSTRACT

The cliché “Sex Sells” is apparently held in high esteem by advertisers who rely on the use of the sexy images as a marketing strategy not only in commercial marketing (e.g., Chang and Tseng 2013; Sengupta and Dahl 2008) but also in social marketing (Reichert, Heckler, and Jackson 2001). A majority of research on the use of sexy images has focused on its impacts on advertising persuasion, ignoring the consumers’ subsequent behaviors following exposures to sexy images.

In the current research, we argue that exposure to sexy images is more likely to evoke indulgent consumption/choice in a subsequent context (when compared with exposure to neutral imagery). Furthermore, we are interested in boundary conditions that could amplify or dampen the priming effects of sexy images on subsequent indulgent consumption. One potential moderator is gender differences. Gender is an important sub-cultural influence on sexual norms (Lopez and George 1995). The other proposed moderator is self-construal. Two types of self-construal, independent and interdependent, distinguish how the self is viewed in relation to others (Singelis 1994).

Nevertheless, we propose that interdependent self-construal may enhance indulgent consumption for women (compared with women with independent self-construal). Priming interdependent self-construal may make one to think collectively and place more on subjective norms (Ybarra and Trafimow 1998). Women show equivalent sexual arousal when the gender norms do not condemn erotica enjoyment (Lopez and George 1995). They are also more responsive to sexy images with romantic love. Since interdependent self-construal is consistent with how female self-regulatory goals, such interdependence will allow women to activate pleasure seeking after exposure to sexy images. Therefore, self-construal could play a dual role when gender differences are considered: independent self-construal enhances males’ indulgent consumption while interdependent self-construal increases females’ indulgent consumption after exposures to sexy images.

In Study 1, empirical data of 2016 World Auto Expo was analyzed. As a sex cue, show girls evoke impulsivity and should be appropriate to promote cars for indulgent purpose (e.g., sports car). We expected that companies were more likely to use show girls for indigent-based cars. The show girl data were assessed through enquires for the brand managers. Using show girl(s) or not served as the dependent variable. The main independent variable was car for indulgence based on two judges who were blind to research purposes. Engine displacement, county of origin, and the marque edition were also considered as independent variables. The results based on the binary logistic regression supported a positive relationship between sex cue and indulgence.

In Study 2, both gender and self-construal were considered as moderators. A 2 (sex cue: sex vs. neutral) X 2 (participant gender: men vs. women) X 2 (self-construal: independent vs. interdependent) between-subjects design was employed. Self-construal was first measured by a 24-item self-construal scale of Singelis (1994). Participants were then watched four videos either sexy or neutral (Van den Bergh et al. 2008). Chocolates (separated package with equal weight and size) were provided for them as appreciation and they

could eat as much as the liked. Chocolate consumption served as the dependent variable. The regression using Model 3 in the PROCESS macro (Hayes 2013) showed a three-way interaction. For men with an independent self-construal, those in the sex cue condition ate more chocolates than the counterparts in the neutral condition. No such difference was found for men with an interdependent self-construal. On the other hand, women with interdependent self-construal in the sex cue condition ate more chocolates than the counterparts in the neutral condition. Similar chocolate consumption was found on women with independent self-construal regardless of the sex cue.

In Study 3, two sex cues were classified. A 2 (sex cue: gratuitous sex vs. romantic love) X 2 (participant gender: men vs. women) X 2 (self-construal: independent vs. interdependent) full-factorial design was conducted. Self-construal was manipulated through movie synopsis with a poster (independent self-construal: *Iron Man*; interdependent self-construal: *Avengers*). Participants were then invited evaluate ten perfume ads (with gratuitous sex or romantic love). Gratuitous sex was presented through the image with a sexually charged close up of a partially clothed men and women passionately embracing each other. Romantic love was manipulated through a pair of wedding rings and a slogan to express their commitment. After participants completed the above measures, they chose one of two tickets to the forthcoming auto expo as a thank-you gift. Sports car and hybrid car exhibition represented indulgent and non-indulgent choice, respectively, which served as the dependent measure. We used slopes analyses (Aiken and West 1991) after the three-way interaction was found. The results indicated that men were more likely to choose an indulgent choice when independent-self was primed. Such effects were stronger when the sex cue contained gratuitous sex. In contrast, women with interdependent-self were more likely to choose an indulgent choice when using romantic love in sex cues.

The current research makes several contributions. First, this research contributes to the sex literature by a) demonstrating subsequent indulgent consumption after sexy image exposure, and b) identifying the boundary conditions in which this effect might occur. Second, this investigation also contributes to the reward-processing literature, which has received recent attention, by demonstrating that motivational mindsets such as sex can have unique effects on consumer choice. Third, it shows that different sexy images may have the dual impacts of both decreasing and increasing indulgent consumption, depending on individual differences in gender and self-construal.

This research points to some interesting directions for future studies. First, it is worth to explore how other typology the sexy images (explicit vs. implicit) (Chang and Tseng 2013) and the level of nudity in sexy images may influence subsequent indulgent consumption. Second, since evolution-based theories suggest gender differences on mating motivations (Malamuth 1996; Symons 1979; Saad 2004), future research may manipulate mating motivation through a priming task to replicate the results found in the current study. Third, since exposures to sexy images may produce a generalized motivation to seek rewarding outcomes and immediate gratification, it is then possible that people become more likely to eat unhealthy foods, procrastinate, and engage in aggression.

Does Bigger Equal Better? How Product-Model Size Ratio and Brand's Social Role Impact Ad Effectiveness

Chun-Tuan Chang, National Sun Yat-sen University, Taiwan

Xing-Yu Chu, National Sun Yat-sen University, Taiwan

Hsin-Yi Wang, National Sun Yat-sen University, Taiwan

Dickson Tok, National Sun Yat-sen University, Taiwan

EXTENDED ABSTRACT

This research examines how advertisers can use the size contrast between product and model images (SCPM) to maximize ad effectiveness. Size (big or small) can be an important metaphor and it shapes perceptions of the significance of social stimuli (Landau et al. 2010). Early studies showed that both children (Bruner and Goodman 1947) and adults (Bruner and Postman 1948) perceive socially significant symbols as physically larger than neutral symbols. People commonly talk about an increase in significance of importance as physical largeness or expansion ("This is a *big* problem, and it is only going to *grow*;" Lakoff and Johnson 1999). Despite its prevalence in our daily life, such the metaphor in advertising remains unexplored.

Before this project, we conducted a content analysis with 1325 ads from popular magazines with various product categories. The results indicated a positive correlation between SCPM ratio and product price ($r=.12, p<.01$): advertisers tended to exaggerate their product images (bigger than the model image) among high-priced products. The observations lead us to propose that SCPM may increase perceptions of power and bring about a sense of the product's worth.

Furthermore, we are interested in the boundary conditions of using SCPM. Brand's social role (BSR) is proposed as a moderator. Consumers tend to treat a brand as a human being (Aaker 1997; Aggarwal and McGill 2012), and interact with the brands in ways similar to interpersonal relationship partners (Aggarwal 2004; Fournier 1998; Swaminathan, Page, and Gurhan-Canli 2007). Two BSRs are distinguished based on brand's social role: leader-like vs. friend-like brand. When a brand positions itself as a leader to its customers, consumers consider it superior to other brands in the same product category. Slogans such as "there is no substitute" (Porsche) and "the king of beers" (Budweiser) are two examples. On the other hand, when consumers perceive the brand as a friend, they feel sincere and trustworthy (Aaker, Fournier, and Brasel 2004). Mutually shared concerns exist between the friend-like brand and its customers (Aggarwal 2004). For instance, Coca-Cola's slogan "the best friend thirst ever had" describes the friend-like relationship between the brand and its consumers.

We propose that processing fluency as the underlying mechanism behind the phenomena above. Fluency is defined as the ease with which new information can be processed (Alter and Oppenheimer 2009; Reber, Schwarz, and Winkielman 2004). The right match between SCPM and BSR is expected to improve processing fluency, which enhances ad effectiveness.

In Study 1, we tested the interaction effect between SCPM and BSR. A 2 (SCPM: large vs. small) x 2 (BSR: leader-like vs. friend-like) between-subjects design was conducted. Chocolates were chosen as the test product category. Godiva and Kinder Bueno were chosen to represent for leader- and friend-like brands. Each participant was presented with one ad selected from the pool of four (i.e., two SCPM for each of the two BSRs). The different SCPM were created. In the large (small) SCPM condition, the size of chocolate (model) image is twice bigger than that of the model (chocolate). In the leader-like (friend-like) brand condition, a capital letter G (K) was placed on the chocolate image with the logo of Godiva (Kinder

Bueno) shown in the ad. Each ad was A5 size. After ad viewing, two dependent variables were assessed: attitudes toward the brand and purchase intentions. The results showed that when facing the leader-like brand, participants in the large SCPM condition showed more favorable attitudes toward the brand and stronger purchase intention than the counterparts in the small SCPM condition. Opposite results were found with participants facing the friend-like brand, participants in the small SCPM condition showed more favorable attitudes toward the brand and stronger purchase intention than those in the large SCPM condition.

In Study 2, we had three objectives: to replicate the results of Study 1 with a different manipulation for BSR, to rule out the effects of product type, and to explore the possible mechanism underlying the predicted effect: *processing fluency*. A 2 (SCPM: large vs. small) x 2 (BSR: leader-like vs. friend-like) x 2 (product type: hedonic vs. utilitarian) between-subjects design was conducted. Since gender differences play an important role in product perceptions, only female participants were recruited. They were first asked to read a magazine article regarding a brand and then asked to view a forthcoming ad. Participants were presented with a brief description of a leader-like (friend-like) brand with a fictitious brand "Mirabelle" designed to prime the brand's social role. The second section was the ads differing on SCPM and product type. The ad materials were identical as those used in Study 1. Perfume and cleanser were chosen to represent as hedonic and utilitarian products. The different ratios between product and model image sizes were created. After the ad was read, purchase intention was assessed. The results was consistent with those in Study 1. We then conducted mediated moderation analysis (Zhao, Lynch, and Chen 2010) and confirmed that the processing fluency mediated the effects of SCPM and BSR on purchase intention

This research contributes to the literature on power in consumer behavior. Previous research has shown that power can be manipulated by the copy embedded in an ad (Rucker, Dubois, and Galinsky 2011). The current research is the first to illustrate that power can be primed through a larger product image (compared with a model image) in an ad. The current work offers rich managerial implications. Advertisers may benefit from taking power difference into consideration and arranging a larger size of the product image (compared with the model image) when promoting a leader-like brand. However, the findings from this work also lend a cautionary note: the strategy of a larger size of product image may not work when the brand is perceived as a friend to consumers. The current investigation provides guidance for brand managers in how to frame the brand's social role in their brand positioning strategies. Brand managers should work closely with ad designers and be judicious in image placement in advertising strategy.

Unbearable Lightness of Shaky Inferences: When Misused Product Inference is Detrimental to Verified Product Hypotheses

Rui Chen, University of Georgia, USA
Marcus Cunha Jr., University of Georgia, USA

EXTENDED ABSTRACT

Consumers often face consumption choices that involve deciding between two competing hypotheses supported by evidence that vary in terms of levels of certainty (i.e., the supporting evidence could be either missing, inferred, or observed). Understanding how consumers integrate multiple pieces of evidence varying in levels of certainty helps marketers develop better arguments for products. Previous research has presented mixed findings regarding the roles of inferred versus observed evidence in consumers' judgment and decision making. On the one hand, preference for certainty suggests that a hypothesis with fully observed evidence should be favored over a hypothesis with one piece of observed evidence and one piece of missing evidence. This is supported by research showing that people favor explanations making fewer (vs. greater) number of predictions (e.g., Sussman, Khehlani and Oppenheimer 2014, Khehlani, Sussman and Oppenheimer 2011) and that consumers prefer brands which signal lower uncertainty (e.g., Muthukrishnan 1995). On the other hand, consumers evaluate products as a function of inferences they make (e.g., Dick, Chakravarti and Biehal 1990), which could lead them to become less sensitive to higher levels of uncertainty about the evidence at hand (Gunasti and Ross Jr. 2009). In addition, it has been shown that spontaneous inference making increases information utilization but only when the inference is diagnostic (e.g., Kardes, Posavac and Cronley 2004).

Our research is the first attempt to directly test how inferred evidence influences the value of observed evidence in hypothesis testing when two hypotheses are pitted against each other. Specifically, we investigate an under-studied pattern of hypothesis-testing bias in which consumers misuse inferences made about the missing evidence supporting only one hypothesis ("to-be-verified hypothesis" henceforth) to evaluate the validity of a competing hypothesis, which is fully verified by observed evidence ("verified hypothesis" henceforth). We label this phenomenon the "*spillover of inferences effect*". We propose that consumers may more heavily rely on inferred than observed evidence when inferred evidence is biasedly perceived to be more diagnostic than observed evidence.

Study 1 established that consumers devalue the observed evidence supporting the verified hypotheses and judge the probability of validity across two hypotheses as a function of the extent to which the inferred evidence favors the to-be-verified hypothesis. In a 4 base-rate (i.e., base rate as 5-14%, 15-24%, 76-85%, 86-95%; between-subject) X 4 scenario replicates (within-subject) mixed design, participants were presented two hypotheses which compete with each other. Participants were asked to judge the validity of these two hypotheses on a 11-point trade-off scale in the end of the study. In each of the four scenarios (wine regions, telephoto zoom lens, virus, and product malfunction), one hypothesis was fully supported by the observed evidence whereas the other hypothesis was only partially supported by one piece of observed evidence because the other piece of evidence could not be observed at the time. However, the base rate of occurrence of that piece of missing evidence in the population of interest was provided. The analysis yielded a main effect of base rate, with participants reporting a statistically significant change in preference from the verified hypothesis to the to-be-verified hypothesis as the base-rate for the missing piece of evidence increased ($F(3, 130) = 38.98, p < .000$).

Study 2 directly tested whether inferences made about the missing evidence for only to-be-verified hypothesis influences the extent to which participants are willing to support or falsify the competing verified hypothesis. The design was a 2 base-rate (i.e., base rate as 30% vs. 70%) X 2 hypothesis conditions (i.e., focus on the verified hypothesis vs. the to-be-verified hypothesis) between-subjects design. We predict that we will replicate the effect in study 1 regardless of which focal hypothesis consumers hold to evaluate evidence. Study 2 allows us to 1) rule out the alternative explanation that the effect documented in study 1 was a result of attention shifted toward the to-be-verified hypothesis and 2) directly show that consumers use the information perceived to be diagnostic (i.e., base rate of the missing evidence) to evaluate the verified hypothesis. We recoded the 11-point measure ratings by centering ratings around 0. Therefore, a rating of zero indicates no preference for either of hypotheses; positive scores (between 0 and 5) indicate preference for the to-be-verified hypothesis and negative scores (between 0 and -5) indicate preference for the verified hypothesis. The analysis revealed that participants who were explicitly instructed to evaluate evidence against the verified hypothesis which was not associated with the missing evidence still used base rate of the missing evidence to judge the validity of this hypothesis ($M_{\text{low base rate}} = -1.333$ vs. $M_{\text{high base rate}} = .318, p < .000$). In support of the null effect of hypothesis focus, the preference rating for the hypotheses was not a function of the interaction between the base-rate factor and the hypothesis-focus factor ($F(1, 202) = .656, \text{NS}$).

Study 3 explored when might consumers misuse high base rates favoring only the to-be-verified hypothesis in detriment of the verified hypothesis. We predict that when the missing evidence does not accommodate a broader scope of evidence in the context, the *spillover of inferences effect* should be offset. This was a single factor scope of evidence (i.e., the missing evidence accommodates a broader scope of evidence vs. not) between-subject design with three levels. In the first and third conditions, the missing evidence accommodated a broader scope of evidence whereas in the second condition, the missing evidence did not. The results supported our prediction that when both hypotheses required equivalent scope of evidence, the *spillover of inferences effect* was offset ($M_{\text{with_scope_discrepancy_condition\#1}} = .655$; $M_{\text{no_scope_discrepancy_condition\#2}} = -1.828$; $M_{\text{with_scope_discrepancy_condition\#3}} = .688, p = .000$).

Our research investigated and empirically showed a puzzling situation in which consumers prefer a product hypothesis supported by inferred evidence over a competing hypothesis supported by fully observed evidence. We further identified the underlying process – the *spillover of inferences effect* and showed when the effect was offset.

Consumer Trust Erosion During an Industry-Wide Crisis: The Central Role of Legitimacy Judgment

Shijiao Chen, University of Otago, New Zealand
Hongzhi Gao, Victoria University, New Zealand
Damien Mather, University of Otago, New Zealand
John Knight, University of Otago, New Zealand

EXTENDED ABSTRACT

Industry-wide product-harm crises (hereafter called “industry-wide crises”) are well-publicized instances of corporate misconduct permeating an industry and causing potential or real product harm. Severe industry-wide crises can exert a catastrophic impact on the affected industry by eroding consumer trust (Cleeren, Dekimpe, & Helsen, 2008; Feng, Keller, Wu, & Xu, 2014; Knight, Gao, Garrett, & Deans, 2008). We have studied the 2008 Chinese milk melamine contamination in which 22 dairy firms were reportedly involved. In this crisis, consumers’ confidence and trust in the Chinese dairy industry was shaken to its core (Qiao, Guo, & Klein, 2012). Most recently, another major industry-wide crisis occurred in Brazil: more than 30 Brazilian meat manufacturers were reported to indulge in unhygienic and illegal practices, causing concerns in export markets and a loss of trust in the safety of meat exported from Brazil. Previous research on product-harm crises mostly focuses on trust erosion in individual firms rather than in entire industries (Coombs & Holladay, 1996; Klein & Dawar, 2004). Industry-wide crises differ from individual firm crises because they are attributable to institutional factors such as deficient regulation, weak quality control, and poorly defined industry norms (Gao & Knight, 2007; Gao, Knight, Zhang, Mather, & Tan, 2012). The present paper contributes to the product-harm crisis literature by investigating the nature of these institutional factors in connection with consumers’ perceptions, judgment, and trust erosion. We seek insights from institutional theory to better understand this connection.

Institutional theory emphasizes the importance of legitimacy in understanding individuals’ responses toward an institutional system and the entities within it (Finch, Deephouse, & Varella, 2015; Suchman, 1995; Tost, 2011). The concept of legitimacy has not gained sufficient attention in the product-harm crisis literature. Two significant remaining gaps still are presented here: (1) Very few studies investigate consumer legitimacy judgment regarding an industry. It is still unclear how consumers judge an industry as legitimate or non-legitimate based on its institutional frameworks. (2) There is a lack of any theoretical explanation with associated empirical support for the role of legitimacy judgment in consumers’ psychological reactions during an industry-wide crisis. It is unclear whether consumer legitimacy judgment of the affected industry can influence consumer trust in the industry. Against this background, this study investigates how consumers make legitimacy judgment of an industry and whether consumer legitimacy judgment plays a critical role in the erosion of industry trust occurring during an industry-wide crisis.

We define consumer legitimacy judgment (CLJ) as consumers’ judgment of an industry’s actions based on the desirability, properness, and appropriateness in the institutional environment. We hypothesize that CLJ plays a central role in the erosion of consumer broad-scope trust during an industry-wide crisis.

We conducted four studies to understand the mechanism of legitimacy judgment. The first three studies used the Chinese dairy industry as the research context because it is perceived as having institutional deficiencies by Chinese consumers (Gao & Knight, 2007; Knight et al., 2008). We used parents of school children as our sample frame because they are frequent decision-makers and

purchasers of food for households and share concerns about food safety (Qiao et al., 2012). Study 1 constructs and validates the CLJ scales by referring to literature, experts, consumer interviews, and a sample of 311 participants. Study 2 examines the mediation effect of CLJ on the relationship between perception of normalization of misconduct and industry trust with a sample of 284 participants. The results indicate that, once consumers perceive stimuli signifying an industry-wide crisis, they tend to engage in legitimacy judgment and this judgment has a significant impact on their trust in the industry. Study 3 validates the CLJ mediation model by assessing whether the information signaling that a crisis is industry-wide serves as the boundary condition for the full mediation effect. We obtained usable responses from 323 participants from the sample frame. The results indicate that consumers rely on an effortful and systematic approach during an industry-wide crisis and rather engage in a conservative and automatic approach during a non-industry-wide crisis. Study 4 ($n=132$) replicates the CLJ mediation model in the setting of the soymilk industry in China which has a low base-rate of crises, in order to investigate the role of base-rate on the CLJ effect. The results indicate that a high base rate of crises strengthens the tendency of engaging in legitimacy judgment and weakens the reliance on pre-existing perceptions.

This paper contributes to the consumer research literature by combining institutional and psychological perspectives to evaluate legitimacy judgment process and the erosion of industry trust. The paper suggests that monitoring consumers’ perceptions of the industry with regard to the focal scandals and base rates and taking appropriate measures to influence consumer legitimacy judgment process are prescriptions for reducing the erosion of industry trust during a crisis.

Color Lightness Shapes Hierarchy: When Darker Comes First

Myungjin Chung, University of Texas at Arlington, USA

Ritesh Saini, University of Texas at Arlington, USA

EXTENDED ABSTRACT

In this paper, we demonstrate that there is a perceptual correlation between brightness and inter-item hierarchy. Specifically, we suggest that darker (lighter) color is related to higher (lower) hierarchy. We posit that this association emerges in response to a deep-seated human urge to structure the stimulus they are confronted with. Without sorting the multitude of external cues into coherent units that provide meaning, the world will be more chaotic and unsettling than what most people find comfortable. Relying on the brightness-hierarchy congruency therefore emerges as a handy solution to organize this chaos into a predictable, orderly pattern.

Five studies confirmed this hypothesis. In Study 1 (n=142 undergraduates), participants were first asked to select the most important attribute while purchasing a fabric detergent: scent or brand. Across two conditions, the font color was darker for one of the attributes and lighter for the other. Results revealed that participants were significantly more likely to prefer an attribute when it was presented in a darker typeface (M(dark)= 64.3% vs. M(light)= 36.1%, $\beta = -1.158$, Wald = 10.96, $p = .001$, OR=0.314).

If color lightness corresponds with product hierarchy, we expect that product bundles where the primary product is darker and the secondary complementary product is lighter will benefit from this congruency effect. The next study examines this proposition. Specifically, study 2 (n=81 undergraduates) tested the effect of color lightness on perceived hierarchy in evaluating product bundles. Participants were randomly assigned to a 2 (primary product package: dark vs. light) \times 2 (secondary product package: dark vs. light) design, where they were asked to evaluate the product bundle on various dimensions (Batra and Ahtola (1988) 8-item attitude scale, $\alpha=0.93$). ANOVA results revealed non-significant main effects for both products' color lightness (All F 's <1). However, as expected, the interaction between the two independent variables was significant ($F(1, 80) = 6.595$, $p = .012$). Specifically, the dark-colored detergent paired with light-colored softener induced more positive product evaluation (M=86.93; SD=9.6) than any of the other three paired bundles.

Study 3 (n=97 undergraduates) reinforced our proposition by replicating the results of study 2 in a different product setting: shampoo and conditioner. Participants were randomly assigned to a 2 (primary product package: dark vs. light) \times 2 (secondary product package: dark vs. light) design, where they were asked to evaluate the product bundle using a 6-item attitude scale ($\alpha=0.84$). ANOVA results revealed non-significant main effects for both products' color lightness (All F 's <1). However again the interaction between the two independent variables was significant ($F(1, 96) = 8.411$, $p = .005$). Specifically, the dark-colored shampoo paired with light-colored conditioner induced more positive product evaluation (M=3.5; SD=0.83) than any of the other three paired bundles.

Previously, it has been suggested that color congruency effects may result from automatic processing (Spence and Deroy 2013). To investigate this proposition, we measured response times in all the three studies described above. Lower response latencies have been strongly associated with automaticity and heuristic-use in decision making (De Neys 2006). None of the studies found any relationship between response time and color-congruent behavior (All F 's <1). In the next two studies, we explore a possible motivational underpinning of this effect. In Studies 4 and 5, we examined the moderating effect of personal-need-for-structure on the color hierarchy correspondence we tested in the first three studies. Consumers differ in their desire for control and structure, and aversion to information ambiguity, a trait referred to as

the 'personal need for structure' (PNS) (Neuberg and Newsom 1993). Stimuli incongruence can be construed as a type of information ambiguity which will be aversive to consumers with high-PNS (Rompay, Pruyn, and Tieke 2009). Therefore, we expect that people high in PNS will display greater preference for a categorization which is consistent with their perceptual hierarchy.

In study 4, all participants (n=216 mTurk workers) were shown 16 different sets of stimuli. Each set included a higher hierarchy and a lower hierarchy item (e.g. Entrée-Appetizer). Here, we define perceptual hierarchy as a system or organization in which items, animate or inanimate, are ranked vertically according to status, authority or some other dimension. Participants were asked to categorize each item into a darker or lighter colored basket as they saw fit. To generalize our findings for a wide variety of colors, we employed five different color types. Also, the presentation order of the 16 item sets was randomized across participants. In addition, all participants also answered the 12-item PNS scale (Neuberg and Newsom 1993). Analysis revealed that 76% of the categorizations were congruent, where the higher hierarchy item was tagged with the darker color basket. This was significantly higher than what would be expected by chance (50%) (Binomial Test, $p>0.0001$). Also, measured PNS was correlated to choice congruency ($r=+0.196$, $p=0.004$) confirming our moderation hypothesis.

Study 5 replicated the results of study 4 by creating real life scenario-based questions. In each scenario, participants (n=216 mTurk workers) were asked to choose the more suitable products (darker vs. lighter) for two different people or item (higher versus. lower hierarchy). Rest of the procedure was identical as previous study. Results showed that 82% of the choices were congruent, as expected, in that people chose a darker-colored item/product for a higher hierarchical person/item and chose a lighter-colored item/product for a lower hierarchical person/item (Binomial Test, $p>0.0001$). Also, measured PNS was correlated to choice congruency ($r=+0.130$, $p=0.056$) reconfirming our moderation hypothesis.

General Discussion

We investigated how consumers relate color lightness with inter-item hierarchy. Five studies provide converging evidence that consumers associate higher (lower) hierarchy items to darker (lighter) colors. In the domain of complementary products, those bundles where the primary product is darker and the secondary product is lighter are more preferred than any other bundle configuration. We also demonstrated that a consumer's "need for structure" motivation moderates this preference.

Obesity and Sensitivity of Food Perceptions and Preferences to Marketing Actions

EXTENDED ABSTRACT

The environment—and particularly the actions of food marketers—strongly influences the perception of food, which then impacts preferences and eating behavior (Chandon and Wansink 2012). Marketing claims (e.g., “good for you” claims, brand positioning), the size and shape of food packages, their labeling (“medium” or “large”) and the range of sizes on the menu all influence food consumption and the perception of food quality (“tasty,” “healthy”) and quantity.

Research on how food marketing influences food perception and preferences has important limitations. First, almost all existing studies have been conducted with lean, healthy, educated, and young people rather than with obese people who are most at risk. This is an important concern because research suggests that obese people have become insensitive to internal satiation signals (Bartoshuk et al. 2006; Yeomans, Blundell, and Leshem 2004) and to reward signals in the brain (Volkow, Wang, and Baler 2011). The second limitation is the lack of studies examining the effects of the most effective weight-loss remedy for obese people—bariatric surgery—and how it interacts with the effects of the marketing environment. About 200,000 Americans undergo weight-loss surgery (gastric bypass or banding) each year. Yet, only a handful of studies show that weight-loss surgery influences not only food intake, but also food preferences, hunger, and taste acuity (Behary and Miras 2015; Scruggs, Buffington, and Cowan 1994). More generally, no research has, to date, examined how medical interventions like weight-loss surgery influence people’s sensitivity to marketing actions when it comes to food perception and preferences.

The goal of this project is to examine the interplay of biological and psychological factors driving eating behavior before and after weight-loss surgery. Our hypothesis is that the drastic psychological and biological changes (e.g., the composition of the gut microbiota and the levels of metabolic gut hormones) caused by bariatric surgery reduce the impact of marketing factors on food perceptions and preferences.

The main study was conducted with the collaboration of the University Hospital of Pitié Salpêtrière in Paris. During five years we collected data on a sample of 73 obese French female patients scheduled for gastric bypass surgery or surgical banding, and 40 lean French females (for the control group). The obese participants belonged to a clinical study conducted by the Institute of Cardiometabolism And Nutrition (ICAN). The obese patients were tested three times: one month before, 3 months after, and 12 months after the surgery. The control group was tested twice, separated by a period of 3 to 6 months in order to verify that the responses were stable over time. The control group was matched with the obese group on socio-demographic variables (age and employment). However, the obese sample had lower levels of education and income. Our analyses focused on the 46 obese patients and 32 control subjects who participated in at least two experimental sessions. The responses of the subjects who dropped the study after the first session were never significantly different from the responses the subjects who continued the study.

We first measured the effects of food stereotypes. Existing research has shown that people tend to categorize food as “good” or “bad” based on stereotypes, regardless of the actual size of the portion, and that these stereotypes strongly influence food perceptions and preferences (Oakes 2005; Rozin, Ashmore, and Markwith 1996). We selected “surprising” pairs of foods where the stereotypically “good” food actually contains more calories than the stereotypically “bad” food (e.g., a can of Minute Maid pure orange juice, worth 152 calories, vs. a can of regular Coke, worth 140 calories). Overall, we replicated both the “health halo” and the “health horn” effects (Chandon 2013; Chandon and Wansink 2007), participants tended to underestimate calories in “good” foods and overestimate calories in “bad” foods. At t1 (before surgery), obese patients stereotyped foods significantly more than control participants, although their stereotyping tended to decrease 3 months after surgery, and significantly 1 year after.

We also measured size labeling effects. While food vendors are free to label the size of their portions however they want (e.g. “small”, “medium”, “large), past research has shown that size labeling can exert a normative influence on consumers’ portion choice and consumption (Aydinoğlu and Krishna 2011). We tested labeling effects within-subject with a scenario that asked participants to choose portions of fries that vary only in “size labels”, but not in actual size. At t1 (before surgery), obese patients were significantly more influenced by size labeling than control participants, but again, they became significantly less influenced 3 months after and 1 year after surgery.

We finally measured assortment effects. Past research has shown that the range of portion sizes available at a food vendor exerts a normative influence on portion choice (Sharpe, Staelin, and Huber 2008); for instance adding a small size or a large size will shift which size will be considered normal, influencing food intake. In a scenario-based task, we found that before surgery, obese patients were directionally more influenced by assortment effects compared with control participants, but that this influence tended decrease 3 months after surgery, and significantly 1 year after.

Obviously, the most interesting comparisons is between the responses of the obese participants before and after weight-loss surgery. If we had found no effect of bariatric surgery, this would have suggested that the higher sensitivity to marketing actions of obese participants is likely driven by personality or other stable individual differences, and thus that the drastic weight loss typically caused by bariatric surgery is not mediated by sensitivity to marketing actions. However, we found that weight-loss surgery made obese people *less* responsive to marketing actions. This provides the first demonstration that weight-loss interventions, such as bariatric surgery, can influence food perceptions, preferences, and choice. It also suggests that differences in response to marketing actions might be one of the reasons for the higher BMI of the obese group.

Sensory or Nutrition Menu Labeling?

A Field Experiment in Aligning Public Health and Restaurant Business Goals

Yann Cornil, University of British Columbia, Canada
Pierre Chandon, INSEAD, France

EXTENDED ABSTRACT

Americans now spend more on foods prepared away from home than on foods prepared at home (ERS 2016), and meals are considerably larger in restaurants than at home (Lachat et al. 2012). This has led health authorities to mandate calorie labeling on restaurant menus, hoping that it will lead patrons to make healthier choices.

However, the evidence on the effects of menu labeling on demand is mixed. In a recent meta-analysis (Long et al. 2015), calorie labeling alone was found to lead to a small (18 kcal) but statistically significant reduction in the calories ordered or purchased per meal. In addition, the restaurant industry has fought aggressively against menu labeling, officially because of their compliance costs, but presumably also for fear that it hurts customer value (Nestle 2011; Tavernise 2015).

Because of the necessity for the food industry to balance health requirements and customer satisfaction (Nestle 2011; Tavernise 2015), some researchers have explored pleasure-based approaches to promote healthier eating. In particular, Cornil and Chandon (2016) argued that focusing on the sensory experience of eating could lead consumers to choose, prefer, and pay more for smaller food portions because it reminds them that the overall hedonic appreciation of a dish peaks with moderate food portions. However, it is unknown whether such approach can be effective with paying restaurant customers over the course of an entire meal, especially when the marginal cost of food is low or nil.

In order to address this question, we designed a field experiment in a restaurant comparing the effects of a “sensory labeling menu” (with vivid sensory descriptions of the foods), a “nutrition labeling menu” (with information on calories and fat), and a control menu on eating behaviors and on the perceived value of the meal. We find that sensory menus can reduce food intake while increasing customer value, whereas nutrition labeling decreases both food intake and customer value. Our research also contributes to the understanding of restaurant customer value by studying mediating factors (food intake, eating pace, sensory expectations) and moderating factors (companionship) that cannot easily be measured in laboratory settings.

The study took place at the restaurant of a culinary school in France; patrons were invited to an all-you-can-order “small plate” meal where they could order as many portions of starter, main course, and dessert as they wanted, at a fixed price of 15 euros. The prix fixe feature was chosen to provide the most conservative test of the effects, since consumers had no incentive to save money by eating less. The dishes were identical for all customers (gnocchi salad, mini-Shepherd pies, lemon tartlets) and the menus were manipulated between-subject. We tested three menus over nine different lunch services, counterbalancing the time of the service across three different mid-week days. The “control menu” had simple descriptions of the food items. The “nutrition labeling menu” used the same descriptions but added information about both calorie and fat content. The “sensory labeling menu” used vivid sensory descriptions and an invitation to use the five senses to appreciate the meal. After the customers had finished consulting the menu, the waiter presented a sample plate displaying one “portion” of each dish and let the patrons indicate the number of portions they desired for each dish. The patrons were brought each dish successively (with their desired number of portions). Before they started eating, the patrons were asked on an

electronic tablet how much sensory pleasure they anticipated. At the end of the meal we inferred the amount of food consumed from the leftovers. We measured post-meal hunger as well as customer value by asking the customers to estimate what would be a “fair price” for the meal they had. Several high-definition hidden cameras were filming the patrons throughout the lunch; we measured how much time each person spent eating, and computed an index of “slow eating” by dividing the time spent eating by the number of consumed calories.

After exclusion of 8 customers who did not follow the instructions or did not answer the questions, 98 customers were included in the analyses (Mean age=54; 53% Female).

Compared with the control condition, customers in the “nutrition labeling menu” condition ordered and ate less food, ate at a slower rate, and derived less customer value from their meal. Mediation analyses showed that the nutrition menu decreased customer value because it made consumers eat less.

Compared with the control condition, customers in the “sensory labeling condition” also ordered and ate less food and ate at a slower rate. However, their sensory expectations improved, and they derived more customer value from their meal. Mediation analyses showed that the sensory menu increased customer value *despite* making consumers eat less, because it increased pleasure anticipation and decreased the pace of eating, suggesting that customers were “savoring” their meal.

Additional analyses also suggested that the effects of sensory menus and nutrition menus were stronger when more people ate together.

In conclusion, starting in May 2017, all US restaurants with at least 20 locations must comply with the 2010 Patient Protection and Affordable Care Act and provide calorie information on menus and nutrient information if there is a nutrition claim (e.g., fat content if the food is described as “low fat”). Our field experiment suggests that such policy may be effective in decreasing food intake, but that it may hurt customer value. We provide evidence that another solution is possible: “sensory labeling menus” should also decrease calorie intake while increasing customer value at the same time.

Don't Count Calorie Labeling Out: Calorie Counts on the Left Side of Menu Items Lead to Lower Calorie Food Choices

Steven Dallas, New York University, USA

Peggy Liu, University of Pittsburgh, USA

Peter Ubel, Duke University, USA

EXTENDED ABSTRACT

Government-mandated calorie information on menus and menu boards has been one of the United States government's favorite tools for combatting the obesity epidemic in the United States (FDA 2016). Indeed, as part of the Affordable Care Act, all chain restaurants nationwide will have to provide calorie information on their menus by May 2018 (FDA 2017). However, the key question remains of whether providing caloric information actually reduces the number of calories that people order, and, if they do, by how much. This question has been the subject of extensive research across multiple disciplines, including marketing, economics, psychology, and public health, and, in general, this abundance of studies has found either a small effect or no effect of calorie counts (see Kiszko et al. 2014 for a review). Accordingly, these findings have led some to call calorie labeling a policy "failure" (Carroll 2015; Singal 2015).

In the present research, we suggest a new account for why calorie information may often have little effect in terms of leading consumers to make lower calorie food choices and, based on this account, propose a trivially simple intervention to increase the effectiveness of calorie information. Specifically, we suggest that one reason calorie information is typically ineffective is because it is currently typically displayed to the right of food items on menus. Although traditional economic thought would suggest that the order in which information is processed should have no impact on decision making (Frank and Bernanke 2008), we suggest that the positioning of calorie information on menus and menu boards (and, as a result, the order in which information is processed) has a significant effect on consumers' food choices. Thus, our key hypothesis in this research is that displaying calorie information to the left of food items will lead to significantly lower calorie orders than displaying calorie information to the right of food items.

According to information processing theory, information encountered earlier is given greater weight than information encountered later (Anderson and Jacobson 1965; Asch 1946; Hammond et al. 1998; Lee et al. 2006; Nisbett and Ross 1980). Given that Americans read from left-to-right, when calorie information is to the right of menu items, as is typically the case, it is only processed after consumers have already processed the food item's name. As a result, the food item's name is likely given substantially greater weight than the calorie information when making the food choice. This is especially troubling in light of recent research which has found that a food item's name cues consideration of the food's taste before its health (Sullivan et al. 2015). Accordingly, even if the calorie information is considered later in the decision process, initial taste information has already been given considerable weight. Thus, the calorie information has a limited effect on consumers' food orders, which is what has been found in the numerous studies that have examined the effect of calorie information on consumers' food choices (see Kiszko et al. 2014 for a review). Thus, we propose that simply moving calorie information to the left of menu items will greatly increase its effect on consumers' food orders. In particular, calorie information to the left (vs. right) of menu items may lead to lower calorie food orders because consumers will view the calorie information earlier, which will lead them to place greater weight on the calorie information.

We tested our main hypothesis—that positioning calorie information to the left (vs. right) of menu items leads to significantly lower calorie food choices in three studies. In Study 1, which was conducted at a casual chain restaurant, customers ordered from a menu with either no calorie information, calorie information to the left of the menu items, or calorie information to the right of the menu items. As predicted, consumers who ordered from a menu with calorie information to the left of the menu items ordered significantly fewer calories than consumers who ordered from a menu with either calorie information to the right of the menu items or no calorie information at all. There was no significant difference in terms of calories ordered between the no calories and right calories conditions.

In Study 2, the goal was to try to determine why calorie information to the left (vs. right) leads to lower calorie food orders. Replicating Study 1, we found that consumers ordered significantly fewer calories when the calorie information was to the left of the menu items (vs. to the right or not present at all). More importantly, though, we found support for a serial mediation model. Specifically, when calorie information is to the left (vs. right) of menu items, consumers view it earlier, and the earlier they view the calorie information, the more weight they place on the calorie information when deciding what to order, which leads them to order lower calorie meals.

In Study 3, we tested for a boundary condition of our effect. Specifically, calorie information to the left (vs. right) is only processed earlier because Americans read from left-to-right. Thus, if the effect is truly driven by the order in which information is processed (rather than, say, the physical position of the calorie information on the menu), we should find that the effect is reversed for consumers who read from right-to-left. Accordingly, Study 3 was conducted with Hebrew-speaking Israelis, who read from right-to-left. As predicted, the effect completely reversed for this sample, with consumers ordering significantly fewer calories when the calorie information was to the right of the menu items (vs. to the left or not present at all).

Thus, it may be premature to call calorie labeling a "failed" policy. Instead, it appears that one reason calorie information has been ineffective is because it is typically displayed to the right of menu items. Accordingly, going forward, it should be required for calorie information to be positioned to the left of menu items, as this appears to greatly increase its positive effect on consumers' food orders.

How Consumption Experience Valence and Perceived Assortment Size Interact to Shape Word-of-Mouth Sharing

Matteo De Angelis, Luiss University, Italy
Gregory S. Carpenter, Northwestern University, USA
David Dubois, INSEAD, France
Michele Costabile, Luiss University, Italy

EXTENDED ABSTRACT

One dimension of word-of-mouth (WOM) that has received ample attention due to its impact in shaping the success or downfall of products is information valence. Following separate investigations of factors encouraging either positive or negative WOM (PWOM or NWOM) in isolation, recent work turned to examine how socio-psychological factors affected the sharing of PWOM and NWOM (De Angelis et al., 2012; Dubois, Bonezzi, and De Angelis, 2016).

This study turns to another key aspect of a consumption experience by examining the extent to which a consumer had access to choices at the time of purchase. We propose that the size of the assortment consumers choose from can shape their tendency to share their positive versus negative experiences. Specifically, we hypothesize that larger, compared to smaller, assortments enhance consumers' likelihood to share positive experiences but impair consumers' tendency to share negative experiences. This hypothesis is rooted in the idea that a consumer experiences increasing feelings of control over her decision-making process as the size of the assortment she chooses from increases (e.g., Inesi et al. 2011). As a result, greater (vs. smaller) assortments elicit an internal attribution process whereby a consumer tends to increasingly attribute the outcome of her decision-making to her actions (Weiner 1985). Because attributing outcomes to themselves triggers feelings of pride (or lack thereof; Smith and Lazarus 1993; Tracy and Robins 2007), we propose that perceived assortment size interacts with consumer experience valence to shape feelings of pride. In turn, we expect that consumers' likelihood to share their positive versus negative experiences will be a function of their feelings of pride. In particular, we posit that consumers having a positive experience might feel increasingly proud as assortment size increases, while those having a negative experience might feel decreasingly proud as assortment size increases. Consequently, consumers will be more (less) likely to engage in WOM as assortment size increases when having positive (negative) consumption experiences.

Experiment 1 aimed to provide initial evidence for the basic effect. One hundred thirty-two respondents were randomly assigned to one of the two conditions (positive vs. negative experience) whereby they recalled and described either a positive or a negative experience with a product or service. Perceived assortment size was assessed by asking respondents to indicate how many options were available during their choice process (1 = I did not have any other option, 4 = I had many other options). In addition, we assessed WOM likelihood by asking respondents how likely they would be to share their experience with other people they felt distant from (1 = very unlikely, 7 = very unlikely). Results revealed a significant interaction between consumption experience valence and perceived assortment size ($b = .40, t = 2.68, p = .01$). First, consumers' likelihood to share positive experiences increased as perceived assortment size increased ($b = .44, t = 2.04, p = .04$). Second and in contrast, consumers' likelihood to share negative experiences decreased as perceived assortment size increased ($b = -.37, t = -1.75, p = .08$).

Experiment 2a (101 respondents) aimed to provide evidence that the shift in consumers' likelihood to share positive and negative experiences stems from the asymmetry in feelings of control associ-

ated with choosing from smaller versus larger assortments. The procedure was identical to Experiment 1, except we asked respondents to what extent they felt that the outcome of the experience described was due to factors within or outside their control (1 = it was definitely due to factor outside my control, 7 = it was definitely due to factor within my control). First, replicating the initial experiment, we found the predicted interaction ($b = .15, t = 1.82, p = .07$). Then, novel to this experiment, results of a moderated mediation model with perceived assortment size as independent variable, feelings of control as the mediator, experience valence as the moderator and WOM likelihood as the dependent variable revealed that the effect of perceived assortment size on feelings of control was positive and significant ($b = .26, t = 2.46, p = .02$). Additionally, a regression predicting WOM likelihood from feelings of control, experience valence and their interaction revealed a significant interaction between feelings of control and experience valence ($b = .20, t = 2.53, p = .01$), suggesting that higher levels of feelings of control, compared to lower levels, triggered higher WOM likelihood for positive experiences but lower WOM likelihood for negative experiences.

Experiment 2b (199 respondents) differed from Experiment 2a because we manipulated assortment size. Replicating Experiment 1, we again found the predicted interaction ($b = .28, t = 2.39, p = .02$). Importantly, consistent with Experiment 2a, results revealed that the effect of assortment size on feelings of control was positive and significant ($b = .62, t = 5.78, p < .001$), while the regression predicting WOM likelihood from feelings of control, experience valence and their interaction revealed a significant interaction between feelings of control and experience valence ($b = .25, t = 3.56, p < .01$).

Finally, Experiment 3 (132 respondents), tested whether trait-level pride (Tracy and Robins 2007) interacted with perceived assortment size and experience valence to affect WOM likelihood. Results showed a significant three-way interaction effect ($b = .09, t = 2.07, p = .04$). Additionally, simple slope analysis (Aiken and West 1991) revealed that at mean and high levels of pride the interaction of perceived assortment size and experience valence was positive and significant ($b_{mean} = .16, t = 2.10, p = .04$; $b_{high} = .32, t = 3.17, p < .01$), while it was not significant at low levels of pride ($b_{low} = -.01, t = -.02, ns$). These results suggest that the basic effect shown in Experiment 1 occurs for consumers with higher rather than lower levels of dispositional pride.

Overall, this research advances knowledge of when individuals are more likely to share positive versus negative WOM by testing the role of the size of the assortment at the time of purchase in shaping feelings of pride and ultimately guiding what information consumers are likely to share.

Intrusive Advertisements in the Online Context: A Meta-Analysis of the Antecedents and Consequent Constructs

Fernando de Oliveira Santini, Unisinos, Brazil
Frederike Monika Budiner Mette, ESPM Sul, Brazil
Valesca Persch Reichelt, ESPM Sul, Brazil
Wagner Junior Ladeira, Unisinos, Brazil
Claudio Hoffmann Sampaio, PUC RS, Brazil

EXTENDED ABSTRACT

Intrusive advertisements started to gain academic attention in the 1960s, when Bauer and Greyser (1968) indicated that commercials are a cause of consumer discomfort. In recent years, especially since the 2000s, related studies have proliferated in accordance with the popularization of the internet. Studies have examined a variety of online contexts, such as unwanted e-mails (Moriomoto & Chang, 2006, 2009; Chang et al., 2013), pop-ups (Edwards et al.), online games (Hernandez et al., 2004) and streaming advertisements (Logan, 2012, Abrantes, 2015). Parallel to this academic attention, companies' investments in digital advertisements reveal the increasing interest in the managerial environment. Indeed, a 2013 forecast published by the Interactive Advertising Bureau (iAb) that notes that in 2017, \$60 billion will be invested in internet ads. Additionally, Li et al (2002) published a study in the Journal of Advertising proposing a method that could measure intrusive advertisements, which further increased the popularity of this topic. Although the proliferation of studies has provided a scope for better understanding the phenomenon, it has also produced conflicting results given the different methodologies used. For example, the irritation construct is described in some intrusive advertisement studies as a positive force (Edwards et al., 2002) and in others as a neutral force (Hernandez et al. Al., 2004). Similarly, the attitude construct has been found to be positive (Morimoto & Chang, 2009), negative (Abrantes, 2015) and neutral (Héroult, 2013). In this context, this research aimed to contribute by developing a meta-analysis. The use of this methodology could lead to definitive conclusions about the investigated subject across different contexts and methodologies (Green, 2005). Meta-analyses allow researchers to eliminate conflicting results found by eliminating the possible biases of studies and to generate more precise estimations of the effect size (Lipsey & Wilson, 2001). To that end, we searched seven databases: EBSCO, ProQuest, Taylor & Francis, Emerald, Science Direct, JSTOR and Google Scholar. The data collected from these databases were coded by two senior researchers. Pearson's correlation coefficient was the metric selected for this meta-analysis. The correlations of the studies were adjusted by the sample size and scale reliability, as suggested by Hunter and Schmidt (2004). In addition, to evaluate the moderating effects, a regression analysis was performed. Our search initially produced 382 studies published and not published in journals. After the first analysis, 30 studies were used in the data analysis. The results revealed some important findings: First, of the four antecedents identified (relevant information, congruence, entertainment, and frequency), two—relevant information and entertainment—presented significant and negative relations with intrusive advertisements. Thus, the theories and the results indicated that the intrusiveness of an advertisement can be mitigated by its information value (Edwards et al., 2002) and entertainment (Chang et al, 2013). Second, all of the consequent constructs identified in the theoretical review presented significant relations with the intrusive advertisements. The irritation construct presented a strong correlation $r = 0.470$, and the consistency was significant ($FSN = 7238$). Thus, the positive relationship between intrusive advertisements and irritation is consolidated, a new fact that could be ques-

tioned according to some analyzed studies; both have neutral results ($R = 0.294$) (Hernandez et al., 2004), and there is a negative relation between intrusive advertisements and attitude ($r = -0.263$; $FSN = 8297$). Third, it has been observed that people in Western cultures tend to feel intrusiveness effects more strongly. This was evidenced in the stronger relationships identified between intrusive advertisements and attitude in Western cultures than in Eastern cultures. This finding strengthens the assumption that Western consumers are more indulgent and individualistic, and intrusive advertisements could disrupt their goal, thus causing even more negative feelings. Fourth, the results obtained through this meta-analysis provide a quantitative integration of the main findings related to the antecedents and consequent constructs of intrusive advertisements applied in the online context. Therefore, it provides considerable generalization, defining what is considered valid and not valid and what is known and unknown about the subject. Fifth, in the managerial area, the results could be applied to reduce the effects of intrusiveness. In this research, the results indicated that advertising messages should be geared towards informative and entertaining content. In this way, the need for segmentation policies is reinforced to direct the messages to the targeted public. Otherwise, the brand relationship may be depreciated by negative feelings evoked by the intrusiveness, such as irritation, avoidance, attitude and negative buying intention.

Why Privacy is Only Salient When not Making Actual Decisions: How Congruency Drives the Privacy Paradox

Joris Demmers, University of Amsterdam, The Netherlands

Alfred F. Zerres, University of Amsterdam, The Netherlands

Willemijn M. van Dolen, University of Amsterdam, The Netherlands

EXTENDED ABSTRACT

Although the discrepancy between consumers' privacy concerns and subsequent disclosure behavior has been well-established in previous work (Acquisti et al. 2015; Kokolakis 2015), much remains to be learned about how consumers weigh benefits and costs of sharing personal information in privacy-sensitive situations (Kokolakis 2015; Martin & Murphy 2016). In the current work we propose an updated view on privacy calculus theory, and test the notion that disclosure decisions are driven by the interaction of psychological distance of costs and benefits of disclosure and diverging mindsets under attitudinal and behavioural conditions of preference formation. Across four studies, we demonstrate that preference formation depends on congruency between one's mindset in a specific condition of preference construction and the psychological distance of benefits and costs of disclosure.

In study 1 we test whether perceived temporal and hypothetical distance differs between self-reported benefits and costs of disclosure. We exposed 115 participants to three binary disclosure choice tasks they are likely to encounter on a regular basis in daily life (accepting cookies, social login, sharing app usage data). For each situation, participants were first asked to generate as many potential consequences as possible of choosing the high disclosure option, then to indicate hypothetical and temporal distance of the generated consequences, and finally to indicate for each listed consequence the extent to which they perceived it as pro/con of the high disclosure option. Results demonstrated that across situations self-reported pros of disclosure were perceived as less temporally ($F(1,852.20) = 44.81, p < .001$) and hypothetically distant ($F(1,845.03) = 24.70, p < .001$) than cons.

In study 2 we tested how different stages in preference formation are associated with different mindsets by exposing 75 participants to either an attitudinal or behavioral preference formation condition, after which we measured their mindset using the behavioral identification form (Vallacher & Wegner 1989). Results showed that attitudinal measures of privacy preferences evoke a more abstract mindset than behavioral measures ($M_{\text{attitudinal}} = 16.86, SD = 4.21; M_{\text{behavioral}} = 14.03, SD = 5.16; F(1,74) = 6.73, p < .05$).

In study 3 we tested whether mindset affects behavioral disclosure decisions in an online setting. The mindset of 161 participants was manipulated using a goal elaboration task (Fujita et al. 2006), after which their disclosure behavior on a website was tracked. Results revealed that participants in the abstract mindset condition were less likely to choose the high disclosure options than participants in the concrete mindset condition in three subsequent situations of increasing privacy intrusiveness (cookie acceptance: 72.0% vs. 93.9%, $\chi^2(1) = 8.33, p < .01$; social login: 70.0% vs. 53.8%, $\chi^2(1) = 4.62, p < .05$; sharing phone data: 18.0% vs. 2.0%, $\chi^2(1) = 7.11, p < .01$).

In study 4 we investigated whether the effect of mindset on privacy preferences is dependent on the psychological distance of the consequences. We manipulated the mindset of 115 participants using a category/exemplar task (Fujita et al. 2006), before exposing them to a description of a usage based insurance (UBI) program of a fictional car insurance company, in which users' driving behavior is tracked via their smartphone during six months of the one year contract in exchange for a 20% discount during the other six months.

As our manipulation of consequence distance, we varied whether the discount preceded the tracking of driving behavior or vice versa. If preference formation indeed depends on congruency between mindset and psychological distance of benefits and costs of disclosure, under concrete mindset conditions people should be more inclined to disclose their personal data when the benefits are close and costs are distant, whereas under abstract mindset conditions, inclination to self-disclose should be larger (smaller) when benefits of disclosure are distant (close) and costs are close (distant). Results showed a significant interaction effect of mindset and distance on inclination to sign up for the program ($F(1,109) = 6.63, p < .05, \eta^2 = .06$). Simple effect tests showed that participants in the concrete mindset conditions were more inclined to sign up when benefits were immediate ($M_{\text{immediate benefit}} = 3.41, SD = .23; M_{\text{distant benefit}} = 2.68, SD = .21; F(1,109) = 5.58, p = .05, \eta^2 = .05$). Moreover, when costs preceded benefits, inclination to sign up was higher under abstract mindset conditions than under concrete mindset conditions ($M_{\text{abstract}} = 3.43, SD = .23; M_{\text{concrete}} = 2.68, SD = .21; F(1,109) = 5.69, p = .05, \eta^2 = .05$).

Together, these findings enhance our understanding of how consumers weigh benefits and costs of sharing personal information in privacy sensitive situations. By providing a novel explanation for the privacy paradox, we answer calls from several scholars for more research on the privacy paradox and the factors that drive privacy preferences and behavior (Martin & Murphy 2016; Peltier et al. 2009). In a time where privacy has become a currency that consumers can exchange for free access to web content, personalized services or discounts (Motiwalla et al. 2014), understanding what drives consumers' "willingness to pay" is paramount.

Reason-Product (In)compatibility: Affective and Cognitive Factors in Consumer Reasoning

Alexander DePaoli, Stanford University, USA

Uzma Khan, University of Miami, USA

Itamar Simonson, Stanford University, USA

EXTENDED ABSTRACT

Previous literature has suggested that consumers who reason about their choices make less satisfying decisions. This effect is a function of consumers making choices based on their reasons rather than based on their preferences (e.g. Wilson & Schooler, 1991; Wilson et al., 1993). We argue that this view is incomplete. While prior work largely characterizes reasons solely as rational and cognitive arguments, we posit that reasons often also take the form of arguments based in affective factors. By introducing this distinction between “cognition-based reasons” (grounded in rational evaluations) and “affect-based reasons” (grounded in feelings and emotions, not to be confused with the mere experience of affect), we illustrate that reasoning is not detrimental as a rule. Instead, post-choice satisfaction depends on whether the reasons being generated are “compatible” with the product category in question. If consumers generate reasons that align with the preference basis of a product category (i.e., cognition-based reasons in utilitarian categories or affect-based reasons in hedonic categories), then consumers will tend to choose products that align well with their preferences. In other words, unlike in previous findings where reasoning leads to the selection of less satisfying options, the use of compatible reasoning will lead consumers to choose the same types of options (and therefore be equally satisfied) as if they had simply chosen on the basis of their preferences. Only when reasoning is “incompatible” with the product category (i.e., cognition-based reasons in hedonic categories or affect-based reasons in utilitarian categories) do consumers’ choices skew toward less satisfying options. We argue that past literature has largely focused on cases of incompatibility to conclude that reasoning leads to lower satisfaction, specifically the case of cognition-based reasoning in hedonic categories, such as strawberry jams (Wilson & Schooler, 1991) or decorative wall posters (Wilson et al., 1993).

Our first goal was to validate the claim that consumers can and do reason on the basis of both cognition and affect. Therefore, 202 participants on Amazon Mechanical Turk were asked to identify an actual purchase they had recently made, and then to explain the considerations that informed their choices. Next, they self-coded their responses according to a set of 14 criteria (drawn from the literature) that mapped onto cognition-based reasoning strategies, affect-based reasoning strategies, and distracter decision-making strategies. These self-codes were submitted to a factor analysis resulting in a two factor solution which corresponded with our dichotomy of cognition-based reasons (eigenvalue=1.298) and affect-based reasons (eigenvalue=1.065). The results provide evidence that consumers can and do use both forms of reasoning when making a decision.

To test whether (in)compatibility has consequences for consumer satisfaction, we ran an experimental study using a paradigm similar to Wilson et al. (1993) in which participants chose between four decorative posters. As consumers generally perceive this product category as hedonic, we predicted that the use of cognition-based reasons would replicate past findings that reasoning leads to lower satisfaction, while the use of affect-based reasons would not reduce satisfaction. In order to observe how changes in choice behavior drive this effect, the posters were pretested such that two were seen as having relatively greater utilitarian appeal (e.g., maps of the world) and two were seen as having relatively greater hedonic ap-

peal (e.g., artistic images of the world). We divided 180 Mechanical Turk participants into three conditions: in the “cognition-based reasoning” condition, participants were asked to report their thoughts about choosing or not choosing each of the four posters; in the “affect-based reasoning” condition, they reported their feelings toward choosing or not choosing each poster; and in the “control” condition, they simply examined the products without providing any reasons. Consistent with our hypothesis, cognition-based reasoning led to lower satisfaction than no reasoning ($b = -0.94, p < .01$), but there was no difference in satisfaction when participants instead reasoned on the basis of affect ($b = -0.53, NS$). This satisfaction result was mirrored in participants’ choice behavior: there was no difference between the affect-based and control conditions ($b = -0.05, NS$), but participants asked to generate cognition-based reasons were significantly more likely to choose the relatively utilitarian posters compared to both the control and affect-based conditions ($b = 0.12, p < .05$). This change in choice behavior was found to mediate the effect of reasoning on satisfaction (bias corrected 95% CI [-0.024, -0.004]). These findings were then replicated with 150 in-lab participants using a greater variety of hedonic products and a paradigm in which participants could win the items they chose, thus increasing the incentive compatibility of the study.

Whereas the first experimental study and its replication looked only at hedonic products, this next study aimed to test the full Reason-Product (In)compatibility model using a product category that was framed as either utilitarian or hedonic. We presented 298 Mechanical Turk participants with a choice between two smoothies, a “healthy” option and a “tasty” option. These smoothies were then framed as either “healthy snacks” (utilitarian) or “deserts” (hedonic). Participants were divided into the same three reasoning conditions as before. Coding the results to look at compatibility (cognition-based/utilitarian and affect-based/hedonic) versus incompatibility (cognition-based/hedonic and affect-based/utilitarian), we find that satisfaction was no different from control under compatibility across both framing conditions ($b = 0.36, NS$) but significantly reduced under incompatibility ($b = -2.14, p < .05$). As before, these effects were driven by changes in choice behavior: a moderated mediation revealed that, under the utilitarian frame, affect-based reasons increased choice of the tasty option, which drove down satisfaction (bias corrected 95% CI [-0.411, -0.101]); while under the hedonic frame, cognition-based reasons increased choice of the healthy option, which drove down satisfaction (bias corrected 90% CI [0.006, 0.186]).

These results support the claim that reasoning does not lead to lower choice satisfaction as a rule, but as a function of incompatibility between reason types and product categories. The results have implications for literatures that look at deliberative or reason-based decision processes, as well as for marketers and salespeople aiming to maximize customer satisfaction for products that call for careful pre-purchase consideration.

Psychological Consequences of Exposure to Variability

Yu Ding, Columbia University, USA

Krishna Savani, Nanyang Technological University, Singapore

EXTENDED ABSTRACT

Greater variability is one of the defining features of the 21st century. In addition to warmer temperatures, greater variability in temperature and precipitation is one of the defining features of the climate change that the world is currently experiencing (Intergovernmental Panel on Climate Change, 2007). For example, the frequency of extreme temperature and precipitation events that are two, three or even five standard deviations beyond the long-term mean is predicted to exponentially increase over the 21st century (Coumou & Robinson, 2013; Hansen, Sato, & Ruedy, 2012; Palmer & Räisänen, 2002). Increased variability is not just restricted to climate change. The variance in average monthly crude oil prices, which consumers experience at the gas station, has increased more than six-fold in the most recent decade compared to the previous decade (Energy Information Administration, 2016). The coefficient of variation, or risk per unit return, of the US S&P500 stock index has been consistently increasing in the last 50 years (S&P, 2015) (note 1). Increased variability is an example of *silent transformations* (Jullien, 2011), processes that take place over long time spans and that go mostly unnoticed until their effects become visible.

What are some of the key impacts of increased variability? In the physical world, in times of high variability, any single negative event, however small, has the potential to severely disrupt the system (McNeil & Matear, 2008). As stated in an article on the Devonian extinction, “During ... chaotic times, any harmful events would be more disruptive than they would be in ‘normal’ periods” (Baraniuk, 2015).

Why would greater variability influence people’s psychological functioning? We suggest that lay people would generalize the above idea from the natural science domain to the social domain, believing that in times of high variability, any harmful event or behavior can be more disruptive to society than during times of low variability. In the social context, harmful behaviors are typically referred to as *unethical behaviors*, “behavior that has a harmful effect upon others and is either illegal or morally unacceptable to the larger community” (Brass, Butterfield, & Skaggs, 1998; Jones, 1991). We predicted that if people share the intuition that any harmful event can pose a greater threat to the social order under times of high variability, then *people would judge others who act unethically more harshly* during times of high variability rather than low variability. One might also propose the alternative hypothesis that in times of high variability, people might think that a wider range of behaviors are acceptable, and thus become less punitive. We test these two competing hypotheses in the present research. Given the increasingly punitive attitudes of citizens (Kury, 1999; Roberts & Hough, 2000) and increasingly punitive criminal justice systems (Pratt, Brown, & Brown, 2005; Western, 2006) in major industrialized countries in recent decades, the question of whether there is a link between variability and punitive attitudes is of both scientific and practical importance.

We theorize that the *objective variability* in weather, prices, and other domains would influence individuals through a *subjective sense of variability*. To assess the causal impact of perceived variability on behavior, we experimentally manipulate both represented and experienced variability using different methods, such as (1) showing people data drawn from distributions with the same mean but with high vs. low variance (Experiment 1), (2) giving people the appearance of high vs. low variability by altering the scale of the vertical axis in

graphical data representations (Experiments 2 and 6), and (3) leading people to experience outcomes with high vs. low standard deviation of successive differences (Experiments 3 to 5). We test whether these manipulations of perceived variability have similar effects on individuals’ punitive judgments, using diverse methods, such as scenarios (Experiments 1 to 4), economic games (Experiment 5), and support for the death penalty (Experiment 6).

Inspired by the recent prolonged droughts in the western half of the US (Ingram & Malamud-Roam, 2013), Experiment 1 tested whether people exposed to high variability in temperature would be more willing to punish a person who violates mandatory water restrictions during drought than people exposed to low variability in temperature. Participants were presented with a line graph purportedly depicting the average annual temperature across the US over the past thirty years. To manipulate perceived variability, we exposed participants to data that were generated from two different normal distributions, both with the same mean (52.9°F) but different variances (1.8°F in the low variability condition and 5.7°F in the high variability condition). Participants were asked to rate how variable they thought the temperature of the US was over the past thirty years (7-point scale ranging from *Not at all* to *Extremely*). A manipulation check confirmed that participants in the high variability condition rated the temperature to be more variable ($M \pm SD: 4.76 \pm 1.19$) than those in the low variability condition (3.17 ± 1.34) [$t(183) = 8.48, p < .001, d = 1.25$]. Participants were then asked to imagine that they were residents of a small island, which depended entirely on rainfall to supply its water needs. Participants were informed that due to a severe drought, the government has imposed mandatory water restrictions, but they witnessed their neighbor watering the lawn and washing the car. Participants were asked to rate how willing they were to report their neighbor to the police, the extent to which their neighbor should be punished, and how bad their neighbor’s behavior was (7-point scale ranging from *Not at all* to *Extremely*; $\alpha = .78$). Consistent with our predictions, participants in the high variability condition were more willing to punish their neighbor ($M \pm SD: 4.61 \pm 1.27$) than those in the low variability condition (4.01 ± 1.28) [$t(183) = 3.19, p = .002, d = .47$].

The goal of Experiment 2 was to test whether high variability in one domain would make people more willing to punish unethical behavior in general. Participants were presented with a line graph of the actual US dollar to Euro average quarterly exchange rate over the past ten years. Then participants were thereafter presented with four scenarios in which people engaged in unethical behaviors that were unrelated to exchange rates, such as cheating, committing tax fraud, stealing money, and appropriating others’ belongings (adapted from Sharma, Mazar, Alter, & Ariely, 2014). Participants in the high variability condition indicated that the unethical behaviors should be punished more harshly ($M \pm SD: 5.45 \pm .86$) than those in the low variability condition ($4.84 \pm .99$) [$t(192) = 4.59, p < .001, d = .66$].

To dissociate variability from uncertainty, Experiment 3 manipulated perceived variability while keeping uncertainty constant. Participants were asked to play 10 trials of a dice rolling game on the computer. Each dice roll was equally unpredictable—the dice could land on any one of its six sides. We manipulated the perceived variability of realized dice rolls by altering the standard deviation of successive deviations (SDSD). In the low variability conditions, subsequent dice rolls were close to previous rolls (i.e., 1, 2, 1, 2, 3,

4, 6, 5, 5, 6; $SDSD = 0.96$) whereas in the high variability condition, subsequent dice rolls were far away from previous rolls (i.e., 1, 6, 2, 5, 1, 5, 3, 6, 2, 4; $SDSD = 3.56$). The actual dice rolls were identical across condition—they were just arranged differently to manipulate perceived variability. In an external manipulation check with 199 participants, this manipulation disentangled perceived variability from perceived uncertainty. We then presented participants with 3 scenarios about people engaging in unethical behavior (adapted from Gino, Shu, & Bazerman, 2010; Sharma, Mazar, Alter, & Ariely, 2014). As predicted, participants in the high variability condition punished the unethical behaviors more harshly ($M \pm SD: 5.80 \pm .80$) than those in the low variability condition (5.38 ± 1.00) [$t(189) = 3.25, p = .001, d = .47$].

Experiment 4 tested whether non-graphical representations of variability have similar effects as graphical representations. Participants were asked to play the dice rolling game as in Experiment 3 but with two changes: participants did not receive the feedback about whether they had accurately predicted the outcome of each dice roll; and on each trial, half the participants were presented with the outcomes of the current and past rolls depicted in a graph, whereas the other half were presented with the outcomes depicted in a table. A main effect of the variability indicated that participants in the high variability condition punished the unethical behaviors more harshly ($M \pm SD: 5.77 \pm .71$) than those in the low variability condition ($5.57 \pm .74$) [$F(1, 200) = 4.00, p = .047, d = .28$]. There was neither a main effect of representation format [$F(1, 200) = .11, p = .745, d = .05$], nor an interaction between representation format and variability [$F(1, 200) = .10, p = .750$]. Thus, Experiment 4 showed that the manner in which high vs. low variability is depicted—whether in a graphical format or a tabular format—does not matter. High variability makes people more punitive in either case.

The first goal of Experiment 5 was to test whether exposure to high variability influences people's behavior, and particularly, whether it makes people more willing to punish others even at a financial cost to themselves. Second, we tested whether merely *experienced variability*, which is not with any accompanying graphs or tables, would be sufficient to make people more punitive. Third, we tested whether high variability does not merely increase punitiveness but instead make people more likely to take action, no matter if it is punishing bad behavior or rewarding good behavior. The study used a 2 (variability: high vs. low) X 2 (response type: punish self-serving behavior vs. reward altruistic behavior) mixed design, with variability manipulated as a between-participant factor and punish vs. reward trials manipulated as a within-participant factor. We used the same dice rolling manipulation in Experiment 4 but this time, did not depict the dice rolls in a graph or a table—participants simply experienced dice rolls with high vs. low standard deviation of successive differences. Participants were then asked to play a three-person strategic game with three roles: the Decider, the Receiver, and the Judge (adapted from Peysakhovich, Nowak, & Rand, 2014; Rand, 2012). The Decider received 10 bonus points and decided whether to keep all 10 points for themselves and give 0 points to the Receiver (i.e., acted in a self-serving manner), or to give 5 points to the Receiver and keep 5 points for themselves (i.e., acted altruistically). The Receiver has no choice but to accept what the Decider gives them. The Judge received 20 bonus points and was informed about the Decider's decision. If the Decider acted in a self-serving manner, the Judge could choose whether or not to give up 5 of their points to punish the Decider, who would receive a deduction of 10 points to end up with nothing. If the Decider acted altruistically, the Judge could choose whether or not to give up 5 of their points to reward the Decider, who would receive 10 additional points to end up with

a total of 15 points. Participants were informed that they would receive their cumulative points in the form of a bonus, with 10 points being equivalent to one cent. Unbeknownst to them, all participants were "randomly" assigned to the role of a Judge. They played 20 rounds, in which the Decider acted egotistically in 10 rounds and altruistically in 10 rounds. The number of times that the Judge chose to punish or reward the Decider served as our behavioral dependent measure. We separately analyzed egotistical and altruistic trials because of large mean differences in the dependent variable base rate for punish trials ($M \pm SD: 5.56 \pm 4.03$) and reward trials (7.01 ± 3.72). The dependent measure was participants' choice on each trial (0 = not to punish, 1 = to punish), and the predictor was experimental condition (0 = low variability, 1 = high variability). As predicted, participants in the high variability condition ($M \pm SD: 5.79 \pm 3.94$) punished the Decider's self-serving decisions more than those in the low variability condition (5.32 ± 4.12), $B = .84, 95\% CI [.04, 1.64], SE = .41, odds ratio = 4.26, z = 2.06, p = .039$. Another hierarchical logistic regression on the 10 altruistic trials revealed that the Judge did not reward the Decider's altruistic decisions more in the high variability condition ($M \pm SD: 7.18 \pm 3.63$) compared to the low variability condition (6.85 ± 3.80), $B = .36, 95\% CI [-.59, 1.30], SE = .48, odds ratio = .54, z = .74, p = .461$.

We tested the underline mechanism of perceived social threat in Experiment 6, using 4 items such as "Our society faces more threats right now than it has faced in the past decade". We then measured participants' support for the death penalty using 5 items (from Tam, Au, & Leung, 2008). Finally, we measured perceived control. A test of indirect effect using Preacher and Hayes's (Preacher & Hayes, 2004) PROCESS Model 4 with 5000 bootstrap resamples revealed a significant indirect effect of variability on death penalty approval through perceived societal threat ($B = .12, boot SE = .05, 95\% CI = [.03, .23], z = 2.44, p = .015$). Importantly, the variability manipulation did not influence participants' perceived control ($M \pm SD: 4.76 \pm 1.34$ in high variability condition vs. 4.56 ± 1.48 in low variability condition) [$t(522) = 1.61, p = .11, d = 0.14$], and the indirect effect of variability on support for death penalty through perceived societal threat remained significant even when perceived control was added as a covariate, $B = .12, boot SE = .05, 95\% CI = [.03, 0.23], z = 2.40, p = .016$.

Six experiments provided evidence for one psychological consequence of exposure to high variability—greater punitiveness. Experiment 1 found that participants exposed to a graph depicting high rather than low variability in temperature were subsequently more willing to punish a neighbor who wasted water despite water restrictions. Experiment 2 found that participants exposed to a graph depicting high rather than low variability in currency exchange rates were more willing to punish individuals who committed unethical acts. Experiments 3 to 5 manipulated experienced variability by presenting participants with successive dice rolls with high vs. low standard deviation of successive differences. Those exposed to high variability were more willing to punish wrongdoers in scenarios, and to punish those who acted in a self-serving manner in experimental games, even at a cost to themselves. However, high variability did not increase the rate with which people rewarded altruistic behavior. Finally, Experiment 6 identified the underlying mechanism—people exposed to high rather than low variability in precipitation perceived the society as being more threatened, and were therefore more willing to support the death penalty.

Increased variability is one of the defining features of the 21st century, yet a silent transformation whose effects would gradually unravel over time. The current research presents the first steps at

identifying how this increased variability would influence people psychologically.

Consumer Value Co-creation in Frontline Healthcare Services

Sarah Dodds, Massey University, New Zealand
Sandy Bulmer, Massey University, New Zealand
Andrew Murphy, Massey University, New Zealand

EXTENDED ABSTRACT

Consumer value co-creation is in the forefront of healthcare research and considered vital to a person's overall health outcomes and wellbeing (McCull-Kennedy et al. 2012; Sweeney et al. 2015). Despite this, little is known about "the process of value creation, when it starts, what it includes and when it ends" (Grönroos 2011, 282). This is surprising, given the growing body of literature focusing on consumer value co-creation in services (Ostrom et al. 2015), product-design and new product development (Schreier, Fuchs and Siller 2012), and healthcare (Danaher and Gallan 2016).

Previous research has uncovered important value co-creation factors that occur prior, during and beyond service interactions (Anderson and Ostrom 2015) however, there is a paucity of research on the process of value co-creation. While conceptually value co-creation is considered "an ongoing, iterative, and continuous process extending well beyond individual transactions" (Vargo and Lusch 2012, 4) there is little empirical evidence to support this. Therefore, this research explores the *dynamics* of the *interaction* between the *consumer* and the *service encounters*, within Complementary and Alternative Medicine (CAM) healthcare services, to shed light on the actual process of value co-creation and its outcomes. The primary goal of this research is to explore how CAM consumers co-create value with their CAM healthcare providers to enhance their wellbeing and achieve specific health outcomes.

This research contributes to the growing body of research on healthcare service marketing, from a consumer's perspective, in three important ways. First, we contribute to the stream of literature on frontline interactive service encounters (Rafaeli et al. 2017), by developing a conceptual framework of consumer value co-creation, that provides new and important insights into how consumers co-create value. Second, we contribute to the stream of literature on consumer value co-creation service experience (McCull-Kennedy et al. 2015) by uncovering new factors (i.e., consumers' approach) of consumer co-creation that interrelate with previously suggested aspects (practice styles). Finally, our research has important implications for healthcare service practice that can ultimately contribute to enhancing peoples' quality of life (Danaher and Gallan 2016).

The research adopted a novel three phase semi-longitudinal multiple method case study research strategy using in-depth interviews and a simplified version of the Zaltman Elicitation Technique (ZMET). Sixteen consumers, 4 male and 12 females ranging from 24 – 77 years, who used CAM healthcare services on a regular basis, participated in the semi-longitudinal study. The first phase included a face-to-face interview with each of the participants which explored the participants' experiences of CAM and where emergent themes on consumer value co-creation surfaced. The second phase involved the participants collecting or taking photographs of images that represent their experiences of CAM. These pictures and images were then discussed in a second interview utilising five of the ZMET steps (Coulter and Zaltman 1995) including storytelling, missed images, sorting task, most representative image and summary image. The third phase involved an interview that explored the process of the participant's CAM health service experience as well as gather feedback on initial analysis from the first two phases. The three phase process allowed us to explore value co-creation over time and enabled methodologi-

cal rigour by using multiple methods over multiple time periods which provided dependable data (Woodside 2010).

We propose a consumer value co-creation framework that demonstrates the value co-creation process in a service context. Fundamentally we confirm that the process is ongoing, iterative, and continuous with no absolute defined beginning or end (Vargo and Lusch 2012). We also show that consumer value co-creation occurs prior, during and beyond the service interaction (Anderson and Ostrom 2015). Importantly this research explains the dynamics of the consumer value co-creation process and how consumers co-create value in frontline services, such as CAM healthcare.

Our findings show three ways that CAM consumers co-create value including: 1) consumer healthcare approach, 2) consumer value co-creation practice styles, and 3) consumer value co-creation activities. Firstly, three consumer healthcare approaches were identified and include: 1) Reactive – consumer has a results outlook; 2) Proactive – consumer has a preventative outlook; 3) Integrative – consumer has a wellness outlook. Interestingly a proactive and integrative approach resulted in enhanced wellbeing. Secondly, three consumer value co-creation practice styles preferred by CAM consumers were identified and include: 1) Advisory – practitioner is perceived as the expert; 2) Consultative – practitioner-client relationship is perceived as collaborative; and 3) Partnership – practitioner-client relationship is perceived as relatively equal with mutual respect. Thirdly, 12 consumer value co-creation activities that consumers engage in to co-create value were identified. The activities include five within practice (e.g. co-operation with practitioner, co-producing treatment plans) and seven outside practice consumer value co-creation activities (e.g. compliance, changing lifestyle factors, building personal knowledge). Engagement in these activities was found to have a positive impact on the health outcomes and wellbeing of the CAM consumer (Sweeney et al. 2015). Importantly, our findings show that a CAM consumers' healthcare approach appears to be influenced by the consumer value co-creation practice styles and consumer value co-creation activities engaged in. In fact, we found evidence that a CAM consumer can transition from one healthcare approach to another. This transition is facilitated by the practice style of the practitioner and the consumer value co-creation activities the consumer engages in.

Our findings have important implications for healthcare practice. A positive service experience with healthcare providers has the potential to contribute to an individual's health outcomes and wellbeing (Sweeney et al. 2015). Healthcare providers and practitioners should consider the practice style/s they adopt and the potential role they have in facilitating a consumer's healthcare approach and encouraging health promoting consumer value co-creation activities. Consultative and partnership practice styles tend to produce better health outcomes for consumers because they foster client-centred, cooperative and collaborative relationships that are educational and empowering. However, more empirical research is required to generalise these findings. Consumer value co-creation is important to understand in all healthcare settings (Zainuddin et al. 2013); therefore further research is required to extend our understanding of the consumer value co-creation process found in this study in a variety of healthcare services, and ultimately other service contexts.

Tasteful Work: The Emergence of an Aesthetic Category

Pierre-Yann Dolbec, Concordia University, Canada

EXTENDED ABSTRACT

EDM is a music category that encompasses a number of different music styles, from tropical house to big room house (Magnetic 2015). Yoga is another example of a category composed of different yoga styles, such as Dharma, Power, and Hot yoga (Ertimur and Coskuner-Balli 2015). The context of this study, the aesthetic category of luxury streetwear, similarly encompasses a number of distinct styles, from street goth to goth ninja. Tastefully practicing the styles of lumped in these categories requires an understanding of different teleoaffective structures—i.e. the set of acceptable ends, orders, uses, and emotions (Schatzki 2002)—that governs the practice of taste (Arsel and Bean 2013) for each style. Yet, these different music styles are lumped together under the same category label. We have yet to understand how such a lumping happens, and what are the implications for our understanding of category emergence.

In this brief article, I make the following theoretical contributions: First, I argue that an aesthetic category is constituted of what I term “distinct-yet-related” taste regimes. These regimes are distinct as they are orchestrated by different teleoaffective structures, but related as they share a number of objects, doings, and meanings. Second, I propose four types of institutional work—circumscribing, bridging, curation, and support—that lead to the lumping of distinct-yet-related taste regimes under the same aesthetic category.

Studying how categories emerge is important as categories are structuring devices that help orchestrate markets and direct market actors’ perception, attention, and efforts (Verge and Wry 2014). When actors evaluate music artists, yoga studios, and fashion products, they refer to these categories as a basis for their evaluation (Zuckerman 1999). I draw from institutional theory and a practice-based approach to taste, to explain how this happens.

Taste is central to this research in two ways: first, it is a well-known boundary-making mechanism which is important because actors use such “conceptual distinctions... to categorize objects, people, practices” (Lamont and Molnár 2002, 168). Consequently, examining new tasteful arrangements should offer cues about the emergence of boundaries associated with these. Second, taste is at the center of the evaluation of products in aesthetic markets (Entwistle 2009; Khaire 2014). I use Arsel and Bean’s (2013) practice-based conceptualization of taste. Arsel and Bean (2013, 900) theorize that the practice of taste is orchestrated by taste regimes, “discursively constructed normative systems that orchestrate the aesthetics of practice in a culture of consumption.” I take as a starting theoretical point that in markets driven by taste, the (cultural) codes on which the understanding of categories relies (Glynn and Navis 2013) are tightly linked with the objects, doings, and meanings that are orchestrated by such normative systems.

I combine this practice-based conceptualization of taste with the concept of institutional work. Institutional work are the actions that create, maintain or disrupt the practices, understandings, and rules sustaining markets (Dolbec and Fischer 2015, based on Lawrence and Suddaby 2006). The types of institutional work I introduce are part of the everyday routines of actors in the fashion market. The accumulation of actions resulting from these four types of institutional work from a multitude of actors leads over time to the emergence of a category. I now introduce the context of this study and briefly describe my methodology.

Method

Luxury streetwear is part of the contemporary menswear market. This novel market category emerged in the mid-to-late 2000s, is used by numerous legitimate publications (such as *Elle*, *Business of Fashion*, *WWD*, and *Esquire*), has redefined menswear (Johnson 2015) and led major high fashion brands towards “a steady move ... into the streetwear market” (Reeve 2012). Albeit the translation of streetwear elements to the realm of high end fashion is nothing new, ‘luxury streetwear’ as a category that is covered by critics, catered to by designers, for which there is a wide consumer interest, and which has a strong influence on the development of menswear is novel (Johnson 2015).

I used a multi-method, longitudinal data collection approach, combining 16 in-depth semi-structured interviews, a netnography of two online forums, the forums’ archives (representing 89 threads and 190 003 posts), the archives of related fashion forums (720 posts in 30 threads), as well as archival data in the form of magazines and newspaper articles (590 articles), as well as material from category actors such as blog posts (115 pages).

My findings emerged from an iterative process moving back-and-forth between data collection, data analysis, and theorization (Spiggle 1994). As my work progressed, I started to focus on the emergence of the luxury streetwear category. I coded each type of data in light of my emergent findings to answer my research questions, using an institutional approach to categorization as my enabling theory.

Institutional Work and the Creation of New Aesthetic Market Categories

Albeit space restriction precludes a thorough analysis of this. The perceived lack of differences between these two looks for regime outsiders serves well to illustrate the distinct-yet-related aspect of these regimes. Although similar to regime outsiders, these two looks showcase the following differences for regime insiders. On the left, we have a consumer wearing a number of brands orchestrated by the goth ninja regime, mostly Rick Owens (the jacket, shorts, and sneakers). On the right, we have a consumer wearing a mixture of high fashion brands associated with the street goth regime such as Pyrex (the shorts), streetwear brand such as Supreme (the hoodie) and mainstream sportswear brands such as Nike (the sneakers). Although divergent, both of these looks highlight similar objects, such as the heavy reliance on the color black and drop-crotch shorts, as well as doings, such as the use of leggings underneath the shorts. Next, I show how four types of institutional work lead to the lumping of distinct-yet-related taste regimes under the same aesthetic category.

Circumscribing Work

Circumscribing work represents the efforts of actors that leads to the lumping of distinct-yet-related taste regimes under the same category. First, some of the media and market-knowledge generating firms lack a proper understanding of the specificities of each regimes and as a result lump them as one of the same, thereby subsuming the regimes’ differences and facilitating the creation of the category. PR executives Ella Dror and Ashley Smith, who represent some luxury streetwear brands, emphasize this point when they mention that “different ‘areas’ [of fashion]... are sometimes lazily grouped together jointly ... within fashion media” although there is “there’s an important distinction to make between” them (Johnson 2015).

For example, Esquire magazine (Deleon 2015) introduce “17 luxury sneakers brands” and presents the Adidas Y-3 ‘Qasa’ sneakers with a description mentioning “goth ninja [as] the go-to descriptor of all things dark, designer, and drapery”, while the shoe is mentioned only 10 times during the last 10 years on the web forum at the center of this taste regime, but is part of adjacent regimes (health goth and street goth). The representation of these objects and some doings as being part of the same category to less informed consumers.

A second insight is that some of these actors who are well-aware of the differences between these distinct taste regimes willingly decide to simplify their complexities and differences and choose to group them as a whole to facilitate their news narrative. For example, Jon Caramanica (2015), of the New York Times “Critical Shopper” column, clumps together brands such as Givenchy, Raf Simons, Rick Owens, and Hood by Air, to explain how “the gulf between luxury fashion and street wear has largely disappeared.” For consumers, constantly seeing these brands grouped together by knowledgeable critics and showcased with pictures of highly similar outfits can orient their sensemaking efforts towards grouping these elements as part of one and the same. Together, these two processes lead to the conflation of multiple distinct regimes that might look the same to regime outsiders into a single category. I next explain three types of institutional work that facilitate circumscribing work and lead to the emergence of an aesthetic category.

Bridging Work

Bridging work refers to the bridging of two or more existing market categories by products or market actors. It has been recognized that category hybridization is often the starting point of a category (e.g. Jensen 2010). The name of the novel category under study, ‘luxury streetwear’, emphasizes this hybridization between luxury menswear and streetwear.

In my context, Rick Owens, and especially his “Dunks” shoes, represents an early example of such bridging work. Released in 2008, these shoes have become a staple of the closet of multiple regimes under the ‘luxury streetwear’ category. Pictured in Figure 1, they exemplify well bridging work: they are at the junction of the sportswear, streetwear, and high-end menswear categories. The sportswear influences are present as the shoe was intended as his “own parody combining Puma, Nike, and Adidas motifs” (Owens in Wallace 2015). The proximity was such that Nike sued Rick Owens (Wallace 2015). The streetwear influences are found within the Rick Owens aesthetic language, with machine-wash leathers, “elegant... goth...street” (Colapinto 2008) which at the start of his career was “real popular with rockers” (Courtney Love in Colapinto 2008). Finally, these shoes are well-embedded within high-end fashion as they were, according the fashion director at Barneys, “perfectly Barneys [and] appeals to a luxury customer” (Colapinto 2008). Following the emergence of the luxury streetwear category, Rick Owens became “fashion’s most imitated designer” (La Ferla 2009).

Bridging work also contributes to the category’s evolution by facilitating its expansion and encouraging the solidification of the links between elements of distinct-yet-related regimes. An example of this is the collaborations between designers and accessible fashion brands. Through collaborations, brands and designers come together and propose products that fit within the emergent aesthetic category. These collaborations are intended to target non-regime-specific consumers, such as “the Adidas consumer” (Mellery-Pratt 2015), rather than regime insiders, extending the reach of the emerging category. Examples abound: Rick Owens and Adidas, Undercover and Nike (under “Nike Giakosu”), and Louis Vuitton and Supreme. These collaborative efforts infuse an emerging category with new products,

serve as a mechanism for established but outsider producers to enter the emergent category, and extend the reach of the category.

Curation Work

Curation work entails the selection and interpretation of elements of regimes as well as their representation through discourses and images. This facilitates the creation of linkages between elements of distinct-yet-related taste regimes and signals to a non-regime-specific audience that the elements of these regimes belong to the same aesthetic category. Examples of this are found in lookbooks and editorials of retailers, which both represent objects of distinct-yet-related regimes together and provide scripts for “grooming rituals” (McCracken 1986). This curation also happens through the brands and designers a retailer chooses to sell. Retailers that span a number of regimes help in bringing these regimes together by offering a selection of brands that span the regimes of an emerging category. For example, SSENSE, a “store and e-store’s menswear [which] buy is focused on ... luxury streetwear” (BOF 2015), distributes brands that are elements of the goth ninja regime such as Ann Demeulemeester and Rick Owens, and brands that are elements of the street goth regime such as YEEZY, Hood by Air, and Off-White. They also represent them together, visually fostering linkages between these regimes. Lastly, I discuss support work and how these facilitates the establishment of convergent elements and sensemaking efforts from external audiences.

Support Work

Support work represents the everyday efforts of actors towards the offer of knowledge and advice around elements of a regime and the tasteful performance of the taste regime. Support work is not equal for all objects, doings, and meanings and acts as an indicator of the centrality of these elements within a regime, allowing actors from the media and market-knowledge generating firms to make sense of emerging regimes more easily. An example of this is the amount of attention given to certain brands cited and talked about on regime-centric web forums. How over time the online conversations crystallized four brands which were the most important ones for the regime.

When major publications such as the New York Times cover the emergence of the ‘luxury streetwear’ category, they leverage what is the most accessible elements of a regime which then become central key elements of the emerging aesthetic category. For example, an article in GQ mentions that “Demeulemeester’s dark designs have a diehard cult following, especially amongst fashion heads who lean towards the Internet-dubbed “goth ninja” aesthetic” (Deleon 2013). Other consumer-driven content pieces use the most-mentioned brands of these web forums as well as the pictures posted on these online communities. For example, the “Goth Ninja RPG Strategy Guide Part I” thread on the widely forum Reddit took “most of the pictures ... from the Stylezeitgeist WAYWT thread” as examples (GarvinCadalance).

Discussion: Categories and Market-Level Changes

Research on markets either has assumed that marketers worked towards the creation of whole markets, as exemplified by the following quotes of articles within that research stream: “brand-mediation market creation process” (Giesler 2012, 56) and “the emergence of a new market within the motorcycle industry” (Martin and Schouten 2014, 855), or has yet to conceptually distinguish between markets and categories. Yet, in the luxury streetwear case, and although the emergence of an aesthetic category in the fashion market led to the constitution of novel designer and retailer identities as well as the

creation of a number of consumption communities and specialized media outlets, the fashion market has mostly continued its evolution following its existing logics, norms, rules, conventions, logistical infrastructure, required technical skills and competencies, pricing mechanism, and competitive space (see Martin and Schouten 2014). More, the set of institutional actors, institutional logics, types of institutional work, and institutional boundaries stayed relatively unaffected (see Dolbec and Fischer 2015). In short, based on existing conceptualizations of markets in the literature (Dolbec and Fischer 2015; Martin and Schouten 2014), a new market was not created. A new market category was. Exploring developments in markets through the lens of market categories not only offers a perspective that addresses changes in markets that are more frequent (vs. the creation of whole new markets), it also opens the door to new research perspectives.

Alcohol Consumption and Risk-Taking Behavior: An Analysis of 17-Year Data on Fatal Traffic Accidents

Ioannis Evangelidis, Bocconi University, Italy

EXTENDED ABSTRACT

Fatal traffic accidents have affected over 1.5 million people in the US during the past 17 years. Among those affected, 653,355 people have ultimately lost their lives. Police and media reports frequently mention alcohol as the leading cause of fatal traffic accidents. Indeed, academic research has found that car drivers who consumed alcohol before driving were more likely to be injured in car crashes (Connor, Norton, Ameratunga, and Jackson 2004). This result is hardly surprising as drivers who consume alcohol and then drive are more likely to exhibit impaired driving performance (e.g., Weiler et al. 2000). In this paper I demonstrate that, beyond its detrimental effect on driving performance, alcohol consumption is associated with increased risk-taking behavior as evidenced by lower restraint use rates among both drivers and occupants of vehicles.

Prior academic research supports the conjecture that alcohol consumption can increase risk-taking behavior. Lab studies have shown that experimental manipulations of alcohol consumption increase people's propensity to seek risky monetary gains (Lane, Cherek, Pietras, and Tcheremissine 2004), as well as their willingness to enter high-risk situations during a driving simulation (Burian, Liguori, and Robinson 2002). Alcohol consumption can increase risk-taking behavior because it reduces people's expectations about potential negative outcomes (Fromme, Katz, and D'Amico 1997). Further, alcohol consumption has been shown to have a detrimental effect on people's attentional processing of threat-related cues (Curtin, Patrick, Lang, Cacioppo, and Birbaumer 2001). In turn, impairments in attention to the threat cue can inhibit fear response. Finally, alcohol consumption inflates positive self-perceptions and increases overconfidence (Schweitzer and Gomberg 2001; Schweitzer and Kerr 2000; Steele and Josephs 1990). Prior research has found that people tend to report positively biased self-evaluations on traits they deem important after consuming alcohol (Banaji and Steele 1989). In the context of transportation, another example of risk-taking behavior beyond dangerous operation of the motor vehicle by its driver is restraint omission by the driver and occupants of the vehicle.

Therefore, based on the aforementioned research, assuming that alcohol consumption reduces people's expectations about potential negative outcomes (such as a potential traffic accident), I hypothesized that both the driver and occupants of a vehicle will be less likely to be restrained after consuming alcohol. I empirically tested my hypothesis in a large dataset of fatal traffic accidents that occurred in the US between January 1, 1999 and December 31, 2015. I derived individual-level data about victims of fatal traffic accidents from the Fatality Analysis Reporting System (FARS) of the National Highway Traffic and Safety Administration (NHTSA). The dataset comprised the following variables: age, race, and type (i.e., driver, occupant, pedestrian, or pedalcyclist) of the person, as well as whether the person was using a restraint (i.e., seat belt or helmet), whether the person was tested for alcohol (including the result of the test), and whether the person was killed.

First, I regressed whether the individual died in the traffic accident on the result of his or her alcohol test. Not surprisingly, a larger percentage of people that tested positive for alcohol died compared to the percentage of people that tested negative. Importantly, I regressed whether the individual was using a restraint on the result of his or her alcohol test and found a significant effect of alcohol consumption. While the majority of victims that tested negative for

alcohol were using a restraint, less than a third of the victims that tested positive were restrained. Note that all effects remain highly significant when controlling for the age, race, and type of the victim. Importantly, the relationship between alcohol and restraint use is significant for both drivers and occupants of the vehicle, as well as for people of all ages and races.
