Preface

Ayelet Gneezy
University of California San Diego, Rady School of Management

Vlad Griskevicius
University of Minnesota, Carlson School of Management

Patti Williams
University of Pennsylvania, Wharton School

The 48th Annual Conference of the Association for Consumer Research (ACR) was held at the Manchester Grand Hyatt Hotel in San Diego, California, October 26-29, 2017. This volume reports the presentations made in special sessions, competitive paper sessions, working paper sessions, forums and videography track.

The conference attracted over 1300 participants and an all-time record of 700 acceptances from 1132: 104 special session (62.5% accepted), 557 competitive papers (46.3% accepted), 444 working papers (80% accepted), 9 forums (100% accepted) and 13 films.

We thank our generous sponsors: The Wharton Marketing Department, The Carlson School of Management at the University of Minnesota, The Rady School of Management at the University of California San Diego, Baruch College, Schulich School of Business at York University, Journal of Consumer Research, Journal of Consumer Psychology, Journal of the Association for Consumer Research, Qualtrics, the Marketing Science Institute, the Wharton Risk Management and Decision Process Center, and the Wharton Baker Retailing Center.

Many wonderful people worked tirelessly to help us. We thank our Program Committee, Competitive Paper Reviewers, Working Paper Reviewers, and Videography Track Reviewers. Special thanks to Andy Gershoff and Maura Scott (Working Paper Chairs), Lisa Cavanaugh and Keith Wilcox (Forums Chairs), Marylouise Caldwell and Joonas Rokka (Videography Track Chairs), Lauren Block and Markus Giesler (Doctoral Symposium Chairs), and Jennifer Argo and Derek Rucker (Early Career Mentoring Workshop). Many thanks also to our excellent Associate Editors: Keisha Cutright, Giana Eckhardt, Amber Epp, Jennifer Escalas, Jeff Galak, Ashlee Humphreys, Selin Malkoc, Brent McFerran, Cassie Mogilner-Homes, Karen Page Winterich, Hilke Plassmann, Aner Sela, Suzanne Shu, Zakary Tormala, and Bram Van den Bergh.

Special thanks to ACR Executive Director Rajiv Vaidyanathan, Conference Manager Paula Rigling, conference administrative assistant Mikhala Stutzman, website guru Aleksey Cherfas, and ACR Executive Assistant Brenda Monahan.

Last but not least, thank you Margaret Campbell, ACR President 2017, for offering us the opportunity to organize the ACR conference and for all the help and support she provided throughout the process.

Ayelet Gneezy, University of California San Diego, Rady School of Management

Vlad Griskevicius, University of Minnesota, Carlson School of Management

Patti Williams, University of Pennsylvania, Wharton School

2017 Conference Co-Chairs

Conference Committees & Reviewers

PRESIDENT

Margaret C. Campbell, University of Colorado, Boulder, USA

CONFERENCE CHAIRS

Ayelet Gneezy, University of California San Diego, USA
Vlad Griskevicius, University of Minnesota, USA
Patti Williams, University of Pennsylvania, USA

ASSOCIATE EDITORS

Keisha Cutright, Duke University, USA
Giana Eckhardt, Royal Holloway University of
London
Amber Epp, University of Wisconsin - Madison,
USA
Jennifer Escalas, Vanderbilt University, USA
Jeff Galak, Carnegie Mellon University, USA

Ashlee Humphreys, Northwestern University, USA
Selin Malkoc, The Ohio State University, USA
Brent McFerran, Simon Fraser University, Canada
Cassie Mogilner-Homes, University of California
Los Angeles, USA
Karen Page Winterich, Pennsylvania State
University, USA

Hilke Plassmann, INSEAD, France
Aner Sela, University of Florida, USA
Suzanne Shu, University of California Los Angeles,
USA
Zakary Tormala, Stanford University, USA
Bram Van den Bergh, Erasmus University
Rotterdam, The Netherlands

FORUMS (PERSPECTIVES, ROUNDTABLES, & WORKSHOPS) CHAIRS

Lisa Cavanaugh, University of British Columbia, Canada

Keith Wilcox, Columbia University, USA

WORKING PAPER CHAIRS

Andrew Gershoff, University of Texas at Austin, USA

Maura Scott, Florida State University, USA

DOCTORAL SYMPOSIUM CHAIRS

Lauren Block, Baruch College, USA

Markus Giesler, York University, Canada

MID-CAREER MENTORSHIP PROGRAM CHAIRS

Jennifer Argo, University of Alberta, Canada

Derek Rucker, Northwestern University, USA

VIDEOGRAPHY CHAIRS

Marylouise Caldwell, University of Sydney, Australia

Joonas Rokka, Emlyon Business School, France

PROGRAM COMMITTEE

Pankaj Aggarwal, University of Toronto, Canada
On Amir, University of California San Diego, USA

Table of Contents

Preface	iii
Conference Committees & Reviewers	iv

2017 ACR Presidential Address

Consumer Research Contribution: Love It or Leave It	1
<i>Margaret C. Campbell, University of Colorado, Boulder, USA</i>	

2017 ACR Fellow Addresses

Consumer Research in the Age of Neoliberal Discontinuities: Incitements to Intellectual Edgework	6
<i>Craig J. Thompson, University of Wisconsin, USA</i>	
The Future History of Consumer Research: Will the Discipline Rise to the Opportunity?	17
<i>Jagdish Sheth, Emory University, USA</i>	
Our Collective Journey	21
<i>Debbie MacInnis, University of Southern California, USA</i>	

Special Session Summaries

It's Not About What You Do, But How You Do It: The Impact of Technology-Enabled Modalities	25
<i>Chair: Melanie S. Brucks, Stanford University, USA</i>	
Paper #1: When Touch Interfaces Boost Consumer Confidence: The Role of Instrumental Need for Touch	
<i>Johannes Hattula, Imperial College Business School, UK</i>	
<i>Walter Herzog, WHU-Otto Beisheim School of Management, Germany</i>	
<i>Ravi Dhar, Yale University, USA</i>	
Paper #2: How the Kinesthetic Properties of a Response Scale Affect Judgment	
<i>Melanie S. Brucks, Stanford University, USA</i>	
<i>Jonathan Levav, Stanford University, USA</i>	
Paper #3: Understanding the Psychology of Smartphone Usage: The Adult Pacifier Hypothesis	
<i>Shiri Melumad, Columbia University, USA</i>	
<i>Michel T. Pham, Columbia University, USA</i>	
Paper #4: When Speech Reflects Mind: Natural Paralinguistic Cues in Voice Convey Presence of Mind	
<i>Juliana Schroeder, University of California, USA</i>	
<i>Alicea J. Lieberman, University of California, USA</i>	

To Be, or Not to Be (Me)? Role of Identity in Creating Custom Products	31
<i>Chair: Jennifer K. Lee, University of Southern California, USA</i>	
Paper #1: Making Meaning: How Consumers Build Their Identity Into Their Own Creative Outcomes	
<i>Kelly B. Herd, University of Connecticut, USA</i>	
<i>Page Moreau, University of Wisconsin, USA</i>	
Paper #2: Being Unique Makes Us Similar: How Example Designs and Their Creators Influence How We Customize	
<i>Jennifer K. Lee, University of Southern California, USA</i>	
<i>Kristin Diehl, University of Southern California, USA</i>	
<i>Lisa A. Cavanaugh, University of British Columbia, Canada</i>	
Paper #3: When “Valentino” Gets Personal: Is Customization the New Luxury?	
<i>Silke Hieke, WU Vienna University of Economics and Business, Austria</i>	
<i>Page Moreau, University of Wisconsin, USA</i>	
<i>Martin Schreier, WU Vienna University of Economics and Business, Austria</i>	
Paper #4: How Cultural Identity Drives the Effectiveness of Mass Customization	
<i>Emanuel de Bellis, University of St. Gallen, Switzerland</i>	
<i>Christian Hildebrand, University of Geneva, Switzerland</i>	
<i>Kenichi Ito, Nanyang Technological University, Singapore</i>	
<i>Andreas Herrmann, University of St. Gallen, Switzerland</i>	
<i>Bernd Schmitt, Columbia University, USA</i>	
Risk Perception and Control in Consumer Healthcare Decisions	36
<i>Chair: Yimin Cheng, Monash University, Australia</i>	
Paper #1: Stigmatized Risk Factors in Health Messages: The Defensive Influence of Moral Identity	
<i>Chethana Achar, University of Washington, USA</i>	
<i>Lea Dunn, University of Washington, USA</i>	
<i>Nidhi Agrawal, University of Washington, USA</i>	
Paper #2: The Burden of Social Proof	
<i>Preyas Desai, Duke University, USA</i>	
<i>Mary Frances Luce, Duke University, USA</i>	
<i>Janet Schwartz, Tulane University, USA</i>	
Paper #3: The Protestant Work Ethic and Preference for Natural Healthcare	
<i>Yimin Cheng, Monash University, Australia</i>	
<i>Anirban Mukhopadhyay, HKUST, Hong Kong</i>	
Paper #4: Unbiased Presentation of Options in Preference-based Medical Decisions	
<i>Tatiana Barakshina, University of Illinois at Chicago, USA</i>	
<i>Alan Malter, University of Illinois at Chicago, USA</i>	
<i>Dimitrios Mastrogiannis, MD, University of Illinois at Chicago, USA</i>	
The Ups and Downs of Uncertainty:	
Novel Antecedents and Consequences of Uncertainty in Consumer Judgment and Choice	42
<i>Chair: M. Yavuz Acikalin, Stanford University, USA</i>	
Paper #1: Guilt-Free Indulgence at the Cost of Certainty	
<i>M. Yavuz Acikalin, Stanford University, USA</i>	
<i>Uzma Khan, University of Miami, USA</i>	
<i>Baba Shiv, Stanford University, USA</i>	
Paper #2: Know Thyself Financially: How Financial Self-Awareness Benefits Consumers	
<i>Nivriti Chowdhry, Rice University, USA</i>	
<i>Utpal Dholakia, Rice University, USA</i>	
Paper #3: The Persuasive Advantage of Change	
<i>Daniella Kupor, Boston University, USA</i>	
<i>Jayson S. Jia, University of Hong Kong, Hong Kong</i>	
<i>Zakary L. Tormala, Stanford University, USA</i>	
Paper #4: How does risk sound? The Fit Between Harsh (Soft) Names and Uncertainty (Certainty)	
<i>Keith Botner, Lehigh University, USA</i>	
<i>Arul Mishra, University of Utah, USA</i>	
<i>Himanshu Mishra, University of Utah, USA</i>	

Impacts of Language on Consumer Behavior 47
Chairs: Ernest Baskin, Saint Joseph's University, USA
Peggy Liu, University of Pittsburgh, USA
Paper #1: The Unexpected Implications of Product Descriptors on Product Perceptions
Ernest Baskin, St. Joseph's University, USA
Peggy Liu, University of Pittsburgh, USA
Paper #2: Make Your Tweety Bird Tweet: Use of Textual Paralanguage in Brand and Spokescharacter Online Communications
Andrea Webb Luangrath, University of Iowa, USA
Joann Peck, University of Wisconsin – Madison, USA
Victor A. Barger, University of Wisconsin – Whitewater, USA
Paper #3: Do you e-care? Analyzing the Impact of Dialogue Dynamics in Online Service Resolutions
Francisco Villarroel Ordenes, University of Massachusetts-Amherst, USA
Dhruv Grewal, Babson, USA
Paper #4: Asymmetry in Emotion Language Is Consequential For Evaluative Judgments
Chiara Longoni, Boston University, USA
Geeta Menon, New York University, USA

Wisdom from Words 52
Chairs: Jonah Berger, University of Pennsylvania, USA
Grant Packard, Wilfrid Laurier University, Canada
Paper #1: Differentiation and Cultural Success
Jonah Berger, University of Pennsylvania, USA
Grant Packard, Wilfrid Laurier University, Canada
Paper #2: How do Authenticity Meanings Evolve? A Longitudinal Analysis of Music Album Reviews
Matteo Corciolani, University of Pisa, Italy
Kent Grayson, Northwestern University, USA
Ashlee Humphreys, Northwestern University, USA
Paper #3: When Words Sweat: Identifying Signals for Loan Default in the Text of Loan Applications
Oded Netzer, Columbia University, USA
Alain Lemaire, Columbia University, USA
Michal Herzenstein, University of Delaware, USA
Paper #4: Make America Tweet Again: A Dynamic Analysis of Micro-blogging During the 2016 U.S. Republican Primary Debates
Ron Berman, University of Pennsylvania, USA
Colman Humphrey, University of Pennsylvania, USA
Shiri Melumad, Columbia University, USA
Robert Meyer, University of Pennsylvania, USA

Brand Journeys: Exploring the Boundaries of Consumer-Brand Relationships 57
Chair: Ignacio Luri, University of Arizona, USA
Paper #1: The Game Day Experience: Consumers, Brands and Brand Celebrations
Tonya Williams Bradford, University of California, Irvine, USA
John F. Sherry, Jr., University of Notre Dame, USA
Paper #2: Follow the Code: The Impact of Linguistic Brand Codes on Brand Journeys
Ignacio Luri, University of Arizona, USA
Hope J. Schau, University of Arizona, USA
Paper #3: Disruptive Self-Brand Play: The Izikhothane Journey
Liezl-Marié Kruger, University of Pretoria, South Africa
Robing A. Coulter, University of Connecticut, USA
Kelly D. Martin, Colorado State University, USA
Paper #4: Where Do We Go From Here? Consumer-Brand Relationships After Brands do Bad
Luciana Velloso, York University, Canada
Eileen Fisher, York University, Canada

Improving Consumer Well-Being Through Meaning vs Happiness	63
<i>Chair: Rhia Catapano, Stanford University, USA</i>	
Paper #1: Meaningful Consumption Provides Long Lasting Benefits at a High Cost	
<i>Erin Percival Carter, University of Colorado Boulder, USA</i>	
<i>Lawrence Williams, University of Colorado Boulder, USA</i>	
Paper #2: Buying Time Promotes Happiness	
<i>Ashley Whillans, Harvard University, USA</i>	
<i>Elizabeth Dunn, University of British Columbia, Canada</i>	
<i>Michael Norton, Harvard University, USA</i>	
Paper #3: Moments that Last: Meaningfulness Slows Happiness Decay	
<i>Rhia Catapano, Stanford University, USA</i>	
<i>David Hardisty, University of British Columbia, Canada</i>	
<i>Jennifer Aaker, Stanford University, USA</i>	
Paper #4: Taking Vacation Increases Meaning at Work	
<i>Colin West, UCLA, USA</i>	
<i>Cassie Mogilner, UCLA, USA</i>	
<i>Sanford DeVoe, UCLA, USA</i>	
Intended and Unintended Signals from Conspicuous Actions	68
<i>Chair: Adelle Yang, National University of Singapore, Singapore</i>	
Paper #1: Prosocial Consequences of Counterfeits: Using Counterfeit Luxury Goods Can Lead to Prosocial Behavior	
<i>Jinjie Chen, University of Minnesota, USA</i>	
<i>Deborah Roedder John, University of Minnesota, USA</i>	
<i>Yajin Wang, University of Maryland, USA</i>	
<i>Courtney A. Carufel, UnitedHealthcare, USA</i>	
Paper #2: When Modesty Pays	
<i>Shalena Srna, University of Pennsylvania, USA</i>	
<i>Alixandra Barasch, New York University, USA</i>	
<i>Deborah Small, University of Pennsylvania, USA</i>	
Paper #3: Promoting Conspicuous Generosity: Justifying the “Brag” by Removing the Choice	
<i>Adelle X. Yang, National University of Singapore, Singapore</i>	
<i>Christopher K. Hsee, University of Chicago, USA</i>	
Paper #4: Prosocial Referral Rewards	
<i>Rachel Gershon, Washington University in St. Louis, USA</i>	
<i>Cynthia Cryder, Washington University in St. Louis, USA</i>	
<i>Leslie John, Harvard University, USA</i>	
A New Look into Intrinsic and Extrinsic Motivations of Variety-seeking.	74
<i>Chairs: Nicole Y. Kim, University of Maryland, USA</i>	
<i>Liang Huang, University of Arizona, USA</i>	
Paper #1: When Variety Isn’t Life’s Spice: The Impact of Implicit Self-theories and Preference Forecasting on Anticipated Consumption Variety	
<i>Joshua J. Clarkson, University of Cincinnati, USA</i>	
<i>Joshua T. Beck, University of Oregon, USA</i>	
<i>Mary C. Murphy, Indiana University, USA</i>	
Paper #2: The Impact of Pain of Payment on Variety Seeking Behavior	
<i>Liang Huang, University of Arizona, USA</i>	
<i>Rafay Siddiqui, The Hong Kong Polytechnic University, Hong Kong</i>	
<i>Anastasiya Pocheptsova Ghosh, University of Arizona, USA</i>	
Paper #3: When Experience is Costly: How Choice Variety Signals Expertise and Status	
<i>Nicole Y. Kim, University of Maryland, USA</i>	
<i>Yajin Wang, University of Maryland, USA</i>	
Paper #4: Assortment Variety and Perceived Expertise	
<i>Aner Sela, University of Florida, USA</i>	
<i>Siân Morgan, University of Florida, USA</i>	
<i>Michal Maimaran, Northwestern University, USA</i>	

Spending and Construing Time to Enhance Well-Being	79
<i>Chair: Jordan Etkin, Duke University, USA</i>	
Paper #1: Goal Conflict Encourages Work and Discourages Leisure	
<i>Jordan Etkin, Duke University, USA</i>	
<i>Aimee Chabot, Duke University, USA</i>	
Paper #2: Control over Time Predicts Greater Life Satisfaction among Millionaires	
<i>Ashley Whillans, Harvard University, USA</i>	
<i>Paul Smeets, Maastricht University, The Netherlands</i>	
<i>Rene Bekkers, VU Amsterdam, The Netherlands</i>	
<i>Michael Norton, Harvard University, USA</i>	
Paper #3: To Thrive or to Suffer at the Hand of Busyness: How Lay Theories of Busyness Influence Psychological Empowerment and Volunteering	
<i>Mahdi Ebrahimi, University of Houston, USA</i>	
<i>Melanie Rudd, University of Houston, USA</i>	
<i>Vanessa M. Patrick, University of Houston, USA</i>	
Paper #4: Rethinking Time for Well-Being	
<i>Hal E. Hershey, UCLA, USA</i>	
<i>Cassie Mogilner Holmes, UCLA, USA</i>	
<i>Jennifer Aaker, Stanford University, USA</i>	
Effects of Resource Scarcity on the Consumer Decision Making Process	85
<i>Chair: Linying (Sophie) Fan, Hong Kong Polytechnic University, Hong Kong</i>	
Paper #1: Resource Scarcity Spurs Effortful Pursuit of Rewards	
<i>Linying (Sophie) Fan, Hong Kong Polytechnic University, Hong Kong</i>	
<i>Zhu Meng, Johns Hopkins University, USA</i>	
<i>Yuwei Jiang, Hong Kong Polytechnic University, Hong Kong</i>	
Paper #2: Childhood Resource Scarcity and Planning Fallacy	
<i>Chiraag Mittal, Texas A&M University, USA</i>	
<i>Juliano Laran, University of Miami, USA</i>	
<i>Vladas Griskevicius, University of Minnesota, USA</i>	
Paper #3: When Thoughts of “Having Less” Promote the Desire to Become One’s Best: Reminders of Resource Scarcity Increase the Desire for Self-Improvement	
<i>Kelly Goldsmith, Vanderbilt University, USA</i>	
<i>Ali Tezer, Université de Montréal, Canada</i>	
<i>Caroline Roux, Concordia University, Canada</i>	
Paper #4: Too Constrained to Converse: Financial Constraints Reduce Word-of-Mouth	
<i>Anna Paley, The Ohio State University, USA</i>	
<i>Stephanie M. Tully, University of Southern California, USA</i>	
<i>Eesha Sharma, Dartmouth College, USA</i>	
Willing and Wanting versus Impervious and Resisting: When Consumers Filter In and Out Motivational Cues	91
<i>Chair: Kathleen D. Vohs, University of Minnesota, USA</i>	
Paper #1: Motivated Construals: How Goals Implicitly Change Object Meaning	
<i>Melissa Ferguson, Cornell University, USA</i>	
<i>Szu-chi Huang, Stanford University, USA</i>	
<i>Ying Zhang, Peking University, USA</i>	
<i>Ayelet Fishbach, University of Chicago, USA</i>	
Paper #2: The Effect of Implicit Theories on Progress or Proficiency in Self-Learning	
<i>Lama Lteif, Baruch College, CUNY, USA</i>	
<i>Ozge Aybat, Penn State Harrisburg, USA</i>	
<i>Pragya Mathur, Baruch College, CUNY, USA</i>	
<i>Lauren Block, Baruch College, CUNY, USA</i>	
Paper #3: Images Change Implicit Attitudes More than Text: Evidence from Corrective Advertising Attempts	
<i>Olivier Trendel, Grenoble Ecole de Management, France</i>	
<i>Kathleen D. Vohs, University of Minnesota, USA</i>	
<i>Marc Mazodier, Nottingham University, China</i>	
Paper #4: When Less is More: Counter-Attitudinal Appeals are More Effective When They Are Ignored	
<i>Steven K. Dallas, New York University, USA</i>	
<i>Gavan J. Fitzsimons, Duke University, USA</i>	

Forward Looking Consumers and Firms: Biases and Economic Consequences 96
Chairs: Liz Friedman, Yale University, USA
Joy Lu, University of Pennsylvania, USA
Paper #1: Putting Duration in Durable Goods: Length of Ownership Neglect in Consumer Choice
Liz Friedman, Yale University, USA
Ravi Dhar, Yale University, USA
Shane Frederick, Yale University, USA
Paper #2: Planning to Binge: How Consumers Choose to Allocate Time to View Sequential Versus Independent Media Content
Joy Lu, University of Pennsylvania, USA
Uma R. Karmarkar, Harvard University, USA
Vinod Venkatraman, Temple University, USA
Paper #3: Don't Fear the Meter: How Time Limits Bias Employment Contract Choices
Indranil Goswami, University at Buffalo, USA
Oleg Urminsky, University of Chicago, USA
Paper #4: Variance Neglect in Consumer Search
Nicholas Reinholtz, University of Colorado Boulder, USA
Daniel M. Bartels, University of Chicago, USA
Jonathan Levav, Stanford University, USA
Oded Netzer, Columbia University, USA

New Insights into the Psychology of Product Assortments 101
Chairs: Sarah Wei, University of Alberta, Canada
Tao Tao, The Chinese University of Hong Kong, Hong Kong
Paper #1: Choice vs. Search Mindsets and Consumers' Assortment Size Preference
Benedict G.C. Dellaert, Erasmus University Rotterdam, The Netherlands
Gerald Häubl, University of Alberta, Canada
Sarah Wei, University of Alberta, Canada
Paper #2: The Role of Abundance Salience in Consumers' Assortment Preference
Yangjie Gu, HEC Paris, France
Yuechen Wu, University of Maryland, USA
Paper #3: The Influences of Randomly Displaying a Set of Products on Shopping Evaluations
Tao Tao, The Chinese University of Hong Kong, Hong Kong
Leilei Gao, The Chinese University of Hong Kong, Hong Kong
Paper #4: Global Context: Extremeness Aversion in a Dual Context Setting
Ryan Hamilton, Emory University, USA
Oleg Urminsky, University of Chicago, USA
Gülen Serial-Abi, University of Bocconi, Italy

Influences of Social Comparison on Consumer Judgment and Choice 107
Chairs: Chelsea Galoni, Northwestern University, USA
Aparna A. Labroo, Northwestern University, USA
Paper #1: When Consumer Rivalry Reduces Desire for Innovation
Chelsea Galoni, Northwestern University, USA
Aparna A. Labroo, Northwestern University, USA
Paper #2: News Consumption on Social Media Induces Distinctiveness Seeking
Jaeyeon Chung, Columbia University, USA
Gita V. Johar, Columbia University, USA
Paper #3: The Price of Faith: Religion's Role in the Endowment Effect
Vivian Qin, Duke University, USA
Gavan J. Fitzsimons, Duke University, USA
Richard Staelin, Duke University, USA
Paper #4: Trickle-Round Signals: When Low Status Becomes High
Silvia Bellezza, Columbia University, USA
Jonah Berger, University of Pennsylvania, USA

Givers and Recipients: When and Why They Don't See Eye-to-Eye	112
<i>Chair: Julian Givi, Carnegie Mellon University, USA</i>	
Paper #1: Sentimental Value And Gift Giving: Givers' Fears of Getting it Wrong Prevents Them From Getting it Right	
<i>Julian Givi, Carnegie Mellon University, USA</i>	
<i>Jeff Galak, Carnegie Mellon University, USA</i>	
Paper #2: Sometimes It's Okay to Give a Blender: Giver and Recipient Preferences for Hedonic and Utilitarian Gifts	
<i>Elanor F. Williams, Indiana University, USA</i>	
<i>Emily Rosenzweig, University of Tulane, USA</i>	
Paper #3: The Quality Versus Quantity Trade-Off: A Dual-Risk Account For How Choices For The Self Versus Others Differ	
<i>Peggy Liu, University of Pittsburgh, USA</i>	
<i>Ernest Baskin, St. Joseph's University, USA</i>	
Paper #4: When Giving Thanks Means More: The Impact of Publicly Versus Privately Sharing Gratitude in Gift-Giving	
<i>Lauren Grewal, University of Pittsburgh, USA</i>	
<i>Mary Steffel, Northeastern University, USA</i>	
<i>Dhruv Grewal, Babson College, USA</i>	
Human-Object Relationships:	
How Consumers Interact with Analog and Digital Things in Analog and Digital Worlds	117
<i>Chair: Donna L. Hoffman, George Washington University, USA</i>	
Paper #1: Ambiguity, Ambivalence and Fragility in Human-Object Relationships	
<i>D. Matthew Godfrey, University of Arizona, USA</i>	
<i>Linda L. Price, University of Oregon, USA</i>	
<i>Robert F. Lusch, University of Arizona, USA</i>	
Paper #2: Being Dumb in the Age of Smart: Analogue Object Entanglements	
<i>Mariam Humayun, York University, USA</i>	
<i>Russell Belk, York University, USA</i>	
Paper #3: Enhancing Wellness: Melding Humans and Objects with Common Purpose	
<i>Hope Jensen Schau, University of Arizona, USA</i>	
<i>Ignacio Luri, University of Arizona, USA</i>	
Paper #4: Consumer-Object Relationship Styles in the Internet of Things	
<i>Donna L. Hoffman, George Washington University, USA</i>	
<i>Thomas P. Novak, George Washington University, USA</i>	
The Time of Our Lives: Examining Utility from Experiential Consumption Over Time	123
<i>Chairs: Alixandra Barasch, New York University, USA</i>	
<i>Gabriela Tonietto, Washington University, USA</i>	
Paper #1: The Material-Experiential Asymmetry in Discounting: When Experiential Purchases Lead to More Impatience	
<i>Joseph K. Goodman, The Ohio State University, USA</i>	
<i>Selin A. Malkoc, The Ohio State University, USA</i>	
<i>Mosi Rosenboim, Ben-Gurion University of the Negev, Israel</i>	
Paper #2: Underappreciating the Thrill of the Familiar	
<i>Ed O'Brien, University of Chicago, USA</i>	
<i>Michael Kardas, University of Chicago, USA</i>	
Paper #3: The Influence of Creating Event Markers on Experienced Time and Enjoyment	
<i>Gabriela Tonietto, Washington University in St. Louis, USA</i>	
<i>Alixandra Barasch, New York University, USA</i>	
Paper #4: Compromised Experiences, Compromised Relationships	
<i>Ximena Garcia-Rada, Harvard University, USA</i>	
<i>Michael I. Norton, Harvard University, USA</i>	
<i>Rebecca Ratner, University of Maryland, USA</i>	

Eyes on the Prize: When Rewards Hurt vs. Help Motivation 129
Chairs: Kaitlin Woolley, Cornell University, USA
Ayelet Fishbach, University of Chicago, USA
Paper #1: How “Effort Balancing” Explains Dynamic Effects of Incentives on Motivation
Indranil Goswami, University of Buffalo, USA
Oleg Urminsky, University of Chicago, USA
Paper #2: Donate to Be a Hero: Social Power Moderates the Effect of Incentives on Donation
Zheshuai Yang, National University of Singapore, Singapore
Yan Zhang, National University of Singapore, Singapore
Yih Hwai Lee, National University of Singapore, Singapore
Paper #3: Immediate Rewards Render Activities More Intrinsically Motivating
Kaitlin Woolley, Cornell University, USA
Ayelet Fishbach, University of Chicago, USA
Paper #4: Journey Takes You Beyond the Destination: The Use of Linguistic Metaphor in Sustaining Post Goal-Attainment Motivation
Szu-chi Huang, Stanford University, USA
Jennifer Aaker, Stanford University, USA

Space and Consumption: Using Lefebvre to Examine an Interplay of Multi-Level Forces in the Consumptive Process of Space 135
Chair: Annetta Grant, Queen’s University, Canada
Paper #1: Home is Where the Tension Is? Examining the Cultural Complexity of Creating the Space of Home
Annetta Grant, Queen’s University, Canada
Jay M. Handelman, Queen’s University, Canada
Paper #2: Home, Contested Home à la Home Sweet Home: Understanding Legitimacy in a Midcentury Modern Taste Regime
Ankita Kumar, University of Wisconsin, USA
Craig J. Thompson, University of Wisconsin, USA
Paper #3: How Multiple Stakeholders Produce Branded Urban Spaces
Rodrigo B. Castilhos, Unisinos Business School, Brazil
Paper #4: Representations of Space: Methodological Tensions in Spatial Consumer Research
D. Matthew Godfrey, University of Arizona, USA
Melanie Wallendorf, University of Arizona, USA

What Makes for Impactful Reviews?
New Perspectives on Factors Driving the Influence of Online Reviews 140
Chairs: Hristina Nikolova, Boston College, USA
Alexander Bleier, Boston College, USA
Paper #1: In Mobile We Trust: How Mobile Reviews Influence Consumers’ Purchase Intentions
Lauren Grewal, University of Pittsburgh, USA
Andrew T. Stephen, University of Oxford, UK
Paper #2: Telling Both Sides of the Story: The Role of Risk in the Perceived Helpfulness of Online Reviews
Ann Schlosser, University of Washington, USA
Abhishek Borah, University of Washington, USA
Paper #3: How the Interplay of Consumption Mode and Time Delay Influences the Persuasiveness of Online Reviews
Hristina Nikolova, Boston College, USA
Alexander Bleier, Boston College, USA
Rebecca W. Hamilton, Georgetown University, USA
Paper #4: Relationship Norms in Response to Online Reviews in P2P Exchanges
Raji Srinivasan, University of Texas at Austin, USA
Nailya Ordabayeva, Boston College, USA
Wayne Hoyer, University of Texas at Austin, USA

The Social Context of Consumption 146

Chairs: Kelley Gullo, Duke University, USA

Peggy Liu, University of Pittsburgh, USA

Paper #1: Are My Dog's Treats Making Me Fat? The Effects of Choices Made for Others on Subsequent Choices for the Self

Kelley Gullo, Duke University, USA

Peggy Liu, University of Pittsburgh, USA

Lingrui Zhou, Duke University, USA

Gavan Fitzsimons, Duke University, USA

Paper #2: Mindful Mimicry of Food Choices: Vertically versus Horizontally Differentiated Attributes

Peggy Liu, University of Pittsburgh, USA

Brent McFerran, Simon Fraser University, Canada

Kelly Haws, Vanderbilt University, USA

Paper #3: The Social Path To Satiation: Satisfying Desire Vicariously via Other's Consumption

Yanping Tu, University of Florida, USA

Ayelet Fishbach, University of Chicago, USA

Paper #4: Suit Up and Shop: Social Confidence and the Influence of Consumer Attire on Purchasing Decisions

Keisha Cutright, Duke University, USA

Shalena Srna, University of Pennsylvania, USA

Adriana Samper, Arizona State University, USA

When Low Control and Uncertainty Do Good 152

Chair: Bora Min, University of Southern California, USA

Paper #1: I Can Do More with My Time, but Less with My Money: The Role of Control on Resource Efficacy Perceptions

Jerry Han, University of Texas at Austin, USA

Adriana Samper, Arizona State University, USA

Andrew Gershoff, University of Texas at Austin, USA

Paper #2: Novelty as Risk and Opportunity: Opposite Effects of Low Personal Control and Perceived Unpredictability on Novelty Seeking

Bora Min, University of Southern California, USA

Norbert Schwarz, University of Southern California, USA

Paper #3: The Surprising Effects of Attitude Certainty on Advocacy and Advocacy Receptivity

Lauren Cheatham, University of Hawaii, USA

Zakary Tormala, Stanford University, USA

Paper #4: Desire to Learn About the Category Sparks Preference for Authenticity

Sharlene He, Northwestern University, USA

Gregory S. Carpenter, Northwestern University, USA

Kent Grayson, Northwestern University, USA

How Can I Help You (or Not)?

Choice Architecture and Consumers' Decision Appraisal in Product Assortments 158

Chairs: Liz Friedman, Yale University, USA

Nahid Ibrahim, University of Alberta, Canada

Paper #1: The Dual Impact of Personalized Product Recommendations on Consumers' Subjective Appraisal of Their Product Choices

Gerald Häubl, University of Alberta, Canada

Benedict G. C. Dellaert, Erasmus University Rotterdam, The Netherlands

Murat Usta, Dalhousie University, Canada

Nahid Ibrahim, University of Alberta, Canada

Paper #2: Purchase Quantity Decisions and Default Effects in Assortments

Liz Friedman, Yale University, USA

Jennifer Savary, University of Arizona, USA

Ravi Dhar, Yale University, USA

Paper #3: Mixing It Up: The Influence of Unsystematic Product Arrangements on Assortment Processing, Exploratory Search, and Product Choice

Maik Walter, University of St. Gallen, Switzerland

Christian Hildebrand, University of Geneva, Switzerland

Gerald Häubl, University of Alberta, Canada

Andreas Herrmann, University of St. Gallen, Switzerland

Paper #4: Label Structure, Processing Disfluency, and Consumers' Responses to Credence-Labeled Foods

Jeffrey R. Parker, Georgia State University, USA

Omar Rodriguez-Vila, Georgia Institute of Technology, USA

Ryan Hamilton, Emory University, USA

Iman Paul, Georgia Institute of Technology, USA

Sundar Bharadwaj, University of Georgia, USA

How Do Humans Interact with Machines? Implications for Experience and Identity. 164

Chair: Eugina Leung, Erasmus University Rotterdam, The Netherlands

Paper #1: Object Experience and Object Consumers

Donna Hoffman, George Washington University, USA

Thomas Novak, George Washington University, USA

Paper #2: Automation and Identity

Eugina Leung, Erasmus University Rotterdam, The Netherlands

Gabriele Paolacci, Erasmus University Rotterdam, The Netherlands

Stefano Puntoni, Erasmus University Rotterdam, The Netherlands

Paper #3: Touch-Sensitive Computing Interfaces as Drivers of Experiential Consumption

Christian Hildebrand, University of Geneva, Switzerland

Johnathan Levav, Stanford University, USA

Paper #4: The Soul and the Machine: Humanlike Machines and Machinelike Humans

Russell Belk, York University, USA

Consumer Financial Decision Making Research with Impact 170

Chairs: Quentin André, INSEAD Europe Campus, France

Nicholas Reinholtz, University of Colorado Boulder, USA

Paper #1: Does Access to FICO Scores Influence Financial Behavior? Evidence from a Field Experiment with Student Loan Borrowers

Tatiana Homonoff, New York University, USA

Rourke O'Brien, University of Wisconsin-Madison, USA

Abigail Sussman, University of Chicago, USA

Paper #2: Consumption Responses to Pay Frequency: Evidence from "Extra" Paychecks

Yiwei Zhang, University of Chicago, USA

Paper #3: Can Food Stamps Reduce Food Consumption? The Unintended Consequences of Restricted-Use Funds on Budgeting Decisions

Quentin André, INSEAD Europe Campus, France

Nicholas Reinholtz, University of Colorado-Boulder, USA

John G. Lynch Jr., University of Colorado-Boulder, USA

Paper #4: Shopping Behavior of Food Stamps Users: The Role of Decision Conflict

Dinesh Gauri, University of Arkansas, USA

Yu Ma, McGill University, Canada

Manoj Thomas, Cornell University, USA

Creativity Triggers: The Influence of Novel Antecedents on Creative Cognition.	175
<i>Chairs: Anoosha Izadi, University of Houston, USA</i>	
<i>Lidan Xu, University of Illinois at Urbana-Champaign, USA</i>	
Paper #1: Physically Short, Mentally Flexible? Exploring the Relationship between Stature and Creativity	
<i>Lei Jia, Ohio State University, USA</i>	
<i>Xiaojing Yang, University of Wisconsin-Milwaukee, USA</i>	
<i>Xiaoyan Deng, Ohio State University, USA</i>	
Paper #2: Can Busyness Influence Consumer Creativity?	
<i>Luke Nowlan, University of Miami, USA</i>	
<i>Juliano Laran, University of Miami, USA</i>	
Paper #3: The Way the Wind Blows: How Direction of Airflow Influences Creativity	
<i>Anoosha Izadi, University of Houston, USA</i>	
<i>Melanie Rudd, University of Houston, USA</i>	
<i>Vanessa M. Patrick, University of Houston, USA</i>	
Paper #4: Can Conspicuous Consumption Experience Affect Consumer Creativity?	
<i>Lidan Xu, University of Illinois at Urbana-Champaign, USA</i>	
<i>Ravi Mehta, University of Illinois at Urbana-Champaign, USA</i>	
<i>Jennifer Argo, University of Alberta, Canada</i>	
 360 Degrees of Social Influence:	
How Others' Presence, Attitudes, and Behaviors Change the Way We Think and Behave	181
<i>Chairs: Rachel Meng, Columbia University, USA</i>	
<i>Youjung Jun, Columbia University, USA</i>	
Paper #1: Perceived Social Presence Reduces Fact-Checking	
<i>Youjung Jun, Columbia University, USA</i>	
<i>Rachel Meng, Columbia University, USA</i>	
<i>Gita V. Johar Columbia University, USA</i>	
Paper #2: Seeing the World Through Others' Lens: When Shared Experience Boosts Novelty	
<i>Yanping Tu, University of Florida, USA</i>	
<i>Yang Yang, University of Florida, USA</i>	
<i>Ayelet Fishbach, University of Chicago, USA</i>	
Paper #3: When Moderation Fosters Persuasion: The Persuasive Power of Deviatory Reviews	
<i>Daniella Kupor, Boston University, USA</i>	
<i>Zakary Tormala, Stanford University, USA</i>	
Paper #4: Social Influence, Habits, and Disrupted Performance Environments	
<i>Dean Eckles, Massachusetts Institute of Technology, USA</i>	
<i>Christos Nicolaidis, Massachusetts Institute of Technology, USA</i>	
<i>Sinan Aral, Massachusetts Institute of Technology, USA</i>	
 Temporal Dynamics of Consumption Experiences	186
<i>Chairs: Sarah Wei, University of Alberta, Canada</i>	
<i>Masha Ksendzova, Boston University, USA</i>	
Paper #1: The Primacy of Experience: Comparing the Contributions of Anticipation, Experience, and Memory to Total Utility	
<i>Masha Ksendzova, Boston University, USA</i>	
<i>Michael I. Norton, Harvard University, USA</i>	
<i>Carey K. Morewedge, Boston University, USA</i>	
Paper #2: Consuming Regardless of Quality: Consumers Overestimate the Impact of Quality Differences on the Amount Consumed	
<i>Tom Meyvis, New York University, USA</i>	
<i>Heeyoung Yoon, New York University, USA</i>	
Paper #3: The Imminent-End Effect: How the Approaching End of an Experience Affects Enjoyment	
<i>Sarah Wei, University of Alberta, Canada</i>	
<i>Gerald Häubl, University of Alberta, Canada</i>	
Paper #4: The Role of Holistic Processing on Enjoyment During Simultaneous Consumption	
<i>Robert Smith, Ohio State University, USA</i>	
<i>Joseph P. Redden, University of Minnesota, USA</i>	

Prosociality With Impact: Examining and Overcoming Roadblocks to Effective Altruism	191
<i>Chairs: Masha Ksendzova, Boston University, USA</i>	
<i>Grant E. Donnelly, Harvard University, USA</i>	
Paper #1: “My Donation is More Helpful if I Benefit”: Personal Gains Signal Impact of Prosocial Spending	
<i>Masha Ksendzova, Boston University, USA</i>	
<i>Remi Trudel, Boston University, USA</i>	
Paper #2: Narrow Bracketing in Ethical Trade-Offs	
<i>Christopher Olivola, Carnegie Mellon University, USA</i>	
<i>Silvia Saccardo, Carnegie Mellon University, USA</i>	
Paper #3: Overcoming Overhead Aversion with Choice	
<i>Elizabeth A. Keenan, Harvard University, USA</i>	
<i>Silvia Saccardo, Carnegie Mellon University, USA</i>	
<i>Ayelet Gneezy, University of California San Diego, USA</i>	
Paper #4: Giving to Receive: Moral Self-Regard and Positive Affect Increase when Giving Time but not Money	
<i>Grant E. Donnelly, Harvard University, USA</i>	
<i>Oliver Hauser, Harvard University, USA</i>	
<i>Francesca Gino, Harvard University, USA</i>	
The Curious Case of Risk and Uncertainty	196
<i>Chairs: Luxi Shen, Chinese University of Hong Kong, Hong Kong</i>	
<i>Kristen Duke, University of California, San Diego, USA</i>	
Paper #1: Risks, Interrupted: The Effect of an Interruption on Decisions of Risk	
<i>Daniella Kupor, Boston University, USA</i>	
<i>Wendy Liu, University of California, San Diego, USA</i>	
<i>On Amir, University of California, San Diego, USA</i>	
Paper #2: Changing How Probability is Represented Attenuates the Reflection Effect	
<i>Kristen Duke, University of California, San Diego, USA</i>	
<i>Daniel Mochon, Tulane University, USA</i>	
<i>On Amir, University of California, San Diego, USA</i>	
Paper #3: Not All Money is Created Equal: Neural Signature of Mental Accounting	
<i>Feng Sheng, University of Pennsylvania, USA</i>	
<i>Ming Hsu, University of California, Berkeley, USA</i>	
<i>Baba Shiv, Stanford University, USA</i>	
Paper #4: Field Experiments on the Effectiveness of Uncertain Incentives	
<i>Luxi Shen, Chinese University of Hong Kong, Hong Kong</i>	
<i>Christopher K. Hsee, University of Chicago, USA</i>	
<i>Joachim Talloen, Carnegie Mellon University, USA</i>	
On the Unique Effects of Self-Connected Brands	200
<i>Chairs: Kristen Lane, University of Arizona, USA</i>	
<i>Jennifer Savary, University of Arizona, USA</i>	
Paper #1: When Ignorance is No Longer Bliss: Seeking Threatening Information About Self-Relevant Brands	
<i>Kristen Lane, University of Arizona, USA</i>	
<i>Jennifer Savary, University of Arizona, USA</i>	
<i>Jesper H. Nielsen, University of Arizona, USA</i>	
Paper #2: Brand Complexity’s Impact on Product Liking and Consumer’s Sense of Self	
<i>Maria A. Rodas, University of Minnesota, USA</i>	
<i>Carlos J. Torelli, University of Illinois at Urbana-Champaign, USA</i>	
Paper #3: The Influence of Incidental Tokenism on Attitudes Toward Stereotype-Typifying Products	
<i>Iman Paul, Georgia Institute of Technology, USA</i>	
<i>Jeffrey R. Parker, Georgia State University, USA</i>	
<i>Sara Loughran Dommer, Georgia Institute of Technology, USA</i>	
Paper #4: Brands as Mitigators of Physical Pain: The Mediating Role of Social Connectedness	
<i>Martin Reimann, University of Arizona, USA</i>	
<i>Sandra Nuñez, Tecnológico de Monterrey, Mexico</i>	
<i>Raquel Castaño, Tecnológico de Monterrey, Mexico</i>	

The Effect of Morality in the Marketplace	206
<i>Chairs: Corinne Kelley, Florida State University, USA</i>	
<i>Sara Baskentli, Baruch College, the City University of New York, USA</i>	
Paper #1: Reducing Peak-Hour Subway Crowding: Investigating the Effectiveness of Financial Disincentives	
<i>Leonard Lee, National University of Singapore, Singapore</i>	
<i>Xiuping Li, National University of Singapore, Singapore</i>	
<i>Catherine Yeung, Chinese University of Hong Kong, China</i>	
Paper #2: The Ambassador Effect: A Pre-Commitment Technique to Increase Consumer Prosocial Behavior and Loyalty	
<i>Corinne Kelley, Florida State University, USA</i>	
<i>Maura L. Scott, Florida State University, USA</i>	
<i>Martin Mende, Florida State University, USA</i>	
Paper #3: Consumer Reactions to CSR: Morality Based Differences	
<i>Sara Baskentli, Baruch College, the City University of New York, USA</i>	
<i>Shuili Du, University of New Hampshire, USA</i>	
<i>Sankar Sen, Baruch College, the City University of New York, USA</i>	
<i>CB Bhattacharya, European School of Management and Technology, Germany</i>	
Paper #4: How Beliefs about the Universal Potential for Ideal Body Weight Influence Fairness Perceptions of Price Discrimination	
<i>Shaobo Li, Nanyang Technological University, Singapore</i>	
<i>Michail D. Kokkoris, WU Vienna University of Economics and Business, Austria</i>	
<i>Krishna Savani, Nanyang Technological University, Singapore</i>	
 Changing For The Better: When And Why People Fail (or Succeed) to Engage in Beneficial Behavior Change	 212
<i>Chair: Alicea J. Lieberman, University of California, San Diego, USA</i>	
Paper #1: The Mere Cost Effect	
<i>Alicea J. Lieberman, University of California, San Diego, USA</i>	
<i>On Amir, University of California, San Diego, USA</i>	
<i>Ziv Carmon, INSEAD, Singapore</i>	
Paper #2: Can NFL Players be Viewed as Victims? How Camera Angles Can Increase Sympathy Towards Athletes	
<i>Kirk Kristofferson, Arizona State University, USA</i>	
<i>Andrea C. Morales, Arizona State University, USA</i>	
<i>Brent McFerran, Simon Fraser University, USA</i>	
<i>Darren W. Dahl, University of British Columbia, Canada</i>	
Paper #3: Good People Don't Need Medication	
<i>Sydney E. Scott, University of Pennsylvania, USA</i>	
<i>Justin F. Landy, University of Chicago, USA</i>	
Paper #4: Sustaining Sustainable Hydration: The Importance of Aligning Information Cues to Motivate Long Term Consumer Behavior Change	
<i>Eleanor Putnam-Farr, Yale University, USA</i>	
<i>Rhavi Dhar, Yale University, USA</i>	
 Who's Looking Where? Social Comparisons and Consumer Behavior	 217
<i>Chair: Julian Givi, Carnegie Mellon University, USA</i>	
Paper #1: Experiential Purchases Trigger More Envy Than Material Purchases do	
<i>Ruoyun Lin, University Of Tübingen & Leibniz-Institut Für Wissensmedien, Germany</i>	
<i>Niels Van De Ven, Tilburg University, The Netherlands</i>	
<i>Sonja Utz, University Of Tübingen & Leibniz-Institut Für Wissensmedien, Germany</i>	
Paper #2: Two's Company, Three's a Crowd: Givers' Oversensitivity to Other Givers' Gifts	
<i>Julian Givi, Carnegie Mellon University, USA</i>	
<i>Jeff Galak, Carnegie Mellon University, USA</i>	
<i>Christopher Olivola, Carnegie Mellon University, USA</i>	
Paper #3: The Inequity Penalty: Consumers Show Heightened Sensitivity to Inequitable Treatment in The Context of Apology	
<i>Emily Rosenzweig, Tulane University, USA</i>	
<i>Clayton Critcher, University of California Berkeley, USA</i>	
Paper #4: How Comparison Standards Influence Tradeoffs Between Absolute And Relative Outcomes	
<i>Sokiente Dagogo-Jack, Boston College, USA</i>	
<i>Joshua Beck, University of Oregon, USA</i>	

You, Me, or We? Conceptualizing and Testing Consumer Choices for Others 222
Chairs: Eugenia Wu, University of Pittsburgh, USA
Sarah G. Moore, University of Alberta, Canada
Paper #1: A Conceptual Framework for Understanding Consumer Choices for Others
Peggy Liu, University of Pittsburgh, USA
Steven Dallas, New York University, USA
Gavan Fitzsimons, Duke University, USA
Paper #2: People Make More Informed Choices for Others
Evan Polman, University of Wisconsin-Madison, USA
Paper #3: The Spirit of Giving: Impure Altruism in Funeral Contracts
Ximena Garcia-Rada, Harvard University, USA
Sarah C. Whitley, Boston University, USA
Dan Ariely, Duke University, USA
Carey K. Morewedge, Boston University, USA
Paper #4: Wine for the Table: Self-Construal and Choosing for Large Versus Small Groups
Sarah G. Moore, University of Alberta, Canada
Eugenia Wu, University of Pittsburgh, USA
Gavan Fitzsimons, Duke University, USA

Possessions and Wellbeing: Increasing, Sustaining and Sharing Happiness 228
Chair: Jingshi (Joyce) Liu, HKUST, Hong Kong
Paper #1: My Favorite Thing: How Special Possessions can Increase Subjective Wellbeing
Jingshi (Joyce) Liu, HKUST, Hong Kong
Amy N. Dalton, HKUST, Hong Kong
Anirban Mukhopadhyay, HKUST, Hong Kong
Paper #2: Satisfying Inherent Preferences to Promote Sustainable Happiness
Yanping Tu, University of Florida, USA
Christopher Hsee, University of Chicago, USA
Xilin Li, University of Chicago, USA
Paper #3: When Consumers Prefer to Give Material Gifts instead of Experiences1: The Role of Social Distance
Joseph K. Goodman, The Ohio State University, USA
Sarah Lim, Cornell University, USA
Paper #4: Losing Our Most Special Possession: The Unexpected Positivity of Dying
Amelia Goranson, University of North Carolina at Chapel Hill, USA
Ryan Ritter, University of Illinois at Urbana-Champaign, USA
Adam Waytz, Northwestern University, USA
Michael I. Norton, Harvard University, USA
Kurt Gray, University of North Carolina at Chapel Hill, USA

This Looks, Feels, and Smells Healthy:
Multi-Sensory Tools to Encourage Healthy Consumption 233
Chair: Dipayan Biswas, University of South Florida, USA
Paper #1: The Primacy of “What” Over “How Much”: How Type and Quantity Shape Healthiness Perceptions of Food Portions
Peggy Liu, University of Pittsburgh, USA
Kelly Haws, Vanderbilt University, USA
Karen Scherr, Duke University, USA
Joseph Redden, University of Minnesota, USA
James Bettman, Duke University, USA
Gavan Fitzsimons, Duke University, USA
Paper #2: Some Like it Hot: The Effect of Serving Temperature on Perceived Caloric Content and Intent to Purchase Complementary Food
Sara Baskentli, Baruch College, CUNY, USA
Lauren Block, Baruch College, CUNY, USA
Maureen Morrin, Temple University, USA
Paper #3: Unpacking Self-Control: When More Categories Lead to Lower Calorie Budgets
Miaolei (Liam) Jia, National University of Singapore, Singapore
Aradhna Krishna, University of Michigan, USA
Xiuping Li, National University of Singapore, Singapore
Paper #4: The Smell of Healthy Choices: The Paradoxical Effects of Ambient Scent on Children’s and Adults’ Food Choices
Dipayan Biswas, University of South Florida, USA
Courtney Szocs, Portland State University, USA

The Darker Side of Giving:

Exploring Implicit Motives that Negatively Shape Prosocial Behavior 238

Chair: Coby Morvinski, Interdisciplinary Center Herzliya, Israel

Paper #1: Goal Proximity, Social Information, and Giving: When Norms Backfire

*Matt Lupoli, UC San Diego, USA
Coby Morvinski, Interdisciplinary Center Herzliya, Israel
On Amir, UC San Diego, USA*

Paper #2: Exalted Purchases or Tainted Donations? The Effects of Product Incentives on Charitable Giving

*Jennifer Savary, University of Arizona, USA
Charis Li, University of Florida, USA
and George E. Newman, Yale University, USA*

Paper #3: Opting In to Prosocial and Standard Incentives

*Daniel Schwartz, University of Chile, Chile
Elizabeth A. Keenan, Harvard University, USA
Alex Imas, Carnegie Mellon University, USA
and Ayelet Gneezy, UC San Diego, USA*

Paper #4: The Value of Sacrifice - Relative Evaluation of Prosocial Behavior

*Gil Peleg, Ben-Gurion University, Israel
Oded Lowengart, Ben-Gurion University, Israel
Danny Shapira, Ben-Gurion University, Israel*

Beyond the Negative Consequences of Crowding:

New Psychological Processes and Behavioral Outcomes 243

Chair: Ying Ding, Renmin University of China, China

Paper #1: The Influence of Social Crowding on Creativity

*Ahreum Maeng, University of Kansas, USA
Robin J. Tanner, University of Wisconsin Madison, USA
Kaiyang Wu, University of Wisconsin, Madison, USA*

Paper #2: The Upside of Social Crowding on Consumer Product Preference

*Ying Ding, Renmin University of China, China
Meng Zhu, Johns Hopkins University, USA
Echo Wen Wan, University of Hong Kong, China*

Paper #3: The Impact of Crowding on Calorie Consumption

*Stefan J. Hock, George Mason University, USA
Rajesh Bagchi, Virginia Tech, USA*

Paper #4: Social Crowding versus Spatial Crowding: Differential Influences on Customers' Preference for Anthropomorphized Self-Service Technologies

*Lili Wenli Zou, The Chinese University of Hong Kong, Shenzhen, China
Echo Wen Wan, University of Hong Kong, China
Chi Kin (Bennett) Yim, University of Hong Kong, China*

Illusions of Diagnosticity 248

Chair: Aner Sela, University of Florida, USA

Paper #1: Seeing the Self in Choices: How Intuition Creates Attitude Certainty

*Sam Maglio, University of Toronto, Canada
Taly Reich, Yale University, USA*

Paper #2: How Self-Control Shapes Inferences from Choice

*Aner Sela, University of Florida, USA
Jonah Berger, University of Pennsylvania, USA
Joshua Kim, University of Florida, USA*

Paper #3: Not All Bad Apples Spoil the Bunch: Order Effects on the Evaluation of Groups

*Janina Steinmetz, Utrecht University, The Netherlands
Maferima Toure-Tillery, Northwestern University, USA
Ayelet Fishbach, University of Chicago, USA*

Paper #4: What Two Wrongs Make Alright: Examining the Psychological Factors Underlying the Tendency to Temper Judgments of Intoxicated People

*Kelly Goldsmith, Northwestern University, USA
Hal E. Hershfield, UCLA, USA
Chelsea Galoni, Northwestern University, USA*

How Past, Present, and Expected Future Resource Scarcity Shapes Decision Making for One’s Present and Future Wellbeing. 253
Chairs: Danit Ein-Gar, Tel-Aviv University, Israel
Caroline Roux, Concordia University, Canada
Paper #1: Early-life Scarcity, Life Expectancy, and Decision-Making
Chiraag Mittal, Texas A&M University, USA
Vladas Griskevicius, University of Minnesota, USA
Paper #2: The Food Scarcity Heuristic: People Overestimate the Caloric Content of Scarce Foods
Julio Sevilla, University of Georgia, USA
Anthony Salerno, University of Cincinnati, USA
Paper #3: Acting on Information: Reminders of Resource Scarcity Promote Adaptive Behavior and Flexible Thinking
Kelly Goldsmith, Northwestern University, USA
Caroline Roux, Concordia University, Canada
Anne Wilson, Harvard University, USA
Paper #4: I Don’t Have Now, But I Will Make Sure I Have Later; Saving for the Future Under Resource Scarcity Mindset
Danit Ein-Gar, Tel-Aviv University, Israel
Liat Levontin, Israel Institute of Technology, Israel
Angela Y Lee, Northwestern University, USA

New Insights on the Role of Aesthetics in Consumer Behavior 258
Chairs: Martin Reimann, University of Arizona, USA
C. Clark Cao, University of Arizona, USA
Paper #1: Say It or Show It: Logo Aesthetics and Consumer-Brand Relationship Development
Samuel Carter Morgan, University of Miami, USA
Tatiana Fajardo, Florida State University, USA
Claudia Townsend, University of Miami, USA
Paper #2: Meaningfulness versus Happiness: The Psychological Impact of High and Low Art
Henrik Hagtvædt, Boston College, USA
Kathleen D. Vohs, University of Minnesota, USA
Paper #3: Muji versus Maharaja: When (and Why) Minimalist versus Maximalist Design Differentially Influence Consumer Self-Brand Connection
Ngoc (Rita) To, University of Houston, USA
Vanessa M. Patrick, University of Houston, USA
Paper #4: Beauty and Control in Collecting: How Desire for Control Drives the Aesthetic Pursuit of Complete Collections
C. Clark Cao, University of Arizona, USA
Merrie Brucks, University of Arizona, USA
Martin Reimann, University of Arizona, USA

The Role of Authenticity in Consumer Behavior 264
Chairs: Katherine M. Crain, Duke University, USA
Michail D. Kokkoris, WU Vienna University of Economics and Business, Austria
Paper #1: The Entity-Referent Correspondence Framework of Authenticity
Julie Guidry Moulard, Louisiana Tech University, USA
Randle D. Raggio, University of Richmond, USA
Judith Anne Garretson Folse, Louisiana State University, USA
Paper #2: The Curse of the Original: When Product Change Undermines Authenticity
Rosanna K. Smith, University of Georgia, USA
George E. Newman, Yale University, USA
Ravi Dhar, Yale University, USA
Paper #3: Signal with Cost: When and Why Identity Signals Are Perceived to Be Authentic
Katherine M. Crain, Duke University, USA
James R. Bettman, Duke University, USA
Mary Frances Luce, Duke University, USA
Paper #4: Self-controlled but Not Myself: When Restraint versus Indulgence Undermines Consumers’ Authenticity and Decision Satisfaction
Michail D. Kokkoris, WU Vienna University of Economics and Business, Austria
Erik Hoelzl, University of Cologne, Germany
Carlos Alós-Ferrer, University of Cologne, Germany

It is All in the Pitch: New Insights into How the Framing of a Charitable Appeal Influences Giving 270

Chair: Anthony Salerno, University of Cincinnati, USA

Paper #1: Charitable Giving to Teachers with the Same Name: An Implicit Egotism Field Experiment

*Kurt P. Munz, New York University, USA
Minah H. Jung, New York University, USA
Adam L. Alter, New York University, USA*

Paper #2: Giving to Versus on Behalf of: Charitable Gift Requests Lead to Less Generous Giving

*Adriana Samper, Arizona State University, USA
Cindy Chan, University of Toronto, Canada
Ryan Hamilton, Emory University, USA*

Paper #3: “You Saved a Life”: How Past Donation Use Increases Donor Reactivation via Impact and Warm Glow

*Edlira Shehu, University of Southern Denmark, Denmark
Michel Clement, Universität Hamburg, Germany
Karen P. Winterich, Pennsylvania State University, USA
Ann-Christin Langmaack, Universität Hamburg, Germany*

Paper #4: Prevention versus Treatment: How Negative Emotion and Charitable Appeal Affect Donation Behavior

*Tatiana Fajardo, Florida State University, USA
Anthony Salerno, University of Cincinnati, USA*

Depends on Your Frame of Mind:

The Wide-Ranging Effects of Framing on Judgments, Decisions, and Behaviors 276

Chairs: Michael O’Donnell, University of California, Berkeley, USA

Alice Moon, Disney Research, USA

Paper #1: Elicitation Dependent Preference Reversals Over Consumer Goods

*Michael O’Donnell, University of California, Berkeley, USA
Ellen R.K. Evers, University of California, Berkeley, USA*

Paper #2: Attribute Matching Increases Confidence

*Hannah Perfecto, Washington University in St. Louis, USA
Jeff Galak, Carnegie Mellon University, USA
Joseph P. Simmons, University of Pennsylvania, USA
Leif D. Nelson, University of California, Berkeley, USA*

Paper #3: Psychological Framing as an Effective Approach to Real-life Persuasive Communication

*Sandra Matz, University of Cambridge, USA
Michal Kosinski, Stanford University, USA
David Stillwell, University of Cambridge, USA
Gideon Nave, University of Pennsylvania, USA*

Paper #4: Choosing or Creating? Framing Choices as Design Processes Increases Perceived Customization of Products

*Alice Moon, Disney Research, USA
Maarten Bos, Disney Research, USA*

Your Money or Your Time: How Consumers Perceive and Respond to

Constraints and Tradeoffs in Money and Time 281

Chairs: Christopher Y. Olivola, Carnegie Mellon University, USA

John J. Han, Carnegie Mellon University, USA

Yana Litovsky, Carnegie Mellon University, USA

Paper #1: Consumers Overestimate Others’ Willingness to Pay AND Wait for Goods: New Findings and Insights Concerning the “X-Effect” Bias

*Christopher Y. Olivola, Carnegie Mellon University, USA
John J. Han, Carnegie Mellon University, USA*

Paper #2: Subjective Resource Deprivation: Consumers Feel More Constrained For Spare Resources Than Similar Others

*Jonathan Z. Berman, London Business School, UK
Nazli Gurdamar, London Business School, UK*

Paper #3: The Resource Focus Effect Nudging Consumer Preferences in Time-Money Tradeoffs

*Yana Litovsky, Carnegie Mellon University, USA
Christopher Y. Olivola, Carnegie Mellon University, USA*

Paper #4: How Do Wealth and Time Horizon Affect Investors’ Risk Tolerance? Evidence from the Field

Ethan Pew, Stony Brook University, USA

Nonconscious Attention and Imagery: Impact on Perception and Preference 286
Chairs: Zachary Estes, Bocconi University, Italy
Aradhna Krishna, University of Michigan, USA
Paper #1: Rapid Evidence Accumulation during Brand Choice: An Eye-tracking Analysis
Rik Pieters, Tilburg University, The Netherlands
Tulin Erdem, New York University, USA
Ana Martinovici, Tilburg University, The Netherlands
Paper #2: Eye Buy: Attentional Scope Affects Product Choice via Visual Exploration
Mathias Streicher, University of Innsbruck, Austria
Oliver Büttner, University of Duisburg-Essen, Germany
Zachary Estes, Bocconi University, Italy
Paper #3: Communicating a Promise of Change: Visual Steps Enhance Process Imagery
Luca Cian, University of Virginia, USA
Aradhna Krishna, University of Michigan, USA
Chiara Longoni, Boston University, USA
Paper #4: The Effect of Visual Cues on the Sense of Completeness
Miaolei (Liam) Jia, National University of Singapore, Singapore
Aradhna Krishna, University of Michigan, USA
Xiuping Li, National University of Singapore, Singapore

Me, Myself, and My Variety: Exploring the Relationship Between Variety and the Self 291
Chairs: Kelley Gullo, Duke University, USA
Jacqueline Rifkin, Duke University, USA
Paper #1: How Variety in Self-Expression Undermines Self-Continuity
Jacqueline Rifkin, Duke University, USA
Jordan Etkin, Duke University, USA
Paper #2: Variety Counts: How Variety is Perceived in the Presence of Self-Regulatory Goals
Hoori Rafieian, Drexel University, USA
Yanliu Huang, Drexel University, USA
Barbara E. Kahn, University of Pennsylvania, USA
Paper #3: Get on My Level: Power and Differential Patterns of Attribute-Level Variety Seeking
Jillian Hmurovic, University of Pittsburgh, USA
J. Jeffrey Inman, University of Pittsburgh, USA
Paper #4: Does Variety-Seeking Vary by Time of Day?
Kelley Gullo, Duke University, USA
Jonah Berger, University of Pennsylvania, USA
Jordan Etkin, Duke University, USA
Bryan Bollinger, Duke University, USA

Salience and Consumer Decision-Making 297
Chairs: Milica Mormann, Southern Methodist University, USA
Evan Weingarten, University of Pennsylvania, USA
Paper #1: The Influence of Number Format on Consumer Attention
Marisabel Romero, Colorado State University, USA
Adam W. Craig, University of Kentucky, USA
Anand Kumar, University of South Florida, USA
Milica Mormann, Southern Methodist University, USA
Paper #2: Perceptual and Cognitive Salience and their Effects on Product Valuations
Evan Weingarten, University of Pennsylvania, USA
J. Wesley Hutchinson, University of Pennsylvania, USA
Paper #3: Promotion Emotion: The Salience of Restrictions vs. Rewards in Framing a Deal
Priya Raghurir, New York University, USA
Jeff Inman, University of Pittsburgh, USA
Kirk Wakefield, Baylor University, USA
Paper #4: How Tradeoff Framing Impacts Attribute Focus and Shifts Choices
Minzhe Xu, University of Florida, USA
Oleg Urminsky, University of Chicago, USA

Understanding the Use of Online Reviews and Recommendations in Consumer Judgment and Decision-Making	302
<i>Chair: Elizabeth C. Webb, Columbia University, USA</i>	
Paper #1: The Drivers and Downstream Consequences of the J-Shaped Distribution of Consumer Online Reviews	
<i>Verena Schoenmueller, Columbia University, USA</i>	
<i>Oded Netzer, Columbia University, USA</i>	
<i>Florian Stahl, University of Mannheim, Germany</i>	
Paper #2: Using Reviews to Determine Preferences: How Variance in Customer-Generated Reviews Affects Choice	
<i>Elizabeth C. Webb, Columbia University, USA</i>	
<i>Itamar Simonson, Stanford University, USA</i>	
Paper #3: “Don’t Tell Me What to Do!” Shoppers Rely Less on Consumer Reviews for Experiential than Material Purchases	
<i>Hengchen Dai, Washington University in St. Louis, USA</i>	
<i>Cindy Chan, University of Toronto, Canada</i>	
<i>Cassie Mogilner, UCLA, USA</i>	
Paper #4: Consumers and Managers Reject (Superior) Algorithms Because They Fail to Compare Them to the (Inferior) Alternative	
<i>Berkeley J. Dietvorst, University of Chicago, USA</i>	
When Modern Consumers Face Moral Violations	307
<i>Chair: Stephanie Lin, Singapore Management University, Singapore</i>	
Paper #1: Explaining Moralized Opposition to Genetically Modified Food in the U.S. and Europe	
<i>Sydney Scott, Washington University in St. Louis, USA</i>	
<i>Yoel Inbar, University of Toronto, Canada</i>	
<i>Paul Rozin, University of Pennsylvania, USA</i>	
Paper #2: The First-Mover Authentic Advantage: How Order of Entry Signals the Purity of Motives	
<i>Brooke Kelly, University of Pennsylvania, USA</i>	
<i>Deborah Small, University of Pennsylvania, USA</i>	
Paper #3: When Feeling Good Feels “Wrong”: Avoiding Hedonic Consumption When It Reflects Immoral Character	
<i>Stephanie Lin, Singapore Management University, Singapore</i>	
<i>Taly Reich, Yale University, USA</i>	
<i>Tamar A. Kreps, University of Utah, USA</i>	
Paper #4: Witnessing Moral Violations Increases Conformity in Consumption	
<i>Ping Dong, Northwestern University, USA</i>	
<i>Chen-Bo Zhong, University of Toronto, Canada</i>	
A Bouquet of Scents: Olfactory Effects on Product Evaluation & Consumption.	313
<i>Chairs: Zachary Estes, Bocconi University, Italy</i>	
<i>Varun Sharma, Bocconi University, Italy</i>	
Paper #1: Seeing is Smelling: Visual Images can Induce Olfactory Imagery and Improve Product Evaluations	
<i>Varun Sharma, Bocconi University, Italy</i>	
<i>Zachary Estes, Bocconi University, Italy</i>	
Paper #2: I smell it as if it were here: Can scented advertising boost product appeal?	
<i>Ruta Ruzeviciute, Vienna University of Economics and Business, Austria</i>	
<i>Bernadette Kamleitner, Vienna University of Economics and Business, Austria</i>	
<i>Dipayan Biswas, University of South Florida, USA</i>	
Paper #3: Follow Your Nose When it Sounds Right: How Brand Names Moderate the Influence of Olfactory Cues on Consumer Preferences	
<i>Marina Carnevale, Fordham University, USA</i>	
<i>Rhonda Hadi, University of Oxford, UK</i>	
<i>Ruth Pogacar, University of Cincinnati, USA</i>	
<i>David Luna, City University of New York, USA</i>	
Paper #4: The Effects of Warm versus Cool Ambient Scents on Calorie Consumption	
<i>Sarah Lefebvre, Murray State University, USA</i>	
<i>Dipayan Biswas, University of South Florida, USA</i>	

Choosing How to Choose: New Perspectives on Information Avoidance and Disclosure for Consumer Decision Making	319
<i>Chairs: Kaitlin Woolley, Cornell University, USA</i>	
<i>Jane L. Risen, University of Chicago, USA</i>	
Paper #1: Delegating Decisions: Recruiting Others to Make Choices We Might Regret	
<i>Mary Steffel, Northeastern University, USA</i>	
<i>Elanor F. Williams, Indiana University, USA</i>	
Paper #2: Avoiding Information to Protect a Strong Intuitive Preference	
<i>Kaitlin Woolley, University of Chicago, USA</i>	
<i>Jane L. Risen, University of Chicago, USA</i>	
Paper #3: Disclosure and the Dog That Didn't Bark: Consumers Are Too Forgiving of Missing Information	
<i>Sunita Sah, Cornell University, USA</i>	
<i>Daniel Read, University of Warwick, UK</i>	
<i>Krishna Savani, Nanyang Technological University, Singapore</i>	
Paper #4: Graphic Warning Labels Curb Purchasing of Sugar-Sweetened Beverages	
<i>Grant E. Donnelly, Harvard University, USA</i>	
<i>Laura Y. Zatz, Harvard University, USA</i>	
<i>Daniel A. Svirsky, Harvard University, USA</i>	
<i>Leslie K. John, Harvard University, USA</i>	
The Interplay between Power and Lay Theories in Influencing Consumer Behavior	324
<i>Chairs: Alison Jing Xu, University of Minnesota, USA</i>	
<i>Sharon Shavitt, University of Illinois, USA</i>	
Paper #1: Too Nice to Be Dominant: How Warmth Impacts an Embodiment of Power in Brands	
<i>Jennifer L. Stoner, University of North Dakota, USA</i>	
<i>Carlos J. Torelli, University of Illinois, USA</i>	
Paper #2: Turning a Blind Eye: When Views of Power Differentials Increase Deal Attractiveness	
<i>Michael J. Barone, University of Louisville, USA</i>	
<i>Xingbo Li, University of Louisville, USA</i>	
<i>Keith B. Lyle, University of Louisville, USA</i>	
<i>Karen P. Winterich, Pennsylvania State University, USA</i>	
Paper #3: The Effects of Power on Emotional Responses to Self-Failure and Self-Success	
<i>Claire Heeryung Kim, McGill University, Canada</i>	
<i>DaHee Han, McGill University, Canada</i>	
<i>Derek D. Rucker, Northwestern University, USA</i>	
<i>Adam Duhachek, Indiana University, USA</i>	
Paper #4: Captivated by Change: A Motivational Consequence of Being Powerless	
<i>Alison Jing Xu, University of Minnesota, USA</i>	
<i>Sharon Shavitt, University of Illinois, USA</i>	
<i>Derek D. Rucker, Northwestern University, USA</i>	
Viewing Social Exclusion with a Broader Scope: Contemporary Consequences of Social Exclusion	330
<i>Chairs: Yuwei Jiang, Hong Kong Polytechnic University, Hong Kong</i>	
<i>Lei Su, Hong Kong Baptist University, Hong Kong</i>	
Paper #1: How The Experience of Social Exclusion Influences Visual Density Preference	
<i>Lei Su, Hong Kong Baptist University, Hong Kong</i>	
<i>Echo Wen Wan, University of Hong Kong, Hong Kong</i>	
<i>Yuwei Jiang, Hong Kong Polytechnic University, Hong Kong</i>	
Paper #2: The Impact of Social Exclusion on Consumers' Attitudes Toward Probabilistic Selling	
<i>Linying (Sophie) Fan, Hong Kong Polytechnic University, Hong Kong</i>	
<i>Yuwei Jiang, Hong Kong Polytechnic University, Hong Kong</i>	
Paper #3: The Broken Bargain: Social Exclusion Reduces Willingness to Incur Personal Costs for the Sake of Society	
<i>Iman Naderi, Fairfield University, USA</i>	
<i>Nicole L. Mead, University of Melbourne, Australia</i>	
Paper #4: Is it Still Important to be a Moral Person When You are Lonely?	
<i>Jinfeng (Jenny) Jiao, SUNY Binghamton University, USA</i>	
<i>Jing (Alice) Wang, University of Iowa, USA</i>	

Challenging Intuitions on Intuitive Statistics	336
<i>Chairs: Quentin André, INSEAD Europe Campus, France</i>	
<i>Nicholas Reinhardt, University of Colorado Boulder, USA</i>	
<i>Bart de Langhe, University of Colorado Boulder, USA</i>	
Paper #1: High Chances and Close Margins: How Different Forecast Formats Shape Beliefs	
<i>Oleg Urminsky, University of Chicago, USA</i>	
<i>Sondre Skarsten, University of Chicago, USA</i>	
<i>Luxi Shen, The Chinese University of Hong-Kong, China</i>	
Paper #2: It's Absolutely Relative: On the Processing of Absolute and Relative Differences	
<i>Dan R. Schley, Erasmus University, The Netherlands</i>	
Paper #3: Variance Spillover in Intuitive Statistical Judgments	
<i>Quentin André, INSEAD Europe Campus, France</i>	
<i>Nicholas Reinhardt, University of Colorado-Boulder, USA</i>	
<i>Bart de Langhe, Ramon Llull University, Spain</i>	
Paper #4: Combining Estimates of Epistemic and Aleatory Uncertainty to Reduce Overprecision	
<i>Daniel G. Goldstein, Microsoft Research, USA</i>	
<i>David Rothschild, Microsoft Research, USA</i>	
It's A Brave New World -	
The Consequences of Consumers' Self-Disclosure in Online Settings	341
<i>Chairs: Francesca Valsesia, University of Southern California, USA</i>	
<i>Kristin Diehl, University of Southern California, USA</i>	
Paper #1: See What I Did or See What I Have: Impression Management Using Experiences Versus Material Goods	
<i>Francesca Valsesia, University of Southern California, USA</i>	
<i>Kristin Diehl, University of Southern California, USA</i>	
Paper #2: Temporary Sharing, Enduring Impressions: Self-Presentation in the Digital Age	
<i>Roland Ruppell, Università della Svizzera Italiana, Switzerland</i>	
<i>Reto Hofstetter, Università della Svizzera Italiana, Switzerland</i>	
<i>Leslie K. John, Harvard University, USA</i>	
Paper #3: Bragging through an Intermediary	
<i>Irene Scopelliti, City University London, UK</i>	
<i>Joachim Vosgerau, Bocconi University, Italy</i>	
<i>George Loewenstein, Carnegie Mellon University, USA</i>	
Paper #4: How Audience Engagement (in the Form of Likes vs. Comments) on Social Media Posts Influences Subsequent Self-Disclosure	
<i>Yuheng Hu, University of Illinois at Chicago, USA</i>	
<i>David Gal, University of Illinois at Chicago, USA</i>	
New Perspectives on Reference Points and Consumer Motivation	346
<i>Chair: Scott Wallace, Duke University, USA</i>	
Paper #1: Goal Specificity and the Dynamics of Consumer Motivation: The Role of Reference Point Focus	
<i>Scott Wallace, Duke University, USA</i>	
<i>Jordan Etkin, Duke University, USA</i>	
Paper #2: Multiple Goals as Reference Points	
<i>Evan Weingarten, University of Pennsylvania, USA</i>	
<i>Sudeep Bhatia, University of Pennsylvania, USA</i>	
<i>Barbara Mellers, University of Pennsylvania, USA</i>	
Paper #3: Why Do Goals Cause Cheating? Unpacking the Confounding Effects of Mere Goals, Social Comparisons, and Pay	
<i>Matthew Chao, Williams College, USA</i>	
<i>Ian Larkin, University of California, Los Angeles, USA</i>	
Paper #4: Anchors or Targets? An Examination of Credit Card Statements	
<i>Daniel M. Bartels, The University of Chicago, USA</i>	
<i>Abigail B. Sussman, The University of Chicago, USA</i>	

New Perspectives on Anthropomorphism: Examining the Role of Anthropomorphism in Financial Decision-Making and Consumer Welfare 350

Chair: Eric Levy, University of Cambridge, UK

Paper #1: Is Money Worth Saving? Money Anthropomorphism Increases Saving Behavior

*Lili Wang, Zhejiang University, China
Sara Kim, University of Hong Kong, Hong Kong
Xinyue Zhou, Zhejiang University, China*

Paper #2: Beauty (Value) Is in the Eye of the Beholder: How Anthropomorphism Affects the Pricing of Used Products

*Junhee Kim, Drexel University, USA
Marina Puzakova, Lehigh University, USA
Hyokjin Kwak, Drexel University, USA
Haeyoung Jeong, Drexel University, USA*

Paper #3: Moral Identity and Brand Anthropomorphism

*Eric Levy, University of Cambridge, UK
Sara Kim, University of Hong Kong, Hong Kong
Americus Reed II, University of Pennsylvania, USA*

Paper #4: The Influence of Anthropomorphism on Choosing Multiple Products from an Assortment

*Rocky Peng Chen, Hong Kong Baptist University, Hong Kong
Echo Wen Wan, University of Hong Kong, Hong Kong*

Why Aren't We Intrinsically Motivated Enough? Novel Insights into the Origination and Expression of Intrinsic Motivation 356

Chairs: Yuechen Wu, University of Maryland, USA

Meng Zhu, Johns Hopkins University, USA

Paper #1: Scarcity and the Intrinsic Motivation to Learn

*Yuechen Wu, University of Maryland, USA
Meng Zhu, Johns Hopkins University, USA*

Paper #2: The Dual Effect of Subjective Busyness on Consumer Motivation

*Keith Wilcox, Columbia University, USA
Juliano Laran, University of Miami, USA*

Paper #3: Process versus Outcome: How Envy and Goal Framing Affect Motivation

*Anthony Salerno, University of Cincinnati, USA
Juliano Laran, University of Miami, USA
Chris Janiszewski, University of Florida, USA*

Paper #4: Underestimating the Importance of Expressing Intrinsic Motivation in Job Interviews

*Kaitlin Woolley, University of Chicago, USA
Ayelet Fishbach, University of Chicago, USA*

Come and Have Fun with Us: Social Influences and Social Perception in Leisure Activities 362

Chairs: Yuechen Wu, University of Maryland, USA

Rebecca K. Ratner, University of Maryland, USA

Paper #1: The Decision to Share: From the Joy of Self-Possession to the Joy of Shared Consumption

*Adelle X. Yang, National University of Singapore, Singapore
Ann McGill, University of Chicago, USA*

Paper #2: Getting the Most from Shared Experiences: The Undervalued Impact of Clear Objectives

*Yuechen Wu, University of Maryland, USA
Nicole Y. Kim, University of Maryland, USA
Rebecca K. Ratner, University of Maryland, USA
Rebecca W. Hamilton, Georgetown University, USA*

Paper #3: Celebrations and Social Support

*Danielle J. Brick, University of New Hampshire, USA
Kelley Gullo, Duke University, USA
James R. Bettman, Duke University, USA
Tanya L. Chartrand, Duke University, USA
Gavan J. Fitzsimons, Duke University, USA*

Paper #4: Wasting Time and Money? How Consumers Evaluate Others' Resource (Mis)Management

*Jenny G. Olson, Indiana University, USA
Brent McFerran, Simon Fraser University, Canada
Andrea C. Morales, Arizona State University, USA
Darren W. Dahl, University of British Columbia, Canada*

Age-related Changes in Decision Preferences: From Mechanisms to Interventions	367
<i>Chair: Vinod Venkatraman, Temple University, USA</i>	
Paper #1: Affective Forecasting Improves Across the Life Span	
<i>Lisa Zaval, Columbia University, USA</i>	
<i>Ye Li, University of California, Riverside, USA</i>	
<i>Eric J. Johnson, Columbia University, USA</i>	
Paper #2: Loss Framing Attenuates Delay Discounting in Older Adults	
<i>William Hampton, Temple University, USA</i>	
<i>Vinod Venkatraman, Temple University, USA</i>	
Paper #3: Taking the Best and Worst First: Age Differences in Preferences for Monetary and Hedonic Sequences	
<i>JoNell Strough, West Virginia University, USA</i>	
<i>Wändi Bruine de Bruin, University of Leeds, UK and Carnegie Mellon University, USA</i>	
<i>Andrew M. Parker, RAND Corporation, USA</i>	
Paper #4: Individual Differences in Skewed Financial Risk Taking Across the Adult Life Span	
<i>Kendra Seaman, Yale University, USA</i>	
<i>Josiah K. Leong, Stanford University, USA</i>	
<i>Charlene C. Wu, Stanford University, USA</i>	
<i>Brian Knutson, Stanford University, USA</i>	
<i>Greg Samanez-Larkin, Yale University, USA</i>	
It's Not What You Say, It's How You Say It:	
New Effects of Choice Elicitation Modes on Decision Outcomes.	373
<i>Chair: Gia Nardini, University of Denver, USA</i>	
Paper #1: Choosing vs. Ranking: Elicitation Modes and Their Impact on Consumers' Subjective Experience of Difficulty	
<i>Yonat Zwebner, University of Pennsylvania, USA</i>	
<i>Rom Y. Schrift, University of Pennsylvania, USA</i>	
Paper #2: When Simplified Choices Backfire: The Role of a Maximizing Mindset	
<i>Gia Nardini, University of Denver, USA</i>	
<i>Aner Sela, University of Florida, USA</i>	
Paper #3: The Effect of Stated Preference on Subsequent Revealed Preference	
<i>Coby Morvinski, IDC Herzliya, USA</i>	
<i>Silvia Saccardo, Carnegie Mellon University, USA</i>	
<i>On Amir, University of California San Diego, USA</i>	
Paper #4: Drivers of Sequential Shortlist Decisions	
<i>Wendy Liu, University of California San Diego, USA</i>	
<i>Itamar Simonson, Stanford University, USA</i>	
Competitive Papers—Full

2017 ACR Presidential Address

Consumer Research Contribution: Love It or Leave It

Margaret C. Campbell, University of Colorado, Boulder, USA

I am honored to be here today. Thank you to the members of the Association for Consumer Research for your confidence. And my special thanks to the ACR Board for their service and help.

Over my 26 years of coming to the ACR conferences, I have always enjoyed the opportunity to hear the presidential addresses. These addresses have been informative, interesting, and inspiring. Now that I am here, I find that these earlier addresses are also intimidating. Informative, interesting, inspiring and intimidating; as a marketing professor, I call these the 4 I's of presidential addresses. My intimidation only increased as I looked over the past presidents and realized how much admiration I have for so many of the people on that list. I very much appreciate the ideas, knowledge and direction that they have provided our field and the opportunity to follow their lead.

The process of developing a presidential address is challenging. You are faced with identifying something that you and at least some other ACR members are likely to think is interesting and informative, and that is without even *hoping* that you may be able to be inspiring. Initially, I spent some time worrying about whether there was anything for me that fit this bill. However, I fairly quickly realized that there is. The contribution of consumer research, both in terms of the contribution of individual papers, and in terms of the contribution of our field, is something that I care very much about and that I think is of general interest to us all. Thus, I would like to use this time to talk to you about contribution.

The title of my talk is "Consumer Research Contribution: Love It or Lose It." I hope that by the end of my talk, and after the development of my nine propositions, you will understand the meaning of this title.

As good academics, let's start with a definition.

Contribution: the thing you believe your paper has, but the reviewers are too (fill in the blank) to see.

OK, so let's look at an actual *dictionary* definition.

The Oxford English Dictionary defines contribution as:

- a. "A gift or payment to a common fund or collection.
- b. The part played...in bringing about a result or helping something to advance."

According to the Cambridge Dictionary, a contribution is:

- a. "Something that you contribute or do to help produce or achieve something together with other people, or to help make something successful."

There are two important aspects of these dictionary definitions. First, these definitions make it clear that a contribution is a piece of something greater. Multiple people contribute pieces to a bigger collection. When one of us produces research that contributes to understanding of consumers, that is a step that moves the field of consumer research forward. Each contribution can be thought of as a gift to the common knowledge fund of the field.

This leads to my Proposition 1: Contribution requires the addition of knowledge that adds to the current common understanding.

Second, these definitions emphasize that a contribution must be considered in terms of to what it is contributing. What is the common fund? What is being helped to advance? Just like positioning a

brand, it is necessary to start with a clear understanding of the frame of reference. A contribution is relative to that frame.

We are all here at the conference for the Association for Consumer Research. As such, it is my proposition that the frame of reference for contribution should be consumers. As consumer researchers, we should contribute to the understanding of consumer-relevant issues. Some aspect of being or behaving as a consumer must be central to provide a contribution to consumer research. Consumer research needs to focus on aspects of people, not just as humans, but people *within their roles as consumers responding in relation to some marketplace*.

When I was growing up, my dad used to tell me about an architect who complained that there were clients who wanted to start with a building and then have the architect, "put the architecture on." Sometimes some consumer research seems a bit like this to me. It seems as if the researcher has wanted to research people, but then decides to, "put the consumer on." Perhaps it is because so many of us work in business schools, or have other incentives for publishing work in journals of consumer or marketing research. However, I recommend that if you want to contribute to some other field, such as psychology or sociology, or anthropology you should—that's great; just do it. But if you want to contribute to the field of consumer research, *start* with a consumer-relevant problem. It should not be the case that the focus is on a human problem, and then study 4 uses some consumer or marketplace stimulus to try to, "put the consumer on." The impetus for a true contribution to consumer research is to understand some aspect of consumer response.

This leads to Proposition 2: A contribution to consumer research focuses on a consumer-relevant issue.

Several years ago, the editors of the *Journal for Consumer Research* (JCR), Mary Frances Luce, Ann McGill, and Laura Peracchio, asked that a contribution statement be included in submissions to the journal. I think that their very good idea was to use this as a nudge to get us all to start thinking about our contribution earlier, and certainly before we submit to JCR. Starting with a contribution statement before writing the paper could be a real boost to the clarity of the work. Given the importance of JCR to our discipline, let's take a look at what JCR provides to guide the contribution statement. The JCR site states that, "Your contribution statement should be focused on the following: 1) the state of scholarship prior to your research; 2) what your research adds."

This is a lovely, concise encapsulation of how to think about contribution. First, what do we already know? Second, what can I add to improve that common knowledge? In other words, what can my research help us understand that advances existing consumer knowledge?

THE IMPORTANCE OF AUDIENCE

This leads to another important issue in terms of contribution. To whom are we speaking? Whom do we wish to help advance? When considering contribution, we need to consider the audience for our contribution. That is, we need to identify the intended beneficiary of the common fund to which we wish to add. Understanding the audience is necessary prior to asking what can be added to improve that common fund.

2 / Consumer Research Contribution: Love It or Leave It

The Association for Consumer Research has a logo with three characters. As many of you know, and as Jeff Inman pointed out in his presidential address, the characters in the logo were created to represent Academia, Industry, and Government. While you, like I, may wonder why there is no character representing Consumers, and why it looks like a family decision-making unit, one way to interpret this logo is that academic research can inform the academic literature, government policy and industry actions in the service of consumer well-being. Thus, while the primary audience for academic consumer research is academic consumer researchers, good research that provides insight to a consumer-relevant problem is likely to be able to be used to improve governmental and/or business decisions.

As academic researchers, we can contribute to consumer welfare by providing evidence-based knowledge that enables industry to provide products and services with value propositions that help consumers to achieve their goals at prices they can afford (a central objective of marketing). Likewise, our research can increase the ability of governments to develop and enact useful policies that help to regulate markets for the overall good of consumers. Further, we can contribute to consumer well-being by increasing consumers' understanding of themselves and ability to make decisions that help them pursue their goals. The dissemination of this last contribution is most typically through teaching, educational materials, and the media.

Proposition 3: A consumer research contribution provides knowledge to the academic literature, government, business, and/or consumers.

So, a contribution to consumer research starts with a consumer-relevant issue and adds to the existing knowledge about that issue. A contribution provides new insight to academia, business, government or consumers. The common fund of current knowledge, however, is contained in the literature that speaks to the consumer-relevant issue. And so, an important question is what then is necessary in terms of specific research to make a contribution to the literature?

THE UNIMPORTANCE OF SURPRISE

I will start with one thing that I do *not* believe is necessary; it is not necessary for each piece of research to propose a new theory. It seems that in consumer research we have moved somewhat away from the idea of scientific progress through applying, refining, adding to, and building upon *existing* theory. I am not contradicting Kuhn's (1962) important insight that there are periods of turmoil and "paradigm shift" within scientific progress. I am focusing attention on Kuhn's (1962) idea that these periods of turmoil interrupt periods of normal, additive progress and that *both* periods are important to overall scientific progress.

Many consumer researchers today seem to have gotten to a point of thinking that each paper must be brand new, either because of a new theory or because of surprising findings. This can lead to stand-alone findings and proliferation of constructs that do not build onto anything. We can end up producing cute research that does not link to existing literature and does not establish a basis for the type of ongoing research that contributes to our deeper understanding of consumers. To stick with the architecture metaphor, award-winning architect David Chipperfield said, "There is a danger when every building has to look spectacular; to look like it is changing the world." We do not need each piece of research to be spectacular or to change the world. In fact, I propose that striving for every piece of research to be surprising limits the advancement of knowledge.

This leads to Proposition 4a: A new theory and/or surprising findings are not necessary for a contribution to consumer research.

Kurt Lewin, the insightful social psychologist who had great impact on social and consumer psychology said, "there is nothing so practical as a good theory" (1943). This is a highly cited quote; he actually seems to have said basically the same thing in at least three different publications and it has been cited hundreds of times (McCain 2015). However, while we cite this, and many of you recognize this and many of you nodded your heads, I would bet that some of those nodding have rejected a paper because it is not "surprising" enough. Now, my central argument is that we need to focus on contribution and I am sure that some of those rejections were appropriate because of a lack of contribution. However, not every contribution needs to be, or even should be, surprising. A good theory is practical because it provides guidance in formulating interesting problems and in understanding productive directions for research. A good theory can help us to advance our understanding of a problem such that we can hypothesize findings that, rather than being surprising, are predicted by the theory. I propose that if, as a field, we are advancing knowledge, many contributions will, in fact, be unsurprising because they are developed from and contribute something to a good theory. Incremental contribution that builds on a good theory is important for the progress of the field.

Thus, Proposition 4b: Incremental addition to a good theory can provide a contribution to consumer research.

THE IMPORTANCE OF CONCEPTUAL UNDERSTANDING

While it is not necessary for a contribution to propose a new theory, it is necessary for a research contribution to advance our conceptual understanding of consumer behavior. A contribution requires conceptual or empirical evidence that supports a nuanced understanding of the process by which a consumer responds within a consumption context.

Does this mean that we always need experiments with mediation analysis? No. As others have pointed out, within an experiment, mediation analysis can be useful to understanding the process, but it is not essential or even appropriate in every case. For example, there are many times when measures of the process are unlikely to be accurate because consumers are unlikely to be able to access the process driving their responses or to be able to respond to a measure in a way that accurately reveals the underlying process.

So in these cases, what *can* we do to provide greater understanding of the process by which a consumer response arises? While not the only way, identifying a conceptually-driven moderator can be extremely useful for this. I sometimes see research, often in a reviewer or editorial role, that seems to have lost sight of the reason that a moderator is useful. An interaction is not proposed for its own sake, just to be able to "show moderation." The research goal is to identify a theoretically-relevant moderator that sheds light on an explanation for an effect.

In her Presidential Address, Alice Tybout (1995) identified a variety of myths and realities of the value of theory in consumer research. Her second myth and reality were:

"Myth 2: It is possible to render a unique explanation for a simple (two-level) main effect.

Reality: Theoretical explanations cannot be tied to any single variable, they are inherently abstract and can only be inferred by employing convergence or triangulation procedures."

Alice Tybout's reality number 2 presents an excellent case for proposing and exploring a moderator. When a researcher examines a theoretically-relevant moderator, a significant interaction provides evidence that the researcher has successfully identified an explanatory aspect of the effect. The interaction between the independent variable and the theoretically-relevant moderator provide evidence of a mechanism underlying the main effect by demonstrating when the effect is more and less likely to occur. Moderators provide value by helping us to better understand the consumer-relevant phenomenon of interest. This offers one way to provide conceptual understanding.

While mediation and moderation primarily apply to experiments, there are many other methods and ways to provide evidence that supports greater understanding of some consumer-relevant response. First, we need to identify an interesting consumer idea. Then we must design and use sound methods. If the methods aren't good, the data aren't good. And we need to develop conceptual understanding of the response. There are many types of data that can provide insight to consumer-relevant issues. In reality, we need to use multiple approaches and multiple types of data in service of better conceptual understanding of consumers.

However we approach the consumer issue, as stated in Proposition 5: A contribution improves the conceptual understanding of consumers.

THE IMPORTANCE OF REPLICATION AND GENERALIZABILITY

I am certainly not the first to make the next point and I will not be the last. A strong contribution to knowledge also requires replication. The often-called "replication crisis" has brought a lot of attention to difficulty other researchers have in replicating previously published results. A few cases of fraud have additionally focused attention on questions of ethics. Because of this, replication is currently often discussed in terms of efforts by independent researchers who attempt to strictly replicate another researcher's work. This type of replication is important to the scientific method. In addition, however, we should not lose sight of the importance of a researcher or research team self-replicating prior to publication. Nor should we lose sight of the importance of conceptual replication, where the stimuli and circumstances are not the same, in strengthening contribution to a real understanding of consumers.

Some researchers repeatedly pretest stimuli and experimental setups until they get to one that "works." They then run a study with this highly pretested setup. It is not clear what the person who reads the paper that contains these without the background of the work that went into "getting it just right" learns. It is not even clear what the researcher, who *knows* all the work that went into it, learns. What, for example, is the construct that took so many iterations by a smart person to successfully manipulate? Do we really have it figured out? What is the purpose of identifying an extremely small set of circumstances that, if perfectly created, give rise to an effect? If the purpose is publication, I suppose this type of method can achieve the purpose. But if the purpose is knowledge creation, it is less clear that the end result of this highly stylized and designed process provides a real contribution.

I see increasing requests by reviewers for "real situations" rather than lab studies. However, it is not lab studies qua lab studies that are the problem. It is not even undergraduates or now, MTurkers, that are the problem (although MTurkers may be a problem). The real problem is asking people, whoever they are, to self-report how they predict that they will behave under a particular set of imagined circumstances. Our own research repeatedly shows, not surprisingly,

that people are not particularly good at self-reporting responses to imagined circumstances. None of *us* knows or is likely to be able to accurately predict how we will behave in imagined circumstances; why do we expect our participants to be able to do this? There are too many conscious, non-conscious and contextual factors that will impact people in ways they do not understand.

One reason that field studies are increasingly desirable is that these examine consumers in real marketplace circumstances, in hotel rooms, or Disneyland, or drug stores. Well-executed field studies enable examination of consumer responses in terms of actual, consequential dependent variables in a "real" environment. There is no consumer guessing or self-prediction of how they will behave; they just behave. While I am a fan of field studies and am impressed by the work that many consumer researchers are taking on, this is not the only way to identify effects that are likely to generalize beyond a particular situation. Well-designed lab studies that move beyond imagined circumstances and self-reports and well-executed field work can provide important, generalizable insight into consumers.

Contribution does not require that every study or paper has to have a "consequential dependent variable" in terms of a "real-world" behavior. Contribution does require that every paper must include research where people are reacting to some consumer-relevant variable, whether in terms of memory, emotions, attitudes, or behavior. And, unless you are trying to understand consumer's lay theories, avoid studies that put consumers in the position of trying to guess their own likely responses.

I will go further out on this limb to propose that a true focus on making a contribution to the fund of knowledge will naturally eliminate a lot of the questionable methods that have been discussed as factors in the replication crisis. We all know that an effect that really makes a contribution can be reproduced; the effect should be open to both exact replication and to conceptual replication. An effect that can only be observed under one, exact set of circumstances is not much of an effect and does not contribute much to our understanding of consumers. Thus, a strong focus on making a contribution leads to self-replication, conceptual replication, multiple methods, larger sample sizes, varying consumer groups for our samples, more realistic stimuli, and more realistic outcome variables.

Proposition 6: Contribution requires that a finding is "real" and replicable, ideally with different conditions.

THE IMPORTANCE OF AGREEABLE DISAGREEMENT

My next point may be a bit controversial. We are, overall, a pleasant community, and this is a good thing. But I am proposing that we be more disagreeable. Disagreement is vital to the advancement of any scientific discipline. So, while I do not actually advocate that we are disagreeable to each other, I do advocate that we express disagreement with each other's ideas in order to push our science forward.

When I started coming to ACR many years ago, there were people who would raise critical questions in our talks. Frankly, it would scare me a little bit to see certain people in the room because I knew that they would openly question me if they did not see the conceptual clarity or supportive evidence that I suggested. But while it made me scared, it also made me better. Because I knew that they would openly question me if they did not see the conceptual clarity or supportive evidence that I suggested, I was very careful in developing conceptual clarity and in providing supportive evidence.

I am not, however, just talking about, or even primarily talking about, critical questions at conferences. More importantly, our journals need to be open to solid, replicated research that disagrees with

something that was published earlier. Sometimes, we may want to provide disagreeable data. Right now, it often seems that publishing something that questions something published earlier—even if that earlier finding has not been replicated outside of the initial publication—is, if not impossible, highly unlikely. In order to get something that is inconsistent with a prior publication through the review process, the researcher often needs to be able to show exactly *why* the results are in conflict. While that is a desired end goal and it is clearly important for building an area to explain differences and introduce moderator variables, I am not sure why conflicting findings can only be published if, using a moderator, the researcher can both replicate and modify the original findings. What if the original findings were wrong? What if the luck of significance testing was such that the less than 5% chance of finding the effect when it didn't really exist turned up? What if we need additional research attention focused on the original problem because it is more complicated than originally assumed? Couldn't disagreeable data be a starting point?

I wonder if the limited publication potential for disagreeable data, combined with the amazing communication ability offered by the internet pushes us toward non-peer-reviewed, and often disagreeable disagreement. The internet has lead us into uncharted territory. We must evolve new standards and rules of decorum to disagree with findings without attacking our colleagues' research and reputations. We must find ways for productive, peer-reviewed disagreement.

Professional disagreement, or even the potential for such disagreement, encourages us to sharpen our thinking and helps to further what we learn. Challenge pushes progress. One way we build overall contribution and knowledge is by challenging each other's ideas. Successful scientific movement is based on competition of ideas, of theories, and of data until we advance to some new, evidence-based understanding. We need to find ways for polite, professional, and, ultimately, peer-reviewed disagreement.

Proposition 7: Polite, professional disagreement about ideas and results can lead to contribution.

THE IMPORTANCE OF IMPACT

I am, frankly, somewhat worried about our overall contribution as a field of research. I am not the first to raise this issue; I am not even the first to raise this issue in an ACR Presidential Address. That, however, does not decrease my concern. I worry that we don't have enough impact. I worry that economists—and even psychologists—seem to have larger or more seats at the table of public interest than we do. I worry when some of our members, researchers with degrees in marketing, and/or psychology, call themselves “behavioral economists” or “behavioral scientists,” I assume because they believe this will help them to have a seat at the table and a bigger impact than if they call themselves consumer researchers. I worry when I am at a cocktail party and someone asks what I do and then says some version of, “huh, I didn't know that even existed.” I worry that our impact is less than other areas and I wonder if part of the reason for that is a lack of strong focus on the contribution of each of our pieces of research and our overall body of research.

Are we, as individual researchers and as an academy, making the level of societal contribution that we would like? If not, what can we do? Once again, I propose that a concentrated focus on contributing to knowledge about consumers can help us have more impact.

Proposition 8: Focus on contribution to knowledge about consumers can lead to greater impact.

At one of my first few ACRs, I had the great pleasure of hearing Morris Holbrook give his ACR Fellow's Address. Morris told a story, as only Morris can, about his father giving eleven-year old

Morris a chemistry set that his father carefully put together piece by piece instead of ordering the neat, matching toy company set that eleven-year old Morris craved. While every piece was superior, it wasn't neat and, most importantly, it didn't come with instructions. After describing some incidents and accidents exploring chemistry without instructions, Morris concluded, “The point, of course, is that—like my father's well-intentioned but somewhat misguided Christmas present—science does not come with an instruction book. Only toy science comes with instructions included. In real science, you must figure out the rules for yourself and you must endure a lot of bad smells, dangerous explosions, crusty messes, broken glass, and bloody fingers.”

At the time I heard this, I was young and idealistic and I thought, “wow, I am in the right place.” Now, I am not young, but perhaps still idealistic, and while I still think this is the right place, I fear that we may have lost sight of the purpose and difficulty of our science. It sometimes seems that for some, the research endeavor has become a game. Researchers often seem to be focused on publication as an end in itself, or a means to a job offer or to tenure, rather than as a way of contributing to knowledge about consumers. Science is messy and difficult and it doesn't come with an instruction booklet. Studies fail, projects have to be tossed out, and progress is always slower than we want. But, if we are sincerely focused on adding to the fund of common knowledge, then we must work hard for that advancement, even when it means throwing out studies and starting over after a research failure.

I think that we are incredibly lucky to get to spend some of our working time thinking about and examining what consumers do and why they do it. But if we want society to continue to support us in this endeavor, we need to make a contribution. I believe that if we approach this work from intrinsic, rather than extrinsic motivation we will naturally address many of these issues. If we do our research, not to have a paper before the job market or for tenure or for fame or for fortune, but because we want to know, and we want others to know about consumers we will use careful methods with sufficient samples to address interesting, real consumer issues. We will build on each other's work and theories and we will make a contribution to consumer research.

Proposition 9: Research contribution stems from a sincere desire to understand consumers.

We need to love consumer research for what we can learn about consumers. If we do consumer research because we love learning about consumers, together we will build findings, strong contributions and impact.

I hope I have made some contribution to your thinking about the consumer research endeavor and I thank you for this opportunity.

2017 ACR Fellow Addresses

Consumer Research in the Age of Neoliberal Discontinuities: Incitements to Intellectual Edgework

Craig J. Thompson, University of Wisconsin, USA

Preface: I owe many thanks to my long-time mentor, friend and, partner in crime, Eric J. Arnould for his constructive feedback on an earlier version of this address.

One of my favorite films is the Coen Brothers' *Barton Fink* (1991) which tells the story of moderately successful New York City playwright—the titular Fink—who is unexpectedly commissioned to write a screenplay for a major Hollywood production. Though at first uncertain about leaving his local sources of creative inspiration, Fink decides to pursue fame and fortune in Tinseltown, but upon arrival, he is stricken with a paralyzing and unremitting case of writers block. From that point, the film takes the Coen brothers' signature surreal turns. However, my own experience of being named an ACR Fellow heightened the personal relevance of Fink's agonizing plight.

Upon official announcement that I was joining my fellow award recipients Debbie MacInnis and Jagdish Sheth as the newest class of ACR Fellows, I was initially stunned and then elated and, of course, deeply honored. However, that glowing aura was soon punctured by a nagging question—"what will you say as an ACR Fellow?"—that haunted me with increasing intensity as this imminent day grew ever closer and the magnitude of the task seemed more and more daunting. And every single time I sought to placate this anxiety by making tangible progress on this talk, I had a Barton Fink moment—blank stare meets blank screen.

But as they say, "adversity is the mother of searching the ACR archives to read prior Fellows' addresses and praying that you can steal some of their ideas without anyone noticing." During the course of that envisioned archival poaching, however, I noticed that these talks seemed to express a kind of collective consciousness, or perhaps, enacted a tacitly understood cultural script of how one makes such an address. This cultural script involves two discernible narrative motifs, sometimes expressed singularly and sometimes melded into a kind of hybrid form. And this inductive realization provided the elusive catalyst for this address—Barton Fink be gone.

In the first motif, an ACR Fellow articulates a vision of the field and uses the bully pulpit of the address to advocate for a particular research direction or methodological program that might allow our sub-discipline to attain a higher level of theoretical development and societal relevance. This motif, for example, can be found in the inaugural fellows address by James Engel (1981)—"The Discipline of Consumer Research: Permanent Adolescence or Maturity?" (also see Bagozzi 1994; Lynch 2011; Wright 1999).

The second narrative motif is more retrospective, introspective, and autobiographical. In these talks, the ACR Fellow offers a personal reflection on his/her career journey and the life and career lessons learned while acknowledging all those who helped along the way (c.f., Belk 1995; Holbrook 1995; Hirschman 1996).

Of these, the second theme seemed to better capture my feelings on being named an ACR Fellow. I started to write a talk that would recognize the numerous peers, mentors, doctoral students, and co-authors who have so greatly enriched my personal and professional life. But, in was reflecting on all those relationships, discussions, and shared experiences, another more reflexive line of questioning began to crystallize in regard to the ACR Fellows Award and its institutional purpose: "This award, instituted in 1979 recognizes the career contributions of ACR individuals, preferably during their lifetime

for "significant impact on scholarly work in consumer behavior" [https://www.acrwebsite.org/web/core-activities/acr-awards.aspx].

This criterion begs a question: why should a consumer researcher, institutionally deemed to have had "significant impact," be so recognized in the first place? To ask such a question will likely strike you dear reader as a peculiar one. The answer seems to be common-sense knowledge that can "go with saying." As with many ritualistic practices, this aura of self-evidence masks that the answer to this seemingly unnecessary question is actually contingent on cultural ideals and values that are given institutional credence and, conversely, those placed in a more marginal position. At this juncture, we can begin to articulate the neoliberal discontinuities referenced in the title of this address and the tensions that they create between two contrasting normative models of consumer research. These ideological discontinuities are represented in the Figure below and which also provides a visual template for the ensuing discussion.

Discontinuous Models of Consumer Research

Figure 1

CONSUMER RESEARCH AS A COLLABORATIVE-COLLECTIVE PROJECT

The first cultural model is, in particular times and places, highly valorized in the consumer research field (as well as other spheres of research)—thought it harbors a nexus of meanings and implications that are often incompatible with the bestowment of a career achievement award.

This model cast consumer research as a cooperative and collaborative enterprise. From this perspective, all researchers are participants in a communal project of knowledge generation and working toward a collective goal of attaining a more comprehensive or refined understanding of "consumers," whether in terms of their choice processes or experiences of the marketplace. This model further highlights that a given consumer researcher, in conducting a given study, draws from a socially co-created body of knowledge and practices, and seeks to add his/her humble contribution to the commons.

This collaborative-collectivist model of knowledge production has become an increasingly prominent feature of our cultural land-

scape where knowledge flows across complex peer-to-peer networks and other modes of commons-based production (Bruns 2008). Media studies scholar Pierre Levy (1999) coined the term collective intelligence to describe this dynamic “wikified” web of knowledge generating and sharing relations. Collective intelligence is *universally distributed intelligence*, constantly enhanced, coordinated in real time, and enjoying a continuous expansion of skills and knowledge. This idea is often summarized by the Web 2.0 aphorism—no one knows everything but everyone knows something (Jenkins 2006).

Analysts of such user-generated networked cultures all too often become intoxicated with a feeling of radical difference and disjuncture, suggesting that we have entered into a revolutionary new epoch, that breaks from historical precedents. More often than not, such claims are hyperbolic ones that elide important continuities manifest in these structural changes. And we can say the same pattern holds for social science research. The production of scientific knowledge, has always has flowed across information networks, albeit operating at a more turgid pace, constituted by papers, conferences and analogue communication networks. To invoke less techno-Utopian (Kozinets 2008) tropes, we could describe this collaborative process as a system of sharing relationships or a grand game of pay-it-forward. In academic life, we often hear the phrase, “standing on the shoulder of giants” to acknowledge our intellectual debt to the past (and the collaborative precedents of others). To further calibrate this debt, let’s further acknowledge that these “giants” were equally dependent on the shoulders of many, many others. Thus, their lofty heights in the academic pantheon presuppose a community that has lifted and supported their enshrinement in the intellectual canon. Or to paraphrase an ancient Hindu parable used to represent infinite regress, and famously discussed by Clifford Geertz (1973, 28-29), the production of knowledge is “shoulders all the way down.”

This more abstract epistemological argument that scientific knowledge is a collaborative-collective enterprise is also supported by more immediate forms of experiential validation. Our research is routinely enriched by feedback from colleagues, the investments made by reviewers and editors, and last but not least, the co-creative actions of readers who will subsequently expand upon a given set of ideas and findings and integrate them into a broader web of collectively woven knowledge. Placed in this cultural frame, the conventional tendency to lavish accolades on a specific researcher seems to be an odd misconstrual of the knowledge production process.

Some members of the academic community do, in fact, strive to enact this collaborative-commonly found in the feminist studies literature, though it has found some expression in the consumer research sphere:

VOICE group (2010), “Buying into Motherhood? Problematic Consumption and Ambivalence in Transitional Phases,” *Consumption, Markets and Culture*, 13 (4), 373-397.

Such anonymous designations highlight the collaborative/collective aspects of the academic research and, conversely, subtly disavow the ethos of possessive individualism that underlies the social construction of academic celebrity, instead endorsing one of social utilitarianism and its ideals of cooperative sharing, universal access to knowledge, and embeddedness in a collective commons.

The institutional realities of academic life, of course, place significant constraints on how extensively this strategy can be applied or even how fully it can be implemented. In general, consumer researchers are situated in academic settings where individually scaled measures of “productivity”— via publications, presentations, and citation counts, and other activities that “count” in digital measures

performance monitoring systems—inform annual evaluations and corresponding administrative decisions about a given consumer researchers’ tenure, promotion, salary, research support, and other institutional incentives that govern our professional activities.

Given this institutional reality, the choice to anonymize and collectivize the published presentation of research—as in the VOICE Group example—is more of a symbolic gesture, which is not to say that it is meaningless or inconsequential. Such unconventional actions can inspire a reflexive assessment of status quo conventions and help to precipitate actions and choices which push the boundaries of established institutional values and norms and the constraints they subtly (and not so subtly) manifest, thereby, testing and potentially expanding the boundaries of an ideological system (c.f., Thompson and Üstüner 2015).

A collective-collaborative framing of the research enterprise also problematizes the ACR Fellows award. If we accept the view that a given researcher is situated in the web of collective intelligence, then such an award arbitrarily designates one node in the network as having been more consequential than all the others that enabled the “designated Fellow” to exert a localized influence that reverberates across some segment of the larger system. For example, an alternative approach would be to bestow fellow status on a concept that has mobilized consumer researchers and shaped our discourses, such as decision heuristics, utility maximization, cultural capital, or ritual action and to celebrate these ideas—not as the expression of a given researchers’ individual brilliance (and whose name may be strongly associated with the salient theory)—but by tracing out its genealogy which in most cases, would lead back to Eastern and Western philosophers of the antiquities.

This collective-collaborative model carries a host of positive connotations that have been well-integrated into our disciplinary self-conceptions, particularly when discussing the normative ideals that should guide the research process, such as an altruistic spirit of discovery; a communal sharing of ideas and knowledge; and a transcendence of egotism and self-interest through the disinterested pursuit of knowledge. While supporting a more virtuous framing of the research enterprise, this model is largely discontinuous with the prevailing institutional conditions that shape the professional lives of many, if not most, consumer researchers situated in academic settings. To negotiate these discontinuities, we apply this model very selectively and tend to ignore its democratizing, “wisdom of crowds” (Jenkins 2006) implications when they overtly contradict institutionalized norms that are premised on assessments of individual accomplishment and that engender a corresponding ideological effect: the production (and reproduction) of academic status hierarchies.

CONSUMER RESEARCH AS AN ENTREPRENEURIAL PROJECT

The second prominent cultural model cast the research process as an entrepreneurial project. In this cultural frame, consumer researchers (like other participants in the academic status game) are promoting their respective ideas, methods, papers, and academic “brand” in a competitive marketplace, or stated alternatively, seeking to maximize the market value of their human/intellectual capital (c.f., Becker 1964). In this spirit, for example, *ResearchGate*—the potentially copyright violating, for profit, academic networking site—promotes its services on the grounds that it can “create exposure for your work: share your work from any stage of the research cycle to gain visibility and citations” [<https://www.researchgate.net/>].

Such rationales seem completely unremarkable in their common-sense rationales. Of course, we want to promote our work and

gain more citations and recognition for our efforts. However, this sense of self-evident validity is one means through which orthodox understandings and beliefs serve to block further questioning of their ideological functions and channel action in certain directions, rather than others, and thus, constrain horizons of possibility (Bourdieu 1984).

In discussing this entrepreneurial model, I take an analytic cue from the critical historian Michel Foucault who described his approach to analyzing power relations in the following manner:

My point is not that everything is bad. My point is that everything is dangerous, which is not exactly the same thing as bad. If everything is dangerous, then we always have something to do. So, my position leads not to apathy or enervation but to a hyper and active pessimism (Foucault 1983, 231-232)

So, what dangers lurk in this orthodox framing of consumer researchers as intellectual entrepreneurs? One clue to this question is that it so closely aligns with the neoliberal vision of a society organized by market competitions, among decentralized and functionally independent economic actors, and where the market is both the ultimate adjudicator of value and the guiding force that governs decision about how one invest their time and efforts (Peck and Tickell 2007). In this neoliberal Utopia, there are no distortions of the competitive market mechanism, such as regulations that impede flows of capital or that might artificially constrain or subsidize the market value of an entrepreneurial skill or that would reduce competitive incentives—this latter logic is often leveraged by critics of the academic institution of tenure, deeming it to function as a disincentive to continued productivity over the course of one's career.

Neoliberal doctrines underlie increasingly ubiquitous political demands that institutions of higher learning align their curriculum with the specific “competencies” desired by corporations and corresponding pressures to deliver high levels of customer service to customer-students. This latter neoliberal figuration further entails that these customer-students are empowered to be “informed consumers,” via rankings and more aggressive branding and positioning activities. This responsabilization of the student-customer also is encouraged by a shift toward loan-based funding of such educational investments in one's human capital—which eventually need to be repaid, rather than governmental grants (Ward 2014).

It is perhaps worth noting that this neoliberal, market-competency, customer-driven approach to higher education is a radical transformation of the normative ideals and intellectual orientations that historically guided higher education. For example consider this passage from John Stuart Mill's inaugural address as Rector of the University of St. Andrews (1867):

Universities are not intended to teach the knowledge required to fit men [women] for some special mode of gaining their livelihood. Their object is not to make skillful lawyers, or physicians, or engineers, but capable and cultivated human beings (218).

Mill's statement reflected his adamant belief that an intellectual culture, which encouraged citizens to think critically and beyond their own immediate self-interests, provided needed societal safeguards from the excesses of mercantilism, what we would now call capitalism, and militarism. Of course, the University of Mill's time was a decidedly elitist institution that reproduced a gamut of social inequities. However, as Ward (2014, 464), discusses, the humanistic ideals manifest in this vision of higher learning “also contained the political seeds for the larger democratization of the university that would slowly take place in the twentieth century.” This democratization of higher education was also contingent upon Keynesian-

oriented welfare state policies that heavily subsidized the cost of secondary education. [As a personal aside, I almost certainly would not be an (entrepreneurially successful) college professor, speaking from the institutional position of an ACR Fellow, without the social safety net assistance afforded by a host of federal and state programs that enabled low income students to have access to higher education.]

In today's academic environment, Mill's idealistic pronouncements seem quaint, as much of our pedagogical efforts are institutionally directed toward the instrumental goal of ensuring that our customer-students will be able to quickly and efficiently transition into productive occupations. In the aftermath of disruptive shocks, however, most recently the financial meltdown of 2008, we sometimes do see critical admonishments that business schools should adopt a more socially redemptive pedagogical mission so as to not produce a new legion of greed-driven, selfish mercenaries, as evinced by redemptive statements from leading B-school administrators (quoted in Green 2009):

Wealth creation is about building a better society, and character and integrity are just as important in a manager's capability. I've always had a very strong view that the role of education is not just to give people technical skills: it's there to give people the context of how to be and how they can contribute, not just to their own gain, but to the gain of everybody else.

– Chris Bones, Dean of Henley Business School

Professor Arnoud De Meyer, director of the University of Cambridge's Judge Business School, says that 2008 will be seen as a “watershed year” for the MBA. He argues that future curricula will have to prepare students for the inevitable increase in financial regulation, and should also focus more heavily on how business interacts with society. The schools, he says, will have to become “a bit more academic, independent, curious and interdisciplinary” in their approach to teaching.

But such reflective cautions and calls for educational reform tend to be short-lived and soon enough, business schools returned to their pro-corporate, neoliberal proselytizing status quo as the financial crisis of 2008 faded into distant memory.

Neoliberalism is also restructuring higher education in ways that are compatible with its veneration of efficiency and “flexibility” (neoliberal shibboleths that often correspond to a practice of reducing labor costs by avoiding the obligations of extended labor contracts). To illustrate, in 1969, non-tenure track faculty were an institutional exception, constituting about 20% of the total teaching force in higher education; however, this precarious category of academic works is the institutional norms who now make up over 70% of the instructional faculty (Shulman et al. 2016).

Stories about the neoliberalization of academe are now commonplace in outlets such as the *Chronicle of Higher Education*, *Times Higher Education*, or, on occasion, the *New York Times* and other news media that reporting on these disruptive transformations. These stories illuminate a brave new academic world where tenure protections are being rapidly eroded by hostile state legislators (as in my home institution of the UW-Madison); where departments are increasingly reliant upon a legion of adjunct faculty who toil in the class room for relatively low pay and little, if any long term, security and where tenured and tenure track faculty (to the extent that those classifications have any institutional meaning) face increasing demands to work more efficiently. That is, to assume more teaching and administrative responsibilities while maintaining established, and sometimes intensified, standards of research productivity.

These dramatic shifts reflect a generation of neoliberalizing budget cuts and an increasing reliance on private funds to keep academic institutions viable; money that generally comes with various expectations and requirements, few of which serve a University's research mission (much less practices of critical inquiry). These neoliberalizing forces also ideologically portray public institutions (and tenured faculty who are the functional equivalent of the trade unions so widely condemned in neoliberal doctrine) as a sphere of market-distorting entitlements that need to be reformed through a logic of privatization and the imposition of competitive pressures (and hence incentives for "excellence").

I am not the first to note that these neoliberal trends pose disconcerting threats to hallowed values such as academic freedom, critical inquiry, and intellectual diversity (Ward 2014). For example, the competitive market may support a plethora of courses in finance and marketing but perhaps not so many in Middle Eastern studies or Slavic languages, leading to a truncation of faculty in fields that do not enjoy high market demand. Such market-driven adjustments create a more intellectually homologous system of higher education that becomes increasingly technocratic in its aims and reciprocally, that produces a student-customer who similarly exhibits an instrumental mindset with few predilections to question the neoliberal status quo.

As academics, it is all too easy to lament this process of neoliberalization as an accursed nexus of demands and constraints that are imposed by extraneous economic forces and political actions beyond our immediate control. Yet, as consumer researchers, we also need to recognize that the neoliberal "skids" have been greased by our own well-worn habits of mind and our naturalized tendency to think and act in ways that are in fact quite continuous with the ideals of efficiency and competitiveness used to justify these neoliberal transformations of the University.

The entrepreneurial model hails each and every one of us to build our academic brand (what right minded marketing academic does not have a personal website and a social media presence?); to maximize the efficiency our workdays so as to be able to produce more papers (our proverbial "widgets"); to manage our production "pipelines"; and to see ourselves as relatively autonomous agents ever ready to transfer our human capital/academic brand to wherever it will be most rewarded by market forces.

The same neoliberalized system which produces a class of adjunct faculty negotiating the stresses of economic precarity (Standing 2011) is also the very one which creates academic celebrities, ACR Fellows, and well-compensated chaired professors. In this winner versus losers neoliberal frame, such outcomes are "optimal" ones that directly reflect different degrees of entrepreneurial acumen. From a more critical standpoint, these outcomes reflect structural inequities which confer competitive advantages to some while creating constraints and barriers for others. In other words, it is much easier to pull yourself up by the (competitive) bootstraps when circumstances have endowed you with a jet pack rather than an albatross.

But, my concern is the more specific dangers that lurk within this entrepreneurial-neoliberal habit of mind as it pertains to the conduct of consumer research. As a thought experiment, think of five or six attributes that you believe would be common among ACR Fellows. My expectation is that "productivity" is likely among them. Of course, productivity can function as a shorthand reference for dedication, commitment, perseverance, and other revered traits which contribute to "productive" outcomes. But, if we reflexively acknowledge the institutional conditions that situate and "nudge" our actions, then it becomes difficult to ignore that the disciplinary valorization of "productivity" also places the research process on an instrumental plane. Tangible measures of productivity—publication

counts by journal rankings, presentations, books, and other tangible signs of intellectual productivity—provide key evaluative criteria in performance assessments and hence, determine the distribution of resources via teaching loads, salaries, promotions, awards, and, of course, recognition.¹

This entrepreneurial model also enjoins the interesting evaluative convention of having to quantify one's particular share of contribution for co-authored works, inducing an annual rite of calculation—"I contributed 57% to the theoretical positioning; 48% to the analysis; and 65% to the conclusion, with my aggregate contribution being 56.7%—that would seem preposterous in a world where the collective-collaborative model held institutional sway.

This entrepreneurial model further encourages a truncation of the intellectual enterprise in the name of efficiency. We all know the narrative of harried academic life—there are only so many hours in the day and between teaching, faculty meetings, reviewing, so little time is left for research that we must be focused and efficient in our efforts. But, academic training—not just in marketing and consumer behaviors—but in many academic fields, creates predispositions toward such "adaptive" habits of mind—that is, we are socially conditioned to function in this neoliberalized system and, conversely, to accept it, tolerate it, and even embrace it, when our entrepreneurial efforts are rewarded.

As just one example of this subtle conditioning process, I would surmise that nearly every Ph.D. advisor and nearly every Ph.D. candidate has had a mentoring exchange that hinges on the importance of the "elevator talk"—those 60 second distillations of doctoral dissertation research that every prospective job candidate stands every ready to deliver to a listener/potential employer. And the "elevator talk" has an undeniable instrumental appeal and no small amount of practical value. On the positive side, to make such a synopsis, a researcher must have a clearly defined research question and contribution points that can be represented as a concise set of bullet points on a power point slide. What is not to love?; or stated conversely, what dangers might lurk in training academics to be predisposed to give an elevator talk or on the audience side, to expect that research will be communicated in such efficient and easily comprehended terms?

A successful elevator talk presupposes a rhetorical continuity between presenters and audiences, taking the form of shared communicative expectations, a common base of knowledge and a shared theoretical vernacular. Those continuities also encourage a more homogenous disciplinary discourse. In other words, a Ph.D. student assumes an additional degree of unwanted systemic risks if his/her theoretical vernacular and questions diverge from orthodox conventions. Translation is a far more complex and time consuming process than speaking in a common vernacular, where communication is further aided by shared body of tacit knowledge.

These neoliberal imperatives also enjoin habits of mind that are conducive to a market-oriented fealty to the established taste of our audience and to operate within those comfortably familiar boundaries. In the elevator talk example, this convention demands that a listener not be pushed too far from his intellectual comfort zone. The "good" elevator talk adds a conceptual or empirical twist upon what the listener already knows and hence, the research story, and its points of theoretical distinction, does not deviate from the tacit assumptions that underlie this state of communicative efficiency and sense of intuitive comprehensibility. An ad campaign from the

¹ This description of the increasingly ubiquitous, performance measurement (and governance) tool Digital Measures succinctly summarizes the problems posed by neoliberalism's reduction of academic life to benchmarking measures: "'Digital measures' document everything and reveal nothing, rendering academic practices as calculable rather than meaningful" (Mountz et al. 2015, 1242).

1980's offers a relevant analogy. In the ad, a nattily dressed, generically handsome man is in a formal restaurant accompanied by an equally well-dressed, and generically pretty women; after glancing at the menu, he proclaims in astonishment "I didn't know Michelob made a light!" And here I suggest, we have the commercial personification of the paradoxical state of unremarkable surprise that results from a successful elevator talk.

This neoliberal-entrepreneurial framing of consumer research (and researchers) is manifest in other interactional rituals that are undertaken throughout the course of our professional lives. For example, a standard ice breaking exchange in academic life is the question of "what you are working on?". If you will allow, I would like to make a slight digression. A few years ago, I was invited (required) to attend a social function to honor a wealthy donor who had made a substantial gift to the school. Upon our initial introduction, the benefactor immediately asks "what are you working on?" I soon realized that this query was not an idle or innocent question. Indeed, this donor really wanted to know what I was working on and as I gave a series of elevator talks, though in this case, "interrogation talks" would be a more fitting description, I could see a cost-benefit calculation going on his head. This wealthy benefactor then repeated this interaction ritual with just about every faculty at the reception as he sought to assess the practical relevance and market value of the research that he was helping to underwrite.

Even when academic peers ask "what are you working on" in a more causal manner at conferences and other like settings, the question is no less fraught with normative expectations and ideological demands. What "are you working on?" is often an invitation to briefly review your "research pipeline," a peculiar trope when you think about, implying that one should have a steady flow of research output and that a break in this flow is quite problematic: my god, your pipeline has run dry! But, the ideological effect is most clearly revealed by considering what is *not* normatively expected – perhaps what you are "working on" is not a research project but a book written by another scholar on a topic that you may or may not eventually study but that broadens your perspective or leads to a reflexive questioning of naturalized beliefs (or that you just found interesting). The neoliberal definition of legitimate work discourages such conversations, rendering such non-instrumental uses of one's work time as taboo. In contrast, the equally relevant question of "what have you read?" (or watched or listened to if we broaden the implied frame-of-reference to include enriching aesthetic experiences) is highly unconventional. The entrepreneurial model frames as legitimate work as the ongoing, individuated production of research and all other activities are rendered as suspect (unproductive) uses of one's time.

There is an emotional complement to the "what are you working on?" question. Passion has become the normatively preferred emotional state of neoliberal entrepreneurs or stated conversely, neoliberal ideologies hail workers to recognize themselves as passionate entrepreneurs (Dilts 2011; McRobbie 2015). Passion is an inducement to efface once sacrosanct boundaries between professional and private life as the career sphere now colonizes time once devoted to leisure and family. Given neoliberalism's instrumental prescriptions, we can add thinking and reflection to this list of temporally displaced activities. Indeed, in the ideal neoliberal world, even recreation should, in some way, build human capital that will further enhance our entrepreneurial acumen.

In this entrepreneurial-neoliberal frame, we are therefore ideologically predisposed to regard our work as the activity that most fascinates us; the domain we want to incessantly talk about; the nexus of questions and ideas that fully occupies our minds when not forced

to attend to other responsibilities and distractions; and as our intellectual sustenance and prime source of self-actualization.

Now, let's flip this ideological script around. We are embedded in a heteroglossic intellectual world where people from all research disciplines study a diversity of issues and grapple with fundamental philosophical questions, seek solutions to pressing societal problems, and generate innovative ways of thinking about the world. Sometimes, we really should be more interested in what others are doing. So, perhaps what we celebrate and valorize as "being passionate about one's research" can also betray an institutionalized tendency toward a narcissistic parochialism.

Through an array of institutional norms and conventional practices, neoliberal habits of mind are subtly propagated as the default option for how one should pursue success in the academic game. Consequently, constraints imposed by this orthodoxy can operate in a naturalized and, hence, unquestioned fashion. Like any ideological system, however, the neoliberalized academic game encompasses a range of institutional goals and countervailing discourses that often create internal inconsistencies and disjunctures (i.e., desires for department bonding and collegiality and the normative ideal of being a good departmental citizen—or serving the communal good through service to the field—can conflict with the ethos of entrepreneurial competitiveness). Such structural gaps also create heterodox spaces where the normative constraints of the entrepreneurial-neoliberal model can be contested and unorthodox practices can be enacted, though these challenges may sometimes be more happenstance than strategic. Nonetheless, they can reveal the limitations implicit to naturalized ideological norms.

My own career path illustrates how such happenstance divergences from the institutional enforcement of neoliberal demands can occur (not once but three times in fact) and how subtle pressures to conform can be resisted, though not without risk. During my Ph.D. program at the University of Tennessee, I had a very significant change of heart regarding the direction I wanted to take my career—a shift from a psychometric/methodological orientation to one that explored the symbolic, experiential, and cultural aspects of consumption (Belk, Sherry, and Wallendorf 1988; Holbrook and Hirschman 1982; Levy 1959; McCracken 1986). Fortunately, my faculty advisor was Professor Bill Locander whose career was also in a transitional moment and he afforded me considerable latitude in this exploration which took me deep down the path of Continental philosophy and its more contemporary manifestation in the field of existential-phenomenology (Merleau-Ponty 1962; Sartre 1956)—a journey greatly assisted by the ever generous Professor of Psychology Howard Pollio. For the next few years in my doctoral program—most particularly around the annual review period—I was consistently put on warning for "spending too much time in the library reading and not enough time doing research." Though I never discovered the source from which the faculty gained this knowledge about my unrepentant library patronage, it was an accurate description. This presumed wasteful behavior dramatically contrasted with my peer groups who were actively working with faculty on projects and generating conference papers galore. Ironically enough, and please forgive the blatant self-promotion, I became the most "productive" doctoral student (from a journal publication standpoint) my Ph.D. program had ever produced, aided in large part from the knowledge and viewpoint gained through all that "unproductive" library time.

In hindsight, I fully understand the rationales and well-meant intent behind those orthodox recommendations to become more "productive." There was a system in place for efficiently learning a particular set of research skills and producing a particular kind of research. But, the horizons of opportunity offered by that model were

constrained. Following the normative conventions of being efficient and “productive” cannot get one out of such a proverbial institutional box, it can only anchor one’s habits of mind to those established conditions and the tacit limitations they impose.

Fast forward a few years more, I am embarking on my career as an assistant professor at the University of Wisconsin-Madison. I had become reasonably proficient in a research model oriented around existential-phenomenological methods and related analytic constructs. And, not incidentally, it was one that had gained traction in the academic market of ideas—being very well-suited to the study of consumer identity projects and their implications for consumer-market relationships (e.g., Fournier 1998). However, I had begun to expand my conceptual horizons with readings drawing from feminist and poststructural cultural studies, which sparked a pronounced feeling of limitation in my phenomenological research orientation. This dissatisfaction sparked a two and half year process of conceptual re-tooling and a massive reconceptualization and reanalysis of my dissertation. None of these actions were efficient (much less normatively advisable) from a career management standpoint, as this process led to a significant gap in my research pipeline. Fortunately, the institutional cushion of my prior publications afforded me some degree of institutional leeway. But, my annual reviews were fraught with expressions of concern and warnings about my lack of productivity. Under less forgiving institutional circumstance, my fledgling academic career at a top tier research university could have easily met a premature end.

As indicated by my current status as an ACR Fellow, this re-tooling led to a “productive” phase that carried me through the tenure process. Post-tenure, due in large part to the prodding of my colleague Doug Holt, I became increasingly aware of sociological oversights and elisions that were inherent to my culturally-oriented research. Thus, I undertook another phase of re-tooling and synthesizing that, in turn, led to a substantial gap in my research output. Though in a far less tenuous position than in my assistant professor days, this fallow period nonetheless had costs that accrued across my annual reports but, again, this “unproductive” phase, and the new competencies and perspective it afforded, eventually sparked an array of publications that investigated a much different and broader range of consumption issues than in my previous work.

My various divergences from orthodox norms of “productivity” were not calculated. In hindsight, the divergent paths I pursued during my doctoral program and early assistant professor days were grounded in a blissful ignorance about the potential risks or perhaps a willful disregard for these consequences. To quote former NBA bad boy Charles Barkley, “I am not a role model” and my desultory intellectual approach is absolutely not a template for how young scholars should manage their careers. But, the broader point is that once you take such risks (and let me add see eventual rewards), it becomes much easier to push against the constraints of normative expectations at a future point. My core message is that the neoliberalized academic system has more flex than you may think and that professional and personal value can be gained from critically reflecting on you what you do, why you do it, how you might do it differently in order to expand your horizons of possibility and, sometimes, taking the risk of following the unconventional paths that those reflections point toward.

GOING SLOW AS A REVITALIZING DISCONTINUITY

To foster such discontinuities with neoliberal demands for efficiency and productivity, consumer researchers need a disciplinary license to proclaim, “Right now, I am more interested in what these

other folks are doing;” “the stuff I have been working on just isn’t that interesting to me anymore and I am searching for something else to do or a new way to think.” The orientation manifest in such statements of generalized curiosity or restless intellectual exploration is not an efficient one; it does not directly fill a pipeline with ongoing research; it does not impress administrators charged with monitoring and rewarding annual productivity (and punishing a lack thereof); and it does not confer much immediate value in the academic status game. But, it can make for more interesting thinkers and in the longer run, more innovative researchers.

Let us consider a hypothetical world that would be discontinuous with this neoliberal, entrepreneurial model. For example, what if the guiding trope was not the time constrained elevator talk but the extended dinner conversation. If so, how might academic training change?; what new habits of mind might be formed? Such a conversationalist would need to cultivate a polyvocal fluency, a breadth of intellectual interests, a capacity to see connections among disparate domains and ideas, and a keen interest in learning from others and gaining resources for re-assessing established beliefs and deeply held assumptions (which does not mean that one might necessarily change his/her world-view but would become more critically reflexive toward its contingencies and dangers).

This alternative world scenario is likely to spark a skeptical reaction; it is completely unrealistic; no one has time for such conversational exchanges as a steady-state academic practice because we have “real” work to do; such time-investments in building such polyglot skills would offer little in the way of tangible, timely pay-offs and so on. And therein lies my point, the entrepreneurial model, as an ideological force, governs behavior by constraining our horizons of possibility and naturalizing contingent states of the world as inevitabilities; and to inculcate a belief that “there is no alternative,” to borrow Margaret Thatcher’s famous rhetorical enshrinement of neoliberal policies as the only credible political solution to Britain’s economic problems (McLean 2001).

And indeed, there can be no alternatives, until we create a space for imagining different worlds and different arrangements of academic life. While this dinner conversation trope may be discontinuous with entrepreneurial/neoliberal frame, it is quite continuous with a collaborative-collective-communal one.

Happily, one such alternative is being proposed and pursued in various quarters of the academy. Modeled on the Slow Food movement which aims to liberate consumers’ foodways from the McDonaldized sphere of fast food and to create a more reflexive, socially conscious global community of eaters (Petrini 2007), Slow Scholarship seeks to break the neoliberalizing cycles that are reshaping academic life. It argues that academic freedom necessitates a “freedom to think” (Hartman and Darab 2012, 53) that can only be attained by reclaiming and reconfiguring the institutional spaces, temporalities, and administrative-governance mechanisms that have been co-opted by the corporatization of the University. The goal is to create an academic setting that encourages and legitimates a more deliberate and reflexive mode of scholarship where researchers can do “productive work” by reading and listening to colleagues; undertake longer courses of reflection and study before embarking on research projects; enjoy greater autonomy from instrumental publish or perish pressures; and engage in a host of other communal and intellectually enriching activities that currently necessitate finding ways to subvert the prevailing neoliberal system (See Mountz et al. 2015).

The Slow Scholarship movement is not inimical to instrumental justifications, arguing for example, that their alternative practices are ways to engender more effective—rather than efficient—research, teaching, and mentoring (Meyerhoff, Johnson, and Braun 2011).

Proposals for implementing Slow Scholarship include a significant number “the personal-is-political” changes that can be made in one’s daily work routine—such as exiting the email spiral which can consume one’s day with administrative trivialities and aiming for minimum allowable productivity benchmarks. This latter option is an interesting one because it enjoins researchers to become less sensitive to the immediate pressures of the academic status game and to accept, in the shorter run, the consequences of being deemed “less productive” (though still falling within an acceptable institutional range) so as to gain longer term benefits (such as more impactful research and, not to be overlooked, a more rewarding and enjoyable academic life).

Importantly, however, these individuated actions need to be undertaken in support of collective ones whereby academics push their institutions to create work environments and evaluative systems that are more conducive to this alternative model of academic life and a slower and more thoughtful conception of productivity and value (Mountz et. al 2015). Such unconventional, orthodoxy-challenging actions constitute forms of ideological edgework, or what in this context could be more specifically characterized as intellectual edgework, that tests the boundaries of an ideological system and seeks to gradually expand its zones of tolerability and legitimacy (c.f., Thompson and Üstüner 2015).

Such modes of intellectual-ideological edgework could also help to redress a concern routinely expressed in ACR Fellows addresses (among many other discursive forums such as ACR Presidential addresses)—the field of consumer research is not generating “new” ideas or having a sufficient impact beyond our disciplinary borders. From my standpoint, however, those concerns—though related to the issues addressed here—are somewhat misplaced. The communal model reminds that no idea or theorization is completely original but, rather, it derives from prior conceptions, perhaps applied in a novel way or blended with other concepts to create an innovative hybrid conception. In regard to the proposed interdisciplinary shortfalls, other disciplines are also embedded in the neoliberal academic game and have their own incentives to be insular, or more accurately, to not readily acknowledge sub-disciplines that are seen as holding a lower status position in the grand academic hierarchy. Consumer research’s limited impact on base disciplines, has as much, or more to do, with the sociological conditions that reproduce status hierarchies among social factions as it does the relative merits and novelty of our research.

However, the neoliberal-entrepreneurial model fosters an unreflexive contentment with what you know (i.e., your stock of existing intellectual capital) rather than a restlessness over what you don’t know and the forms of intellectual capital that could be garnered through exploration of the broader, heteroglossic collective intelligence. This habit-of-mind prefers the comfort of well-rehearsed routines and skills (which allow for ready displays of technical proficiency) to the inefficient struggles of acquiring new ones. And it is a habit-of-mind that is continuous with the neoliberalized institutional structures. In contrast, practices of intellectual-ideological edgework can cultivate habits of mind that are discontinuous with these socializing and normalizing structures.

SUBVERSIVE DISCONTINUITIES

Periodically, we do encounter colleagues who, for any variety of reasons, diverge from this entrepreneurial-neoliberal orthodoxy. They may be situated in an institutional space where the reach of neoliberal doctrines have not yet extended or they may have found (or created) a haven where such unorthodox actions could flourish (at least temporarily).

In this spirit, I suspect (and indeed hope) that over the course of your academic life, you have been (or will be) have a colleague who embodies this collaborative-collective model. In my own professional life, I can think of no better example than my dear departed friend Per Østergaard. Per was a voracious and eclectic reader who loved to discuss ideas with doctoral students, other faculty members, and geographically dispersed colleagues such as myself. In most cases, these discussions did not directly relate to any specific research project that Per might have been working on. More commonly, these discussions concerned broader ideas and theoretical debates that Per wanted to share and discuss with others or they were motivated by Per’s insatiable interest helping others negotiate conceptual or methodological road blocks.

Per was a quintessential Slow Scholar long before this term entered the academic parlance. And Per’s deliberately-paced, communal orientation also carried an institutional “cost.” He was not a highly productive scholar in terms of the number of papers he published. However, the research he did publish was innovative, provocative, and boundary spanning (Belk, Østergaard, and Groves 1998; Bode and Østergaard 2013; Jantzen, Østergaard, and Vieira 2006; Jantzen, Fitchett, Østergaard, and Vetner 2012; Lindberg Østergaard 2015; Østergaard and Fitchett 2012). And, Per was a great facilitator of research who never hesitated to provide detailed feedback on a colleague’s paper—often pushing the author to think more broadly about the topic and to find a more interesting question lurking within the research context.

Per’s failure to produce published papers on annual basis did create friction with administrators. However, his home institution, Southern Denmark University, had an established, collectivist tradition of assessing research productivity at a unit level and thus, his role as a facilitator of research could be assigned enough institutional value to keep the administrative wolves at bay. And here we can recognize some degrees of freedom that are afforded when at least some institutional credence is given to the logic of the collaborative-collective model. Of course, such an institutional haven is discontinuous with entrepreneurial-neoliberal model and, as we speak, the Scandinavian academic system is also undergoing its own historically contextualized version of neoliberalization (Steensen 2008).

These neoliberalizing changes to academic life are the consequences of much broader socio-political transformations and, they are quite likely to be the structural conditions academically-oriented consumer researchers will be negotiating (and perhaps resisting at times) for years to come, barring dramatic shifts in the broader political sphere. For this reason, I am not celebrating Per’s communal-collaborative orientation as a normative ideal that other consumer researchers should necessarily emulate or, even, as exemplar of how to resist or defy neoliberal imperatives for efficiency and productivity.

Rather, I want to highlight the synergies that exist when an academic institution is able to find ways to create continuities between the collaborative-collective model and the entrepreneurial-neoliberal one. In the case of Per, his communal orientation could in fact, be legitimately interpreted as enacting a subtle entrepreneurial move but one seeking different rewards than those who play the neoliberal academic game in a more orthodox fashion. Per’s approach to academic life existed in a highly functional, complementary relation to his colleagues who were engaged in the conventional quest to build their research records and external reputations (i.e., academic brands) through passionate productivity.

Looking at this synergy in more general sociological terms, we can say that a communal academic engages in activities (i.e., reading, discussions, participating in seminars, reading groups, etc.) that enrich his/her stock of intellectual capital. However, the goal of such

capitalizing activities is not to gain symbolic capital, or status, in the academic publishing game, but to acquire social capital in an academic field (be it a department or a research community). Reciprocally, whenever such conversions of intellectual capital into social capital aid an entrepreneurially oriented colleague in building his/her publication record, this (collective) achievement enhances the value of the social capital circulating in that particular field.

A related lesson that can be drawn from the career of Per Ostergaard is that neoliberalism is not a unified, hegemonic order, but instead, it is a nexus of ideals and practices that intersect with established institutional conventions and histories to create what political scientists characterize as “actually existing neoliberalisms” (Brenner and Theodore 2002). And these practical adaptations of the neoliberal project often create institutional ambiguities and contradictions. These messy actualities, in turn, also afford greater degrees of freedom than one might realize to engage in intellectual-ideological edgework (c.f., Thompson and Üstüner 2015) and to liberate one’s habits-of-mind from the constraining demands of the neoliberal academic status game.

Such intellectual discontinuities make it more likely that one will be able to draw connections, discern interesting and novel relationships, and recognize limitations in orthodox frameworks that would likely elude those whose habits of mind are continuous with the prevailing institutional doxa. In a more political vein, such intellectual discontinuities also sustain a critical-reflexive perspective toward institutional norms and status quo conventions (including those that are naturalized as unquestionable structural givens). While such a critical-reflexive awareness may not necessarily lead to wholesale structural changes (i.e., some power relations may not be easily surmounted), it does create pathways and incentives for subverting or reshaping institutional conditions in ways that mitigate some of the restrictive demands of neoliberalized academic life.

HOW TO DO “INTELLECTUAL EDGEWORK”

1. Be less instrumental: In pushing against the limits of the neoliberal-entrepreneurial model, a first step would be to pursue research projects that afford opportunities for enriching one’s stock of intellectual capital. This guideline, in turn, suggests that the research process would also have to encompass the inefficiencies posed by the acquisition of new knowledge.

As consumer researchers, we can always say that such learning outcomes are attained (efficiently) from empirical results—(e.g., from this study, I learned that this variable exerts a moderating effect on this process, given this set of mediating conditions). While such empirical discoveries are, indeed, a kind of (quite legitimate) learning, this process entails adding a new node to an existing network; it therefore constitutes an extension of one’s established knowledge base but it does not significantly expand one’s stock of intellectual capital. Conversely, one might choose a project because it requires them to expand their methodological horizons, explore an unfamiliar theoretical domain or develop in depth knowledge about previously unfamiliar social contexts or issues, such as by reading historical analyses or literary portrayals. The end game is not the research output per se; rather, research becomes the means to push the constraints of one’s established habits of mind and to gain a reflexive and critical perspective on institutional conditions that otherwise demand fidelity to an instrumental vision of “productivity.”

Least this suggestion seem Pollyannaish, this boundary expanding orientation can aligned with the demands of neoliberal evaluative standards by producing multiple papers (i.e., products) that draw from this acquisition of new forms of intellectual capital. The key is

to gain institutional recognition that such theoretical innovations do not necessarily follow the mandates of annual reporting conventions. Slower scholarship serves a longer run vision of impact and when institutional norms militate against such activities, we can see a place where the neoliberal model can be challenged on the countervailing grounds of research impact and entrepreneurial innovation. In other words, neoliberal standards can be subverted in ways that serve a goal of institutional transformation.

2. Be more communal: The process of expanding one’s intellectual horizons affords an outstanding opportunity to attend seminars (hosted by other departments and schools at your University); to attend conferences that might be out of your standard portfolio and to meet and discuss issues with researchers who had, heretofore, not been part of your academic social network. [A much wider gamut of recommendations for incorporating more communal practices into one’s academic life are provided by proponents of Slow Scholarship (see Mountz et al. 2015)].
3. Don’t let passion become an excuse to avoid critical reflections: “Loving what you do” does not absolve a consumer researcher from an ethical responsibility to periodically reflect on the reflexive question “is what I do really worth doing?; “whose interests are being served and to what purpose? Are my actions driven by careerism and instrumentalism or am I doing things that are pushing my habituated intellectual boundaries in ways that allow me to engage in creative intellectual edgework?

Though I am clearly advocating for this horizon expanding criterion (and its subversion of the entrepreneurial-neoliberal model) as a normative guide, there are other logics of normative justification that could be deployed in this reflexive assessments, such as helping to redress major social problems and providing knowledge that can lead to a more equitable and sustainable society. The subfield of transformative consumer research (Mick et al. 2012) is oriented around this justificatory logic. Whether a justification is grounded in an ideal of theoretical innovation, civic virtue, or some other normative model (see for example Boltanski and Thévenot 2006), however, reflexive justifications are not rationalizations. The aim of such critical self-appraisals is to critically assess the merits of our chosen criteria and the degree to which our research practices and their outcomes realize those normative aims.

THE INCITEMENTS OF DISCONTINUITY

The institutional discontinuities that frame consumer research can function as incitements to reflection and reflexive assessment, creating potential for change and growth. Habits of mind that align with the entrepreneurial-neoliberal model are not necessarily bad but they harbor hidden dangers when we presume that there is no alternative to such an orientation. Reflexive questioning should engender unrest and unease with patterns set by institutional norms, habits of mind engrained by years of academic training, and the path dependencies established in the course of building one’s academic brand. And, at least some of the time, I suggest that there is much to be gained, institutionally and personally, in diverging from these neoliberal hailings by adopting a more communal, intellectually curious, and non-instrumental approach to scholarship.

I began this decidedly inefficient reflection on the question of “why award an ACR Fellow?” At this juncture, a distinct but related question arises: what does the ACR Fellows Award represent? From a conventional standpoint, this award celebrates achievement and social distinction. ACR Fellows are celebrated for being thought leaders, innovators, and who think differently from the “masses” of

consumer researchers. And this conventional meaning has a mythic function; that is, it masks contradictions and inconsistencies that would otherwise threaten the normative legitimacy unreflexively granted to naturalized institutional norms and practices (Barthes 1972).

This mythic construction obscures that celebrated ACR Fellows are the ideological exceptions who prove the institutionalized norms. This mythic framing suggests that ACR Fellows' inherently possessed discontinuous habits of mind (creative aptitude, intellectual curiosity, penchants for unconventional insights) that enabled them to play the academic more effectively, rather than acknowledging that they were beneficiaries of somewhat anomalous institutional conditions that created opportunities for playing the academic game *differently*. Their distinction hinges on the vast majority of others conforming to the instrumental mandates of the neoliberal-entrepreneurial model. In effect, ACR Fellows have found means to be rewarded for doing parkour while most others are running timed laps around a track.

However, it is possible to subvert the meaning of the ACR Fellows Award and place it in the service of critically assessing the institutional conditions that render these discontinuous habits of mind to be exceptional and in turn, to reconfigure the entrepreneurial-neoliberal status game in ways that would be more conducive to forming habits of mind that are communal, less instrumental in orientation, and predisposed toward critical self-reflection and intellectual edgework. Such institutional shifts would serve to democratize the discontinuous habits of mind, whose currently rarefied distinction now confers distinction in the academic status game.

One could counter this proposal by asking in riposte, "Why make such efforts to diverge from the neoliberal norms that govern our research activities?" Maybe you don't see these dangers as being all the risky and the neoliberal system is working just fine for you. One response, consistent with the ideals of Slow Scholarship, is that such intellectual edgework can afford long term benefits such as building a more diversified portfolio of intellectual capital; generating collaborative connections and synergies; enhancing creativity and afford experiences of enrichment (both experientially and intellectually) that render the (reworked) academic game more meaningful than the atomizing, competitive pressures of the neoliberal-entrepreneurial model.

Another level of response to this question circles back to the first narrative motif of ACR Fellows talks—proposing changes that could potentially enhance the theoretical significance and societal relevance of consumer research. To explain this implication, we also need to look beyond the particularities of the academic status game. And here, I turn to the critical journalist George Monbiot's (2016) discussion of how neoliberal policies—which have helped to generate a radical upward distribution of wealth, rising budget deficits, crisis inducing economic instabilities in global financial markets, and a structural inability to address systemic environmental threats—have retained their hegemonic status in the face of glaring failures:

When laissez-faire economics led to catastrophe in 1929, Keynes devised a comprehensive economic theory to replace it. When Keynesian demand management hit the buffers in the 70s, there was an alternative ready [neoliberalism]. But when neoliberalism fell apart in 2008 there was ... nothing. This is why the zombie walks. The left and center have produced no new general framework of economic thought for 80 years.

While neoliberalism serves the economic interests of those who occupy relatively privileged institutional positions, the destructive

and destabilizing costs of neoliberalism's myriad "externalities" are mounting and becoming more problematic every day. We also stand on the verge of a radical techno-displacement—which is actually well underway—of many conventional occupations as AI and robotic technologies are now becoming capable of performing a wide range of jobs across the blue, pink, and white-collar sectors, encompassing everything from construction work to performing medical diagnoses, legal and financial services, and writing news stories (Keohane 2017). Many technology experts predict that close to 50% of existing jobs will be automated inside of two decades (Morgenstern 2016). The counterbalancing argument is that this in-process technological revolution may generate a surfeit of new jobs whose exact characteristics are difficult to image in the present moment (echoing the historical effects of the industrial revolution) (Whitehouse, Rojanasakul, and Sam 2017). However, the neoliberal political economy, with its commitment to a reduced social safety net, is ill-prepared to the cushion the societal shocks posed by this economic transition (assuming the more optimistic projections hold) and it also harbors the potential to, at least for some time, exacerbate economic inequalities as an elite ownership class profits from low labor costs of production, while a displaced workforce is simultaneously plunged into an impoverished state of perpetual underemployment.

Whether in regard to looming threats of ecological collapse or technodisplacements, these conditions point to a pressing need for new frameworks of economic thought that can offer an alternative to the uncontested hegemonic status of neoliberal doctrines in key policy circles. Such an alternative is not likely to arise so long as social science researchers (including consumer researchers') habits of minds and academic practices mirror these same ideological influences.

Nor can it be piecemeal undertaking from isolated researchers. Neoliberalism arose from a collaborative-communal process of developing an alternative to Keynesian economics, building social capital among policy makers, and diffusing and implementing these ideals through networks of political influence (c.f., Foucault 2008; Giesler and Veresiu 2014). Though still in its nascent stages, an interdisciplinary movement is beginning to coalesce that is seeking to create a viable solutions to the systemic problems (like climate change) that neoliberalism exacerbates through its antipathies toward any regulatory interventions on the market or that its policies have helped to create (such as an ever increasing concentration of the wealth; national debt bombs; hyper volatile investment markets) (see Jones and O'Donnell 2017; Schor 2010). As an interdisciplinary field that studies consumer behaviors as they unfold in market contexts, the consumer behavior field possesses a latent potential to contribute to this communal-collaborative conversation but, to do so, many of our institutionally ingrained, neoliberalized habits of mind will need to be changed. I hope this address might be one small step toward such a change.

And to close on a more personal-retrospective note, the receipt of this ACR Fellow afforded me with an opportunity to reflect on roads taken, those not taken, and perhaps less traveled paths that should be explored. Less than an affirmation, this award has provided instigation and, for that, I will be ever grateful.

2017 ACR Fellow Address

The Future History of Consumer Research: Will the Discipline Rise to the Opportunity?

Jagdish Sheth, Emory University, USA

INTRODUCTION

I am both honored and grateful to be inducted as ACR Fellow.

Exactly five decades ago (1967) I published my first paper titled “A Review of Buyer Behavior” in *Management Science*. It was a philosophy of science perspective of the extant knowledge of buyer behavior. The paper concluded that buyer behavior as a discipline resembled more like the proverbial five blind men and the elephant. What it needed was a theory that unified the diverse perspectives and provided explanation of why we buy what we buy.

My doctorate is from the University of Pittsburgh. My major was: Individual and Group Behavior. My minor was social psychology and I chose marketing as my applied field. This led to a life transforming and life long relationship with John A. Howard, who became my advisor and my mentor. He invited me to co-author the book *The Theory of Buyer Behavior*, which was published in 1969. The main focus of the theory was to explain why consumers become loyal to a brand and end up buying by habit. The theory was anchored to learning, perception, and information search constructs from psychology. It came to be known as the Howard-Sheth Theory of Buyer Behavior. John Howard and I left University of Pittsburgh in 1963 and came to Columbia University, where I started my academic career in Consumer Behavior. The Howard-Sheth Theory became the foundation for a large-scale longitudinal research called the Columbia Buyer Behavior Project. It attracted great doctoral students including George Day, and eminent faculty including John Farley from Carnegie Mellon University, and Don Lehman from Purdue University.

I extended the Howard-Sheth theory to industrial buying behavior and also to family buying behavior with a focus on joint decision making and inherent conflict among the family members due to their divergent goals and perceptions.

My next book in consumer behavior was *Consumption Values and Market Choices* (with Bruce Newman and Barbara Gross,) published in 1991. It articulated that all consumer choices can be attributed to functional, social, emotional, epistemic and situational values provided by the product and brand choices at all three levels of consumption: 1. To consumer or not to consume; 2. If yes, what type to consume; 3. Which brand to consume within a type or category. Based on more than 150 studies of students and homemakers, ranging from playing on pinball machines to marijuana smoking to pizza consumption to choosing brands of shampoo and toothpaste, it provided a structured survey instrument with which to predict future behavior. The accuracy of the future choice behavior was in the nineties across different studies and the determinants of choice varied from functional to social to situational values. This theory was extended to voting for political candidates at the local, state, and national elections with excellent prediction of election outcomes.

My research in consumer behavior shifted to relationship marketing and organizational buying behavior. With the establishment of the Center for Relationship Marketing at Emory University, we began research on why customers engage in a relational exchange and develop a strong vendor loyalty. This led to several articles written with my colleague Atul Paravatyar including a *Handbook of Relationship Marketing* published by Sage in 2000.

In the eighties and the nineties, I wrote two papers on consumer research both published in the *Journal of the Academy of Marketing Science* (JAMS). The first one reviewed the spectacular growth of consumer research anchored to multi attribute attitude models and information processing. The paper, titled “Surpluses and Shortages in Consumer Behavior Theory and Research” strongly suggested that the discipline needs to broaden out and focus on “irrational” choices as well as on excessive and deviant consumption.

The second paper titled “Acrimony in the Ivory Tower” was a painful plea to be more inclusive and tolerant of alternative perspectives and methods. It suggested that ideological acrimony and personal attacks were not healthy for the progress of the discipline.

I became the President of ACR in 1984. In that year, I also initiated the first international conference. It was held in Singapore in 1985 and hosted by Professor Tan Chin Tiong at the National University of Singapore (NUS). We invited Jim Engel, the Founder of ACR, to be the keynote speaker. The conference was a great success. I am glad that the tradition of hosting an international conference continues even today.

More recently, I have been doing research on cross-cultural consumption. It is based on gene migration theory and provides an explanation for the cultural differences between Northern and Southern Europeans with respect to basic necessities such as food, clothing, and shelter. However, it also provides an explanation for *why* cultures vary with respect to individualism, punctuality, territorialism, friendship, social status, and material possessions. While we know the dimensions of cultural differences, we don't have an explanation as to *why* cultures vary on those dimensions. My most recent book on this topic, *Genes, Climate, and Consumption Culture: Connecting the Dots* (2017), is published by Emerald Publishing.

I have provided a brief history of my personal journey in consumer research. Now, I would like to provide a brief history of consumption and consumer research. Finally, I will suggest seven new areas of research opportunities.

BRIEF HISTORY OF CONSUMPTION, MARKET RESEARCH, AND CONSUMER RESEARCH

Consumption

Consumption is as old as mankind. In the hunters and gatherers stage of human evolution, consumption was highly individualistic and primarily for day to day survival.

At the farming stage of human evolution, consumption expanded beyond food to shelter and clothing. Also, collective living with others in a community developed social norms on consumptions of basic needs. In other words, consumption became partly driven by personal belief systems and partly by social norms of others.

Consumption also expanded from basic necessities such as food, shelter, and clothing to what we refer to as wants and desires. Consumption went beyond day to day survival and into socially desirable and aspirational possessions of products and artifacts.

As the Industrial Revolution shifted the farm based economies into manufacturing based economies, consumption added many new products and services such as electricity, running water, television,

appliances, and automobiles. Today, with the digital revolution and the cellphone economy, consumption has gone beyond anyone's imagination. Today, cellphones and the Internet are as much a necessity as food, shelter and clothing. Also, consumption has gone global after the liberalization of trade in the nineties. Today, I can buy products and even services from anywhere in the world and I can have choices of products and brands in my supermarket and superstores from all over the world. With the advent of eCommerce and online retailers such as Amazon, Alibaba, and Flipkart, the whole world today can buy products and services virtually from any country.

Finally, with the explosive growth of social media such as Facebook, What's App, WeChat, Instagram and whatnot, consumers today communicate and interact in real time and inform and influence each other about products and services. This peer to peer network of information and influence amounts to word of mouth (WOM) gone wild. WOM has transformed from the local neighborhood to global community and it reaches not just neighbors but also total strangers.

Market Research

While consumption is as old as mankind, market research is less than 150 years old. It became a standard function in companies as a way to gather consumer demographics, activities, interests, opinions, and values.

The origins of market research dates back to sampling and tasting of foods and beverages either as pre-product feedback or as post-product experience. Market research, over time, has evolved into a standalone industry consisting of experts and methods. It has also evolved from understanding the consumer to measuring the impact of advertising and communication as well as calculating Return on Marketing Investments (ROMI) and Customer Lifetime Value (CLV). It has also evolved from qualitative research such as focus groups to highly sophisticated analytical techniques such as stochastic models, multivariate statistics, and predictive analytics. It has become a marketing science. Marketing research is mostly empirical and prides in gaining consumer insights from the feedback and behaviors of consumers. It is devoid of theory and therefore, resembles a discovery science.

Consumer Research

Consumer Research is a very young discipline. It is less than fifty years old. It began with explanatory science by focusing not as much on *what* consumers do or believe but *why* they buy what they buy and *why* they become loyal to brands and products as well as *why* they transcend market transactions as expected by theories of self-interest and maximization of utility.

In the fifties, consumer research also began to distance from economic theories of rational choices and instead focused on psychological theories of emotional choices. The basic proposition was that consumers do not behave logically, but they behave psychologically.

Most scholars and practitioners in consumer behavior belonged to Division 23 (Consumer Psychology) of the American Psychological Association (APA). I was inducted as the APA Fellow in 1975 and became the President of Division 23 in 1979.

The members of the Consumer Psychology Division were mostly psychologists and did consumer research on advertising and communication. It was eventually divested by the APA which led to the formation of the Society for Consumer Psychology (SCP) as a standalone membership organization.

Consumer behavior became a standalone discipline with publication of seminal theories such as the Howard-Sheth Theory of Buyer Behavior and Jim Bettman's Theory of Information Processing. It

divorced itself from market research by establishing its own membership organization called the Association for Consumer Research (ACR). Its founder, James Engel, organized the first workshop in 1970 at Ohio State University and co-opted a few of us to become co-founders of ACR. This separate identity was further cemented by having a separate journal called the Journal of Consumer Research (JCR) dedicated to consumer behavior.

In the early days, consumer behavior was driven by what is referred to as motivation research including subconscious and unconscious motivations. The pioneers such as Ernst Dichter and Sidney Levy developed techniques and tools to understand the psychology of choices of brands and products, and what motivates consumers. These qualitative techniques (in-depth interviews and focus groups) were augmented by physiological (or biological) measures such as pupil dilation, galvanic skin pressure, heart rate, and more recently, brain imaging. Finally, consumer research today focuses on laboratory experiments with the protocol of three research studies similar to what psychologists do in experimental and social psychology.

Five Phases of Consumer Research

Over the years, consumer research has evolved into at least five research traditions. The first is referred to as the multi-attribute attitude models. These models provide explanations of how consumer attitudes are developed and whether prior consumer attitudes and intentions predict future behaviors. Most of the research was based on survey research methods with the use of well-defined survey questions. This was followed by research on information processing led by Jacob Jacoby at Purdue University and Jim Bettman at Duke University. Information processing, as the name implies, focused on how consumers engage in selective exposure, selective attention, and selective retention of information and how consumers engage in active search for information.

Information processing research shifted from survey research to experimental research in behavioral labs located in psychology departments and in business schools. The subjects were students and sample sizes were small compared to household research on multi-attribute attitude models.

Both of these research traditions were challenged because they reflected only partial reality. Also, they focused on the buyers as opposed to the users. It led to the third and the fourth traditions. They are referred to as Odyssey Research and Transformative Consumer Research. Odyssey Research, led by Russel Belk, resembled the anthropological tradition of immersing into and experiencing the cultures of consumption. It believed in theory in use which was anchored to grounded reality; and it resembled more like group safaris. The fourth tradition called Transformative Research began to focus on the world of music and movies and emotive aspects of consumer behavior. This tradition was led by Morris Holbrook and eventually it led to focusing on several other neglected areas in consumer research such as cross-cultural consumer research and consumer policy research.

Behavioral Economics

The fifth and current tradition is what is referred to as behavioral economics. It is mostly experimental research focused on exposure and manipulation of stimuli to evoke hypothesized consumer responses with respect to brand or product choices. It is following the typical protocol of three studies (Study 1, Study 2, Study 3) with scientific rigor to establish a causal relationship between the experimental treatment and the predicted outcome while controlling for moderator variables.

Behavioral economics is also transforming the discipline of economics. Indeed, several non-economists such as Herbert Simon and Daniel Kahneman have been awarded the Nobel Prize in economics for bringing the psychological or behavioral perspectives in the economic behavior of markets, consumers, and organizations. The most recent 2017 award was given to Richard Thaler “for his contributions to behavioral economics.”

Over time, the field of consumer research has become narrow both in its perspective and in its methodology. I refer to this as the *discipline myopia*. In my view, consumer research needs to become more eclectic both with respect to perspective and with respect to methodology. I think the discipline needs to promote the big tent mentality and encourage diverse perspectives and methods.

THE FUTURE OF CONSUMER RESEARCH

There are seven great opportunities to broaden the scope and nature of consumer research. They are depicted in the pie chart below:

Figure 1. Seven Great Opportunities

User Experiences

First, we need to redefine who is the consumer. The consumer is not just a buyer; he or she is also a user and a payer. Most of consumer research in all five traditions I have described above is focused on the consumer as a buyer. This is due to our roots in marketing that have been primarily interested in the buying behavior. Most consumer research scholars are faculty in the marketing departments.

Consumer as user, however, is a more critical and relevant area to study. It shifts the focus from buying and choice making to usage and post-purchase experience. It is interesting to note that most R&D departments in companies focus on the user and not the buyer whether it is automobiles, appliances, cellphones, or prescription medicine. The customer as user is obvious in service industries where consumer experience matters. This is becoming even more relevant now that users report their experiences on social media.

Similarly, consumer as payer is not studied well. This includes family budgets, credit history, debt obligations and monthly

cash flow management. It was the corner stone of thinking by John Maynard Keynes in what he articulated as propensity to save vs propensity to consume; and how discretionary income, interest rates, and tax rate mattered in propensity to consume. In other words, it is not just the willingness to pay but the ability to pay. Following the micro economics tradition, the discipline of home economics focused on family issues of budgets, savings, and cash flow. It needs to be included and encouraged in consumer research.

Social Media Engagement

The largest nation in the world is not China or India. It is the Facebook nation with a population of more than two billion. In the monarchy era, it would be declared as the largest global empire probably as big, if not bigger than the Roman and the British Empire. This social media nation has global reach with very rich content revolving around consumption, if you define social activities as acts of consumption. The impact of social media and peer to peer information sharing and influencing is key for future research in consumer behavior. It is WOM gone wild and can champion or destroy a world class brand including personality brands. Fortunately, social media data are publicly available for research. It will, however, require learning new methods of analysis and the language of text messages. The evolution of natural language processing (NLP) as a tool is based on cognitive psychology and seems very suitable for research in consumer behavior.

Of course, social media engagement by consumers is not limited to Facebook. You have WeChat, What’s App, Snapchat, Instagram, etc. The masses love social media and social media need the masses to scale up. This symbiotic relationship is likely to last for a long time barring regulation, policy intervention, or anti-globalization sentiments. It will definitely transform consumer behavior in the way we gather information, share our experiences, and transact our buying behavior. It will rekindle consumerism as a movement not led by one person such as Ralph Nader but by the grass root movements. Crowdsourcing of consumerism is an interesting area of new research opportunity.

Mindful Consumption

Mindful Consumption is a growing area of research interest for policy makers as well as marketers. Consumers in advanced countries are beginning to appreciate that carbon footprint is global and borderless. Also, it is simply not possible for mother nature to regenerate itself quickly enough to provide resources for more than three billion people from the emerging markets of China, India, and Africa who all want to buy branded products rather than make them at home.

Mindful Consumption means consciousness about how consumption impacts the environment from the time consumers procure the product, store it for future consumption, and dispose of as waste. It is estimated that more than seventy percent of the carbon footprint happens at home and not in the factory. It is the home, the refrigerator, the freezer, and the automobile which are responsible for increased carbon in the atmosphere. As consumers become more aware of the unintended consequences of their consumption, they are searching for ways they can minimize the side effects of consumption. This is particularly key with respect to the storage of foods, presence of large homes, and inefficient waste collection and disposal.

More companies are realizing that consumers today are looking for meaning in consumption and that they are serving the society through their consumption. It is “doing well by doing good.” Today, therefore, marketers are all trying to associate some social cause with their brands.

Crowd Consumption

The Internet's increased reach is unprecedented. There are no more six degrees of separation. Today, there is no degree or only one degree of separation. Therefore, it is possible to galvanize a crowd on any issue or problem. This has been very evident in crowd sourcing and crowd funding. For example, it was social media and viral marketing that led to the unprecedented success of the Ice Bucket Challenge for increasing awareness and raising funds for ALS.

I believe crowd consumption is a potentially very important area of research. Crowd Consumption is similar to the band wagon effect of the ice cream man who attracts children from the neighborhood. It is more than viral events or unplanned gathering of friends; and its scope is simply massive.

What motivates people to join the crowd? How does crowd consumption get organized? What is the life cycle of crowd consumption? Is it similar to trends in fashion?

Crowd Consumption, like Woodstock in the Seventies and New Year's Eve at Times Square, requires managing supply chain and dynamic pricing.

Multi-Cultural Consumption

As ethnic diversity is rising all over the world, it is becoming increasingly important to study consumption differences between subcultures of a nation. For example, California is already a multicultural state with a non-white majority. So will be Texas and Florida, which are the next two largest states in terms of population size. Therefore, taking the WASP (White Anglo-Saxon Protestant) perspective is becoming increasingly myopic and may lead to missed opportunities. In my own research, I find that, today, minorities are the opinion makers and influence the consumption by the white majority. For example, African Americans lead in music and fashion. In the United Kingdom, fish and chips is replaced with chicken tandoori with increased immigration from South Asia. In the United States, potato chips are replaced by tortilla chips, and ketchup by salsa. Indeed, it seems that minorities gain acceptance in the U.S. by the majority consuming minority culture's products and services and thereby becoming good followers. In other words, opinion leadership theory is turned upside down. Minorities are the new opinion leaders. They now also include Asians such as Korean, Indian, and Chinese consumers.

Low Income Consumption

Low Income Consumers are growing faster than the average as the middle class is shrinking and extreme income groups are rising. The Base of the Pyramid (BOP) market defined as those who earn less than two dollars a day income totally represents a \$5 trillion economy. Low Income Consumers consume products and services just as all consumers do. However, we have not studied their decision-making process. Since their needs and wants are the same, what matters most is, therefore, to study their resource constraints including income, time, and expertise.

What matters most to low income consumers is affordability, accessibility, and awareness to such critical issues as health and economic well-being. As of today, we do not have a well-accepted theory or a paradigm for low income consumers. Scientific research on their brand choices and use of products and services may be very valuable for public policy, economic development, and corporate social responsibility (CSR).

Consumption of Public Goods

Public goods are shared goods. Generally, they are free or heavily subsidized. It is estimated that more than fifty percent of consumption is directly related to public goods. These include highways, airports, schools, education, parks and recreation, arts and cultural festivals, and public health.

Since the market mechanism with price as the mediator between the supply and the demand (at a point in time or at the equilibrium) often fails in public goods, it is important to discover or develop concepts and theories of public goods consumption. For example, how does shared consumption impact consumer attitudes and behaviors? Why do consumers engage in road rage? Is road rage also relevant in air travel or at the grocery store? Is collective consumption culture bound? Why does it do well in Scandinavia and not so well in other cultures? These are just a few areas of research. This research does not have to be just experimental (three studies in a laboratory), it can also be qualitative or empirical in nature.

To conclude, I believe consumer research needs to consciously broaden out from the current narrow focus on three experimental laboratory studies on a microscopic aspect of consumption. Instead, it can dwell on issues that are vastly more impactful and that will benefit society at large from scientific (versus anecdotal) findings.

2017 ACR Fellow Address

Our Collective Journey

Debbie MacInnis, University of Southern California, USA

Thank you for such an amazing introduction Russ. I am deeply honored to stand here with two eminent colleagues (Jag Sheth and Craig Thompson) to give an ACR Fellows address, and I am so happy to have my husband and so many friends here to share in this special occasion.

I thought my ACR Fellows Address would be an appropriate time to take a broad view of the field and look at how we are evolving over time. Our field's founders, people like Jim Bettman, Jag Sheth, Gerry Zaltman, Hal Kassarian, Joel Cohen, Russ Belk, Morris Holbrook, Jack Jacoby and others staked out a view of consumer behavior that was broad and deep.

CONSUMER BEHAVIOR AS DECISION MAKING

Jack Jacoby aptly captures this broad vision in what is now regarded as a widely held definition of consumer behavior. Consumer behavior includes not just decisions about *what* people consume, but also decisions about whether, when, where, why, how, how much and how often people engage in consumption. Importantly, the field of consumer behavior is differentiated from allied disciplines by virtue of its focus on *consumption*, where consumption includes all means of acquiring, using and disposing of marketplace offerings. Consumer behavior is not restricted to the consumption of *products*. It includes myriad entities, including brands, services, ideas, people, places, gifts, and experiences. Decision making units include not just the *decider* but the information gatherers, users, and influencers like friends, family, communities, and other reference groups who exert normative or informational information in person or virtually. Moreover, consumer decision making is conceived as varying *across time*, whether in units of seconds, hours, seasons, or life stages.

If we look carefully at this definition, we realize that at its core, consumer behavior has been defined in terms of *consumption decisions*. That is, while we are interested in a broad array of topics like consumer experiences, emotions, brand relationships, or how consumers are influenced by celebrities and other opinion leaders, the lens through which we view them is the lens of decision making.

This focus on decision making in a consumption context is not surprising. After all, decisions about acquisition, usage and disposition link consumer behavior to marketing and economics. Moreover, consumption provides a rich context in which we can explore decision making from a multidisciplinary perspective. Indeed, our field has been greatly enriched by perspectives from psychology, sociology, anthropology, history and other core disciplines. Nor is it surprising that decision making in a consumption context is a focal part of the definition of the field. Indeed, the birth of the field of consumer behavior coincided with highly influential works by decision making experts inside and outside our field. Consider, for example, Howard and Sheth's *Theory of Buyer Behavior*, Jim Bettman's "*An Information Processing Theory of Consumer Choice*". Kahneman and Tversky's *Judgment under Uncertainty: Heuristics and Biases*, and Herb Simon's work on bounded rationality.

Moreover, we've learned a lot about consumer decision making since the birth of ACR. We've learned that consumers make different *types* of decisions depending on whether they are motivated by functional, symbolic, and hedonic goals. These decisions can be described in terms of a goal hierarchy and they can influence or be in-

fluenced by emotions. We've studied a set of *dimensions* along which decisions can be described, among which include the degree to which decisions are effortful, the degree to which they are objective vs. biased, and the extent to which they are made with a greater vs. a lower sense of decision commitment. We've learned that consumer decisions span a *journey* that includes myriad processes like search, attention, sensory perception, categorization and more. We've learned that decisions can have *paradoxical outcomes* or effects, as when the decisions we make in the short term can have negative effects over the long term. Or when reliance on a technological product can make us feel powerful when it works but powerless when it doesn't. We've studied how the *portfolio* of products consumers have like special possessions, collections, and heirlooms reflect one's identity. Moreover, once they are owned, we may be reluctant to part with them, and demand a higher selling price than what they are objectively worth. And we've learned that consumer decisions are *contingent*. They're impacted by, among other things, the physical environment consumers are in, the physical states of their bodies, who they are with, and the socio/cultural context in which they've embedded.

A NEW/OLD FOCAL DOMAIN: CONSUMER BEHAVIOR AND RESOURCES

These insights are obvious to us. But what may be less obvious is I think field is rallying around another focal domain. And one that also has a great bearing on consumption decisions. Like consumer decision making, this domain can also be described in terms of dimensions, processes, paradoxes and portfolios. But because work in this other domain is sometimes done in circles of influence that don't always intersect, it may not be immediately obvious to people that this other domain is becoming more and more focal. What is this focal domain? It's centered around the idea of "Resources". What is a resource? One definition is that a resource is "an asset that helps to achieve a desirable end state".

The concept of resources is not new. In fact, it's been relatively foundational to marketing. Specifically, consumers enter the marketplace spending time and money in return for a good or service that provides value. This perspective underlies our concepts of willingness to pay, willingness to spend, and value. Moreover, when it comes to consumption decisions, consumers give up resources so as to gain other resources. Resources given up, and those gained can occur at any stage of the consumption cycle, from acquisition, to usage, to disposition.

But as I see it, the concept of a resource is gaining greater attention and it is being conceptualized more broadly. As case in point, Zaltman and Zaltman's recent book on marketing metaphor suggests that the concept of "resources is one of the 7 deep metaphors that guides consumers' thinking. What is a deep metaphor? It's a way of thinking about the world that serves as a lens for which we look at everything. Although these deep metaphors are largely unconscious, they influence how we express our thoughts and feelings, and they influence how we think and respond to things emotionally. It's interesting to consider that while the academic study of consumer behavior uses the lens of decision making, consumers view their own world through the lens of resources.

Zaltman and Zaltman identify things beyond money, goods, services, and time that consumers think about as resources. Among them include brands/companies, wisdom, or the mind, the environment, relationships and health. Yet, I think we, as a discipline are considering an even broader set of factors that consumers might regard as resources. Among them include status and power, information, attention, access, physical space, and more.

Resources and Markets

What makes this more expanded view of resources interesting? First, a more expansive view of resources can more readily accommodate the types of markets that consumers find themselves in. That is, those in which they give something with the expectation of return. Clearly, we have markets that include the market for goods and services, the health care market, and the financial services market. But an expanded view of consumer resources includes other types of markets, including those that might not always be so obvious to us. Among them include the dating marketing, the market for experimental drugs, the spirituality market, and the philanthropy market. This expanded view of resources also extends to markets where what the “giver” gives may be non-monetary. Examples include the endorser market, the organ donor market and the volunteer market. But what else does a more expansive view of “resources” offer our field?

Resources as A Big Tent for Consumer Researchers

A resource view also accommodates various perspectives on the different types of relationships consumers have with brands. As my dear friend and colleague CW Park noted in his ACR Fellows address last year, when consumers are attached to brands they devote resources like time, money and reputation to the brand, and they also co-opt the brand’s resources as their own. Moreover, if we take a look at the content of our journals, it is clear that many of us are studying resources. But because our field is broad, people who study one type of resource, for example time, might not look at papers published by others who focus on a different resource—say attention, or power, relationships or technology. But thinking broadly about all of these entities as “resources” makes the notion of “resources” a construct that can link disparate research areas. *It makes the construct of resources highly foundational to consumer behavior.*

New Areas of Study

Moreover, in the same way that decisions can be described in terms of dimensions or processes so too can resources be similarly described. In fact, we, as a field are learning more and more about these foundational dimensions and processes associated with resources. *Thinking broadly about what constitutes a “resource” allows us to ask comparative questions that can help us understand whether all resources operate in similar ways.* For example, not having enough money makes us plan and stretch our resources, which we see as rather painful and costly. Yet, not having enough money can also increase creativity, as it requires us to think more broadly about how we can get what we want given the money we have. One wonders, do we observe similar effects when the resource that is scarce is health, or peace of mind?

Some of our most vulnerable populations—the poor, the illiterate the homeless -- are characterized by a lack of resources and a dependency on others for access to resources. Are there other vulnerable populations. Or consider the elderly, who might have a lifetime of goods, insurance that gives them peace of mind, and all the time in the world. But these populations are vulnerable in different ways—lack of access to transportation, declining knowledge, failing health, and a tendency to view technology as a curse vs. a blessing.

Can vulnerability be used broadly to describe any population characterized by a lack of resources and dependency on others? Is the college graduate, who lives at home and who is dependent on parents for money, and goods, while also having limited privacy, space, and power also a member of a vulnerable population?

Whereas being dependent on others for resources sounds like a bad thing, communities of consumers, like the long-distance running community, are preserved when community members depend on community members for social and economic support. Are there other contexts where resource dependencies create stability in consumption contexts?

We know that we’re more likely to buy impulsively, eat more and exercise less when our physical and mental resources, are depleted. Does the same principle hold when resources like power or hope are depleted? Is sharing of information motivated by similar or different things than sharing money, sharing time, or power?

Consumers behave differently depending on how resources are categorized. We behave differently when we categorize time as “work time”, “leisure time”, “personal time”, or “family time”. We budget differently when we categorize a year as involving 12 months or 365 days. Categorizing relationships as “communal” vs “exchange” has a huge impact on whether we expect immediate reciprocity from an exchange partner or not, as well expectations of reciprocity of the same resource vs. a different one. Do consumers have mental categories for things like nature, technology, or status? How would these categories change their consumption behavior?

ACR is a perfect time to talk about ACR’s new journal JACR. As many of you have undoubtedly seen, Chris Janiszewski and Luc Warlop co-edited a special issue of this journal focusing on the topic of how consumers *value resources*. Understanding resource valuation is critical to understanding consumer decision making. What influences how one resource is valued vis a vis another? While time is money, what makes people value time more than money? How does one compare the value of having health vs. having power? When will consumers value nature over technology?

Resources (or lack thereof) As Drivers of Consumer Decision Making

But more fundamentally, while an understanding of resources is foundational to decision making, I think a resource perspective focuses our attention less on the offering than on consumers themselves. It makes the lens through which consumers are viewing the world more focal. Our classic choice models show that consumers’ choices are focused on comparing brands along a set of features or attributes, with attribute importance being a driver of choice. But I’m not sure we’ve given enough attention to *the portfolio* of the consumer’s resources and *how it affects their choices*. In fact, it’s easy to imagine various consumer choices that have nothing to do with the characteristics of a brand or even the competitive landscape in which that brand operates. A consumer may refuse to buy a new car and to instead get around using Lyft and public transportation. This decision is not based on the fact that there are no good brands on the market. Rather, it’s based on the fact that from the consumer’s standpoint, this decision gives her more resources, time, money, and perhaps greater feelings of power and control. I think that the world is changing in such a way that it is forcing consumers to think more deeply about the resources they have and don’t have. *As a result, I think that resource considerations are figuring more prominently into consumers’ decisions.*

Resource Paradoxes and Trade-offs

One reason why is that these resources can have paradoxical effects on other resources. For example, it's clear that investment in technology can make us more connected to others in a virtual environment. However, such investments can come at a cost of weakening other resources, like personal relationships. Having more stuff also means having less space. Having more space to accommodate all the stuff means bigger houses on larger lots, which, in turn, means less opportunities to form relationships with neighbor, not to mention greater outlays of money. Acquiring information on the web often means giving up aspects of our privacy, which can leave us feeling less secure. Acquiring information from the news should make us more informed. But stories about fake news make us wonder. Moreover, the content of that information, like nuclear threats, unstable political leaders, and stories about powerful men who abuse women is definitively reducing the resource of peace of mind. I think these tradeoffs are causing consumers to take more categories of resources into consideration in their decision making. As such, consumer decision making may be becoming more and more complex.

Resource Portfolios. Moreover, we've historically thought about resources *in terms of a specific transaction*—that is, what the consumer is willing to give up in order to get a resource in return. We've focused on things like willingness to pay, search costs, and the like. But maybe what we really need to focus on is what drives consumers to the market in the first place. Perhaps what drives consumers to the marketplace are the resources in which they feel deficient. Maybe we will learn more about decision making if we consider the portfolio of resources consumers have and the resource domains in which they feel flush or constrained. Resource constraints bring people to the marketplace, while resource surpluses may influence what we're willing to exchange to obtain that resource.

Resources and Other Deep Metaphors

Zaltman and Zaltman's work on metaphors identifies other deep metaphors that guide consumers' thinking. These metaphors are

shown in red here. For example, consumers regard having *connections* to others as a foundational resource. Having resources provides consumers with some sense of *control*. Consumers keep resources in a *container*, whether that container is a bank, a wallet, or a mental account. Consumers' *journey* to the marketplace and make decisions that have the potential to *transform* them. This transformation results in a state of *balance*, perhaps by rectifying a resource deficiency. Thinking about how all of these deep metaphors operate on consumers thoughts about consumption is quite interesting.

Resources and Happiness

Thinking about consumer behavior in terms of one's portfolio of resources also has the potential to help us understand what it means to be happy. Whereas one might argue that we are most happy when we have a surplus of all types of resources, the paradoxical nature of resources that I just described suggests that such a state is impossible to achieve. Maybe happiness is not a state marked by having more of every resource. It's a state of equilibrium where one's current portfolio of resources leaves us not wanting for more.

Final Thought

Let me leave you with one final thought that brings my presentation full circle. Looking back on the definition of consumer behavior, coupled with the increasing attention being devoted to resources makes me wonder...Should consumer behavior be more broadly defined so as to explicitly include resources and their influence on decision making? Should our definition of consumer be changed in such a way to reflect the totality of decisions about the allocation of resources regarding the consumption of an offering by decision making units over time

While I wish I could say more, my time is up, my own resources are depleted, and, just as we've benefitted greatly from Craig's remarks, I know that Jag will undoubtedly have incredibly interesting thing say. Thank you for the resources you have given me—most notably, your time and attention. Thank you!

Special Session Summaries

It's Not About What You Do, But How You Do It: The Impact of Technology-Enabled Modalities

Chair: Melanie S. Brucks, Stanford University, USA

Paper #1: When Touch Interfaces Boost Consumer Confidence: The Role of Instrumental Need for Touch

Johannes Hattula, Imperial College Business School, UK
Walter Herzog, WHU-Otto Beisheim School of Management, Germany
Ravi Dhar, Yale University, USA

Paper #2: How the Kinesthetic Properties of a Response Scale Affect Judgment

Melanie S. Brucks, Stanford University, USA
Jonathan Levav, Stanford University, USA

Paper #3: Understanding the Psychology of Smartphone Usage: The Adult Pacifier Hypothesis

Shiri Melumad, Columbia University, USA
Michel T. Pham, Columbia University, USA

Paper #4: When Speech Reflects Mind: Natural Paralinguistic Cues in Voice Convey Presence of Mind

Juliana Schroeder, University of California, USA
Alicea J. Lieberman, University of California, USA

SESSION OVERVIEW

Recent advancements in hardware and software provide consumers with new forms of interaction with companies and products. People can now consume the same products and information across different electronic devices (e.g., laptop, touch-based smartphone, or text-to-speech reader), and companies can assess consumer preferences through different elicitation modes (e.g., providing either a sliding scale or a fill-in-the-blank box to indicate price preference in a search). Yet, there is little research investigating if or how these different technology-enabled modalities impact consumer behavior.

The aim of this session is to bring attention to and discuss the underlying psychological mechanisms at play when consumers use these prevalent, new modalities. We will begin our session with physical interactions afforded by technology—touch-based interface and slider scales—and examine how these factors can influence judgments and decision-making as well as metacognitive outcomes. Next, we will shift our focus to the downstream consequences of using different technology-enabled modalities, investigating the role of these modalities in emotion (as attachment objects) and communication (via paralinguistic cues).

First, Hattula, Herzog, and Dhar examine how using touch-based computer interfaces can influence a diverse set of consumer judgments and decisions. Across five studies, they demonstrate that using a touch-based interface causes less choice deferral, increased propensity to take risks, and higher perceptions of credibility due to increased confidence, especially among consumers who have high instrumental need for touch. In the second paper, Brucks and Levav propose that the kinesthetic properties of responding can induce corresponding psychological processes used to generate the response. In four experiments, they demonstrate that the sensorimotor action of dragging a cursor to an answer prompts the momentary consideration of each value passed by the cursor, leading to responses that are closer to the scale endpoint and reduced confidence. In the third pa-

per, Melumad and Pham examine the role of smartphones as attachment objects. In two lab experiments and a large correlational study involving smoking cessation, they show that using one's smartphone (vs. PC) can induce feelings of comfort and provide relief from stress, and that the device can serve as a substitutive source of stress relief for consumers highly susceptible to stress: people who recently quit smoking. Lastly, Schroeder and Lieberman find that communication modalities impact impressions of the communicator. Through four studies, they demonstrate that paralinguistic cues can convey the communicator's mental capacities, and thus, modalities that contain and enhance paralinguistic cues (e.g., speech, headphones, etc.) can lead to more favorable impressions of the communicator.

By demonstrating that the way in which a consumer experiences and interacts with content has important and diverse implications, these papers suggest that the different modalities afforded by technology are not interchangeable. Drawing from a wide array of literature including haptic and sensorimotor information processing, constructed preferences, attachment theory, and linguistics, this session exposes important underlying psychological processes embedded in technology use. Given the ubiquity of technology in consumption, we believe that this session has both theoretical and practical relevance and will attract a broad audience, cultivating collaborations and innovative research.

When Touch Interfaces Boost Consumer Confidence: The Role of Instrumental Need for Touch

EXTENDED ABSTRACT

Touch-enabled computer interfaces have become prevalent in consumers' lives and increasingly substitute traditional interfaces such as mice and keyboards. For instance, consumers use touch-screen-based devices (e.g., smartphones, tablets) for online shopping or ordering food in restaurants. Similarly, new hybrid computer devices (e.g., Lenovo Yoga) enable consumers to easily switch from non-touch to touch-type interfaces to interact with computers. Despite growing interest in understanding how touch-based devices affect consumers' decision processes, only few studies have empirically examined this relationship.

We add to this body of research by exploring meta-cognitive consequences of using touch-based computing devices. Specifically, we find that touch (vs. non-touch) interfaces can increase consumer confidence in multiple judgment and decision making contexts. For example, when consumers navigate on a touchscreen to shop online, they are less likely to defer purchase decisions and they tend to be more confident in product choices. Similarly, users of touch interfaces are more inclined to take risks because of the touchscreen-induced inflation in confidence.

We propose that the touchscreen-induced inflation in confidence occurs because consumers do not sufficiently distinguish between touching evaluation objects in physical contexts (e.g., products in a store) and touching screens of computing devices which merely display evaluation objects (cf. Brasel and Gips 2014; Shen, Zhang, and Krishna 2016). In physical contexts, consumers touch objects

to examine their haptic properties and thus to derive confidence in their judgments about these objects. In contrast, in a digital context, consumers touch the screen of computing devices merely to operate the devices and they do not generate relevant haptic information on the displayed evaluation object; hence, their judgmental confidence regarding the object should remain unchanged. However, as consumers do not sufficiently distinguish between physical and digital contexts, we hypothesize that the mere use of touch (vs. non-touch) interfaces may nevertheless increase their confidence level (e.g., their confidence in choosing among products online). Moreover, our rationale of a parallel between physical and digital contexts implies that the extent to which consumers develop confidence when using touchscreen devices is directly linked to the extent to which they develop confidence when touching physical evaluation objects—that is, their instrumental need for touch (INFT, Peck and Childers 2003). Hence, we hypothesize that high INFT consumers are more likely to show the touchscreen-induced confidence inflation than low INFT consumers. We test this prediction in four different decision making contexts to show the robustness of the hypothesized effect.

In Study 1, we use the likelihood of making (vs. deferring) a choice as a confidence measure (Dhar 1997). $N=243$ US-based MTurk consumers used either touch or non-touch interface devices when completing a choice task. They were provided with two pen alternatives and as in normal purchase situations, they had the option of choosing a pen (high confidence) or not choosing either of the two alternatives (low confidence). Supporting our theorizing, a positive interaction between type of interface and INFT on participants' likelihood of choosing a pen emerged ($\beta=.45$, $z=2.10$, $p<.04$). Spotlight analysis at one standard deviation unit above (high INFT) and below (low INFT) the mean of INFT revealed no significant difference between touch and non-touch interface when INFT is low (non-touch: 70%; touch: 61%; $p>.35$). However, when INFT is high, the likelihood of making a choice increased significantly from 65% for non-touch interface users to 81% for touchscreen users ($p<.05$).

In Study 2, we experimentally assigned consumers to touch-based and non-touch interface conditions to enhance the causal validity of our findings. Applying a forced choice setting, participants ($N=188$) made a choice between two video game consoles and indicated their confidence in their choice. In support of our theorizing, a significant interaction effect between interface type and INFT emerged ($\beta=.49$, $t=1.91$, $p<.06$), such that high INFT consumers reported more confidence in their choice when using a touchscreen (vs. non-touch) interface ($M_{\text{highINFT,non-touch}}=5.07$, $M_{\text{highINFT,touch}}=5.99$; $\beta=.92$, $t=2.30$, $p<.02$). No such difference was found for low INFT ($M_{\text{lowINFT,non-touch}}=5.34$, $M_{\text{lowINFT,touch}}=5.18$; $\beta=-.16$, $t=.41$, $p>.69$).

In Studies 3 and 4, we propose that the touchscreen-induced confidence inflation also gets manifest in a higher propensity for risk-taking. This proposition builds on research showing that confidence-inducing (vs. unconfidence-inducing) emotions increase individuals' risk-taking preference (Lerner and Keltner 2001) and that overconfident investors hold riskier portfolios (Odean 1998). In Study 3, 155 participants—randomly assigned to touch-based or non-touch interfaces—were asked to participate in one out of two lotteries (Duclos et al. 2013; safe option: 80% chance of winning \$100, 20% chance of receiving nothing; risky option: 20% chance of winning \$400, 80% chance of receiving nothing). Supporting our predictions, we again found a significant interaction between interface condition and INFT ($\beta=.59$, $t=2.20$, $p<.03$) on risk preference, such that high INFT consumers were more inclined to choose the risky option when using a touch (vs. non-touch) interface ($M_{\text{highINFT,non-touch}}=1.91$, $M_{\text{highINFT,touch}}=2.80$; $\beta=.88$, $t=2.28$, $p<.02$). No significant difference

was found for low INFT ($M_{\text{lowINFT,non-touch}}=2.84$, $M_{\text{lowINFT,touch}}=2.54$; $\beta=-.30$, $t=-.83$, $p>.41$).

In Study 4, 150 participants were free to use a touchscreen-based or non-touch interface device to complete a financial investment task. They were asked to invest in one of two possible stock portfolios with the same expected utility but asymmetrical risk (safe option: 90% chance of returning £18,000, 10% chance of losing £37,000; risky option: 50% chance of returning £50,000, 50% chance of losing £25,000). Again, a significant interaction between the type of interface and INFT ($\beta=.89$, $t=2.04$, $p<.04$) emerged. High INFT consumers were more likely to invest in the risky option when they used a touchscreen-based (vs. non-touch) device (non-touch: 78%, touch: 95%; $p<.02$) to complete the task. We find no significant difference for low INFT (non-touch: 79%, touch: 70%; $p>.44$).

Overall, our research provides further support that consumers do not sufficiently distinguish between touching objects in physical contexts and touching digital representations on computer screens. We extend recent work to meta-cognitive experiences and show that using touch-based interface devices can boost consumers' confidence level in multiple contexts. This effect is particularly pronounced among high INFT consumers who derive confidence from touching physical objects and (mistakenly) apply the touch-confidence relationship to a digital context.

How the Kinesthetic Properties of a Response Scale Affect Judgment

EXTENDED ABSTRACT

The physical ways in which consumers can respond to a question or indicate a preference have multiplied with the growth of new technologies (e.g., swiping on Tinder, scanning a finger print with Apple Pay, or sliding on a scale in a consumer satisfaction survey). The present research investigates how these kinesthetic properties of responding can induce different psychological processes used to generate the response and thus, change the response itself.

We rely on a long tradition of literature (Prinz 1987) that suggests that how people process information is grounded in physical experiences (Barsalou 2008). We often use our bodies to guide and orient processing, like counting with our fingers (Wilson 2002) and using gestures (Kita, Alibali, and Chu 2017). Because of this connection between sensorimotor function and cognition, research demonstrates that physical actions can influence processing (e.g., Labbro and Nielsen 2010; Wells and Petty 1980). In line with these findings and drawing on work showing that preferences and judgments are partially determined by tasks that influence the information attended to when responding (Fischhoff 1991; Payne and Bettman 1992), we hypothesize that the physical motion of responding can impact how information is processed, changing the judgment or decision made.

Specifically, we embark on this investigation in the context of radio button and slider multiple choice scales, which differ in the kinesthetic nature of their responses. For radio buttons, the respondent must click the cursor directly on the desired response; for a slider, the respondent must hold the cursor down and drag past other possible selection options. By restricting the slider to the exact same discrete responses as the radio buttons, the only difference between these two scales is the movement required to provide a response. Importantly, these two scale types are used ubiquitously (and oftentimes interchangeably) in research, and thus constitute a meaningful context to begin our empirical exploration into the impact of response kinesthesia.

We propose that the sensorimotor action of dragging the cursor to an answer prompts a corresponding psychological process of se-

rial hypothesis testing (Tversky and Kahneman 1974). Specifically, we predict sliding past each value on the scale elicits the momentary consideration of that value, leading to the selection of the first response that fits within the latitude of acceptance (i.e., the first to seem suitable), which produces responses that are closer to the scale endpoint and decreases confidence.

We conducted four studies to examine the impact of physical movements on judgments using the slider and radio button scales. In Study 1, as an initial test of the effect of scale type and its generalizability, 6017 participants were randomly assigned to use a radio button or slider scale to respond to questions regarding personality, numerical estimates, moral judgments, willingness to pay, attitudes, net promoter score, consumer satisfaction and philosophical standing across three batches of data collection. Each scale had the same discrete options available and, to control for anchoring, both scales were preset on a non-option of “0” (see appendix). Merging the data across all tasks, we observe a small, robust effect of scale type on response: participants using a slider ($M = 4.66$) responded with significantly lower values than participants using radio buttons ($M = 4.86$, $p < 2 \times 10^{-16}$). This effect consistently emerged for each individual task when analyzed separately.

We predict that using a slider lowers the response because participants select the lowest value that falls within their range of plausible responses. If this is the case, the slider effect should be reversed if participants begin at the highest value of the scale and drag the cursor past lower values. To test this, in Study 2, participants entered a 2 (slider vs. radio button) \times 2 (side: left vs. right) design where they made numerical estimates. All participants selected a value from 1-8, but participants assigned to the left (right) side had the non-option of “0” (“9”) preselected as a holding place. We observe a significant interaction of scale type and side ($p < .0001$), such that participants assigned the left side replicated Study 1 ($p < .001$) but participants assigned the right observed a flip: responding via slider yielded higher values than responding via radio buttons ($p < .001$).

Study 3 extends the generalizability of the effect to an incentive-compatible context and tests process in a new way. Specifically, serial hypothesis testing stipulates that participants will select the response at the edge of their latitude of acceptance. If this is the case, participants that have more knowledge about the question context (i.e., a narrower latitude of acceptance), should exhibit an attenuated slider effect. To test this, in Study 3, 2016 participants watched a trailer for the movie “Office Christmas Party,” estimated how much money the movie would make during its opening weekend using either the slider or radio buttons, and then indicated self-reported knowledge of movie box office revenue. Estimates closest to the actual value earned them an extra 50 cents. We replicate the scale effect: participants responding via slider reported a lower estimate than participants using radio buttons ($p = .003$). Importantly, this effect was moderated by knowledge ($p < .10$), such that the effect of scale type was significant among people with low knowledge (1SD below), but not among participants who were knowledgeable (1SD above).

If the slider scale induces serial hypothesis testing, then participants using this scale should feel less confident in their response as they satiated by stopping at the boundary of their latitude of acceptance rather than generating the number that is most reflective of the latent value in their head. To test this, in Study 4, we had 2014 participants estimate numerical values and after each estimate, we asked them about their confidence in the estimate. As expected, not only were the estimates on average lower in the slider condition compared to the radio button ($p < .001$), but participants were also less confident in their responses ($p = .001$).

These findings provide initial evidence for the hypothesis that the kinesthetic properties of a response scale can impact people’s judgments.

Understanding the Psychology of Smartphone Usage: The Adult Pacifier Hypothesis

EXTENDED ABSTRACT

Consumers are officially spending more time on their smartphones than on any of their other electronic devices, and in 2015 the amount of time spent on the device increased by 35% from 2014 alone (Yahoo! Insights 2015). While not clinically recognized as a behavioral dependence (American Psychiatric Association 2013), the term “smartphone addiction” has been commonly used to describe consumers’ seemingly nonstop use of their device (e.g., The Guardian 2016). Although common wisdom largely assumes that this apparent addiction is driven by the functionalities offered on the device (e.g., email, web browsing) (e.g., Aoki and Downes 2003), in reality the features available on smartphones are available across many other electronic devices. Yet, we continue hear about consumers’ apparent “addiction” not to their laptops or tablets, but to their smartphones in particular.

What might account for many consumers’ persistent increase in smartphone use? While the marketing implications of mobile platforms are receiving emerging attention in the marketing modeling literature (e.g., Danaher et al. 2015; Ghose et al. 2013), still very little is known about the consumer psychology of smartphone usage. The purpose of this research is to investigate why consumers often have such a strong drive to engage with their smartphones. We advance the hypothesis that this phenomenon is driven in part by a general and developmentally primitive psychological mechanism: namely, that smartphones can often fulfill the role of an “attachment object” or “adult pacifier” for many consumers—which we refer to as the Adult Pacifier Hypothesis. Specifically, we propose that insight into the psychology of smartphone usage can be found in the developmental literature on attachment theory, which describes how children form strong emotional attachments to certain objects that come to represent a source of security and comfort for them (e.g., Winnicott 1953). These “attachment objects” tend to contain two key physical properties: they are often tactile in nature, and small or lightweight enough to be carried around for use across different contexts (e.g., Lehman et al. 1992). In addition to these characteristic physical properties, attachment objects involve a set of defining behavioral patterns (e.g., Litt 1986). In this research we report results from three studies, including two controlled lab experiments and one large correlational study, showing that smartphones can exhibit at least two of the defining behavioral patterns associated with attachment objects.

Specifically, one defining pattern of attachment objects is that owners feel heightened comfort as a result of engaging with the possession (e.g., Bowlby 1982). The purpose of Study 1 was to examine whether using one’s smartphone increases felt comfort to a greater extent than using a comparable device: one’s personal computer. To test this, participants were randomly assigned to browse content on either their smartphone or their laptop, and were asked to indicate their situational feelings – including their feeling of comfort – at two points in the study: Prior to using their assigned device, and after using their device.

The results of Study 1 show that, holding the content consumed across devices constant, participants assigned to use their smartphone reported a greater increase in felt comfort relative to participants assigned to use their laptop. Moreover, participants did not

differ along any of the other situational feelings measured. In other words, the results show that smartphone use distinctly impacts feelings of comfort in particular, which is central to the argument that the device can serve as an attachment object.

Another primary characteristic of attachment objects is that they are comforting enough to provide relief from a stressful situation (e.g., Mikulincer and Shaver 2007). Building off of this, in Study 2 we tested the hypothesis that, holding everything else constant, using one's smartphone provides a faster recovery from stress than using one's PC. Participants in Study 2 first underwent a stress induction, and were then randomly assigned to browse the same content either on their smartphone or on their laptop. Participants' felt comfort was measured at three points throughout the study: (1) prior to the stress induction, (2) after the stress induction/before device usage, and (3) after using their assigned devices.

The results of Study 2 reveal that, after undergoing stress, participants showed a greater increase in their felt comfort after smartphone usage than after PC usage, such that participants who used their smartphone (vs. PC) felt significantly greater comfort immediately after use of the device. Further, whereas participants who used their PC recovered to their baseline level of comfort upon arrival to the study, participants assigned to use their smartphone reported *greater* comfort than they did when they first arrived to the study. Again, none of the other situational feelings differed across conditions as a function of time. The results of Study 2 therefore confirm that engaging with one's smartphone can be comforting enough to provide relief from stress, which is another defining characteristic of attachment objects.

Study 3 builds on the findings of Study 2 to test a corollary real world prediction that using one's smartphone will be particularly appealing to consumers who are particularly vulnerable to anxiety or stress – for example, people who have recently quit smoking cigarettes. Research has shown that cigarettes can serve as a source of stress and tension relief for smokers and that, soon after they quit smoking, people crave a substitutive means through which to relieve feelings of anxiety (e.g., Burr 1984). If the recent cessation of smoking is a source of stress and anxiety, people who have recently quit smoking may more intensely engage with their smartphone as a substitutive source of comfort. Study 3 therefore compared smartphone usage patterns among participants who either recently quit smoking cigarettes or who were still smoking at the time. The results show that the drive to use one's smartphone becomes especially pronounced among consumers who have recently quit smoking relative to consumers who are still currently smoking, which provides further evidence suggesting that smartphones contain tension-relieving properties.

Taken together these findings provide insight into the psychology underlying smartphone usage, supporting the proposition that smartphones can often serve as an attachment object for many consumers.

When Speech Reflects Mind: Natural Paralinguistic Cues in Voice Convey Presence of Mind

EXTENDED ABSTRACT

Language is used as a tool to communicate one's mind and can be expressed via voice or text (Pinker & Bloom, 1990). Beyond the semantic content of such communication, the voice itself contains natural paralinguistic cues that convey emotion and intention (McAlear, Todorov, & Belin, 2014; Scherer, Banse, & Wallbot, 2001). As such, hearing someone's thoughts via speech (versus text) provides greater insight into their mental states (Kruger et al., 2005)

and, at least under certain circumstances, makes the communicator seem more mentally capable because the paralinguistic cues signal mindfulness (Schroeder & Epley, 2015, 2016). These prior findings suggest that systematically removing natural paralinguistic cues in voice could reduce impressions of a communicator. To test this, we ran four experiments in which we removed or distorted natural paralinguistic cues in voice and measured impressions of communicators. To manipulate paralinguistic cues we either removed them entirely (i.e., via text, Study 1), reduced them using actors' voices (Studies 2 and 4), or subtly distorted them by changing the medium by which they were observed (headphones vs. speakers, Studies 3 and 4).

In an initial experiment, we test whether listeners perceive the mental capacities of a communicator differently if they listen to a message *with* paralinguistic cues (speech) versus the same message *without* paralinguistic cues (text). Critically, the actual words were the same in both conditions. We taped communicators ($n=20$) talking about an experience that involved decision-making. Participants ($n=231$) then listened (audio condition) or read (text condition) one of these speeches and rated the communicator on a battery of items measuring perceptions of the communicator's mental capacities. As predicted, participants believed communicators were more capable thinkers—more competent, thoughtful, and more uniquely human—when they listened to the speeches than when they read them, $t(227)>3.29$, $ps<.01$. Participants also reported higher impressions of communicators they heard ($M_{\text{voice}}=2.84$, $SD=1.17$) than those they read, ($M_{\text{text}}=2.32$, $SD=1.25$), $t(227)=2.66$, $p<.01$. In this experiment, we provide initial evidence that removing paralinguistic cues in voice (i.e., via text) can reduce impressions of a communicator. However, this manipulation presents confounds: the act of reading is different from the act of listening in many ways.

In a second experiment, we used a different manipulation to reduce paralinguistic cues; we asked professional actors to read a written statement “as if the words had no meaning” (mindless voice condition) and to read the same statement naturally, “imbuing the words with the thoughts and feelings of the writer” (mindful voice condition). In this way, speeches from the mindless voice condition lacked natural paralinguistic cues. Analyses of the paralinguistic cues in each of these voices revealed meaningful differences; the mindful voices had higher average pitch and amplitude, and greater variance in pitch and amplitude ($ps<.01$). We then asked a separate sample of evaluators ($n=359$) to either listen to a mindful voice, listen to a mindless voice, or read the original text, and then evaluate the communicator. As predicted, participants who listened to a mindless voice perceived the communicator as significantly less intelligent ($M=3.97$, $SD=1.24$) than participants who listened to a mindful voice ($M=4.70$, $SD=0.97$), $t=5.12$, $p<.001$, and than participants who read the text ($M=4.39$, $SD=1.07$), $t=2.91$, $p<.001$. We also conceptually replicated the finding in Study 1 such that participants who listened to mindful voices believed communicators were more intelligent than those who read text, $t=2.23$, $p=.027$.

In a third experiment we test a more subtle manipulation by making it slightly harder for listeners to hear the paralinguistic cues in the voice. Headphones deliver noise directly into the ear, allowing the listener to pick up on nuances in the voice, while speakers provide reflections of sound, masking some of its subtle detail. By dampening the listener's ability to detect the paralinguistic cues, we predicted that listening to someone's voice through speakers will make the communicator seem less thoughtful and competent than when heard through headphones. Participants ($n=1132$) listened to a clip using either headphones or speakers of a mother and daughter telling their true story of being homeless. Participants then rated the communicators on 10-items rating their warmth and competence,

which we combined into a single scale measuring communicator impression ($\alpha=.84$). Consistent with our hypothesis, participants who listened to the message via speakers reported a less positive impression of the communicators ($M_{\text{speakers}}=5.13$, $SD=0.87$) than those who listened via headphones ($M_{\text{headphones}}=5.23$, $SD=0.84$), $\beta = -.10$, $t(1130)=1.99$, $p=.047$, although this effect was smaller than effects observed in prior studies.

In a final experiment, we demonstrate that listening to a communicator via headphones versus speakers only affects impressions of the communicator when there are natural paralinguistic cues to observe. Participants ($n=1,001$) again listened to a clip either via headphones or via speakers. Half of the participants heard the same clip of the mother and daughter from the previous experiment, while the other half heard a recreation of the clip that contained the same semantic content but was read mindlessly by two actors. Consistent with the results from Study 3, participants who listened to the original (mindful) clip via speakers perceived the communicators as less warm and competent ($M_{\text{speakers}}=5.21$, $SD=0.78$) than those who listened via headphones ($M_{\text{headphones}}=5.43$, $SD=0.91$), $\beta = -.22$, $t(512)=2.91$, $p=.004$. Conversely, participants who heard the mindless clip reported no difference in impression when heard via speakers versus headphones ($p=.795$).

These findings make a significant contribution to understanding the power of the voice on interpersonal perceptions and how these judgments can be influenced by the media in which speech is consumed. Our results provide novel insights into the psychological consequences of auditory media consumption and perceptions, applicable to communicators and consumers alike.

SESSION OVERVIEW

The customization of products is generally regarded as a way to match one's preferences with one's identity (e.g., Franke and Schreier 2008; Mugge, Brunel, and Schoormans 2011). When football fans customize apparel with team colors or coffee aficionados create custom coffee blends, the customization literature has considered this mostly a *reflection* of their identities. However, few studies have considered that consumers' identities are inherently *intertwined with* the customization process. The papers in this session take this novel perspective and ask: how do identities interact with and shape the customization process? Specifically, they examine how different aspects of the customization process interact with consumers' identities, from more micro-level aspects (e.g. whether resources are constrained or examples of customized products are provided, papers 1 & 2) to more macro-level aspects (e.g. the industry or cultural context, papers 3 & 4) of the customization process. Jointly these papers highlight a theoretically and substantively important relationship between identity and the customization process that was previously overlooked.

Herd and Moreau examine how consumers' creations are affected by salient identities. Products created when a familiar identity is active are seen by consumers as less creative and less meaningful. However, when resource inputs are constrained during the creation process, consumers with activated identities exert more effort and create products that are more meaningful.

Lee, Diehl, and Cavanaugh examine how a consumer's design decisions are affected by customization examples of other consumers, specifically the identity of the example creator (i.e., close vs. distant social other). Customized examples by a close other suggest that target consumers should express uniqueness. In order to express uniqueness, consumers make customization choices that are actually more dissimilar to close others relative to distant others.

Hieke, Moreau, and Schreier examine customization decisions in the luxury context. When consumers integrate their identities into luxury products, the designer's identity or essence inherent to the product is diminished. Their findings suggest an optimal self- to designer-essence ratio, where customized products are perceived as having both the consumer's essence and the luxury brand's essence, can maximize purchase intent of customized luxury products.

De Bellis, Hildebrand, Ito, Herrmann, and Schmitt examine how cultural aspects of identity affect customization. Because cultural background influences how individuals think and process information, the choice architecture of customization decisions should be tailored to consumers' culture-specific processing styles. The findings show that congruence between a customization choice interface and consumers' culture-specific processing style increases mental simulation of and satisfaction with customized products.

Together, these papers examine how consumer identities are not merely reflected by customization decisions but in fact crucially shape customization decisions. All papers are at an advanced stage of completion with multiple studies completed. This session will provide novel insights to a wide range of researchers, notably those interested in customization, product design, and creativity as well as those examining the role of individual and group identities and identity-based motivation in consumer contexts.

Making Meaning: How Consumers Build Their Identity Into Their Own Creative Outcomes

EXTENDED ABSTRACT

When consumers engage in a creative task – whether scrapbooking or customizing a sneaker – often one of their key goals is to develop or reinforce their self-identity and to express aspects of themselves (Dahl and Moreau 2007). However, identity domains are often chronically accessible simply because they are used to guide behavior so frequently. This accessibility can be a detriment in the context of creativity (Aarts and Dijksterhuis 2000; Rietzschel et al. 2006). Because of this possibility, we propose that consumers whose identity is activated will exert more effort and create more meaningful outcomes when resource inputs are constrained. When identity is not activated, however, input constraints will not yield a significant effect on the meaning of the outcome.

In our first study ($N = 110$), we manipulated two factors between participants: identity prime (present vs. absent) and constraints (high vs. low). All participants were asked to create a desktop wallpaper using Microsoft Paint. Participants in the “identity prime” condition were asked to think about how their design could represent or reflect something interesting or important about them. Those in the “no identity prime” condition were asked to think about the types of products that could have a background wallpaper like the one they were designing. We manipulated input constraints by providing participants with either limited or extensive shape/ color inputs. Participants evaluated their drawings on four 7-point scales which captured how much their design reflected who they are, how much it expressed aspects of their identity, how proud they were of it, and how much they would like to show it to others (Richins 1994; $\alpha = .91$).

The results revealed a main effect of identity prime ($M_{\text{identity}} = 3.84$ vs. $M_{\text{no identity}} = 2.96$; $F(1, 105) = 8.88, p < .01$) and a significant interaction ($F(1, 105) = 5.42, p < .05$). When an identity prime was

present, participants designing with fewer inputs created outcomes they judged to be more meaningful than those who had more inputs at their disposal; this effect was attenuated when the identity prime was absent.

In addition to identifying the process underlying the effects observed in study 1, the next study is designed to replicate these effects in a new context and to test a boundary condition: the structure of the task. In the next study ($N = 302$), three factors were manipulated between-participants: identity prime, constraints, and task structure. All participants received a blank piece of white paper and a closed pencil box containing (either 6 or 15) colored pencils. The identity manipulation was similar to the manipulation used in study 1. In the “unstructured” task environment, participants were not given any specific directions regarding how to approach the task. As in study 1, we simply told them to begin drawing whenever they were ready. In the “structured” task environment, they were provided step-by-step instructions (e.g., “When thinking about your design, you might find it helpful to focus on the specific elements of your drawing such as shapes, colors, lines, symmetry”). The same items used to capture meaning in study 1 were used in this study ($\alpha = .85$). We also captured self-reported effort. Participants responded to three 7-point scales indicating the extent to which they put a lot of effort into the task, were engaged in the task, and felt it important to create a good design ($\alpha = .82$).

The results revealed both the expected main effect of the identity prime as well as the predicted three-way interaction on meaning. As in study 1, participants primed with their identity prior to the task rated their drawings as more meaningful than those who did not receive an identity prime ($F(1, 294) = 6.28, p < .02$). When the creative task was unstructured, the results from study 1 replicated. When the creative task was structured, there were no significant effects of identity prime, input constraints, or their interaction. A similar pattern emerged for effort and moderated mediation analyses revealed that input constraints’ direct effect on meaning was moderated by identity prime and input constraints’ indirect effect on meaning was mediated by effort and moderated by identity prime with a 95% confidence interval excluding zero (-.77 to -.02), but not in the no identity condition with a 95% confidence interval excluding zero (-.12 to .50; Hayes 2012).

In our third study ($N = 181$) we manipulated identity prime and input constraints. All participants read a news article. Those in the identity condition were asked to think about how that article relates to their identity and how they could integrate those ideas into their drawing; those in the no identity prime condition were asked to think about what came to mind when they read the article and how they could integrate those ideas into their drawing; those in the control condition read the article and no further directions were provided in relation to their drawing. The meaning measure from the previous studies was adapted to fit the context ($\alpha = .82$). The results revealed a main effect of the prime ($F(1, 181) = 10.04, p < .01$), which was qualified by a significant interaction $F(1, 181) = 3.13, p < .05$. Participants in the identity prime condition created more meaningful designs when inputs were constrained ($M_{\text{identity, low constraint}} = 3.79$ vs. $M_{\text{identity, high constraint}} = 4.31$; $F(1, 181) = 4.54, p < .05$), but no significant difference emerged across the other prime conditions.

In this research, we contribute to the growing creativity literature by highlighting the importance of identity activation on consumers’ evaluations of their own creations. We find that while identity may motivate creative behavior, activating a familiar identity can lead consumers to generate familiar ideas. When constraints are introduced, consumers generate more meaningful creations. In doing so, we reconcile the opposing findings across the creativity and cus-

tomization literatures which have shown that constraints can enhance (e.g., Moreau and Dahl 2005; Sellier and Dahl 2011) or inhibit (e.g., Franke et al. 2010) evaluations of a consumer’s creative outcome.

Being Unique Makes Us Similar: How Example Designs and Their Creators Influence How We Customize

EXTENDED ABSTRACT

To aid and inspire consumers during the customization process, marketers often provide examples of how other consumers customized their products. Yet, providing such examples can seem incongruous given that a primary reason people customize is to express uniqueness (Lynn and Snyder 2002). We examine how customization examples shape the target consumer’s customization decisions. We particularly focus on the target consumer’s relationship with the example creator, namely whether the creator is a close or distant other.

Previous findings suggest that people often exhibit greater choice similarity with close (versus distant) others as a means of affiliation (Bearden and Etzel 1982; Mead et al. 2010). When consumers learn which product a close (versus distant) other purchased, consumers frequently choose something similar to affiliate with the close other. However, these findings are based on learning about others’ *ready-made* product choices - products with pre-set designs, unaltered by consumers. We argue that affiliation with close others will manifest differently when encountering *custom-made* products - products with designs created or altered (i.e., customized) by the consumer.

Customization and expressions of uniqueness are closely intertwined (Lynn and Snyder 2002). Hence, we suggest that encountering examples of customized products highlights the need to express uniqueness. Because individuals want to affiliate more with close (versus distant) others, individuals who see close (versus distant) others express their uniqueness via customization will be more inclined to also express their own uniqueness. This situation parallels findings that when a group’s objective is to be creative and original, people who want to affiliate with the group generate more divergent ideas (Bechtoldt et al. 2010). Hence, unlike the ready-made context, here, consumers will *not* make the same customization choices as the close other (i.e., choice similarity decreases). Notably, we expect that people want to affiliate more with close (versus distant) others in situations involving ready- and custom-made products, but *how* this affiliation manifests in their choices differs based on the decision context. When close others *customize* products on the basis of expressing uniqueness, individuals will affiliate by also expressing uniqueness through making divergent choices.

Three experiments test these predictions. All experiments used product examples pre-tested to have appealing designs to mitigate the possibility that choice dissimilarity with the product example was due to unappealing designs.

Study 1 ($N=290$) tested whether example type (ready- versus custom-made) and example creator (close versus distant other) influenced individuals’ propensity to make customization decisions similar to the example. Participants imagined running into either a *close friend* or *distant acquaintance* wearing a backpack. They then viewed an image of this backpack (i.e., the product example), which was decorated with eight different patches. The backpack design was held constant, but participants in the ready-made condition were told the backpack was designed by the retailer whereas participants in the custom-made condition were told the backpack was designed by their *close friend* [distant acquaintance]. All participants then customized a backpack by adding eight of 24 patch options onto their backpack. The number of selected patches that matched those on the example

backpack served as our measure of choice similarity. A significant interaction of example type and example creator ($F(1, 286)=9.52, p<.003$) was found. For the ready-made backpack example, encountering a close other's ($M=3.87$) backpack increased choice similarity with that example compared to seeing a distant other's ($M=3.28; F(1, 286)=5.57, p<.02$). However, for custom-made backpack examples, encountering examples by close others ($M=3.03$) decreased choice similarity relative to distant others ($M=3.49; F(1, 286)=3.98, p<.05$).

While Study 1 was scenario-based, participants in **Study 2** ($N=186$) actually created and kept their customized products. All participants saw an example notebook customized with emojis. Again, this example was attributed to either a close or distant other. Participants then customized their own notebook with emojis. We replicate our finding that custom-made examples by close others ($M=3.04$) led to decreased choice similarity relative to examples by distant others ($M=3.48; F(1, 185)=6.18, p<.02$).

Study 3 ($N=802$) tested an alternative explanation for our findings. White and Argo (2011) found that people react negatively when their individuality has been compromised (e.g., copied) for high acquisition possessions (e.g., customized products). Thus, participants in our studies may have made dissimilar choices preemptively to avoid potential negative reactions from close others who had customized their products. To test this possibility, we manipulated whether one's customization decisions (i.e., their product design) were private or public. When others are unaware of one's customization decisions, individuals will not need to avoid negative reactions (by making dissimilar choices) from close others who customized.

Participants encountered an example tissue box design that was either ready- or custom-made and attributed to either a close or distant other. Before participants customized their own box, they were told that their design (i.e., their customization decisions) would be shared with the example creator, either publicly with their name attached or privately without their name. We replicate our previous interaction effect of example type and example creator ($p<.001$), but find no difference between the public and private conditions (three-way interaction: $F<1$). That is, even when designs were private, individuals made more dissimilar choices when the custom-made examples they saw were from a close ($M=1.71$) versus distant other ($M=2.13; F(1, 794)=6.18, p<.02$). Moreover, regardless of example type, participants anticipated greater negative reactions for copying distant ($M=4.04$) rather than close ($M=3.76; F(1, 794)=4.86, p<.03$) others, suggesting that anticipated negative reactions do not account for our effects.

While marketer-provided examples may seem at odds with customization, providing examples from close others can increase customization as consumers affiliate with expressions of uniqueness.

When “Valentino” Gets Personal: Is Customization the New Luxury?

EXTENDED ABSTRACT

New product development in luxury fashion used to be the exclusive responsibility of professional designers. Luxury fashion designers appear to dictate what fashion really is. Moreover, consumers believe designers have some sixth sense about aesthetics and that designers transfer their essence into the luxury products they design. Consequently, consumers highly value this designer essence, as they view the designer as sublime in taste and fashion-expertise. Indeed, Fuchs et al. (2013) found that leaving the designer aside, by labelling luxury fashion products as crowdsourced, can backfire as consumers perceived these luxury products to be lower in quality and fail to

signal high status. These findings would then recommend refraining from customization in the luxury sector.

In sharp contrast, innovation is increasingly being democratized and consumers across industries are taking on an active role in the new product development process (von Hippel and Katz 2002). For example, consumers using mass customization technology are enabled to self-design their own products, which the company then produces. Extant research has highlighted the numerous positive effects of self-customization (Franke, Schreier, and Kaiser 2010). By designing a product, the consumer's self-essence is transferred into the product.

This leaves the question of how well self-customization resonates with customers of luxury brands. In order to optimize purchase intent, should brands maximize the designer's essence or should consumers be able to customize and transfer their self-essence into luxury products? Despite the promising findings in the non-luxury sector, little research has addressed the effects of mass customization for luxury fashion products.

In Study 1 ($N=127$), a repeated-measures ANOVA revealed that consumers' purchase intent for Valentino sneakers differed significantly as a function of design source (professionally-designed, self-customized, and crowdsourced; $F(2, 125)=49.73, p=.00$). This study shows a clear consumer preference for customized products ($M_{\text{customized}}=5.06$) over purely designer-designed, standard products in the luxury fashion context ($M_{\text{professionally-designed}}=4.32, t=-4.16, p=.00$). Additionally, we replicate the findings of Fuchs et al. (2013) with respondents indicating the least preference for crowdsourced luxury products ($M_{\text{crowdsourced}}=3.23$).

Study 2 ($N=324$) revealed that an increase in solution space (low vs. medium solution space), that is, the range of design options provided to the consumer, results in higher purchase intent ($M_{\text{low}}=4.25, M_{\text{medium}}=4.65$). We obtain similar results when treating respondents' purchase intent for their selected standard shoes merely as a control variable (i.e., adding it as a covariate to a simple ANOVA on respondents' purchase intent for their self-customized shoes). In contrast to our purchase intent results, an ANOVA on perceived designer essence reveals a significant negative effect of the treatment. Respondents with medium solution space feel that there is less designer essence in their customized shoes ($M=4.85$) compared to those with low solution space ($M=5.25, F(1, 315)=9.07, p<.01$). A noteworthy finding is that perceived designer essence is positively related to respondents' intent to buy their self-customized shoes ($b=.22, SE=.09, p<.05$).

This raises the question if, besides designer essence, the contribution of the consumer's self-essence also drives his or her preferences for customized luxury fashion products. Hence, an optimized relation between self- and designer essence might result in an increase in purchase intent.

Study 3 ($N=366$) builds on these ideas and extends the pattern of results of Study 2 by documenting an inverted U-shape effect of solution space (low vs. medium vs. high). Importantly, this effect was mediated by the ratio of self- to designer essence: the “essence-ratio”. An ANOVA on self- in relation to designer essence (essence-ratio), reveals that the solution space manipulation has a linear effect on this variable ($F(2, 353)=38.94, p<.001$); respondents in the high solution space condition indicate to perceive more self- in relation to designer essence in the customized product ($M=2.66$) compared to those in the medium solution space condition ($M=2.14, F(1, 237)=4.59, p<.05$) who themselves indicate to perceive more self- in relation to designer essence than those in the low solution space condition ($M=1.50, F(1, 239)=11.03, p<.001$). In order to test for the predicted inverted U-shape relationship between the essence-ratio

and the value of self-customization in the context of luxury fashion brands, we ran a hierarchical quadratic regression model. Critically, we find that the addition of the squared term of the essence-ratio significantly increased the explanatory power of the model (change in $F(1, 352)=14.89, p<.001$). As predicted, we find a negative effect of essence-ratio squared ($\beta = -.58, t = -3.86, p<.001$). Interestingly, this pattern of results does not emerge for either of the two essence measures if analyzed separately.

The theoretical insight here is that at first, an increase in self-essence adds more value than what the simultaneous decrease in designer essence detracts in value. However, further increases in self-essence may add less value as designer essence continues to decrease. Thus, there is a point in the essence-ratio beyond which increases in self-essence negatively relate to preference.

Many of the customization tools currently offered equip consumers with very low levels of design freedom. Our findings indicate that incrementally increasing the solution space might create incremental value for consumers. Critically, managers need to identify the sweet spot on the solution space continuum to allow consumers to imbue enough self-essence into the product while simultaneously maintain enough designer essence; the optimal essence-ratio thus brings about self-customized products that are seen by consumers as both designed by themselves and designed by the luxury brand's designers.

Furthermore, we have shown that perceptions of designer essence are important in understanding consumer preferences. In other words, consumers not only buy luxury fashion products for their superior product quality or to signal high status (Berger and Ward 2010; Han, Nunes, and Drèze 2010; Rucker and Galinsky 2009), but also because they value the designer "being in the product." Finally, our research qualifies the recommendations made by the extant literature on user involvement in the luxury brand context. While Fuchs et al. (2013) find that consumers are not very excited when other consumers are involved in the design of luxury fashion brands (e.g., "Prada designed by consumers"), our research demonstrates that, under certain conditions, consumers want to see themselves in their custom luxury products.

How Cultural Identity Drives the Effectiveness of Mass Customization

EXTENDED ABSTRACT

One important factor that shapes people's identity is the culture they live in (De Mooij and Hofstede 2011). Prior research revealed that one's cultural background determines how individuals think and how they process information. For instance, Easterners share the belief that different pieces of information coexist interdependently and thus process visual information more holistically, whereas Westerners share the belief that each item exists autonomously and therefore process information more analytically (Nisbett and Masuda 2003). Firms that provide similar user interfaces to consumers across markets do not take these important cross-cultural differences into account and may not market their products most effectively (Haig 2011).

This shortcoming is particularly pronounced for mass customization (MC) systems that allow consumers to express their unique preferences (Simonson 2005). While the popularity of such systems is increasing among consumers, manufacturers still employ nearly identical interfaces around the globe. For example, consumers configuring an automobile at Audi's country-specific websites in North America, Europe, or Asia always walk through exactly the same

configuration process: first they select a model, an exterior color, and their preferred rims, followed by a number of interior features and add-ons. We propose, and find based on both lab and field data, that such attribute-by-attribute customization (Valenzuela, Dhar, and Zettelmeyer 2009) is not uniformly beneficial to all consumers; they may be effective for Western consumers but less so for East Asians, given their habitual, more holistic processing style.

In study 1, which examined whether conventional attribute-by-attribute customization may be suboptimal for East Asian consumers (e.g., Chinese or Singaporeans), we collected field data in cooperation with a large European car manufacturer. The key dependent measure was the conversion rate of customers when configuring a car online. The dataset comprised 31,271,002 unique page visitors who configured their car using the company's online car configurator in 17 markets. In line with our proposition, we found significantly lower conversion rates for consumers in Eastern ($M=3.11\%$) versus Western markets ($M=6.62\%$; $t(15)=-3.20, p=.006$), a finding that could not be explained by differences in economic status or familiarity with the interface. These results provide a first hint toward conventional MC systems being less beneficial to East Asian consumers. However, the reported findings have limitations: they are based on correlational data and do not necessarily indicate causation. Subsequently, we examined the effect and underlying process in three follow-up cross-cultural experiments.

Our key hypothesis was that consumers experience greater mental simulation of product use and therefore evaluate their customized product more favorably if an MC system matches consumers' habitual processing style. To test these predictions, we designed three experiments involving prospective car buyers in Singapore and Germany. In our experiments, participants configured a car using a mock-up configurator of a large European car manufacturer. Participants were randomly assigned to one of two predominant choice architectures: attribute-by-attribute customization versus choosing from prespecified alternatives. In the former architecture, participants customized their car sequentially, selecting an option for each of three attributes. In the prespecified condition, participants chose a car from a set of already prespecified alternatives. We controlled for the overall attribute space such that the prespecified alternatives resembled all possible attribute combinations of the attribute-by-attribute architecture. Before consumers configured their preferred car, they completed the Kimchi similarity task (Kimchi and Palmer 1982) to assess their culture-specific habits of information processing.

In line with our predictions, study 2 ($N=175$) revealed that when Easterners (vs. Westerners) used the prespecified (vs. attribute-wise) architecture, they experienced an increased ability to mentally simulate using the car ($F(1,171)=9.55, p=.002$) and were more satisfied with their choice ($F(1,171)=9.41, p=.003$). As expected, these effects were moderated by consumers' processing styles such that the influence of a prespecified architecture was amplified for consumers with a more holistic processing style and vice versa ($b=-.10, SE=.04, CI_{95}=[-.19;-.03]$). Thus, a congruence between the interface and consumers' culture-specific processing style proved beneficial.

In study 3 ($N=456$), we tested whether priming consumers with their habitual processing style (i.e., priming Easterners holistically and Westerners analytically using the Navon letters task; Förster 2009) may offset the detrimental effects of an attribute-by-attribute architecture. As indicated by a significant interaction between priming and market for mental simulation ($F(1,448)=8.84, p=.003$) and satisfaction ($F(1,448)=6.27, p=.01$), study 3 showed that priming Easterners with a holistic processing style before using the attribute-by-attribute architecture increased mental simulation as well as

choice satisfaction. For Westerners, priming them with an analytic processing style before using the prespecified architecture also increased mental simulation and choice satisfaction. In other words, priming consumers with their habitual processing style positively affected their experience with an otherwise poorly matching choice architecture.

In study 4 (N=166), we aimed to replicate the previous findings by employing a more realistic priming technique. We therefore created two 45s videos based on the partner company's TV commercials. The "holistic video" included scenes that are closely related to holistic perceptions by focusing on overall broad-based characteristics of a car. In contrast, the "analytic video" included scenes highlighting single product items. A pretest (N=84) confirmed the intended priming effect of the videos on the Kimchi similarity task ($t(82)=2.17, p=.03$). Using these realistic stimuli, study 4 replicated the previous effects as indicated by a significant interaction between priming and market for mental simulation ($F(1,162)=10.87, p=.001$) and purchase intention ($F(1,162)=6.93, p=.009$). Hence, the priming of habitual processing styles increased consumers' mental simulation as well as their intention to purchase the car if they used a choice architecture that is not tailored to their habitual style of information processing.

This research provides evidence that firms can benefit from tailoring the provided choice architecture to customers' culture-specific processing styles, therefore contributing to the emerging fields of cross-cultural consumer psychology and marketing (Burton 2009). Importantly, we show that consumers' cultural identity constitutes an important boundary condition for the success of MC systems in international markets. Given the increasing individualization of East Asian markets and the constant rise of MC, the current research provides a new lens on how culture-specific information processing can be aligned with interactive choice environments.

SESSION OVERVIEW

Healthcare is a huge industry. In 2012, U.S. healthcare expenditures were \$3 trillion and growing by 4% annually (Munro, 2012). Healthcare decisions are extremely important because they are crucially related to people's physical and mental wellbeing, and even lives. However, in many cases, healthcare decision makers are ordinary consumers who lack domain expertise and are easily influenced by psychological factors. In this special session we investigate (1) what are the novel aspects of healthcare decisions that have been under-investigated in the existing literature (stigma messages, social proof, naturalness, and risk presentation method), and (2) what psychological factors influence consumer reactions to these aspects (moral identity, reactance, the Protestant Work Ethic, and pre-existing preference).

In paper 1, Achar, Dunn and Agrawal examine how and when the presence of stigmatized sources of risk (e.g., unsafe sex) influences health persuasion. Whereas past literature has demonstrated many positive outcomes of moral identity, three studies show that salient moral identity triggers defensive responses (e.g., self-positivity bias) to health appeals that implicate stigmatized behavior. Normalizing the stigmatized behaviors reduces the negative effect of moral identity.

Consumers are defensive not only to stigma-induced ego-threats, but also to persuasion by social proof. In paper 2, Desai, Luce and Schwartz find that the effectiveness of social proof in encouraging medical screening tests is short-lived and may be attenuated when the medical test is very threatening. Moreover, high social proof causes more felt pressure and lower confidence in the accuracy of the test, a negative consequence that is rarely seen in other unthreatening contexts.

In paper 3, Cheng and Mukhopadhyay find that the Protestant Work Ethic, a work-related core belief, can spill over and influence naturalness preference in healthcare decisions (e.g., natural childbirth vs. C-section). Combining publicly available data with experimental data, four studies show that individuals (and countries) who believe strongly in the PWE prefer relatively natural healthcare options, due to stronger dislike of external interventions.

While first-time childbirth decisions are influenced by core beliefs, second-time childbirth decisions are further affected by emotional and medical outcomes of previous delivery experiences. In paper 4, Barakshina, Malter and Mastrogiannis studied VBAC versus repeat C-section decisions using 64 longitudinal, dyadic interviews with 40 pregnant women and their physicians. They find that strong pre-existing preferences shaped by fear and other factors biased patients against objective risk/benefit information on delivery choices presented by physicians. Physicians' own biased preference for different presentation modes exacerbated the problem. Based on these findings, a new patient decision aid was developed to improve objective risk assessment.

The proposed session presents emerging topics in consumer healthcare research and identifies key psychological factors. Our studies examine both hypothetical and real healthcare behavior (Paper 2, Study 3; Paper 3, Study 1; and Paper 4) and employ diverse methodologies (experiments, secondary data, depth interviews). Healthcare is a high-impact area which is relatively under-investigated by consumer researchers. Our session features novel approaches to study consumer healthcare decisions, raises important questions for debate and discussion, and should appeal to a wide range of ACR attendees.

Stigmatized Risk Factors in Health Messages: The Defensive Influence of Moral Identity

EXTENDED ABSTRACT

Extant research in psychology suggests that social stigma is so threatening that the mere implication of a stigmatized risky behavior may discourage individuals from seeking healthcare solutions (Young et al. 2007). In contrast, research in health suggests that communications that do not sensationalize stigma provide individuals with solution and self-efficacy (Ditto et al. 1988; Block and Keller 1995; Lundgren and McMakin 2013) should be effective. The current research integrates these two literatures and finds a novel moderator to the impact of perceived stigma on health message effectiveness: moral identity. Salient moral identity – individuals' self-concept organized around moral traits (Aquino and Reed 2002) - has generally been shown to have outcomes such as increased charitable behaviors (Reed et al. 2007), time donations (Reed, et al. 2015), ethical behavior (Reynolds and Ceranic 2007), and well-being (Hardy et al. 2013). The current research illuminates that moral identity may not always result in such welfare outcomes. Specifically, we consider the cases where a stigmatized behavior (e.g., engaging in unprotected sex) is implied as a source of health risk.

Our central premise is that there is an inconsistency between a salient moral identity and acknowledgement of engaging in a stigmatized risky behavior. This inconsistency stems from the facet of morality as norm conformity (Forsyth 1985; Aquino and Reed 2002) and the facet of stigma as indicating an undesirable deviance from norms (Archer 1985). Thus, among those with a strong self-concept of being moral, the implication of engaging in a stigmatized behavior (i.e., a behavior that violates a societal norm) will be an ego-threat. In such a scenario, in contrast to the previously documented healthy behaviors (Hardy et al. 2013), moral identity might motivate ego defense against health messages. Unlike previous research in health messaging which shows ego defense being triggered by risk perceptions (Kunda 1987; Raghurib and Menon 1998), this is a case where

the source of defense against health messages stems from a threat to one's salient identity, not from threat to one's health. This research shows contrasting effects of salient moral identity; in general, high (vs. low) moral identity leads to healthy consumption, but backfires when the healthy consumption implies engagement in a stigmatized risky behavior. Further, based on our premise that this ego defense is driven by norm-conformity of moral identity and norm-deviance of stigma, we posit that 'normalizing' the stigmatized behavior should attenuate this effect. A series of three experiments establish this moderating effect of moral identity, demonstrate the underlying process, and present an intervention.

Basic Effect and Underlying Process

In studies 1 and 2, participants were shown a health message that briefly described three potential factors that could lead to a disease and presented a preventive vaccination. Stigma associated with the infection was manipulated in the third risky behavior listed on the message. The risk factors were: 1) being of age 16 – 45 years, 2) sharing food and beverages with others and 3) not using the hand sanitizer regularly (*low stigma condition*) OR having multiple sexual partners (study 1) or having

In study 2, participants were primed with moral identity to address any concerns about measured personality correlates. A panel of online participants ($n=171$) were assigned to one of the four conditions in a prime (moral vs. neutral) \times message stigma (high vs. low) design. Individuals' defensive processing of the health message was measured through their perceptions of disease risk to themselves versus an average other. Defensiveness was operationalized in the form of self-positivity (tendency to see self as less susceptible to risk than an average other). As predicted, participants primed with moral (vs. neutral) identity exhibited greater self-positivity bias in their perceptions of disease risk after seeing a high (vs. low) stigma vaccination message, which mediated vaccination intentions.

Intervention

We reasoned that use of vernacular phrasing de-stigmatizes a risky behavior by making it appear more 'normal'. For this purpose, we developed an 'intervention' health message which described the same stigmatized behavior in study 2, but used vernacular language to describe it. In study 3, students in an introductory nutrition course were randomly assigned to read a health pamphlet about a disease in a prime (moral vs. neutral) \times behavior framing language (formal vs. vernacular) design. Those primed with moral (vs. neutral) identity indicated greater willingness to pay for a vaccination when they were presented a health message that indicated a stigmatized behavior, but used vernacular (vs. formal) language.

This work makes several interesting contributions to the field. First, we contribute to the understudied topic of stigma in consumer behavior by demonstrating how and when the mere implication of engaging in a stigmatized behavior could influence the effectiveness of health persuasion. Second, we show that moral identity can have a negative influence on health outcomes through a defensive mechanism. Finally, we develop and test a theory-based intervention to reduce the negative interaction of stigma and moral identity.

The Burden of Social Proof

EXTENDED ABSTRACT

A proliferation of insights from the behavioral sciences has recently been called upon for public service. Appeals to be healthier, wealthier, and more environmentally aware have been bolstered by well-documented phenomena such as framing (Tversky and Kahn-

man 1984), defaults (Johnson and Goldstein 2003), and social influence (Cialdini 1984). These insights are leveraged to create more effective behavioral interventions, and mainly capitalize on evidence that behavior is often shaped by peripheral environments rather than by exclusively individual motivations. The success of this approach has been well-received, especially in the case of challenging public policy problems where behavioral change can be taxing. Additionally, many of these insights work as interventions because they align people's behaviors with already positive attitudes and intentions—many want to be healthier, wealthier, safer, and more environmentally aware, but they lack the necessary tools to bridge the intention-behavior gap. To that end, subtle changes to the physical or rhetorical decision making environment can "nudge" (Thaler and Sunstein 2008) people along what is ostensibly a desired path.

Relatively little attention has been paid, however, to situations in which people are being persuaded to do something that is threatening. That is, behaviors that people might be strongly inclined to avoid, even though they are ultimately beneficial. These situations present a dual problem in that consumers need to be motivated to make positive changes but they also must be able to cope with or otherwise overcome the threats associated with the advocated behavior. Research has shown that people can be particularly avoidant in situations that produce negative emotions (Luce 1998), such as when they are required to make difficult trade-offs or may receive negative information. This research seeks to better understand how one form of persuasion, social proof (Sherif, 1935), influences aversive decisions and the tendency of some to avoid acting. Medical screening tests are a timely example, as most people are aware that early detection and treatment of disease can prevent it from worsening. At the same time, submitting to these tests can, for many people, be unpleasant and anxiety provoking.

Study 1

Participants ($N = 408$ adults) were randomly assigned to conditions in a 2 (disease severity = Multiple Sclerosis or Migraine headaches) \times 2 (social proof = 75% or 25% get tested) \times 2 (symptom onset = sooner or later) experimental design. They were asked to imagine they had recently been feeling unwell and their doctor suspects the problem could be Multiple Sclerosis (Migraine headaches) that could become worse very soon (in several years). The participants were then told that 75% (25%) of people in their situation opt for a test to confirm the diagnosis and went on to rate how likely they would be to take the test on a scale of 1 to 7 where higher numbers indicated a greater willingness to test. Social proof was least effective in the most threatening situation (early onset MS).

Study 2

We attempted to attenuate the initial reactance to the threat of a serious medical diagnosis with a longitudinal design that allowed participants ($N = 551$ adults) to think for one week about whether to get tested to confirm MS. The results showed that social proof was even less effective over time—meaning that participants in the high social proof condition were significantly more interested in testing than those in the low social proof condition, but only at Time 1 ($p < .01$). One week later, there were no differences between the high and low social proof groups in terms of likelihood to get tested. This suggests that social proof has a limited shelf-life, and can be over-ridden with deliberation.

Study 3

Study 3 attempted to capitalize on the limited shelf-life of social proof by giving people ($N = 289$ adults) a chance to take a real medi-

cal screening test (for Type 2 diabetes) immediately. High versus low social proof was effective in getting people to take the test, however, those in the high proof condition felt significantly more pressured and significantly less confident in the accuracy of the test to diagnose Diabetes than people in the low proof condition ($p < .001$ for both analyses). This suggests while social proof can increase a desired behavior, it exerts unpleasant influence and can even undermine belief in the accuracy of the results.

Taken together, our results from both hypothetical and real medical testing situations show that social proof has a modest impact on increasing medical testing intentions and actual testing behavior. This power degrades as the situation becomes more threatening and with time. Although it may be possible to capitalize on the limited shelf-life of social proof, changing people's behavior via this channel of persuasion can lead to feelings of pressure and reduced confidence in the accuracy of the test's results.

The Protestant Work Ethic and Preference for Natural Healthcare

EXTENDED ABSTRACT

Science and technology have substantially changed the way healthcare is delivered, by introducing numerous new options that never existed before in the world. While herbal remedies have a history as long as mankind, the modern pharmaceutical industry relies more on chemical synthesis, bioengineering, and computer-aided drug design. Similarly, although natural delivery remains the choice of the majority for giving birth, Cesarean section rates in the U.S. increased by about 60% from 1996 to 2009 (Martin et al. 2012).

Consumers may not have the expertise to evaluate the scientific qualities of these modern methods, and it is unclear whether their healthcare decisions are always made rationally. So what determines people's preferences for natural healthcare? Not much research addresses this question, and the results are mixed. Some researchers have found that consumers have a strong naturalness preference for food but not for medicine (Rozin et al. 2004). In contrast, others have found that worries about new technology make consumers prefer natural health products to those with synthetic additives (Deveich, Pedersen and Petrie 2007). In this paper, we investigate one psychological antecedent of preferences for natural healthcare, namely, belief in the Protestant Work Ethic (Weber 1905).

Sociologist Max Weber first introduced the Protestant Work Ethic (henceforth PWE) to explain the historical rise of western capitalism. Psychologists have since developed psychometric scales to measure PWE (e.g., Mirels and Garrett 1971) and treated PWE as a secular concept that describes the extent to which a person believes in hard work, asceticism, frugality and self-reliance (Cheng, Mukhopadhyay and Schrift 2017; Furnham 1990; Miller, Woehr and Hudspeth 2002). People high in PWE tend to engage in work-related activities during trips to and from their workplaces (Greenberg 1978) and to blame the unemployed for their laziness (Furnham 1985). Up till now, however, most psychological research on PWE has tested its consequences only in work-related domains (Cheng et al. 2017 as an exception). Because PWE is a core value (Hsu 1972), we suggest it may spill over and influence work-unrelated consumer behaviors, such as naturalness preference in healthcare decisions.

Why would people high in PWE prefer natural healthcare options? An important component of PWE is self-reliance. Previous literature suggests that the strong emphasis on self-reliance makes high-PWE people dislike external intervention. For example, Moen (1978) found that American elderly who were likely influenced by the PWE tended to refuse assistance and social welfare, even

thought they were old, poor, sick and disable. Similarly, Furnham (1983) found that those believe strongly in the PWE are more likely to oppose taxation externally imposed on them. Because high-PWE people dislike external intervention and naturalness represents the absence of external intervention (Rozin 2005, 2006; Spranca 1992), higher PWE may lead to stronger preference for natural options. In four studies, we tested our central hypothesis that high PWE is associated with stronger naturalness preference. We also provided evidence that this effect is driven by the stronger dislike of interventions among high-PWE people.

Study 1 used publicly available survey data to test whether country-level PWE predicted country-level Cesarean-section rates. We obtained C-section rates from UNICEF and WHO reports, and assessed country-level PWE using 13 questions in the *World Values Survey*. Regression analysis was performed on 41 countries with no missing data between 2005 and 2009. As predicted, countries with higher PWE have significantly lower C-section prevalence. This effect held when GDP per capita and religiosity were statistically controlled for.

As C-section and natural delivery differ in multiple dimensions other than naturalness, study 2 was designed to disentangle these dimensions. Childless women who planned to have children in the future ($N=137$) imagined being pregnant and expecting babies. Participants read short descriptions of vaginal deliveries and C-sections. In the three framing conditions, participants read one additional sentence, "*It is commonly believed that... vaginal deliveries are more NATURAL than C-sections are /... vaginal deliveries are more PAINFUL than C-sections are / ... vaginal deliveries require more EFFORT from mothers.*" PWE was measured using a scale (Mirels and Garrett 1971). Only in the "naturalness salient condition", women with higher PWE evaluated vaginal delivery as better for their and their baby's health than C-section. Higher PWE did not predict stronger preference for vaginal delivery in the other two conditions. This result suggests that high-PWE women's preference for vaginal delivery was due to their preference for naturalness rather than their preference for effort or pain.

Studies 3a and 3b directly manipulated the degree of external intervention to test the underlying mechanism. Study 3a asked MTurkers ($N=133$) to evaluate the relative efficacy of ginseng harvested in the wild versus farmed on farmlands. Farming ginseng was framed as involving either high or low external intervention. PWE was measured as before. Higher PWE is associated with less favorable efficacy judgment for farmed ginseng only when farming ginseng involved high external intervention, but not low external intervention. Study 3b (MTurkers= 122) replicated study 3a. Higher PWE was associated with less favorable efficacy judgment of lab-synthesized paclitaxel (a chemotherapy medicine) relative to tree-derived paclitaxel only when the lab synthesis process was framed as involving high external intervention, but not low external intervention.

Although naturalness is a ubiquitous concept in branding and promotion, it has only started to be researched recently (Rozin 2005, 2006; Rozin Fischler and Shields-Argeles 2012; Rozin et al. 2004) and most studies are in domain of food. Existing research has successfully documented an overall pattern of preference for naturalness, and the current research contributes by identifying important individual heterogeneity in these preferences as a function of the Protestant Work Ethic. Our findings have practical implications as well. For example, international healthcare organizations should put more effort in educating individuals (and countries) low in PWE about the benefits of natural childbirth. Pharmaceutical companies that emphasize natural manufacturing processes may want to target consumers high in PWE.

Unbiased Presentation of Options in Preference-based Medical Decisions

EXTENDED ABSTRACT

Healthcare services are associated with higher uncertainty and more serious risks for consumers, compared to other credence services (Mitra, Reiss, Capella 1999; Ngamvichaikit and Beise-Zee 2013). Among medical services, some treatment decisions are more risky and uncertain than others. The classification of medical decisions into evidence-based and preference-based is directly related to uncertainty (Edwards and Elwyn 2009). While a patient (at least formally, in U.S. healthcare) makes the decision on her treatment, the choice between available options is clearer when medical evidence supports one treatment over another. Yet, for many decisions, patient choices are preference-based, meaning one option is not definitively better than another. In such instances, a patient's personal values, preferences and beliefs may heavily influence the final choice.

Due to logistical and resource constraints, many studies in consumer behavior, medical decision-making, and patient counseling examine the patient or physician perspective, but rarely a 360-degree view. Perception of risk by patients and physicians and confirmation bias on both sides have been studied broadly in consumer behavior, mostly in experiments using student or online subject pool samples (Khan and Kupor 2017; Mittal and Griskevicius 2016; Yan and Sen Gupta 2013). Research using participants who have actually made the focal medical decisions is rare (exceptions include Thompson 2005; Morris et al. 1994).

In our research, we interview both patients and their physicians in the clinic immediately following consultations. Consumer behavior scholars have long noted the need to empirically study doctor-patient interactions (Friedman and Churchill 1987) but few consumer studies have ever studied the actual interaction. Obtaining the perspective of each decision participant adds real-life context and dynamic complexity of the environment where physicians and patients interact. Direct examination of the patient-physician dyad enhances theoretical understanding, provides more actionable, relevant recommendations and can improve the interaction process.

Specifically, we examine three important aspects of the decision-making process. First, in the initial interaction between provider and patient, does either party have a pre-existing preference towards one option (driven by experience, subjective information, or personal beliefs)?

Second, how are the risks/benefits of alternatives presented by the provider, and is this presentation biased by a pre-existing preference? Medical uncertainty can be presented in three ways: verbal, visual, and experiential. In the verbal approach, patients will vary in how they understand verbal probabilities. Stating probabilities linguistically or numerically were found to yield different perceptions of risk (Budescu, Weinberg and Wallsten 1988). Patient risk was better understood as frequencies than percentages (Ancker et al. 2006; Fagerlin et al. 2007; Waters et al. 2016). An even more effective way to communicate low, yet considerable probabilities, is the experiential approach (Sandman et al. 1994), in which a physician references life situations from a familiar environment (to perceive riskiness of a "3% risk," ask the patient whether she would board a plane if it had a 3% chance of being hijacked).

Third, how is risk/benefit information perceived and processed by a medical services consumer: Are the explained risks and benefits heard and understood, and how are they interpreted?

In sum, our study focuses on two key research questions: How do pre-existing preferences influence a patient's ability to perceive risk/benefit information for treatment options, and which risk pre-

sentation method used in actual consultations yields minimally biased, well-informed patient choice?

We employ a grounded theory approach in a clinical field setting. Our study domain is childbirth decisions, specifically delivery decisions by women following a previous C-Section. These women must choose between a repeat Cesarean or attempted natural childbirth (VBAC), a decision defined by the medical community as preference-based (Bernstein et al. 2012).

Methodology. We report 64 longitudinal, dyadic in-depth interviews, which elicit both patient and physician perspectives on the decision process. Initial interviews were conducted with 40 pregnant women at a Women's Health clinic in Chicago, all of whom had a C-Section on a previous delivery and now faced a choice of repeat C-section or VBAC. Interviews were conducted immediately after a regular routine pregnancy visit with an OB/GYN physician. A second patient interview was conducted closer to delivery to obtain a "decision journey" perspective, and to track how the delivery decision evolved during the pregnancy. Each patient interview was matched to a brief interview with the counselling physician immediately after the patient visit.

Our findings compare patient and physician perspectives. First, we turn to the patient view. Many patients showed a strong pre-existing delivery preference, which made them less receptive to understanding and processing risk/benefit information provided by the physician. This, in turn, prevented an unbiased consideration of both options. We find that pre-existing preference for one delivery option (C-section or natural) formed early in or even prior to pregnancy, shaped mainly by fear factors from the previous C-section delivery experience (fear of anesthesia, fear of longer recovery, etc.).

From the physician perspective, the main finding involves how physicians choose to present decision options to patients. Each physician has a preferred method of risk presentation, not a holistic approach. The effects of different tactics used by physicians to present risk/benefit information are compounded by the patient's varying understanding of risks. As a result, most patients develop a clear understanding of the benefits of their preferred delivery option, while never fully understanding or outright disregarding the benefits of the alternative option.

Our research has theoretical and practical implications. On a theoretical level, we contribute to understanding how pre-existing patient preference (driven by need to cope with fear associated with previous experience, as discussed in Luce 2005) is expressed by patients, and what approaches to presenting risks and benefits will result in a less biased choice. On a practical level, we use the findings to develop a decision aid that offers a comprehensive visual approach to more easily present and compare risks and benefits across both delivery options. Our future research will focus on improving the decision aid via a series of experiments (O'Connor et al. 2007) testing its effect on healthcare decisions and emotional outcomes.

Paper #4: How does risk sound? The Fit Between Harsh (Soft) Names and Uncertainty (Certainty)

Keith Botner, Lehigh University, USA
Arul Mishra, University of Utah, USA
Himanshu Mishra, University of Utah, USA

SESSION OVERVIEW

Consumers deal with uncertainty on a regular basis: They have to navigate uncertainty in their preferences, process uncertain marketing information, make decisions that could have uncertain outcomes, and even make choices under the influence of incidental feelings of uncertainty. Given the ubiquitousness of uncertainty in consumer environments it is imperative to understand how individuals deal with uncertainty and how their decisions are affected by it in order to gain a comprehensive understanding of consumer behavior.

The papers in this session showcase a variety of novel antecedents and consequences of uncertainty in consumer contexts. Furthermore, the session sheds light on how consumers and marketers may use uncertainty strategically to their benefit. Covering a wide range of important implications such as increasing persuasiveness of marketing communications, improving consumer welfare through better financial decision making, reducing consumer guilt, and improving product names, the research presented here provides rich and multifaceted contributions.

In paper 1, Acikalin, Khan, and Shiv illustrate that consumers can strategically choose uncertain options over certain options. The finding is contrary to prior research arguing that consumers are uncertainty averse. Authors show that choosing uncertain options over certain ones make consumers feel less guilty about the outcome.

In paper 2, Chowdhry and Dholakia demonstrate how uncertainty about one's own financial situation negatively impacts financial decisions. They show that increased self-awareness reduces uncertainty, which increases self-efficacy, allowing improved performance on financial management with increasing levels of financial literacy.

In paper 3, Kupor, Jia, and Tormala establish that the mention of changes about a product induces uncertainty in the form of a perceived knowledge gap. They illustrate that this uncertainty sparks curiosity, which boosts processing of information about the changed product when consumers receive a message containing compelling information.

In paper 4, Botner, Mishra, and Mishra find that amidst decisions associated with higher uncertainty or volatility, consumers elicit a preference for (brand or product) names with lower phonetic

comfort. Grounded in linguistics and decision theory, their results illuminate how the seemingly uninformative yet inescapable factor of the sound of a word influences consumer decisions.

Taken together, these papers showcase how uncertainty can be studied in many different consumer contexts to answer both theoretically and managerially important questions. In doing so, the session offers novel insights into how uncertainty influences consumer judgement and choice, raising fundamental questions such as "How can we improve consumer welfare by intervening in how consumers deal with uncertainty?", "When do consumers benefit from the presence of uncertainty?", "How can marketers strategically increase and reduce uncertainty to their benefit?", and "How can marketers capitalize on uncertainty when they have no control over it?". The session not only advances the theoretical understanding of how uncertainty drives judgment and behavior, but also generates novel hypotheses for further research. The session is likely to appeal to a broad audience, as the papers investigate the role of uncertainty in a variety of popular consumer behavior contexts such as persuasion, brand and product choice, and financial decision making.

Guilt-Free Indulgence at the Cost of Certainty

EXTENDED ABSTRACT

Past research has documented that consumers are averse to uncertainty (Gneezy, List, and Wu 2006; Simonsohn 2009). In this research, we propose that consumers may counterintuitively choose uncertain options over certain options. We build on the notion that consumers often find themselves in situations where they would like to choose a particular option, but they do not want the responsibility associated with the choice. For instance, choosing an indulgent, hedonic, vice, or even more expensive alternative can induce guilt (Dahl, Honea, and Manchanda 2003; Dhar and Wertenbroch 2000; Khan and Dhar 2006; Kivetz and Simonson 2002). In such contexts, where consumers anticipate feeling guilty as a result of a choice, we posit that they may demonstrate a preference for uncertain options.

We postulate that choosing an uncertain (or stochastic) option (e.g., 90% chance to get the unhealthy option and 10% chance to get the healthy option) reduces responsibility and thus the guilt arising from the choice. We further predict that individuals are relatively insensitive to the amount of uncertainty, where even a small amount of uncertainty can reduce guilt. Thus, compared to a fair coin flip, consumers may prefer stochastic options that make receiving the preferred outcome more likely. In other words, these options may not only relieve the guilt associated with the decision, but also maximize the chances of receiving the preferred, otherwise guilt-inducing outcome. We test these predictions and provide process evidence across three studies (S1-S3).

In S1 participants (N=101) were asked to make a choice between two \$20 gift cards (GC): a GC to a hedonic ice-cream store and a GC to a utilitarian juicery (Options in all studies were pretested to be relatively hedonic or utilitarian. Hedonic options were perceived as less healthy and more guilt inducing for all stimulus sets, $p < 0.001$). Participants received the following options and were entered into a lottery for a chance to receive a GC based on their choice.

Receive a...

A) \$20 GC to Rick's Ice Cream with 100% probability.

- B) \$20 GC to Rick's Ice Cream with 70% probability and a \$20 GC to Pressed Juicery with 30% probability.
- C) \$20 GC to Pressed Juicery with 70% probability and a \$20GC to Rick's Ice Cream with 30% probability.
- D) \$20 GC to Pressed Juicery with 100% probability.
- E) \$20 GC to Pressed Juicery with 50% probability and a \$20GC to Rick's Ice Cream with 50% probability.

Results revealed that a significant proportion of participants chose stochastic options (B and C) over both certainty (A and D) and indifference (E; $p < 0.0001$), showing a preference for uncertain options over certain ones. Participants choosing stochastic options (B and C) while an indifference option (E) is present indicates that the observed preference for uncertain options is not simply due to indifference. Moreover, the difference in guilt ratings between the two options significantly increased the likelihood of choosing a stochastic option ($\beta_{\Delta\text{Guilt}} = 0.40$, $z = 2.13$, $p = 0.033$). In other words, anticipating more guilt as a result of the choice increased the preference for an uncertain option.

In S2 ($N=500$), participants chose between a set of more hedonic or utilitarian snack bars. The design was similar to S1. After the choice, participants reported how guilty they felt about their choice. They also completed the Test of Self-Conscious Affect (Tangney 1990). This allowed us to uncover individual differences in how people deal with guilt. If individuals choose uncertain options to attribute a guilt-inducing outcome on "chance" and hence feel less guilty, then those with a stronger tendency to blame negative self-conscious emotions on external factors should prefer stochastic options more. Results were consistent with this logic: A significant proportion of participants chose a stochastic option, and this choice was associated with the perceived guilt difference between options. Moreover, individuals with higher tendencies to blame external factors for negative self-conscious feelings were in fact more likely to choose a stochastic option (but not indifference; $\beta_{\text{Blame-Guilt}} = 0.46$, $z = 3.55$, $p = 0.00039$). This provides further evidence for uncertainty serving as a guilt reduction mechanism. Moreover, those choosing a stochastic option reported less guilt associated with the decision ($\beta_{\text{DecisionGuilt}} = -0.75$, $t = -2.89$, $p = 0.0041$), suggesting that choice of an uncertain option is an effective guilt-reduction mechanism.

S3 ($N=132$) further tests the suggested guilt-reduction process. The choice was similar to S1, with the exception that this time we manipulated whether participants choose among mixed (healthy and unhealthy) or homogeneous (healthy- or unhealthy-only) choice-sets consisting of 25\$ GCs. If the preferences for uncertain options are driven by a motive to reduce guilt, then people should be more likely to choose uncertain options in mixed choice-sets as compared to homogenous choice-sets, because the anticipated guilt is larger when choosing an unhealthy option over a healthy one, compared to choosing among various unhealthy options (Dhar and Wertenbroch 2012). As predicted, participants were more likely to choose stochastic options (and not indifference) from mixed as opposed to homogeneous choice-sets, ($\beta_{\text{MixedvsHomogeneous}} = 1.02$, $z = 2.05$, $p = 0.04$) supporting the hypothesized guilt-reduction role of uncertainty in this choice context.

Despite the ubiquitousness of uncertainty aversion in consumer choice, we demonstrate a context where consumers elicit a preference for uncertainty. Our work contributes to several streams of literature: We contribute to self-control and guilt literatures by showing that consumers can strategically use uncertainty as a guilt-reduction mechanism. Our results also contribute to research on self-signaling by showing that individuals take diagnostic costs of their choices into account while making a decision. Finally, we find that by choosing stochastic options that reveal one of the options to be

preferred, consumers systematically violate stochastic dominance, a fundamental axiom of choice.

Know Thyself Financially: How Financial Self-Awareness Benefits Consumers

EXTENDED ABSTRACT

To combat financial challenges faced by Americans such as low savings rates, high rates of impulsive spending and debt levels, one approach that has been pursued vigorously is greater financial education. Current methods focus on teaching consumers basic economic and financial concepts such as interest rates, inflation, and differences between individual stocks, bonds, and mutual funds. However, despite years of spending princely sums on financial education programs (\$670 million was spent in 2012 alone), evidence regarding its beneficial effects on financial behaviors is shaky. For example, a recent meta-analysis of 201 studies examining the relationship between financial knowledge and financial behaviors found virtually null effects, leading the study's authors to conclude that "financial education as studied to date has serious limitations" (Fernandes, Lynch, and Netemeyer 2014, p.1861). Further, despite an abundance of financial tips and recommendations on broadcasts and in books, consumers are confused and frustrated about how to handle the many different aspects of their personal finances (Neiser 2016).

In this research, we propose a different approach. Specifically, instead of general knowledge about financial concepts, we propose that a more effective way to encourage prudent financial behaviors is by reducing uncertainty and raising consumers' self-awareness regarding their own current financial situation. We refer this to this type of certainty and self-knowledge as "Financial Self-Awareness" (FSA), defining it as certainty about one's current financial assets, liabilities, and spending patterns. Our central thesis is that a higher level of FSA will be associated with more positive downstream financial behaviors for the consumer. Our research thus makes the important conceptual distinction between two types of consumer knowledge regarding personal finances: a general understanding of economic and financial principles (i.e., financial literacy), and the specific understanding of one's own current financial condition (i.e., FSA).

We expect that the positive effects of FSA on downstream financial behaviors will be mediated by perceptions of efficacy about handling personal finances, which we call financial self-efficacy (FSE). This prediction is based on existing research showing that self-efficacy, defined as beliefs regarding one's capabilities for a particular task, is positively related to performance only when uncertainty is low (Schmidt and DeShon 2010). In the context of our research, FSA reduces uncertainty by improving consumers' clarity regarding their personal financial situation. The basis of this hypothesis is that higher levels of self-awareness, which also correspond with lower uncertainty, will increase the individual's confidence in one's abilities to handle personal finances (Bandura and Cervone 1983).

We also distinguish between three categories of financial outcomes: financial satisfaction, spending decisions, and saving and investing decisions. We hypothesize that the consumer's financial literacy will moderate the direct effect of FSA only on saving and investing decisions via response efficacy. Long-term financial decisions are inherently complex; consequently, we expect that having factual understanding of economic and financial principles will contribute to making better choices (e.g., Lusardi and Mitchell 2011) and channeling one's self-control into more effective actions (Gibson, Wardle, and Watts 1998) when the consumer is aware of his or her current financial condition. Financial literacy is not needed to evaluate financial satis-

faction or make spending decisions – FSA is enough to evaluate both financial satisfaction and spending decisions.

We test these hypotheses in a series of seven studies. Studies 1A-1C create and validate our measure of FSA and test the hypothesized mediating role of financial self-efficacy. Study 2 tests the main effect of FSA and moderating effect of financial literacy on saving and investment. Study 3 extends the findings of study 2 to financial satisfaction and spending, while also establishing test-retest validity of our FSA measure. In study 4, we manipulate the effects of FSA and investigate the differential effects of low (vs. high) FSA on saving, investment, and spending decisions. In study 5, we test our full conceptual model with financial satisfaction and patterns of spending and saving. In our sixth and final study, we use data from the 2015 National Financial Capability Study, a largescale national survey (of over 27,000 people) to test our hypotheses and provide external validity. The findings of these studies provide consistent support for our hypotheses and help to generate new insights into the role played by consumers' financial knowledge in affecting their downstream behaviors.

The findings of these studies provide consistent support for our hypotheses and help to generate new insights into the role played by consumers' financial knowledge in affecting their downstream behaviors. In conclusion, by demonstrating the importance of greater certainty and awareness about one's current financial condition and by providing a practical approach to measure consumers' financial self-awareness, this research offers a straightforward and effective way of promoting prudent financial behaviors among consumers. Its results also clarify the role of consumers' financial literacy in affecting downstream financial behaviors, specifically by showing that financial literacy amplifies the positive effect of FSA on saving and investment decisions. However, financial literacy has no effect on financial satisfaction or spending decisions. We thus take a step forward in reconciling the mixed results regarding the effectiveness of financial literacy found in earlier research and identify a new construct that may complement financial education programs.

The Persuasive Advantage of Change

EXTENDED ABSTRACT

Which would prompt more purchases: An advertisement highlighting a product's long-standing health benefits, or an advertisement for an equivalent product that frames these health benefits as the result of an ingredient change? Which would generate greater support: An advertisement highlighting the long-standing advantages of a policy, or an advertisement for the equivalent policy noting that the advantages arose from a change? Across these contexts, both messages describe equivalent alternatives with the same attributes; however, one message frames them as the result of a change while the other message does not. Does merely mentioning that something has changed affect the persuasiveness of a message promoting it?

Previous research suggests that consumers often prefer the status quo over change, and suggests that consumers' preference for familiarity contributes to this preference. In fact, consumers prefer the exact same object when they perceive it to be familiar or the current state of affairs compared to when they perceive it to be less familiar or a deviation from the current state (Bornstein 1989; Zajonc 2001; Kahneman, Knetsch, and Thaler 1991). Despite consumers' frequent aversion to change from the status quo, we theorize that references to change can promote preference in the context of persuasion. In particular, we theorize that a reference to change prompts a meta-cognitive awareness of a knowledge gap regarding the etiology and likely consequences of that change, which in turn sparks curiosity.

We further predict that this heightened curiosity leads people to more deeply process information regarding the changed product, which can increase the information's persuasive impact (e.g., consumers' real purchase decisions) under specifiable conditions. We test these predictions in five studies.

In Study 1, participants from a community college read strong arguments promoting a chocolate, and were randomly assigned to read that it had either changed or not; all other information was kept constant. Participants who read that the chocolate changed purchased more chocolates ($M = 2.83$) than participants who did not ($M = 1.73$; $t(97) = 2.76, p = .007$).

If this effect occurs because change increases processing, then it should be largest among consumers low in Need for Cognition (NFC). This is because interventions which operate by increasing processing have their largest effect among low-NFC (vs. high-NFC) consumers (Cacioppo et al. 1984). We tested this prediction in Study 2. Participants read information containing strong arguments promoting granola that was framed as having (vs. not having) changed. An interaction emerged between change condition and consumers' NFC ($b = 1.02, t = 2.20, p = .03$): The change effect emerged among low-NFC individuals ($p = .001$) but not high-NFC individuals ($p = .927$).

Increased processing increases sensitivity to information quality (Petty and Cacioppo 1979). Therefore, if messages referencing change prompt greater processing, then strong (vs. weak) arguments should (vs. should not) boost persuasion in response to those arguments. Study 3 tested this possibility. Participants were randomly assigned to read either that granola had changed or not, and to read either strong or weak information promoting the granola. Analysis revealed the predicted 2 (Argument Strength: Strong vs. Weak) \times (Granola: Changed vs. Unchanged) interaction on participants' attitudes towards the granola, and their desire to purchase it, $F_s(1, 347) > 6.33, p_s > .010$: Among participants who read strong arguments promoting the granola, participants who did (vs. did not) read that the granola changed had more favorable attitudes towards it, and were more likely to purchase it, $F_s(1, 347) > 6.03, p_s < .010$. In contrast, change had no impact among participants who read weak arguments, $F_s(1, 347) < 1.35, p_s > .247$.

Study 4 examined our prediction that change increases processing by sparking curiosity. Participants read strong arguments regarding the health benefits of minerals in Alaska's tap water. The current level of minerals was the same across conditions, but participants read that this level had either changed or not, with no mention of previous levels. Change resulted in more favorable attitudes, $t(200) = 2.53, p = .012$, greater processing, $t(200) = 2.06, p = .040$, and greater curiosity, $t(200) = 3.60, p < .001$. A serial mediation model with bootstrapping showed that referencing change increased the strong information's persuasive impact because it fostered curiosity, which increased processing, which fostered more favorable attitudes (95% CI: .0247, .1587).

Because references to change increase processing, Study 5 finds that change references promote greater attitude certainty. Attitudes held with greater certainty are more persistent over time and are more resistant to persuasive attack (Rucker, Tormala, Petty, and Briñol 2014). Participants read about a sports team that either extended Player A's contract (in the no change condition) or added Player A to its roster (in the change condition). All participants read strong arguments regarding Player A's skills. Participants in the change condition had more favorable attitudes towards Player A, processed the information more deeply, and were more curious about it, $t_s(198) > 2.32, p_s < .021$. The same serial mediation documented in Study 4 replicated in Study 5 (95% CI: .0199, .1346). In addition, change also boosted attitude certainty ($t(198) = 2.87, p = .005$), and this ef-

fect persisted when controlling for attitude extremity ($F(1, 197) = 4.23, p = .041$). A serial mediation showed that change increased certainty because it fostered curiosity, which increased processing and then boosted certainty (95% CI: .1010, .3106).

Together, we find that referencing a change can increase the persuasive impact of information. Mediation and moderation designs provide converging evidence that this occurs because mention of change sparks curiosity, which boosts information processing. These results are the first to demonstrate that references to change in persuasive messages can play an important and generalizable role in shaping consumers' attitudes, preferences, and real purchase decisions. Besides having numerous applications for marketing promotion, our findings contribute to the curiosity literature by uncovering a previously undocumented antecedent to curiosity—the awareness of change. Our findings also contribute to the literature examining people's preference for familiarity and the status quo by uncovering systematic conditions in which the reverse preference emerges.

How Does Risk Sound? The Fit Between Harsh (Soft) Names and Uncertainty (Certainty)

EXTENDED ABSTRACT

The words we use, while simply a composition of sounds, profoundly influence decisions and experiences. The linkage between sound and meaning—known as sound symbolism (Hinton, Nichols, and Ohala 1994)—has been shown to influence such perceptions as shape (Köhler 1947), density (Koriat and Levy 1977), brightness (Newman 1933), and size (Sapir 1929). Moreover, the perceived fit between a product's attributes and its name is believed to influence preference (Klink 2000; Lowrey and Shrum 2007).

In this research, we propose that the sound of a word—an unavoidable but uninformative factor inherent in decision-making—affects the level of investment when a decision is made under uncertainty. For instance, imagine two investment stocks equivalent on all objective criteria, differing only by name; e.g., *Kiki* and *Bouba* (borrowing from Köhler's (1947) example). While normative theory would predict indifference between these two options, we predict that *Kiki* (*Bouba*)—a name shown to result in a more volatile (well-rounded) perception—would be preferred in more uncertain (certain) decision scenarios. Specifically, we develop a coding schema that places names on a comfortable–uncomfortable continuum, adapted from extant research (Smith 1998) and referred to as *phonetic comfort score* (PCS). We suggest that softer-sounding (i.e., high-PCS) names are likely to be preferred in more certain scenarios, whereas harsher-sounding (i.e., low-PCS) names will be preferred amidst greater uncertainty. Importantly, we differ from past work that focuses on just one aspect of a name; rather, we consider it in totality, increasing applicability of our findings.

We propose such a pattern is attributed to the perceived fit (Slooman 1996; Tversky and Kahneman 1974) between a harsher-sounding (softer-sounding) name and a more uncertain (certain) situation. We posit that such a fit is derived from differences in the perceived variance of possible outcomes when the same decision (e.g., a horse race wager) appears with a harsh versus soft name. We find that a harsh-sounding name makes the entity appear more volatile, such that the possible outcomes are perceived as having greater variance (i.e., a wider range). Conversely, a soft-sounding name makes the entity appear less volatile, with the possible outcomes perceived as having less variance (i.e., a narrower range). Based on one's tendency to seek risk (avoid failure) when the probability of winning is low (high), we propose that one is likely to use the upper (lower) bound of possible perceived outcomes as a cue when making a decision.

Therefore, amid greater uncertainty (certainty), we expect to find greater preference for harsher-sounding (softer-sounding) names.

We first use data from thoroughbred racing (Kentucky Derby) to examine wagering as a function of PCS (of the horse's name) and odds of winning (set by odds-makers). Our analysis finds that high (low) PCS is preferred in the context of high (low) chances of success. Second, we find that in times of uncertainty (we use public debt as a proxy for volatility), people have elected presidential candidates with names lower (rather than higher) on PCS. Third, after testing our propositions with real world data, we validated them in a controlled lab setting. We presented participants with names and certainty (odds of winning) in a double-randomized fashion, and measured the amount wagered over five simulated races. Fourth, in order to examine the theoretical proposition that low-PCS names signal greater variance of outcomes, participants provided projected finish position for horses with low-PCS or high-PCS names as one of twelve (equiprobable) entrants in a series of ten horse races. We find greater volatility (in the form of mean absolute deviation) in the estimated finish for names low (vs high) on PCS.

Fifth, we procure process evidence using physical response data from a simulated horse race using a hand grip dynamometer. We measure static force applied to “power” a horse, and examine how this force might differ based on PCS (high or low) and odds (favorite/more certain or long shot/uncertain). With extant research on optimism linking increased confidence to effort (Carver and Scheier, 1998, 2014), we would expect to find greater force for low (high) PCS for long shots (favorites). Results indicate greater force applied when PCS is low (high), suggesting greater optimism for low (high) PCS amidst greater uncertainty (certainty). Finally, we propose that if our theorizing is correct—i.e., if this effect occurs because of the fit between harsh (soft) names and uncertainty (more certainty)—then we should find that this pattern reverses when the scenario changes from the gain (e.g. winning) to the loss (e.g., preventing a loss) domain. We utilize hurricane data made available through Jung et al. (2014) that measures select variables relating to fatalities from past US hurricanes. We calculate the PCS of the hurricane name and predict storm fatalities as a function of PCS, storm severity, and their interaction. Consistent with our theorizing, we find evidence that low-PCS (high-PCS) names are perceived as more of a reality—and thus see greater compliance—amidst higher (lower) risk scenarios.

In sum, the seemingly uninformative yet inescapable factor of the sound of a name influences decisions under uncertainty. Our findings have significant implications. Marketers can seek to align brand names with product usage perceptions; e.g., a more certain (uncertain) product may be better suited for a high-PCS (low-PCS) name. Moreover, consumers can use these findings as an aid in decision making, ensuring greater reliance on informative, objective criteria relating to certainty of a product's success, and less reliance on the uninformative, subjective factor of name. Finally, policy makers can use this information to better predict adoption, raise awareness, or maximize compliance of a given public initiative based on its name and expected chance of success.

Paper #4: Asymmetry in Emotion Language Is Consequential For Evaluative Judgments

Chiara Longoni, Boston University, USA

Geeta Menon, New York University, USA

SESSION OVERVIEW

Since the days of the Whorfian hypothesis (Whorf 1956), much research has been done on how language shapes both cognition and emotion. The role of language in affecting consumer behavior is less well-understood, however. Yet language is highly important in consumers' lives, whether in the form of descriptors on product packages or even in terms of consumers' own linguistic engagement with brands. In this session, we have assembled four papers that collectively examine how different facets of language shape consumer behavior. As a group, these papers raise two main questions: how can language be used to influence consumer cognitions and emotions, and how can marketers take advantage of these influences and structure the language content of their promotions to take advantage of consumer biases.

First, Baskin and Liu examine the effects of unknown language descriptors on product perceptions, finding that consumers make inferences about products, both in terms of price and taste, despite not understanding the descriptor's meaning and having no a priori associations with the descriptor. They present nine studies showing how price perceptions are increased while taste perceptions are decreased when consumers are uncertain about the meanings of product descriptors.

Second, Luangrath, Peck, and Barger examine language use on Twitter, in particular, textual paralanguage and explore how its usage affects perceptions of brand competence and warmth. They present four studies showing that introducing non-word items into a brand's messaging can decrease competence perceptions of the brand.

Third, Ordenes and Grewal examine language through automated text mining on a sample of online dialogues (N=2,084) between customers and employees of various companies including Amazon and Tesco as a way of understanding the impact of interactional control on the service resolution. They use this data to show that, beyond sentiment, interactional control within a dialogue has a non-linear effect (diminishing returns) on the service resolution. In addition, they show that the nonlinear effect of interactional control is stronger for

dialogues in which the trend of employee positivity across messages is increasing.

Finally, Longoni and Menon examine emotional language and its effects on evaluative judgments. Across six studies, they show that the use of positive emotion words lowers emotion intensity and product evaluation.

Overall, all of these papers are at advanced stages, and a range of methods—from lab experiments to text mining—are employed. By examining the multi-faceted impact of aspects of language on consumer perceptions, we hope that this session helps to spur on a new wave of research that delves deeper into aspects of language and how they affect consumer behavior. We expect this session to appeal to researchers interested in the topics of language, word-of-mouth, and online marketing.

The Unexpected Implications of Product Descriptors on Product Perceptions

EXTENDED ABSTRACT

Imagine going to a restaurant and seeing meaningless descriptors on the menu to describe the food items. For example, envision the items, “fiducated cornbread” or “faldered hamburger steak” as you peruse the menu. Even though you are unaware of the meaning of “fiducated” or “faldered” (in fact, they have no meaning), how might they change your perception of the item they are associated with? In particular, would the descriptors affect your price or taste perception of the menu items?

In this research, we examine the effects of meaningless descriptors on perceptions of products, both in a restaurant menu context, as well as more broadly. In particular, we examine how adding descriptors, even meaningless ones with no inherent meaning, affect product price perceptions and in the case of food, taste perceptions. We show that meaningless descriptors increase price perceptions through increasing consumer uncertainty about the product. Thus, consumers may assume the product is more exceptional. Regarding taste, we draw from the notion that consumers are risk averse both generally and especially in the food domain to predict that the uncertainty about product characteristics may lead to increased risk perceptions and thus a decrease in predicted taste.

We present a series of nine studies to test these hypotheses. First, we pretest meaningless descriptors in order to ensure that they are, in fact, unknown to the majority of our participants. In study 1, we establish our main price effect in the food domain. In addition, we show that meaningless descriptors actually hurt predicted taste and enjoyment and have negative downstream consequences for food purchase intentions. Next, in studies 2a and 2b, we replicate our main price effect and show that it holds both inside and outside the food domain. We also find evidence against processing fluency as an alternative explanation by showing that descriptor complexity, one measure of fluency, does not affect price perceptions in 2a. Study 2b further rules out fluency by using a different manipulation of fluency, hard-to-read font, and showing that meaningless descriptors affect price and taste perceptions over and above the effect of fluency. Next, study 3a, shows our serial mediation mechanism for price perceptions in that meaningless descriptors create uncertainty about the general characteristics of a product which then leads people to predict that the product will be more exceptional thus leading to

increased price perceptions. Study 3b shows our serial mediation mechanism for taste perceptions in that meaningless descriptors decrease taste perceptions by increasing uncertainty and increasing potential product risk therefore leading to decreased taste perceptions. Additionally, we look at two potential boundary conditions for the price effect. Study 4a provides additional support for the role of uncertainty by showing that, when product uncertainty is decreased by showing participants a photograph of the product in question, the effect is attenuated. Study 4b then provides additional support for the role of product exceptionality by showing that special occasion products, which are already exceptional, also act as a moderator for our effect. Finally, study 5 shows that the price effect obtains even when price is given to the consumer.

In summary, this research contributes to a number of literatures. First, it contributes to the area of linguistic psychology and the price perception literature writ large. The literature in this area has not been able to disentangle the effects of descriptors as all studies that we are aware of confound the existence of descriptors with the meaning that they give to the products that they describe. While we do not believe that the meaning gained from descriptors has no effect on perceptions [many studies have shown that it does in areas that we find a negative effect in, such as taste (Wansink, Painter, and Van Ittersum 2001)], we do believe that a large portion of the pricing perceptions effect may arise from the existence of the descriptor rather than anything related to the content of the descriptor itself and its relation to the product being described. In addition, we contribute to the linguistics literature by showing an area where a lack of linguistic meaning is taken by consumers as a cue to a change in their visualization about the product being described. We grant further evidence that language is a factor in forming cognitions and biases in everyday life. Finally, we also contribute to the nascent field of textual paralinguistics by showing a new instantiation of meaning that supplements the literal meaning of the written language inherent in the descriptor.

Make Your Tweety Bird Tweet: Use of Textual Paralinguistics in Brand and Spokescharacter Online Communications

EXTENDED ABSTRACT

For years, Kellogg's has been utilizing textual paralinguistics in its advertising for Frosted Flakes cereal, printing "THEY'RE GR-R-REAT!" next to the image of Tony the Tiger. Through repetition of the letter 'r', Kellogg's communicates that the word "great" is to be spoken in a drawn out, tiger-like growl. Recent research defines textual paralinguistics (TPL) as written manifestations of nonverbal audible, tactile, and visual communication (Luangrath, Peck, and Barger 2017). In this research, we examine the effects of TPL use by brands and brands' spokescharacters on social media.

There is growing interest in online communications and the insights to be gained from text-rich data. Much of the existing work on language in consumer research has focused on word usage, such as explanatory phrases (Moore 2015), assertive advertisements (Zemack-Rugar, Moore, and Fitzsimons, *forthcoming*), refusal words (Patrick and Hagtvedt 2012), vowel sounds (Lowrey and Shrum 2007), figurative language (Kronrod and Danziger 2013), closeness-implying pronouns (Sela, Wheeler, Sarial-Abi 2012), and meaningless words (Liu and Baskin, *working paper*). Recent work has been instrumental in advancing sentiment analysis beyond dichotomous classifications of positive/negative to a more nuanced consideration of sentiment strength, implicit meanings, and patterns of sentiment (Villarroel-Ordenes et al. *forthcoming*).

We approach the study of language from an alternative perspective, shifting focus from the meaning and interpretation of specific words to the ways in which the words are communicated. While word-based language assessment is a critical component of linguistic analysis, we believe that aspects of messages conveying properties of speech and communication context are important as well. TPL in text is analogous to nonverbals in face-to-face communication.

Study 1a examines how prominent U.S. brands use TPL in text-based marketing communications. Two sets of brands were selected for this study: Forbes' list of "The World's Most Valuable Brands" (Badenhausen 2013), including brands such as Nike, Google, and Disney, and Time's list of "The 13 Saggiest Brands on Twitter" (Grossman 2014), including brands such as Hamburger Helper, Orbitz, and Old Spice. A Python program was written to collect brand tweets and TAMS Analyzer was used to code the tweets for TPL. Of 5,214 brand tweets, 1,011 (19.4%) contained TPL. Use of TPL was markedly higher by the sassy brands (32.1%) than the Forbes' brands (12.7%). Using these lists as proxies for brand warmth and competence, we hypothesize that sassy brands are likely to be perceived as warmer while Forbes brands, which are more traditional and conservative, are likely to be considered more competent.

Study 1b explores the relationship between TPL and consumer perceptions of warmth and competence. Participants on Amazon's MTurk (N=1,847) were randomly presented with one brand name from the list of Forbes' and Time's brands (study 1a) and asked for their perception of the brand's warmth (Aaker et al. 2010) and competence (Aaker 1997). Results indicate that the Forbes' brands are perceived to be more competent ($M_{\text{ForbesComp}} = 3.78$, $M_{\text{TimesComp}} = 3.29$, $F(1,1846) = 165.28$, $p < .001$), but less warm than Time's sassy brands ($M_{\text{ForbesWarm}} = 3.02$, $M_{\text{TimesWarm}} = 3.27$, $F(1,1846) = 25.70$, $p < .001$). Pearson correlation coefficients reveal that TPL use correlates positively with perceptions of brand warmth ($.16$, $p < .01$) and negatively with perceptions of brand competence ($-.05$, $p < .05$).

To test this relationship, Study 2 investigates whether TPL affects perceptions of brand warmth and competence. Ninety-eight undergraduate students participated in an online study and were asked to imagine that a brand tweets the following: "Big things come in small packages [BIG, Awww, ☺]." Tweets either contained TPL or did not. Results reveal that a tweet containing TPL as compared to a tweet without TPL does not significantly affect perceptions of brand warmth ($M_{\text{NoTPL}} = 3.52$; $M_{\text{TPL}} = 4.06$; $F(1, 97) = 2.89$; $p = .09$) but negatively affects perceptions of brand competence ($M_{\text{NoTPL}} = 4.73$; $M_{\text{TPL}} = 4.09$; $F(1, 97) = 4.58$; $p = .04$).

In Study 3, we investigate whether a brand's spokescharacter can mitigate the negative effects of TPL on perceptions of brand competence. Spokescharacters are often created to imbue brands with personality (Fournier 1998), which may give them leeway to be more informal, humorous, and relatable. A 2 (TPL/no TPL) x 2 (brand/brand mascot) study was conducted with 476 participants on Amazon's MTurk. Participants were asked to imagine that a [brand/brand's mascot] tweets the following: "A penny saved is a penny earned [!!!!, Yippee!, *thumbs up*]." The avatar displayed next to the tweet was either an image of a brand mascot (i.e., a frog) or a neutral brand image (i.e., a green circle). Results indicate that perceptions of brand warmth are not significantly affected by TPL ($M_{\text{NoTPL}} = 4.89$, $M_{\text{TPL}} = 4.69$, $F(1,475) = 2.48$, $p > .10$). Similar to study 2, we find that TPL negatively affects brand competence ($M_{\text{NoTPL}} = 4.96$; $M_{\text{TPL}} = 4.62$; $F(1, 475) = 6.61$; $p = .01$). A significant interaction between the spokescharacter and the TPL condition ($F(1, 475) = 3.79$; $p = .05$) suggests that when a brand tweets using TPL, perceptions of brand competence decrease significantly ($M_{\text{Brand/NoTPL}} = 5.13$; $M_{\text{Brand/TPL}} = 4.52$; $F(1, 472) = 9.72$; $p = .002$). However, when

a spokescharacter tweets using TPL, there is no significant positive or negative effect on perceptions of brand competence ($M_{\text{Frog/NoTPL}} = 4.80$; $M_{\text{Frog/TPL}} = 4.71$; $F(1, 472) = .21$; $p = .65$). In addition, we rule out the possibility that the presence of a smiling frog led to greater positive affect ($M_{\text{Frog}} = 5.54$, $M_{\text{Brand}} = 5.67$, $F(1, 475) = 1.49$, $p > .10$).

This research suggests that, when using TPL in online communications, a brand can avoid negative effects on brand competence by tweeting from a spokescharacter account rather than the brand's main Twitter account. We reason that consumers expect an informal character to use more informal language, but when a brand, a more formal source, uses informal language, it makes the brand seem less formal and thus less competent. As social media platforms continue to add to the range of available text-based symbols, images, and stickers, Frosted Flakes should leave the growling to Tony.

Do you e-care? Analyzing the Impact of Dialogue Dynamics in Online Service Resolution

EXTENDED ABSTRACT

Consumers are increasingly providing feedback and interacting with brands in digital communicational channels. This has given rise to the growing concept e-care, that is, customer service through social online channels such as Twitter and Facebook. For example, the volume of tweets targeted to brands has doubled, and the percentage of users visiting Twitter for customer services increased by 70% during 2013–2014 (McKinsey 2015). Many companies use sentiment analysis—an automated process for deciphering the sentiment contained in text—to assess the sentiment of these conversations, yet this method is limited by its inability to capture dialogue dynamics resulting from consumer-employee interactions. Limited consumer research explicates how language patterns at a dialogue level, can inform the use of sentiment analysis for consumer research (Ordenes et al. 2017).

Relational Communication Theory (Soldow and Thomas 1984) posits that every message comprises content (i.e. substance of a message) and form (i.e. structure of the content). Whereas content relates to the informational aspect, form serves the interpretation of the message in terms the interactional control within a dialogue. Through the form of the message, an interactor positions him- or herself toward dominance, deference, or equality. The interactors' reciprocal propositions entail various combinations of control positions which have an influence on the effectiveness of the interaction.

By theorizing on relational communication (Soldow and Thomas 1984) we posit that the interactional control has non-linear effect (diminishing returns) on the service resolution (hypothesis 1). Then, in line with research on affective meaning (Warriner and Kuperman 2014), we suggest that an increasing trend in positivity across employee messages, has a positive effect on the service resolution (hypotheses 2). Finally, in line with research on the interplay between content and style (Ludwig et al. 2013) we posit that the positive effect of interactional control is stronger when positivity across employee messages increases (hypothesis 3).

A dataset of Twitter and Facebook, consumer initiated dialogues with an employee (all complains), between November 2014 and May 2015, was scraped and pre-processed (e.g. duplicates deleted and data was structured at a dialogue level) by using Knime Analytics 3.2. We identified 2084 dialogues of the retail firms Amazon, Tesco, and Walmart, as well as the car manufacturer Ford.

The dependent variable, service resolution, was coded manually for each dialogue. Two coders coded the service resolution in terms of whether the customer ended up the dialogue satisfied (1) or

dissatisfied (0). Coder inter-reliability was assessed using Krippendorff's alpha, resulting in a value of 0.82.

Interactional control was operationalized using the Relational Communication Framework (Soldow and Thomas 1984). Two coders manually coded each sentence for every message of a dialogue. Each sentence was assigned to a Digit 1 (message author), Digit 2 (grammatical form), Digit 3 (response mode). Then a control position relative to the previous sentence from the customer and the employee was determined (i.e. 1 = deference, 2 = equality, 3 = dominance). Finally, to determine the overall interactional control, an average was calculated from the sentence control positions (SCRL) across the dialogue (1 being the lesser control and 3 being the greater control). Coder inter-reliability was examined by using the Krippendorff's alpha resulting in .99, .89 and .84 for digits "1" "2" and "3" respectively.

To assess the trend of employee positivity across dialogue messages, LIWC (Linguistic Inquiry and Word Count) text analysis software was used (Tausczik and Pennebaker 2010). In line with Ordenes et al (2017), a single positivity trend per dialogue was obtained by computing the slope of positivity across the employee messages within a dialogue. Several control variables such as the number of messages exchanged, picture presence, average employee response time (minutes), social media type, industry type, third participant, and message arousal (Ordenes et al. 2017; Schweidel and Moe 2014; de Vries, Gensler and Leeftang 2012) were included.

In line with our hypotheses, we specified a hierarchical logistic regression approach to estimate 1) the non-linear effect interactional control, 2) employee positivity trend, and 3) their interaction effect. Model 1 represents the baseline of the hierarchical regressions in which we only evaluated the effect of basic sentiment analysis on the service resolution. Model 2 included the nonlinear effect of the interactional control on the service resolution. Our findings supported H_1 by finding a diminishing returns relationship of interactional control. The results of Model 3 supported the proposition of H_2 . A higher level of employee positivity across sentences increases the likelihood of a satisfactory service resolution. Finally, Model 4 incorporated the interaction effect between dialogue interactional control and employee positivity trend. Our results partially supported H_3 , by confirming that dialogues in which employees increase their positivity across sentences, strengthen the relationship between interactional control and the service resolution.

By using the lenses of relational communication theory, the present study informs research on online consumer-employee dialogues. Theoretical contributions in the area of consumer language and managerial implications concerning the development of conversational analytics' methods are offered.

Asymmetry in Emotion Language Is Consequential For Evaluative Judgments

EXTENDED ABSTRACT

Imagine two football fans Tweeting about their team winning the Super Bowl; one fan uses 2 positive emotion words whereas the other fan uses 6 positive emotion words. Which fan will rate the victory as more emotionally intense? Which fan will enjoy the victory more? Content-focused models of judgments (Higgins, 1996) predict that the fan who used 6 positive emotion words experiences the victory more intensely, and therefore enjoys the win more. Contrary to this prediction, we show that for positive (but not for negative) emotion words, the effect is reversed: the greater the number of positive emotion words a person associates with an event, the lower the emotion intensity and evaluation of an event.

We ground our predictions in diverse literatures spanning emotions and how emotions are conceptualized (Barrett, 2007; Lindquist et al., 2006). We also rely on several lines of research that have examined production and development of emotion language (i.e., the vocabulary we use to refer to emotions) in both children and adults. These lines of research are suggestive — although not testing directly—that positive emotion words are less readily available than negative emotion words. For example, in 4-month olds, negative emotions such as anger and fear grab attention more than positive emotions such as happiness, as measured via gaze orientation, recall, and recognition (Montague and Walker-Andrews, 2001). Young children spontaneously and more frequently talk with their parents about the causes of unpleasant emotions than the sources of positive feelings (Dunn et al., 1987; Dunn et al., 1991), and are more prone to reminisce about negative past events than positive ones (Miller and Sperry, 1988). The qualities of parent-child narrative discourse and interactions also suggest that positive emotions are less salient than negative ones. For example, parental questioning, the act of parents enquiring, “what is the matter?”, “what is bothering you?”, is more likely to prompt children to elaborate and think about negative than positive emotions (Lagattuta and Wellman 2001).

Together, these lines of enquiry indirectly suggest that negative emotions are more salient than positive emotions. We test this hypothesis directly and examine its implications for evaluative judgments in a variety of domains. Specifically and across 6 studies, (a) we show that emotion language affects evaluative judgments, (b) we document an asymmetry in positive (vs. negative) active emotion vocabulary, (c) we show that this asymmetry has hedonic consequences across various contexts, and (d) we show that the effect of emotion language on judgments is mediated by the subjective experience of effort associated with emotion generation.

First, we directly test the hypothesis that there is lower chronic accessibility of positive (vs. negative) emotions words. In study 1, we asked participants to generate as many positive or negative emotion words as they could in a set time frame. Participants were able to generate fewer positive emotions than negative emotions, suggesting that negative emotion words dominate the working emotion vocabulary of the average individual ($p < .001$). This difference reflects the English vocabulary (406 positive emotions vs. 499 negative emotions).

Second, we show that this differential accessibility of positive (vs. negative) emotion words is consequential for evaluative judgments in various domains, including recalls of personal experiences, evaluation of photos and blog posts, and product reviews. In studies 2 and 3 we measured the relationship between the number of positive (negative) emotion words used when recalling a personal event, and how intensely positively (negatively) one felt about that personal event. In study 2, participants wrote a post about a personal event that was meaningful to them, had taken place in the recent past, and in which they were happy or unhappy (order counterbalanced). In study 3, participants wrote about current positive and pleasant (or negative and unpleasant) events. In both studies, participants who reminisced about happy past life experiences or recalled pleasant current events subsequently felt less happy the greater the number of positive words they had included in the recall (for past events, $p = .02$; for current events, $p = .01$), whereas the number of negative emotion words they used did not affect mood ratings.

The same effect emerged for evaluation of photos and blog posts in studies 4 and 5. Participants who described positive stimuli (a photo of a smiling child, a photo of the zoo) using 6 positive emotion words rated these stimuli less favorably compared to participants who used 2 positive emotion words ($p = .001$ and $p < .001$ res-

spectively), with the difference in evaluations fully mediated by the effort associated with emotion generation (indirect effect bootLLCI: 0.044 bootULCI: 0.745; bootLLCI: 0.012 bootULCI: 0.518 respectively). However, the number of negative emotion words used to describe negative stimuli did not predict evaluation, nor did effort in emotion generation mediate evaluation.

Finally, in study 6 we tested the proposed phenomenon in the context of product reviews. Participants who used 8 positive emotion words as hashtags after reviewing a cafe subsequently gave the establishment lower star ratings compared to participants who used 3 positive emotion words as hashtags ($p = .001$), unless participants assigned the star rating before reviewing the cafe.

Overall, across several studies, measurements, and contexts, we present a novel framework that advances our understanding of emotions and emotion language, and furthers our knowledge of the consequences of emotions on judgments. Importantly and from a practical standpoint, this research shows how encouraging consumers to express positive affective states, like it is often customary online by use of hashtags, tweets, and short posts, may have aversive consequences on evaluations.

SESSION OVERVIEW

From posting online to texting with friends, more and more of our lives now leave digital traces. Further, the burgeoning digitization of cultural items (e.g., song lyrics) provides an additional wealth of information. How can researchers use all this textual content to study consumer behavior? And what does the language we use reveal about our motivations, relationships, and likely future actions?

This session integrates a variety of perspectives to showcase how textual analysis can provide behavioral insight. Can language shape what becomes popular? Indicate whether someone will default on a loan? How does the meaning of authenticity change over time? Which narratives diffuse through culture and why? Using a diverse set of methods and data sources, this session sheds light on these and other questions as it demonstrates insights from language.

First, **Packard and Berger** examine why things catch on, investigating how differentiation shapes cultural success in popular music. Textual analysis and chart performance of thousands of songs reveals that the more different a song's lyrics are from its genre, the more successful it is. Further analysis reveals that the effect of lyrical differentiation varies across genres (e.g., less important in Dance music, more important in Rap), consistent with their conceptual account.

Second, **Corciolani, Grayson and Humphreys** examine how the meaning of authenticity evolves over time. Looking at nearly five decades of music critic reviews from *Rolling Stone* magazine, they find that a music genre's authenticity evolves from language about product quality (in early phases), to cultural or artistic sincerity (in mature genres), supporting the authors' contentions regarding field-dependency in cultural evolution.

Third, **Netzer, Lemaire and Herzenstein** demonstrate how the language consumers use when requesting loans indicate their future behavior and likelihood of default. Analyzing over 18,000 loan requests from an online crowdfunding platform, and using text-mining and machine-learning tools, they find that references to the future, family, and God are among several language-based factors that improve the ability to differentiate good from bad consumer debtors.

Finally, **Berman, Humphrey, Melumad, and Meyer** analyze over 3 million tweets from before, during and after the 2016 U.S. presidential debates to examine how the Twittersphere influences the diffusion of political information. While one might hope that this new channel of communication has helped better inform the electorate, they find that topics shift from the substantive to the sensational as time passes around each debate, shifting the medium's quality from relatively journalistic to more tabloid in value.

Taken together, these papers highlight how words shed light on important behavioral and cultural phenomena. Notably, each offers an example of how psychological insights can be pursued outside the laboratory. They also illustrate how a variety of researchers can use unstructured data sets (i.e., "big data") and textual analysis to answer relevant consumer behavior questions. The session should be of interest to anyone who studies social influence, word of mouth, financial decision making, and authenticity, as well as those who are interested in this toolkit more generally.

Differentiation and Cultural Success

EXTENDED ABSTRACT

Why do some cultural items succeed while others fail? Academics and practitioners have long been interested in why music, ideas, and other tastes become popular while others languish (Gladwell 2006; Simonton 1980; Lieberman 2000). Some movies, for example, become blockbusters and some songs reach the top of the charts. Even domain experts have difficulty predicting hits (Bielby and Bielby 1994; Hirsch 1972), however, leading some to argue that success is random (Hahn and Bentley 2003; Salganik, Dodds and Watts 2006), driven more by social dynamics than anything specific to the cultural items themselves.

In contrast, we suggest that inter-item similarity, or how similar something is to related cultural items, plays an important role in success. In the context of music, for example, some Country songs have lyrics that are quite similar to other Country songs, while others have lyrics that are quite different. How might similarity or differentiation shape whether something becomes a hit?

We suggest that things that are more differentiated from others will be more popular. People have a drive for stimulation (Zuckerman 1979), and from an early age, children are attracted to novel stimuli, or those that are different from what they have seen before (Flavell, Miller, and Miller 2001). Taken to a collective level, cultural items that are more different from their peers may be liked more, and, as a result, become more popular.

Importantly, the differentiation we suggest is not infinite, but bounded. A song whose lyrics sound like death metal would be extremely different from most country songs, but would also be unlikely to be classified as a country song in the first place. Thus, we examine whether *among* songs classified as belonging to a given genre, those whose lyrics are more atypical, or differentiated from other genre members, are more successful. By adhering enough to genre conventions to be classified as such, these songs may succeed by blending similarity and distinction (Berger, Bradlow, Braunstein, and Zhang 2012). Similar enough to the genre to evoke the warm glow of familiarity (Monahan, Murphy, & Zajonc, 2000), but different enough to be novel and liked more (i.e., two stage valuation; Zuckerman 2016).

Method

We analyze thousands of songs, testing how lyrical differentiation (i.e., how different a song's lyrics are from others within its genre) shapes popularity.

First, we collected song data. We captured consumer demand using Billboard's digital download rankings. This measures sales data from major paid song services (e.g., Apple iTunes). We obtained all songs ranked each quarter for three years (2014-16) for each of seven major genres (e.g., Pop, Rap, Rock). This resulted in a dataset of 4,200 song rankings and 1,879 unique songs.

Next, we used latent Dirichlet allocation (LDA, Blei 2012) to determine key lyrical features. LDA takes a number of texts (songs in our case), and by measuring word co-occurrence, determines the key latent topics or themes that make up those texts, and the words that make up each topic. In this case, some of the themes identified were "car cruising" (e.g., words like "road," "ride," and "drive"), "uncertain love" (e.g., "heart," "need," "love"), and "body movement" (e.g., "shake," "bounce," "clap").

Then, we used these latent topics to calculate how different each song is from songs in its genre. The LDA model outputs the proportion of each song that belongs to each latent topic. One song, for example might be 25% "car cruising," 45% "uncertain love," 10% "body movement," and so on. Averaging across all songs in a genre provides the genre's mean use of language. Country songs, for example, talk a lot about "girls and cars" (39%) and "uncertain love" (36%) and less about "body movement" (2%). We calculate the differentiation of each song by taking the difference between its score and the genre mean for a given topic, aggregating across topics.

Finally, we use an OLS regression to examine the relationship between lyrical differentiation and song performance.

Results

Results demonstrate a significant relationship between lyrical differentiation and popularity. The more different a song's lyrics are from its genre, the more successful it is. 16% lyrical differentiation from the genre mean corresponds to a one position improvement in chart ranking. These results hold controlling for numerous covariates (e.g., artist, radio airplay, prior chart appearance, genre, and presence in multiple genres) and alternative specifications, including those accounting for non-linearity or selection. The results are also robust to whether we compute topics across or within genres. Across all specifications, differentiation was linked to success.

More or Less Typical?

Differentiation could occur in one of two ways. While Rap songs with more differentiated lyrical topics are more successful, for example, this could be because they include even *more* rap-associated content than other Rap songs or because they include *less* Rap-associated content and more content associated with other genres.

Results suggest the latter. Successful songs tend to use less of their genre's own typical topics (e.g., "bad man" in Rap) and more of topics associated with other genres (e.g., country's "uncertain love" in Rap).

Moderation by Genre

Finally, we examined whether the relationship between lyrical differentiation and success varied by genre. Differentiation was good overall, but lyrics may matter less in Dance music, for instance, where attributes that drive movement (e.g., the beat) may be more important than lyrics (Fabbri 1981). Results are consistent with this prediction. Lyrical differentiation matters less in Dance, as well as Pop music, which, almost by definition, is more about mainstreaming than differentiation (Frith 1986).

Conclusion

In conclusion, analysis of thousands of song suggests that differentiation plays an important role in cultural success. More generally, this work demonstrates how natural language processing can be used to study cultural dynamics, and sheds light on psychological drivers of why things catch on.

How do Authenticity Meanings Evolve? A Longitudinal Analysis of Music Album Reviews

EXTENDED ABSTRACT

Research has shown that consumers value authenticity (Grayson and Martinec 2004; Rose and Wood 2005; Valsesia et al 2015). As past research has emphasized, authenticity can be generally defined in one of two ways: (a) being true to one's self, which we call sincerity, but has also been known as expressive authenticity or creative authenticity (Dutton 2004; Ilicic and Webster 2014; Valsesia et al 2015) or (b) being true to some established type or genre, which we call heritage, but is also known as iconic authenticity (Grayson and Martinec 2004) or type authenticity (Davies 2001). In this research, we explore how changing field-level factors can influence the definition of authenticity preferred by music critics. By examining the context of music album reviews, we longitudinally analyze how authenticity meanings evolve over the development of a music genre. The music industry is one domain in which authenticity has particular value to consumers (e.g., Grazian 2003; Peterson 1997). Because audiences value authenticity in music, artists often seek to create authentic music and to perform it authentically, and critics often comment on the authenticity of a musician and his or her music (Peterson 1997; Valsesia et al 2015).

Although previous research has examined the individual and small-group effects involved with evaluating authenticity (Grayson and Martinec 2004; Grayson and Shulman 2000; Valsesia et al 2015) and coping with its paradoxes (Rose and Wood 2005), it has not accounted for field-level dynamics—changes in the age, number, and variety of alternatives—on criteria for evaluating authenticity. Using theoretical tools from cultural sociology and institutional theory, we examine the change of criteria for judging authenticity over time and in conjunction with changes in field age and size.

In our work, we empirically study the evolution of authenticity meanings over time by focusing on the music albums reviewed by the magazine *Rolling Stone* from 1967 to 2014. Our sample consists of 4,924 reviews, which were downloaded from the official website of the magazine. We first conducted a qualitative analysis to identify the most common ways in which the concept of authenticity was discussed. This first analysis enabled us to identify three different types of authenticity most common in our dataset, and which are similar to those identified by Napoli et al. (2014): quality commitment, sincerity, and heritage. Then, we conducted a quantitative, automated text analysis of *Rolling Stone*'s music album reviews (Humphreys 2014) to measure the change in these types of authenticity over time.

We find that, when a genre is new, music reviews tend to mention authenticity in association with quality commitment. As the genre matures, reviewers focus more on authenticity as sincerity, evaluating the motives of the artist. Then, as a genre matures further and faces competition from sub-genres and other genres, reviewers focus more on authenticity as heritage, evaluating it in relation to an ideal type for that genre. We argue that this progression is common across most genres because, over time, the resources available to critics change (as well as the resources available to artists and audiences). By "resources," we mean common understandings among stakeholders about the genre.

Criteria for evaluating authenticity in our dataset therefore has three distinct periods. Specifically, in Phase I (1960s-1970s), quality commitment resulted to be the dominant dimension. During Phase II (1980s-1990s), sincerity was the main dimension. In Phase III (2000s-2010s), heritage was the salient dimension. By drawing both historical and cross-sectional comparisons, we can assess differences according to field-level dynamics of both size and age of the genre. For example, *avant-garde*, which has remained a small genre, went through quality commitment and sincerity stages, but has not yet shifted to evaluation of authenticity according to heritage or type.

Earlier in the development of a music genre, critics, artists, and audiences do not have the resources to judge authenticity according to type. Instead, they rely on a definition of authenticity that does not require field-specific knowledge that people have developed across domains—namely, the common understandings they have regarding how to judge whether someone is being true to self or quality according to some abstract standard.

Using work from cultural sociology, we argue that cultural resources are needed to develop criteria for judging authenticity based on type. As Peterson (1997) points out, an artist cannot be true to an established model until a model has been established. For critics to feel comfortable referring to a musician's adherence to the standards of a genre, industry stakeholders (including both critics and audiences) must have a sufficient level of field-specific knowledge regarding a genre's history and tropes. Commenting about the difference between country music in the 1990s versus the 1920s (when the genre was in its infancy), Peterson argues that: "the most obvious change ... is that there was then no clear tradition of country music with its own past, its own iconic progenitors, its own institutional delivery system, and its own self-conscious fan community" (Peterson 1997, p. 223).

This research makes several contributions to our understanding of authenticity. First, we identify the differential role of field-dependent and field-independent knowledge in criteria for assessing authenticity. That is, field-dependent knowledge leads to assessments of quality commitment and sincerity, but assessments of heritage require more sophisticated knowledge of fields and attributes. Second, the findings explore a kind of cultural capital that is different from that examined previously. Bourdieu defines cultural capital as a resource that an individual person builds up in order to gain advantage in a field. The cultural capital needed to define and promote heritage-based authenticity is not really "owned" by a particular person (although some can be more/less knowledgeable about it) but is instead a resource that everyone in the field can access and refer to when making aesthetic judgments. Although previous research has enumerated different types of authenticity, it has not specified how these are related or may shift in relation to institutional, field-level dynamics.

When Words Sweat: Identifying Signals for Loan Default in the Text of Loan Applications

EXTENDED ABSTRACT

Unprecedented loan default levels were at the heart of the financial crisis of 2008-9 (Lewis 2015). While the majority of these loans were mortgages, a significant amount was in consumer loans. As a result, it became difficult for consumers to secure a bank loan—as much as 30% of the people who wished to get a loan were not able to obtain one through conventional channels (Dogra and Gorbachev 2016). Consequently, Americans turned to other sources. In 2011, 14% of American households (over 16 million households) reported using "non-bank credit," which includes payday loans and pawn shops (Mills and Monson 2013). Arguably, a better alternative

to these "shark" loans emerged in the form of online crowdfunding platforms, which serve as a marketplace for lenders and borrowers. These platforms have become a substantial financial market, with over 1,250 sites and \$34.4 billion in raised funds in 2015 (Crowdfunding industry report, Massolution 2015).

While the idea of crowdfunding may be appealing to both borrowers, who may not be able to get a loan elsewhere, and lenders, who may be able to get better returns on their investments, default rates in crowdfunding sites are high, which puts the entire concept at risk. In comparison to more secured channels such as bank loans, default rates are especially important in crowdfunded loans because the crowdfunding process is riskier and more uncertain—lending money to strangers without any collateral. Furthermore, the online nature of crowdfunding platforms eliminates the human interactions around the financial transaction of granting a loan, which has been shown to reduce default rates. Indeed, Agarwal and Hauswald (2010) found that supplementing the loan application process with the human touch of loan officers decreases default rates significantly due to better screening on the bank's part and higher interpersonal commitment on the consumer's part.

We propose that in a similar vein to loan officers, who are able to assess default likelihood in the offline banking environment, the text that borrowers write when requesting an online crowdfunded loan may leave some traces—similar to body language detected by loan officers—that can improve predictions of future repayment behavior. Specifically, we investigate whether borrowers leave traces of their intentions, circumstances, emotional states, and personality traits in the text they write that are predictive of whether they will default on their loan up to three years after the text was written. To answer these questions we apply text-mining and machine-learning tools to a large dataset of loans from the crowdfunding platform Prosper.

We began by creating an ensemble of predictive models consisting of decision trees and regularized logit models. We find that the predictive ability of the textual information alone is of similar magnitude to that of the financial and demographic information. Moreover, supplementing the financial and demographic information with the textual information improves predictions of default by as much as 4.03%.

Next we used a multi-method approach to uncover the words and writing styles that are most predictive of default. Using a naive Bayes and an L1 regularization binary logistic model we find that loan requests written by defaulting borrowers are more likely to include words related to the borrower's family, financial and general hardship, mentions of God and the near future, as well as pleading lenders for help. We use a latent Dirichlet analysis (LDA) to identify the loan purpose, life circumstances, and writing styles that are most associated with loan default. We find that loans whose purpose is to help with a business or medical circumstances are riskier than other loan types in terms of their default likelihood. Consistent with the naive Bayes results, we find that lenders pleading for help and providing explanations are also associated with higher risk of default.

We further explore the writing styles and personality traces embedded in the loan request text using the Linguistic Inquiry and Word Count dictionary (LIWC; Tausczik and Pennebaker 2010). We find that defaulting loan requests are written in a manner consistent with the writing style of extroverts. This is not surprising as extroverts aspire to have exciting lives, more so than others, and hence spend their money on experiences and worry less about the financial consequences (Brown and Taylor 2014). We further find that defaulting loan requests are written in a manner consistent with the writing style of liars. While we are unable to claim that defaulting borrowers were intentionally deceptive when they wrote the loan request, we believe

their writing style may have reflected their doubts in their ability to repay the loan.

Our research shows that in an environment characterized by high uncertainty, verifiable and unverifiable data have similar predictive ability. While borrowers can truly write whatever they wish in the textbox of the loan application—supposedly “cheap talk” (Farrell and Rabin 1996)—their word usage reveals something about them that we could not have inferred from their financial dossier alone, namely their personality and intentions.

**Make America Tweet Again:
A Dynamic Analysis of Micro-blogging
During the 2016 U.S. Republican Primary Debates**

EXTENDED ABSTRACT

The 2016 presidential election illustrated the growing role that micro-blogging sites such as Twitter play in electoral politics. Whereas politicians once relied on stump speeches to reach potential voters, candidates can now directly speak to their audiences in real time from the convenience of their devices, whether it be to react to a comment made by another, or express a view about an emerging news event. Indeed, the pervasive influence of micro-blogging has been such that *New Yorker* writer Nathan Heller (2016) called the 2016 U.S. presidential campaign the country’s first “Twitter Election”—one where the battle for the “Twittersphere” loomed almost as large as the election itself.

Whether this new channel of communication has helped better inform the electorate in elections, however, is unclear. On one hand, the increased volume of messages from candidates allows them to reach a broader cross-section of potential voters, something that could enhance knowledge about their positions on key issues. On the other hand, the fact that these messages come in the form of 140-character sound bites implies that this broader reach could come with a loss of depth.

In this paper we attempt to explore this issue by reporting an analysis of a unique dataset that characterizes how the substantive and affective content of Tweets evolved before, during, and after the course of three critical Republican Primary debates leading to the presidential election. We focus on the primary debates because past work has shown that they have the largest influence in shaping voter opinion about the candidates—more so than the final presidential debates, when voter opinions are typically solidified (McInney and Warner 2013). We examine how Tweeting behavior—who is Tweeting, what is being Tweeted, and the sentiment that is expressed in the Tweets—changed as the debates evolved over time.

We emerge with three major sets of findings that collectively offer a disquieting view of the ability of the “Twittersphere” to serve as a substantive source of information about the debates. First, we found that as the debates proceeded the Twittersphere provided an increasingly backward-looking account of the debates, as original content describing the event were increasingly dominated in number by re-Tweets of the more popular Tweets posted earlier. In other words, as time progressed the Twittersphere increasingly resembled a replaying of the “greatest hits” from earlier in the debate.

More critically, we found that that this shift to retweeting was also accompanied by a change in the tone and content of what was being posted. While Tweets posted during the debates often mentioned substantive policy issues, after the debate Twitter looked more like a news tabloid, dominated by re-Tweets of content focusing on the more sensationalistic events that occurred during the debates. For example, early in the August 2015 debate there was an initial flurry of Tweeting about the acidic exchange between Donald Trump

and Megyn Kelly about his views toward women. This quickly died out, however, as Tweets shifted their attention to the more substantive policy topics being discussed by the candidates. But by the end of the debates there was a sudden resurgence of interest in the Trump-Kelly exchange, such that one hour after the debates that single topic dominated the Twittersphere.

The third major finding was more theoretical in nature: statistical analyses of the drivers of re-Tweeting rates suggested that the mechanism that drove the popularity of a given Tweet was more complex than that reported in prior research on the drivers of content sharing (e.g., Berger and Milkman 2012). Surprisingly, simple negative and positive emotion tended to be *negatively* associated with re-Tweeting counts. In our case Tweet popularity was positively associated with more nuanced factors such as visual appeal, criticisms expressed through humor, and words related to reward and achievement (e.g., “won,” “lost”).

We suggest that this finding may be explained by the unique motivations for sharing content during live broadcast events on Twitter relative to other media. Unlike message sharing on more restricted networks (e.g., texting, email, or even Facebook), Tweets have the potential to reach particularly broad audiences, such that Tweeters may be motivated to create and/or share posts that allow them to gain as large a share of the Twittersphere as possible during the short span of the events (e.g., Barasch and Berger 2014). If Tweeters believed that the most popular content would be that eschewing substance and embracing sensationalism, as time progressed Tweets containing the latter should come to dominate. In essence, what emerges might be a norm of sensationalism (Heath 1996), where the Twittersphere is dominated by the most extreme instances of this norm; the funniest videos, the most sensationalist moments from the debates.

While our analyses here focused on the dynamics of Tweeting during political debates, we suggest that the findings may generalize to other televised live events such as sporting matches, election coverage, and awards shows — events where there is typically a high flurry of Tweeting activity during a relatively short period of time. There, like here, we might expect to see re-Tweeting come to dominate the generation of original content as events wear on, with the most sensationalist content having the longest staying power. We conclude the paper with a discussion of both the theoretical implications of the work for research on message sharing as well as substantive implications of the findings for political processes.

SESSION OVERVIEW

The importance of relationships between consumers and brands is made manifest by the amount of attention that the topic has received from researchers and practitioners alike (Fournier 1998). We propose a session exploring dynamic consumer-brand relationships. These consumer brand journeys start with firms' strategic efforts to strengthen ties with consumers, and consumers' agency defining brand relationships in their own terms. Consumer-brand intimacy creates a sense of inclusion (we-ness) that enhances brand loyalty and brand equity. Inevitably, inclusion necessitates exclusion (otherness) that sparks controversy and consumer resistance. As consumer-brand relationships escalate, dialectical wars and oppositional discourses generate within consumers and between consumers and their brands. At the extreme, relationships become dysfunctional when consumers engage with brands in disruptive ways, or when firms abuse the trust of consumers. The studies in this session unpack the tensions between brand acculturating forces and consumer agency that may result in brand loyalty, opposition, or brand abandonment.

In the first paper, the authors propose a model to explain firms' roles in initiating and supporting consumer-brand relationships. In the second paper, researchers explore consumer's agency interpreting brand cultural objects (Schroeder 2009) and show how the strengthening of consumer-brand ties inevitably results in ingroup-outgroup dynamics and exclusion. A third paper explores disruptive consumer-brand relationships illustrating the manner in which consumers normatively excluded from high-end brands still use those brands in anti-normative ways in order to express aspirational pseudo-identities. In a fourth study, the authors investigate what happens when valued brands do bad, and consumers engage in repair processes to continue the relationship to avoid the potential loss of identity related with a breakup.

The presenters take a variety of interpretive approaches and methodologies to analyze data from four very different contexts (tailgating, Starbucks, a South African subculture, and Volkswagen community). Together, the studies shape a lively conversation on consumer-brand relationships in the form of a "brand journey" from the initial steps towards building intimacy to the dissolution of ties. These papers further our understanding on consumer-brand relationships, exploring a purposely broad the spectrum of relationships to illustrate what happens at and beyond the boundaries of

consumer-brand ties. Brand journeys have significant managerial and theoretical implications, and our session aims to generate discussion and raise questions, such as: How are brand communities and brand-engaged subcultures created and maintained, leveraging brand cultural objects and consumers' active negotiation of meaning? How do the respective roles of firms and consumers impact the nature and strength of consumer-brand relationships; what is the interplay between these relationship partners and the consequences of their interplay? How does "good" and "bad" consumer and firm behavior impact consumer-brand relationships and their boundaries?

The Game Day Experience: Consumers, Brands and Brand Celebrations

EXTENDED ABSTRACT

Brand communities are embraced by marketers and consumers alike for the keen ability of those communities to enliven the brand and keep it connected with its users. Beyond the experience of community, the present research seeks to explain how events engage communities in support of the brand. Prior studies of Trekkies and their conventions (Kozinets 2001), Harley Owner Group (HOG) members and their rallies (McAlexander et al. 2002), or distance runners (Thomas et al. 2013) theorize the import of community member interactions. In particular, those studies find roles for shared rituals and norms to sustain community engagement and interaction of members over time through various mechanisms. While much is understood about how relationships between consumers and brand contribute to brand loyalty, there is an opportunity to explore roles for the firm in contributing to and sustaining consumer-brand relations beyond brand actions themselves. One mechanism that seems to be impactful in the development and continuity of community for some brands is the orchestrated gathering of community members to celebrate the brand.

Through an ethnography of collegiate tailgating, we explore roles for firms in supporting consumer-brand relationships. More specifically, we seek to explain roles for firms in constructing and executing events for brand communities in service to developing relationships to the brand through events orchestrated on behalf of the community, and to foster relationships with other fans. Collegiate tailgating is often a university orchestrated event where the university invites alumni, donors, and fans to celebrate the brand around a football contest. While colleges are a unique form of brand, many firms aspire to create loyalty similar to that fans have for their favorite athletic teams. The zeal of fans for athletics is not lost on university officials who recognize home football games as opportunities to engage with various stakeholders in support of broader university goals and objectives. And, many universities have developed formal organizations to orchestrate such events. Consider this account:

We have an Office of Special Events and Protocol... [w]e formed an Ad Hoc committee...It was probably a 15 or 17 person committee. It had alumni on it... [University] trustees...security personnel from the NFL...It was a very diverse group, and they studied the whole game day experience at Blackthorn because, intuitively, we felt that it could be better. We were getting a lot of feedback around the tailgating and the pregame activities that wasn't really positive...This group did their work and they broke it down into three buckets – safety and security is number one; hospitality is number two; and communication is number three...[The] report had about

22 major global recommendations.... [Game Day] has become, in a short period of time I'm proud to say, an industry best practice within college [football], because we've taken a lot of elements of the pros and adapted [it] to what is Blackthorn. So we've cherry-picked the best ideas from different folks, selected the ones that made sense here, and applied it to Blackthorn, so it's a uniquely, genuine Blackthorn experience. ~ Game Day Executive

Blackthorn recognizes their varied constituents (e.g., home, visiting, and competitor fans; neighbors; Athletics; Academic departments; Development) and seeks to address the diverse needs represented among them through an orchestrated Game Day experience. Within this highly orchestrated event, participants are provided opportunities to engage with formal and informal activities which serve to enhance brand engagement.

We have identified four themes that reflect the experience of Game Day as an orchestrated brand event for communities: connectivity, ceremony, congregation, and contiguity. Connectivity reflects the consumer-consumer and consumer-brand bonds generated and sustained through the Game Day experience and manifesting most prominently through 'neighborhoods' of tailgaters. The connections participants foster through joint activities and allegiance encourages further engagement with the brand. Ceremony encompasses the shared rituals and traditions within the community that are enacted across the event. The ritual of tailgating, from the journey and preparation to the traditions carried out in the parking lot, provides opportunities to engage collectively in developing brand meaning and symbolism more so than the physical acts performed. Congregation consists of the gathering of tailgaters around a central concept or ideal. Each congregation strives to reach a common goal: to live in the unifying spirit of brand which is football. This sense of belonging and community propagates beyond neighboring tailgates and can impact the larger tailgating community. Contiguity refers to the expansion of one community to others thus forming a continuous entity. We find that as an orchestrated brand community event, Game Day is how participants invigorate membership in the brand community, and infuse meaning into the brand.

Firms aspire to attain the level of engagement and satisfaction fans have with athletic teams. Blackthorn found a means to leverage athletic contests as they engage their varied constituents in manners that increase satisfaction and ultimately contribute to brand loyalty. In particular, from the themes generated in this study of collegiate tailgating and the orchestration of the football game day experience, we develop recommendations for firms seeking to extrapolate these findings into a hosted brand community event to support the brand, community members, and brand-consumer relations all with the intent of enhancing brand loyalty, and ultimately brand equity.

Follow the Code: The Impact of Linguistic Brand Codes on Brand Journeys

EXTENDED ABSTRACT

Successful brands are active producers of cultural objects, rather than mere parasites that appropriate popular culture. Indeed, brands create symbols, myths, and even prescriptive models for the way consumers think and behave – their goals, ideals, and values. Eavesdropping on someone ordering a drink at Starbucks or talking about Star Trek will make obvious that brands also change the way consumers talk. Despite the widely-accepted centrality of language to culture (Crawford & Valsiner 1999), brand-specific linguistic codes have been largely overlooked in cultural approaches to consumer research.

Despite the lack of deliberate examination, the existence of linguistic codes shared and used within consumption communities and brand communities is widely recognized. Thomsen, Straubhaar and Bolyard (1998) use the words "jargon or group speak" to describe the insider code used within cyber-communities. Schau and Muñiz (2002) find a "community jargon" shared in brand-related personal websites. Langerak et al. (2003) use the term "specialized language" for the jargon spoken within an e-brand's virtual community. In their ethnography of the new bikers, Schouten and McAlexander (1995) define subcultures of consumption as having unique jargons, and their data illustrates several examples of "biker vernacular." One of the Trekker sub-communities described by Kozinets (2001) revolves around the constructed language Klingon. Muñiz and Schau (2005) describe a characteristic "formulaic language" within users of the discontinued Apple Newton. Whereas the presence of brand codes has been repeatedly acknowledged, their relevance to consumer researcher theory and marketing implications have yet to be explored. This study aims to fill this gap in the literature by putting the spotlight on this particular brand cultural object.

We bring together Bourdieu's cultural capital theories (e.g. Bourdieu 1986, Bourdieu & Passeron 1990), a brand culture approach (Schroeder 2009), and a consumer research reading of sociolinguistics to study the practices and discourses created by branded jargon and dialects. Starbucks is our context for studying brand codes. Brand-specific linguistic codes were studied using an netnographic (Kozinets 2002) approach complemented with in-store observation. Brand related conversations were extracted from official and fan-created websites, Twitter messages and YouTube videos. Findings were further informed by naturalistic observation in Starbucks coffeehouses.

Findings confirm the appropriateness of the "brand language" metaphor, revealing the ubiquity of its use among consumers and illustrating the many ways in which linguistic brand codes mirror natural languages. Specifically, this study sheds light on the largely unexplored topic of how "brand literacy" (Bengtsson & Firat 2006) is acquired. Careful examination of Starbucks' linguistic brand code reveals "jargon" to be an insufficient term to refer to a code with grammar-like properties in which issues of syntax (e.g. word order), pragmatics (e.g. tacitness and sub-textuality), and style (e.g. redundancy) matter. Linguistic competence in "Starbuckese" is revealed as a continuum ranging from complete lack of fluency to "native-like" competence. Two main opposing discourses co-exist around Starbucks' ordering script. A wide range of oppositional and skeptical consumers see the brand code as unnecessarily cryptic, putatively designed to pretentiously sound "vaguely European" or simply exert Starbucks cultural hegemony. A second discourse (as voiced by baristas, and endorsed by most fans) is to discount the need for the code and the barriers to learning it without denying its complexity.

Among the most brand loyal customers endorsing the latter discourse, competence in Starbucks linguistic code signals commitment to the brand (and hence, status within the fan community). These fans often police the brand discourse and community in such a way that lack of fluency is tolerated, if looked down upon, but oppositional discourse is attacked and silenced.

On the other ideological end, oppositional customers, in their own words, "make a point" of not learning or using the linguistic brand code while ridiculing those who do and sharing with like-minded users their successes in defying Starbucks cultural dominance. Interestingly, they do so while still being Starbucks customers (many of them declared frequent customers).

Amid this dialectical war, occasional and unaligned Starbucks customers must still manage to navigate the brand code. Lacking

fluency, they do so using a variety of compensatory strategies that typically result in negative feelings or suboptimal outcomes.

Fans use brand codes as a field-specific cultural capital and a source of identity, belonging, and group status. In the case of a highly accessible brand like Starbucks, cultural capital is more tied to how to consume and less to what is consumed (Holt 1998). Whereas less-than-expert customers are needed if code competence is to be a signal of high status, deniers of the value of “speaking the brand” are a menace to status-seeking fans who have learned the code. Lack of fluency is described by consumers as a source of rejection and anxiety. Consistent with previous theory (Bourdieu and Passeron 1990, Lamont and Lareau’s 1988), cultural and social exclusion prove to be a central component of the status game. On the other hand, and deviating from previous literature on consumer resistance, we find oppositional consumers who are “anti-Starbuckese” rather than anti-Starbucks. Consumers can be polarized not only for and against a brand (as in Thompson & Arsel 2004, Kozinets & Handelman 2004) but for and against a brand’s cultural objects while still consuming the brand. Etic interpretation of this form of consumer cultural resistance is that consumers are inverting the sign of marketer-imposed codes (Ozanne & Murray 1995) while still using them for status-seeking purposes. As Holt (2002) points out, opposition does not liberate from the market, but instead drives consumers to build their resistance identity through the market. We extend Holt’s findings by adding that even opposition to a brand’s cultural objects does not emancipate from the brand: knowing and denying brand cultural objects can be two fields within the same context; two strategies in the same status-seeking game of cultural capital.

Disruptive Self-Brand Play: The Izikhothane Journey

EXTENDED ABSTRACT

Consumer-brand relationships take on myriad forms. A preponderance of this research has focused on the more positive associations between consumers and their brands as relationship partners (Fournier 1998), as extensions of self (Escalas and Bettman 2003), and as identity signals (Levy 1959; Schau and Gilly 2003), yet others have pointed to more adverse aspirational, materialistic, and compulsive consumption practices (Belk 1988; Rindfleisch, Burroughs, and Denton 1997). In this research, we introduce *self-brand play*, defined as incorporating brands into the self to create an alternative play reality, with no rules or responsibilities. The self is tied to the brand, and the brand determines the value of the self. Self-brand play is viewed as an escape with purpose of enhancing the self. When one plays, the rules and norms of society do not apply, actively allowing for play accompanied by moral disengagement. Bandura (1999) propounds that different types of moral disengagement strategies are employed to make detrimental conduct acceptable through self-regulatory systems. Indeed, moral disengagement has previously been used to explain the perpetration of inhumanities, both actual (Leidner, Castano, Zaiser and Giner-Sorolla 2010; Osofsky, Bandura and Zimbardo 2005) and in virtual video games (Hartmann and Vorderer 2009).

Disruptive self-brand play operates at the intersection of brand signaling, aspirational consumption, and moral disengagement. We argue that when moral disengagement ensues, consumer-brand relationships can escalate beyond what is deemed appropriate and acceptable by standard social norms, and result in detrimental consequences to the brand, oneself, and others. The context for our research is the Izikhothane subculture within South African townships. Izikhothane is the term coined for the behavior of poor South African township males who as collectives (or “crews”) engage in aspiration-

al consumption of high-end brands and participate in dissing practices (or “battles”) to destroy these expensive brands, as evidence of their ability to afford them (Howell and Vincent 2014; Mnisi 2015; Nkosi 2011).

We explore *disruptive self-brand play* as part of Izikhothane subculture practices using an interpretive approach. We first conducted a focus group with five Izikhothane members to obtain a general understanding of the subculture, individual roles within the crew, rituals and practices with regard to expensive brand consumption, shared norms (e.g., having gold plated teeth sharing shape symbols), and the preparations and practices related to battles. These discussions provided the groundwork for the depth interview protocol in which we examine the journey of members of the Izikhothane subculture, specifically the enticement and motivations for self-brand play, moral disengagement for aspirational consumption and experiences in disruptive self-brand play, as well as moral reengagement as part of the Izikhothane journey. We purposively sampled from four Izikhothane crews, recruiting 29 members. All informants were at least 18 years of age when interviewed, having participated in the Izikhothane subculture for two to ten years. Four interviewers from a South African research firm conducted the interviews in Soweto, South Africa at specific locations identified by participants. The interviews were recorded and transcribed for analysis.

Our findings document that the Izikhothane subculture is grounded in the informants’ life circumstances, marked by broken middle class homes in South African townships, where these young men are looking for ways to express their identity, and vie for fame and attention. They are attracted to this subculture because of their love of brands, high fashion associations, dancing, and observed “famous” lifestyle. Expensive brands, cash, taxis, and music are the key props for the battles between the crews. The subculture is bound by, “Live life as if you have money, even though you don’t,” with the intent of creating a pseudo-identity.

As informants report becoming more committed to the Izikhothane subculture, we observe moral disengagement. The township youth, with few financial resources of their own, lie to get cash from their family members, save their lunch money, hustle jobs, and sometimes sell drugs or stolen cell phones to buy these expensive shoes, clothes and food products needed for the battles. Crews organize the battles, which are typically one-on-one “competitions” in which food and alcohol are thrown at one another with the express intent to destroy the expensive brands; sometimes there is tearing of expensive clothes and burning of cash. Informants, across all crews, reframe their conduct to downplay the consequences from the behavior, and devalue or dehumanize victims of harm. Moral disengagement occurs throughout and is not only related to high-end brands, but also with regard to girls who serve as groupies and “snacks.”

As informants reflect on their Izikhothane membership over the years, many acknowledge their moral disengagement as having significant collateral damage, and report that they are in the process of leaving the Izikhothane. They link the disruptive self-brand play to distraction from schooling and the need to repeat grades or even drop out, with disrespect of parents and teachers, and with the denigration of others which often leads to jealousy. Some suggest their Izikhothane “successes” and “fame” make them safer, whereas others have concern for their own safety, perceiving their visible display of high-end brands makes them targets of crime and violence. As informants contemplate their futures, they recognize their failures (not going to school or working to their potential) and their wastefulness of money (that could be used for my family or others who have financial needs), as well as the bad influence they have on their siblings and young township children. Their reflections acknowledge

a moral reengagement, and a call to question the value of this disruptive self-brand play. As they morally reengage, this play stops. Many report transitioning from the Izikhothane lifestyle by rather focusing on the practicality of life with attention to life goals of completing their education and finding jobs.

Our research contributes to the work on consumer-brand relationships and consumer journeys, providing unique insights into how disruptive self-brand play is at the center of creating an aspirational pseudo-identity. Moral disengagement serves the Izikhothane well through their self-concept enhancement in a resource-constrained environment, yet acknowledgement that this pseudo-identity has deleterious effects over time reengages a moral compass to pursue a new life-path and identity.

Where Do We Go From Here? Consumer-Brand Relationships After Brands do Bad

EXTENDED ABSTRACT

“On September 3, 2015, Volkswagen AG disclosed at a meeting with the California Air Resources Board and the U.S. Environmental Protection Agency that emissions software in four-cylinder diesel vehicles from model years 2009 until 2015 contained a ‘defeat device’ in the form of hidden software that could recognize whether a vehicle was being operated in a test laboratory or on the road. The software made those vehicles emit higher levels of nitrogen oxides when the vehicles were driven in actual road use rather than laboratory testing.” (Michael Horn’s testimony, as President and CEO of Volkswagen Group of America, before the U.S. House Energy and Commerce Committee, 10/08/15)

Brands do bad. Volkswagen’s “Dieselgate” scandal is but one example of the deliberate misdeeds brands sometimes engage in that we might expect to provoke outrage among consumers and culminate in relationship dissolutions (Bechwati and Morrin 2003; Hemetsberger, Kittinger-Rosanelli, and Friedmann 2009). Even heartfelt love may become hate, as devoted consumers feel betrayed and seek revenge through anti-brand activity (Grégoire and Fisher 2008; Grégoire, Tripp, and Legoux 2009; Johnson, Matear, and Thomson 2011).

Although transgressions are often thought to lead to weakening or termination of consumer-brand relationships, previous research has shown that other trajectories are possible, and some consumers do retain relationships after revelations of malfeasance (Aaker, Fournier, and Brasel 2004; Lin and Sung 2014; Sung and Choi 2010). The present paper thus investigates the repair processes consumers undertake to continue in relationships with wrongdoers.

Prior research has focused on factors that motivate consumers to maintain such relationships, while overlooking consumers’ active relationship repair work. For example, Aaker et al. (2004) emphasize how brand personality matters to relationship progress after good brands do bad, finding that violations prompt the reinvigoration of relationships with exciting brands (i.e., those associated with energy and youthfulness) through gains in knowledge about the partner and the relationship (per intimacy and partner quality development), reactivation of self-connections, and intensification of interdependency levels. The consumer-brand relationship literature also posits that there may exist different kinds of relationship dynamics that prevent consumers from turning away from transgressors, including love, mixed-valence (e.g., love-hate engagements), and negative relationship types (e.g., master-slave, dealer-addict, and villain-victim) (Alvarez and Fournier 2016; Batra, Ahuvia, and Bagozzi 2012; Fournier 1998; Fournier and Alvarez 2013). Sung and Choi (2010) reinforce that consumers might not easily discontinue the relationship with

a brand if they perceive they have made a great investment which could not be recovered if the relationship dissolved. Lin and Sung (2014) argue that brand identity fusion (i.e., consumers’ feelings of oneness with a brand) trigger relationship-sustaining behaviors because individuals interpret brand misbehaviors as threats to their identities, increasing their tendencies to engage in biased information processing and motivated reasoning that confirms their positive beliefs about the brand.

Arsel and Stewart’s (2015) research constitutes one notable effort to uncover the coping strategies consumers use to continue relationships in the face of negative information about the brand. They find that consumers may deny brand failures, claim moral superiority as they develop oppositional narratives, and keep product use secret from others. However, the authors investigate consumers’ response to identity-degrading meanings arising from doppelgänger images rather than ethical missteps. These two situations may pose different challenges to consumers.

Our qualitative research has analyzed online consumer posts about “Dieselgate” in the comments sections of major US news outlets, automotive magazines, and blogs. Data collection and analysis started at the outbreak of Volkswagen’s emissions scandal in September of 2015, and continued for the following seventeen months. Results show that consumers engage in three main repair processes to maintain relationships despite awareness of brand misdeeds: contextualizing, recalibrating, and refocusing.

“Contextualizing” refers to mobilizing the institutional context of the automobile industry (and its long history of scandals) to downplay negative interpretations of “Dieselgate” by contrasting Volkswagen’s misdeeds with other automakers’ misbehaviors “just like” or “worse than” theirs. In the process of “recalibrating,” consumers reframe the magnitude of the sins, for example, by positioning the use of defeat devices as acceptable when regulations are considered excessive or unwarranted. They may also weigh Volkswagen’s wrongdoings against unethical behaviors pervasive in everyday life (e.g., gaming school tests), and compare the pollution caused by vehicles with defeat devices to that caused by “legal” technologies (e.g., older car models, factories). Finally, in “refocusing,” consumers minimize the importance of certain product features (e.g., environmental benefits) while playing up other attributes (e.g., economic benefits) as the critical ones for everyday usage. Implications for both the consumer-brand relationship and the branding literatures are discussed.

SESSION OVERVIEW

Much of consumer research assumes that the primary motivator in consumer choice is the pursuit of happiness. Yet, much of the consumer experience does not focus on maximizing for happiness alone. Parents opt to spend their time and money on their children, although child rearing generally decreases happiness (e.g. McGregor and Little, 1998), and individuals consistently try to find ways to improve their self-control despite its negative impacts on their happiness (Baumeister, 2002). Another important driver of choice and decision-making is the pursuit of meaning. Previous research provides insight into what actions and decisions are considered meaningful and how meaning differs from happiness (Baumeister, Vohs, Aaker and Garbinsky, 2013; Choi, Catapano and Choi 2016). However, several important questions have received less attention: How do consumers make trade-offs between pursuing happiness and meaning? How can consumers maximize for happiness and meaning beyond the present moment?

Our session sheds light on these questions. Paper 1 (Carter and Williams) explores how consumers make trade-offs between happiness and meaning. Compared to more pleasure focused consumption, consumers expect the benefits of meaningful consumption to pay off over a longer period of time, require a larger time investment, and require greater knowledge to prove beneficial. These results have important implications for understanding when consumers choose to engage in meaningful versus happy consumption.

The next two papers examine how consumers can maximize their long-term happiness. Paper 2 (Whillans, Dunn, and Norton) demonstrates that individuals who spend money on time-saving services report greater life satisfaction. Providing causal evidence, working adults reported greater happiness after spending money on time-saving purchases as compared to material purchases. Paper 3 (Catapano, Hardisty, and Aaker) explores how meaning can promote long-lasting happiness from experiences. In a series of field and lab studies, more meaningful memories show less happiness decay, therefore making individuals happier for longer. In addition, this prolonging of happiness improves consumer brand attitudes and purchase intentions in response to meaningful advertising.

Finally, Paper 4 (West, Mogilner, and DeVoe) explores how individuals can increase their meaning experienced at work through a

happy experience, taking a vacation. They find that taking vacation has a significant positive effect on meaning at work, which holds controlling for the effect of vacationing on meaning in life overall. This result suggests that sometimes, taking time away from a common activity may actually increase the meaning derived from future engagement with the activity.

Together, the four papers in this session enhance our understanding of how consumers can experience more happiness and meaning, and the downstream consequences of these experiences. They incorporate a variety of perspectives on an area of consumer behavior that has only just begun to be explored. We believe this session will attract a broad audience, and facilitate interesting discussions and collaborations that can generate valuable insights for researchers, marketers, and policy makers who aim to help consumers get off the hedonic treadmill. Ultimately, by considering how choices provide happiness as well as meaning, we may develop a stronger vision of the significance of consumer research.

Meaningful Consumption Provides Long-Lasting Benefits at a High Cost

EXTENDED ABSTRACT

Consumer well-being is of increasing interest to consumer researchers. While the study of consumer well-being largely draws from a hedonic approach to the topic (Kahneman, Diener, and Schwarz 1999), a growing body of evidence finds that meaning is an important and distinct aspect of well-being (Baumeister et al. 2013; Deci and Ryan 2008; Waterman 1993). Following others, we define *meaning-oriented consumption* as consumption motivated by a desire for self-growth, social connectedness, and the pursuit of personal fulfillment in life requiring a more cognitive evaluation (eudaimonia; Baumeister et al. 2013; Deci and Ryan 2008), whereas *pleasure-oriented consumption* is motivated by a desire to maximize positive affect and minimize negative affect requiring more affective evaluations (hedonia; Bentham 1789/1948, Kahneman 2000).

We propose and demonstrate that consumers expect (1) the benefits of meaningful consumption to persist after the experience has ended, (2) the minimum time investment (MTI) necessary to benefit from a consumption experience is greater for meaningful consumption compared to pleasure-focused consumption, and (3) knowledge to benefit meaningful but not necessarily pleasurable consumption.

Lasting Benefits

In studies 1A and 1B, we ask participants to reflect on books, movies, or trips that they have not consumed but would like to and that they expect to be either particularly meaningful or particularly pleasurable. We then measure the extent to which participants believe consuming the product will be beneficial at four time points. We expect the benefits of meaningful consumption to persist to a greater degree at later time points.

Two studies confirmed our hypothesis. In study 1A (n=300), we manipulated condition and time point within subjects and order of the presentation and product category between subjects. A mixed effects analysis (Judd, Westfall, and Kenny 2012), revealed significant effects of condition ($F(1, 3.04) = 24.18, p = .02$) and time ($F(3, 2084.18) = 57.35, p < .001$) qualified by a significant condition x time point interaction ($F(3, 2084.18) = 15.59, p < .001$). In study 1B (n=148), we manipulated product category and time point within

subject and condition between subjects. We again found that participants believed that the benefits of meaningful experiences would last longer than the benefits of pleasurable experiences ($F(3, 1618) = 4.84, p = .002$).

In study 2 ($n=404$), we tested this hypothesis with actual consumption experiences. We asked participants to reflect on the meaningful versus pleasurable (per condition) benefits they experience while using streaming entertainment services (HBO, Netflix, Spotify, Sirius XM) and to indicate how successful the service was at providing meaning or pleasure (per condition). A mixed effects analysis revealed a two-way interaction between condition and the extent to which the service was deemed successful ($F(1, 331.82) = 12.9, p < .001$) in predicting enduring benefits, with successfully meaningful services perceived to provide longer lasting benefits. We also find that reflecting on how a service was meaningful made participants more likely to indicate that they would continue to subscribe in the future ($F(1, 374.04) = 3.03, p = .08$).

Minimum Time Investments

Analogous to studies 1a and 1b, here we examined consumers' expectations about the minimum time investment (MTI) for pursuing meaningful versus pleasurable consumption experiences. We again asked participants to consider self-generated stimuli drawn from three different product categories (movies, books, and trips). We instructed participants to think about consuming the product they had just identified and to indicate the minimum amount of time someone could spend consuming the product and still benefit from the consumption.

Both studies were mixed designs. In study 3A ($n=148$), we manipulated condition within subjects and product category between subjects. Using a mixed effects analysis, we found that overall, participants believed that the MTI necessary to benefit from meaningful experiences was greater than the MTI necessary to benefit from pleasurable experiences ($t(144) = -2.866, p = .005$). In study 3B ($n=147$), we manipulated product category within subject and condition between subjects and again found participants believe that the MTI necessary for meaningful experiences is greater than the MTI necessary for pleasurable experiences ($t(144.02) = -2.041, p = .04$).

In our next set of studies, we explore an implication of meaning-oriented consumption being associated with longer MTIs. Because the MTI necessary for meaning is greater than the MTI necessary for pleasure, it is reasonable to expect that longer experiences will lead to more satisfaction when those experiences are associated with meaning. However, this effect should *only* apply to the window of time starting at and immediately following the MTI for meaning; before or beyond that window, we expect that there will be no difference in expected satisfaction. Stated differently, we do not expect that more time is necessarily always better for meaning as compared to pleasure; we expect that having *enough* time is more important for meaning than for pleasure and that what qualifies as enough time is greater for meaning than for pleasure.

In the domains of sexual (4A, $n=588$), musical (4B, $n=680$), and dining experiences (4C, $n=508$), we find that people expect meaningful experiences to be more satisfying than pleasurable experiences when they expect them to be longer, but only within an appropriate time investment window. Importantly, both before and beyond this window the difference in satisfaction associated with meaningful versus pleasurable experiences is attenuated.

Cognitive Effects

Finally, in study 5 ($n=184$), we examine the role of knowledge and expertise in facilitating meaningful but not pleasurable con-

sumption. In this study, we asked participants to watch a short film and to either find pleasure or meaning in the film. We also manipulated whether or not participants received supplementary information explaining the symbolism and message of the film prior to watching and measured baseline expertise with short films. We expected that among participants pursuing meaning, novice participants would benefit from the additional information, expert participants would have worsened experiences as a result of receiving the additional information, and that there would be no effects of expertise or additional information among participants pursuing pleasure. A significant three-way interaction of the condition, manipulated knowledge, and measured expertise supported this hypothesis.

Buying Time Promotes Happiness

EXTENDED ABSTRACT

In a 2010 survey, respondents were asked if they often had time to spare. As Brigid Schulte explains in her book *Overwhelmed*, “exactly zero percent of mothers with children under six said yes.” Fathers and working adults without children express similar concerns about the time famine of modern life. One survey found that over 80% of adults—with and without children—reported wishing they had more time to spend with their families (Duxbury and Higgins 2001). Indeed, trying to keep up with the tasks of daily life can chip away at the time we might otherwise spend engaging in the kinds of activities that endow life with meaning.

Rising incomes could provide people with one way out of the “time famine” of modern life (Perlow 1999). Wealth offers the opportunity to have more free time, such as by paying to live closer to work or paying someone to run errands. Yet, some evidence suggests that wealthier people spend more time engaging in stressful activities, such as commuting (Kahneman et al. 2006). Because time and money are largely interchangeable in the modern economy, it is possible for people to spend money to buy free time. Exchanging discretionary income to buy free time should reduce the negative effects of the modern time famine, promoting well-being.

As an initial test of this hypothesis, we surveyed Mturk workers in the US ($N=366$), a representative sample of employed Americans in the US ($N=1,265$), adults in Denmark ($N=565$) and Canada ($N=325$), a nationally representative sample of individuals in the Netherlands ($N=1,231$), and a sample of Dutch millionaires ($N=818$). In all studies, respondents completed two questions about whether, and how much, money they spent each month to increase their free time by paying someone else to complete unenjoyable daily tasks. In addition, participants were asked to rate their satisfaction with life and to report their annual household income, the number of hours they work each week, age, marital status, and the number of children living at home.

Across samples ($N=4,570$), 28% of respondents spent money to buy time each month ($M_{amount} = \$185.08$ USD). Participants who spent money in this way reported greater life satisfaction, $d=0.24, p<.001$, 95% CI [0.17, 0.31]. This effect held controlling for our key set of covariates ($N=3,988$), $d=0.19, p<.001$, 95% CI [0.11, 0.26].

Across samples, there was also a significant interaction between time-saving purchases and time stress, $Z=3.87, p<.001$. Decomposing this interaction, time stress was associated with lower life satisfaction among people who did not spend money on time-saving purchases ($N=1,504$), $B=-0.18, Z=9.12, p<.001$, 95% CI [-0.22, -0.14]. In contrast, for people who spent money on time-saving purchases ($N=804$), the negative effect of time pressure on life satisfaction was relatively weak, $B=-0.04, Z=1.69, p=.091$, 95% CI [-0.08, 0.01].

By presenting all participants with the same spending questions, we could detect comparable results across diverse samples. A limitation of this approach is that our findings might depend on the specific question wording used. To overcome this limitation, we presented a new sample of working adults in the US ($N=1,802$) with a broader definition of time-saving purchases. Faced with our broader definition, 50% of participants reported spending money in this way each month ($M_{\text{amount}}=\$60\text{-}\79 USD). Again, participants who spent money on time-saving purchases reported greater life satisfaction, $\beta=0.24$, $p<.001$. These results were unchanged controlling for our pre-determined set of covariates, $\beta=0.22$, $p<.001$. These results also held after controlling for how much money participants spent on non-durable expenses (groceries), material goods, and experiential purchases, $\beta=0.15$, $p<.001$. There was a significant interaction between time-saving purchases and time stress, $\beta=0.24$, $p<.001$. Decomposing this interaction, time stress was associated with lower life satisfaction among people who did not spend money on time-saving purchases ($N=901$), $B=-0.17$, $p<.001$, 95% CI [-0.25, -0.10]. For people who spent money on time-saving purchases ($N=901$), the negative effect of time pressure on life satisfaction was non-significant, $B=0.05$, $p=.227$, 95% CI [-0.03, 0.12].

Across seven studies with over 6,000 participants, spending money on time-saving services was linked to greater life satisfaction. From our theoretical perspective, this broad link stems from the cumulative day-to-day mood benefits that are caused by the reduction in time stress that these purchases provide. To zoom in on this causal pathway, we conducted a two-week within-subjects experiment. In this experiment, we recruited working adults to spend two payments of \$40 on two consecutive weekends ($N=60$). On one weekend, participants were randomly assigned to spend \$40 on a purchase that would save them time. On the other weekend, we assigned participants to spend \$40 on a material purchase. We chose this as a comparison because material purchases would be unlikely to save time. Our manipulation checks confirmed this assumption. We counterbalanced the order of the spending weeks: results did not differ by order. After making each purchase, participants received a phone call at 5:00pm and were asked to report on their positive affect, negative affect, and time stress. We hypothesized that people would report greater well-being after making a time-saving (vs. material purchase). We further predicted that these benefits would be explained by reduced feelings of time-stress that day.

Consistent with our hypothesis, participants reported greater end-of-day positive affect after making a time-saving purchase ($M=4.00$, $SD=0.64$) than after making a material purchase ($M=3.71$, $SD=0.81$), $t(59)=2.57$, $p=.007$, 95% CI [0.10, 0.48], $d=0.33$. After making a time-saving (vs. material) purchase, participants also reported lower levels of negative affect, $t(59)=-2.45$, $p=.009$, 95% CI [-0.45, -0.08], $d=0.32$, greater affect balance, $t(59)=2.63$, $p=.006$, 95% CI [0.21, 0.92], $d=0.35$, and lower feelings of time stress, $t(59)=-2.76$, $p=.004$, 95% CI [-1.18, -0.29], $d=0.35$. These results could not be explained by differences between the purchases in social status, exceptionalness, or perceived usefulness. Across all indicators, time-saving vs. material purchases increased well-being by reducing end-of-day feelings of time stress.

Overall, buying time reduces feelings of time pressure on a given day and provides cumulative benefits by buffering against the deleterious effects of time pressure on life satisfaction—potentially enabling people to spend more time engaging in meaningful pursuits.

Moments that Last: Meaningfulness Slows Happiness Decay

EXTENDED ABSTRACT

Although consumers frequently make decisions with the goal of maximizing their own happiness (Chang and Pham 2003; Mogilner, Aaker and Kamvar 2012; Mogilner, Aaker and Kamvar, 2011), little is known about the experience of happiness over time. What we do know indicates that generally, happiness is fleeting and difficult to hold on to. How, then, can this decay of happiness from a prior event be slowed? We propose that one way to prolong happiness is through meaning. While these actions and activities are often less pleasurable than other alternatives, often involving some form of cost or pain, they give people a sense of purpose and allow them to connect to something larger than the present moment (Bronk 2014), two elements that may be key to stepping off of the hedonic treadmill.

In Study 1 ($n=85$), participants were asked to capture five moments throughout a single day of their life, using their iPhone, iPad, or iPod touch. After capturing a moment, they rated how happy and meaningful the moment was, and wrote a short description. A single-item self-report was chosen as preferred measure of happiness, based on previous work suggesting that even single item self-reports tend to correlate well with both longer scales and other non-self-report measures (Sandvik, Diener, and Seidlitz 1993). One day and one week later, participants completed follow-up surveys, where they looked at the pictures they had taken, and rated how happy they were currently, looking back on the moment.

We find that in general, happy moments decayed linearly with time, $b = -0.41$, $p < 0.001$. However, more meaningful moments tended to decay more slowly, such that greater meaningfulness predicted a smaller decrease in happiness after one week, $b = -.18$, $p = .003$, and even after a single day, $b = .14$, $p = .03$.

Study 2 ($n=94$) explored this phenomenon in a more controlled lab setting. Participants were presented with a cupcake and instructed to eat as much or as little as they wanted. Then participants rated happiness and meaning (on 10-point scales). One week later, participants completed a follow-up survey, where they were asked to think back on the cupcake and indicate how happy they were looking back on the moment. As in Study 1, greater meaningfulness predicted less decay, $b = -.28$, $p = .02$. In other words, when the cupcake moment was experienced as more meaningful, the happiness from that moment was more lasting.

Next, we sought to expand happiness decay to a common consumer setting, advertising. To investigate the effect of slowed happiness decay on consumer preferences, in Study 3 ($n=400$), participants watched an excerpt from a video advertisement for a GoPro handheld video camera. They then completed surveys measuring the happiness and meaning they experienced during the commercial. One week later, participants completed a follow-up survey regarding their attitudes toward GoPro and the commercial including purchase intent, willingness to pay, and product interest, as well as current happiness and meaning upon reflecting on the commercial.

Consistent with previous studies, when the advertisement was initially rated as more meaningful, happiness decayed more slowly, $b = -0.15$, $p = 0.03$. Subsequently, those with less happiness decay responded more favorably on all consumer behavior measures used, $ps < .001$. Further, a mediation analysis (with recommended bootstrapping procedures) of the relationship between meaning and consumer attitudes revealed a mediating role of happiness decay, indirect effect = 0.06, 95% CI [0.01, 0.12]. In other words, more meaningful experiences show less happiness decay, relative to their less meaningful counterparts. In turn, this happiness decay influences consumer at-

titudes, such that those who experienced less happiness decay expressed greater purchase intent.

The studies so far show that for everyday life experiences, food, and video commercials, more meaningful experiences are less prone to happiness decay. However, in the preceding studies, meaning is never directly manipulated, but rather varies as a function of the experience captured (Study 1) or individual differences in meaning experienced (Studies 2 and 3). In Study 4 ($n = 141$), we directly manipulated the meaning experienced from the same action. Participants were recruited for an in-lab experiment where they spent 10 minutes on Facebook. In the manipulated condition, participants were asked to spend their time doing things that are happy, with a focus on activities that are meaningful by connecting them with others. In the control condition, participants were instructed to spend their time doing things that are happy, but not particularly meaningful. Immediately after their time on Facebook, and one week later, participants rated happiness and meaning as before.

To test the effect of the manipulation on happiness decay, we ran a mediation analysis, testing the hypothesis that focusing on meaning through connections increases experienced meaning, which in turn decreases happiness decay. The analysis revealed a significant indirect effect for the meaning focus condition on happiness decay, indirect effect = -0.36 ; 95% CI $[-0.67; -0.13]$. In addition, participants did not engage in different activities based on condition, and happiness did not differ by condition, $ps > 0.10$, suggesting that the focus on meaning was the primary distinction driving this effect.

Overall, then, happiness decays over time, such that the happiness experienced when reflecting on an experience a week later is significantly lower than the happiness during the experience itself. However, one way to mitigate this decline in happiness is through more meaningful experiences. Meaningful experiences slow happiness decay, thereby improving consumer attitudes.

Taking Vacation Increases Meaning at Work

EXTENDED ABSTRACT

Americans are not taking their allotted paid vacation days. Up to 42% of employees with paid time off do not use their full entitlement, foregoing an average of \$2,226 in unused benefits per year (Oxford Economics, 2014). What are the implications for the American worker? To answer this question, this research investigates the psychological consequences of taking vacation. Specifically, vacation may be important in fostering engagement and a sense of meaning at work.

When companies seek to cultivate a workplace that is engaging, they tend to focus on features and practices of the work itself. For instance, employers might make efforts to adjust the structure of their employees' tasks, workflow, or communication channels in order to make the work more engaging and fulfilling. Many employers are also beginning to offer a wider array of 'perks' as part of employee wellness programs, including onsite daycares, workout spaces, and cafeterias. These practices are seen as especially important in attracting and retaining 'millennial' employees in high-skill jobs. The aim is to improve the quality of experiences at work, often with the explicit goal of making grueling work schedules more pleasant and meaningful. Most employers – even those that are highly motivated to promote a more purpose-driven workplace – tend to neglect the influence of employees' time *away* from work. We examine the possibility that vacation may help employees find a greater sense of meaning in their work. Breaks from the workplace may present an opportunity for people to step back and evaluate the broader purpose

of their work and how it fits into their life. Two studies explore how taking vacation relates to meaning at work.

Study 1 uses the 2008 National Study of the Changing Workforce (NSCW), a representative sample of the US labor force, to explore associations between utilization of paid leave and various measures of work engagement and fulfillment. Using a sample of 3,502 working adults, the 2008 NSCW captures a wide range of information on practices in the workplace, attitudes about work, and issues related to work-life balance. For our analysis, only fully-employed workers who receive paid vacation were included, leaving a sample of $n=1,898$. Survey respondents provided information on the number of paid vacation days to which they were entitled in the previous calendar year and how many of these days they actually used, so a vacation utilization rate could be determined.

The results show that people who used a larger percentage of their allotted paid vacation reported a greater sense of meaning at work ($r = 0.071$, $p < 0.01$). This association held even after controlling for respondents' overall life satisfaction ($\beta = 0.087$, $p < 0.001$).

Study 2 replicated and extended the findings from this nationally representative sample through a study design using natural variation in vacation utilization. A sample of 689 fully-employed adults in the United States were recruited via Amazon's Mechanical Turk. The study was conducted on Friday January 20, 2017, four days after Martin Luther King Day (MLK), a federal holiday. Since employers in the United States are not obligated to provide federal holidays as paid vacation, a significant portion of the fully-employed workforce continued to work on MLK day. Amongst the 689 working adults sampled for this study, 352 (51.1%) took MLK day off. This even split was found for people working in the majority of industries represented in the sample. The exceptions were government workers, nearly all of whom took MLK as a vacation, and workers in agriculture, manufacturing, and retail industries, in which roughly 35% took MLK day as a vacation.

Consistent with the results of Study 1, the results of a one-way ANOVA show that taking off MLK day as a vacation was associated with a higher sense of meaning at work, $F(1, 688) = 10.56$, $p = 0.001$. The relationship between taking this vacation day and meaning at work again held controlling for overall life satisfaction ($\beta = 0.087$, $p < 0.014$). This finding suggests that even a one-day vacation can lead people to find more meaning in their work. The effect is unlikely to be a result of simply feeling rested and rejuvenated following a vacation since meaning was measured four working days after the long weekend, and earlier studies have shown that temporary rejuvenation effects from vacation tend to wear off after approximately three days (Bloom et al., 2009).

The results of these two studies should be interpreted with caution as they are correlational, but they indicate what may be an important relationship between time *away* from work and finding meaning *at* work. We will soon be conducting studies to establish causation and assess the underlying mechanism for the effect. The implications of the current results are meaningful: employers who are expending great effort and resources to cultivate a purpose-driven workplace may be neglecting the importance of employees' experiences outside of work. These experiences are not only important for employees' overall well-being; they may also be a critical part of developing meaning at work.

SESSION OVERVIEW

Because consumers want to be perceived well by others, they are motivated to signal status or generosity to others. However, such conspicuous actions may also convey information about consumers' self-serving motives (Berman et al. 2015, Newman and Cain 2014).

When do consumers' conspicuous actions lead to inferences that their motives are self-serving? And how do consumers strike a balance between their desire to do good deeds and to effectively communicate them to others? This special session explores how consumers manage these interactions between self-interested motives and prosocial behaviors in both directions. In particular, these papers examine how self-serving signals can affect one's own (paper 1) and others' (paper 2) prosocial responses, as well as how anticipating others' interpretation of self-serving signals can affect one's intention to engage in prosocial behaviors (papers 3 & 4). Each paper examines interpretations of conspicuous actions in a different social context, and identifies the corresponding social and prosocial consequences.

The first two papers examine how inferences about self-serving motives from conspicuous actions can affect prosocial responses. That is, status signaling can impact both how consumers feel about themselves and how others treat them. **Chen, John, Wang and Carufel** find that for owners of authentic status goods, using counterfeit goods poses a threat to their self-image and hence increases their willingness to engage in compensatory prosocial behaviors. In other words, consumers may attempt to signal generosity to atone for the inauthenticity of their status signals. Similarly, **Srna, Barasch and Small** show that consumers' use of status goods affects others' inferences of their prosociality. Those engaged in conspicuous consumption are perceived as less cooperative and generous and are thus avoided in situations where cooperation is desired.

The second two papers further investigate these strategic choices, showing how consumers anticipate negative consequences of conspicuous signals and adjust their behavior accordingly. Interestingly, these adjustments can actually result in more prosocial outcomes, with implications for charities and companies hoping to encourage these outcomes. **Yang and Hsee** examine anticipated social inferences of self-serving motives from conspicuous prosocial behaviors. They find that making the public display of a prosocial

behavior mandatory instead of voluntary can assuage consumers' concerns about negative social inferences and motivate them to engage in conspicuous prosocial behaviors they might otherwise avoid. **Gershon, Cryder and John** investigate the anticipated social inferences of self-serving motives in the context of referral programs. They demonstrate that consumers are more likely to refer friends when incentives are purely prosocial, rather than partially or purely self-serving, to avoid conveying the impression that they have self-interested motives.

These findings deepen our understanding of conspicuous actions and their interpretation in a dynamic social context. Together, these papers show how people's sensitivity to the inferences others make about their conspicuous behaviors can motivate them to engage in less status-signaling and more prosocial actions. All four working papers have at least three studies completed. We expect this session to attract researchers interested in a wide variety of topics, including conspicuous consumption, status, prosocial behavior, authenticity, and incentives.

Prosocial Consequences of Counterfeits: Using Counterfeit Luxury Goods Can Lead to Prosocial Behavior

EXTENDED ABSTRACT

Counterfeit luxury products remain popular with consumers, who desire the status-signaling benefit associated with luxury goods at a fraction of the cost of authentic ones. However, there are psychological costs associated with using counterfeit goods. As demonstrated by Gino, Norton, and Ariely (2010), participants felt less authentic and behaved more unethically after using a counterfeit luxury product. For example, counterfeit users were more likely to cheat for a monetary award in a subsequent task.

In contrast, we show that using counterfeit luxury products can have positive consequences, specifically increasing prosocial behavior. In four studies, we give women a counterfeit luxury product to use, followed by an opportunity to engage in prosocial behavior. We find that counterfeit users are more likely to volunteer and donate money to charity (study 1 & 2). Further, we find that this effect is moderated by whether counterfeit users are owners of authentic luxury products. Counterfeit use increases charitable donations primarily among luxury owners versus non-owners (study 3), and these higher donation levels are diminished for luxury owners *if* they are given an opportunity to self-affirm their values in other ways (study 4).

We theorize that using a counterfeit product can constitute a threat to the moral identity of users, and when given an opportunity to compensate for this moral transgression, counterfeit users will engage in more prosocial behavior. This prediction is consistent with prior work on moral cleansing (Jordan et al. 2011; Sachdeva et al. 2009; Tetlock et al. 2000). However, we posit that moral cleansing in the counterfeit luxury context emerges primarily for counterfeit users who own authentic luxury goods and consider luxury goods to be part of their self-concept. This prediction agrees with prior research showing that self-threats are consequential only if individuals identify with the domain in which the threat occurs (Aronson et al. 1999). Thus, when given an opportunity to behave in a prosocial way, these counterfeit users respond in a very generous way to regain their moral self. Further, an opportunity for self-affirmation prior to donation eliminates this effect.

Our findings contribute to a better understanding of the consequences of using counterfeit luxury goods. Contrary to prior research, we show that counterfeit use can result in more positive and prosocial behaviors, particularly for owners of authentic luxury goods. We also contribute to the moral cleansing literature by showing that engaging in an unethical activity may be insufficient to trigger this process. The focus of the immoral/unethical behavior (luxury goods) must also be one where the consumer feels a personal connection to their self-concept, in our case, by having purchased authentic luxury products in the past.

Study 1

We demonstrate that using a counterfeit product constitutes a threat to the user's moral self-image, and to compensate, counterfeit users are more willing to behave pro-socially. Female participants ($n=62$) were randomly assigned to wear either a counterfeit Tiffany bracelet or an unbranded bracelet (control), and afterwards, were asked to indicate their feelings on several personal dimensions (including honest and genuine) and their willingness to help volunteer and donate to charities (6-item moral activity scale, adapted from Shelton and McAdams 1990). Counterfeit users indicated feeling less honest/genuine (6.12 vs. 6.48, $p<0.05$) and were more willing to volunteer and donate to charity than control group participants (4.52 vs. 4.10, $p<0.05$).

Study 2

We replicated the findings from study 1 using actual monetary donation to charity as the measure of prosocial behavior. The procedure was identical to the one described for study 1, except that the moral activity scale was replaced by a real donation opportunity. Participants ($n=58$) were told they would receive \$5 as compensation for participating in the study, and were encouraged to donate a portion of this money to a charity. As expected, counterfeit users donated more money to charity than control group participants (3.61 vs. 2.65, $p<0.05$).

Study 3

We show the effect of counterfeit use on prosocial behavior is moderated by ownership of authentic luxury goods. We predicted that counterfeit users who are luxury owners would donate more money to charity than counterfeit users who are not luxury owners. We reasoned that although use of counterfeit luxury products can be considered a threat to one's moral self-identity, this feeling is most likely to occur among consumers who own and feel a personal connection to authentic luxury goods. Thus, owners of luxury goods who use a counterfeit were expected to donate more money.

The procedure of the main study was similar to that of study 2, except all participants ($n=126$) used a counterfeit luxury item (small Louis Vuitton handbag) and indicated whether they owned products from luxury brands. As predicted, owners of authentic luxury handbags donated more to charity after using the counterfeit handbag than did non-luxury owners (4.13 vs. 3.48, $p<0.05$).

Study 4

We provide additional process evidence by introducing a self-affirmation task, where participants ($n=139$) are encouraged to affirm their personal values (Cohen et al. 2000). The procedure was similar to study 3, with a 2 (Luxury Ownership: owner vs. non-owner) \times 2 (Self-affirmation task: yes, no) between-subjects design. A manipulation check using the self-integrity scale (Sherman et al. 2009) confirmed the efficacy of the self-affirmation task.

An analysis of donation amounts for participants who donated to charity revealed that, among luxury owners, donations were lower in the self-affirmation versus control condition (4.07 vs. 4.64, $p<0.05$). This finding is consistent with our theorizing that counterfeit use is more likely to have consequences for luxury owners, who compensate by larger donations, *unless* they have an opportunity to self-affirm their values in another way. For non-owners, the self-affirmation task did not affect the amount of their donations (4.28 vs. 4.53 $p>0.19$), consistent with the idea that these individuals do not identify with the domain of luxury goods as do luxury owners, and thus feel less need to compensate for their counterfeit use through either prosocial behavior or self-affirmation. This experiment provides additional evidence that threat to the self-concept is what drives the prosocial behaviors among luxury owners after using counterfeit luxury products.

When Modesty Pays

EXTENDED ABSTRACT

The attainment of status, or being higher on dimensions that are valued by society, is a fundamental drive (Nelissen and Meijers 2011; Huberman, Loch and Onculer 2004). People signal status in order to reap the benefits afforded to people who have high status, such as wealth and social influence (e.g., Eastman, Goldsmith and Flynn 1999). A common way to signal status is through conspicuous consumption of luxury goods (e.g., Berger & Ward 2010; Han, Nunes and Dreze 2010), and the demand for luxury goods implies its advantages.

Yet, conspicuous consumption may be socially disadvantageous in certain contexts. Specifically, we propose that signaling status through conspicuous consumption signals self-interest, which is inherently at odds with cooperation (Barasch, Berman, and Small, 2016; Lin-Healy and Small, 2013). Across six studies (total $N = 1,824$), we demonstrate that conspicuous consumers are perceived as less good and cooperative than modest consumers. As a result, people prefer to interact with modest partners in tasks requiring cooperation. We further show that people strategically avoid status signaling in cooperative contexts, suggesting some awareness that conspicuous consumption reduces cooperation.

Studies 1a-1d

We examine judgments of individuals wearing clothes with either high-status brand logos or the same clothes without logos. For example, in Study 1a, participants ($N = 401$, MTurk, behavioral lab) were asked to evaluate a young man in one of two photos. The images were identical except for the presence of a Ralph Lauren logo on the man's shirt. As predicted, participants viewed the individual who was wearing the Ralph Lauren shirt as less good (nice, sincere, a good person, generous; $\alpha = .922$; $F = 6.981$, $p = .009$), less cooperative (scale adapted from Cloninger et al. 1993; $\alpha = .790$; $F = 21.063$, $p < .001$), and more of a show off ($\alpha = .925$; $F = 31.388$, $p < .001$) than the man wearing a plain shirt. In Studies 1b-1d, we replicated these findings using different stimuli and brands (e.g. owning a Chanel handbag; all $ps \leq .05$)

Study 2

We examine whether people prefer to interact with someone who is modest rather than someone who signals status. Participants ($N = 202$, MTurk) were told that they would be working with a virtual partner on a task that was a variant of the Prisoner's Dilemma game. Participants were told that they could choose either a partner who had made an "avatar" or a partner who had not made an ava-

tar. They were further told that the avatar partner chose whether to include luxury-branded clothing (e.g. Prada, Gucci) on their avatar. Participants were then randomly assigned to one of two conditions: in the *branded clothing* condition, the partner who made an avatar chose to dress their avatar in luxury-branded clothing, while in the *unbranded clothing* condition, the partner who made an avatar chose unbranded clothing.

Results showed that when the avatar partner chose unbranded clothing, 71% of participants preferred that partner to the neutral partner. However, when the avatar chose branded clothing, only 27% preferred that partner to the neutral partner ($\chi^2 = 40.12, p < .001$). Replicating Study 1, the branded partner was evaluated as less good and cooperative (p 's $< .001$) than the unbranded partner. Additionally, both measures of goodness (95% CI [-0.571, -0.124]) and cooperativeness (95% CI [-0.532, -0.084]) mediate the effect of clothing condition on participants' partner choice (PROCESS Model 4; Hayes 2013). Furthermore, when asked to predict whether the partner would cooperate or defect, 47% thought the avatar partner wearing unbranded clothing would defect, while 85% of participants thought the avatar partner wearing branded clothing would defect ($\chi^2 = 33.48, p < .001$). Thus, the choice of branded clothing seems to signal that the person is less likely to cooperate, and people do not want to play a Prisoner's Dilemma game with someone who is going to defect.

So far we have examined how people judge others wearing brands that signal status, and how that impacts their behavior towards status-signalers. In the final study, we examine whether individuals choose these brands for themselves in a strategic manner. Specifically, we test if individuals are aware that it pays to signal modesty in cooperative contexts.

Study 3

Participants (N = 214, MTurk) created an avatar of themselves by selecting their hair color, skin tone, and clothing in a web application. After generating their avatar, participants chose whether to put a brand on their selected clothing. They could choose between eight high-status logo options (e.g., Prada, Gucci) or they could choose not to put a logo on their clothing. Participants were then randomly assigned into one of two conditions. In the *neutral* condition, participants were told that their avatar choices would merely be shown to a partner, but that that partner would not make any decisions with regards to them. In the *cooperation* condition, prior to making the avatar, participants learned that they would subsequently play a Prisoner's Dilemma game with their partner, similar to Study 2. We reasoned that when anticipating a Prisoner's Dilemma, individuals would dress their avatar in a way that they believed would influence their partner to cooperate. Thus, if they correctly infer the advantage of remaining modest, then participants in the cooperation condition should be less likely to choose branded clothing compared to the neutral condition. Indeed, 50% chose branded clothing when there was no mention of a game, whereas in the cooperation condition, only 33% of participants chose branded clothing for their avatar ($\chi^2 = 6.592, p = .010$).

In sum, although signaling status is often desirable and advantageous, we find that when the goal is cooperation, modesty pays. Conspicuous consumers are perceived as less good and more self-interested, and are thus less preferred as partners in cooperative tasks. Furthermore, individuals show some awareness of the benefits of modesty and refrain from signaling status when it is advantageous to do so. This work contributes to variety of areas in consumer behavior, including conspicuous consumption, status, and cooperation.

Promoting Conspicuous Generosity: Justifying the "Brag" by Removing the Choice

EXTENDED ABSTRACT

People often feel conflicted about publicizing their pro-social behaviors. Although people want to be considered generous (Ariely, Bracha, Meier 2007, Bénabou and Tirole 2010, Ellingsen and Johannesson 2011, Harbaugh 1998), publicizing one's good deed often leads others to attribute the good deed to the very desire to enhance their reputation (aka the braggart's dilemma, Berman, Levine, Barasch, and Small 2015, Scopelliti, Loewenstein and Vosgerau 2015). As a result, charity organizations often find it difficult to leverage these image motives to increase participation in, or voluntary broadcasting of, conspicuous charity campaigns.

How can this dilemma be resolved so that charity campaigns can be more successful and people's desire for conspicuous generosity can be fulfilled? We propose that, people may be more willing to participate in prosocial campaigns if they are provided with a justification for bragging about their prospective good deed. We term this strategy "brag-binding", that is, making the voluntary publicity of their participation mandatory instead, as a prerequisite for participation or a condition for additional prosocial benefits. We predict that brag-binding may alleviate people's concern for negative social attribution associated with conspicuous prosocial behaviors and hence, increase people's willingness to engage in such behaviors.

This proposition contradicts predictions of normative theories because the terms of a voluntary-brag are more attractive than a mandatory-brag for two reasons. First, before participation, those who dislike social attention may only wish to take part in the voluntary-brag campaign, but not the mandatory-brag campaign. Second, during participation, those in the voluntary-brag campaign will have the freedom to choose whether to publicize their good deed, unlike those in the mandatory-brag campaign.

We present four experiments including one field study. We first examine in Study 1 people's predictions of others' attribution of their prosocial behaviors. In a 3(no-brag, voluntary-brag, mandatory-brag) x 2(scenario replica) between-subjects design, 293 participants ($M_{age} = 36, 49\%$ Male) read one of two scenarios in which they contributed to a charity and another person accidentally found out about their good deed. In all conditions, participants' contribution was posted on social media to further promote the charitable campaign. In addition, the other person either did not see the post (no-brag), or saw it and learned that it was participants' voluntary action (voluntary-brag), or saw it and learned that it was a prerequisite for contributing (mandatory-brag). Participants then answered how much they believe the other person would attribute their prosocial behavior to image motives (e.g., desire for reputation) vs. genuine generosity. There was no effect of scenario so we combined them. Overall, participants indicated that others would be more likely to attribute their good deed to genuine generosity in both the no-brag (3.2) and mandatory-brag (3.4) conditions than the voluntary-brag condition (4.2; $F(1, 290) = 9.5, p < .001, \eta_p^2 = .06$). The difference between no-brag and voluntary-brag conditions (3.2 vs. 4.2, $p < .001$) is consistent with actual social attribution found in prior work (Berman et al. 2015). More importantly, predicted social inference was more favorable for mandatory-brag than voluntary-brag (3.4 vs. 4.2, $p = .001$). Therefore brag-binding can assuage participants' concern for negative social inference.

Then in a field experiment, students at a dining hall in a Midwestern University were approached by hypothesis-blind research assistants to fill out a one-page questionnaire about the St. Jude children's research hospital. Students who completed the questionnaire

($N=162$, $M_{\text{age}}=22$, 57%Male) were asked if they would take another 4 minutes to color a cartoon image with encouraging messages (e.g., “Feel better soon!”) to help cheer up the recovering children at the hospital. Volunteers for the task would receive a large fluorescent yellow sticker that says “I provided my creative help to St. Jude children’s research hospital, have you?” to further promote campus awareness of the campaign. Participants either read that each volunteer could choose to wear the sticker for a day (voluntary-brag), or read that each volunteer must commit to wear the sticker for a day in order to participate (mandatory-brag). Every participant was told that the same information that they received was given to all students who were approached in the campaign. The results revealed that brag-binding was more effective in soliciting volunteers: more participants in the mandatory-brag condition agreed to help than those in the voluntary-brag condition (41.0% vs. 23.5%, $\chi^2=4.5$, $p=.045$, $\eta_p^2=.17$).

Next, we further compare the effect of brag-binding (mandatory-brag) to no-brag and voluntary-brag conditions on donations (Study 3), and explore a theoretical moderator - information asymmetry between people considering prosocial actions and their potential audience (Study 4). In Study 3, we randomly assigned 661 mturkers ($M_{\text{age}}=35$, 55%Male) to 3(no-brag, voluntary-brag, mandatory-brag) conditions. Participants read that if they were to donate \$28 to a community charity, they would achieve VIP donor status and their donation would be matched. The manipulation across conditions was similar to earlier experiments. Participants donated more to the campaign in the mandatory-brag condition than no-brag or voluntary-brag conditions (\$24.0 vs. \$18.0, \$19.3; $F(2, 658)=5.7$, $p=.003$, $\eta_p^2=.017$). Plus, more participants donated to achieve VIP status in the mandatory-brag condition (54.6% vs. 42.6%, 41.7%, $\chi^2=9.3$, $p=.009$).

In Study 4, 304 social media users ($M_{\text{age}}=34$, 36%Male) were randomly assigned to voluntary-brag or mandatory-brag conditions for a social-media campaign that solicits volunteers for a local animal shelter. We measured participants’ frequency in using social media as a proxy for perceived information asymmetry between people and their audience on the social media platform – the more frequent, the greater overlap of information. We predicted that the effect of brag-binding would be stronger when participants believe that others have sufficient information to interpret their brag. Overall, participants indicated greater willingness to volunteer in mandatory-brag than voluntary-brag condition ($M=5.3$ vs. 4.9, $t(302)=2.0$, $p=.049$). This effect was marginally stronger among heavy social media users ($F(1, 298)=3.7$, $p=.056$, $\eta_p^2=.012$).

In sum, by removing contributors’ choice about whether to brag and justifying their prospective conspicuous prosocial behavior, “brag-binding” makes people more willing to both help and to spread word about the charitable cause, and facilitates a win-win situation among contributors, charity organizations, and their recipients.

Prosocial Referral Rewards

EXTENDED ABSTRACT

Previous research has shown that incentives can effectively increase customer referrals, however, it remains unclear how companies can optimize their reward structure. Some research finds that referral rewards, while often beneficial to a firm, can also produce a negative effect in the form of psychological costs, whereby the addition of an incentive makes the recommender feel selfish or disingenuous (Ryu and Feick 2007).

In this research, we propose that consumers will be most likely to refer friends when there is no personal incentive, and instead, their

referred friend receives the entire referral reward. With such “prosocial” referral rewards, customers can reap all of the psychological benefits of helping a friend (Aknin et al. 2013; Dunn, Aknin, & Norton 2008), without incurring the psychological costs of feeling selfish. Our hypothesis has important implications because while many companies use referral rewards to increase customer acquisition, very few offer the full reward to the referred friend; instead they often opt to share the reward between the referrer and referee, or, to allocate the entire reward to the referrer.

Study 1

Mechanical Turk participants ($N=750$) were randomly assigned to one of 4 conditions: 1) No Reward, 2) Selfish Reward: Participants were told that they would receive \$10 for each friend that joined a new program, 3) Shared Reward: The participant and their friend would each receive \$5, or 4) Prosocial Reward: The referred friend would receive \$10. We also manipulated context sensitivity, using either a sensitive context (health clinic) or a non-sensitive context (Amazon loyalty program). We manipulated reward context both as a robustness check, and because previous research suggests that consumers may find (selfish) incentives particularly distasteful when the context is personal or sensitive (Kornish and Li 2010).

In the study, participants were asked to imagine that they were either members of an Amazon loyalty program or patients at a free health clinic. They were asked, “How likely are you to refer a friend to become a member of this program (go to this health clinic)?” There were no significant differences between consumer contexts, so moving forward those results are collapsed.

Across contexts, participants were most likely to refer a friend in the “Prosocial Reward” condition. The propensity to refer a friend was significantly higher for the Prosocial Reward condition (70.89% likelihood) versus No Reward (58.28%; $p<.001$), Selfish Reward (52.04%; $p<.001$) and Shared Reward (61.63%; $p=.006$) conditions. In sum, study 1 suggests that consumers are most likely to refer when offered a generous rather than a selfish or shared reward.

Study 2

Study 2 explores the process underlying this preference for prosocial referral rewards. Specifically, we manipulated the transparency of the referral in a 2(reward: selfish, generous) x 2(transparency: control, opaque) between-subjects design. Using the Amazon loyalty program from Study 1, we showed participants a sample referral email that Amazon was interested in sending to their friend. In the opaque condition, we mentioned after the e-mail that their friend would NOT be informed that the referrer will receive (or will not receive) a reward if they join. We then asked “How likely are you to refer your friend to Amazon BOLD?” along with additional questions designed to measure feelings of selfishness and generosity due to the referral.

There was a significant interaction between reward type and transparency ($p < .001$). In the Control condition, participants were again more likely to refer their friend when the reward was prosocial (76.8%) versus selfish (66.3%, $p=.006$). We find the opposite pattern in the opaque condition, however; in the opaque condition, where participants knew their friend would not learn of their generous role, participants were more likely to refer when the reward was selfish rather than prosocial. While psychological costs (feelings of selfishness) were higher for the selfish reward across conditions, feelings of generosity were only significantly higher in the control condition. This indicates that when participants believed their friend would not know whether they are being generous or selfish, participants preferred to gain the selfish reward.

Study 3

We further tested the degree to which the preference for prosocial referral rewards occurs because referrers seek social benefit. The study used a 2(reward: selfish, prosocial) x 2(recipient: friend, stranger) between-subjects design. 575 participants were asked to imagine that they were members of Amazon BOLD and again saw a sample referral email that Amazon is interested in sending to either 1) their close friend or 2) a potential customer (who the participant doesn't know). We then ask "How likely are you to refer your friend (this potential customer), to Amazon BOLD?"

We find a significant interaction between referral reward and referral recipient on referral likelihood ($p < .001$). Consistent with our previous studies, participants were more likely to refer a friend when offered a prosocial (79.2) rather than a selfish referral reward (70.3%; $p = .005$). However, when asked to refer a stranger, the selfish reward (64.8%) was more successful than the generous reward (41.7%; $p < .001$). This suggests that consumers are not universally more motivated by prosocial referral rewards, but rather, prefer prosocial incentives when a meaningful social relationship is involved.

Currently, companies typically incentivize referrals by rewarding the referrer or both the referrer and their friend. We find evidence that consumers may instead be most likely to refer friends when the entire reward goes to their friend. However, this effect relies on social benefit; it reverses when the referred individual is a stranger (versus a close friend) or when the referred friend will not know the terms of the referral (whether the reward was selfish or generous). This preference was found in two different consumer contexts and provides both conceptual insight about prosocial rewards and practical insight into successful referral reward strategies.

SESSION OVERVIEW

What motivates consumers to avoid rather than seek variety in their choices? The importance of variety seeking in consumer choice and its practical implications has long been recognized by consumer researchers. In this special session, we investigate consumer variety seeking from two novel perspectives: the intrinsic drivers that lead consumers to prefer less variety in their choices and extrinsic social signals that a choice of lower variety can convey to others. Four papers in this session present previously unexplored motivations for variety seeking and provide compelling empirical evidence for these propositions.

The first two papers approach variety seeking from an intrinsic motivation perspective. While previous work has identified various extrinsic influences on variety seeking, such as product display (Simonson and Winer 1992) and environmental constraints (Levav and Zhu 2009), the first two papers examine two novel intrinsic factors: consumers' implicit self-theory and pain of payment. In the first paper, *Clarkson, Beck, and Murphy* investigate the role that implicit self-theory plays in determining consumers' preference for variety. Across seven studies, they show that a belief that the self is fixed (vs. malleable) can induce more stable future preference predictions, which in turn, results in lower preference for variety. They further show that such reduction in variety increases consumers' satisfaction in the long run. The second paper by *Huang, Siddiqui, and Pocheptsova Ghosh* show how the pain of payment a consumer incurs affects their decisions to include more or less variety in their choice. Five studies demonstrate that when consumers experience higher (vs. lower) pain of payment, they perceive the options to be less attractive, and choose less variety.

The next two papers investigate extrinsic motivations for variety seeking, offering a fresh take on how variety affects interpersonal perceptions. *Kim and Wang* test a novel social consequence of choosing less variety: status perception. Through four studies, they show that less (vs. more) varied choices in a high-cost product category (i.e. luxury) signals greater status, due to inferences of a costly prior

preference learning stage. Finally, *Sela, Morgan, and Maimaran* examine how assortment variety serves as an expertise signal. In three studies, they find that when consumers want to appear as experts, novices choose more variety whereas experts choose less variety.

In sum, this session enriches our understanding of consumer variety seeking behaviors by demonstrating novel motivations for variety seeking, ranging from internal processes such as certainty in one's self-concept and psychological pain, to external considerations such as status and expertise perceptions. This session will appeal to a broad set of scholars interested in variety seeking, affective forecasting, preference formation, luxury and conspicuous consumption, and consumer knowledge.

When Variety Isn't Life's Spice: The Impact of Implicit Self-theories and Preference Forecasting on Anticipated Consumption Variety

EXTENDED ABSTRACT

Many of our routine decisions involve anticipating future consumption. This act of anticipation forces consumers to *guess* about their future preferences (Ratner, Kahn, and Kahneman 1999; Simonson 1990). While a wealth of research demonstrates that consumers opt for variety in their experiences and products to reduce their uncertainty of future preferences (Kahn and Lehmann 1991; Simonson 1990; Simonson and Winer 1992), not all consumers opt for variety in their future preferences. In other words, when anticipating future consumption, some consumers diversify their experiences whereas others opt to repeat the same experience. The focus of the present research is to provide a novel perspective on this question by understanding the impact of consumers' *implicit self-theories* on this decision to seek out the same versus different experiences when considering future consumption.

Across a series of experiments, the findings repeatedly demonstrate a consistent influence of consumers' beliefs in the stability of the self-concept—that is, their implicit self-theory—on their tendency to repeat versus diversify future consumption experiences. In particular, those who believe the self to be fixed (entity theorists) preferred less variety than did those who believe the belief to be malleable (incremental theorists). Moreover, this effect occurred across a host of products (e.g., candybars, toothpastes, sodas), held when the choices were consequential, and occurred regardless of whether implicit self-theories were measured or manipulated. Thus, implicit self-theories appear to exert a robust influence on the diversity in consumers' anticipatory consumption.

Additionally, we document the role of preference forecasting in explaining this robust influence. Preference forecasting is defined as the perceived durability consumers attribute to their preferences over time. We argued that, given that entity theorists view the self-concept as durable over time, they should also view features of the self-concept such as preferences as equally durable (Dweck, Chiu, and Hong 1995; see Dweck 2000). This perception of durability is critical, as heightened durability should heighten preference certainty and thus decrease the need for variety to cope with uncertainty in future preferences (Kahn and Lehmann 1991; Simonson 1990; Simonson and Winer 1992). Consistent with this logic, entity theorists not only perceived their preferences as more stable than incremental theorists, but this difference in preference forecasting mediated the

effect of implicit self-theories on variety-seeking. Indeed, directly manipulating consumers' beliefs in the temporal stability of their preferences impacted variety-seeking, such that those who viewed their preferences as more (versus less) stable over time were less likely to anticipate variety.

Moreover, the mediating role of preference forecasting was independent of several alternative motivations related to variety-seeking. For instance, the desire for life change, curiosity, or impulsivity could not account for the documented effect of implicit self-theories on variety-seeking. Additionally, showing this difference by directly manipulating consumers' preference forecasts offers further support against alternative explanations related to broader motivations stemming from consistency-seeking. Of course, this is not to say that consumers' implicit self-theories are irrelevant to these alternative motivations; rather, we would argue that these motivations could still impact the effect of implicit theories on variety-seeking under specific circumstances. In general, however, the results offer clear support for the importance of preference forecasting to this decision to seek out the same versus different experiences when considering future consumption.

As further evidence of this preference forecasting mechanism, the findings demonstrate the effect of implicit self-theories on variety-seeking is pronounced when consumers are required to engage in preference forecasting (i.e., anticipate future consumption); when consumers focus on their immediate preferences, we see no differences in preference variety as a function of their implicit self-theories. This finding outlines a critical boundary condition for the influence of implicit self-theories on variety-seeking while also offering unique insight into when consumers are satisfied with less—as opposed to more—variety in their actual consumption (cf. Ratner et al. 1999). Indeed, entity theorists reported greater satisfaction with their actual choices despite consuming less variety than incremental theorists. Thus, perceiving the self—and one's preferences—as durable over time can cause consumers to not only more accurately anticipate the actual amount of variety they consume but can also maintain satisfaction in this consumption despite a lack of variety.

Finally, this effect of implicit self-theories on consumers' decision to seek out the same versus different experiences when considering future consumption was shown to influence preferences for different subscription and reward programs. In particular, entity theorists valued initiatives that promoted low levels of variety consumption; incremental theorists, on the other hand, valued initiatives that promoted high levels of variety consumption. We believe these findings provide a clear illustration for the managerial implications of the present findings, especially with regards to the efficacy of loyalty initiatives so critical to consumer retention (Watson, Beck, Henderson, and Palmatier 2015).

In sum, then, the present research provides clear and consistent support for the role of implicit self-theories (i.e., beliefs about the malleability of the self) in anticipated consumption variety. Specifically, those who perceive their preferences as durable (entity theorists) are less likely to seek out diversified consumption experiences than are those who perceive their preferences as tenuous (incremental theorists). In doing so, these findings offer several conceptual and strategic insights into consumers' tendency to repeat versus diversify future consumption experiences. In particular, these findings speak to both when and why consumers (i) anticipate less variety in their future experiences (rather than more: Kahn and Lehmann 1991; Read and Loewenstein 1995; Simonson 1990) and (ii) gain greater satisfaction in this desire for less variety in future experiences (rather than more: Etkin and Mogilner 2016; Ratner, Kahn, and Kahneman 1999). Thus, this conceptual framework provides an alternative

means by which to understand consumers' (mis)calibration with anticipatory choice, a potent downside of 'growth mindsets' in evoking overestimation errors, and implications for actual experiential satisfaction as well as loyalty programs that incentivize different levels of future consumption variety.

The Impact of Pain of Payment on Variety Seeking Behavior

EXTENDED ABSTRACT

Frequently, consumers acquire multiple products in the same product category and may choose a greater or lesser variety of products. Research on factors affecting variety-seeking behavior has been of great interest to marketing researchers (Kahn and Isen 1993; Ratner and Kahn 2002; Read, Loewenstein, and Kalyanaraman 1999; Read and Loewenstein 1995). We propose that a novel predictor, pain of paying for consumption, would influence consumers' desire for variety in their choices.

When consumers purchase products, the manner in which they pay for the products can vary. One may pay with cash or credit card; similarly, one might pay for products before or after consumption. The different methods and schedules of payment have been shown to influence consumers' experienced pain of payment and change consumer preferences (Prelec and Loewenstein 1998, Monger and Feinberg 1997; Raghuram and Srivastava 2008; Thomas, Desai, and Seenivasan 2011). We extend these findings to the previously unexplored domain of variety seeking.

Specifically, we propose that lower pain of payment will increase consumers' propensity to seek variety. We build our proposition on prior work by Chatterjee and Rose (2012), that demonstrates that priming consumers with the concept of cash (i.e., a more painful payment method) can focus them more on the costs and negative attributes of products while making the concept of credit card (i.e., less painful payment method) more salient makes consumers focus more on the benefits of products and, consequently, form more favorable evaluations of the choice set. Since variety seeking has been found to increase when more options in the choice set have favorable evaluations (Goukens et al. 2007; Faraji-Rad, Jazani, and Warlop 2013), we propose that lower pain of payment will increase the number of favorable options in the choice set and, therefore, lead to more variety-seeking.

We test our proposition in five studies. In study 1, we test whether low (versus high) pain of payment, which we manipulated by changing the timing of payments (pre-pay vs. post-pay), leads to greater variety seeking. Participants imagined buying tickets to visit a museum in one month, and then chose four museum sections to visit from four general categories (e.g., "History," "Science"). Participants in the low pain (vs. high pain) condition were told that the ticket payment was made one month before their visit (vs. must be made one month after their visit). The number of different categories that participants selected served as our measure of variety seeking. As predicted, participants who prepaid for their museum visit demonstrated greater variety seeking compared to those who paid one month after the visit ($M_{LowPain} = 2.65$, $M_{HighPain} = 2.23$; $F(1, 40) = 6.03$, $p < 0.05$).

In study 2, we replicate the effect and rule out timing of consumption as an alternative explanation (Simonson 1990). Participants imagined a trip to Sri Lanka either right now or in one month and then selected different vacation activities. Pain of payment was again manipulated by pre- versus post-payment. Pre-payment led to greater variety seeking regardless of whether consumption occurred in the future or in the present, ruling out timing of consumption as

an alternative explanation ($M_{LowPainPresent} = 2.93$, $M_{HighPainPresent} = 2.68$, $SD = .80$, $M_{LowPainFuture} = 2.92$, $M_{HighPainFuture} = 2.73$; $F(1, 296) = 5.79$, $p < .05$).

In study 3, we replicate our findings using a different pain of payment manipulation. Instead of manipulating the timing of payment, we manipulate the method of payment. Participants were asked to imagine choosing online services to subscribe to for a four-month period, and paying for those services using either cash or credit. Results were consistent with our prior studies, demonstrating that participants in the low pain of payment, i.e., credit, condition chose a greater variety of services compared to those in the high pain of payment, i.e., cash, condition ($M_{LowPain} = 2.07$, $M_{HighPain} = 1.69$; $F(1, 90) = 4.60$, $p < .05$).

In study 4, we tested whether the effect of pain of payment on variety seeking will be attenuated for products with highly favorable evaluations. Participants were given 18 ice cream flavors to rank. Participants chose five scoops of ice cream from their top-ranked (vs. low-ranked) flavors. Pain of payment was manipulated as in study 3. The results revealed the expected interaction ($F(1, 155) = 3.54$, $p = .06$). When choosing among least favorable flavors, participants who experienced low rather than high pain of payment chose greater variety ($M_{Lowpain_lowrank} = 3.59$, $M_{Highpain_lowrank} = 2.95$; $F(1, 155) = 5.69$, $p < .05$), replicating our previous findings. However, as expected, there was no effect of pain of payment on variety seeking when the choice set included highly favorable options ($M_{Lowpain_highrank} = 3.68$, $M_{Highpain_highrank} = 3.74$; $F(1, 155) = .058$, n.s.).

In study 5, we tested whether the predicted effect replicates for real choices. Participants received either cash or a coupon with which they could buy either five candy bars (highly attractive product) or five drink powders (less attractive product) of various flavors (between subjects; based on pre-test). Replicating our prior results, a significant interaction ($F(1, 199) = 6.67$, $p < .05$) revealed that lower pain of payment led to greater variety seeking when participants chose between energy drink powders ($M_{Lowpain_powder} = 3.15$, $M_{Highpain_powder} = 2.71$; $F(1, 199) = 5.67$, $p < .05$), but not when they chose between candy bars ($p > .1$).

In five studies we demonstrate that pain of payment affects consumers' variety-seeking behavior, providing evidence that lower pain of payment can increase variety in consumers' choices. We make a contribution to the literature by establishing a causal link between pain of payment and variety seeking, thereby integrating these two important streams of research. While past research has focused on a number of extrinsic factors which may influence variety seeking, we show how a factor intrinsic to any purchase situation, the mode and timing of payment, may influence variety seeking. Further, past research has shown the negative consequences of a low pain of payment, such as becoming more indulgent (Thomas et al. 2011). We demonstrate a new positive consequence of experiencing a low pain of payment: a greater diversity in consumption and experiences.

When Experience is Costly: How Choice Variety Signals Expertise and Status

EXTENDED ABSTRACT

Past research has demonstrated that incorporating high variety in choices lead to more positive impressions such as appearing more interesting, unique, and expressive, while low variety in product choices may have negative social connotations of being boring and rigid (Fishbach, Ratner, and Zhang 2011; Kim and Drolet 2003; Ratner and Kahn 1999). We demonstrate that under contexts where consumption experiences are costly, for instance, luxury products,

the pattern will reverse such that low variety will convey a positive impression on one's expertise and status.

We propose that consumers perceive a preference learning process for high cost product categories, through its behavioral manifestation in others' consumption choice variety. It is believed that consumers initially go through an exploration stage mirrored in greater variety-seeking to accumulate knowledge and experience, and subsequently make less variety choices once their preferences are stable. Such inferences are particularly salient when the product category is high cost, due to greater perceived motivations to search for the best option, and less ambiguity in attributing consumption decisions to one's preference. Thus, when a consumer chooses less variety in high cost contexts, observers infer greater expertise of the consumer in the product category. Furthermore, we propose that the nature of high cost products introduces an interesting downstream social consequence of such expertise perceptions. Specifically, perceived prior consumption experiences in contexts where experience is costly (e.g. luxury products) translate into greater status perception.

Study 1 aimed to test the main hypothesis that low variety signals expertise, only when the product category is high cost. A 2 (product category: high cost vs. low cost) X 2 (choice pattern: low vs. high variety) between-subjects design was conducted. After reading a description of a consumer purchasing four bottles of wine with *low variety* (i.e. all Pinot Noir), or *high variety* (one of each Champagne, Chardonnay, Pinot Noir, and Zinfandel) at either a high-end or regular wine store, participants (N=140) rated perceived expertise of the consumer. Consistent with our prediction, participants inferred that the consumer purchasing low variety had significantly greater expertise than one purchasing high variety ($M_s = 5.26$ vs. 4.28, $F(1, 136) = 11.587$, $p = .001$) in a high-end wine store scenario, but not in a regular wine store scenario ($M_s = 4.99$ vs. 4.97, NS).

In Study 2, we replicate the main effects on perceived expertise found in Study 1 and demonstrate its impact on perceived status, focusing on the high cost product category. Participants (N=123) read a description of a consumer visiting a premium beer shop in a 2 (choice pattern: low vs. high variety)-cell between-subjects design. They were told that the consumer purchased three bottles of craft beer with *low variety* (i.e. all from one brewery) or *high variety* (i.e. all different breweries). Results for perceived expertise replicated results of Study 1 ($p = .004$). Perceived status mirrored the effects, such that low variety signaled greater status than high variety ($M_s = 5.77$ vs. 5.29, $F(1, 121) = 3.746$, $p = .055$). Furthermore, perceived expertise mediated the main effect of choice pattern on status perception (95% CI: [.0584, .4688]).

In Studies 1 and 2, we find a boost in status perception for low variety, and demonstrate that this effect is driven by perceived expertise. Both perceptions arise from an inference of prior costly preference learning processes. We posit that if low variety choices are framed around features that are non-specific to a high cost product category, low variety may not convey information regarding one's costly prior consumption experiences, and thus lose its signaling impact on expertise and status. In Study 3, participants (N=273) imagined a consumer at a luxury chocolate store. We manipulated the focal feature of choice variety by framing the choices around their choice of wrapper colors (*non-specific feature* condition) or around their choice of chocolate flavors (*specific feature* condition). Next, in a similar fashion to prior experiments, participants are told to imagine that the consumer's choice was *low variety* (i.e. just one flavor/color) or *high variety* (i.e. six different flavors/colors). A 2 (choice pattern: low variety vs. high variety) 2 (focal feature: color vs. flavor) ANOVA on status perception supported our predictions. While low (vs. high) variety conveyed greater status in the specific

feature condition ($M_s = 7.13$ vs. 6.14 , $F(1,269) = 7.817$, $p = .006$), there was no difference in the non-specific feature condition ($M_s = 6.40$ vs. 6.63 , *NS*).

Study 4 sought to explore the boundary condition where high variety seeking can also convey high status by manipulating the process directly. Specifically, if high variety choices can be seen as selections equally based on one's expertise as low variety choices, then we should observe no difference between two choices sets in terms of status perception. A 2 (quality of choice: control vs. high) X 2 (choice pattern: low variety vs. high variety) between-subjects design was conducted. Participants ($N=255$) read a similar description as Study 1's high cost wine store. Participants in the *high quality* condition were told that both low and high variety selections of wine purchased by the consumer were all ranked as the best wine by a respected wine magazine. Participants in the *control* condition were not given such information. As predicted, in the *control* condition, the results replicated the previous studies, where low variety signaled greater status than high variety ($M_s = 5.87$ vs. 5.15 , $F(1, 251) = 9.603$, $p = .002$). However, when both choice sets were explicitly told to be comprised of the best quality, participants inferred that both consumers had similar levels of status ($M_s = 5.81$ vs. 5.75 , *NS*).

This research makes several important contributions. First, these studies expand the variety-seeking literature by examining its novel link to status perception. Moreover, we identify an important construct (i.e. consumption cost) that moderate traditional findings in favor of high variety. Second, while the notion that preference is shaped through experience and knowledge is not new – decades of research suggest variety-seeking and consistency's sequential relationship (Chernev 2003; Clarkson et al. 2013; Hoyer and Ridgway 1984) – this research contributes by showing that lay consumers intuit this relationship and use it when observing purchase behaviors. Finally, this research also contributes to the luxury consumption literature, suggesting that the pattern in which choices are made within luxury products matters.

Assortment Variety and Perceived Expertise

EXTENDED ABSTRACT

Choice conveys information about the chooser's level of expertise. Consumers who wish to portray themselves as experts often choose unique, rare, or sophisticated options, and they often draw spontaneous inferences about others' expertise from the type of options others choose (Feick and Higie 1992; Gershoff, Broniarczyk, and West 2001). But regardless of the specific type of options chosen, might the mere level of assortment variety chosen also serve as a signal of expertise? And, if so, does more or less variety signal greater expertise?

We propose that consumers strategically use assortment variety as a means of signaling their category expertise to others. Moreover, the relationship between assortment variety and perceived category expertise varies as a function of the perceiver's own level of expertise in that category. Specifically, category experts perceive less assortment variety as an indication of greater expertise in that category (and consequently choose less varied assortments to portray themselves as experts), whereas novices perceive more assortment variety as an indication of expertise (and choose accordingly when they wish to appear as experts).

We suggest this based on findings in expertise, impression management, and variety research. Both novices and experts want to be respected and viewed as knowledgeable (Leonard-Barton 1985; Feick and Price 1987), but they have different knowledge structures (Alba and Hutchinson 1987), and when they wish to accumulate

product category knowledge, experts seek narrower and more specialized options whereas novices seek breadth (Clarkson, Janiszewski, and Cinelli 2013). Consequently, we propose that novices see greater assortment variety as an indication of category expertise, and choose more variety when they wish their selection to be seen as reflecting expertise. Conversely, experts perceive less assortment variety as an indication of expertise, and accordingly, choose less varied assortments when they wish to showcase their expertise.

Three experiments test these hypotheses. Experiment 1 examines how experts and novices interpret another person's choice of either high or low assortment variety. First, participants rated their own level of expertise in the gourmet chocolate category. Then, following several filler tasks, participants read one of two descriptions of a hypothetical consumer who bought a box containing individually selected gourmet chocolate truffles. In the high assortment variety condition, we told participants that the protagonist chose many different truffle flavors. In the low assortment variety condition, the protagonist chose only a few different truffle flavors. The quantity bought, sixteen truffles, was the same across conditions. Participants rated the likelihood that the protagonist was a gourmet chocolate connoisseur. Consistent with our prediction, an assortment variety (high vs. low) x own-expertise (continuous) regression analysis revealed a crossover interaction effect on perceived expertise of the protagonist ($p < .001$), with no main effects. Whereas novices (i.e., participants one SD below the mean level of expertise) perceived the protagonist as more of an expert in the large variety condition than in the small variety condition, experts (i.e., those one SD above the mean expertise) perceived the protagonist as more of an expert in the small variety condition than in the large variety condition.

Experiment 2 examines how consumers strategically choose variety to demonstrate expertise. Participants chose an assortment of fine chocolate truffles for an important friend. We manipulated participants' motivation to showcase their expertise by framing the friend as a fine chocolate connoisseur in one condition only. A pretest confirmed that our manipulation increased participants' motivation to showcase their expertise, equally for experts and novices. Participants saw a list of 22 different truffle flavors and indicated the number of units they wanted to buy of each type (the total number of units participants could choose was not limited). To measure assortment variety, we calculated for each participant a Herfindahl index, a measure of assortment diversity, and controlled for the number of units selected (see Dhar, Hoch, and Kumar 2001; Simonson and Winer 1992). Finally, participants rated their own level of expertise in the category (ratings were unaffected by the experimental manipulation). Analysis revealed the predicted crossover recipient-framing X own-expertise interaction ($p = .01$), with no main effects. Compared with the control condition, novices increased and experts decreased the variety in their assortments (holding total quantity constant) when selecting for a connoisseur and hence motivated to showcase their expertise.

An alternative explanation for these results is that experts simply know which options are best, and thus choose less variety for the connoisseur. Experiment 3 rules out this possibility by using fictitious craft beer brands (validated in a pretest), of which neither experts nor novices had any prior knowledge. We told participants that they would be helping a specialty gift basket company to design a beer gift basket. In one condition (expertise-signaling goal), we asked participants to design a beer basket that would be especially appealing to beer connoisseurs, and we told them that they would receive \$25 if a panel of experts rated their basket highest on expertise. In the control-goal condition, we used an identical procedure except that we asked participants to design a beer basket that would appeal

to average customers, and we told them that they would receive \$25 if a panel of average customers evaluated their gift basket as the most appealing. Participants then chose from a list of fictitious beer brands. Finally, participants rated their own expertise in beer. Analysis revealed the predicted choice-goal X own-expertise crossover interaction effect ($p < .001$), with no main effects. Compared with the control goal condition, novices selected a more varied assortment whereas experts selected a less varied assortment when attempting to get a high expertise rating.

Variety is often used to convey uniqueness and interestingness to others, but we show that it can also be used to signal expertise. Furthermore, whereas prior research suggests that people unidirectionally choose more variety when self-presentation concerns are present, we show that people may choose smaller or larger assortment variety to signal expertise, depending on their own levels of category expertise.

Paper #4: Rethinking Time for Well-Being

Hal E. Hershfield, UCLA, USA
Cassie Mogilner Holmes, UCLA, USA
Jennifer Aaker, Stanford University, USA

SESSION OVERVIEW

Time is one of our most precious resources. With only 24 hours a day seven days a week, consumers must decide how best to allocate their finite time to maximize well-being. Reflecting the importance of this decision, researchers have devoted themselves to understanding the happiest ways to mentally construe and spend time (e.g., Aaker, Rudd, and Mogilner 2011; Etkin and Mogilner 2016; Mogilner and Aaker 2009; Mogilner and Norton 2016). This stream of work has yielded many important insights: thinking about time (vs. money; Mogilner 2010; Mogilner and Aaker 2009) and expanding one's sense of time (Chance, Mogilner, and Norton 2011; Rudd, Vohs, and Aaker 2012) increase happiness. Time spent socializing, volunteering, and on leisure pursuits make people happier than work (Aaker et al. 2011; Kahneman et al. 2004; Thoits and Hewitt 2001), and time spent on freely chosen activities makes people happier than imposed ones (Csikszentmihalyi and Hunter 2003).

While the prior work informs how to think about time and what to spend time on in order to enhance well-being, what leads consumers to construe and spend time in these beneficial ways has received less attention. Time spent on leisure may make people happier than work, for example, but what affects how people allocate time between work and leisure? Feeling time constrained may detract from well-being, but how can people construe their time in a more positive light?

This session tackles these questions. Four papers investigate factors that affect the expenditure and construal of time to enhance well-being. Papers 1 and 2 examine time spent on work versus leisure. Etkin and Chabot investigate the role of goal conflict and time scarcity. Five experiments show that perceiving greater conflict between one's personal goals makes time seem scarcer, which leads people to spend more time on work and less on leisure. Whillans, Smeets, Bekkers, and Norton focus on wealth and autonomy. Two large-scale surveys of millionaires and the general population show that wealth predicts life satisfaction by enabling greater autonomy in work and leisure. Paper 3 (Ebrahimi, Rudd, and Patrick) examines time spent volunteering and the role of busyness and empowerment.

Five studies show that holding the lay theory that busyness is good (vs. bad) increases psychological empowerment, which makes people more likely to volunteer. Finally, Paper 4 (Hershfield, Mogilner, and Aaker) proposes a theory of how to re-conceptualize time—by taking a “bird’s-eye” view of the past, present, and future—to improve well-being.

Together these papers inform what affects the use and construal of time to enhance well-being. Going beyond identifying specific happy ways to spend and perceive time, this session demonstrates a variety of novel factors—goal conflict, wealth, busyness beliefs, abstraction—that influence consumers' propensity to spend and construe time in these beneficial ways. The findings advance understanding of the psychology of time allocation and perception and its connections to well-being, and suggest numerous interventions to improve consumer well-being. The session should have broad appeal to scholars interested in time, well-being, happiness, work vs. leisure, and volunteering.

Goal Conflict Encourages Work and Discourages Leisure

EXTENDED ABSTRACT

Aside from basic needs, leisure is one of the most desired human behaviors. Leisure activities are enjoyable and done for their own sake, rather than their external benefits (Grazia 1962; Neulinger 1974). People desire leisure more than social interaction and sex, and even more than addictive behaviors like smoking (Hofmann, Vohs, and Baumeister 2012).

The desire for leisure is well-founded. In addition to being fun, leisure provides many physical and psychological benefits. Leisure alleviates stress, increases positive affect, reduces burnout, boosts life satisfaction, and improves well-being (Kahneman et al. 2004; Reich and Zautra 1981; Tinsley and Tinsley 1986).

Nevertheless, people frequently forgo leisure in favor of other activities (Gershuny 2005; Hofman et al. 2012)—namely, work. Even when working more provides few additional benefits (e.g., one's basic needs are already met), many people choose to spend more time on work rather than leisure (Kuhn and Lozano 2008; Schor 1991). Given the appeal and benefits of leisure, why do people so often choose work instead?

We suggest that goal conflict plays an important role. Building on recent research, which shows that perceiving greater conflict between one's personal goals makes people feel that they have less time (Etkin, Evangelidis, and Aaker 2015), we argue that goal conflict should increase the need to feel justified in how time is spent. Because activities that feel productive tend to be more justifiable than merely enjoyable ones (Giner-Sorolla 2001; Kivetz and Simonson 2002; Southerton and Tomlinson 2005), we predict that perceiving greater goal conflict will increase time spent on activities that feel productive (i.e., “work,” Laran and Janiszewski 2011) and decrease time spent on activities that feel enjoyable (i.e., “leisure”)—even when those tasks are unrelated to the conflicting goals.

Five experiments tested our predictions. The first four followed the same basic paradigm: first, we manipulated perceived goal conflict by asking participants to list two personal goals and then describe a time when they did versus did not feel conflict between them; second, as an ostensibly unrelated task, we measured time spent on work versus leisure either via engagement in an activity (experiments 1a and 1b) or choice (experiments 2a and 2b).

Experiment 1a examined coloring. After manipulating perceived goal conflict, participants read that they would spend more time coloring simple shapes, and we manipulated how coloring was framed. Coloring is a simple activity that is fun to do (Lepper, Greene, and Nisbett 1973). Accordingly, in the “work-frame” condition, we told participants, “coloring is useful for cultivating creativity...spending time coloring helps people be more creative in their work”); in the “leisure-frame” condition, we simply allowed coloring to be fun (as it naturally seems). We recorded how long participants spent coloring, then tested the effect of goal conflict in each frame condition. As predicted, when framed as work, goal conflict increased time spent coloring ($M_{\text{high-conflict}} = 218.33$ seconds vs. $M_{\text{low-conflict}} = 164.53$ seconds; $F(1, 311) = 3.27, p = .071$), but when coloring seemed fun, goal conflict decreased time spent coloring ($M_{\text{high-conflict}} = 186.61$ seconds vs. $M_{\text{low-conflict}} = 238.19$ seconds; $F(1, 311) = 8.29, p = .004$).

Experiment 1b replicated the results of experiment 1a with a different activity: watching a video. After manipulating perceived goal conflict, we framed watching a movie either as work (“Documentaries are a good way to learn and develop critical thinking...”) or leisure (“Movies are a good way to relax and be entertained...”), then measured time spent watching. As predicted, when framed as work (leisure), goal conflict increased (decreased) time spent watching the video.

Experiments 2a and 2b explored the proposed underlying process. Experiment 2a tested for mediation. After manipulating perceived goal conflict, we asked participants to choose a puzzle (one that would be effortful and feel like “work” vs. one that would be enjoyable and feel like “leisure”), then measured feelings of time affluence (five-items on 7-point scales from Etkin et al. 2015). Supporting our theory, perceiving greater goal conflict made participants feel that they had less time ($M_{\text{high-conflict}} = 2.93$ vs. $M_{\text{low-conflict}} = 3.54$; $F(1, 148) = 7.12, p = .008$), and these reduced time perceptions increased choice of the work task over the leisure one ($\chi^2(1) = 4.04, p = .045, \eta^2 = .027$). Experiment 2b examined moderation. After the goal conflict manipulation, we manipulated feelings of time affluence (via an awe induction, Rudd, Vohs, and Aaker 2012), then asked participants to allocate their next 15 minutes between a “work” activity (catching up on school or work email) and a “leisure” activity (browsing social media). Supporting our reasoning, in the control condition, participants allocated more time to work versus leisure, but encouraging participants to feel as if they had more time attenuated this effect.

Our final experiment examined whether, despite choosing to spend more time on work, people who perceive greater goal conflict would be happier if they instead spent more time on leisure. To test this, we modified the previous paradigm in two ways: first, all participants received the high goal conflict manipulation, and second, rather than measuring time spent on work versus leisure, we manipulated how long people spent. Like in experiment 1b, we framed watching a video as work versus leisure, manipulated the time spent, then measured happiness (2-items on 7-point scales from Etkin and Mogilner 2016). Results showed that, while spending more time watching the video framed as work had no impact on subsequent happiness ($M_{\text{long-time}} = 4.18$ vs. $M_{\text{short-time}} = 4.21$; $F < 1$), spending more time watching the video framed as leisure made participants happier ($M_{\text{long-time}} = 4.78$ vs. $M_{\text{short-time}} = 4.21$; $F(1, 176) = 4.35, p = .039$).

These findings contribute to understanding of the effects of goal conflict in people’s everyday lives. Leisure has many benefits: alleviating stress, increasing positive affect, boosting happiness, and improving life satisfaction (Kahneman et al. 2004; Reich and Zautra 1981; Tinsley and Tinsley 1986). In addition to increasing feelings of time pressure, goal conflict further undermines well-being by en-

couraging people to spend less time on what would make them better off.

Control over Time Predicts Greater Life Satisfaction among Millionaires

EXTENDED ABSTRACT

When and why does wealth result in greater life satisfaction? Wealthier people experience greater stress than the general population and do not necessarily experience greater life satisfaction (Kahneman et al., 2006), such that the relationship between income and life satisfaction is non-linear (Kahneman & Deaton, 2010). However, wealth enables people to exert greater control over their lives, including greater autonomy over how they spend their time (Kraus et al., 2012). Although past research has explored time use in the general population, the number of very wealthy individuals in these samples is small, and the very wealthy often behave quite differently than the less wealthy (Smeets, Bauer, Gneezy, 2015). Using two large-scale surveys of millionaires ($N=863$ $N=690$) and the general population ($N=1232$, $N=306$), we examine whether wealth predicts life satisfaction to the extent that wealth shapes time-use. Specifically, we examine whether millionaires are happier than the general population in part because they exert greater control over two critical domains that occupy most of their time: leisure and work.

Study 1 examines whether millionaires exert greater control over leisure activities by engaging in more active (e.g., volunteering, exercising, socializing) than passive leisure (e.g., relaxing, napping, watching television). Active leisure requires greater personal control (Whillans et al., 2017). Study 2 examines whether millionaires exert greater control over work activities, including time spent engaged in self-chosen goals.

In Study 1, Dutch millionaires ($N=863$, $M_{\text{wealth}} = \text{€}2,375,905$) reported their life satisfaction and how they had spent time in the last 24 hours. A nationally representative sample of Dutch adults completed the identical survey ($N=1,232$, $M_{\text{wealth}} = \text{€}37,500$).

Millionaires reported greater life satisfaction ($M=8.12$, $SD=1.00$) than the general population ($M=7.48$, $SD=1.32$); t -test $p < 0.001$. Millionaires reported the same amount of overall leisure as the general population (40.4% and 40.7% respectively) but spent this leisure time differently. Millionaires spent significantly more of their time on active leisure (16.1% versus 10.5%; $p < 0.001$) and significantly less of their time on passive leisure (24.3% versus 30.2%, $p < 0.001$). These results held controlling for differences between the two samples including age, gender, and employment status.

Active leisure was positively – and passive leisure was negatively – associated with life satisfaction for both millionaires and the general population. These results were robust controlling for differences in observable characteristics of the wealthy and general population. Further, we observed two significant indirect effects: (1) to the extent that wealth predicted active leisure, wealth in turn predicted greater life satisfaction and (2) to the extent that wealth predicted lower levels of passive leisure, wealth in turn predicted greater life satisfaction. These results held controlling for demographic differences between the rich and non-rich. Overall, both groups derived benefit from active leisure, but the rich engaged in more active leisure and therefore reported greater life satisfaction.

Millionaires spent less time working and commuting than the general population; yet, this was entirely explained by the larger fraction of millionaires who were retired. Among the employed, millionaires spent a larger fraction of their time at work and commuting than the general population: 29.5% versus 24.5%, $p < 0.01$. Among the retired, millionaires also spent a larger fraction of their time

working and commuting: 9.1% versus 6.2%, $p < 0.01$. Time spent working was not associated with life satisfaction, suggesting that work hours could not explain higher life satisfaction among the rich.

Study 1 revealed that the amount of time spent working did not predict differences in life satisfaction. In Study 2, we focused not on the amount but rather on the type of work that individuals completed. We suggest that the relationship between work and life satisfaction may critically depend on the extent to which people have control over the activities that they complete while at work. Thus, we assessed respondents' level of autonomy at work, predicting that millionaires would report greater autonomy than the general population, and that this autonomy would be linked to greater life satisfaction.

Dutch millionaires ($N=690$, $M_{wealth} = €3,351,234$) and a nationally representative sample of Dutch adults ($N=306$, $M_{wealth} = €101,677$) indicated the number of hours that they worked yesterday and the fraction of those hours that they had control over work tasks. Both samples also reported on three components of work autonomy: the extent to which they had control over the methods they used at work, the extent they could control when they worked, and the extent they could control the goals they pursued at work. Respondents also completed the identical life satisfaction measure from Study 1.

Once again, the rich reported greater life satisfaction ($M=8.10$, $SD=0.84$) than the general population ($M=7.60$, $SD=1.09$); t -test $p < 0.001$. Consistent with research demonstrating a positive association between income and job autonomy using representative samples (Bryson & MacKerron, 2016), millionaires reported greater job autonomy than the general population. Among employed individuals, both millionaires and the general population worked approximately 7.5 hours in the last 24 hours.

Of those hours, millionaires decided what to do and how to do it during 92.6% of the hours that they spent working as compared to 76.4% for the general population ($p < 0.01$). Millionaires also reported having more control over the methods that they used at work, when they worked, and their goals at work ($ps < 0.01$).

Work autonomy predicted life satisfaction for both millionaires and the general population. Yet, as with active leisure, to the extent that wealth predicted job autonomy, wealth in turn predicted greater life satisfaction. Although both samples reported higher life satisfaction from greater job autonomy, the rich experienced greater job autonomy, which contributed to the gap in life satisfaction between the rich and non-rich.

An emerging body of research focuses on the distinct contributions of time and money to life satisfaction. While previous research has focused on the direct relationships between money and life satisfaction—in many cases directly plotting income against life satisfaction—our results suggest that wealth translates into life satisfaction to the extent that it influences a third key variable: time. When wealth enables people to take control over leisure and work activities, wealth is more likely to translate into greater life satisfaction.

To Thrive or to Suffer at the Hand of Busyness: How Lay Theories of Busyness Influence Psychological Empowerment and Volunteering

EXTENDED ABSTRACT

Time is becoming an increasingly precious human resource and, with each passing decade, consumers report feeling increasingly busy (Gershuny 2005; Szollos 2009). Research finds that feeling busy has a negative psychological impact on consumers, hindering work-life balance and increasing distress, depression, and anxiety (Roxburgh 2004; Roxburgh 2006). The current research argues that how individuals view their busyness can have social and societal

implications and asks, if people feel busy, are they simply less likely to volunteer?

Volunteering rates in the US have been declining for over a decade (Bureau of Labor Statistics 2007, 2011, 2016), and society's current busyness epidemic is often blamed as the culprit. But although some empirical evidence does indeed support the notion that busyness breeds a lack of volunteering intent (Johnson 2004), is that the full picture? Other evidence suggests that it is busy individuals who are more likely to volunteer (Corporation for National and Community Service 2007). For instance, amongst full time workers, those who work more hours are more likely to volunteer (Wilson and Musick 1997). In an example close to home, reviewers for academic journals or conference special sessions (volunteers) are often also the most prolific (busy) researchers (Lindsey 1976). To help resolve this evidentiary inconsistency, we propose that it is *not* busyness per se, but rather people's lay theory about the feeling of busyness (i.e., feeling "busy=good" or feeling "busy=bad") that influences volunteering behavior.

We suggest that, when feeling busy, consumers who hold the lay theory that feeling busy is good should feel more invigorated, intrinsically motivated, and in control of their lives—feelings which give rise to greater feelings of psychological empowerment (Zimmerman and Rappaport 1988). In contrast, holding the lay theory that feeling busy is bad causes the individual to focus on the stress, hassle, and inflexibility associated with busyness. Stressful situations narrow individuals' focus and deploy cognitive and emotional resources to deal with the immediate threat (LeDoux 1995) and lower feelings of empowerment (Mullainathan and Shafir 2013). Notably, we propose that even keeping objective busyness constant, holding one lay theory (feeling "busy=good") allows individuals to psychologically thrive, while holding the other (feeling "busy=bad") causes them to suffer. Moreover, because individuals who feel psychologically empowered are more likely to reach out to satisfy other people's needs (Erez, Mikulincer, van Ijzendoorn, and Kroonenberg 2008; Wilson 2012), we also propose that holding the lay theory that "busy=good" (vs. "busy=bad") should lead to greater volunteering.

Across five studies, we predicted and found that people are more inclined to volunteer when they hold the lay theory that feeling "busy=good" (vs. "busy=bad") and that this effect is driven by enhanced feelings of empowerment.

Using a correlational design, study 1a measured the valence of participants' busyness lay theory and their feelings of empowerment. Our findings reveal that people naturally hold different beliefs about the valence of feeling busy: Approximately 50% of participants believed the "busy=good" lay theory and 50% believed "busy=bad". As predicted, the "busy=good" lay theory was significantly positively correlated with feelings of empowerment.

In study 1b, participants' lay theories were manipulated by randomly assigning participants to listen to one of two ostensibly real science podcasts that discussed scientific findings that showed that feeling busy is good (vs. bad). Participants then responded to manipulation checks and reported feelings of empowerment (e.g. "I feel in control"). Analyses revealed that, as predicted, participants in the "busy=good" (vs. "busy=bad") condition felt significantly more empowered.

Study 2 used a different lay theory manipulation: an ostensibly real science magazine article that claimed either that feeling busy is good or bad. After reflecting on the article's findings by providing supporting examples from their own lives, participants responded to manipulation checks, reported their empowerment, and (in a purportedly unrelated survey) responded to a scenario-based measure of volunteering intentions (e.g. "How likely would you be to volunteer

your time to help at a senior citizens' home?"; Henderson, Huang, and Chang 2012). Participants in the "busy=good" (vs. "busy=bad") condition were significantly more likely to volunteer and felt significantly more empowered. The effect of busyness lay theory on volunteering intentions was mediated by feelings of empowerment.

Study 3 provided additional support for the mediating role of empowerment by manipulating both lay theories of busyness (as in study 2) and empowerment (by having participants recall a time they either did or did not feel empowered). We expected that when people hold the lay theory that feeling "busy=good," they already feel empowered and thus the empowerment manipulation should not influence their volunteering. However, when people believe that feeling "busy=bad," they feel disempowered and thus boosting their feelings of empowerment should lead to greater volunteering. As predicted, our analyses revealed that participants in "busy=bad" condition reported greater willingness to volunteer their time in the high (vs. low) empowerment condition, but participants in the "busy=good" condition were equally likely to volunteer across empowerment conditions.

Study 4 sought to conceptually replicate the prior effects of lay theory on volunteering using measures of real volunteering behavior. After completing the same lay theory manipulation from study 2, participants reported feelings of empowerment, and (in a purportedly unrelated survey) were given the opportunity to participate in at least one real volunteering event 1-2 weeks after the survey. Whether participants signed up for at least one event served our first measure of volunteering. Last, at the end of the experimental session, participants were asked to volunteer their time to assemble first-aid kits for families in need. Whether or not participants actually made at least one kit served as another measure of volunteering. The results revealed that participants in the "busy=good" (vs. "busy=bad") condition felt significantly more empowered, were significantly more likely to sign up for a volunteering event, and were significantly more likely to assemble first-aid kits. Further, empowerment mediated the effect of lay theory on both measures of volunteering behavior.

Taken together, our research elucidates the link between feeling busy and volunteering behavior; connects the lay theory, empowerment, and volunteering literatures; and offers firms and consumers a novel volunteering intervention.

Rethinking Time for Well-Being

EXTENDED ABSTRACT

In this conceptual paper, we examine the construct of time with the goal to improve how consumers think about and use time to advance consumers' well-being, not just in terms of happiness but in terms of health, financial well-being, and a deeper sense of meaning (Aaker 2014; Baumeister, Vohs, Aaker, and Garbinsky 2013; Mick 2006). To this end, we briefly review prior work on time in the consumer behavior literature, and document a predominantly dichotomized view of time, which assumes a stark distinction between the present and the future. We then find inspiration from three other domains (emotions, financial decision-making, and social relationships) where researchers have demonstrated the positive effects of treating their given domain in a more integrated way. Finally, we propose our new, integrated treatment of time and discuss one way consumers can adopt it – by taking a "bird's-eye" view of time where the future, present, and past become equally visible and thus subjectively relevant. From this perspective, events from different time points are treated and experienced as part of one's overall life and being.

Much Western psychology-based research on time reduces it to a linear construct placing the consumer as the center point (Gra-

ham 1981; Ji, Guo, Zhang, and Messervey 2009). From that point, the line is parsed between the past, present, and future. Investigating how consumers navigate the journey from the present to the future is of utmost relevance to behavior and decision-making (Seligman, Railton, Baumeister, and Sripada 2013). Thus, in an effort to understand time in a way that makes sense for consumers' lives, the way that we as consumers and researchers have come to understand time is largely through temporal dichotomies between the present and the future, or the near versus distant future. For example, the influential research on temporal construal dichotomizes time between the near and distant future to understand how viewing potential outcomes through either temporal lens affects consumers' judgments and predictions (e.g., Trope and Liberman 2010). Similarly, the research on intertemporal choice builds off the notion that consumers are perpetually choosing and making tradeoffs between the present and the future.

And yet, research from at least three domains speaks to the power of integrating across formerly bi-furcated categories. This work has shown that a more integrated approach leads to positive outcomes and enhanced well-being in the domains of (1) emotions (i.e., allowing for the experience of mixed emotions wherein oppositely valenced emotions co-occur; e.g., Larsen, Hemenover, Norris, and Cacciopo 2003), (2) financial decision making (i.e., when debt and savings are thought of as components of an overall goal; e.g., Sussman and O'Brien, in press), and (3) social relationships (i.e., when other people are included in the self-concept; e.g., Aron, Paris, and Aron 1995).

Here, we argue for a similar re-construal in the domain of time. Rather than pitting the present against the future, we propose a different lens on time: one that does not force a tradeoff between the two, and instead allows the present and future to co-exist. Our proposed rethinking of time wherein the present and the future are not dichotomized reflects the fact that the future will at some point be the present, and the present is perpetually shifting. As the writer Harriet Beecher Stowe anecdotally observed, "The past, the present and the future are really one: they are today." To take an example from biology, the genetic blueprint of butterfly wings exists inside the caterpillar, and the "spine" of the caterpillar continues to exist within the newly formed butterfly. This approach to time highlights that all pieces of one's time are equally relevant to one's existence. The present is ultimately important, not because it should be weighed more heavily than the future, but because it *is* the future (or will be at some point). And along the same lines, the future is ultimately important because in a way, it is contained within the present.

One way to utilize this re-conceptualization of time involves adopting a new perspective of one's time course, whereby individuals pull up and away from the ground-level linear trajectory where only the immediate present is visible, and instead assume a bird's-eye view where the future, present, and past are equally visible and subjectively relevant. Namely, we propose a rethinking of time that involves consumers mentally lifting up and away from that shackled temporal line, obtaining a view over one's time course such that moments and days and years in the future or past are equally visible and thus personally relevant. This approach is much like looking down on one's calendar, with the squares representing each day or month laid out alongside each other. Every equivalent unit of time is the same size and is equally visible, reflecting its equal importance. A day is the same size as any other day; it is not distorted by its proximity to the square representing the current day.

Lastly, we discuss three ways that this analogy might benefit well-being. First, by shifting decisions from *whether* one can do something to *when* one can do something, assuming a bird's-eye

view of time releases people from the cognitive and circumstantial constraints that previously kept them from spending time in personally important ways. Second, a bird's-eye view may help consumers act more patiently: if a future reward is equally visible to a more immediate reward, consumers will focus on actual differences in value between two rewards, and the temporal distance will become less relevant. Third, a bird's-eye view of time may boost meaning in life: past research has found that people who had an easier time simulating the past and future (measured both neurally and behaviorally) also reported greater meaning in their lives (Waytz, Hershfield, and Tamir 2015). Rather than needing to traverse great temporal distances in a linear fashion, a bird's eye perspective could prompt consumers to more nimbly mentally jump from one period of time to another, leading to elevated levels of meaning.

SESSION OVERVIEW

Consumers are surrounded with cues that emphasize the limited nature of resources. Given the pervasiveness of scarcity cues, consumer researchers have started to document the impact of resource scarcity on various aspects of consumer behavior, such as cognition (Laran and Salerno 2013; Mehta and Zhu 2016; Sharma and Alter 2012), motivation (Roux, Goldsmith, and Bonezzi 2015), attention (Mani et al. 2013), physiological responses (Sevilla and Redden 2014; Zhu and Ratner 2015), and decision making (Griskevicius et al. 2013).

Despite the recent findings demonstrating the linkage between resource scarcity and consumer behavior, we are still scratching the surface of the effects of scarcity. As an attempt to provide deeper insights into the range of scarcity effects on the consumption process, the four papers in the current special session illustrate the impact of resource scarcity on the following consumer decision making stages: need recognition, purchase planning, purchase decision, and post-purchase behaviors (Kotler and Armstrong 2004). Enhancing our knowledge of the interplay between resource scarcity and consumer decision making, these papers examine how various constraints influence consumers’ pursuit of rewards, planning, product choice, and word-of-mouth engagement.

The first two papers examine how resource scarcity shapes consumers’ need recognition and purchase planning. **Fan, Zhu and Jiang** show that the salience of resource scarcity stimulates consumers’ desire to demonstrate their achievement, which consequently spurs consumers’ effortful pursuit of rewards. **Mittal, Laran and Griskevicius** further find that when facing financial scarcity, people growing up wealthier tend to have higher self-efficacy beliefs, increasing the likelihood of the planning fallacy because of their underestimation of task time. The third paper by **Goldsmith, Tezer and Roux** reveals the impact of resource scarcity on consumer’s product choice. Specifically, they find that resource scarcity increases consumers’ interest in and willingness to pay for products that offer self-improvement related benefits. Finally, the fourth paper by **Paley, Tully and Sharma** examine the post-purchase behaviors under scar-

city. They argue that consumers with financial constraints reduce purchase-related word-of-mouth because of the decreased pleasure of discussing monetary outlays.

Taken together, the four papers in the current special session demonstrate the impact of resource scarcity on consumer behavior at various decision making stages. With an attempt to integrate the impacts of resource scarcity in consumer research, this session should appeal to a broad ACR audience interested in topics such as scarcity, consumer motivation, social sharing, planning, and consumer judgment and decision making.

Resource Scarcity Spurs Effortful Pursuit of Rewards

EXTENDED ABSTRACT

The face of human society is ever changing. As we mastered mass production, resource availability has emerged as the order of living in modern industrialized societies, starting to supplant scarcity (Côté 1993, 1996; Riesman 1950). Simultaneously, individuals’ drive to exert effort and achieve rewards has been a fundamental force propelling human society forward (McClelland 1961).

One question that arises is: how does the increasing resource availability in our society affect individuals’ effort exertion during the pursuit of rewards? More importantly, will activating a general sense of resource scarcity versus resource abundance lead to different level of effort tolerance? While extant literature has extensively examined the impact of resource availability on consumers’ cognitive performance (Mani et al. 2015; Mehta and Zhu 2016; Mittal et al. 2015), attention allocation (Mullainathan and Shafir 2013; Shah, Mullainathan, and Shafir 2012) and choice strategies (Griskevicius et al. 2013; Laran and Salerno 2013; Roux, Goldsmith, and Bonezzi 2015; Zhu and Ratner 2015), the motivational consequences of scarcity versus abundance on consumer effort exertion remains an intriguing, uninvestigated question. This issue holds significance as consumers are frequently exposed to contextual cues that may remind them of resource scarcity or resource abundance in daily lives, and such encounters can impact their motivational orientation and affect subsequent reward achievements.

The current research proposes that overall perception of scarcity versus overall perception of abundance increases consumers’ effort tolerance. We argue that this effect occurs because scarcity induces an achievement orientation in the reward-seeking process, i.e., the motivation by which individuals strive to be competent after effort inputs (Elliot and Church 1997). The activated tendency to seek achievement subsequently enhances consumers’ effort exertion during the pursuit of rewards. Our theorization is based on several separate streams of research suggesting that scarcity brings higher perceived constraints and deprives people’s sense of personal control (Lachman and Weaver 1998; Mittal and Griskevicius 2014), the feeling of achievement can potentially serve as a mean to restore personal control through the behaviour-outcome contingency (Heckhausen 1993; Seligman 1975), and that effortful process often provides a sense of value and competence (Aronson and Mills 1959; Norton, Mochon, and Ariely 2012; Weiner 1972).

In experiment 1, participants (N = 171) were asked to either recall three or four situations where they felt that resources are scarce or abundant (Fischhoff et al 2003; Mehta and Zhu 2016; Roux et al. 2015), or recall three or four things they did during the past week as a baseline control condition. Next, in an ostensibly unrelated task,

participants were asked to type some randomly generated 6-letter strings (e.g., “rlgows”) in the reversed order (e.g., “swoglr”). For each correct string typed, participants received a monetary reward and they were given a maximum of 3 minutes for the task. As expected, participants in the scarcity condition typed more strings and persisted longer in the task than those in the abundance and control conditions (No significant difference was found between the two).

Experiment 2 demonstrates that, rather than activating a general motivation to earn monetary incentives, scarcity only increases consumers’ intention to pursue rewards when the reward-seeking process requires effort exertion. We employed a 2 (scarcity vs. abundance) \times 2 (effortful vs. effort-free) between subject design ($N = 447$). After completing the same resource manipulation as experiment 1, participants indicated their intention to join a customer reward program. We manipulated effort perception by informing participants that they would need to call the customer service and provide a 10-digit validation code to the representative in order to receive a monetary rebate after each purchase (effortful condition), or that they would receive the monetary rebate after each purchase without any extra procedure (effort-free condition). Whereas participants in the scarcity (vs. abundance) condition indicated higher intention to join the effortful reward program, there was no significant difference across the two groups when the reward program was effort-free.

Experiment 3 provides direct process evidence by showing the mediating role of achievement orientation and the moderating role of consumers’ lay belief about the relationship between effort and achievement. After finishing the same resource (scarcity vs. abundance) recall manipulation as in experiments 1 and 2, undergraduates ($N = 209$) indicated their intention to join an effortful reward program provided by a chain coffee shop, which required consumers to download a smartphone app and enter a 10-digit validation code into the app to receive a future discount after each purchase. Consistent with our theorization, participants in the scarcity (vs. abundance) condition indicated higher intention to join the reward program, an effect mediated by achievement motivation and attenuated for those participants who did not believe that greater effort leads to greater achievement (Mirels and Garrett 1971).

Experiment 4 provides further process evidence by demonstrating the moderating role of self-affirmation through a 2 (scarcity vs. abundance) \times 2 (affirmation vs. control) between subject design. Participants ($N = 470$) first read a fictitious news article that highlighted either the scarcity or abundance of five natural resources, and wrote about how the article could be relevant to them and affect their personal life. Next, while half of the participants wrote about three or four positive aspects of themselves, or occasions in which they behaved positively (Blanton et al. 2001; the self-affirmation condition), the other half listed three or four features of their immediate environment (the control condition). Finally, all participants indicated their intention to join a customer reward program similar to the one used in experiment 3. As expected, participants in the scarcity (vs. abundance) condition indicated higher intention to join the reward program, a difference that disappeared when the participants’ sense of achievement was restored through self-affirmation.

The current research contributes to the existing scarcity literature by documenting a positive linkage between scarcity and consumers’ effort tolerance during reward-seeking. By systemically investigating the mechanism underlying this effect, this research also extends our understanding of achievement orientation in the marketing context. Further, our research offers rich practical implication for marketers in terms of how to better utilize the level of consumer effort embedded in their marketing activities.

Childhood Resource Scarcity and Planning Fallacy

EXTENDED ABSTRACT

25% of children in the U.S. live below the poverty line and 23% more can be classified as living in low-income households (Addy and Wight 2012). How does growing up in a world of resource scarcity affect people’s judgment and decision making? Previous research has predominantly found that growing up in resource-deprived conditions is associated with poor judgment and decision making. This paper suggests that this may not always be true.

We report results from three experiments showing that people growing up wealthier are more likely to exhibit a planning fallacy by underestimating the time it would take them to carry out future tasks. Additionally, consistent with recent research, the effects of childhood environment on planning fallacy were observed only under current conditions of financial threat. This suggests that the effects of childhood resource scarcity on people’s planning psychology may be dormant until they experience a threat later in life.

The goal of Study 1 ($N=138$) was to examine whether childhood resources influence people’s estimates of task completion times. Participants were randomly assigned to one of two conditions: financial threat or control. Those in the financial threat condition wrote three indicators that suggest the economy is becoming increasingly unpredictable and that resources are becoming scarcer. Those in the control condition wrote three indicators that suggest the economy is getting better and that resources are becoming abundant. Next, participants were informed that they would be seeing a piece of text on the next screen and that their task was to accurately count the number of times the letter ‘e’ appears in it. But before they started, they were asked to estimate the time they thought it would take them to complete the task. The number of seconds participants entered served as the dependent variable. Finally, a validated measure assessed participants’ level of childhood resource-availability (Rindfleisch et al. 1997).

Results from Study 1 show that people from different childhood environments had significantly different task completion estimates in response to threat ($F(1, 134)=13.46, p < .001$). As predicted, people who reported higher childhood resources estimated that it would take them a shorter time to complete the task especially in the financial threat condition ($\beta = -.26, p = .030$) but not in the control condition. This means that those from resource-rich backgrounds exhibited a planning fallacy during conditions of financial threat. No effects were observed for the actual time spent on the task.

Study 2 replicated the results of Study 1 using a consumer shopping task. Participants ($N = 141$) were randomly assigned to either a control or a financial threat condition as in Study 1 and were told that their task was to search and report the current prices for products on a ‘holiday shopping’ list from three popular retail websites: Amazon.com, Target.com, and Walmart.com. Before beginning the shopping task though, they were asked to estimate the time they think it would take them to do the task given that most people took about 325 seconds to do it (based on a pretest).

Results from Study 2 once again showed that people’s estimates of how long it would take them to complete the shopping task depended on resource availability during childhood as well as their current condition ($F(1, 137)=6.3, p = .013$). Further analysis confirmed that people with greater level of childhood resources estimated lower amount of time (planning fallacy) but only in the financial threat condition ($\beta = -.29, p = .016$). As predicted, there were no differences in actual time taken to complete the shopping task indicating that time estimates do reflect an error in judgment.

Study 3 investigated the psychological mechanism underlying the effect of childhood resource scarcity on planning fallacy. Considerable past research suggests that the tendency to have lower time estimates for future tasks (i.e. planning fallacy) occurs because of people's optimistic beliefs regarding their own abilities (Buehler, Griffin, and Peetz 2010; Kruger and Dunning 1999; Taylor and Brown 1988). Based on this work, we predicted that people from different socioeconomic backgrounds may have different estimates of task completion times because of varying levels of self-efficacy. Thus, we tested whether self-efficacy may be a psychological mechanism underlying this effect.

The procedures and materials for Study 3 ($N=152$) were identical to those used in Study 1. The only major change in Study 3 was the inclusion of an established measure of self-efficacy beliefs (Lachman and Weaver 1998). Results again showed that people from wealthier childhoods underestimated task completion times especially in response to financial threat ($F(1, 148) = 5.48, p = .021$), replicating findings from Studies 1 and 2. Furthermore, we also found a similar interaction for self-efficacy beliefs ($F(1, 148) = 6.57, p = .011$), such that participants from wealthier childhoods reported significantly higher self-efficacy in the financial threat condition ($\beta = .45, p < .001$) but not in the control condition. Finally, a 5000 resample bootstrap using PROCESS macro revealed an indirect effect of childhood resources and financial threat on time estimates via self-efficacy beliefs, $b = -3.08, 95\% \text{ CI } [-8.89, -.42]$, establishing statistical mediation.

Taken together, three studies showed that people from wealthier backgrounds underestimated the time it would take them to complete future tasks in response to conditions of threat, indicating a planning fallacy. Furthermore, mediation analyses showed that the reason for this effect is that facing financial threat changed people's perceptions of self-efficacy as a function of their childhood environment. People from wealthier backgrounds indicated greater self-efficacy in response to threat, leading them to commit a planning fallacy. These studies are among the first to show that growing up wealthy can have negative effects on consumers' judgment and decision making.

When Thoughts of "Having Less" Promote the Desire to Become One's Best: Reminders of Resource Scarcity Increase the Desire for Self-Improvement

EXTENDED ABSTRACT

Although a great deal of research has investigated how consumers make trade-offs between choice outcomes that offer comparatively utilitarian versus hedonic benefits (e.g., Dhar and Wertenbroch 2000), far less is known about the psychological antecedents of how consumers weigh self-improvement related benefits in their decision making (Allard and White 2015). The current research addresses this by examining how considerations of resource scarcity affect the desire for self-improvement and the relevant consequences for consumer decision making.

We draw from previous research demonstrating that reminders of resource scarcity promote the desire to advance one's own welfare (e.g., Aarøe and Petersen 2013; Durante et al. 2015; Roux, Goldsmith and Bonezzi 2015) to offer the novel prediction that considerations of resource scarcity will increase the desire for self-improvement, and accordingly will increase consumers' interest in and willingness to pay for products offering self-improvement related benefits. Indeed, products that offer self-improvement related benefits contribute to advancing one's own welfare through the improvement of one's relative standing (Sedikides and Skowronski 2000; Sedikides et al. 2006). Having superior qualities or skills can be considered as

a resource that an individual possess over others (Brock and Brannon 1992). Further, these types of resources can be particularly useful for the advancement of one's own welfare in contexts of heightened interpersonal competition (e.g., an economic recession; Durante et al. 2012; Griskevicius et al. 2012; Hill et al. 2012).

We tested our predictions in four experiments. Experiments 1 ($N=82$) first examined whether considerations of resource scarcity increase the desire for self-improvement. Participants in the scarcity condition were asked to recall times when they felt resources were scarce, whereas those assigned to the control condition were asked to list activities they did in the past week (Roux et al. 2015). Next, all participants completed a 4-item desire for self-improvement measure (Allard and White 2015). Finally, all participants completed a 4-item measure designed to assess their perceptions of scarcity (Roux et al. 2015). Participants in the scarcity condition showed an increased desire for self-improvement ($M_{\text{Scarcity}} = 2.45$ vs. $M_{\text{Control}} = 2.06; p = .04$). Further, participants' perceptions of scarcity mediated the effect of scarcity on the desire for self-improvement (95% CI = [.013; .396]).

Next, experiment 2 ($N=116$) tested whether the effect of scarcity on self-improvement carries over to product choice. Participants first completed the scarcity manipulation used in experiment 1. Next, participants were presented with a choice between two bottles of VitaminWater, one which was framed as offering self-improvement related benefits (i.e., improving mental performance) and one which was not (i.e., providing hydration; Allard and White 2015). Considerations of scarcity increased choice of the self-improvement related product ($P_{\text{Scarcity}} = 65.9\%$ vs. $P_{\text{Control}} = 46.7\%; p = .05$).

Experiment 3 ($N=170$) tested whether the effect of scarcity on the desire for self-improvement had implications for willingness-to-pay (WTP) using an incentive-compatible, consequential choice task (adapted from Becker, DeGroot and Marschak 1964). Participants first completed the scarcity manipulation used in studies 1 and 2. Next, participants were presented with a set of Post-it Notes, for which self-improvement benefits were either highlighted or not (adapted from Allard and White 2015). WTP was assessed using 20 binary choices, where participants had to indicate their preference between receiving the product they had been shown or a certain amount of money (\$0.10-\$2.00 in \$0.10 increments). Participants were instructed that, following the completion of the experiment, the computer would randomly select one of their choices and they would receive the option selected. Results showed an interaction between scarcity and self-improvement related benefits ($p < .01$). When self-improvement related benefits were highlighted, scarcity increased WTP ($M_{\text{Scarcity}} = \$0.73$ vs. $M_{\text{Control}} = \$0.47; p = .03$), but conversely decreased WTP ($M_{\text{Scarcity}} = \$0.43$ vs. $M_{\text{Control}} = \$0.56; p = .04$) when these benefits were not highlighted.

Experiment 4 ($N=81$) tested whether individual differences in desire for control (DFC; Burger and Cooper 1979) moderated the effect of scarcity on self-improvement. Prior research has shown that the desire for self-improvement is rooted in the desire to control future outcomes (Sedikides and Skowronski 2000; Sedikides et al. 2006; Trope, Gervy, and Bolger 2003), suggesting that the preference for self-improvement related benefits, following considerations of resource scarcity, should be accentuated (attenuated) for individuals that have a higher (lower) DFC. Participants first completed the 20-item Desirability of Control Scale (Burger and Cooper 1979). Next, scarcity was manipulated by asking participants to list things they would be unable to do if certain resources were unavailable (e.g., water; Roux et al. 2015). Participants in the control condition were asked to list things that they could do with the same resources. Finally, participants reported their likelihood of trying a smartphone application offering self-improvement related benefits (Allard and

White 2015). Results revealed that scarcity increased trial intentions ($M_{Scarcity}=5.07$ vs. $M_{Control}=4.26$; $p=.04$). Further, there was a significant interaction between scarcity and DFC ($\beta=.86$; $p=.014$), with scarcity (vs. control) increasing trial intentions for participants whose DFC score was 5.00 ($\beta=.38$; $p=.05$) and above.

In summary, across four experiments, we demonstrate that considerations of resource scarcity promote the desire for self-improvement, which in turn increases consumers' interest in and willingness to pay for products offering self-improvement related benefits. Although further research is necessary to fully understand the boundaries of these effects, this research provides an important step towards a better understanding of the specific desires that are instantiated in response to considerations of resources scarcity and their consequences.

Too Constrained to Converse: Financial Constraints Reduce Word-of-Mouth

EXTENDED ABSTRACT

Financial constraints are defined as the belief that one's financial situation restricts her desired consumption (Tully, Hershfield, and Meyvis 2015). Such constraints are prevalent and span multiple socioeconomic levels (Lusardi, Schneider, and Tufano 2011; Moore 2013), and researchers have demonstrated how such constraints impact a range of preferences and purchasing decisions. However, less research has examined whether financial constraints influence post-purchase behavior. In this work, we examine one form of post-purchase behavior that has been shown to greatly impact both consumers' future behavior and company performance: word-of-mouth.

Word-of-mouth (WOM) is the highest ranked source for trustworthy recommendations of products and services (Nielsen 2015). Accordingly, it is increasingly important for companies to understand factors that drive purchase-related WOM. In this work, we argue that financial constraints reduce the propensity to engage in WOM. Although it may be enjoyable for people to tell others about purchases they have made, we argue that the pleasure of discussing one's purchases is lessened when one feels financially constrained, because monetary outlays are less pleasant to discuss. Accordingly, we do not expect financial constraints to reduce consumers' likelihood of sharing in general. Instead, we expect this effect to be specific to one's monetary outlays (e.g., products they have purchased vs. received as gifts).

We demonstrate the predicted effect with consumers' real purchases using a range of purchase categories, measures of WOM, and audience types. Through both mediation and moderation, we provide evidence for the proposed process, while ruling out other possible accounts (e.g., impression management concerns, decreased interest in sharing in general).

In study 1, we assessed the relationship between WOM frequency and perceived financial constraints. In counterbalanced order, we measured participants' financial constraints using a 4-item scale. We also measured the frequency with which participants discuss both products and brands they buy. Participants who felt more financially constrained indicated talking less frequently about products they purchase, $b = -.248$, $t(398) = -3.81$, $p < .001$. They also reported having less frequent discussions about brands they buy, $b = -.330$, $t(398) = -4.89$, $p < .001$. This relationship emerged irrespective of whether participants indicated their financial constraints before or after reporting their frequency of purchase-related word-of-mouth.

In study 2, we explored the association between consumers' financial constraints and their decision to discuss their purchases in an anonymous online context. We created two real online chat rooms

and invited participants to engage with others about their purchases (vs. a pretested alternative topic: local/state parks). We measured participants' financial constraints using the 4-item scale from study 1 and then tracked their posting behavior. Results revealed that those who felt financially constrained were less likely to choose to post in the purchases chatroom, $b = -.186$, $SE = .082$, $p = .023$.

In study 3, participants first identified an upcoming discretionary purchase. Next, they were randomly assigned to one of two between-subjects conditions. They either reflected on the factors contributing to their financial constraints (financial constraint condition) or listed 10 facts they know to be true (control condition). Then, participants indicated their likelihood of engaging in WOM. As predicted, financially constrained consumers were less likely to engage in both online and interpersonal WOM about the purchase they mentioned, $F(1, 251) = 5.23$, $p = .023$. This effect was explained by reduced anticipated pleasure from discussing one's purchase, 95% CI [-.8788, -.1251] (Hayes 2013).

In study 4, we considered whether financially constrained consumers were less likely to share because they did not want to publicize unnecessary spending for fear of negative judgments from others. Therefore, we examined whether the proposed effect persisted for utilitarian purchases. Participants wrote about an upcoming hedonic or utilitarian purchase and then were assigned to one of the two financial constraint conditions from study 3. Although participants were more willing to discuss hedonic (vs. utilitarian) purchases, $F(1, 400) = 27.96$, $p < .001$, this effect did not depend on their level of financial constraints, $F < 1$. Critically, financially constrained participants were less likely to share regardless of purchase type, $F(1, 400) = 7.18$, $p = .008$. Participants in the financially constrained condition anticipated less pleasure from discussing their purchases. These feelings mediated the effect of financial constraints on reduced WOM, 95% CI [-.4843, -.0177], and other process accounts (e.g., self-presentation concerns) could not similarly explain the effect, $F_s < 1$.

We have proposed that financially constrained consumers are less likely to engage in word-of-mouth because of the reduced pleasure associated with discussing their monetary expenditures. If this effect is indeed a function of financially constrained consumers' aversion to discussing their monetary outlays, then our results should not apply to all word-of-mouth contexts. Instead, the effect should be specific to contexts in which participants are discussing their own monetary expenditures. Thus, study 5 followed a 2(financial constraint vs. control) x 2(product: purchase vs. gift) design. Conducted during the holiday season, all participants identified a future discretionary purchase and then imagined either purchasing that item or receiving it as a gift. They then received either the financial constraint or control manipulation. We expected that participants in the financial constraint and control conditions would be equally likely to engage in WOM about products received as gifts (vs. ones they purchased themselves). Results aligned with this prediction, $F_{interaction}(1, 852) = 5.85$, $p = .016$. Among those who imagined purchasing the item mentioned, participants in the financial constraint condition had lower posting intentions than participants in the control condition, $F_{purchase\ simple\ effect}(1, 852) = 9.85$, $p = .002$; however, the same difference did not emerge among those who imagined receiving the item as a gift, $F_{gift\ simple\ effect} < 1$.

In sum, we find that financially constrained consumers are less likely to engage in WOM for their purchases. This research is among the first to examine how financial constraints affect consumers' post-purchase behavior, and contributes to our understanding of the drivers of WOM. From a managerial perspective, it suggests that the extent to which companies can dissociate purchases from the costs spent, they may more effectively increase social media engagement.

SESSION OVERVIEW

Consumers often are actively voracious in their attention to cues fitting their momentary goals, sucking in relevant information. Yet, just as common is the contrasting situation, when external influences (such as by change agents) attempt to make inroads with consumers who have little motivation to comply. This session's papers present cutting-edge research aimed at identifying when, why, and how goal-directed efforts by consumers and external agents alike meet with success.

Two talks (Huang, Lteif) focus on features of goal-relevant environments that are differentially effective as a function of people's goals. Huang and colleagues took a fine-grained approach. They found that when consumers have an active goal, their basic perceptual processes change. Consumers are sensitive to features of goal-relevant objects that are particularly suited for their goal, thereby transforming the very meaning of objects to enhance the odds of goal attainment. Lteif and colleagues explored an increasingly common consumer goal setting — attempts to gain new skills or knowledge via self-learning. Using features of common smartphone applications (e.g., Duolingo, Luminosity), they found that consumers' entity versus incremental theories of self-change alter the effectiveness of learning cues. Consumers holding a chronic or temporary entity theory are motivated to learn and actually learn more when feedback details progress (e.g., number of tasks completed) than when providing proficiency feedback (e.g., skilled learned). Incremental theorists are motivated by and learn more when given proficiency cues.

The latter two talks (Trendel, Dallas) discuss persuasive attempts that prior literatures suggest would run the risk of being ineffectual at best or counterproductive at worst. Each finds how these approaches can in fact be successful. Trendel and colleagues studied corrective advertising and warnings about fraudulent brands as a vehicle to understand how to change implicit attitudes. In these cases, consumers lack intrinsic drives to change their attitudes about a brand; rather, a

third-party (e.g., U.S.'s Federal Trade Commission) seeks to make that change. They found that most common route of conveying information verbally (e.g., press releases) changes only explicit attitudes while leaving the implicit attitude unchanged — and thus positive. Images, though, are successful in changing both explicit and implicit attitudes, thereby making imagery the most powerful route to changing attitudes. Last, Dallas and Fitzsimons detail a surprising new route to getting through to recalcitrant consumers. Tightly-controlled experiments studying adults and a naturalistic field study of teens showed that allowing people to habituate to a message that would otherwise resist not only diffuses it of its reactance power — but can flip the typical effect and produce the desired behavior.

These talks will be of interest to scholars interested in changing consumer behavior, from goals scholars to those concerned with policy efforts. Together, they raise questions concerning how marketers can identify, ex-ante, when consumers possess relevant goals and when they do not, and how to create settings, applications, and messages that are efficient and effective at changing consumer behavior.

Motivated Construals: How Goals Implicitly Change Object Meaning

EXTENDED ABSTRACT

The last two decades of work in social and cognitive psychology suggests that the meaning of an object is extremely fluid and context-based (e.g., Aarts, Dijksterhuis, and DeVries 2001; Balcetis and Dunning 2006; Bruner 1957; Forster, Liberman, and Higgins 2005). Any given object has myriad features and memories associated with it, and people's understanding—or construal—of the object depends on which are most accessible in memory at the moment. Water, for example, can be construed in terms of swimming, bathing, drinking, or farming features. The particular features that end up populating a given construal then influence behavior toward the object. When people's construal of water happens to be based on its bathing features, for example, they should be less likely to use it to quench their thirst.

This fluidity in object construal has important implications for consumers' self-regulation. Our research shows that an individual's currently active goal implicitly constrains the meaning of objects in a way that makes him/her more likely to attain this goal. We also found that those with goal-driven construals showed more goal-facilitative behaviors. Together, our findings reveal a new route of motivated cognition: goals change the implicit construal of objects to be more goal-facilitative, which then increases goal-facilitative behavior toward those objects. In this way, what consumers want subtly transforms their mental assessment of the environment in a way that nudges behavior toward attaining their goal.

In Study 1, we tested whether activating a goal of fitness would change the implicit construal of tempting foods. We first manipulated the activation of the fitness goal between subjects using a scrambled sentence task. Participants then moved on to the second task—a lexical decision task, through which we measured the kinds of features most accessible for each of a series of tempting foods to capture participants' implicit construal of temptations. Specifically, the prime stimuli consisted of 5 temptation foods (chocolate, burger, chips, cake, and steak) or a nonsense stimulus (“zxcvbnm”). The targets consisted of features that were specific to each primed temptation

and were either typical and thus eating-related (e.g., for burger: juicy, hot, grilled) or atypical and thus eating-irrelevant (for burger: disk, round, and brown). We measured the time it took participants to categorize each target word as a real or non-word.

We submitted reaction times to a repeated-measures ANOVA with Prime (temptation, nonsense) and Target (eating-relevant, eating-irrelevant) as the within-subject variables, Goal Condition (fitness, control) as the between-subject variable, and reaction times to neutral target trials as a covariate to control for individual differences in responding. We found the hypothesized 3-way interaction between Goal Condition, Prime, and Target, $F(1, 69) = 8.77, p = .004, \eta_p^2 = .113$. Decomposing this 3-way interaction, we found a significant 2-way interaction between Target and Goal Condition for temptation primes, $F(1, 69) = 8.30, p = .005, \eta_p^2 = .107$, but not for nonsense primes. Specifically, for eating-irrelevant target words, participants were faster to respond in the fitness ($M = 519$ ms, $SE = 13.6$) versus control condition ($M = 567$ ms, $SE = 16.62$), $F(1, 69) = 4.88, p = .03, \eta_p^2 = .066$. For eating-relevant targets, however, participants responded directionally slower in the fitness ($M = 541$ ms, $SE = 8.34$) versus control ($M = 522$ ms, $SE = 10.1$) condition, $F(1, 69) = 2.15, p = .15, \eta_p^2 = .030$. As predicted, when participants' fitness goal was activated, they responded significantly faster on trials where temptations were followed by "eating-irrelevant" features, e.g., construing a burger as something round and brown instead of juicy.

We hypothesized that this motivated construal is goal-facilitative, which would discourage the consumption of unhealthy food. We tested this possibility in Study 2. We used the same 5 tempting foods as in Study 1, and directly manipulated whether those temptations were associated with eating-irrelevant features (or not) using a lexical decision task. For those in the "Eating-Irrelevant" condition, the 5 temptation primes were always paired with the eating-irrelevant targets in the 15 trials (e.g., burger-round), and the nonsense prime stimulus was always paired with the neutral targets. For those in the "Control" condition, the temptation primes were always paired with the nonsense targets, and the nonsense prime stimulus was always paired with the eating-irrelevant targets. We then measured participants' desire to consume these temptations. We found that for those who believed that these temptations were unhealthy (and thus wanted to reduce their consumption), they reported significantly lower likelihood of consuming the temptations in the eating-irrelevant condition ($M = 6.65$) than in the control condition ($M = 7.74$), $B = -1.10, t(109) = -2.92, p = .004$; associating temptations with eating-irrelevant features thus reduced their intent to consume these items. We did not find this effect among participants who believed that these temptations were healthy.

Study 3 used a similar paradigm as Study 2 but with a different goal—drinking water to quench thirst. Based on our hypothesis, when people think of water in terms of drinking-irrelevance such as bathing, farming, and swimming, they should be less likely to drink water. We first made half of the participants thirsty (by eating pretzels) and another half not thirsty (by eating cherry-tomatoes) under the cover story of snack tasting. Then we experimentally manipulated participants' construal of water by strengthening (vs. not strengthening) the association between water and drinking-irrelevant stimuli through a lexical decision task. We then measured participants' intake of water. We found that participants whose thirst was experimentally increased (vs. not thirsty) responded more slowly to pairings of water and drinking-irrelevant words, but did not respond differently to the control pairings. This suggests that thirsty people are less likely to construe water in terms of "irrelevant associations" that would discourage them from drinking it. In addition, exposure to these drinking-irrelevant pairings decreased thirsty participants'

actual consumption of water, compared with the control conditions. Therefore, changing the construal of an object influences the consumption of that object.

The Effect of Implicit Theories on Progress or Proficiency in Self-Learning

EXTENDED ABSTRACT

The marketplace has seen a proliferation of products, such as websites, fitness trackers, and smartphone applications that encourage consumers to engage in self-learning behaviors. These products often provide feedback that informs users about the extent of their self-learning, highlighting the extent of completion on the learning task (i.e., task-progress cues), or emphasizing performance and proficiency (i.e., task-proficiency cues). Examples abound. Duolingo, a language learning application, tells gives completion rates (e.g., language lessons per week), thus providing task-progress cues. Elevate, a cognitive training application, gives feedback on the specific skills users have learned, thus giving task-proficiency feedback. Still others, such as Luminosity, blend the two feedback cues. The two types of feedback seem to map onto differences in how consumers approach learning opportunities, namely differences in implicit theories of change.

We proposed that entity-theorists, who have performance-completion goals, view achievement situations as tests designed to evaluate their competence. Therefore, entity-theorists favor cues that allow them to document the adequacy of their abilities, and signal their positive traits. Incremental-theorists, in contrast, seek to improve their performance. They are driven by learning-goals, and view achievement situations as opportunities to increase their competence. Thus, we predicted that by enhancing their sense of accomplishment, task-progress cues help entity-theorists, while task-proficiency cues only help for incremental-theorists.

Study 1 investigated how learning behaviors of individuals with different implicit-theory orientations are impacted by task-progress cues. At the beginning of a semester, undergraduates ($n=104$) completed the Implicit-Theory Scale (Levy et al. 1998). As an extra credit self-learning task, students were asked to read four different marketing-related chapters and complete a brief assignment after each chapter. Students were allowed to submit quizzes at their convenience, but were given a recommended weekly schedule for submission dates. After submitting assignments, respondents received progress feedback stating how many assignments they had thus far completed. Number of assignments submitted on schedule served as a measure of their learning behavior. Results revealed that entity-theorists evaluated the extra credit assignment more favorably than incremental-theorists ($M_{ET} = 5.98, M_{IT} = 5.38, p < .001$). Importantly, more incremental (vs. entity) theorists adhered to the recommended schedule ($M_{IT} = 22.2\%, M_{ET} = 15.2\%, p < .05$) thereby demonstrating stronger learning behaviors.

Study 1 established that entity (vs. incremental) theorists possess a systematic preference for task-progress cues. Study 2 tested how self-learning behavior would be impacted by task-progress, task-proficiency, as well as mixed-cues. In a 2 (implicit-theory) \times 3 (cue: progress vs. proficiency vs. mixed) between-subject computerized study ($n=291$), participants were induced with either an entity or incremental orientation (Poon and Koehler 2006), and then completed a (fictitious) Morse code training course in four modules. After each module, respondents viewed task-progress cues (i.e., progress bar showing percent completed), task-proficiency cues (i.e., statements of skills learned), or mixed-cues (i.e., progress bars showing the skill learned). Participants then evaluated how much they liked

the product, and answered questions about the Morse codes; the number of correct answers measured performance. Results revealed that entity-theorists evaluated the product less favorably when given task-proficiency cues as compared to task-progress or mixed-cues ($M_{ET\text{-}proficiency} = 4.34$, $M_{ET\text{-}mixed} = 4.21$; $p < .05$; $M_{ET\text{-}progress} = 5.37$; $p < .001$). Incremental-theorists evaluated the product more favorably when they encountered task-proficiency (vs. task-progress) cues ($M_{IT\text{-}proficiency} = 5.55$, $M_{IT\text{-}progress} = 5.03$; $p < .05$). As anticipated, entity-theorists' product evaluations did not differ when they viewed task-progress or mixed-cues ($p = .09$). Incremental-theorists' evaluations were similar when they encountered mixed and task-proficiency cues ($p > .30$). Performance measures indicated that incremental-theorists' self-learning behavior was unaffected by any feedback forms, and entity-theorists' performance declined when under task-progress cues.

The objective of Study 3 was to identify conditions for when an individual's learning behaviors would be immune to the interactive effects of implicit-theory and feedback cues. In a 2 (implicit-theory) \times 2 (task-progress cue: present vs. absent) \times 2 (perceived task-difficulty: low vs. high) study, 220 participants were told that they would be learning to proofread. Implicit-theory was manipulated as in Study 2. After learning basic proofreading skills, participants in the difficult learning task proofread a chemistry article, whereas those in the low-difficulty task proofread a celebrity gossip article. Furthermore, half the respondents received feedback in the form of task-progress cues. Outcome measures were participants' evaluations of liking the task, and performance measures computed as the difference between number of typographical errors identified by respondents and actual number of errors. Results revealed that for the demanding task, entity (vs. incremental) theorists were less accurate when progress cues were present ($M_{ET\text{-}Cue} = -26.70$, $M_{IT\text{-}Cue} = -19.61$; $p < .05$), but not when absent ($M_{ET\text{-}no\text{-}Cue} = -19.11$, $M_{IT\text{-}no\text{-}Cue} = -19.48$; $F < 1$), thus suggesting that their self-learning behavior was less effective in the presence of task-progress cues. In contrast, incremental-theorists' performance was unaffected by the presence of task-progress cues ($F < 1$). A similar analysis on the task evaluation index revealed a three-way interaction among the predictor variables ($p < .05$), and a significant two-way interaction between implicit-theory and task-progress cues conditions ($p < .05$). In the presence (vs. absence) of task-progress cues, entity-theorists evaluated the task more favorably ($p < .001$), whereas incremental-theorists evaluated the task less favorably ($p = .07$). For the less demanding task, both theorists evaluated the task similarly regardless of the presence or absence of task-progress cues ($F_s < 1$).

In conclusion, the present research demonstrates that an individual's implicit-theory orientation is a critical determinant of the kind of product feedback cues that are most effective. In demonstrating these effects in a self-learning setting, this work has the potential to contribute to self-motivation, learning, and goal pursuit literatures.

Images Change Implicit Attitudes More than Text: Evidence from Corrective Advertising Attempts

EXTENDED ABSTRACT

The primary goal of marketing arguably is persuasion. Information aimed at changing attitudes is one of the most central and significant aims of marketing messages. Two basic routes by which marketers can convey their message are text or pictures, each of which have advantages and drawbacks. The current research compared the effectiveness of text versus image-based information in changing implicit (i.e., spontaneous, unintentional) attitudes using corrective advertising and product recall as contexts for our investigation.

Perhaps surprisingly, research on implicit attitude change has primarily examined responses to verbal information (see Gawronski and Sritharan 2010 for a review). Yet, images are a central component of marketing promotions in print, television, and online formats.

Furthermore, to our knowledge, studies on the effectiveness of text versus image-based information to attitude change have been limited to explicit, self-reported attitudes (Wyer, Hung, and Jiang 2008). Explicit attitudes are evaluative judgments about a target, whereas implicit attitudes are evaluative reactions that are automatically activated upon exposure to the target. Given that both attitudes independently predict behavior (Perugini, Richetin, and Zogmeister 2010), neglecting predictors of implicit attitude change means missing a potentially powerful influence of consumer behavior.

Based on the characteristics of visual imagery as well as dual-process theories, we expected image-based information to be particularly effective in changing implicit attitudes (Epstein and Pacini 1999; Sloman 1996). The rationales undergirding expectations that pictures will alter implicit attitudes better than text are anchored in the characteristics of visual imagery as well as dual-process theories. Visual imagery involves image-based representations in long-term memory that can be evoked without the original stimulus (Kosslyn, Ganis, and Thompson 2001). Dual-process theories and empirical findings point to System 1 — which underlies implicit attitudes — as better able to comprehend concrete, as compared to abstract, information (Epstein and Pacini 1999; Sloman 1996). Imageability (i.e., imagery-evoking aspects) and concreteness ratings of words share up to 72% of variance (Kousta et al. 2011).

The main hypotheses were that even when pictures and text lead to the same change in explicit attitudes, pictures are more effective than text in changing implicit attitudes. Further, our work sought to establish that pictures are superior to text because they produce visual mental images (i.e., visual imagery) of counterattitudinal valence. That is, pictures have the power to produce a representative scene in people's minds, replete with evaluative tags that can modify implicit evaluations. Furthermore, we aimed to show that text that can create visual imagery also can change implicit attitudes.

For all experiments, the counterattitudinal stimuli were extensively pretested to ensure equivalent levels of explicit persuasiveness (resulting in equivalent levels of explicit attitude change) between conditions. These tests were aimed at guarding against the concern that image-based information may be more influential in changing implicit attitudes because they are more persuasive as measured by explicit assessments. In all experiments, we also tested and found that text versus image-based information led to largely equivalent changes in explicit attitudes. A meta-analysis of all six experiments that compared imagery-based conditions to conditions that did not allow for visual imagery confirmed that there was not a significant difference in affecting explicit attitude change.

Six experiments tested the hypotheses. Experiments 1-4 used similar procedures. Participants first were given positive information (e.g., ads) about a novel brand, after which we assessed participants' implicit and explicit brand attitudes. Participants then were assigned to one of the counterattitudinal conditions (i.e., unfavorable pictures, unfavorable text, unfavorable imagery-provoking text), after which we reassessed participants' implicit and explicit attitudes toward the brand.

Experiment 1 tested and found support for the prediction that pictures and imagery-provoking text would change implicit attitudes better than would text, as well as that visual imagery valence would mediate the change in implicit attitudes. Experiment 1 also ensured that the order of the implicit and explicit measures did not influence the results. Experiment 2 replicated experiment 1's finding that pic-

tures change implicit attitudes more than does text, and found again that highly-valenced visual imagery accounts for the change. This experiment also extended experiment 1's findings by showing that instructions to imagine a scene were just as effective as seeing pictures in changing implicit attitudes.

Experiment 3 tested a boundary condition based on individual differences in visual and verbal information processing, and showed that the previous mediation of visual imagery valence is moderated by consumers' cognitive style.

Experiment 4 showed that when people do not possess clear mental images of a brand, seeing brand-relevant pictures produces vivid mental imagery, which in addition to the images' valence, mediated the effect of text-based versus pictorial counterattitudinal information on implicit attitude change. Experiment 5 also addressed, and ruled out, concerns that the hypothesized effects were due to different levels of affective reactions elicited by the counterattitudinal information.

Last, experiment 6 directly manipulated people's ability to visualize mental images. It found that a visual load task that prevented people's ability to engage in visualization also prevented implicit attitude change, whereas a cognitive load task did not affect implicit attitude change. This last finding supports the contention that System 1 (i.e., automatic processes) underlies implicit attitude change from pictures. Experiment 6 also replicated experiment 5's key findings that a visual load task hampered pictures' ability to alter implicit attitudes whereas a cognitive load task had no interfering effect.

In summary, imagery-based materials consistently changed both explicit and implicit attitudes, whereas non-imagery based materials changed only explicit attitudes. This work has the potential to fundamentally alter not only the effectiveness of warnings and product recall campaigns, but could enhance the capability of a variety of health messages or public service campaigns that aim to make powerful, fast, and enduring changes in consumer attitudes.

When Less is More: Counter-Attitudinal Appeals are More Effective When They Are Ignored

EXTENDED ABSTRACT

Changing behavior is no trivial task. From an early age, people learn that the world is filled with individuals and organizations that are interested in changing their behavior, be they family, friends, employers, advertisers, or governments. As a result, people become skeptical of persuasion attempts and develop a defensive machinery as children that is designed to actively resist such appeals (Friestad and Wright 1994). What is a well-intentioned persuasion agent to do to counter the often potent defensive response to their attempts to change a person's behavior, often in the best interests of that person? We suggest a novel and counter-intuitive path that can effectively "nudge" behavior change. We propose that when using a counter-attitudinal persuasion appeal, a subtle appeal that consumers are able to habituate to leads to greater behavior change. Accordingly, we suggest that the typical approach of using in-your-face, attention-grabbing persuasion appeals is less effective than more subtle appeals when the message is counter-attitudinal. This hypothesis builds on research demonstrating that habituation leads to decreased attention (Glanzer 1953), and that decreased attention can increase persuasion (Festinger and Maccoby 1964). We tested this hypothesis in three studies.

Study 1 tested whether habituation to a counter-attitudinal appeal increases its effectiveness. Undergraduate business students ($N=37$) were randomly assigned to either a habituation or non-habituation condition, and were exposed to a counter-attitudinal poster

criticizing capitalism. Participants in the non-habituation condition, who were given no time to habituate to the counter-attitudinal appeal, responded to the dependent variable immediately after viewing the poster, which was whether they were willing to provide their email address to receive more information about volunteering at a soup kitchen. We predicted that the counter-attitudinal poster criticizing capitalism would make participants defensive and supportive of capitalism, which would make them resistant to helping others for no economic gain. In the habituation condition, participants only responded to the dependent variable after completing an hour of unrelated studies, which gave them plenty of time to habituate to the counter-attitudinal poster (which was constantly in their peripheral field of vision). As predicted, a chi-square test revealed that significantly more participants in the habituation condition (38.89%) requested additional information about volunteer opportunities at the soup kitchen than participants in the non-habituation condition (5.88%; $X^2(1) = 5.40, p = .020$). Accordingly, people who had habituated to the persuasive appeal were significantly more likely to behave consistently with the appeal—by volunteering to help the needy without any economic gain—than people who had not habituated to the persuasive message.

In Study 2, we sought to rule out repeated exposure (Zajonc 1968) as an alternative explanation for our results. Specifically, participants in the habituation condition were exposed to the counter-attitudinal poster for longer before responding to the dependent variable than participants in the non-habituation condition, so it is possible that they consciously exposed themselves to the poster multiple times before responding to the DV, and that this repeated exposure led to increased behavior change. Thus, in this study, participants ($N=224$) were exposed to a counter-attitudinal poster admonishing city life and encouraging people to spend more time in the country (this study was completed by students in New York City) at the beginning of the study, and, in both the habituation and non-habituation conditions, they did not respond to the dependent variable (their likelihood to sign up for an outdoor education program) until the end of the hour session. However, right before responding to the DV, participants in the non-habituation condition were asked to look at the poster again, whereas participants in the habituation condition were not. Thus, both conditions had similar levels of conscious exposure to the poster, but only the non-habituation condition experienced dishabituation prior to responding to the DV. As expected, participants in the habituation condition ($M=4.03$) were significantly more likely to indicate that they would participate in the outdoor education program than participants in the non-habituation condition ($M=3.44; t(201)=1.98, p=.049$).

In the third study, we wanted to demonstrate the impact of habituation to a counter-attitudinal appeal in the real world. Accordingly, we partnered with a high school and placed a sign in its student center that warned students to not be late to school, and we tracked when tardy students arrived at school over the course of several months. We predicted that the poster would have no effect initially but, after students habituated to it, it would lead to a meaningful decrease in students' tardy behavior. We first tested whether the poster had an effect on lateness behavior and, as predicted, it did. Prior to the poster being hung, students who arrived late were, on average, over 33.63 minutes late to school whereas, when the poster was up, students who arrived late were only 14.85 minutes late for school, on average ($t(229)=2.64, p=.009$). A similar drop in lateness times did not occur for middle school students ($F(1, 301)=2.80, p=.096$), or for high school students the previous year ($F(1, 429)=3.96, p=.047$).

We next tested our main hypothesis—that the influence of the poster on lateness times increased over time as students habituated

to it. A one-way ANOVA revealed a significant effect of week ($F(2, 45) = 3.89, p = .028$), such that students who were late during the first week the poster was up ($M=26.60$) were significantly later than students who were tardy during week 2 ($M=12.47; p=.022$) or week 3 ($M = 14.29; p=.046$). However, there was no significant difference in lateness times for weeks 2 and 3 ($p=.831$). Once students habituated to the motivational poster (after week 1) and it faded into the background, it had a greater influence.

In summary, we have evidence that subtle counter-attitudinal persuasion appeals that consumers can habituate to may be an effective way to “nudge” behavior change among resistant consumers.

SESSION OVERVIEW

To make optimal choices and maximize happiness, consumers and firms must be forward looking: decisions made today should account for expectations about the uncertain future. For example, the utility people get from products and experiences depends on how much they will use them and the sequence in which they are enjoyed. Or the amount of time spent engaging in a task may depend on the cost of your time, an estimate of how long the task will take, and the expected benefits from task completion. Past research has documented numerous mistakes in decisions involving time, including neglecting duration in retrospective evaluations (Fredrickson and Kahneman 1993), mispredicting future enjoyment (Nelson, Meyvis, and Galak 2009), and misperceiving future slack (Zauberman and Lynch 2005). The current session adds to this literature by documenting four novel ways, across a variety of domains, in which forward-looking decision makers fail to maximize utility and monetary value.

Taken together, the four papers seek to address two questions: In what ways do consumers and firms inadequately incorporate the future into their decisions? What are potential monetary consequences of these forward-looking mistakes?

The first two papers specifically look at whether people anticipate temporal effects on consumption utility. Paper 1 (Friedman, Dhar, and Frederick) focuses on how consumers fail to spontaneously consider time and product usage when making purchase decisions, and therefore underweight the time benefits of each product. The authors demonstrate that when consumers are reminded to consider future usage of durable goods, they may increase their preferences for higher quality options. Paper 2 (Lu, Karmarkar, and Venkatraman) looks at binge-watching, which is encouraged by streaming services like Netflix. The authors show that when planning future consumption, consumers are willing to pay more to binge-watch, particularly if episodes are sequentially connected rather than independent with points of closure. These results run counter to prior research that suggests people would get greater utility from spreading consumption experiences out.

Papers 3 and 4 focus on the cost-benefit tradeoffs associated with forward-looking behavior. Paper 3 (Goswami and Urminsky) demonstrates through a series of incentive-compatible studies that managers often prefer flat-fee payment structures in cases where hourly payment would cost them less, because they overestimate the time that it takes for employees to complete tasks. As a consequence, they end up overpaying for services. Paper 4 (Reinhardt, Bartels, Levav, and Netzer) examines the amount of time consumers spend searching for good prices before purchase. The authors find consumer search behavior is inconsistent with economic incentives, which suggests consumers should search more when prices are more disperse. Instead, consumers use an economically-irrelevant heuristic: they search more when the prices are higher.

In summary, these four papers document situations in which people fail to optimize decisions involving time, either when weighing time within the utility function during choice or estimating how much time should be allocated to a task. The papers, taken together, illustrate specific limits of consumer and firm foresight and the costs—both monetary and hedonic—associated with them.

Putting Duration in Durable Goods: Length of Ownership Neglect in Consumer Choice

EXTENDED ABSTRACT

A long running ad for Acura assured potential customers that, *“Paying for quality can be a difficult decision at first, but over time it gets a lot easier to live with.”* In line with Acura’s assurances to prospective customers, we suggest that that premium products will be regarded as more affordable if the duration of ownership is emphasized – both because price premium can be amortized over repeated uses, and because quality differences aggregate with repeated uses. We demonstrate this pattern across a variety of durable goods. Moreover, we show that reminders of repeated use do not increase preference for premium products that are consumed in few sittings (like a bottle of wine) or used infrequently (like a holiday sweater).

Whereas previous research has explored duration neglect in retrospective evaluations (Fredrickson and Kahneman 1993), how considering the cost of time influences purchase decisions (Mogilner and Aaker 2009), or the role of the future self in purchase decisions (Bartels and Urminsky 2015), our research is the first to show how buying decisions shift when consumers are prompted to consider how long they will own the product.

We test our hypothesis in six studies. Studies 1A-C demonstrate that considering future usage increases choice of the higher price, higher quality option. All participants were faced with a choice between a higher priced and lower priced option (\$105 vs. \$195 digital cameras in 1A and \$24 vs. \$44 backpacks in 1B and 1C). Participants in the control condition simply made a hypothetical purchase selection, whereas participants in the future-use condition were first asked to briefly write about how long they expected to own the camera or backpack. Writing about length of ownership increased choice share for the expensive option versus control for both the cameras in study 1A ($M_{\text{control}}=64\%$, $M_{\text{future-use}}=79\%$, $p=.013$) and the backpacks in study 1B ($M_{\text{control}}=46\%$ vs. $M_{\text{future-use}}=60\%$, $p=.018$). Moreover, in study 1B, after choosing, participants were asked to explain why they made their decision. An analysis of the thoughts listed revealed that significantly more people wrote about usage over time in the future-use

condition than the control condition ($M_{\text{control}} = 7\%$ vs. $M_{\text{future-use}} = 22\%$, $p = .001$). In study 1C, we added a third choice elaboration condition, where participants were asked to elaborate on the choice to test whether the observed pattern results from mere elaboration, or specifically from considering future use. We also specified that both backpacks were expected to last five years, to show that the effect is driven by considering additional utility during a fixed time of ownership, and not because the more expensive option is perceived as lasting longer. As expected, participants bought the expensive backpack more often in the future-use condition than control ($M_{\text{control}} = 41\%$ vs. $M_{\text{future-use}} = 56\%$, $p = .010$), but there was no effect of elaboration ($M_{\text{control}} = 41\%$ vs. $M_{\text{elaboration}} = 44\%$, $p = .618$).

According to our theory, thinking about future use cues consideration of the cumulative benefits offered by each option, which increases preference for the higher quality option. However, for goods with no recurring streams of utility, such as consumable or infrequently-used goods, we expect thinking about future use should have no effect. We test this in studies 2 and 3. In study 2, we ran a pre-test to match a durable and consumable good on median price paid, and selected a bottle of wine and a cell phone case (\$15). We used a 2 (cell phone case vs. wine) \times 2 (future-use vs. control) between subjects design, for \$10 vs. \$30 in all conditions. As expected, more participants bought the \$30 cell phone case in the future-use condition ($M_{\text{control}} = 44\%$ vs. $M_{\text{future-use}} = 64\%$, $p = .007$). For the wine, there was no difference between conditions ($M_{\text{control}} = 21\%$ vs. $M_{\text{future-use}} = 23\%$, $p = .652$). In study 3, we used a 2 (frequently-used vs. infrequently-used good) \times 2 (future-use vs. control) design. Participants in the frequently-used condition evaluated two coffee makers, and those in the infrequently-used condition evaluated two ice cream makers, for \$39 vs. \$79 in both cases. For participants who chose between the coffee makers, significantly more opted for the higher priced option in the future-use condition than in control ($M_{\text{control}} = 42\%$ vs. $M_{\text{future-use}} = 56\%$, $p = .023$). For those who chose between the ice cream makers, there was no difference between conditions ($M_{\text{control}} = 55\%$ vs. $M_{\text{future-use}} = 52\%$, $p = .636$).

Finally, in study 4, we use a more subtle manipulation to increase the salience of future use: framing the choice as an investment. Since investments are thought of long-term purchases, we posit that using the word investment would be sufficient to cue considerations of future use. We used a 2 cell design (choice vs. investment), where participants chose between the same backpacks as study 1B. At the top of the page, there was a line that read, "Make a great [choice / investment] today!" The dependent measure also asked, "Which backpack would you [choose / invest in]?" As expected, more people chose the premium option when the choice was framed as an investment than when it was framed as a choice ($M_{\text{choice}} = 46\%$, $M_{\text{investment}} = 61\%$, $p = .015$).

The current research provides preliminary evidence that consumers often do not consider how long they will own the products when deciding between higher and lower priced alternatives, so they do not sufficiently recognize that the differences in benefits cumulate with repeated use. Making time or usage salient increases purchase of the higher priced option for goods that are used over time, but not for goods that are consumed or used infrequently.

Planning to Binge: How Consumers Choose to Allocate Time to View Sequential Versus Independent Media Content

EXTENDED ABSTRACT

Firms that offer streaming services like Netflix have embraced the phenomenon of "binge-watching" by offering entire seasons of a

television-style series at once instead of releasing episodes weekly. The prevalence of binge-watching seems to conflict with prior research suggesting that when individuals can choose to allocate their time, they often prefer to savor good experiences by delaying them (Loewenstein 1987; Shah and Alter 2014) or spreading them out (Loewenstein and Prelec 1993; Nelson, Meyvis, and Galak 2009).

One factor that could explain this clash is the degree to which these elements are seen as independent events, as in the savoring research, or as sequential progress towards a completion goal (Evers, Inbar, and Zeelenberg, Barasz et al., in press). Therefore, we hypothesize that binge-watching preferences may depend on the sequential nature of the individual episodes of an experience (i.e., episodes of a TV show) because of the additional utility from completing sequential or connected experiences, which we test across 6 studies and 1 set of field data.

In Study 1, we asked participants to either categorize TV shows as independent or sequential, or by the likelihood to binge or watch episodes one-by-one ($N = 120$). We found a significant positive correlation ($r = 0.61$, $t(58) = 5.86$, $p < 0.001$) between the percentages of participants who categorized the show as sequential ("Sequential Index") and binge-watchable ("Binge-Watch Index"), which provides preliminary correlational evidence in support of our hypothesis.

In Studies 2 and 3, we directly manipulated the perceived independent or sequential nature of the programming using descriptions of fictional TV shows. In Study 2, participants ($N = 682$) indicated the number of sessions they would want to complete the series, with fewer sessions corresponding to more binge-watching. In the sequential condition, participants planned to binge-watch more by choosing fewer sessions ($M = 5.52$, $SD = 3.33$) compared to the independent condition ($M = 6.16$, $SD = 3.46$, $F(1, 676) = 6.57$, $p = 0.01$). In Study 3, we replicated the results with participants ($N = 192$) creating a 5-day calendar schedule for watching the TV shows. Participants in the sequential condition ($M = 0.45$, $SD = 0.16$) created significantly "clumpier" calendars (Zhang, Bradlow, and Small 2014) than those in the independent condition ($M = 0.35$, $SD = 0.18$, $F(1, 190) = 87.19$, $p < 0.001$).

In Study 4, we demonstrated that people were also willing to pay more for the opportunity to binge-watch more sequential content. Participants ($N = 218$) imagined they were planning to watch a fictional show on Amazon Video for \$20, with the episodes released one-by-one each week. Participants were willing to pay more ($M_{\text{diff}} = \$1.55$, $SD = 7.03$, $F(1, 108) = 5.58$, $p = 0.02$) to have all episodes be made available at once for the sequential (vs. independent) content, which would enable them to binge-watch immediately.

In Study 5, we test for evidence of completion utility for sequential TV shows by looking at how the perceived quality, as measured by the IMBD episode ratings, changed across seasons. We found a significantly positive relationship between rating change and the Sequential Indices from Study 1 ($\beta = 0.22$, $t = 2.72$, $p < 0.01$), suggesting that the audience may experience utility from completion for sequential shows over time. However, it is important to note that firms could be strategically designing more sequential shows to progress climactically.

In Study 6, we directly test for evidence of completion utility by measuring the enjoyment (7-point Likert scales) of independent vs. sequential videos at two separate time points within an incentive-compatible setting. We found that when participants ($N = 279$) watched two related sequential videos, their enjoyment significantly increased after watching the second video (and thus "completing" the video series) if they binged the content by not taking a break ($M = 5.84$, $SD = 1.38$, $t(96.71) = 2.91$, $p < 0.01$), but not if they savored by taking a break in between the first and second videos ($M = 5.52$,

SD = 1.82, $t(85.43) = 1.55$, $p = 0.12$). We found no differences in enjoyment among participants who watched the independent videos.

Finally, we tested the robustness of these findings in a set of field data. We examined the activity of 553 students enrolled in two online courses offered on Coursera: Marketing and Accounting. Marketing was taught over 4 weeks by three professors, and consisted of 34 lectures, with each week's content independent of the content of other weeks. Accounting was taught over 4 weeks by a single professor and consisted of 29 lectures. Each week, the material built on the lectures from the previous week and contributed to an overarching case study. We predicted that students would be more likely to binge-watch the sequential Accounting lectures compared to the more independent Marketing lectures.

We calculated the average time between "sessions" of lecture video consumption, defined as lecture videos watched within 15 minutes of each other. Greater inter-session times indicate more savoring and less binge-watching. On average, students waited 43.09 minutes (SD = 144.88) more between sessions for the more independent Marketing course compared to the more sequential Accounting course ($t(519) = 6.78$, $p < 0.001$). This suggests that when taking a course with independent content, students are more likely to savor and spread sessions out compared to when taking a course with more sequential content. We also found that across two weeks when the courses overlapped, session lengths increased significantly for the Accounting course ($t(514.73) = 3.01$, $p < 0.01$), but not for the Marketing course ($t(312.86) = 0.37$, $p = 0.71$), which is consistent with our hypothesis that consumers prefer binge-watching sequential content because of the utility derived from approaching completion.

In summary, we find that consumers prefer to binge-watch experiences consisting of sequential episodes compared to independent episodes. This may occur because for sequential episodes, consumers derive enjoyment from making progress and completing a sequence. Our findings have implications for how firms should advertise and release shows with sequential vs. independent content.

Don't Fear the Meter: How Time Limits Bias Employment Contract Choices

EXTENDED ABSTRACT

Prescriptive models of cost-benefit analysis assume that decision makers can either accurately estimate relevant inputs, such as managers estimating workers' time, or can at least estimate an unbiased probability distribution of the time needed (Sugden and Williams, 1978). We study how choices between flat-rate and metered compensation options may be non-optimal due to the impact of deadlines on managers' timing estimates. We contribute to a recent literature on flat-rate biases, by identifying a new misestimation-based process, distinct from prior research, which affects preferences for flat-rate contracts with implications for choices in both employment and consumer contexts. Across six studies, we find that both lay people and experienced managers, playing the role of employers in an economic game, exhibit a strong preference for flat-fee contracts, particularly when deadlines are longer.

For the first set of studies, we had a sample of 113 workers solve a digital jigsaw puzzle, under either a long time limit (15 minutes) or a short time limit (5 minutes), and the workers were paid either a flat fee, or per-minute. In Study 1, online participants (N=171) served as "managers", and made incentive compatible choices between hiring a worker, from the pool, with a flat-fee contract or a per-minute contract. Based on the worker's actual completion times, the per-minute contracts had significantly higher expected value than the flat-fee contracts ($p < .001$), particularly for the longer time-limit condition.

Nevertheless, the majority of managers (71%) chose the suboptimal flat-fee contract. In particular, managers were more likely to choose the flat-fee contract under the long-time limit (89%) than the short time-limit (51%, $p < .001$), leading to lower earnings in the long time-limit condition ($p < .001$).

This occurred because managers over-estimated workers' completion times (Goswami and Urmitsky 2016), more so in the long time-limit condition than the short ($p < .001$). In fact, most managers (87%) chose the contract that would be optimal based on their time estimates. The time estimates fully mediated the effects of time limit on contract choices. In contrast, participants' choices differed in a risk-preference task (choosing between a fixed payment and a gamble) constructed to be equivalent to the contract options ($p = .041$ overall, $p < .001$ long time-limit condition), which rules out a risk aversion explanation. In fact, the effects of deadlines on contract choice held controlling for risk preference.

Study 2 (N=146) replicated these results in a study in which online participants serving as managers made similar contract choices for hiring a set of 50 workers (rather than just one, as in Study 1). Study 3 (N=178) again replicated the results in a variation of the manager task in which the managers knew that they had been *randomly* assigned to one of the two deadlines (long or short) in order to eliminate potential information conveyed by time limits. Lastly, Study 4 replicated the findings with a sample of experienced managers (N=92).

In the second set of studies, we used a spelling proofreading task, in which, unlike the jigsaw puzzles, the quality of the completed work could potentially vary. Workers (N=429) completed either an easy or difficult proofreading task under short or long time limits and were either paid a flat-fee or per-minute. In Study 5, a set of online participants serving as managers (N=438) then made incentive-compatible choices between hiring a worker paid a flat-fee or per-minute, in which their payment was determined by both how much time their worker took and how accurate the worker's job was. Based on the actual workers, the expected value was higher for the flat fee contracts under either time limit ($ps < .001$), but more so for the long time-limit condition ($p = .04$). Managers nevertheless preferred the flat-fee contract, particularly in the long time-limit condition (83% vs. 44%, $p < .001$), regardless of task difficulty. Because the per-minute contract was in actuality even more profitable in the long time-limit conditions, the managers' choices were more suboptimal in the long-time limit conditions (easy task, difference $p = .013$; difficult task, difference $p = .022$).

These findings were due to managers' overestimation of workers' completion times, especially in the long time-limit condition. In fact, the time estimates explained the contract choices of the majority of managers (77%), and the estimates fully mediated the effect of time limits on contract choices. Participants' contract choices differed from their preferences in the equivalent risk-preference task ($p < .001$), and the results held controlling for risk preferences. The findings were also not explained by differences in beliefs about worker productivity, taking task quality into account, under the different contracts. The findings were replicated in Study 6 (N=62) with a sample of experienced managers.

Prior research has documented flat fee biases for ongoing service usage, where decision makers are shown to prefer a fixed payment schedule for unlimited usage of telephone minutes (Train et al., 1987) and gym access (DellaVigna and Malmendier, 2006). Such preferences have been attributed to risk aversion (Lambrecht and Skiera, 2006), cognitive ease (Nunes, 2000), or the motivational benefits of pre-commitment. In this paper, we document a parallel bias in a new domain, which cannot be explained by any of these

factors. Specifically, we find that decision makers prefer a fixed payment when hiring temporary workers and we provide evidence that this is due to misestimating completion time. Salient environmental cues like external time limits can systematically affect decision makers' judgments about others' task completion times, resulting in the erroneous preference for flat fee contracts, yielding significant economic losses and inefficiencies.

Our research provides a counterpoint to prior work on employment decisions, which has emphasized the role of rational factors (e.g., ease and cost of monitoring, uncertainty in the environment, workers' type) in contract choices. These findings may provide a starting point for also investigating other belief-based biases that can influence general choices between contracts under incomplete information in consumer contexts.

Variance Neglect in Consumer Search

EXTENDED ABSTRACT

Consumers often know exactly what they want, but are not sure how much they will have to pay to get it. In these situations, a consumer must search to find an acceptable price for the product or service they are seeking. Because the exact same product can vary in price greatly between retailers (Baye, Morgan, and Scholten 2004; Brynjolfsson and Smith 2000; Isard 1977; Varian 1980), a consumer can probabilistically expect to find a better price by visiting more retailers. However, there are diminishing returns to search. The more retailers a consumer has visited, the less likely the next retailer she visits will have a better price than one she has already seen. There is also a cost to extending search. This cost may simply be time (opportunity costs), but could also be monetary if, for example, searching requires travel. Essentially, the problem of search is whether to accept a known cost of search for the probabilistic prospect of a marginal gain in terms of price.

Normative models of consumer price search uniformly agree that price dispersion—the variance in prices across retailers—should be the primary determinant of search persistence (e.g., McCall 1970; Rothschild 1974; Weitzman 1979). When price dispersion is higher (i.e., greater absolute differences between prices), consumers should search more extensively because the expected marginal return from additional search is greater. We use an experimental paradigm to explore whether consumers follow this economic prescription. Across a series of studies, we find that contrary to the implications of economic models, consumers do not search more when price dispersion is higher. In fact, when price dispersion is higher, we frequently observe consumers searching less. Additionally, we find that the magnitude of prices—whether a product is cheaper or more expensive—influences search persistence even though it is unrelated to the expected marginal return from additional search.

In our studies, we use a simplified, computer-based experimental paradigm in which participants are asked to find a “good” price for a specific product (i.e., there is no variation in quality, only price). They can “visit” retailers by clicking a button and incurring a cost (a three second delay) and can stop search at any time by selecting a previously seen price without cost. We measure search persistence as the number of retailers a consumer visits before making a purchase. Prices in our studies are randomly drawn from Gaussian distributions. To measure the effects of price dispersion and price magnitude, we vary the standard deviation and mean of the price distributions, respectively.

In Studies 1 (hypothetical) and 2 (incentive compatible), we present evidence of “variance neglect”: Consumers fail to increase their search persistence in response to increased price dispersion. In

fact, they search less when price dispersion is higher—the exact opposite behavior prescribed by normative search theories. Further, in these studies, we find consumers search more when the average price of the product is higher (holding price dispersion constant). Normative models suggest that price magnitude should be an inconsequential factor in determining search persistence.

While these findings may trouble those who believe regular people can approximate the economic behavior prescribed by rational actor models, we suggest that they may be evidence for how boundedly-rational people “solve” the complex problem of search. The previously described studies orthogonally manipulate price magnitude and price dispersion. But in the marketplace, these two variables exhibit high correlation (Grewal and Marmorstein 1994; Pratt, Wise, and Zeckhauser 1979). Thus, searching more for higher priced items could be an ecologically rational heuristic, since higher price items tend to have higher price dispersion.

Our proposition is that consumers learn to use average price instead of price dispersion as a cue for search persistence. While this heuristic will not fully approximate optimal search, we believe it is more cognitively tractable for boundedly-rational consumers. This is supported by research on numerical cognition, which shows people can more accurately learn about the central tendency of an observed distribution than they can learn about the dispersion (Obrecht, Chapman, and Gelman 2007, Peterson and Beach 1967).

In Study 3, we show that consumers indeed expect higher price dispersion for higher prices, suggesting they are capable of hypothesized inference process. In fact, they are quite accurate based on previous surveys of the marketplace. Further, in Study 4 we show that the strength of this belief predicts differences in search persistence: People's beliefs about the price-magnitude/price-dispersion relationship are a significant predictor of their search persistence.

Although inferring price dispersion from price magnitude will frequently yield results consistent with normative theory, it can also lead to over-persistence (when high priced products have low price dispersion) and under-persistence (when low priced products have high price dispersion). In Study 5, we examine cases in which the hypothesized consumer inferences should be more or less accurate. We find that when the price magnitude-dispersion relationship matches consumer beliefs, search behavior looks normative. However, when the magnitude-dispersion relationship violates consumer beliefs, consumers fail to update their expectations and respond in a manner opposite to that suggested by normative models.

Gülen Serial-Abi, University of Bocconi, Italy

SESSION OVERVIEW

Is less always more, when it comes to assortment size? Do consumers always prefer well-organized assortments? Can contextual factors overcome extremeness aversion? Despite an abundance of literature in the area of product assortments, the answers to these questions remain contentious. As such, four papers in this session address these questions. In particular, although much is known about the consequences of assortments (e.g., Chernev, Böckenholt and Goodman 2015, Iyengar and Lepper 2000; Mogilner, Rudnick and Iyengar 2008, Simonson 1989), we know much less about what influences consumers' preferences for assortments with different features. These four papers look at situational factors (e.g., processing mindset, global context of the assortment, and shopping motivation) to show how these factors influence the way consumers evaluate assortments of different features and, ultimately, their product selection and decision quality. In doing so, this session provides crucial insight into consumers' evaluation of and reaction towards assortments.

The first two papers speak to how different factors influence the preference for assortment size. Dellaert, Häubl, and Wei demonstrate that consumers prefer smaller assortments in a choice mindset than in a search mindset. Consequently, being in a choice (vs. search) mindset increases choice deferral and reduces decision quality in a large (vs. small) assortment. Employing a different approach, Wu and Gu demonstrate that abundance salience can increase the appreciation of a small assortment by boosting the feeling of control, which offsets the disadvantage of a small set. Consequently, consumers prefer small assortments over large assortments under abundance salience.

Alongside with the discussion about evaluating assortments, Tao and Gao focus on the how an assortment is displayed. Counter to the intuition that a well-categorized assortment tends to benefit consumers, they demonstrate that when the shopping activity is not task-oriented and when it is positively perceived by consumers, a randomly displayed assortment can also lead to more favorable evaluations by eliciting arousal, which intensifies feelings of pleasure.

Moreover, the contextual information of an assortment can also influence the appreciation of it. Hamilton, Urminsky, and Serial-Abi show that a global context (e.g., the reputation of a retailer) can change the evaluation of a local choice set, making the extreme alternative (e.g., the cheapest one) seem more like a compromise option hence reducing extremeness aversion.

In summary, these four papers share a focus on investigating how various situational factors influence the preference for and evaluation of assortments with different features. This session enriches the understanding of product assortments. Consumers prefer a small assortment over a large one when they are in a choice (vs. search) mindset (Dellaert et al.) or when the concept of abundance is made salient (Wu and Gu). And consumers enjoy a consumption experience more in a randomly display assortment (Tao and Gao). Further, the global context of an assortment can reduce extremeness aversion (Hamilton et al.) The complementary findings of these four papers gain new insights into understanding the preference and evaluation of product assortments with different features and provide counter-intuitive ideas for marketers to enhance their assortment attractiveness.

Choice vs. Search Mindsets and Consumers' Assortment Size Preference

EXTENDED ABSTRACT

Normatively, large assortments should increase the likelihood that consumers can identify their ideal alternatives relative to small assortments (Baumol and Ide 1956; Chernev 2003; Kahn and Lehmann 1991) However, some detrimental consequences (such as choice overload) for consumers when choosing from large assortments are also well documented in the literature (Iyengar and Lepper 2000; Chernev, Böckenholt and Goodman 2015). Despite the substantial amount of prior work on how assortment size affects consumer choice, little is known about what size of assortment consumers would actually prefer for a given purchase decision, and the limited findings to date are mixed (Broniarczyk, Hoyer and McAlister 1998; Chernev 2006).

The present research introduces consumers' choice versus search mindset as an important driver of consumer assortment size preferences. In a *choice mindset*, consumers focus on evaluating alternatives already known to them, and on making comparisons among these alternatives. By contrast, in a *search mindset*, consumers focus on what alternatives they have yet to discover, and on assessing the attractiveness of each individual alternative as they encounter it. These two mindsets are closely connected to the typical task that a consumer faces when making a product choice among a relatively small, predetermined set of alternatives (e.g., buying a grocery product) versus when searching for a product to purchase in a large and relatively unfamiliar category (e.g., booking a hotel in a new city). We suggest that these mindsets can be activated by procedural or situational aspects of the decision process (e.g., whether alternatives in the assortment are presented simultaneously or sequentially, or whether a decision task suggests a choice versus search process to the consumer). Based on the distinct properties of these mindsets, we hypothesize that consumers prefer smaller assortments when they are in a choice mindset and larger assortments when they are in a search mindset.

In our first set of studies (Studies 1a and 1b and Study 2), we examined how a choice versus search mindset affects consumers' assortment-size preferences. In Study 1a, participants ($N=126$) indicated how many alternatives they would like to "choose from" versus "search for" (between-subjects) in five different product categories. Participants in the search mindset preferred more alternatives than participants in the choice mindset across all five different product domains ($p < .001$). In Study 1b ($N=177$), we replicated this effect ($p < .001$) by manipulating choice versus search mindset through descriptions of the decision interface. In the choice condition, participants envisioned having all alternatives presented simultaneously in one large table; and in the search condition, participants envisioned having all alternatives presented sequentially (one at a time), without the opportunity to revisit alternatives.

In Study 2 ($N=196$), we replicated the influence of choice versus search mindset on consumer preferences for assortment size in a highly naturalistic setting, across 50 different product categories. For each product category, we asked participants to indicate whether they would be more likely to employ a "choice" or "search" strategy when selecting a product. We also asked participants how many alternatives they would like to see to identify their preferred alternative. As hypothesized, a search (versus choice) mindset significantly predicted a higher preference for larger assortments ($p < .001$).

Next, in the second set of studies (Study 3 and Study 4), we examined the downstream consequences of a choice mindset versus search mindset in terms of purchase deferral and decision quality in differently sized assortments. In Study 3 ($N=453$) participants received \$0.20 as a bonus pay and could choose to keep it or to use it to buy a lottery from an assortment of 6 (small assortment condition) or 30 lotteries (large assortment condition). In the choice mindset condition all lotteries were presented simultaneously in a table, while in the search mindset condition, they were presented sequentially, one at a time, without the opportunity to revisit alternatives. Moreover, this experiment also introduced an intermediate condition in which participants were presented with alternatives sequentially, but could revisit any alternative that they had already inspected. Thus, Study 3 employed a 2 (assortment size: small vs. large) by 3 (decision strategy: choice vs. search vs. intermediate) between-subjects design. The results showed a significant interaction between decision strategy and assortment size on choice deferral rate ($p=.012$) and objective decision quality – the expected payoff of selected lotteries in cents ($p=.011$). In the choice mindset, a small assortment decreased choice deferral (22.7% vs. 33.3%; $p=.013$) and increased objective decision quality ($M_{\text{Small}}=27$, $M_{\text{Large}}=25$; $p=.033$), while in the search mindset, a small assortment increased deferral (51.4% vs. 35.9%; $p=.024$) and decreased objective decision quality ($M_{\text{Small}}=24$, $M_{\text{Large}}=26$; $p=.05$). Assortment size did not affect choice (29.7% vs. 32.5%; $p=.74$) nor objective decision quality ($M_{\text{Small}}=27$, $M_{\text{Large}}=26$; $p=.13$) in the intermediate condition.

In Study 4, participants were asked to select an apartment with the lowest rent per square foot (no choice deferral allowed). Study 4 employed the same design as Study 3, and extended the finding of an interactive influence between assortment size and mindset from objective decision quality – rent per sf of selected apartments ($p=.006$) to subjective decision quality -- decision satisfaction ($p < .001$). Increased assortment size decreased both objective ($M_{\text{large}}=1.93$ vs. $M_{\text{small}}=1.89$; $p=.020$) and subjective decision quality ($M_{\text{large}}=7.58$ vs. $M_{\text{small}}=8.72$; $p=.002$) in the choice mindset, and increased objective ($M_{\text{large}}=1.94$ vs. $M_{\text{small}}=1.97$; $p=.033$) and subjective decision quality ($M_{\text{large}}=6.40$ vs. $M_{\text{small}}=5.28$; $p=.003$) in the search mindset. Again, no effect was found in the intermediate condition (objective: $p=.33$; subjective: $p=.12$).

This research shows that consumers' assortment-size preference depends critically on whether they approach a purchase decision in a choice mindset or a search mindset. Consumers prefer smaller assortments when they are in a choice mindset than in a search mindset (Studies 1a, 1b and 2). Moreover, consumers' choice versus search mindset also affects choice deferral and decision quality in differently sized assortments (Studies 3 and 4).

The Role of Abundance Salience in Consumers' Assortment Preference

EXTENDED ABSTRACT

In the marketplace retailers often pride themselves on their large product assortments to their customers even at the expenses of increasing operational costs. However, recent research shows that although consumers generally prefer larger product assortments (e.g., Iyengar and Lepper 2000), there does not exist a positive relationship between assortment size and category sales (Broniarczyk et al. 1998; Chernev 2003b). To offset these disadvantages of having large assortments, the current research examines whether abundance generates the benefits that would substitute for the advantages offered by a larger assortment. Will consumers like the smaller assortment more when the product inventory is abundant (vs. baseline), or in general, when they are put in an abundant mindset?

Most prior research on product supply focuses on whether the scarce availability of a particular product in a given assortment impacts consumers' evaluation of the product (Gierl and Huettl 2010; Inman, Peter and Raghurir 1997). Relatively little research in marketing has examined whether and how abundant product supply impacts consumers' choices among assortments prior to selecting a particular option from one of the available assortments. Building on prior literature that consumers prefer large (vs. small) assortments because large assortments satisfy the need for control (Averill 1973; Lefcourt 1973; Zuckerman et al.1978), and a possible link between abundance and a replenishment of control (Mehta and Zhu 2015; Mittal and Griskevicius 2014; Vohs, Mead and Goode 2006), we propose that abundance boosts feelings of control, consequently increasing consumers' relative preference for smaller (vs. larger) assortments. We tested these propositions in four studies.

Study 1 employed an incentive-compatible test to examine our main proposition that abundance increases consumers' evaluations of small (vs. large) assortments. Participants ($N=290$) were provided with toothpaste catalogs from two supermarkets. To manipulate abundance, half of the participants read that both supermarkets had great quantities of each type of toothpaste and they were always able to get the toothpaste listed on the catalog ("abundant-condition"), while the other half read that the toothpastes listed on both catalogs may or may not be in stock ("baseline-condition"). Participants were then told that the two catalogs had 24 and 48 options, respectively, and were asked to select one catalog to choose a tube of toothpaste from. To make the decision consequential, participants were informed that 50% of them would win the toothpaste they chose. As predicted, more participants in the abundant (vs. baseline) condition chose the smaller assortment (39% vs. 27.8%; $p=0.04$). Participants in abundant (vs. baseline) condition also liked the smaller assortment catalog to a greater degree ($M_{\text{abundant}}=4.49$ vs. $M_{\text{baseline}}=4.96$; $p=0.026$).

Study 2 ($N=160$) tested whether the observed findings in study 1 can be generalized beyond a category-level abundance manipulation to a broader sense of abundance manipulation. We manipulated abundance by instructing half of the participants to recall situations where they felt they had plenty of resources ("abundant-condition") and the other half to recall things they did in the past week ("base-

line-condition"; Fischhoff et al. 2003). Participants were then asked to imagine purchasing a bottle of wine, and choosing between two stores with either 12 or 36 options. Replicating previous findings, participants in the abundant (vs. baseline) condition liked the smaller assortment more ($M_{\text{abundant}}=5.09$ vs. $M_{\text{baseline}}=5.68$; $p=0.025$).

Study 3 has two purposes. First, it tested whether the observed effect was driven by a decrease in liking for larger assortments or an increase in liking for smaller assortments. Second and more importantly, it examined the mediating role of control. Study 3 ($N=160$) adopted a 2 (abundance: abundant vs. baseline) X 2 (assortment: large vs. small) X 2 (selection type: fruit, gym) mixed-model design with selection type as a within-participants factor. Participants imagined purchasing a type of fruit from a selection of 8 or 24 items and buying a gym membership at a gym that offered 5 or 10 equipment (counterbalanced order). Abundance manipulation was identical to study 1. We measured participants' evaluations of the store and feelings of control regarding the purchase situations (Chen et al. 2016). Results showed that in the "baseline" condition, participants liked the larger assortment more ($M_{\text{large}}=5.77$ vs. $M_{\text{small}}=5.14$; $p=0.004$). However, the liking of large and small assortments was comparable in the "abundant" condition ($M_{\text{large}}=5.71$ vs. $M_{\text{small}}=6.00$, NS), suggesting that the effect was driven by a boost in liking for the smaller assortment. Moderated-mediation analysis showed that feelings of control mediated this effect in the small condition but not in the large condition (small: $CI=[0.14, 0.54]$; large: $CI=[-0.2, 0.21]$).

If abundance serves as another source of control, increasing consumers' liking towards the smaller assortment, this effect of abundance should be mitigated when feelings of control are experimentally threatened. To test this possibility, study 4 ($N=290$) used a 3 cell (baseline/no-control-threat vs. abundance/no-control-threat vs. baseline/control-threat) between-subjects design. Participants were first asked to do a scrambled-sentence task in which they were asked to form 20 seven-word sentences, each out of a list of eight words (Bargh et al. 1996; Wang et al. 2013). In the "no-control-threat" conditions, the target sentences were unrelated to the concept of lacking control (e.g., "Michael Jordan is a great basketball player") while in the "control-threat" condition, the target sentences were associated with control-threat concepts (e.g., "I am unable to control many outcomes"). The abundance manipulation was identical to study 1. As predicted, when control was not threatened, participants in the abundant (vs. baseline) condition liked the smaller assortment more ($M_{\text{abundant/no-control-threat}}=4.4$ vs. $M_{\text{baseline/no-control-threat}}=5.4$; $p<0.001$); however, the positive effect of abundance on the evaluation of smaller assortment was mitigated when participants' feelings of control were threatened. Specifically, participants' relative preference for smaller assortment in the "abundant/control-threat" condition was lower than that in the "abundant/no-control-threat" condition ($M_{\text{abundant/control-threat}}=4.98$ vs. $M_{\text{abundant/no-control-threat}}=4.4$; $p=.03$) and similar to that in the "baseline/no-control-threat" condition ($M_{\text{abundant/control-threat}}=4.98$ vs. $M_{\text{baseline/no-control-threat}}=5.4$; $p=.14$).

Overall, these findings showed that the abundance satisfies consumers' feelings of control and substitutes for the sense of control provided by large assortments, which manifests itself in an increase in the relative preference for smaller assortments.

The Influences of Randomly Displaying a Set of Products on Shopping Evaluations

EXTENDED ABSTRACT

Although the literature has documented the negative influences of not categorizing products (Mogilner, Rudnick, and Iyengar 2008; Kahn and Wansink 2004), consumers often report enjoyment and

satisfaction when they shop in a store in which the products are randomly displayed, such as flea markets and daily sale websites (Abrahamson and Freedman 2007; Hudson 2007). The present research aims to examine when and why a randomly displayed set can lead to more favorable shopping evaluations.

In a categorized display, products are organized into subgroups according to products' dominant features or functions. Consumers can quickly form a general impression of the set by processing category labels and several featured products in each category (Park, Milberg, and Lawson 1991; Sujan and Bettman 1989). In contrast, products in a randomized set are displayed without an a priori order and thus consumers need to process more options (Hoch et al. 1999). Hence, compared to a categorized set, a randomized set signals to consumers that a greater amount of information needs to be processed, which makes them experience greater arousal (Berlyne 1971; Mehrabian and Russell 1974). Based on the conclusion that arousal can magnify people's affective responses and evaluative judgments (Reisenzein 1983; Russell and Mehrabian 1976), we propose that greater arousal elicited by a randomized set will intensify the pleasantness associated with a shopping activity and subsequently result in greater choice satisfaction and more enjoyable shopping experiences.

The occurrence of this positive randomization effect, however, requires two prerequisites. First, the shopping activity should not be task-oriented. When consumers go shopping out of necessity to obtain needed products (Kaltcheva and Weitz 2006) and thus engage in selective processing (i.e., screening off unrelated products and processing target product's information; Janiszewski 1998), they are less likely to be aroused by a randomized set because it would not significantly increase the amount of information needs to be processed (Mehrabian 1977). In addition, since category labels facilitate product searching and enhance perceived variety when consumers engage in task-oriented shopping (Hoch et al. 1999; Mogilner et al. 2008), we should observe a positive categorization effect. Second, shopping should be considered as a pleasant activity (Bloch and Richins 1983; Holbrook and Hirschman 1982). When shopping is unpleasant, the polarizing effect of arousal (Reisenzein 1983) will intensify the negative feelings, leading to lower shopping evaluations. Many factors determine whether consumers' attitude towards a shopping activity is positive, such as consumers' initial preference for the offered products, and promotions which can spontaneously induce a positive affect among consumers (Naylor et al. 2006).

Five experiments were conducted. Experiment 1 determined whether a randomized display increases individuals' arousal level relative to a categorized display. Participants were invited to browse products sold in an online store. Sixty-four stationery products were arranged in four columns and 16 rows and were either sorted into 16 sub-categories or randomly displayed. Their feelings of arousal were measured (Havlena and Holbrook 1986) both before and after browsing the choice set. Results showed that participants reported greater arousal in the randomized condition than in the categorized condition after browsing the products (5.03 vs. 4.25; $t(95) = 2.63$, $p < .01$), but not before (3.90 vs. 3.88; $t < 1$).

Experiment 2 examined the randomization effect. To fulfill the prerequisite conditions, participants were induced to consider a leisure shopping situation by reading a short paragraph (Kaltcheva and Weitz 2006) and then browse 64 stationery products that were either categorized or randomized. Then they rated their feelings of arousal and pleasure. After that, participants saw the same product set again and indicated the products they would like to buy. Then, they rated choice satisfaction and shopping experience. Results showed that participants reported greater choice satisfaction when the set was

randomized than categorized (6.81 vs. 5.70; $t(69) = 2.61, p < .05$). Similar results were detected on shopping experience (6.53 vs. 5.66; $t(69) = 2.09, p < .05$), arousal (5.50 vs. 4.86; $t(69) = 2.06, p < .05$) and pleasure (6.61 vs. 5.86; $t(69) = 2.60, p < .05$). Mediation analyses revealed that arousal and pleasure sequentially mediated these randomization effects.

Using 54 chocolates and 64 stationery products, Experiment 3 and 4 investigated the moderating role of task orientation by manipulating a specific shopping target (Chernev 2003b) and a general task orientation (Choi and Fishbach 2011), respectively. Experiment 3 showed that compared to a categorized set, a randomized set increased choice satisfaction when participants did not indicate their chocolate preference (7.95 vs. 8.60; $F(1, 135) = 4.14, p < .05$), but decreased satisfaction when they indicated their chocolate preference and hence was expected to shop for that target (8.41 vs. 7.74; $F(1, 135) = 5.22, p < .05$). Similar results were detected in Experiment 4. Choice satisfaction was higher in the randomized condition than in the categorized condition when shopping was experience-oriented (6.94 vs. 5.97; $F(1, 132) = 4.55, p < .05$) but lower when shopping was task-oriented (6.22 vs. 7.14; $F(1, 132) = 4.64, p < .05$). Experiment 4 further demonstrated that arousal and perceived variety mediated the randomization and categorization effect, respectively.

Employing either 40 good-looking or creepy-looking endangered animals, Experiment 5 tested the moderating role of ‘shopping’ valence. Results showed that regardless of the shopping valence, participants reported a greater feeling of arousal after browsing a set of randomly displayed animals than a set of categorized animals (6.22 vs. 5.65; $F(1, 139) = 7.43, p < .01$). However, shopping valence moderates the influences of display method on choice satisfaction ($F(1, 139) = 7.77, p < .01$). Specifically, for attractive animals, participants reported greater satisfaction when the set was randomized than categorized (7.31 vs. 6.45; $F(1, 139) = 4.90, p < .05$); the effect was reversed for unattractive animals (4.16 vs. 4.84; $F(1, 139) = 2.99, p = .09$).

This research demonstrates a positive effect of product randomization. Our findings enrich the extant knowledge about the impacts of display method (Diehl et al. 2015; Kahn and Wansink 2004; Mogilner et al. 2008) and also provide useful marketing implications for store arrangements.

Global Context: Extremeness Aversion in a Dual Context Setting

EXTENDED ABSTRACT

Research on extremeness aversion has typically defined extremeness in terms of the local consideration set (Prelec, Wernerfelt, and Zettlemeyer 1997; Neumann, Bockenholt, and Sinha 2016; Simonson 1989). For example, in one demonstration of extremeness aversion, study participants tended to choose the middle of three drink options, regardless of the sizes of the three drinks offered (Sharpe, Staelin, and Huber 2008). These studies have demonstrated that consumers often avoid extreme options, where extremeness is a function of the local context.

But consumer choice rarely occurs in the completely isolated contexts used in laboratory experiments. When making real consumption decisions, consumers typically have several layers of context available to them to inform their evaluations and decisions. Consider a consumer choosing from among three brands of pasta sauce, ranging from a high priced, high quality sauce down to a low priced, low quality option. Extremeness aversion predicts that in such a situation, consumers will be attracted to the compromise or middle option.

But how would that consumer’s choices change if an additional, “global” context were introduced? What if consumers were told that this set of pasta sauces was being sold at Whole Foods, a store with a reputation for high prices? Would the preferences change if consumers evaluated exactly the same option set, with exactly the same prices, but at Walmart instead of Whole Foods?

In this research, we propose that both global and local context jointly determine consumers’ evaluations of attribute extremity, and therefore both affect how extremeness aversion influences choice. Specifically, we argue that consumers interpret the local context (e.g., the set of pasta sauces being considered) through the lens of the global context (e.g., the store in which the pasta sauces are seen). The global context can shift the “extremity” of one or more of the attributes being evaluated.

For example, if the consumer was shopping at Whole Foods, a store with a notoriously high price image, he or she might assume that all the prices in the set were high, relative to what is available on the market. This could shift the assessment of what is considered extreme. If all the options are thought to be relatively expensive based on the global context, the cheapest option in the set might seem more like a compromise option. Extremeness aversion in this context would lead to a preference for the least expensive option, rather than the middle option.

We tested this prediction in a series of studies. First, we replicated Prelec, Wernerfelt, and Zettlemeyer’s (1998) iconic poncho study, in which participants were asked to imagine it had started raining and so chose a length of poncho to buy: 38”, 40”, or 42”. As might be expected, people tended to choose a poncho length based on their height: with short people choosing the 38” and tall people choosing the 42” option. The global context in this case was manipulated by changing the location of the poncho vendor. Some participants were told that they were on vacation in the Netherlands, where “residents are among the tallest people in the world,” and others were told that they were vacationing in Indonesia, where “residents are among the shortest people in the world.” Changing the global context shifted preference in poncho length.

Converting the lengths to a 3-point scale, participants in the control condition (no additional global context), the average poncho length was 2.38. When participants were told they were shopping in the Netherlands, there was a significant shift toward the shorter poncho (2.38 vs. 2.05; $p < .01$). Likewise, there was a significant shift toward the taller poncho when participants were told they were shopping in Indonesia (2.38 vs. 2.58, $p = .05$). And the preferences in the Netherlands and Indonesia conditions were, of course, significantly different from each other (2.05 vs. 2.58; $p < .001$).

Additional experiments supported the influence of global context on how extremeness aversion manifests in choice. One study asked participants to take a virtual grocery shopping trip. They were shown 4 national-brand options from each of 4 categories: frozen pizza, pasta sauce, maple syrup, and tuna. The participants were shown the same set of options, at the same prices, but were told that the options they were considering came either from a store with a reputation for high prices (e.g., Whole Foods) or low prices (e.g., Walmart).

Across the four product categories, 29.4% of choices were for the lowest priced brands when participants were shopping in the low price image store. In the high price image store, the choice share of the lowest-priced brands increased to 41.7%—this despite the fact that the prices and products were the same in both conditions. This pattern held across all four product categories: frozen pizza (27.7% vs. 35.7%), pasta sauce (44.7% vs. 54.5%), maple syrup (30.4% vs. 50.0%), and tuna (14.9% vs. 26.8%).

In another study, we replicated the findings in the field. We conducted the study in three different restaurants in Milan, which all serve the same penne arrabbiata pasta (i.e., spicy pasta). The restaurants were Calabrese (known for spicy dishes), traditional Italian, and American. We had a total of two hundred and ninety-six participants (167 male; $M_{\text{age}} = 37.72$, $SD = 14.65$). Participants were asked to imagine they wanted to order arrabbiata pasta from the restaurant they were currently dining in, and had the option of telling the chef how spicy to make it on a 7-point scale. We predicted that those who were in the Calabrese restaurant would order the least spicy pasta because the global context was a very spicy restaurant. In contrast, those in the American restaurant would order the spiciest pasta because there the global context was a restaurant with non-spicy food. The results supported our prediction. Those in the American restaurant ordered their pasta to be spicier ($M = 4.92$, $SD = 1.39$) than those in the traditional ($M = 4.38$, $SD = 1.61$; $p < .01$) and the Calabrese ($M = 3.68$, $SD = 1.13$; $p < .001$) restaurant. Moreover, those in the Calabrese restaurant ordered their pasta to be less spicy than those in the traditional Italian restaurant ($p < .001$).

Across experiments (including others not summarized here in the interest of brevity), we found consistent support for a dual-context explanation of how extremeness aversion influences consumer choice. Our data support the idea that consumers are averse to extremes. However, we find that extremeness is not limited to the local consideration set, but is in fact jointly determined by the local context and the global setting, including the reputation of the retailer in which the consumer is shopping.

SESSION OVERVIEW

The growth of social media has increased immediate access to information about others and increased the ability to make social comparisons. As a result, recent consumer research has focused on issues pertaining to social comparisons, including how people assess their social status, and the consequences of social comparison, such as conspicuous consumption (e.g. Ordabayeva and Chandon 2011; Xu Shen and Wyer Jr. 2012). This session brings together four papers that extend existing theory in novel ways. In the first two papers, we first investigate social distance and anonymity with the comparison target as antecedents to different consumer mindsets, identity goals, and choices. In the next two papers, we then investigate how choice is impacted when consumers suppress or cope with social comparison.

In particular, while competing (vs. cooperating) is known to increase a focus on differences, in paper 1, Galoni and Labroo find that when the referent is a close other, differentiating can feel difficult, and ironically, increase focus on similarities and reduce creativity and desire for innovative products. Compatible with paper 1, but focusing on newsfeeds and anonymous others, in paper 2, Chung and Johar find that the salience of anonymous crowds on social news channels motivates consumers to seek a distinctive self-identity, unless consumers are able to express their identity by actively engaging in social media. In paper 3, Qin, Fitzsimons and Staelin present a unique consequence of suppressing social comparison – the overvaluation of one's own possessions. They find the endowment effect is enhanced among religious individuals who are taught to not engage in social comparison or covet the goods of others. In paper 4, Bellezza and Berger further consider how consumers cope with social comparison. They find that high-status consumers often adopt low-status goods in effort to further differentiate themselves from mid-status consumers.

As a set, the papers present a highly convergent, novel, and important perspective on social comparison processes and their consequences for consumer behavior. As a set, the papers offer theoretical advances and practical insight into how social comparison impacts choice and how consumers suppress or cope with it. While all papers explore social comparison, they also bridge distinct consumption do-

mains ranging from the desire for innovation, to identity signaling, to the endowment effect and religion, and conspicuous consumption. As a result, the session is likely to have a broad appeal within the ACR audience, and draw researchers interested not only in social comparison, but also in these listed domains. All of the papers are at an advanced stage of completion. Overall, they comprise 17 studies, and employ lab and online experiments, as well as archival data analysis. Given the cross-sectionality of interest in social comparison and its diverse influence on consumer behavior, we anticipate this session will spark fruitful discussion and generate opportunities for future research.

When Consumer Rivalry Reduces Desire for Innovation

EXTENDED ABSTRACT

Relentless exposure to the successes of close others on social media can increase the tendency among consumers to engage in competitive social comparison (Garcia et al. 2006; Primack et al. 2017). But might doing so impact subsequent preferences? If so, how?

A widespread view is that competing with others (vs. cooperating or merely considering them) increases a need for differentiation and a focus on differences (Ames 1981; Colpaert et al. 2015; Stapel and Koomen 2005). This increased focus on differences can increase divergent thinking by making disparate information accessible in memory (e.g. Ashton-James and Chartrand 2009; Zhong, Dijksterhuis and Galinsky 2008). It follows that divergent thinking might increase creativity and make innovative products appear more desirable. However, one important aspect of these studies is that they employed newly acquainted or hypothetical others who are socially or psychologically distant from consumers when in reality competition is more often with those who are close. Coke considers Pepsi its competitor, siblings consider each other their referents, and close, not distant, friends develop rivalries. We posit that the consequences of competing with a close other are quite different (and in fact, the reverse).

We propose that competitive differentiation with a close other feels difficult because of the high trait overlap between the self and close others. This feeling of difficulty can lead consumers to infer that they are even more similar to the close other than if they had not been looking for differences (such as when a consumer merely considers or cooperates with the other). In supporting research, metacognitive difficulty associated with generating many versus few instances of aggression is known to result in lower perceptions of that person's aggression. Thus, the difficulty of finding differences might serve to increase perceived similarity and reduce preference for innovative products. This prediction is in contrast to when a consumer competes with a distant other and differentiation is easy. We therefore predict that engaging in competitive social comparison (vs. non-competitive comparison) with a close other increases a similarity mindset and decreases a desire for innovative products.

We tested this hypothesis across three studies. Study 1 employed a 3 (action: compete, cooperate, control) \times 2 (referent: close, distant) between-subjects design. Participants first completed a writing task describing the action \times referent they were assigned to, then completed a similarity-focus measure by indicating how much overlap they perceived between themselves and the other, and then listed creative uses for two objects as indicators of divergent thinking. The

cooperation and control conditions were designed to be conceptual replications. The results were similar within these conditions and were therefore collapsed. The similarity-focus measure revealed the predicted interaction ($F(1, 212) = 4.78, p = .03$). As predicted, competing (vs. not) with a close other increased similarity ($M = 4.30$ vs. $M = 3.76, t(212) = 2.19, p = .035$). While competing with a distant other reduced similarity, consistent with past research ($M = 2.86$ vs. $M = 3.12$), this difference was non-significant ($t < 1$) perhaps because past research employed less engaging hypothetical comparisons. Analysis on the creativity measure revealed the predicted interaction, $F(1, 212) = 3.43, p = .066$. Competing (vs. not) with a close other reduced creativity ($M = .80$ vs. $M = 1.49, t(212) = 1.89, p = .06$). Competing (vs. not) with a distant other increased creativity, albeit not significantly ($M = 1.38$ vs. $M = 1.10, t < 1$).

Study 2 replicated these results using a general measure of a similarity mindset (perceived similarity of two abstract artworks), and also a different measure of divergent thinking (preference for a product when framed as innovative vs. not). Again, competing (vs. not) with a close other increased a similarity mindset ($M = 4.83$ vs. $M = 2.86, t(210) = 3.06, p < .001$), but competing with a distant other decreased it ($M = 3.48$ vs. $M = 4.39, t(210) = -2.06, p = .04$). Moreover, competing (vs. not) with a close other reduced preference for a product when its innovativeness was highlighted ($M = 3.45$ vs. $M = 4.21, t(210) = -1.92, p = .05$), but competing with a distant other had no effect ($M = 3.56$ vs. $M = 3.39, t < 1$).

Studies 1 and 2 showed that competing with a close other increases both integral and general similarity mindsets, reduces divergent thinking, and reduces preference for innovative products. While all results for distant others were in the direction of past research, they only tended toward significance, perhaps because our task is less hypothetical than that in past research and elaboration might be moderating those past effects. Our goal in study 3 was to test the underlying process that the difficulty of generating differences with a close other results in a similarity mindset.

Study 3 ($N = 276$) manipulated the difficulty of generating differences by having participants list their own traits or the traits of close-others first. We reasoned that the salience of one's own traits makes it difficult to generate different traits for others. In contrast, this difficulty will be reduced if a person first considers the traits of the other person. A 3 (action: compete, cooperate, control) \times 2 (order: own traits first, other traits first) between-subjects ANOVA on innovation preference revealed a significant interaction ($F(2, 271) = 5.25, p = .006$). Replicating prior studies, competing (vs. not) with a close other reduced innovation preference ($M = 3.52$ vs. $M = 4.58, t(274) = 2.53, p = .01$), but only when participants considered their own traits first. It instead directionally increased innovation preference when the other was considered first ($M = 4.20$ vs. $M = 3.48, t(274) = 1.71, p = .089$).

Across three studies, we found that competing with a close other evokes a similarity mindset and reduces desire for innovative products. This finding is important theoretically because ample research would suggest that competing increases divergent thinking. It also merges research on metacognitive experiences with understanding social influences. Practically, even small instances of daily consumer rivalry may shift preferences away from innovation.

News Consumption on Social Media Induces Distinctiveness Seeking

EXTENDED ABSTRACT

The decline in print media subscriptions and television viewership, and the emergence of the Internet challenge news organizations

to find more effective ways of connecting with their readers. News organizations have developed multiple online communication mechanisms in response to this crisis. For example, CNN uses both their traditional homepage (e.g., cnn.com) and social media websites (e.g., [Twitter.com/CNN](https://twitter.com/CNN)). Unlike traditional news websites that are driven by top-down dispersion of news content, news on social media platforms is consumed by an anonymous crowd that makes its presence felt via comments and likes. Based on the crowd literature (Xu, Shen and Wyer Jr. 2012) they are likely to interpret it as an indication of their affiliation motivation. Consequently, in a product choice task, they choose options that others consider desirable. When people perceive that their close proximity to others results from circumstances beyond their control, however, they feel that their personal space is violated and experience a need for to express their individuality. In this case, they are more likely to choose products that distinguish themselves from others.”DOI”:"10.1016/j.jcps.2011.06.006”,ISSN”:"1057-7408”,shortTitle”:"Does the distance between us matter?”,journalAbbreviation”:"Journal of Consumer Psychology”,author”:[{"family”:"Xu”,given”:"Jing"}, {"family”:"Shen”,given”:"Hao"}, {"family”:"Wyer Jr.”,given”:"Robert S."}],issued”:[{"date-parts”:[["2012”,7]]}],schema”:"https://github.com/citation-style-language/schema/raw/master/csl-citation.json"} and the optimal distinctiveness theory (Brewer 1991), five experiments demonstrate that the salience of an anonymous crowd on social (vs. traditional) news media motivates consumers to seek a distinctive self-identity so that they can stand apart from the crowd. This tendency is attenuated when consumers can express their distinctive identity by actively engaging (vs. passively reading) news content on the platform through liking, sharing and commenting on the news.

Experiment 1 tests our basic hypothesis that social news media consumption elicits the distinctiveness-seeking goal. In the guise of a “News Headline study,” 143 participants either browsed CNN.com (*traditional-media*) or CNN Twitter (*social-media*). Next, all participants completed a word-flash task that measured the implicit activation level of the distinctiveness-seeking goal (Loveland et al., 2010). Upon seeing a flashed target word (e.g., *disdunt*), participants chose one word out of 4 choices (e.g., *distinct*, *district*, *distract*, *disturb*). The frequency of choosing the distinctiveness-related word in 6 target questions out of 12 questions served as a mediator. The dependent variable was the self-perception score in relation to others (Stapel & Marx, 2007). Analysis revealed that the exposure to social news channels increases the goal to be distinctive ($p = .033$), which predicts participants’ tendency to view themselves as being less similar to others ($M_{\text{social-media}} = 4.08$ vs. $M_{\text{traditional-media}} = 4.53, p = .042$) (Indirect effect: $CI = [-.1313, -.0021]$).

Building on the initial findings, Experiment 2 provides evidence on distinctiveness-goal activation by using goal-satiation as a moderator, and by comparing another social media news website - Mashable, with a traditional news website - Yahoo news. Employing a 2 (media: Yahoo vs. Mashable) \times 2 (goal satiation: no vs. yes) between-subjects design, participants ($N = 203$) first read news on one of the two news websites, followed by a “product survey” task that manipulated goal-satiation through 4 scale questions (e.g., “how many pairs of unique shoes do you have?” *distinctiveness-not-satiated*: 0-4 pairs/5-9 pairs/10-14 pairs/15-19 pairs/20 pairs or more vs. e.g., *distinctiveness-satiated*: 0 pair/1 pair/2 pairs/3 pairs/4 pairs or more). In the third marketing study, all participants rated two museum taglines: (A) “Visited by Over a Million People Each Year,” (B) “Stand out from Crowd” (Huang et al., 2014). Results revealed that when the distinctiveness-seeking goal is not satisfied, participants on social (vs. traditional) media preferred distinctive tagline more (M_{so}

cial-media? not-satisfied = 1.50 vs. $M_{\text{traditional-media, not-satisfied}} = .37, p = .038$), but not when their distinctiveness-goal was satisfied through the scale manipulation ($M_{\text{social-media, satisfied}} = -.26$ vs. $M_{\text{social-media? satisfied}} = .10, n.s.$).

If the goal to be distinctive is the mechanism underlying the effect, then the effect should be attenuated when consumers express their distinctive self-identity by actively engaging in social media. To test this idea, participants ($N = 123$) in Experiment 3A were randomly assigned to one of the three conditions (traditional-media vs. social-media vs. social-media-active) where they either browsed CNN.com (*traditional-media*) or CNN Twitter (*social-media & social-media-active*). Additionally, participants in the *social media-active* condition wrote down 4 tweets. Then, all participants responded to a marketing study where they rated two fashion taglines: (a) “Catch up the popular trend of fashion”, (b) “Stand out from the crowd by expressing who you are.” Results revealed that participants in the *social media* condition preferred the distinctive tagline more than those in the *traditional media* (preferences score = (b) – (a); $M_{\text{social-media}} = -2.28$ vs. $M_{\text{traditional-media}} = -2.91, p = .051$), and in the *social media-active* conditions ($M_{\text{social-media-active}} = -3.36, p = .002$). This finding was again replicated in Experiment 3B that employed 3 conditions, with a more subtle manipulation for the social media-active condition where participants engaged in social media by simply clicking likes/shares, by utilizing BBC news agency and a product-choice task.

Together, we posit that an active engagement satisfies consumers’ goal to reclaim their individuality, which subsequently attenuates their preferences for distinctive products.

Experiment 4 ($N = 153$) provided process-evidence of this prediction by employing the identical media manipulation as in Experiment 3A, followed by the word-flash task in Experiment 1 as a mediator, and a post-it product preferences task as a marketing DV. Specifically, participants evaluated 3 post-its, where two colors of post-its were presented as being commonly consumed, while the third was presented as more distinctive. Then participants indicated how much they liked each of the post-its. Results again showed that participants in the *social media* condition ($M_{\text{social-media}} = .75$) preferred the distinctive colored post-it more than those in the *traditional media* ($M_{\text{traditional-media}} = -.20, p = .023$) and *social media-active* conditions ($M_{\text{social-media-active}} = -.40, p = .007$). Mediation analysis on word-flash task also revealed that participants in the *social media-active* condition no longer pursued the distinctive goal after the active engagement ($M_{\text{social-media-active}} = 2.09$ vs. $M_{\text{traditional-media}} = 1.83$ vs. $M_{\text{social-media}} = 2.66$; indirect effect: $CI = [-.093, -.002]$), which led to an attenuation of their preferences for the distinctive post-it.

Overall, this research contributes to the literature exploring social media’s new role as a news channel where the crowd reveals its presence through likes, shares and comments. Further, we reveal that passive (vs. active) immersion by the anonymous crowd is the driver in consumers’ preferences for distinctiveness, and demonstrate that the active (vs. passive) engagement through commenting, liking and sharing can fulfill their distinctiveness-seeking motive. This insight provides direct managerial implications to marketers on brand positioning that can be tailored to respective social and traditional news channels.

The Price of Faith: Religion’s Role in the Endowment Effect

EXTENDED ABSTRACT

Previous studies have identified three major causes of the endowment effect: loss aversion, mere ownership and the different effects of valuation and market prices across the buyers and sellers.

We put forth a new explanation, specifically the degree to which an individual endorses religious teachings that emphasize being content with one’s belongings and not comparing oneself to others and coveting their possessions. We focus on these since coveting (the opposite of contentment) is explicitly mentioned in the Ten Commandments (i.e., “You shall not covet”), which has special importance in the Judeo-Christian Scripture. Believers of these faiths feel that these commandments were directly delivered by God, indicate personal obedience and are intended to be an enduring record of his moral demands. Also coveting, an outcome of a social comparison that leads one to desire the “missing” good from one’s own life that the other possesses is frequently mentioned in the Bible and is regarded as the root of many sins. Such beliefs about not coveting can be found in multiple religious traditions (e.g., Samaritan). The Qur’an contains a parallel verse “Do not covet the bounties that God has bestowed more abundantly on some of you than on others. The Ten Disciplines in Hinduism include similar teachings about non-violence, devotion, and contentment. The Four Noble Truths in Buddhism reveal that craving causes suffering. To overcome craving and achieve happiness, people need to be content with their belongings. All this leads us to postulate that sellers will place more value on their own possessions and the increase in valuation will increase with the degree of religiosity.

We test our theory in a number of different ways. In each case we have participants randomly assigned to the role of seller or buyer of a non-durable product and indicate the price for which they are willing to sell (seller condition) or willing to pay for (buyer condition) the product. In the first study religiosity is measured by “How important are your religious beliefs to you” on a 5-point scale from “Not important at all” to “Very important.” Model free results show no significant difference in seller and buyer prices for those who indicate their religious beliefs were not important at all ($t = .91, p > .3$). Using a linear model we find that buyers’ willingness to pay did not significantly change with religiosity, whereas sellers significantly increased their selling prices as religiosity increased ($\beta = 0.70, p < 0.01$). This lead to individuals who are in the top 66% of religiosity displaying the endowment effect. We replicated the findings with real transactions in a second study and a different measure for religiosity in a third. All three studies provide a very consistent pattern where sellers with stronger religiosity ask for higher prices compared to those with weaker religiosity while buyers’ prices are not a function of their religiosity.

We next manipulate religion by making it more or less salient. Although the endowment effect was evident in the control condition, it was significantly weaker than the religion condition. This difference was due to sellers in the religion condition asking for significantly higher prices compared to those in the control condition, while no differences were found for buyers’ willingness to pay.

We explored our proposed mechanism (contentment with one’s own possessions) by measuring participants’ agreement towards the statements, “Religion allows me to express myself” and “Religion reminds me to be content with what I have”. Results show that when participants’ beliefs about contentment were one standard deviation below average, neither buyers nor sellers’ changed their prices with the religion prime and there was no significant endowment effect. In contrast, when participants’ attitudes towards contentment were one standard deviation above average, the endowment effect was present in both the religion and the control conditions. Importantly buyers did not change their willingness to pay across conditions, while sellers significantly increased their asking prices ($\beta = 0.42, p < 0.01$). Thus the endowment effect was significantly stronger in the religion condition ($\beta = 0.67, p < 0.01$). The statement “Religion allows me to

express myself” did not interact or mediate the two-way interaction of seller and religion prime.

We also manipulated different religious teaching. In the “religion as self-expression” condition, participants described how religion provided them a sense of self-worth. In the “religion as contentment” condition, they described how religion provided “a sense of satisfaction and sufficiency.” In the control condition, they wrote about their daily routines. The results show that both the “religion as self-expression” condition ($\beta = 2.62, p < 0.05$) and the control condition ($\beta = 2.79, p < 0.05$) exhibited the endowment effect. However, the endowment effect in the “religion as contentment” condition was much stronger ($\beta = 6.08, p < 0.001$). This was because the sellers in the “religion as contentment” condition asked for significantly higher prices than those in the “religion as self-expression” condition ($\beta = 3.45, p = 0.05$) and marginally higher prices than those in the control condition ($\beta = 3.28, p < 0.10$).

We used an archival dataset to provide evidence of external validity for our results by collecting data on the religiosity ranking based on the county-level number of congregations per 10k people and the asking prices for three types of popular used cars both for individual sellers and dealers. We find dealers’ prices do not significantly change with the number of congregations, whereas individuals’ prices significantly increase as the number of congregations increases ($\beta = 75.21, p < 0.001$).

Overall, we find strong support for the role of religious beliefs playing a key in the endowment effect. This impact is driven by a social comparison that leads religious people to feel they shouldn’t covet missing goods possessed by others, and as a result leads them to overvalue their own goods.

Trickle-Round Signals: When Low Status Becomes High

EXTENDED ABSTRACT

Conspicuous consumption and trickle-down theories suggest that fashions start with high-status individuals and move their way downwards (Simmel 1957; Taylor 1974; Veblen 1899/2007). But a number of examples seem to contradict these approaches. Jeans were originally worn by miners and factory workers before celebrities adopted them and famous chefs use commercial junk food in their sophisticated dishes. When and why do high-status individuals sometimes adopt tastes associated with low-status groups?

This article proposes a trickle-round theory of fashion that explains why high-status individuals sometimes adopt items clearly associated with low-status or marginalized groups. Field and lab studies demonstrate that high-status individuals adopt “downscale” tastes, in part, to distance themselves from the middle-status. Because emulating low-types is too costly and risky for middles to copy, it provides an alternative way for high-types to distinguish themselves. Thus we propose tastes and styles may trickle-round directly from the bottom of society to the upper-class, only after diffusing to the middle.

Importantly, this strategy hinges on the presence of multiple signaling dimensions. Rather than trying to be seen as completely low-status, high-status individuals mix-and-match high and low signals (e.g., Lobster Mac ‘n Cheese or wearing a trucker hat with Gucci loafers) as a way of distinguishing themselves from middles.

Four studies consider the adoption of low-status signals and related status dynamics in a variety of identity-relevant contexts (e.g., food, clothing, and a stylized signaling game). Study 1 provides a test of our trickle-round theory in the field, demonstrating that high-status restaurants are disproportionately likely to offer low-brow dishes. We collected a random sample of 1,520 dishes offered at different price tiers of restaurants (all American cuisine, located

in New York City). Two coders rated the level of association of each dish with “lowbrow food,” that is the extent to which the dish, or part of it, included links to downscale, low-status, or working class recipes or ingredients (e.g., Fish and Chips, Mac ‘n Cheese, and Tacos). Naturally, as restaurant price increased, the number of lowbrow menu options tended to decrease. More importantly, as predicted, this pattern reversed for high-status restaurants, where the percentage of lowbrow dishes increased again ($\beta = 3.56, t(1,516) = 4.71, p < .000$). Moreover, we use textual analysis to demonstrate that, as predicted, when offering lowbrow items, high-end restaurants tend to mix-and-match them with highbrow ingredients.

Study 2 (N=382) uses a more controlled design to test whether high-status individuals are more likely to prefer downscale fashion products. Specifically, we compare the choices of fashion-savvy respondents recruited through a Luxury club (i.e., high-status group) to two control groups with analogous demographic, but lower fashion knowledge. We selected four pairs of products, three of which (i.e., two bags, hats, shoes) were pretested so that one option was seen as significantly more downscale than the other, and one pair (i.e., two glasses) perceived equivalently in terms of status. In addition to an effect of fashion knowledge ($Wald \chi^2 = 13.91, p < .001$), results revealed the predicted interaction ($Wald \chi^2 = 6.81, p = .009$). As predicted, for choice pairs where one option was more downscale, high-status respondents were more likely to pick the downscale products ($M_{high} = 55\%$ vs. $M_{low} = 34\%$, $Wald \chi^2 = 37.94, p < .001$). In categories where the two options were neutral, however, there was no effect of status on choice ($M_{high} = 42\%$ vs. $M_{low} = 38\%$, $Wald \chi^2 = .47, NS$).

Studies 3 and 4 test the proposed mechanisms using a novel signaling paradigm in the lab. In study 3, participants (N=256) imagined a society with three types of people (highs, middles, and lows) where signaling occurs exclusively along two dimensions: shape and color. Each status grouping is associated with a certain shape and color combination (high-status people are yellow-triangle, middle-status are red-square, low-status are blue-circle). All participants are assigned to high type and are told that they will play a number of rounds of a signaling game, in which they can choose one of three colors and one of three shapes as a signal to send to an observer. If the observer correctly identifies their high status, they will win extra compensation (\$1). To test our proposed mechanism, we manipulate between rounds whether high-status signals are co-opted by the middle-status group. As predicted, while almost no one selected low-status associated options in the first round, in the second round, when faced with imitation from middles, a significant percentage of people switched to low-status associated options ($Wald \chi^2 = 29.91, p < .001$).

We also asked participants to explain their thought process after the second choice and coded their open-ended comments on three dimensions (i.e., distinction, uniqueness, authenticity). As hypothesized, a logistic regression predicting whether participants picked low-status associated choices in the second round as a function of the three motives demonstrated that only “seeking distinction” was significantly related to choice ($B = .72, Wald = 56.29, p < .001$).

Finally, study 4 (N = 169) tests the role of multiple signaling dimensions in these effects. We use the paradigm from study 3 and manipulate the number of status signaling dimensions available. Half the participants receive the same society as study 3, where two dimensions (i.e., shape and color) are available, while the other half receive a simpler society, where signaling occurs exclusively along one dimension (i.e., shape). As predicted, the adoption of low-status associated guises in the second round ($M_{2-dim} = 32\%$) is significantly reduced when the ability to express status is confined to one signaling dimension ($M_{1-dim} = 11\%$; $z = 3.47, p = .001$). Finally, we again measure our hypothesized underlying process of distinction and find

that it mediates the effect the effect of condition on choice of low-status associated signals (indirect effect = .57; 95% C.I. = .07 to 1.15).

In conclusion, this research demonstrates that high-status individuals may purposely choose to adopt tastes and habits associated with low-status groups as an alternative signaling strategy to distinguish themselves. This work contributes to understanding signaling dynamics, social influence, and the diffusion of fashion.

SESSION OVERVIEW

This past holiday season, the average U.S. adult planned to spend roughly \$1,000 on gifts (American Research Group, Inc. 2016). Though undoubtedly with great intentions in mind, it seems that many of these givers missed their marks as UPS expected to ship 1.3 million gifts back to retailers on "National Returns Day" in early January (Farber 2017). Taken together, these statistics demonstrate that a) gift giving is a custom with major economic ramifications, and b) consumers often err in their gift choices. To that end, it is for good reason, then, that in recent years consumer researchers have devoted a considerable amount of time to studying gift giving – specifically asymmetries between givers and recipients. However, the field is only just beginning to develop an understanding of this tricky practice and there is still much to learn (Galak, Givi, and Williams 2016). Thus, in an effort to do just that, the papers in this session collectively ask: When and why do givers and recipients not see eye-to-eye?

The first two papers in the session examine asymmetries in the types of gifts givers give vs. the ones recipients prefer to receive. Specifically, **Givi and Galak** study givers' and recipients' views of sentimentally valuable gifts and gifts that match the explicit preferences of recipients. They demonstrate that givers overly-give the latter, relative to what recipients prefer, and that this arises because givers feel uncertain about whether sentimental gifts will be well-liked. **Williams and Rosenzweig** examine givers' and recipients' assessments of hedonic and utilitarian gifts, and show that givers give hedonic gifts more often than recipients prefer. Further, they demonstrate that this is the result of givers focusing more on the moment of the exchange vs. long-term ownership, than recipients, and that this mismatch contributes substantially to gift returns. **Liu and Baskin** study how the more general topic of self-other decision making can inform gifting errors, and investigate how consumers make the quality vs. quantity tradeoff when deciding for the self vs. others. Their results show that people choose quality over quantity more when choosing for others than for the self, and that this is driven by asymmetries in the perceived usage and social risks associated with choosing a lower quality option. To conclude the session, **Grewal, Steffel, and Grewal** (fittingly) examine how recipients are misguided in how they express gratitude *after* receiving a gift. Specifically, they find that recipients express their gratitude publicly less often than givers

prefer, because recipients err in their perceptions of how personal public expressions are perceived.

In sum, these four papers examine novel asymmetries between givers and recipients (in both gift selection, and behavior after the gift is exchanged), identify the mechanisms driving these mismatches, and demonstrate important downstream economic consequences. Given the wide range of literature drawn on by the authors, this symposium is likely to be of great interest to a broad audience, including those interested in gift giving, self-other decision making, prosocial behavior, risk, attribute tradeoffs, and gratitude expressions.

Sentimental Value And Gift Giving: Givers' Fears of Getting it Wrong Prevents Them From Getting it Right

EXTENDED ABSTRACT

The utility a consumer extracts from a possession can come in many different forms, however in the present research we focus on two: preference-matching utility and sentimental value. Preference-matching utility is the utility a consumer derives from an object because it has features, functions, and specifications that match the consumer's hobbies and interests. Sentimental value is the value derived from an object's associations with significant others or special events or times in one's life (Yang and Galak 2015). We examine how givers and recipients weigh these two forms of utility when faced with the choice between preference-matching and sentimental gifts. We hypothesize, and empirically demonstrate, that givers do not give sentimental gifts as often as recipients would prefer.

Our logic as to why this might occur is as follows: Recipients should be able to relatively accurately predict their enjoyment from potential gifts, as they know their likes and dislikes, and uncertainty is minimal. Thus, when indicating which of potential gifts they would like to receive, recipients will simply pick the gift that maximizes their utility, whether it be a sentimental or preference-matching gift. On the other hand, there is uncertainty in givers' decisions, and they must make educated guesses as to what recipients will like. Under these circumstances, preference-matching gifts allow givers to reduce the uncertainty in their choice, as givers are aware (from past observations) that recipients like these types of items. In contrast, sentimental gifts might be construed as relatively less certain to be liked by recipients. That is, givers have limited knowledge about recipients' opinions of potential sentimental gifts, relative to their knowledge of recipients' views of potential preference-matching gifts, and as a result, will feel less certain that the former will be liked. Thus, when choosing between a preference-matching and sentimental gift, givers' choices will be biased towards the former, relative to what they would prefer as recipients.

Study 1 serves as an initial test of our predictions that givers do not give sentimental gifts as often as recipients would prefer, and that this is because givers feel uncertain that these gifts will be liked by recipients. Specifically, givers hypothetically choose between a preference-matching gift (a framed picture of the recipient's favorite band), and a sentimental gift (a framed picture of the giver and the recipient on a day they had a lot of fun together), and the occasion is manipulated to be either the recipient's birthday or going away party. Recipients indicate which of these two items they would prefer to receive from the giver. We hypothesized that in both contexts, givers will perceive the sentimental gift as being less certain to be liked by recipients, compared to the preference-matching gift, and thus will

give the latter more often than recipients will prefer to receive it; however, in the context of a going away party, the uncertainty associated with the sentimental gift should be reduced, and thus givers should be more likely to give it as a going away present, than as a birthday present. The results confirmed these predictions: At both the birthday party (63% vs. 79%; $p = .02$) and going away party (76% vs. 96%; $p < .001$), givers chose the sentimental gift less often than recipients preferred, and less givers chose the sentimental gift as a birthday gift, than as a going away gift, (63% vs. 76%; $p = .07$).

Study 2 serves to further rule in an uncertainty explanation for givers' shunning of sentimental gifts. Specifically, givers are placed into a risk (seeking / aversion) mindset by writing about a time they took a risk and it (paid off / failed), and then choose between giving (as a birthday gift) a preference-matching gift (a bicycle made by the recipient's favorite brand, and he/she has other products made by this brand), or a sentimentally valuable gift (a bicycle that looks identical to a bicycle the giver and the recipient rode as children, but is not made by the recipient's favorite brand). We hypothesized that if givers are typically uncertain about whether sentimental gifts will be liked by recipients, then when givers think (positively / negatively) about risk, they should be (more / less) likely to give a sentimental gift. As expected, givers in the former condition chose the sentimental gift more often than givers in the latter condition (48% vs. 35%; $p = .01$).

To test whether our effect holds in a real-life setting, in study 3, we had romantic couples choose between gifts, and real gifts were exchanged. To begin, the couples were first asked to go into separate rooms, and then the giver (randomly assigned) started the first half of the study. Specifically, the giver wrote down the recipient's favorite store, and then selected which of six sentimental items (e.g., a picture with their two names inside a heart) he/she thought the recipient would like the best. Next, givers were informed that after the study there would be a lottery, and that if their name was drawn, the researchers would give them one of two items so that they could give it to the recipient: a) A \$25 gift card to the recipient's favorite store; or b) The sentimental item selected earlier. After givers made their choice, recipients completed the second half of the study. Specifically, recipients imagined that the giver was choosing a gift for the recipient and narrowed his/her choice down to the two items mentioned above, and then chose which item they would prefer to receive from the giver. As expected, givers did not give the sentimental gift as often as recipients preferred to receive it (24% vs. 34%; $p = .02$).

In sum, these studies demonstrate a novel error in gift giving, and contribute theoretically to the literatures of gift giving and self-other decision making.

Sometimes It's Okay to Give a Blender: Giver And Recipient Preferences For Hedonic And Utilitarian Gifts

EXTENDED ABSTRACT

Anticipating which gift will make someone happiest can be challenging. When choosing a gift, givers often find themselves torn between gifts that are fun but frivolous and gifts that are more useful but less enjoyable, too often opting for the former, as scores of dusty knickknacks, unwatched movies, and regrettably-eaten chocolates can attest. Adding to the literature that highlights situations when and reasons why giver and receiver preferences may be misaligned (e.g., Galak, Givi, and Williams 2016; Gino and Flynn 2011; Steffel and LeBoeuf 2014; Zhang and Epley 2012), we show that givers place undue emphasis on giving hedonic gifts, underestimating recipients' preferences for more utilitarian ones.

Our first study examined people's perceptions of the best gifts they had ever exchanged with a friend. Participants described the best gift they had ever given and the best gift they had ever received, and indicated how fun and enjoyable and how useful and necessary each was. People believed the best gift they had given was more hedonic than utilitarian, but this effect is attenuated for the best gift they had received, resulting in a significant interaction ($F(1, 131) = 25.99, p < .001$). Participants felt the best gift they had received was much more utilitarian than the best gift they had given (*paired t*(132) = 18.70, $p < .001$). Further, this difference held regardless of whether the other person in the exchange was a close other or a causal acquaintance, and was not driven by how material or experiential the gift was.

Study 2 investigated consumers' prospective preferences for gifts. Participants considered a friend for whom they would buy a gift in the next few months, or who would buy them a gift. They indicated how important six dimensions (fun, enjoyable, attractive, useful, needed, practical) would be in determining what they give to their friend, or how important they would like those features to be in determining what their friend would give to them. Recipients want their friend to take utilitarian factors into account more, and hedonic factors less, than givers plan to ($F(1, 234) = 5.50, p = .02$).

Next, study 3 shows that this asymmetry determines givers' and recipients' preferences for specific items. Participants imagined exchanging small stocking stuffer gifts with five friends, and chose which five gifts from a list of fourteen possible options they would opt to give to or receive from their friends. Half of the items were hedonic, like a book of crossword puzzles or a dance music CD, and half were utilitarian, like a corkscrew or set of coasters. Participants wanted to receive a higher proportion of the utilitarian items than they would choose to give to their friends ($t(244) = -2.43, p = .02$).

Study 4 examined why givers underestimate how much recipients appreciate utilitarian gifts and gift features. Participants imagined taking part in a Secret Santa exchange, in which they were going to give or to receive a flash drive. They or their coworker were choosing between either a plain flash drive or a snowman-shaped drive with slightly less storage capacity. Givers were more likely to prefer to give the less-useful-but-more-fun snowman drive than recipients were to receive it ($t(278.72) = -2.80, p = .005$). Givers were also more likely to report focusing on the moment of exchange (rather than the gift's long-term value) when choosing the flash drive they preferred than were recipients ($t(282) = -2.27, p = .02$). This differential focus on exchanging the gift versus ownership of the gift mediated participants' choice of flash drives (95% CI: .05 to .67).

Finally, we tested whether this mismatch in preferences for utilitarian gifts might drive gift returns. Ten days after Christmas, we asked participants to think about a gift they had or were planning to return, and to indicate their reasons for doing so by choosing from a list of potential reasons. These reasons included two about the gift being insufficiently hedonic ("The gift was something useful and I wanted something more fun" and "The gift wasn't fun enough") and two about the gift being insufficiently utilitarian ("The gift was something fun and I wanted something more useful" and "The gift wasn't useful enough"). A sign test reveals that significantly more participants indicated that wanting something more utilitarian (12.9%) than wanting something more hedonic (2.3%; $Z = -3.95, p < .001$) was the reason why they returned a gift most recently. By erring on the side of hedonic gifts, givers not only mismatch their recipients' preferences, but may even be more likely to give them gifts they wish they had not received.

Overall, our work suggests that to make their recipients happier, givers might consider more what their recipients might need and less

what they might enjoy. At the very least, givers underestimate the degree to which recipients often appreciate a gift with useful features. Givers might wish to remind themselves that sometimes, it's okay to give that blender.

The Quality Versus Quantity Trade-Off: A Dual-Risk Account For How Choices For The Self Versus Others Differ

EXTENDED ABSTRACT

Imagine a consumer plans to spend \$15 on a coffee shop gift card and is choosing between a coffee shop with higher quality but more expensive coffee, such that she can buy fewer cups of coffee for the same cost (the “quality” option for short), and another coffee shop with lower quality but less expensive coffee, such that she can buy more cups of coffee for the same cost (the “quantity” option). Or, imagine a consumer planning to spend \$10 on either a smaller bottle of higher quality shampoo or a larger bottle of lower quality shampoo. Clearly, in both examples, the consumer faces a tradeoff between quality and quantity. Will her choice differ depending on whether she is choosing for herself or for another person and if so, why?

Drawing from a growing literature suggesting that choices for self and other differ in systematic ways (Choi et al. 2006; Laran 2010; Polman 2012a, 2012b), we examine the effect of choice recipient—self or other—on the quality-quantity tradeoff. We propose that consumers will be more likely to favor quality over quantity when choosing for another person versus for oneself.

We further propose that this effect will arise because of differences both in the perceived usage risk associated with choosing a lower quality option for other versus self and in the perceived social risk associated with choosing a lower quality option for other versus self. First, with regard to perceived usage risk, we propose that consumers will be fairly certain that they will like the lower quality option enough to use it, such that they can derive savings benefits from the larger quantity. In contrast, consumers will be more uncertain about whether another person will like the lower quality option enough to use it, such that the larger quantity is less important (unused product is wasted). Second, with regard to social risk, we propose that consumers feel that sacrificing quality for quantity is more embarrassing when choosing for another person, based on literature indicating that “cheap” behavior is considered embarrassing (Ashworth, Darke, and Schaller 2005) and that embarrassment is heightened when thinking about the presence of others (Dahl, Manchanda, and Argo 2001).

Study 1 (N = 330) found support for our basic effect: consumers were more likely to choose quality over quantity for others than for the self (close other vs. self: $p = .003$; distant other vs. self: $p = .005$). There was no difference between choices for a close versus distant other ($p = .864$), providing some evidence against the alternative explanation that construal level differences might drive our effects because a construal level account predicts different effects when choosing for close versus distant others (Baskin et al. 2014)).

Study 2 (N = 210) used two different product types (soap, coffee gift card) and replicated the main effect of choice recipient observed in study 1 ($p < .001$). Moreover, study 2 provided evidence for our proposed dual process account whereby the effect of choice recipient on preferences for the quality – quantity tradeoff was mediated both by perceived usage risk for the lower quality – higher quantity option (95% CI: $-.5097, -.0679$; Hayes 2013) and by social risk (95% CI: $-.8996, -.2940$; Hayes 2013), both of which were higher when choosing for other rather than self. Finally, we found further evi-

dence against the potential alternative explanation that differences in construal level was explaining our results: whereas BIF was found to mediate effects of perspective (chooser, recipient) on choice of desirable (vs. feasible) product (Baskin et al. 2014), we found that BIF did not mediate effects of choice for self (vs. other) on choice of quality (vs. quantity) (95% CI: $-.1607, .0473$; Hayes 2013).

Study 3 (N = 304) generalized these findings to a non-gift-giving context, in which a consumer makes a product choice on behalf of another person who provides the money for the purchase. We again found that consumers were more likely to choose quality over quantity for others than for the self ($p < .001$). These findings suggest that it is not something special about the gift-giving context that leads to these effects and processes but rather about choosing for others more generally.

Study 4 (N = 1205) identified a boundary condition that further supported our process account. Specifically, study 4 had a 2 (choice recipient: self, other) \times 2 (choice recipient has had prior positive experience with both options: unspecified, yes) between-subjects design. We found a significant interaction ($p = .024$), such that the effect of choice recipient on the quality-quantity tradeoff was eliminated when the chooser was aware that the choice recipient has previously had positive experience with both choice options. Presumably, this boundary condition occurs because the elevated risks associated with choosing a quantity option for another person are mitigated.

In sum, across four studies involving real and hypothetical choice, we present consumers with a quality-quantity conflict and show that consumers are more likely to favor quality over quantity when choosing for others (vs. themselves). Study 1 demonstrates the basic effect of choice recipient on choice in a gift-giving setting. Study 2 provides support for our proposed underlying process through parallel mediation. Study 3 extends our findings to a non-gift-giving context while replicating the parallel mediation findings from study 2. Study 4 identifies a boundary condition, showing that our effect is eliminated when the chooser is aware that the choice recipient has previously had positive experience with both choice options. Finally, we rule out a construal level account for our effect.

Our research offers contributions to two literatures. First, we contribute to the literature on attribute tradeoffs by identifying a new factor that affects the little-understood quality versus quantity tradeoff. Second, we contribute to the literature on choosing for others both by identifying a new difference in choice when choosing for self versus other. Moreover, we also identify two novel mechanisms that have not been identified in this literature to the best of our knowledge: usage risk (preference uncertainty) and social risk (purchase embarrassment).

When Giving Thanks Means More: The Impact of Publicly Versus Privately Sharing Gratitude in Gift-Giving

EXTENDED ABSTRACT

For anyone who has ever received a gift, one of the first responses is to properly express gratitude. Much of the research has focused on the asymmetries between gift-givers and recipients from the point of view of the gift itself (Belk 1976; Steffel and LeBoeuf 2014; Ward and Broniarczyk 2011). Our research, however, addresses the question of asymmetries that occur in the gift-giving experience from a novel angle—how gift-recipients inaccurately forecast how gift-givers will respond to gratitude expressions. As gift-givers continually spend increasingly large amounts of money on gifts, understanding how recipients can enhance the experience for not only themselves, but for the givers is important to understand. Gifts are

chosen to express some symbolic meaning to the recipient, thus the expression of “it’s the thought that counts” may extend to the response of the recipient in a gift exchange for when they contribute to the gift exchange through their reactions (Zhang and Epley 2012).

We predict that gift-recipients may fail to anticipate how givers prefer to be thanked. Recipients may believe that expressing gratitude publicly rather than privately may be seen as more impersonal as broadcasting is typically focused on self-presentation goals (Baumeister et al. 2001) while narrowcasting is focused on sharing useful information to others (Barasch and Berger 2014). Conversely, gift-givers may perceive all gratitude to be equally personal (as gratitude, regardless of audience size, seems focused and directed towards them), and thus will appreciate gratitude regardless of how it is shared. We explore this discrepancy regarding gratitude expressions in four studies.

In Study 1, participants (N=136) were asked to recall a recent gift-exchange and were randomly assigned to one of two conditions (giver, recipient). After walking through a gift-exchange, participants were asked to choose whether they would share [receive] thanks publicly on the gift giver’s Facebook wall or privately through a Facebook message. In line with our predictions, we found that gift-givers chose to be thanked publicly more often than recipients chose to express gratitude publicly ($\beta = .710$, $\chi^2(1) = 3.88$, $p < .05$). These findings imply that gift-recipients are possibly missing opportunities to express gratitude in the gift-givers preferred way. To understand why this discrepancy occurs, Study 2 tests our proposed process.

In Study 2, participants (N=395) were randomly assigned to a condition in a 2(role: giver or recipient) \times 2(expression: public or private) design. Participants imagined either expressing or receiving gratitude in a private or public Facebook message after a gift-exchange. Using 7-point Likert-scales, gift-recipients predicted how the gift-giver would feel about the recipient (i.e., closeness) and about the expression itself (i.e., liking of expression, how the expression was perceived: personal, sincere, proud, comfortable) while givers predicted how they would feel.

There was a significant interaction between role and audience on expectations of givers’ felt closeness to the recipient and liking of the expression (both $p < .001$). Gift-givers equally liked the expression and felt equally close to recipients regardless of the gratitude expression (both $p > .36$). Alternatively, gift-recipients thought that gift-givers would like the expression less and feel less close to them when gratitude was expressed publicly (both $p < .001$).

We next examined the process underlying these discrepancies by testing for moderated mediation (Model 8, Hayes 2013) of liking and closeness as DVs (two separate models), expression type as IV, role as the moderator, and feelings regarding the expression (personal, sincere, proud, and comfortable) as parallel mediators. We found that how personal the gratitude expression seemed positively predicted both liking (CI₉₀[.00, .27]) and closeness (CI₉₀[.01, .21]). This was not true for any of the other possible mediators (all 90% CI contain 0). The indirect pathways through personal-ness to gift-recipient liking and felt closeness were significant for public expressions of gratitude (CI₉₅[.07, .25] and CI₉₅[.08, .30], respectively) but not for private expressions (both 95% CI contain 0). The results of this study show that gift-recipients believe public displays of gratitude will be poorly received due to being seen as less personal (though gift-givers do not share this belief).

In Study 3 (N = 106), we explored why gift-recipients believe that public expressions of gratitude will be seen as less personal. Participants were randomly assigned to one of two conditions (giver, recipient). After walking through a gift-exchange, participants were asked, when considering a public Facebook expression of gratitude,

how much they thought about the reactions/feelings of the other person in the exchange and how much they thought about the reactions/feelings of other people who could see the gratitude expression (measured on two sliding scales where the total percentage had to equal 100% between the two options). We found that gift recipients thought more about the reactions of others compared to gift-givers ($p = .004$). This finding supports the idea that gift-recipients believe public gratitude will be seen as more impersonal due a focus on a larger audience (i.e., broadcasting) compared to gift-givers.

In Study 4 (N = 409), we explore a boundary condition to this discrepancy in gratitude expressions. As we have seen in previous studies that the discrepancy between gift-recipients and gift-givers occurs due to gift-recipients incorrectly believing public gratitude to be less personal due to a larger imagined audience, we believe this effect will be specific to gratitude shared virtually where there can be a larger audience. To test this prediction, participants were randomly assigned to a condition in a 2(role: giver or recipient) \times 2(context of expression: offline or online) design. Participants imagined a gift-exchange and were asked to choose whether they would share [receive] thanks publicly or privately online [offline through Secret Santa scenario]. In line with our predictions, we found a significant interaction between role and context ($\beta = .37$, $\chi^2(1) = 12.91$, $p < .001$). Looking at the simple effects, givers chose to be thanked publicly significantly more than recipients chose to thank publicly online ($p = .001$) while offline, there were no differences between gift-givers and gift-recipients ($p = .37$).

We are currently running studies to determine situations when recipients will be more likely to share gratitude publicly online.

SESSION OVERVIEW

What emerges when consumers and objects interact? How do these emergent relationships impact consumers' lives? This special session draws on the far-ranging, diverse apparatus of assemblage theory (Canniford 2015; Delanda 2016; Price and Epp 2015), as well as Hodder's theory of entanglements (Hodder 2011; 2012; 2014), to examine the complex relational patterns that unfold as objects and humans interact.

Prior theory and research has highlighted object performativity and the role objects play in the socio-material ordering of consumers' lives (c.f. Epp and Price 2010; Kozinets, Patterson and Ashman 2016; Latour 1996; Verbeek 2004). The four papers in this session focus on the assemblage relationships that emerge as objects, be they analog or digital, interact with humans as they go about their analog or digital consumption pursuits.

The first paper by Godfrey, Price and Lusch ("**Ambiguity, Ambivalence and Fragility in Human-Object Relationships**") examines how ambiguity emerges from material forces that integrate or disintegrate an assembled object. Through in-depth ethnographic fieldwork, online research and consumer interviews involving shoe repair, the authors find the extent of a shoe's durability or fragility is always uncertain, leading to both ambiguity and ambivalence in the relationship between shoe, consumer, and repair service provider. This triadic service relationship extends conventional dyadic models by including the focal objects that define many service exchanges. Situated in a low technology context, the object-oriented ontological perspective of this research presents important implications for considering the life trajectories of things, including high technology objects.

Next, the paper by Humayun and Belk ("**Being Dumb in the Age of Smart: Analogue Object Entanglements**") explores why consumers are drawn to analog objects, even as our lives become more Internet-connected. Drawing on consumer narratives of using film cameras and paper notebooks, they find that analog objects let consumers disengage with the digital world at the same time that they create further object-on-object entanglements.

The third paper, by Schau and Luri ("**Enhancing Wellness: Melding Humans and Objects with Common Purpose**") inves-

tigates wearable technology use by three discrete app-related fitness communities over-time. The authors' findings highlight how wearable technologies are networked into consumers' technology and human relations. Importantly, extended interaction between the wearable technology and the user evolves and codifies relational norms. The power of these objects in the production of a wellness regime is illustrated, as is the relative omnipotence of the object in this performance, and the vulnerability of the regime to object fragility.

In the concluding paper ("**Consumer-Object Relationship Styles in the Internet of Things**"), Hoffman and Novak offer a conceptualization of the range of consumer-object relationship styles that have the potential to emerge when consumers interact with Internet-connected objects with sophisticated capacities of their own. Set in the smart home domain, the paper analyzes four broad classes of consumer-object relationship styles defined by the interpersonal circumplex model (Kiesler 1983). In this model, dimensions correspond to the agentic and communal expressive roles of the consumer and the object. The model reveals important implications for the role and evolution of communion and agency in object-human relationships.

Ambiguity, Ambivalence and Fragility in Human-Object Relationships

EXTENDED ABSTRACT

A material turn in social sciences over the past three decades brought non-human objects into examinations of social life. The work of Appadurai (1986), Kopytoff (1986) and Miller (1987), in particular, fueled multiple productive streams of consumer research. In this conceptualization, objects produced and consumed by people have social lives, interdependently tied to personal, collective, and societal uses and values (Appadurai 1986). This perspective aided development of a vital body of consumer research oriented toward symbolic properties of material objects (e.g., Wallendorf and Arnould 1988; Belk, Wallendorf, and Sherry 1989; Lastovicka and Fernandez 2005) and constantly changing and contingent human-object relations that make up social life (e.g., Epp and Price 2010; Canniford and Shankar 2013; Martin and Schouten 2014).

Objects are part of every human practice, and material things shape and give meaning to consumers' lives as much as consumers shape and give meaning to things (Miller 2010). However, theory focusing on the symbolic importance of objects abstracts away from the uniquely material value and characteristics of things. While materialist assemblage theories move beyond meaning-based models of human-object interactions to emphasize the interconnected, relational nature of social and material life (Law 1992; Latour 1996; DeLanda 2006), they also too easily hide or lose sight of the material essence of the object itself within a vast network of connections and effects.

We follow Harman's (Harman 2010, 2013, 2016) object-oriented philosophy by foregrounding the material life of the object within its social relations, rather than focusing on these relations themselves. Although material life drives and is driven by these relations, foregrounding the object itself enables a more precise conceptualization of the end of object life and of interventions such as repair, which attempt to alter an object's life trajectory. These are crucial aspects of an object's social and material life that have yet to be examined

in consumer research. While prior research has touched on aspects of object disposal (Price, Arnould, and Curasi 2000; Lastovicka and Fernandez 2005; Türe 2014), few studies have fully examined the “radical act” (Marcario 2015) of consumer repair.

By examining an object’s materiality against the backdrop of its relationships with other actors, we can understand the nature of both materiality and social life more fully. Further, we use the concept of material fragility to extend Harman’s object-oriented ontology, enabling a more precise and empirically grounded conceptualization of the end of object life than his philosophy currently provides. Our research demonstrates empirically that the ambiguity inherent in an object’s integrated, dynamic essence emerges from material forces that serve to integrate or disintegrate the assembled components of the object. An object-oriented ontological perspective allows us to uncover the processes and relationships that create a desire among human beings to intervene between the material forces of fragility and durability that shape objects’ life trajectories.

Our study explores the context of consumer shoe repair, in which cobblers provide an inherently material service to consumers through their shoes and boots. We conduct in-depth research that includes ethnographic fieldwork in shoe repair shops, interviews with consumers, and analysis of online data including consumer reviews, blogs, and discussion forums. We find that shoes have a powerful yet ambiguous physical singularity that emerges from the tension between the material forces that hold the shoes together and those that threaten to disintegrate them. The extent of a shoe’s durability or fragility is always uncertain, leading to both ambiguity and ambivalence in the relationship between shoe, consumer and repair service provider. External material forces of fragility act on shoes’ internal durability, resulting in inevitable aging and decay but also personalized form and meaning. Through these ambiguous and ambivalent relationships, however uncertain, decisions about repair emerge. Repair punctuates the relatively stable essence of a shoe and irreversibly alters its life. When successful, cobblers magically bring shoes back to life; when unsuccessful, shoes may face an early death.

Adopting an object-oriented ontological perspective changes how we conceptualize service exchanges by foregrounding the central role of focal objects in defining many exchanges. We move from a traditional conceptualization of a consumer-service provider dyad to a triadic relationship between consumer, service provider and object. The inherent opacity of a focal object’s material essence exposes the vulnerability of service exchanges in the face of materiality, a tension resolved temporarily and ambiguously through a magical service provision. In this way, triadic service exchanges such as repair more closely resemble a physician-patient relationship than a conventional seller-customer transaction. Although a patient or a shoe might have a common ailment, the unique essence of each patient or shoe necessitates tailoring every service. This requires learning and adapting during the process of service provision itself, as new information about the object emerges. In this way, our research has broad applications for managing the material forces of fragility and durability that shape objects’ life trajectories in diverse realms beyond shoe repair including healthcare, technology, housing and system infrastructures.

Being Dumb in the Age of Smart: Analogue Object Entanglements

EXTENDED ABSTRACT

We are constantly entangled with the digital world (Belk 2013). And yet, even as our possessions and identity projects move online and become digitized, there is a strong movement of analogue

consumption which is on the rise. From the unplugging ethos of “#digitaldetox” to rising sales of vinyl records: the materiality of the disconnected analogue objects seems to be steady (Magaudda 2011; Sax 2016; Bartmanski and Woodward 2016). Nokia recently re-booted the original 3310 touting it as the “dumb phone” that can accompany you on your holidays and provide the very basic functionality of making a call and offer limited internet access (Bogost 2017). With concerns about data privacy, even the Kremlin has invested in analogue typewriters (Irvine 2013). Negroponte (1998) argued that the digital would be felt by its absence, not its presence. We could even be said to be living in an era that is ripe for “postdigital” consumption (Berry 2015; Cramer 2015).

In this paper, we analyze why consumers still seek out “dumb” or analogue objects in a time where everything is “smart”. In particular, what object entanglements do such analogue objects create or undo? Objects have been of interest to researchers for decades (Levy 1959; Belk 1988; Belk, Wallendorf, and Sherry 1989; Fournier 1998; Belk, Ger, and Askegaard 2003; Miller 1987; Latour 1992). In recent years there has been an emphasis on understanding the materiality of objects in and of themselves (Borgerson 2005). Objects have been studied for the connections they invoke in the lives of a family, they have been analyzed in the process of becoming fetishes, they have been explored as heirlooms being passed down and even as souvenir objects and objects of value (Epp and Price 2010; Lastovicka and Fernandez 2005; Türe and Ger 2016; Decrop and Masset 2014; Marcoux 2016; Figueiredo and Scaraboto 2016). However, thus far the role of entanglements that objects create, maintain or truncate is yet to be fully examined.

Using Hodder’s theory of entanglements, we explore the notion of how things and objects depend and co-constitute each other and are immersed in various entanglements (Hodder 2011; 2012; 2014). Entanglements represent how humans and things are bound together in interrelationships of “dependence and dependency” (Hodder 2012, 89). For example, we have a dependence on social media networks to connect us: these dependences can be co-creative. *Dependency* on the other hand might run the risk of an asymmetric relationship and be constraining or disabling. For example, not being able to consume dinner until food photos are uploaded to Instagram. Objects and humans depend on each other to extend what they can do (Belk 2014; Hodder 2012).

We explore these ideas through the context of two brands that symbolize analogue consumption, Moleskine paper notebooks and Leica film cameras. While both brands have digital alternatives, our focus is on their analogue models that are not as seamlessly digitized. Based on consumer interview narratives from eight interviews, archival data from newspapers and online news publications and blogs and a netnography lasting from 2013-2015, we analyze how humans depend on these analogue objects that in turn are entangle them with connections to nostalgic and distant others. Our findings reveal that the use of such objects provides avenues of paradoxical entanglements *and* disentanglements from the digital world. Some consumers feel that the use of an analogue object allows them to be more mindful and present in their consumption as they invoke more intense labour and engagement. The material nature of the analogue objects also adds a sense of concreteness that the digital world sweeps away. We seek out some human-on-human entanglements which are mediated via these analogue objects as they in turn are enlivened by the connections they maintain to past others, be it famous writers or artists who used such objects. These objects allow for a sense of continuity to human existence.

These disconnected objects also provide a means of disentanglement from the corporations that create them and allow for avenues of escaping controlled consumption where all our data is

curated by algorithms that stare back at us in the forms of things we want. We also found that while these analogue objects provide the chance to disengage with the digital world, they also invoke other entanglements which perhaps these consumers are complicit with. Paradoxically, the analogue nature of such objects creates further object-on-object entanglement that is difficult to undo. Our findings reveal how asymmetric dependencies between objects and humans emerge and are maintained. To summarize, we find that we seek out dumb/analogue objects that depend on us more and that entangle us more in an age where smart objects may not need us as much. Our findings also have implications for material aesthetics of analogue objects and issues of consumer privacy and creative authenticity.

Enhancing Wellness: Melding Humans and Objects with Common Purpose

EXTENDED ABSTRACT

Everyone is bio-tracking. Tracking their steps, their miles, their heartrate, their speed, their flights climbed, and their calories. Wearable technologies permeate the mainstream marketplace and are touted as the most valuable assets in healthcare innovations (Collier and Randolph 2015). Surprisingly little consumer research focuses on wearables' wellness potential, specifically their wellness, medical diagnostic and treatment compliance capacity.

Perhaps more interesting is that wearable technologies have been inspiring wellness innovations for centuries (Rubenstein et al 1992). Even those that vehemently oppose the notion of alternative healthcare options as ancient practices, cite a specific window when these treatments entered Western culture as 1800-1850, now a century and a half ago (Mosley 2010). Depending on how we define wearables, they may even have been around since the first tools were used to craft the first jewelry (Calinescu 1996, Ogden 1982). Early jewelry was often fashioned to enhance spiritual and physical wellness and ward off negative fates. This talisman functionality of body adornments is not unlike wearable technology that monitors bodily activities with a purpose of promoting wellness as well as for ornamentation. Many organized religions continue to utilize jewelry as part of a spiritual health regime and to promote physical robustness (e.g., rosaries, crosses, Stars of David). These talismanic amulets shield the wearer from negative mortal outcomes, promote virility and enhance welfare in the afterlife. Precious stones have been mined since ancient times, treated and made into jewelry primarily to grant the healing power of the gems to the wearer (Kunz 1971). Stones and metals still comprise wellness amulets as complementary care options (Rao et al 2003). In essence, wearables are not new.

Using a process theoretic approach (Giesler and Thompson 2016) and an assemblage theoretic lens (Deleuze and Guattari 1987), we investigate the current use of wearable technologies as part of a networked wellness assemblage. Specifically, we focus on wearables' wellness capacities and their agentic properties as bodily adornments over time. We identify wellness wearable users as a subset of the larger US culture, and three discrete app-related fitness communities. We selected people beginning their journey with wearables to those with an extended history of use. Further, our data are longitudinal as we track the people's wellness assemblage over one year via digital diaries and multiple interviews, augmenting this data set with online forums dedicated to the use of wellness wearables (Nike+, MyFitnessPal and FitBit). Thus, our inquiry is the examination of change within a health centered assemblage connected to communities devoted to health promoting wearables. More specifically, our sampling frame consists of people who opt to adopt a wearable for a wellness regime and even at the onset make a commitment

to an extended trial. While these consumers may not achieve extended use, that is their stated goal which accompanies other commitment markers: weight loss goal, discrete fitness level, physician recommended lifestyle change, and treatment regimes. We focus on the relational ties, agentic roles and evolving capacities within the networked health assemblage.

Our preliminary results suggest that with extended use, the human object relationships change, becoming codified into wellness centered lifestyles. The key here is extended use and there is considerable attrition from wearable trial to extended use with most consumers' use fizzling out long before the one year mark. For those whose relationships endure to the year mark and beyond the human object relationship becomes *simpatico*. Extended use is seldom if ever casual. It is characterized by a sense of dependence. Wearable consumers wear the device multiple hours a day, often accounting for all conscious hours, and rely on the wearable to track critical success measurements in their wellness goal attainment. The wearable data is archived and at times shared with friends, family, goal-oriented coaches and physicians. Consumers with extended use patterns imbue the wearables with a sense of omnipotence bordering on magical, where the wearable is the arbiter of truth with the power to evidence for reward or punishment. Not far from the roots of sacred talismans, consumers afford these wearables perfect perception and moralize these results. Loss of an extended use wearable is tantamount to loss of a sacred object. Unmoored from their omnipotent object, consumers experience loss not only of the object but of the efficacy in the regime.

Our study contributes to the examination of wearables as wellness objects. We examine compliance to the health regime via the perceived omnipotence of the wearable object as record keeper. In perfect symbiosis, the human and object can achieve the greatest success. Breaking the established bond via loss or damage causes the user to experience loss and doubt their ability to succeed at their goals through regime compliance. In summary, we contribute to our understanding of extended human object relationships.

Consumer-Object Relationship Styles in the Internet of Things

EXTENDED ABSTRACT

The consumer Internet of Things (IoT) has the potential to revolutionize consumer experience. Previous research (Hoffman and Novak 2017) has developed an assemblage theory conceptual framework that details how consumer experience and object experience emerge from interactions in the consumer IoT. In that conceptualization, consumer experience, through its emergent properties and capacities, has two broad facets: extension experience and expansion experience. Hoffman and Novak (2017) also developed a parallel conceptualization of the construct of object experience, arguing that it can be perceived by consumers through the mechanism of anthropomorphic metaphorism, an object-oriented approach to anthropomorphism perceptions.

In this paper, we build on this conceptualization to examine the consumer-object relationship styles that emerge when consumers and objects interact in the assemblage. We consider emergent expressive roles of assemblage components in terms of distinctions along the agency and communion orientations in relationships with others (Kurt and Frimer 2015). Habitual interactions between consumers and smart objects are likely to reflect these orientations, with agentic interactions characterizing effectance and independence, and communal interactions emphasizing integrating with close others (Guisinger and Blatt 1994).

We propose that consumer-object relationship styles can be represented on a circumplex model by dimensions corresponding to the agentic and communal expressive roles of the consumer and the object (Horowitz, et. al. 2006; Kiesler 1983; Wiggins 1991). We believe this is the first application of Kiesler's (1983) circumplex model of interpersonal complementarity in the consumer behavior literature.

The interpersonal circumplex (Pincus and Ansell 2003; Wiggins, Trapnell and Phillips 1988) identifies four broad classes of relationship styles (Kiesler 1983). The styles are dynamic and evolving over time. The horizontal axis of the circumplex displays the degree of communal orientation, from indifferent on the far left (Horowitz, et.al. 2006) to warm and agreeable on the far right. The vertical axis represents agentic orientation, with dominant at the top and submissive at the bottom. The four styles specify interpersonal patterns between two entities according to their degree of complementarity on the dimensions of agentic and communal orientation (Kiesler 1983): a) complementarity, b) isomorphic complementary, c) semimorphic complementary, and d) anticomplementary.

Complementarity patterns involve reciprocity (i.e. opposite values) on agency and correspondence (i.e. similar values) on communion, representing balance in the regulatory system defining the relationship (Pincus and Gurtman 2006) and promoting interaction stability. Complementarity patterns (panel a) reflect master-servant relationship styles that are either trusting (high communal) or indifferent (low communal). In general, the object servant-consumer master relationship style occurs when the consumer agentic role is high and the object agentic role is low. If communal expression is high for both consumer and object, the object is a trusting servant of its consumer master, but if communal expression is low for both, then the object is an indifferent servant. Consumer servant-object master relationship styles are also possible when the consumer agentic role is low and the object agentic role is high.

Isomorphic complementary relationship styles are defined by nonreciprocity of agency and correspondence of communion, and involve identical agentic and communal expressions by consumer and object (panel b), are less stable than complementary styles, and motivate behaviors that increase separation of agentic roles (Horowitz, et.al. 2006). For example, consumers and objects are active partners in the relationship when agentic and communal expression is high for both (upper right of circumplex in panel b), but detached interactors when expression is low across the board (lower left of circumplex in panel b).

Semimorphic complementary relationship styles are reciprocal for agentic expression but do not correspond in communal expression (panel c). These styles are also less stable and motivate behaviors that encourage convergence of communal expressions. The final set of relationship styles are anti-complementary, involving non-reciprocal agentic expressions and non-corresponding communal expressions (panel d). These are the most unstable styles; they are minimally rewarding and present few opportunities for sustained interaction.

We address four research directions, including 1) measurement and validation of the relationship styles; 2) how the assemblage processes of territorialization and coding impact the emergence of different relationship styles; 3) the impact of relationship styles on consumer behavior outcomes such as task performance, and 4) the dynamics underlying the "relationship journey" (Ring and Van de Ven 1994) of consumers and objects.

SESSION OVERVIEW

Time may be the most precious resource consumers have at their disposal, and a growing literature suggests that consumers' decisions about how to spend their limited time are crucial determinants of their overall well-being (Aaker, Rudd, and Mogilner 2011; Mogilner, Chance, and Norton 2012; Van Boven and Gilovich 2003). While ample research highlights the importance of prioritizing experiences, there is limited research to guide people's choices of which experiences to consume (Bhattacharjee and Mogilner 2014) or how to consume them (Tonietto and Malkoc 2016).

Given the importance of considering the multiple sources of utility we derive from experiences across time (Elster and Loewenstein 1992; Kahneman 1994), this session contributes to our understanding of experiential consumption at multiple stages: *during* the actual experiences, *beforehand* while anticipating those experiences, and *afterwards* from the memories and symbolic meanings of those experiences. Each paper focuses on a different piece of utility from these stages: discounting of utility in anticipation (Goodman, Malkoc, and Rosenboim), predicted utility (O'Brien and Kardas), experienced utility (Tonietto and Barasch), and expected future utility (Garcia-Rada, Norton, and Ratner).

The first paper focuses on the discounting of utility in anticipation of future experiences. **Goodman, Malkoc, and Rosenboim** find that consumers are more impatient toward experiential compared to material consumption, discounting the future utility of experiences to a greater degree. This arises from the singular consumption episode characterizing most experiences, and declines when experiences are consumed over multiple episodes.

The second paper bridges between anticipated and experienced utility. **O'Brien and Kardas** show that people underestimate how much they will enjoy repeating an experience. Though repetition may seem to offer little utility in anticipation, people enjoy the thrill of the familiar more than they expect.

The third paper focuses on consumption utility. **Tonietto and Barasch** find that generating content that marks the passage of time (i.e., event markers) during experiences enhances utility. In particular, creating event markers increases engagement with the experience, leading time to feel as though it is passing more quickly, and ultimately increasing enjoyment.

Finally, the fourth paper examines trade-offs between experienced and future utility. **Garcia-Rada, Norton, and Ratner** find that consumers may choose a less desirable experience in order to share that experience with a co-consumer. Sacrificing utility during the experience can signal commitment to a shared future, and is associated with higher future utility from relationship satisfaction.

Understanding how different sources of utility shift and interact over time is essential to leading happier and more fulfilling lives. This session sheds new light on how consumers evaluate multiple sources of utility over time, as experiences approach, unfold, and impart enduring meaning. All four projects are working papers with at least three studies completed. Given the widespread applicability of the issues discussed, we expect this session to attract researchers interested in utility and experience, experiential versus material consumption, happiness and well-being, the psychology of time, affective forecasting, and satiation. We hope that these diverse approaches to studying experiential consumption will generate a lively and fruitful discussion.

The Material-Experiential Asymmetry in Discounting: When Experiential Purchases Lead to More Impatience

EXTENDED ABSTRACT

Consumers routinely decide whether and when to spend money on doing things (experiential purchases) or having things (material purchases), either in the present or future. When delaying consumption, consumers are impatient and show high rates of discounting (for a review see Berns, Laibson, and Loewenstein 2007; Urminsky and Zauberman 2014). Yet, most of the literature examining consumer impatience has predominantly considered monetary outcomes (i.e., delaying dollars), assuming (perhaps implicitly) that how the money will be spent is irrelevant to how consumers delay outcomes. We study systematic differences in impatience towards material and experiential purchases and propose a key distinction between the two—the duration under which a purchase is consumed.

Studies 1A and 1B initially tested our prediction using common manipulations of material and experiential purchases from the literature. In Study 1A participants first generated that they would likely make around \$100 that is either a material or experiential. Next, they completed a standard delay discounting task (e.g., Malkoc and Zauberman 2006), indicating the least amount of money they would be willing to accept to delay the purchase by one week, one month, or three months. To rule out alternative explanations, we also measured excitement and anticipated regret (neither had an effect and are thus not discussed further). Consistent with our prediction, we found a significant main effect for purchase type, where participants in the experiential condition ($M=756.28$) required higher premiums to delay than those in the material condition ($M=310.70$; $F(1,344)=29.75$, $p < .001$). We also found a significant time by purchase type interaction ($F(2,344)=12.92$, $p < .001$). The decline in discounting was steeper for experiences ($M_{1\text{week}}=1,444.79$, $M_{1\text{month}}=496.23$, $M_{3\text{months}}=327.83$; $F(1,189)=24.95$, $p < .001$) compared to material goods ($M_{1\text{week}}=409.07$, $M_{1\text{month}}=352.91$, $M_{3\text{months}}=170.13$; $F(1,196)=5.43$, $p < .01$), demonstrating an attenuation (accentuation) of present bias in material (experience) conditions.

In Study 1B participants considered delaying either a \$950 couch (material) or \$950 vacation (experiential) by 1 week, 1 month, and

3 months (within). We again found a main effect for purchase type, indicating that participants in the experiential condition ($M=618.60$) required higher premiums to delay, and thus were more impatient, than those in the material condition ($M=263.78$; $F(1,160)=30.90$, $p < .001$). As before, the time by purchase type interaction was also significant ($F(1,160)=31.55$, $p < .001$), showing a relatively weaker present bias in the material condition.

We designed the next three studies to rule out two alternative explanations: social nature (Study 2), re-scheduling difficulty (Study 3), and the hedonic nature (Study 4) of experiential purchases. We designed Study 2 similar to Study 1B, except the following additions: (1) a new third condition, asking participants to imagine going to a vacation alone, (2) a repeated choice method to elicit impatience and (3) several variables that help better understand the process (e.g., scheduling, time sensitivity, memory, positive emotions). We found a significant effect of product type on impatience ($F(2,303)=6.71$, $p < .01$): Consumers made fewer impatient choices when delaying a material purchase ($M=2.68$) compared to delaying a social experience ($M=3.69$; $t(303)=3.44$, $p < .001$) or a solitary experience ($M=3.53$; $t(303)=2.80$, $p < .01$). The solitary and social experience conditions did not differ ($t(303) < 1$). Testing our alternative processes, we found that while a concern for scheduling did lead to impatient choices ($F(2,292)=17.59$, $p < .001$), it did not mediate the effect of purchase type on impatience (nor did any of the other measures).

In Study 3, we used an incentive-compatible design, and controlled for rescheduling by asking participants to schedule a massage appointment (experience) or massager pick up (material) time prior to indicating their intertemporal preferences. They also scheduled their delay appointment/pick up the following week. They then made a series of ten choices, indicating preference between receiving their massage [massager] this week or next week for an additional compensation (from \$0 to \$45, with \$5 intervals). Consistent with our previous studies, participants who considered delaying the experience made significantly more impatient choices ($M=2.17$) than those who considered delaying a material item ($M=1.64$; $t(196)=2.14$, $p < .05$).

Study 4 manipulated the consumption goal (hedonic/utilitarian) and material/experiential nature. We found that experiences lead to more impatience ($M_{\text{experiential}}=4.34$, $M_{\text{material}}=3.50$, $F(1,351)=9.11$, $p < .01$, regardless of the consumption goal. Consumption goal did not moderate the material-experiential effect ($F(1,351) < 1$, $p > .6$).

Finally, Study 5 directly tested whether differences in the number of consumption episodes drives the effect. We pre-tested different purchases that matched on attractiveness, but differed in terms of being more or less material-experiential. We generated four items for each of the four replicates: (1) material purchase consumed over a long time, (2) material purchase consumed over a short time, (3) experiential purchase consumed over a long time, and (4) experiential purchase consumed over a short time. As expected, participants made significantly more impatience choices when delaying purchases consumed over a single episode ($M=4.02$) compared to multiple episodes ($M=3.47$; $F(1,187)=4.59$; $p < .05$). Since our material-experiential manipulation no longer varied in terms of consumption duration, we did not find a main effect of purchase type ($M_{\text{experiential}}=4.33$ vs. $M_{\text{material}}=3.51$; $F(1,187) < 1$; $p > .5$). That is, the material-experiential asymmetry on impatience was eliminated once consumption duration was controlled.

Our findings demonstrate that the type of purchase (i.e., material vs. experiential) systematically alters the extent of consumer discounting and impatience, indicating that a different consumption pattern over time can have significant effects on the compensation consumers require to delay a purchase. This result helps explain why

some research has found vastly differently discount rates across experimental stimuli, particularly in quantitative modeling and product adoption that has focused on durable (i.e., material) goods (Dube, Hitsch, and Jindal 2015). Further, our results highlight an instance where material purchases, that are ordinarily have negative associations (e.g., materialism, overspending), lead to a desirable outcome (i.e., less impatience).

Underappreciating the Thrill of the Familiar

EXTENDED ABSTRACT

People prefer novelty and variety when seeking to maximize their enjoyment for foods, vacations, social events, consumer goods, and many other everyday experiences (McAlister and Pessemier 1982; Kahneman and Snell 1992; Ratner, Kahn, and Kahneman 1999; Read and Loewenstein 1995; Simonson 1990)—consuming or doing something “new” rather than something that one has consumed or done in the past. Rather than choosing to re-experience the same things over and over again, people tend to quickly abandon familiar entities for newer, frequently more expensive, alternatives.

Why? Almost all previous research on novelty and variety has focused on the allure of the newer alternatives by which people are tempted (e.g., in advertising efforts that highlight desirable updates: Fennis and Stroebe 2010). From this perspective, an aversion to repetition reflects people’s imagination of the future novel experience, often an exaggeration of its value if actually acquired (Wilson and Gilbert 2003). However, people might also misconstrue the *familiar* experience, by underappreciating the richness that could be reaped if actually repeated. Hedonic states, like a pleasurable taste while eating food or feeling excited while watching a movie, are considerably more intense, more absorbing, and more dynamic in the moment of consumption compared to their simplified, stripped-down, and static mental representations (Ariely and Loewenstein 2006; Hsee and Zhang 2004; Morewedge et al. 2010; Robinson and Clore 2002). Doing the same thing over and over again may therefore provide unique immersive thrills in the actual moment (e.g., sustained affective/visceral sensations; discovering missed details and nuances; developing new interpretations) but in one’s mind seem like a tedious overdose of the same simplified thing. An aversion to repetition could reflect a mistaken intuition about the remaining value hidden in the familiar.

To address this question, participants were exposed to an enjoyable activity and reported their reactions. Some were asked to repeat the activity a number of times in a row and rated each exposure. Others simply imagined repeating the activity and predicted their reactions. Five studies followed this procedure, across a variety of experiential domains. This affords a conservative test because immediate repetition (versus after some delay) may promote *actual* dullness, working against the hypothesis.

Study 1 was conducted in naturalistic settings with visitors at a science museum. All participants went through the Genetics exhibit, among the most popular at the museum. Afterwards, they rated their enjoyment for the experience. Then, some were asked to go through Genetics again, and afterwards rated their enjoyment for this second visit. Others simply imagined repeating the exhibit and predicted their enjoyment.

Do people underappreciate the fun of repetition? Yes. Predictors assumed a decline: while the original experience was quite enjoyable, they believed that going through the exhibit again would be significantly less enjoyable ($B = .63$, $p < .001$). In reality, this was not the case: actual experiencers enjoyed the return visit just as much as the first time around ($B = .09$, $p = .55$).

In study 2, all participants played a video game for a set playing period, then were asked to actually play or to simply imagine playing the same game, from the same starting point, for six subsequent periods back-to-back. While the reactions of predictors and experiencers did not differ at first or second exposure ($Bs \leq .36$, $ps \geq .11$), predictors significantly underestimated their excitement for replaying the game a third, fourth, fifth, and sixth time in a row ($Bs \geq .78$, $ps \leq .001$).

In study 3, all participants watched a video of a motorcycle ride, three times in a row. Again, while predictors accurately reported their excitement for the initial viewing ($B = .02$, $p = .94$), they significantly underestimated their excitement for re-watching a second and third time in a row ($Bs \geq .49$, $ps \leq .04$).

In study 4, all participants viewed a collage of evocative photographs (e.g., an image of a cliff diver) for set viewing period, for a total of five consecutive periods. Yet again, predictors accurately reported their excitement for their initial exposure to the collage ($B = .24$, $p = .24$), but significantly underestimated their excitement for re-viewing the collage a second, third, fourth, and fifth time in a row ($Bs \geq .60$, $ps \leq .009$).

Study 5 ruled out general repetition effects (e.g., mere exposure), highlighting the role of simplification. Some participants completed the task from study 4: they saw the rich evocative collage and either experienced or imagined repeat viewings. Others saw a simplified collage that stripped away all richness and evocative imagery, holding its theme constant (e.g., a cartoon danger symbol rather than an actual cliff diver). For the rich collage, the misprediction replicated: although predictors and experiencers did not differ in their excitement at the initial exposure ($B = .20$, $p = .29$), predictors significantly underestimated their excitement for viewing a second, third, fourth, and fifth time in a row ($Bs \geq .54$, $ps \leq .04$). Repetition was, again, surprisingly thrilling. But for the simplified collage, this effect disappeared: participants *accurately* predicted their reactions to each viewing ($Bs \leq .28$, $ps \geq .17$). Unexpected thrills from repeated exposure may not derive from the act of repetition but from the simplified nature of how people mentally represent rich hedonic states. When repeating experiences that are already “simplified,” people’s dulled intuitions about repetition can serve them well.

Unfortunately for the rational decision maker, most enjoyable activities are hedonically rich, not dull. An aversion to repetition may generally pose a problem. Because people may avoid repeating these experiences in daily life, they rarely discover the hidden benefits of actually doing so. Instead, people pay a novelty premium. Previous research has touted many benefits of novelty and variety for individual wellbeing (Lyubomirsky, Sheldon, and Schkade 2005), but a growing societal emphasis on the “new” may also explain growing consumption waste (OECD 2014). Before intuitively seeking something new, knowing to consume the same thing a few more times might help reduce costs while also maximizing the value of the thing itself. Repetition too could add a (surprising) spice to life.

The Influence of Creating Event Markers on Experienced Time and Enjoyment

EXTENDED ABSTRACT

Consumers commonly create content about aspects of an experience as it unfolds. For example, during an experience, consumers often write posts for real-time social media updates and frequently send messages to others (Ahonen 2013) about their experience.

Importantly, when consumers generate information during an experience, they punctuate the intervening events within the experience, creating event markers. Prior research suggests that such mark-

ers can alter retrospective time perception and make events feel more distant (Zauberman et al. 2009), while related work suggests that reminders of past events can enhance utility from memory (Zauberman, Ratner, and Kim 2009). However, no past research investigates how creating markers during experiences might affect current time perception and enjoyment.

We propose that because activities which capture the unfolding experience increase engagement with the task (Diehl, Zauberman, and Barasch 2016), creating event markers will lead time to feel as though it is passing more quickly, resulting in the experience feeling perceptually contracted. That is, when consumers are more engaged, they tend to pay less attention to the passing of time, which can lead time to feel as though it is passing more quickly (Conti 2001). Finally, because consumers tend to infer greater enjoyment when time is perceived as passing more quickly (Gable and Poole 2012; Sackett et al. 2010), we further predict that creating markers within an experience will increase enjoyment.

Four studies examine how creating markers can alter experienced time and enjoyment. All of the studies follow a similar set-up: participants took a virtual tour by watching a first-person video of someone touring a particular city. Following the tour, we measured time perception using two items: how quickly did time seem to pass and how long did this tour experience seem to last (reverse-scored). Study 1 also measured how engaged participants felt and Studies 1-2 measured how much they enjoyed the experience.

In Study 1 ($N=165$), all participants imagined that they were experiencing a tour with a friend. Those in the *marker* condition were provided with five text boxes to write messages related to the ongoing experience to their friend at any point during the video. Those in the *control* condition simply watched the video and were not instructed to write any messages. We found the predicted effect, whereby those in the *marker* condition ($M=40.33$) perceived the experience as passing more quickly than those in the *control* condition ($M=27.50$, $p<.01$), and also felt more engaged ($M_{\text{Marker}}=56.62$, $M_{\text{Control}}=45.36$, $p=.016$) and enjoyed their experience more ($M_{\text{Marker}}=43.53$, $M_{\text{Control}}=35.78$, $p=.08$). Moreover, we found evidence for our proposed serial mediation (markers→engagement→time perception→enjoyment; 95% [CI]=0.418, 3.960).

In Study 2 ($N=210$), we sought to replicate the results of Study 1 while also including an additional control group, where participants receive messages from a friend rather than creating content. Demonstrating that the effect is a unique outcome of *creating* markers, rather than the result of mere distraction from any marker during the experience, we found that creating markers ($M=32.09$) led time to feel as though it had passed more quickly compared to both the control ($M=18.54$) and friend-generated content conditions ($M=23.09$, $ps<.02$), which did not differ from each other ($p=.25$). Further, self-generated markers ($M=30.66$) led the experience to be more enjoyable compared to both the control ($M=20.60$) and other-generated conditions ($M=18.61$, $ps<.01$), which did not differ ($p=.58$). Replicating Study 1, we found evidence for our proposed mediation (self-generated markers→time perception→enjoyment; 95% [CI]=0.731, 3.644).

In Studies 1 and 2, we operationalized marker-creation using sharing. While sharing behavior may be one particularly common way that markers are created in everyday life, any content that consumers create during an experience should serve as a marker and therefore show our effect. As such, in Study 3 ($N=202$), rather than sharing, participants in the marker creation conditions wrote self-notes about their experience. Further, we included an additional marker-creation condition in which participants wrote the notes whenever they were prompted to do so rather than at any time they

chose. We found that creating markers led participants to perceive the experience as passing more quickly whether participants controlled the timing of the markers ($M=53.10$) or not ($M=60.53$), compared to control ($M=46.07$, $ps<.05$). Study 3 demonstrates that the effect of marker-creation is robust to removing both the sharing aspect and the control that participants have over the timing of the markers.

Importantly, prior research defines markers as intervening events that directly relate to a past experience (Zauberman et al. 2009). As such, in order to test whether our observed effect is driven by relevant marker-creation (rather than from creating any content), in Study 4 ($N=107$) we manipulated the relevance of the content to the ongoing experience in a 2 (relevance; within-subjects) \times 2 (self vs. other-creation, between-subjects) design. Participants in this study went on two separate tours. Those in the self-generated markers condition were once again instructed to write messages to a friend during their tour experience, but to only write content that was directly relevant to the ongoing experience in one tour and only content that was irrelevant in the other tour (counter-balanced). Those in the other-generated conditions instead *received* messages from a friend that were relevant for one tour and irrelevant for the other (counterbalanced). We found the predicted interaction on time perception ($p=.014$) such that, for relevant content, self-generated markers ($M=42.81$) led time to pass more quickly compared to other-generated content ($M=32.62$, $p<.01$), but no such difference emerged for the irrelevant content ($M_{\text{Self}}=32.76$, $M_{\text{Other}}=33.18$, $p=.92$). Further, in the self-generated markers conditions, relevant content led time to pass more quickly compared to irrelevant content ($p<.01$), but no such difference emerged for the other-generated conditions ($p=.86$). This study therefore demonstrates that temporal markers must be self-generated and directly related to the ongoing experience in order to influence the experience of time.

We find that creating event markers during an experience can positively impact enjoyment by increasing engagement and leading to the sense that time is passing more quickly. This research contributes to the literature examining the effects of event markers while providing implications for marketers to improve consumer experiences by encouraging content-creation.

Compromised Experiences, Compromised Relationships

EXTENDED ABSTRACT

When taking a flight, faced with the choice of two uncomfortable adjacent seats in the last row of the plane, or two seats in the economy comfort section that are not next to each other, what do consumers in relationships choose? We explore decisions about such shared experiences and examine the consequences of these choices for satisfaction with both the experience itself and the relationship. We suggest that some interaction partners compromise the objective quality of an experience to share that experience with a co-consumer (such as a romantic partner) – and that such choices are associated with higher relationship satisfaction.

Previous work has shown that shared experiences can be more pleasurable and preferred over both solo experiences and material possessions (Capriello and Reis 2013). Sharing an activity with another person amplifies the experience (Boothby, Clark and Bargh 2014) and leads to more coherent evaluations (Ramanathan and McGill 2007). Moreover, consumers often feel inhibited from engaging in hedonic public activities alone as they anticipate negative inferences from others about their social connectedness (Ratner and Hilton 2015). We build on this work and suggest that consumers not only prefer sharing an experience with someone else over enjoying alone but that they will sacrifice objective quality of the experience

to enjoy the experience right next to a close other (H1). Additionally, we build on work on interpersonal closeness to demonstrate that the type and quality of a relationship can explain how consumers make choices for shared experiences. We argue that because consumers in close relationships perceive themselves as interdependent and focus on sharing their resources and perspectives with close others (Aron & Aron, 1986; Berscheid, Snyder, & Omoto, 1989) they will be more likely to choose shared worse experiences (H2A). Specifically, in the context of romantic relationships, we hypothesize that such sacrifices are associated with higher relationship quality (H2B).

In Studies 1A and 1B, we document this ubiquitous phenomenon. First, we analyzed Trip Advisor reviews of the interactive play “Sleep No More.” This is an experience that has been designed to be enjoyed solo: the company encourages visitors to have a unique solo experience and then exchange stories with other group members at the end. We obtained 675 reviews submitted by consumers who visited this show. Two coders read the reviews and identified how the person went through the play (1=alone, 2=with other people, 0=unclear). We find that 26.7% of the visitors decided to stay with their co-consumer(s) and that these people reported enjoying the experience significantly less ($M_{\text{review rating}}=3.23$, $SD=1.54$; $n=40$) than those who went through the experience alone ($M_{\text{review rating}}=4.39$, $SD=1.05$, $n=110$, $t(52.69)=4.42$, $p<.001$). In Study 1B, we document these sacrifices using a broader set of experiences ($N=200$). We asked participants to indicate whether they could recall a time when they had to choose between enjoying an experience with someone or taking a better experience but enjoying it separately or alone. Seventy-one percent said they could recall facing this decision, and 60% of these decisions were made over the last year. Taken together, Studies 1A and 1B suggest that choices between better experiences or shared experiences are common.

Studies 2A and 2B explored whether such seemingly suboptimal choices – worse experiences – may come with benefits: better relationships. We recruited participants in romantic relationships (Study 2A; $N=200$) and romantic dyads (Study 2B; $N=216$) and asked them to make choices for several experiences they could share with their romantic partner. We created multiple vignettes describing experiences that involved a decision between a “good apart” option and a “bad together” one. We manipulated the quality of the experiences by varying the level of comfort (e.g. seats for a flight), duration (e.g. time of a videogame), location (e.g. front row vs. last row seats for lecture), and perceived quality (e.g. basic vs. premium spa session). In these two studies, we observe that consumers generally prefer a “bad together” experience to a “good apart” one (proportion of people who chose “bad together” for each activity ranges from 50-96%) and that quality sacrifices are greater when there is more opportunity for interaction during the experience. Interestingly, we find that giving up quality of experience (i.e., choosing “bad together” experiences over “good apart” ones) positively correlates with relationship quality measures such as satisfaction, commitment, gratitude, and interpersonal closeness (these effects hold in our two samples, all $ps<.05$).

In the final two studies, we manipulate the type of experience (Study 3) and the type of relationship (Study 4) and examine how these two dimensions impact choices. In Study 3, we framed the same experience (a cooking class) either as utilitarian or hedonic and asked participants to choose seats ($N=200$). We observe that 77% of participants chose two adjacent seats in the last row of the class where they couldn’t see the instructor properly (over two non-adjacent first row seats) when they had a hedonic goal compared to 60% when they had a utilitarian goal ($\chi^2(1)=6.70$, $p=.010$). In Study 4, participants were asked to choose seats for a flight they were tak-

ing with their romantic partner, a close friend, or a distant coworker ($N=303$). We find that participants in the partner condition displayed the highest level of sacrifice (56.4% chose the two adjacent seats in the last row of the plane over two comfortable non-adjacent seats), followed by close friends (38.0%) and distant coworkers (11.8%; $\chi^2(2)=40.80, p<.001$).

Our results contribute to research on shared experiences, examining when and why consumers make quality tradeoffs for shared experiences with close others. Our archival data suggests that being alone can enhance the quality of the experience, but our relationships data suggest that being together leads to happier couples. Thus it appears that, in some cases, people must choose either to enjoy the experience or solidify their relationships: compromising an experience can help to keep relationships from being compromised.

SESSION OVERVIEW

Consumers use rewards to increase motivation, and rewards appear to work. Financial incentives successfully help consumers lose weight (John et al. 2011; Volpp et al. 2008a), stop smoking (Volpp et al. 2009), exercise more (Acland and Levy 2015; Charness and Gneezy 2009), and adhere to medication (Volpp et al. 2008b). Indeed, rewards can engender lasting behaviors, such as creating a habit to exercise even after their removal (Charness and Gneezy 2009).

Yet the effect of rewards on motivation is often unclear, as rewards can also hurt goal pursuit by crowding out intrinsic motivation (Deci and Ryan 1985; Lepper and Greene 1978). For example, providing thank-you gifts reduced the amount of money donors gave to charity (Newman and Shen 2012). The body of research presented in this session accordingly explores the nuanced ways in which rewards influence motivation. Across four papers, we investigate when rewards increase versus decrease motivation and, in particular, test effects of rewards on intrinsic motivation and post-reward engagement.

Specifically, the first two papers explore positive effects of rewards on motivation. In the first paper, Goswami and Urminsky show that the effect of rewards on reducing motivation (the crowding out effect) is temporary. Across four studies, they find that a short-term reduction in task engagement following a temporary reward is caused by a desire to balance effortful goal pursuit with the enjoyment of benefits. In the second paper, Yang, Zhang and Lee, in the context of donating, identify power as a moderator of the effect of rewards on motivation. In three studies, they find that whereas rewards reduce powerful individuals' desire to donate, rewards actually increase powerless individuals' donation tendency.

The last two papers explore the effect of reward timing on motivation. In the third paper, across five studies, Woolley and Fishbach find that immediate rewards increase intrinsic motivation (e.g., for exercising, visiting museums, and reading) more than delayed rewards. This effect is specific to intrinsic motivation, and does not generalize to an increase in extrinsic motivation. In the fourth paper, Huang and Aaker identify a novel factor, the use of metaphor, to frame the reward of goal attainment as part of the process, prevent-

ing disengagement from goal-congruent behaviors after goal attainment. Four experiments demonstrate that using a journey metaphor associates the rewards from goal attainment with the process of goal pursuit (vs. the outcome), thereby increasing motivation.

These papers explore a classic problem in goal pursuit, how to motivate behavior, and examine underlying processes that shed light on when rewards will increase versus undermine motivation. Further, they explore post reward and post goal attainment motivation, providing practical insights for increasing motivation and goal-congruent behaviors. This session will have broad appeal to scholars interested in incentives, donation behavior, motivation in general, and post goal attainment motivation in particular, as well as connections between these topics.

How “Effort Balancing” Explains Dynamic Effects of Incentives on Motivation

EXTENDED ABSTRACT

Incentives are fundamental to marketing, yet the widespread use of incentives raises potential concerns about the effects on intrinsic motivation. This concern originates with a large and influential literature which argues that conditional incentives can undermine or crowd-out intrinsic task interest, by changing either task perception or beliefs about own preferences (Deci and Ryan 1985; Lepper and Greene 1978). As a result, the change in belief or task perception is predicted to result in a persistent disengagement after incentives end (Deci, Koestner, and Ryan 1999).

Recent research has challenged this long-standing view, finding that the post-incentive reduction in engagement is brief when it occurs and is less likely to occur in highly rewarding situations (e.g., high payment or fun tasks; Goswami and Urminsky 2017). We test an “effort balancing” account, which reconciles previous findings and generates new predictions. In this view, post-incentive changes in task engagement are driven by a psychological desire to balance effortful goal pursuit with enjoyment of benefits. After exerting additional beneficial effort in response to modest external incentives, decision makers will temporarily prefer extra leisure to restore their perceived sense of balance.

In this paper, we test empirically predictions of the Effort-Balancing account that shed light on our understanding of intrinsic motivation. According to this account, to the extent that post-reward behavior is driven by a psychological desire, we expect that this desire can be either heightened or suppressed by situational factors. In a series of controlled experiments, we vary the desire to restore balance by manipulating aspects of the decision environment.

In our experiments, we track trial-by-trial engagement in an incentivized task before and even after rewards have ended. Participants make a series of choices between 30-second tasks, either a beneficial work task (a math problem) or a leisure task (watching a video). Repeated choices were grouped into three rounds – pre-incentive, during incentive, and post-incentive. Participants in the incentive condition were informed of the amount and duration of the incentive (e.g., 5 cents per correct answer for the next 10 tasks) at the beginning of the incentive round.

In Study 1 (N=437), we exogenously varied the effort exerted when rewards were available by having the computer assign the tasks in each round using a 2(reward, no-reward) x 2(effort-level in round

2: low, high) design. We hypothesized that the reward group required to exert more effort would have a heightened desire to restore balance compared to the reward group required to exert low effort, and this would manifest as a greater reduction in engagement after the rewards end, but would last only momentarily. Online participants chose the math task 63% of the time in the pre-incentive period. Immediately after the incentive ended, 51% of the online participants in the low-effort reward group chose to do the math task, compared to 41% in the high-effort reward group ($p=.009$ hierarchical regression, controlling for individual choices in round 1). However, the overall engagement with the math task recovered quickly, and overall round 3 there was no difference between the two groups (low-effort: 58% vs. high-effort: 54%), and both were similar to the no-reward controls, replicating the momentary nature of post-reward task disengagement.

In Study 2 ($N=702$), we used a 2(reward, no-reward) \times 2(pre-incentive experience vs. no pre-incentive experience) design to test the self-perception alternative account directly. If participants make inferences about their preferences from their own past behavior, they would be more sensitive to incentives when they have not already had a non-incentivized experience of choosing the task. However, we found no effect of prior experience. In the first choice after the incentive ended, a similar proportion of participants in the reward groups chose to do the math task in the two-round (no pre-incentive experience) and three-round conditions (63% and 56% respectively; difference $p=.12$). Overall, there was no difference in the average choices of the incentivized task during the entire post-incentive round (no pre-incentive experience: 65% vs. pre-incentive experience: 61%), consistent with the effort-balancing account, rather than self-perception.

Based on the motivational role of pride on perseverance (Williams and DeSteno 2008), we hypothesized that reflecting on task performance could reduce the psychological desire for leisure. In Study 3 ($N=217$), we added a second incentive condition in which we prompted participants to reflect upon and take pride in their effort, before they began their post-incentive round. After the incentive ended, the pride-reflection group chose to do the math task 75% of the time, similar to the non-incentive control group (74%) and marginally more than the no-intervention reward group (56%; $p=.065$).

In Study 4 ($N=134$), we distinguish between effort-balancing and depletion. We tested whether the reduction in post-incentive engagement is mitigated when choosing between leisure and a novel effort task. After the incentivized math-tasks ended, participants chose between videos and a similarly effortful verbal-spelling task. Compared to the control (65%), there was no reduction in engagement immediately after the rewards ended (63%; $p=.38$), or in the entire post-reward period (reward 41% vs. control 46%, *n.s.*). This demonstrates that incentivizing a specific beneficial effort does not reduce engagement with other types of beneficial effort, contained in a different mental account. From a practical standpoint, this suggests that marketers promoting healthy purchase using discounts are unlikely to see even a temporary reduction in consumers' motivation to buy other products from that brand after the promotion ends.

Taken together, our research replicates the temporary post-incentive reduction in task-engagement, due to a temporary desire for a break to balance effort and leisure after exerting extra effort for the incentive. We rule out depletion and self-perception as alternative accounts. The temporary reduction in engagement is mitigated when people exert less effort, take pride in their accomplishment, or make choices involving novel tasks.

Donate to Be a Hero: Social Power Moderates the Effect of Incentives on Donation

EXTENDED ABSTRACT

Early in the 1970's, Titmuss (1970) pointed out that providing incentives to blood donors might create an unintended effect of reducing blood supply. Later research confirms his projection, showing that the provision of extrinsic rewards could, in fact, undermine the intrinsic motive to help, thus leading to a reduction of altruistic behaviors (Deci, Koestner, and Ryan 1999; Deci and Ryan 1975; Gneezy and Rustichini 2000). Offering incentives also dilutes the signaling value of a donation behavior and makes it difficult to judge whether the donor is really trying to do good to others (Ariely, Bracha, and Meier 2009).

However, there is also research showing the opposite. For example, research finds that the introduction of monetary incentives in the market for live and cadaveric organ donations increases the supply of organs for transplant sufficiently to eliminate the very large queues in organ markets (Becker and Elias 2007). Thus, there is an unresolved inconsistency in the findings on the effect of incentives on donation behavior. Although we know much about why incentives reduce donation, we know very little about when and who are more likely to be affected by the unintended consequence of incentives. In this research, we study one important moderator of the effect of providing incentives, namely, perceived social power.

Social power is typically defined as asymmetric control over valued resources in a social relationship (Galinsky, Rucker, and Magee 2015). In this research, we suggest that perceived social power increases one's donation tendency when the donation is framed as a pure pro-social action. Emotional satisfaction, the enjoyment of enhancement of self-esteem and demonstration of competence, is recognized as one of the major self-based motives behind donations (Andreoni 1990; Batson and Powell 2003). We suggest that powerful individuals are interested in creating a heroic and noble self-image and anticipate a stronger emotional satisfaction when thinking about the act of donation. The feelings of self-satisfaction largely come from the fact that the act of donation demonstrates one's competence, one of powerful individuals' biggest advantage, in positively affecting the recipient's life. This implies that the positive effect of power on donation behavior will disappear, and sometimes even backfire, when incentives are offered. The effect of incentives on powerless individuals, however, can be very different. Donation generates less emotional satisfaction among powerless individuals who are still struggling with getting control over their life and environment. Thus, they are predicted to be less interested in making positive impacts on others and experiencing the emotional satisfaction derived from such prosocial actions. This also implies that self-benefiting incentives would have a positive effect on the powerless individuals.

We tested these predictions in three experiments. In Experiment 1, we manipulated whether monetary incentives were provided for a hair donation decision. Participants first were asked to recall an experience that they felt powerful or powerless. Next, the experimenter introduced to participants a charitable organization "Wigs for Kids" and presented himself as a volunteer from this organization. The experimenter then explained that the organization makes wigs with donors' hair for kids suffering from hair loss due to cancer. Then participants were randomly asked to read one of two advertisements. The two advertisements were identical except that one offered a monetary incentive. The headline for the no-payment conditions read "Donate Your Hair", whereas the one for the with-payment conditions read, "Donate Your Hair, Get \$20 Compensation". Afterwards, participants were asked to leave their names, emails and

cellphone numbers if they were willing to donate. Because such incentives would make one's donation behavior seem selfish and consequently stop people from deriving emotional satisfaction about themselves, we reasoned that incentives would reduce powerful individual's donation tendency. We also expect that incentives would increase powerless individual's donation tendency because it provides a tangible benefit for donation. As expected, offering \$20 reduced powerful participants' donation percentage from (48.7%) to (17.1%), $\chi^2(1) = 9.12, p = .003$, whereas offering \$20 significantly increased powerless participants' donation percentage from 17.5% to 48.7%, $\chi^2(1) = 8.72, p = .003$.

Self-benefiting incentives can also be non-monetary. For example, some organ-donation organizations try to persuade people to donate by arguing that donors enjoy the benefit of being able to continue living after death in another way. Experiment 2 adopted a non-monetary incentive in the design. To manipulate power, we had participants imagine that they were a boss or an employee. Participants then moved onto an ostensibly unrelated study which asked for their opinions about a cornea donation advertisement. They were randomly assigned to read one of two advertisements. One advertisement used a tagline of "donate your cornea", and the other "donate your cornea to continue to see the world". A pretest shows that the second advertisement highlighted more benefits to donors. Afterwards, participants indicated the extent to which they were willing to donate and how likely they would donate cornea after they passed away on 0 (very unwilling/unlikely) to 10 (very willing/likely) scales. A 2 (Power) \times 2 (Incentive) ANOVA on donation intention returned a significant interaction between power and advertisement type, $F(1, 194) = 4.35, p = .038, \eta_p^2 = .022$. Again, powerful participants showed a greater donation intention for the without-incentive advertisement ($M = 5.68, SD = 2.50$) than for the with-incentive advertisement ($M = 4.84, SD = 3.23$), $F(1, 194) = 2.10, p = .149$, but it caused an opposite effect among powerless participants ($M = 4.69, SD = 3.14$) for the without-incentive advertisement and ($M = 5.52, SD = 2.34$) for the with-incentive advertisement), $F(1, 194) = 2.25, p = .135$.

In experiment 3, we measured, instead of manipulated, power, and replicated our findings. This suggests that the interactive effect of power and incentives on donation does not hinges on the activation of the power concept.

Taken together, three experiments provide corroborative evidence that offering self-benefiting incentives reduces powerful individuals' donation intention but increases powerless individuals' donation intention. Thus, the research sheds light on when and who tend to be negatively affected by self-benefiting incentives in prosocial decisions.

Immediate Rewards Render Activities More Intrinsically Motivating

EXTENDED ABSTRACT

Can an immediate, extrinsic reward make exercising feel more like playing? Whereas prior research documented that extrinsic rewards crowd out intrinsic motivation (Deci and Ryan 1985; Lepper, Greene, and Nisbett 1973), we hypothesize that receiving an immediate (vs. delayed) reward can increase intrinsic motivation for activities consumers care about pursuing (e.g., exercising; visiting museums; reading). We predict that immediate rewards foster intrinsic motivation by strengthening the temporal association between an activity and its outcome, such that the activity becomes "an end in itself" (Kruglanski et al. 2013).

Most activities that consumers pursue offer both intrinsic and extrinsic rewards to some degree. At the gym, for example, intrinsic rewards include "having an enjoyable workout" and extrinsic rewards are external to a task, such as "losing weight" or "improving one's health" (Woolley and Fishbach 2016). An activity is intrinsically motivated to the extent that it is experienced as internally derived and the activity serves as an end in itself rather than as a means to another end (Fishbach and Choi 2012; Heath 1999).

Across five studies ($N=1125$), we explore whether immediate rewards, which increase the temporal activity-outcome association, render the experience of pursuing an activity as more intrinsically motivated—an end in itself. We explore this basic effect, as well as the possibility that immediate rewards increase intrinsic—but not extrinsic—motivation, that they do so by strengthening the association between the ends (outcome) and means (activity), and that only the timing of reward delivery matters for intrinsic motivation, whereas the size of the reward does not.

In Study 1, participants read rewards people receive from exercising and visiting a museum and indicated whether each activity was more similar to playing (intrinsic) or working (extrinsic). We framed rewards as arriving during the activity (immediate) or after the activity (delayed). For example, "Exercise that feels enjoyable [while/after] I do it." As predicted, participants perceived exercising as more intrinsically motivated in the immediate (vs. delayed) condition, $t(87) = 2.51, p = .014$. Similarly, participants perceived a museum visit as more intrinsically motivated (i.e., more similar to playing) in the immediate (vs. delayed) condition, $t(98) = 2.19, p = .031$. Thus, immediate (vs. delayed) rewards lead people to perceive exercising and visiting a museum as more intrinsically motivating.

In Study 2 participants completed an experimental task in exchange for chocolate. Participants received chocolate and the task simultaneously (immediate-condition) or learned they would receive chocolate after completing the task. We measured intrinsic motivation to pursue the experimental task using a four-item scale (enjoyable; interesting; more like fun; future interest; see Ryan 1982). As predicted, an immediate reward rendered an experimental task as more intrinsically motivated compared with a delayed reward, $t(99) = 2.57, p = .012$.

Study 3 tested whether an immediate delivery of an extrinsic financial incentive increases intrinsic motivation, and also added a no reward control group. Participants read a book excerpt in return for payment. In addition, they expected to receive an immediate bonus (\$1.00 now) a delayed bonus (\$1.00 in a month) or no bonus. As in Study 2, we measured the intrinsic experience of reading, and included a behavioral measure, examining participants' task selection during a free choice period absent a reward (Etkin 2016). As predicted, an immediate bonus increased the intrinsic experience of reading compared with control conditions (delayed and no bonus), $t(181) = 2.84, p = .005$. Participants in the immediate condition were also more likely to continue reading absent a reward (63.3%) compared with those in the delayed (44.4%) and no bonus conditions (50.8%), $\chi^2(1, 184) = .403, p = .045$, with no difference between the control conditions, $\chi^2(1, 124) = .51, p = .477$. In a follow up study, we examined temporal discounting as an alternative explanation, and find that the effect is driven by differences in reward timing, rather than reward magnitude.

Study 4 examined the specificity of the effect of immediate rewards on motivation to better understand the underlying process. Participants viewed a product advertisement that described an immediate arrival of rewards from using moisturizer (immediate-reward condition) or did not mention timing of rewards (delayed-reward condition). We measured intrinsic motivation to use the moisturizer

(enjoyable, positive experience) and extrinsic motivation (important, useful). As predicted, moisturizer use was more intrinsically motivated in the immediate versus delayed reward condition, $t(198) = 2.45, p = .015$, with no effect of timing on extrinsic motivation, $t(198) = .25, p = .800$.

To examine the process, Study 5 tested whether immediate rewards increase intrinsic motivation by strengthening the activity-outcome association. As in Study 4, participants viewed an advertisement for a moisturizer (immediate vs. delayed reward) and completed intrinsic and extrinsic measures. To capture the degree of overlap between the activity (using moisturizer) and the outcome (smooth skin), we created seven pairs of circles that overlapped to different degrees, from completely separate to very overlapped (Aron et al. 1992). Replicating Study 4, using moisturizer was more intrinsically motivated in the immediate (vs. delayed) condition, $t(199) = 3.63, p < .001$, with no effect for extrinsic motivation, $t(199) = .69, p = .493$. Further, participants reported greater overlap between moisturizer and smooth skin in the immediate (vs. delayed) condition, $t(199) = 3.69, p < .001$. The increased association between moisturizer and smooth skin mediated the effect of immediacy on intrinsic motivation ($\beta_{\text{indirect}} = .15, SE = .06; 95\% CI [.05, .30]$).

Overall, we provide evidence that immediate rewards increase the intrinsic experience of activity pursuit. Our research suggests marketers can harness immediate rewards to increase the intrinsic experience of activity engagement, with implications for increased persistence. For example, airlines can offer promotions to customers immediately after a flight, potentially increasing customers' intrinsic experience of using their airline.

Journey Takes You Beyond the Destination: The Use of Linguistic Metaphor in Sustaining Post Goal-Attainment Motivation

EXTENDED ABSTRACT

People pursue goals throughout their lives. Students attend study groups to excel in school, and dieters count calories and monitor portion sizes to lose weight. While some of these pursuits may end with failure, many end with success—the goal is attained. However, despite the frequent occurrence of goal attainment experiences, prior literature remains relatively silent on what happens after a goal has been attained. Attaining a goal implies that one can now disengage from actions directed at achieving this goal (Ferguson and Bargh 2004; Forster, Liberman, and Higgins 2005). This post-attainment disengagement could be detrimental, however, as goal-congruent behaviors could be beneficial by themselves. Consider, for instance, those who achieved a weight-loss goal but begin eating poorly again, or students who completed their education but stop acquiring knowledge.

In this research, we propose that one variable that sustains goal-congruent actions post goal attainment is how meaningful the goal acquisition process is (Baumeister, Vohs, Aaker, and Garbinsky 2013). To do so, we explore the use of metaphor, a cognitive tool that shapes people's perception of an experience without changing the experience itself (Kövecses 2010; Landau, Meier, and Keefer 2010). We show that adopting a journey metaphor (compared to no metaphor or a destination metaphor) helps people derive greater meaning from the attained goal and thus become more motivated to continue goal-congruent behaviors.

We began with two pilot studies that compared the journey metaphor against a control and a destination metaphor. All participants first listed a learning or fitness goal they recently attained, and indicated on a 100-point slider where they were right now on this

goal as a check. The text then invited those in the journey [destination] condition to take a moment to: "...see yourself actually working [actually attaining this goal], taking the necessary steps *during this journey* [reaching this final destination], and have this picture in your mind." In Pilot Study A, participants received additional text prompts to enhance the effectiveness of linguistic metaphor, e.g., to think about the steps they took during the journey [vs. what reaching this destination is like for them]. In Study B, participants received additional visual aid instead of text prompt; they saw a picture of a black-and-white country road with the word Journey [Destination] highlighted at the beginning [ending] part of the road. Following procedures in metaphor literature, participants in the control condition did not do any metaphor practice. The results of both studies showed that the journey metaphor stimuli successfully enhanced perceived continuity from the original goal-initiation state (i.e., who they were when they first started pursuing this goal) to the goal-attainment state; that is, the stimuli we designed indeed guided participants to adopt a journey (vs. no or destination) metaphor as intended (Landau, Meier, and Keefer 2010; Landau, Sullivan, and Greenberg 2009). We also ruled out alternative accounts such as perceived difficulty, effort, goal value, visualization vividness, and mood effects.

Next, Study 1 used linguistic metaphor to test its effect on executives who have successfully achieved a learning goal (applying business education to improve their corporate practices) in an executive program in Africa. Three on-site interviewees executed a 30-minute individually-guided thought practice (journey vs. destination metaphor) during the graduation ceremony. The content of the thought practice was transcribed and emailed to the participants. A cohort was excluded from this practice to serve as a control group. Six months after graduation, executives received the follow-up survey from the program and reported their goal-congruent behaviors in the past six months, e.g., "I have made changes to my supply chain that will help my company scale." Executives who described their goal attainment experience as a journey were more likely to continue goal-congruent behaviors after completing the program, comparing to not having metaphor or using a destination metaphor (the latter two groups did not differ).

Study 2 replicated the findings in Study 1 with a different group of goal achievers—dieters who have recently attained a fitness goal. In addition, we included a future-journey condition to rule out construal level as an alternative account. Three hundred dieters wrote about the fitness goal they recently attained, went through the same manipulation check, and then proceeded with the linguistic metaphor thought practice (journey vs. destination vs. future-journey). Those in the future-journey condition were asked to visualize themselves continue working for this fitness goal in the future, "to see yourself actually working, taking the necessary steps *to continue this journey*, and have this picture in your mind." The results revealed that participants in the journey condition were more motivated to continue goal-congruent actions than those in the destination and future-journey conditions (the latter two groups did not differ). Further, follow-up survey on actual behaviors after two weeks revealed the same pattern.

Next, Study 3 examined the driving role of meaning among students who recently completed an academic goal. College students were assigned to either a journey or destination metaphor condition to describe their goal attainment experience and the actions they took. They then reported their desire to continue these goal-congruent behaviors, as well as the meaning they derived from the completed pursuit. As predicted, the students who used the journey (vs. destination) metaphor derived greater meaning, which led to greater

willingness to continue taking goal-congruent actions (mediational path index = .0801, 95% CI = .0115 to .1994).

Lastly, Study 4 employed a Metaphor (journey vs. destination) × Goal Initiation (autonomous vs. imposed) design among college students who recently completed an academic goal. We obtained our hypothesized effect of journey (vs. destination) metaphor among students who achieved the academic goals they autonomously adopted for themselves, but not for those who achieved the academic goals others imposed on them. This finding provided further support that the impact of metaphor on goal-congruent behavior occurred by providing meaning; when the achieved goals were imposed by others, the meaning one could derive is limited, rendering the journey metaphor less effective. The results are discussed in light of extant research on goal pursuit, metaphor, and meaning.

SESSION OVERVIEW

Consumer researchers have a growing interest in spatiality. Early spatial research in consumer literature considers the ways marketers engineer space to convey brand ideologies that enable certain consumption activities and prescribed values (Borghini et al. 2004). This stream of retail research, known as “servicescape” research, also focuses on understanding how consumers co-create meanings in marketer-structured spaces (Borghini et al. 2009; Kozinets et al. 2004; Sherry 1998). More contemporary research considers how consumers engage in resisting dominant ideas of what space is and how people should use it (Bradford and Sherry 2015; Visconti et al. 2010). Responding to a recent move to consider the “more phenomenological and social-relational dimensions” of space (Chatzidakis, McEachern and Warnaby 2015), in this session, we ask what is the interplay of multi-level forces by which space shapes, and is shaped by, consumption? We organize the session around Henri Lefebvre's (1991) theory of the production of space.

Lefebvre's theory is premised on a cultural understanding of space. This perspective departs from a view of space as a concrete, material object, to a view of space as socially created which, in turn, creates and organizes society. In this perspective, the creation of space entails an interplay between material and social forces, and the actions of people. This model focuses on the micro and macro-level forces that contribute to shaping space and its meanings, and how consumers negotiate these forces in the material enactment and cultural understanding of space. It also emphasizes the various contradictions that exist within space, and the historical evolution from which these contradictions derive.

Each paper in this session highlights one or two elements in Lefebvre's model to collectively arrive at an examination of the forces and processes that shape, and are shaped by space. Paper 1 examines the consumption surrounding home renovations to provide an understanding of the confluence of media, marketers and consumers that create meanings of the home, and how these meanings shape the material enactment of homes. Paper 2 examines the different expressions of taste and ensuing contestations over legitimacy of the dominant midcentury modern aesthetic between contemporary neighborhood residents with different cultural capital endowments.

Paper 3 distinguishes the key elements in the production of branded urban spaces, analyzing how they concur to constitute the material, imagined, and lived dimensions of space. Paper 4 explores the methodological tensions between consumers' lived spatial experiences and researchers' representations of these experiences to consider ways that researchers can better align theoretical and methodological perspectives on space.

This session informs a rising interest in spatiality research. We extend the role of resistance (Paper 2) and introduce the role of harmony (Paper 1) as components in the process of shaping space. We enrich understanding the strategic use of space in reproducing dominance (Paper 3). We also contribute to methodologies relevant to spatiality research (Paper 4). This session is relevant for researchers interested in spatiality as it expands a theoretical perspective of the multi-level societal forces and processes in the recursive shaping of space and consumption.

Home is Where the Tension Is? Examining the Cultural Complexity of Creating the Space of Home

EXTENDED ABSTRACT

The home is “the epicenter of...citizens' emotional bonds, leisure practices, and financial portfolios” (Rosenberg 2012). It shapes and defines one's place in the world. Consumer literature implies that people constantly create and recreate home through consumption practices. Consumer research draws attention to the home as a space laden with meaning and of ubiquitous importance in consumers' daily lives: it is central to a person's identity (Belk 1988; Tian and Belk 2005), the enactment of family (Epp and Price 2008; Epp and Price 2010; Wallendorf and Arnould 1991), and the enactment of taste, aesthetics, and refinement (Arsel and Bean 2013; Dion, Sabri and Guillard 2014; Üstüner and Holt 2010). This literature reveals inherent paradoxes in the way consumer researchers understand home. The home is a site for self-expression (Belk 1988), but it is also a site of conformity, to taste for example (Arsel and Bean 2010). The home is a site for family practices of doing crafts together at the kitchen table (Epp and Price 2010), which may conflict with social norms of tidiness that manifest in the home (Dion, Sabri and Guillard 2014). Thus, the home as the epicenter of consumers' lives is also a contentious site. The consumer literature tends to examine the formation of home through specific facets of what happens in the home (e.g., as a place for the individual, family, or taste). However, we also know that macro historical forces have a hand in shaping the meaning of home. Governments have historically encouraged home ownership through affordable mortgage policies. The home has come to occupy cultural importance, at the macro-level, to the prosperity of a country (Cohen 2004; Rudolph 2015). Therefore, the home is a space of incredible complexity and cultural importance, however, the ubiquity of the home masks its cultural complexity. The purpose of this work is to examine how consumers navigate the cultural paradoxes, multi-level forces, and overall work of creating and recreating the space we call home.

We employ Lefebvre's (1991) model of the production of space as a theoretical lens to understand how consumers negotiate and create home as a space. This model attunes us to the many macro and micro-level dynamics within which one is immersed when constructing the space called home. Using the context of home renovations, Lefebvre's

model focuses our attention to the creation of space as a negotiation between an historical understanding of the home (*spatial practice*), the representation of home by media and designers (*representations of space*), and the home as a site for the enactment of self (*lived space*). This context of home renovations is relevant as it captures consumers' experience of transforming a space. Consumer literature that examines public spaces demonstrates that underlying meanings of space become most salient when people physically transform the space (Bradford and Sherry 2015; Visconti et al. 2010). Our data provides a comprehensive view of the market surrounding home renovations. It includes an observation of the market and media surrounding home renovations, in addition to 21 depth interviews with consumers engaging in home renovations and four interviews with industry providers.

Our analysis leads to three major findings. First, the consumer experience of home renovations is characterized by stress and anxiety. We find that these feelings emerge from a misalignment between Lefebvre's notions of *representations of space*, or the space as represented by designers, magazines, and television shows, the *spatial practice*, or an understanding of space as the result of the historical understanding of space, and *lived space*, where images and symbols of what space should be are made material. We find that homeowners' experience of stress manifests from maintaining alignment between these nodes of space. Homeowners hold an ideal image for enacting their ideal life in the home, but struggle with understanding how to materially enact it in a way that aligns with the historical-cultural ideals of home.

In a second finding, consumers' stress stems from a perceived anonymous gaze in the home criticizing and judging their home. Based on informants' reports, this anonymous gaze is representative of a marketplace actor who is "more fashionable, more modern, and more with it" than our informant consumers. We propose the consumer is subject to a panopticon-like gaze that they appease by way of a market intermediary.

Thus, as a last finding, this work introduces the concept of the Market Visionary. The market visionary is adept at understanding both the consumer and the market, and, thus, it is well-positioned to guide homeowners in aligning the nodes of space that Lefebvre identifies in his model. In their role, market visionaries aid consumers to imbue renovation materials with meanings that are aligned with the consumer's identity. In so doing, the market visionary translates the representations of the ideal home into the homeowners' personal space and aligns the enactment of the consumer's ideal home in ways that both the market and consumer deem acceptable. In so doing, the Market Visionary helps to appease the anonymous gaze.

Our findings contribute to a strategic understanding of how the creation of space leads consumers to engage with the market. We introduce a new type of market intermediary who is deeply embedded in understanding both the market and the consumer, and the consumer's quest to bring space into cultural alignment between an historical understanding of the home, marketers' representations of home, and the home as a site for self-enactment. Lastly, the creation of space is commonly thought to occur through resistance (c.f. Visconti et al. 2010). Our findings show that balance and harmony are equally important aspects in the creation of space.

Home, Contested Home à la Home Sweet Home: Understanding Legitimacy in a Midcentury Modern Taste Regime

EXTENDED ABSTRACT

Taste has lately become a central domain of research in CCT (Arnould and Thompson 2005). While the most influential perspec-

tive employs a Bourdieuan lens to examine how consumers employ taste in the performance of identity and social distinction (Arsel and Thompson 2011; Bourdieu 1984; Holt 1998; McQuarrie et al. 2013; Üstüner and Holt 2010; Üstüner and Thompson 2012), more recently researchers have used experiential-practice theory accounts to direct attention toward the aesthetic pursuits of consumers and the market orchestration of taste (Arsel and Bean 2013; Hennion 2007; Maciel and Wallendorf 2017; Warde 2014). However, such trickle-down interpretations do not illuminate how consumers with different levels of cultural capital understand, interpret and challenge, from their particular socially situated subject positions, the normative aesthetic ideals perpetuated by cultural authorities (Holt and Thompson 2004; Üstüner and Holt 2010).

We address these issues in this paper, through an investigation of the ways in which contemporary homeowners in a postwar neighborhood in the Midwestern US, variously interpret the meanings and ideals of the midcentury modern (MCM) design aesthetic. We investigate how tastes are 'actually' practiced and what conflicts ensue from interactions between consumers possessing high and low levels of cultural capital (HCC and LCC respectively). This research is based on in-depth interviews with homeowners and visual analysis of the 13 homes. As a theoretical lens, we draw on Bourdieuan insights on taste (Bourdieu 1984; Holt 1998).

Participants' understandings and realizations of the MCM design aesthetic are determined by their field dependent cultural capital, but not generalized cultural capital. In practice, displays of cultural capital operate through the processes of singularization (Kopytoff 1986) and emulation. In this "legitimizing theatricalization" (Bourdieu 1990, p. 139), reproduction of the MCM home décor and taking a curatorial and informed attitude to the unique history and aesthetics of the homes by preserving the original wallpaper or "Cherokee Red" concrete floor become conspicuous markers of taste and qualify these HCC homeowners to participate in architectural tours, which grant them considerable symbolic capital. Interestingly, in an effort to achieve aesthetic purity or uniformity, heirloom furniture and articles of home décor are desacralized and either discarded or banished to the more private spaces of the home. In addition to valuing this aesthetic, the residents tend to idealize the midcentury practice of community (Boym 2001). Even maintaining tranquility in the neighborhood by helping older residents and being responsible dog owners and parents, are normative expectations in the recreation of the imagined midcentury ambience. On the other hand, the LCC articulation encompasses invocations of autonomy and private property rights. Thus, we have "two antagonistic world views" (Bourdieu 1984, p. 199), forced to reside closely, which inevitably leads to conflicts over what may be deemed legitimate taste.

Midcentury homes with small galley kitchens, dearth of storage space and carports are often incompatible with contemporary lifestyle practices. The architectural control committee from the 1950s has expired so residents are no longer legally bound to follow the original stringent design guidelines. Since many of the newer residents are paying premium prices and implicitly selecting into the neighborhood, their plans for modifications to the inside or more concerningly, to the exterior of the home are met with consternation when they disregard the original design aesthetic. We trace the unfolding of the dynamic of conflict and negotiation of compromise owing to collective pressure that leads to tenuous balances between communal and individual identity projects.

Bourdieu has argued that individuals perceive each other through a "symbolic veil of honor" attached to their practices and "misperceive the real basis of these practices: the economic and cultural capital that both underlies the different habitus and enables their

realization” (Weininger 2002, p. 145). In this upper middle-class research context, we find that the HCC group (which includes individuals with varying levels of economic capital) inflicts symbolic violence on the LCC groups that serves to impress upon the LCCs their lack of taste. They counter this affront with appeals to personal autonomy, private property rights and the plea that the MCM aesthetic is outmoded and impractical. However, through collectively exercised power, which recognizes the legitimacy of the MCM taste culture, the aberrant LCC individuals are forced to make reparations, which while not eliminating the offending architectural features, serve to make them less salient. Thus, the HCC and LCC groups have the different identity outcomes of aesthetic self-expression and aesthetic subordination.

The identification of these tensions adds to Arsel and Bean’s (2013) conceptualization of taste regimes. The experiential-practice theory perspectives tend to downplay (though not completely ignore) such struggles over taste in favor of analyzing how tastes are linked to practices. An interesting question that is posed by this research is what about the MCM aesthetic lends itself to this kind of conflict which appeared to be more or less managed by the Apartment Therapy discourses.

We investigate the undertheorized area of tensions between individuals with different levels of cultural capital forced to exist in close proximity to each other. In this analysis of the ‘politics of space’ we look at the taste practices through which individuals build symbolic capital within a field as well as the operations of symbolic violence and contestations over legitimacy of tastes. Finally, this study reveals the ideologies and subjective consumer experiences at play in consumption surrounding homes in an upper middle-class context (Holt 1998; Lung-Amam 2013; Miller 2010; Sherry 2000).

How Multiple Stakeholders Produce Branded Urban Spaces

EXTENDED ABSTRACT

Inspired by the spatial turn in social sciences (Soja 1980), recent developments in consumer research have started to discuss how market actors concur to produce different types of spaces and how space recursively shapes markets (Castilhos, Dolbec, and Veresiu 2017). These studies advanced pioneer accounts of the relations between the managed materiality of servicescapes and consumer experiences (Sherry 1998), shedding light on the many forms through which consumers and producers negotiate meanings and ideologies and appropriate commercial and public spaces through consumption and market practices (Bradford and Sherry 2015; Chatzidakis, Maclaran, and Bradshaw 2012; Maclaran and Brown 2005; Visconti et al. 2010). Although conflict and compromise between multiple market actors are more or less explicit in such an emerging stream, we still lack more systematic empirical analyses of how different stakeholders dynamically concur to produce different dimensions of space.

To address this theoretical blind spot, I deploy Lefebvre’s (1991) spatial triad to analyse the development of a branded urban space — a complex spatial entity that emerges in post-industrial cities, which includes private (shops, residences, and offices) and public (parks, streets, and natural resources) spaces and is bounded by a strong brand narrative. To Lefebvre (1991), the production of space unfolds in three intertwined and overlapping moments (or levels) of space: first, the spatial practice (material space) refers to the material geographies and concrete spatial forms; second, representations of space (imagined space) refer to the conceptualized space of urban planners, architects, policy makers, and artists among others; third,

representational spaces (lived space) refers to space as experienced by consumers, who can comply or resist to material and symbolic determinations. So how do market actors concur to produce material, imagined, and lived dimensions of space in branded urban spaces?

To answer my research question, I conducted an extended case study of the implementation of Jardim Europa neighbourhood (JE) in Porto Alegre, south of Brazil. Developed by a single firm, JE is a complex of upscale condominiums surrounding a large public park, which is located on the frontier between upscale and lower-class neighbourhoods, including squatter areas. Bounded by a brand narrative that caters to the aspirations of local upper-middle-classes and at the same time that excludes lower-class consumers, JE development unfolds through a complex set of negotiations between consumers, producers, and regulators. To account for these complex relations, I have collected three types of data from January of 2012 to December of 2016: first, I conducted interviews with residents from the condominiums and squatter areas as well as interviews with the developer’s employees, municipality representatives, and park users; second, I conducted participant observation in the neighborhood, especially at the park; third, I also collected archival data, specifically from the municipality, the local media, and the developer. My dataset is composed of 37 hours of audio recording, totaling 518 single-spaced pages of transcription, 46 pages of field notes, 577 pictures, 40 minutes of video footage, and more than 500 pages of archival data.

I distinguish three key elements in the production of branded urban spaces that recursively concur to constitute the three dimensions of space (Lefebvre 1991): first, architecture and urbanism relate to the material dimension of space by assembling and linking private spaces of family exclusivity with communal and public spaces of leisure, consumption, and contemplation that enable a self-rewarding daily life for condo residents. It also relates to the imagined dimension of space as its materiality constantly and carefully evokes sophistication, cosmopolitanism, and privilege; second, brand narrative relates to the imagined and lived dimension of space by as-signing meanings and ideals to the neighborhood’s materiality and by providing a discursive system that links material reality to daily consumption practices, offering prescriptions and normative cues that orient consumers’ spatialized experiences; third, spatial governance establish a link between material and lived space by normalizing behaviors and amenity uses, providing patrimonial maintenance, and reassuring isolation from the outside via integration between security systems and residents’ conduct inside the condominiums. Moreover, at the public level, spatial governance seeks to manage potential threats to JE’s value proposition that could arise due to the proximity with the popular surroundings through a systematic vigilance over lower-class groups in their uses of public spaces.

Taken together, these elements contribute to successfully legitimize JE as an upper-middle-class neighborhood in the city while recursively creating a shared identity among upper-class residents and reproducing objective and subjective forms of exclusion of lower-class consumers. This detailed analysis of the production of branded urban spaces sheds light to intensified forms of exclusion in the city. While traditional segregating spaces (e.g., gated communities) create a sharp division between insiders and outsiders (Caldeira 1996), branded urban spaces gradually colonize public space, controlling the spatial narrative and imposing a set of acceptable behaviors according to the dispositions and aspirations of targeted consumers. Lefebvre’s (1991) spatial triad provided a unique lens that allowed to unveil the complexity of the production of branded urban spaces, providing a more political and systemic perspective to the emerging body of spatial studies in consumer research.

Representations of Space: Methodological Tensions in Spatial Consumer Research

EXTENDED ABSTRACT

Attention to the importance of space and place has increased across the social sciences in recent decades. Consumer research has followed suit, examining a myriad of ways in which space influences culture and behavior, and vice versa (Castilhos, Dolbec, and Veresiu 2017). We extend this productive discussion through the methodological development of geographic ethnography, a novel combination of ethnographic and Geographic Systems (GIS) data and analyses.

Prior spatial consumer research tended to focus either on the macro-level forces shape that space and place, or on ways that consumers use or understand space and place as symbolically meaningful. These perspectives correspond with what Lefebvre (1991) terms spatial practice, or the reproduction of spatial orders, and representational space, or the contested and embodied meanings of space. Largely missing, however, are discussions of a third node of Lefebvre's spatial triad: representations of space, which are ways that order is imposed upon space through scientific codification of space and place. Researchers, like city planners, may fall prey to problems of representation through translating consumers' lived spatial experiences into data for analysis and publication.

Research based largely on qualitative interviews (e.g., MacLaran and Brown 2005) or longitudinal text analysis (e.g., Giesler and Veresiu 2014; Humphreys 2010) provide a rich understanding of the symbolic meaning and long-term social changes. However, these methods may run the risk of flattening out either space or time in ways that obscure their important dynamics. Ethnographic methods have the potential to bridge these gaps by capturing both spatial and temporal dynamics. However, we argue that consumer research has yet to fully realize this full potential. Studies such as those by Visconti et al. (2010), who employ participant observation to uncover contestations of the meaning and use of public space, and Bradford and Sherry (2015), who use ethnographic fieldwork to examine the domestication of public spaces, gather rich spatial data but still remain grounded primarily at the level of consumer meaning. In translating dynamic experiential observations into field notes, memos, photographs, and interview transcripts, much of the original spatial and temporal richness can be lost in translation.

We propose geographic ethnography as a methodological remedy that retains, as far as possible, the dynamics of time and space as observed and experienced in the study context. The method begins with spatially-oriented ethnographic fieldwork. In our research, we focus on a "public market" recently constructed as part of a wider urban redevelopment initiative. We observe, participate in, and talk with consumers, vendors, and management about the space as it changes and unfolds through two years of fieldwork. In addition to conventional field notes, we capture data in explicitly spatial formats. These include visual data such as video and photographs, maps drawn in field notes, and geocoded data captured from interviews and participant observation. Next, we situate these data temporally through the analysis of archival newspaper articles and planning documents that chronicle the history of public markets in the region from the early 1900s to the present. We also record temporal changes in the spatial data collected within and between visits to the field site. Finally, we utilize GIS software to map consumer movement across the city to understand the ways people move between the public market and other related consumption sites.

Through our geographic ethnography we find that public markets occupy a strikingly similar position in the contemporary United

States as they did at the beginning of the twentieth century. First, public markets offer a means for consumers, vendors, and developers to stake territorial claims in space. Consumers and vendors exert ownership over tables, chairs, and areas in the market. But public markets also act as vehicles for urban renewal and the territorialization and displacement that occur through these processes. Non-Anglo ethnic groups are either explicitly or implicitly excluded from full participation in these redeveloped urban spaces. Spatially, the public market spaces we studied play a less central role in these marginalized consumers' daily consumption practices.

Second, territorial claims are legitimized through social negotiations over ownership rights. These owners—whether social or legal—receive and maintain social legitimation by taking responsibility for spaces and objects through maintenance and care, benevolent interactions, and respect of the ownership rights of others. For example, café patrons in the market are welcome to work at communal tables for extended periods of time, but according to baristas, "people are supposed to bring their own dishes back." Over time, the spatial layout and roles permitted in public market spaces shift to accommodate these new "owners" and their practices—such as a new coffee shop bar and additional wifi-enabled seating.

Finally, people who are perceived as not taking adequate spatial responsibility compared to the rights they claim are not allowed to claim maintain their rights to public market spaces. Rights are typically lost through redevelopment and redistribution of space by actors with more power and socially legitimate claims to ownership of the space. For example, for several years families were permitted to picnic with outside food in a market courtyard, but when playful kids started throwing rocks management paved over their favourite gravel play area. Additionally, in the metropolitan region of our study, nearly all of the historical farmers' markets that survived more than a decade were located (or relocated) in predominantly white, affluent areas.

This research provides important points of discussion regarding the state of space, place, and "representations of space" (Lefebvre 1991) in consumer research. We show that by making research methods more spatially and temporally sensitive and explicit, scholars can push theory about space and place beyond current conceptualizations and toward a more holistic understanding.

SESSION OVERVIEW

When was the last time you booked a hotel without checking what others have to say about it online? More than 80% of consumers indicate that reviews from peers are an important determining factor for their purchase decisions (eMarketer 2016). Consumers also trust reviews to a much higher degree than marketer-initiated communications (eMarketer 2010). Yet, not all reviews are equally persuasive or useful to consumers. The goal of this session is to illuminate the factors that determine the impact of online reviews. Specifically, the four papers identify novel ways in which the device from which a review is posted (mobile vs. desktop, Grewal and Stephen), its content (one-sided vs. two-sided reviews, Schlosser and Borah; mentions of utilitarian or hedonic attributes, Nikolova, Bleier, and Hamilton), as well as product/service (purchase risk, Schlosser and Borah), consumer (relationship orientation, Srinivasan, Ordabayeva, and Hoyer; consumption mode (solo vs. joint), Nikolova et al.), and provider type and characteristics (P2P vs. commercial, professional vs. amateur, warm vs. competent, Srinivasan et al.) impact the usefulness and persuasiveness of online reviews.

First, Grewal and Stephen examine how the device from which an online review is posted influences its persuasiveness. Their findings show that mobile reviews are persuasive to consumers and lead to higher purchase intentions because such reviews are perceived as more effortful to write. Next, Schlosser and Borah study how the interplay of content (one-sided vs. two-sided reviews) and product characteristics (amount of purchase risk) impacts the helpfulness of reviews. They show that in contexts with low purchase risk (social, monetary, performance), consumers perceive two-sided reviews as more helpful than one-sided reviews; however when the purchase risk is high, two-sided reviews become less helpful to consumers than one-sided reviews. The third paper by Nikolova et al. continues the exploration of review content, examining how consumption mode (solo, joint) and time lag between consumption and review writing influence review persuasiveness. Their findings show that when there is no time lag between consumption and review writing, reviews

about joint consumption are more persuasive than those about solo experiences; however, as the time lag increases, solo reviews become more persuasive due to the greater number of statements about utilitarian attributes included in them. Finally, Srinivasan et al. examine how consumer and provider characteristics interact to influence the persuasiveness of online reviews in the context of peer-to-peer (P2P) exchanges. They demonstrate that consumers with communal (exchange) relationship orientation are more responsive to reviews of P2P (commercial) providers, amateur (professional) and warm (competent) P2P providers.

Altogether, this session provides important theoretical and practical insights into the factors (e.g., device, content, product, consumer and provider characteristics) that drive the persuasiveness and helpfulness of online reviews. Due to the wide-ranging insights offered by the researchers who approach the question of “what makes reviews persuasive and helpful” from unique and novel angles in contexts of increasing practical importance (e.g., increased use of mobile devices, social consumption, and the new sharing economy), we anticipate that this session will be of substantial interest to a broad audience at ACR.

In Mobile We Trust: How Mobile Reviews Influence Consumers' Purchase Intentions

EXTENDED ABSTRACT

The use of mobile devices has become ubiquitous in modern life. Over half the world's population now uses mobile devices; rightly making mobile the “defining technology of the age” (The Economist 2015). A common consumer-related use of mobile devices is the sharing of information with other consumers by creating user-generated content (UGC) and disseminating it through online platforms and social media. This includes posts on networks such as Twitter and reviewing on platforms such as TripAdvisor. This latter type of UGC—online ratings and reviews—is the focus of this research. In practice, some UGC sites differentiate between reviews posted from mobile versus non-mobile devices. For example, TripAdvisor uses a “via mobile” label to denote reviews from mobile devices. However, the extent to which such information impacts consumers is unknown.

While the device from which a consumer posts online reviews may seem inconsequential, we find this not to be the case. In fact, how consumers process and are influenced by online reviews can be affected by knowing if the information was generated on a mobile device (e.g., iPhone) or a non-mobile device (e.g., desktop computer). We find that knowing a review was written on a mobile device can make that review more persuasive due to the perceived effort to write the review (i.e., increased physical and cognitive requirements; Chae and Kim 2004; Sweeney and Crestani 2006). Building from previous literature (e.g., Kruger et al. 2004), we believe that when consumers perceive UGC has been more effortful to craft, there are conditions when consumers' purchase intentions will increase. Thus far, we've tested these “device-effort-purchase” lay-belief predictions using real data and four experiments.

Study 1 looks at real-world online review data from TripAdvisor covering 1,547,219 reviews for 2,379 hotels in the US between February 2012 and September 2015. TripAdvisor, in February 2012 began publicly labeling mobile reviews with a “via mobile” badge.

In testing the effect of this badge, controlling for many other factors, we find that reviews with this mobile indicator are voted by users as significantly more helpful ($b = .022$, $c^2 = 28.40$, $p < .001$). This finding suggests that the mobile reviews are deemed more useful, influential, and worth reading—which should lead to higher purchase intentions.

Study 2 ($N = 369$) uses an experimental design to examine the impact of knowing an online review was written on a mobile device on purchase consideration. In this study (and all subsequent studies) participants in all conditions viewed the same hotel review. All that varies is the device label on the review; “via mobile” in the mobile condition, “via desktop” in the desktop condition, and no device label in the control condition (this replicates all non-mobile reviews online).

We found a significant positive effect of mobile ($b = .17$, $p = .001$) such that participants who saw “via mobile” on the review were more likely to consider staying at the hotel compared to those who saw the desktop or control conditions. There was no significant difference in purchase intentions for those who saw the desktop condition and control condition ($b = -.01$, $p = .915$).

Study 3 ($N = 182$) uses a 2(mobile, non-mobile) \times 2(effort attribution, control) design to test whether consumers have a lay-belief that more effort goes into the review-writing process for a mobile compared to a non-mobile device (i.e., process by moderation). We found a significant interaction on purchase consideration ($b = -.158$, $p = .006$) such that the effect of mobile on purchase intent was positive and significant in the control condition when there was no effort attribution to interfere with the “device-effort” lay theory ($b = .20$, $p = .019$). The simple effect of mobile was not significant when participants believed there was equal effort put into the review regardless of device, i.e., when the effort lay theory was interfered with.

Study 4 ($N = 205$) examines how the “fit” between UGC and the device it was written on influence perceived effort. We predict that it is not always a case of mobile-written content being seen as more effortful; but rather, when there’s an incongruence between the device and the online platform, perceived effort increases. To test this, participants considered a device (mobile or desktop) and for different platforms rated the perceived effort (six items; $\alpha = .87$) and perceived fit between that device and the content. Mobile was perceived as more effortful for online reviews ($b = .18$, $p = .05$) and seen as a significantly worse fit for the content ($b = -.63$, $p < .001$). Importantly, in a different platform (Twitter), this effect was reversed. Desktop-written content was perceived as more effortful than mobile content ($b = -.48$, $p < .001$) and seen as a significantly worse fit ($b = .67$, $p < .001$).

Study 5 ($N = 414$) examines when the “device-effort” lay-belief does not influence purchase considerations in a 2(mobile, non-mobile) \times 2(positive, negative) design. The interaction effect of device type and review valence on purchase consideration was significant ($b = .22$, $p < .001$). The simple effect of mobile on purchase intent was positive and significant when the review was positive ($b = .52$, $p < .001$) but not when it was negative ($b = .09$, $p = .162$). Despite this difference in purchase intention across review valence, we found a main effect of device on perceived effort ($b = .40$, $p < .001$), such that mobile-written reviews were always seen as more effortful. Lastly, we ran a mediated moderation model (Model 15; Hayes 2013) to further test this relationship. We observed a significant index of moderated mediation ($b = .08$, $se = .03$, $CI_{95} [.02, .16]$), which specifies that the path from effort to purchase intentions is moderated by the valence of the review, while the path from device to effort is left untouched.

This research looks at how the context in which an online review is written—mobile or non-mobile—affects consumers’ attitudes and purchase intentions. Future research will examine this process in greater detail.

Telling Both Sides of the Story: The Role of Risk in the Perceived Helpfulness of Online Reviews

EXTENDED ABSTRACT

Websites often encourage reviewers to identify both a product’s pros and cons in their review (two-sided reviews) rather than present only the pros or cons (one-sided reviews). For example, among Google’s tips for writing great travel reviews is to “include both the positive and negative aspects of your visit.”¹ Similarly, others such as the Better Business Bureau encourage reviewers to consider “the other side of the story.”² Such guidelines may seem justified given that presenting multiple sides (vs. one side) on a topic increases the chances of appealing to everyone, especially when an audience’s views are unknown (Tetlock, Skitka, and Boettger, 1989) or varied (Schlosser 2005), as is often the case with online reviews. Furthermore, a common consumer warning is that overly positive online reviews may be “fake” reviews posted by a firm.³ Thus, reviewers might believe that presenting multiple sides will boost their credibility. Indeed, two-sided ad claims often increase advertiser credibility (Crowley and Hoyer 1994). Yet, unlike advertisers, peer reviewers do not have a clear incentive to sell. As such, the credibility gains from two-sided ads may not generalize to peer reviews (Schlosser 2011). In fact, we propose that in higher-risk product contexts, encouraging reviewers to present multiple sides can backfire.

Both one-sided and two-sided messages have advantages and disadvantages. For instance, because one-sided messages provide only one view, there are no conflicting views to resolve (Sorrentino et al. 1988). Yet, a potential consequence of one-sided messages is that it can suggest that the author either did not consider alternative viewpoints or withheld one side (Sorrentino et al. 1988). Applied to online reviews, the audience might question one-sided reviewers’ credibility.

As mentioned earlier, two-sided ads often increase an advertiser’s credibility (Crowley and Hoyer, 1994). Furthermore, in a non-advertising context, two-sided messages suggest that the author considered alternative viewpoints (Sorrentino et al. 1988). Thus, based on these literatures, encouraging reviewers to write two-sided (vs. one-sided) reviews might increase reviewer credibility, and thus perceptions of review helpfulness. However, because two-sided messages introduce conflicting information, there is inconsistency and ambiguity. As such, they can cause consumers to feel more ambivalent than providing them with consistent information (Wang, Batra and Chen 2016; Zemborain and Johar 2007). Thus, an alternative expectation is that two-sided (vs. one-sided) reviews will be deemed less helpful.

We propose that the perceived credibility and helpfulness of two-sided versus one-sided reviews will depend on the product context: whether risk is high or low. According to prospect theory (Kahneman and Tversky 1979), when risk is low, people are risk seeking, and prefer uncertain over certain outcomes when uncertainty has advantages (e.g., a higher payoff). However, when risk is high, people are risk averse, and prefer certainty over uncertainty (Kahneman and Tversky 1979; March 1996). Thus, we expect that

1 <https://support.google.com/maps/answer/2519605?hl=en>

2 <http://bbbpnw.org/2014/02/28/7-tips-for-writing-good-online-reviews/>

3 <https://www.consumer.ftc.gov/articles/0027-comparing-products-online#read-reviews-and-be-skeptical>

in high risk contexts, two-sided reviews will no longer be perceived favorably. Indeed, risk aversion is related to discomfort with uncertainty (Johanson 2000). As a result, people who are risk averse respond more positively to procedures that reduce uncertainty than do those who are risk seeking (Colquit et al 2006; Desai, Sondak and Dickmann 2011).

Based on this, we expect that in low-risk contexts, two-sided (vs. one-sided) reviews will be more congruent with individuals' preferences for uncertain (but also, more balanced, complete) information. In contrast, in high-risk contexts, two-sided (vs. one-sided) reviews will be less congruent with individuals' preferences for certain, unambiguous information. Indeed, messages are more effective when they match individuals' orientations (Cesario et al. 2004; Lee and Aaker 2004), because this match, or fit, increases truth judgements (e.g., "it rings true" or "feels right"; Cesario, Higgins and Scholer 2008; Schwarz 1990; Schwarz & Clore 1988). Thus, if two-sided (vs. one-sided) reviews are more congruent with individuals' preferences in low-risk contexts, then we predict that individuals will perceive the two-sided reviewer to be more truthful, and thus, the two-sided review to be more helpful when risk is low. In contrast, if two-sided (vs. one-sided) reviews are less congruent with individuals' preferences in high-risk contexts, then we predict that individuals will perceive the two-sided reviewer to be less truthful, and thus, the two-sided review to be less helpful when risk is high. Because fit should increase truth judgments, we expect only judgments of reviewer trustworthiness (and not expertise) to mediate our predicted effects.

Five studies test these hypotheses in both the lab and the field across a variety of products and types of risk: social risk (studies 1-2), monetary risk (studies 3-4), and performance risk (study 5). Across lab studies, the content of the one-sided review contained only favorable information, whereas the two-sided review was largely positive with a mild negative claim. As predicted, the risk \times review interaction was significant across lab studies, with the two-sided review being rated as more helpful than a one-sided review when risk was low, but not when risk was high. In studies 2-3, we also find that reviewer trustworthiness (and not expertise) is the mediator. In studies 4-5, we test the robustness of our helpfulness findings in the field by using data from amazon.com. The dependent variable in both studies was the proportion of helpfulness votes (number of helpful votes/ total number of votes), while the independent variables were risk and two-sided intensity. We identified the extent to which each review used two-sided versus one-sided claims (i.e., two-sided intensity) by using the Linguistic Inquiry and Word Count program. Across both field studies, we show that with greater risk, two-sided reviews have a negative effect on helpfulness votes.

This research makes several important contributions. First, our research contributes to the message sidedness literature by introducing risk as an important moderator of receptivity to two-sided messages. We also contribute to the credibility literature by finding that two-sided (vs. one-sided) messages increase source trustworthiness (but not expertise) perceptions, but only in low-risk contexts. Third, our research provides important managerial insights by suggesting that the current practice of encouraging reviewers to identify both pros and cons in their reviews can be suboptimal.

How the Interplay of Consumption Mode and Time Delay Influences the Persuasiveness of Online Reviews

EXTENDED ABSTRACT

Online reviews are among the most important pieces of content on the Web. For consumers, they play a key role in decision-

making, as studies show that 88% of shoppers read online reviews to determine the quality of local business and trust online reviews as much as they trust personal recommendations (Anderson 2014). Businesses also pay particular attention to online reviews due to their direct impact on revenues (e.g., Zhu and Zhang 2010). As a result, academic research is becoming more and more interested in the effects and relevance of online reviews (e.g., Chevalier and Mayzlin 2006; King and Bush 2014; Zhu and Zhang 2010).

While reviews have been investigated from various angles (e.g., Ludwig et al. 2013; Purnawirawan, De Pelsmacker, and Dens 2012; Schlosser 2011), two aspects that remain unexplored are the consumption mode (i.e., whether the reviewed product/service is consumed by a solo individual or jointly with another person) and the time lag between the consumption experience and the writing of the review. Our research focuses precisely on this gap— and examines how the interplay of consumption mode (individual vs. dyadic consumption) and time delay between consumption and review writing influences (1) review content and (2) review persuasiveness. We anticipate consumption mode and time delay to jointly impact review content and persuasiveness either by influencing the information encoded during consumption and recalled later at the time of writing the review or by influencing consumers' beliefs about which dimensions of the experience are most appropriate to report (Ratner and Hamilton 2015).

In Study 1 we used 3,723 reviews from TripAdvisor where reviews are identified as based on an individual experience ("solo") vs. based on an experience with another person ("couple"). We collected reviews for three types of services: hotels ($n=1,487$, 50% solo), museums ($n=1,313$, 48% solo), and restaurants ($n=923$, 37% solo). For each review, we obtained the star rating (1-5 points), the text of the review, the consumption mode of the experience (i.e., identified as "solo" and "couple" reviews on TripAdvisor), the date when the service was consumed, and the date when the review was written. Average time lag between the consumption date and the review date was 43.46 days and did not vary across consumption modes. We used the Linguistic Inquiry and Word Count (LIWC) program to obtain an objective measure of the persuasiveness of each review (Pennebaker, Booth, and Francis 2007), that is, the variable "clout," which indicates the extent to which the reviewer's language is influential and conveys expertise and confidence. A regression analysis where review persuasiveness was predicted by the interaction of consumption mode and time lag as well as a set of covariates (e.g., whether the review was written on a mobile device, review length, service type) revealed that when written immediately after the service consumption, couple reviews contain more persuasive language than solo reviews ($b=20.97$, $p<.0001$). However, as the time lag increases, solo reviews become more persuasive ($b=.02$, $p=.02$) while the persuasiveness of couple reviews remains unchanged ($p>.1$) such that the difference in persuasiveness between couple and solo reviews diminishes ($b=-.02$, $p=.03$).

The objective of Study 2 was to examine the potential content differences that might explain the joint impact of consumption mode and time lag on review persuasiveness. We collected the same information as in Study 1 for 240 reviews of solo and joint experiences from TripAdvisor for two types of classes: cooking ($n=152$, 36% solo) and yoga ($n=88$, 86% solo). Average time lag was 1.13 months and did not vary across consumption modes. To analyze the content of the reviews, we divided them into 3,426 snippets (pieces of text that communicate only one idea). Three independent coders content-coded these snippets for claims about utilitarian service attributes (e.g., class content quality, class process, staff competence) and hedonic service attributes (e.g., class enjoyment, studio atmosphere

and design, staff warmth). Inter-rater reliability was 97% or higher with disagreements resolved by discussion.

We find that the consumption mode determines how review content, specifically the number of claims about utilitarian and hedonic service attributes, changes as a function of time between the experience and review writing. Two separate regressions of utilitarian/hedonic claims on the interaction of consumption mode and time lag as well as review length as a covariate reveal no difference in the number of utilitarian and hedonic claims between solo and joint reviews when they are written immediately after the service experience (both p 's > .54). However, with increasing time lag, solo reviews include more utilitarian claims ($b=.17$, $p=.01$) while couple reviews do not ($p=.37$). Yet, while over time the number of hedonic claims remains unchanged for solo reviews ($p=.12$), the difference in the number of these claims compared to couple reviews diminishes as more time passes since the experience of the service ($p=.05$). Altogether, this suggests potential encoding/memory differences in utilitarian and hedonic attributes based on consumption mode. Importantly, a mediation analysis using bootstrapping (Hayes 2012; Model 8) on the persuasiveness of the reviews (measured as in Study 1) predicted by the interaction of consumption mode and time lag with review length as a covariate and the number of utilitarian and hedonic claims in each review as simultaneously operating mediators show that only the number of utilitarian claims emerges as a significant mediator ($b=-.43$, $SE=.31$, 95% CI: -1.38 ; $-.04$), while the number of hedonic claims does not (95% CI: $-.29$; $.51$).

In sum, our research involving more than 4,000 reviews demonstrates that reviews about joint experiences are more persuasive than those about solo experiences when written immediately after a service consumption; however, with increasing time between the experience and the review writing, solo reviews become more persuasive due to the greater number of statements about utilitarian service attributes included in them. Our next steps involve conducting a set of lab experiments to (1) investigate the mechanism behind the review content changes over time for solo and couple reviews and (2) test whether the content differences in solo and couple reviews impact purchase intentions for consumers planning to experience the reviewed service alone vs. jointly with another person.

Relationship Norms in Response to Online Reviews in P2P Exchanges

EXTENDED ABSTRACT

Traditionally, marketing exchanges have involved commercial buyer and seller exchanges. However, in today's Internet-enabled world, another form of exchange, peer-to-peer (P2P) exchange, which involves peers selling products to other peers, is gaining prominence (Boesler 2013).

There are distinctive characteristics of P2P exchanges that motivate this research. First, sellers in P2P exchanges share their personal property (e.g., apartment) for economic benefits with peers, who are unknown to them (Habibi, Kim, and Laroche 2016). Second, unlike traditional commercial providers operating under the aegis of brands and subject to quality controls, P2P exchanges are conducted by small, independent providers, resulting in variability in product quality. One way for potential P2P buyers to reduce their uncertainty about product quality is to read previous users' online ratings (Fradkin et al. 2015). Further, P2P exchanges are driven by not only exchange norms, but also by communal norms, which involve concern for the welfare of others. In view of these differences, it is unclear whether the insights on consumers' responses to online ratings in traditional marketing exchanges will apply to P2P exchanges.

Addressing this key research gap, we examine whether consumers' responses to users' online reviews in P2P exchanges are different from those in traditional marketing exchanges.

We develop a theory relating consumers' relationship norms and users' online ratings to consumers' P2P buying intentions. We hypothesize that a match between the communal (vs. exchange) norms of consumers and the communal characteristics of P2P providers (vs. exchange characteristics of traditional providers) should strengthen consumers' P2P buying intentions.

We further hypothesize that two characteristics of P2P providers will change the balance of communal vs. exchange norms in P2P exchanges, moderating the responses of communal- (vs. exchange-) oriented consumers' to users' online ratings. First, as amateur P2P providers treat their income as supplementary (vs. professionals treat their income primary), they tend to not invest (vs. significantly invest) in service provision (Li et al. 2015). Hence the differences in the economic (vs. social) motivations of amateur (vs. professional) P2P providers may shift the balance toward communal (vs. exchange) norms in P2P exchanges. Second, people differentiate between others on the basis of warmth and competence (e.g., Cuddy, Fiske, and Glick 2008). P2P providers' positioning as being warm (vs. competent) may change the balance of communal (vs. exchange) norms in the P2P exchange.

Accordingly, we hypothesize that communal-oriented versus exchange-oriented consumers will respond differently to users' online ratings of amateur (vs. professional) and warm (vs. competent) P2P providers. Further, we hypothesize that the responses of communal- (vs. exchange-) oriented consumers to users' online reviews of P2P providers will be mediated by consumers' certainty about the P2P provider offering (Faraji-Rad, Samuelson, and Warlop 2016) and increase their intention to buy the P2P offering. Six studies tested our theory.

In Study 1, participants read a positive (5-star) online review of a traditional (Hotels.com) or a P2P (Airbnb.com) accommodation provider. Participants indicated their purchase interest in the accommodation and completed a scale of relationship (communal vs. exchange) orientation (Mills and Clark 1994). As expected, whereas individuals with a communal orientation were more responsive to the online review of a P2P accommodation provider (i.e. they were more likely to book the accommodation following a positive review), individuals with an exchange orientation were more responsive to the online review of a traditional provider.

Study 2 tested whether this effect is symmetric for positive and negative P2P provider reviews, and it examined the underlying process. Participants read a positive (5-star) or a negative (1-star) review of a P2P accommodation provider and indicated their purchase interest. They then completed the scale of relationship orientation and indicated their subjective certainty about the provider. As expected, compared to exchange-oriented individuals, communal-oriented individuals were had more positive responses toward P2P providers following a positive review and more negative responses to P2P providers following a negative review, and this effect was mediated by individuals' certainty about the provider.

Study 3A replicated the effect of consumers' communal (vs. exchange) relationship orientation on their responses to P2P provider reviews using an established manipulation (Aggarwal and Law 2005), instead of an inherent measure, of relationship orientation. Study 3B showed that this effect does not depend on reviewers' communal (vs. exchange) orientation.

Study 4 tested the effect of consumers' relationship orientation on responses to online reviews of amateur versus professional P2P service providers. Participants completed the manipulation of rela-

tionship orientation from Study 3A. They then read a positive (5-star) review of a P2P meal (dinner) provider on a popular P2P meal service platform (Eatwith.com). The P2P provider was described as either amateur (“self-taught home cook”) or professional (“professionally trained chef”). Participants expressed their purchase interest and indicated their certainty with the provider. The results showed that communal orientation increased individuals’ response to an amateur P2P provider, whereas exchange orientation increased individuals’ response to a professional P2P provider. This effect was mediated by individuals’ certainty about the provider.

Study 5 tested the effect of consumers’ relationship orientation on responses to online reviews of P2P providers with warm versus competent positioning. Participants read a positive (5-star) online review of a P2P meal provider on Eatwith.com. The provider positioned themselves as either warm or competent in their self-description. Participants indicated their willingness-to-pay for the dinner hosted by the provider, and they completed the scale of relationship orientation. The results showed that individuals with a communal orientation had a higher WTP for a meal following a positive review of a warmly positioned P2P provider, but individuals with an exchange orientation had a higher WTP for a meal following a positive review of a competently positioned P2P provider.

Our findings have important implications for existing theory, which has so far overlooked the role of online reviews in the increasingly prevalent P2P exchange paradigm. Our results generate useful insights for managers of P2P platforms (who wish to increase the effectiveness of their platforms and to compete with traditional commercial platforms for the share of the service market) and P2P providers (who wish to increase the appeal of their offerings to different segments of consumers).

SESSION OVERVIEW

Consumer choices and consumption are rarely solitary. They often involve others in an array of ways, from choosing for others, to co-consuming with others, to viewing others' consumption, or even just thinking about others. While decision-making research has taught us much about how people make choices for themselves (e.g., Bettman, Luce, and Payne 1998), less is known about how this rich social context affects consumption decisions for the self.

Therefore, it is important for both researchers and practitioners to understand the nuances of the array of roles that others play in consumers' choices. How do the consumption choices made by and for others affect subsequent choices for oneself? How does thinking about others' consumption and others' perceptions of us affect our own consumption choices?

In this symposium, four papers explore these questions by considering the multitude of roles that others play in affecting our consumption choices. The four papers address various social aspects of consumption: choosing for others, consuming with others, considering others' consumption and considering others' perceptions of the self.

The first paper (Gullo, Liu, Zhou, Fitzsimons) considers how choosing for others affects subsequent choices for the self. Specifically, the authors examine how choices for others in the domain of a personal goal affect subsequent goal-relevant choices for the self. Three studies show that making a personal goal consistent (inconsistent) choice for a relationally close other—such as one's child, friend, or even pet—liberates (reinforces) a subsequent goal-relevant choice for the self, but only if the chooser also views the relationship as non-competitive.

The second paper (Liu, Haws, McFerran) considers how co-consuming with others affects concurrent choices for the self. Specifically, the authors propose a new conceptual basis based on product attributes for predicting when and why consumers match their co-consumers' choices. Six studies show that consumers are more likely to match their own choices with their co-consumers' choices

on vertically-differentiated attributes (e.g., price or portion size) than on horizontally-differentiated attributes (e.g., flavor).

The third paper (Tu and Fishbach) considers how viewing others' consumption affects one's own consumption. Specifically, the authors propose that people can satiate on what other people eat vicariously. Five studies demonstrate that, when the other is similar to the self, people experience lower desire to consume food that is similar (rather than dissimilar) in taste to what they have viewed others consume.

Finally, the fourth paper (Cutright, Srna, Samper) considers how thinking about others' perceptions of oneself affects choices for the self. Specifically, the authors propose that believing that others will view their decisions positively (i.e., having social confidence) leads to greater purchase intent. Four studies demonstrate that consumers feel more socially confident when wearing formal clothing (vs. casual clothes), which causes them to be less hesitant about their purchases, ultimately increasing purchasing.

Across four papers and 18 studies, this session investigates decisions in a wide array of "others" contexts. This session is directed at a wide audience including those interested in social influences on choice, choices for others, and interpersonal goal pursuit.

Are My Dog's Treats Making Me Fat? The Effects of Choices Made for Others on Subsequent Choices for the Self

EXTENDED ABSTRACT

Consumers often make choices for others intermixed with choices for themselves—parents choose activities for their children, coworkers grab lunch for each other, and pet owners choose snacks for their pets. Do choices made for someone else's consumption affect subsequent choices for our own consumption?

Prior research has shown that preceding choices for the self can impact subsequent choices (Fishbach and Dhar 2005; Huber, Goldsmith, and Mogilner 2008; Khan and Dhar 2006). Even thinking about refraining from indulging or being in the presence of healthy options can license indulgent subsequent decisions (Fitzsimons, Nunes, and Williams 2007; Wilcox et al. 2009). These prior findings suggest that making a choice for someone else may have the potential to affect a subsequent choice for oneself. However, little research has examined whether, when, and how choices for others affect subsequent choices for the self.

Across three studies, we show that when a consumer makes a personal goal consistent (inconsistent) choice for someone else's consumption—such as for children, friends, and even pets—it liberates (reinforces) a subsequent goal inconsistent (consistent) choice for the self. We identify two important boundary conditions: the extent to which the target other is perceived as included in the self and the competitiveness of the relationship with the target other. We theorize that, when the other is close and non-competitive, people encode the choices they make for others as progress (or lack of progress) toward their own goals. We argue that this falsely perceived progress towards one's own goals liberates (reinforces) the goal in a subsequent choice for the self.

Study 1 had a 2 (choice for other: healthy vs. indulgent) between-subjects design. Participants (N = 312) were MTurk workers who reported having a health goal and as being a parent of a child

between the ages of 8 and 12 years old. To activate their health goal, all participants edited an article about healthy eating (adapted from Haws and Winterich 2013). Then, participants imagined registering their child for a summer day camp. As the manipulation of choice for other, the registration process had participants choose between either two healthy (e.g., whole wheat pita sandwich) or two indulgent (e.g., bacon cheese burger) lunch choices for their child to eat while at camp. Then, participants were informed that one participant would actually be randomly selected to receive an Edible Arrangement fruit basket of their choice. The dependent variable was whether they chose a healthy (all fruit) or indulgent (chocolate-covered fruit) basket as their drawing prize. As predicted, parents were more likely to choose an indulgent prize for themselves if they chose a healthy lunch for their child ($M = 45.16\%$) than if they chose an indulgent lunch for their child ($M = 35.67\%$, $p = .088$).

Study 2 explored the moderating role of closeness with other. In this field study, we recruited dog owners ($N = 109$) at a 50-acre off-leash dog park where visitors must hike through uphill trails to get to the main area of the park. Thus, visitors are likely to have a health or active lifestyle goal, and simply being at the park should activate this goal. All participants then completed an incentive-compatible grocery shopping task in which they chose between pairs of products (of importance, one choice was randomly selected to be real for each participant). The manipulation was whether participants were randomly assigned to choose between two healthy treats or two indulgent treats for their dog. The dependent variable was whether participants then subsequently chose a healthy apple or an indulgent chocolate bar as a snack for themselves. We also measured the extent to which the dog was included in the self (Inclusion of Other in Self, "IOS", Aron et al., 1992). As predicted, a logistic regression on snack choice for self (apple vs. chocolate) by IOS and manipulated choice for other (healthy vs. indulgent) revealed a significant 2-way interaction ($p < .05$). To decompose this interaction, we used the Johnson-Neyman technique to identify the range of IOS for which the simple effect of the manipulated choice for other was significant. There was a significant effect of choice for other on the likelihood to choose chocolate as a snack for the self for any dog owner who has an IOS score of 6.62 or higher ($B_{\text{N}} = -1.18$, $SE = .5998$, $p = .05$), but not for dog owners with an IOS score less than 6.62.

Study 3 explored competitiveness as a boundary condition. Participants ($N = 426$) were MTurk workers who reported having a health goal. All participants completed the same health goal activation task as in Study 1 and provided the first name of a close, same gendered friend. Then, they imagined picking up lunch for their friend as a favor. Choice for other was manipulated via choosing between either two healthy (e.g., salad) or two indulgent (e.g., fries) side options to go along with their friend's entree. Then, all participants completed the dependent variable as Study 1 and the same measure of closeness with their friend as Study 2. Finally, participants completed a measure of relational competitiveness (item 15 from Ryckman et al. 1990).

As predicted, a logistic regression on prize choice for self (fruit vs. chocolate) by IOS, relational competitiveness, and choice for other reveals a significant 3-way interaction ($p = .019$). Follow-up simple-effects analyses revealed the following pattern of results: with a low IOS other (i.e., less than 4), there was no simple 2-way interaction between CFO and competitiveness ($p > .20$). However, with a high IOS other (i.e., greater than 6), there was a significant simple 2-way interaction between CFO and competitiveness ($p < .05$) such that at low competitiveness, the choice for other led to the same basic effect as in the prior studies whereas at high competitive-

ness, the basic effect was reversed (i.e., choosing healthy for other led to decreased likelihood of choosing indulgent for self).

Across three studies, we demonstrate that, when consumers choose for close "others," such choices can affect subsequent choices for the self.

Mindful Mimicry of Food Choices: Vertically versus Horizontally Differentiated Attributes

EXTENDED ABSTRACT

Much consumer behavior occurs in a social context involving co-consuming alongside others (Etkin 2016; Gorlin and Dhar 2012; Liu et al. 2013; Lowe and Haws 2014; McFerran et al. 2010). For instance, friends may have ice cream together, and co-workers may each have a glass of wine after dinner. Prior research in the eating/drinking domain has produced divergent findings on whether consumers match their co-companions' consumption choices. On the one hand, mimicry research suggests that consumers match (McFerran et al. 2010; Tanner et al. 2008). For example, McFerran et al. (2010) found that consumers matched companions' portion size selections. On the other hand, other research suggests that consumers sometimes do not match (Ariely and Levav 2000). For instance, Ariely and Levav (2000) found that consumers did not match their co-consumers' beer selections.

We propose a new conceptual basis for predicting when matching is more (and less) likely to occur, based on *product attributes*. This framework helps reconcile these apparently divergent findings and also generates new predictions. Specifically, we distinguish between attributes that are perceived to be more vertically versus horizontally-differentiated. These terms are commonly used in economics and quantitative marketing to indicate ranked/objective (vertical) versus unranked/subjective (horizontal) attributes (Lauga and Ofek 2011; Randall, Ulrich, and Reibstein 1998; Sutton 1986). We propose that consumers match co-consumers on vertically-differentiated attributes, but not horizontally-differentiated attributes.

Our rationale is that mismatching on vertically-differentiated (vs. horizontally) attributes represents a greater social norm violation. Namely, people are highly attuned to relative rank/performance (Duesenberry 1949; Festinger 1954; Frank 1985). Furthermore, people both dislike being lower rank (Kuziemko et al. 2014) and dislike being a target of upward social comparison (Exline and Lobel 1999). We thus propose that in the consumption context, consumers match co-consumers on vertically-differentiated attributes because occupying different positions generates discomfort. In contrast, occupying different positions on horizontally-differentiated attributes does not convey relative rank/performance differences and thus consumers need not match (and may even mismatch for various reasons).

Our conceptualization can thus help explain apparently divergent prior findings, which has frequently shown mimicry of others' portion sizes (vertically-differentiated attribute) and has also shown non-mimicry but typically examined flavor selections (horizontally-differentiated attribute). A pre-test and six studies tested our novel conceptualization.

For the pre-test, participants ($N = 154$) were provided with definitions of horizontal and vertical differentiation and rated food-related attributes (1 = *completely horizontally differentiated* to 7 = *completely vertically differentiated*). Portion size ($M = 4.27$) and price ($M = 5.37$) were deemed more vertically-differentiated, whereas flavor ($M = 3.31$) was deemed more horizontally-differentiated, as one-sample *t*-tests indicated that the mean ratings for portion size and price were both greater than the scale midpoint (portion size: $p = .086$; price: $p < .001$), whereas flavor was less than the midpoint ($p <$

.001). Studies 1 and 3-6 thus operationalized the vertically-differentiated attribute using portion size (Study 2 used price), and all studies operationalized the horizontally-differentiated attribute using flavor.

Study 1 had a 2(friend's portion size: small, large)×2(friend's flavor: chocolate, vanilla)+1(control: friend's order not specified) between-subjects design. Undergraduate participants (N=205) first provided a same-gender friend's name and imagined arriving at an ice creamery together. Participants viewed a four-option menu: 1 scoop chocolate, 2 scoops chocolate, 1 scoop vanilla, and 2 scoops vanilla. Depending on random assignment, participants were told that their friend ordered one of these four options. Participants then chose an option for themselves. First, regarding portion size, participants were significantly more likely to choose a large portion size themselves if their friend chose a large versus small portion size (68.4% vs. 51.2%; $p = .028$). Second, regarding flavor, participants were similarly likely to choose the chocolate flavor if their friend chose chocolate versus vanilla (56.6% vs. 53.6%; $p = .703$). There were no interactions between the friend's portion size and the friend's flavor on the participant's portion size choice ($p = .767$) or flavor choice ($p = .643$). Study 2 replicated these effects with actual food choices.

Study 3 had a 2(friend's price: low, high)×2(friend's flavor: fruity, earthy)+1(control: friend's order not specified) between-subjects design. MTurk participants (N = 315) provided a same-gender friend's name and imagined arriving at a wine bar with their friend. Participants viewed a menu with four glass-of-wine options: Grenache–fruit-flavored (\$4), Malbec–fruit-flavored (\$8), Syrah–earthy-flavored (\$4), and Chianti–earthy-flavored (\$8). Depending on randomly-assigned condition, participants were told that their friend ordered one of these four options. Participants then chose an option for themselves. Study 3 results generally replicated Study 1-2's. Participants were significantly more likely to choose a higher-priced glass of wine if their friend chose a higher-priced versus lower-priced glass (40.9% vs. 24.8%; $p = .007$). However, participants were marginally *less* likely to choose the fruity flavor if their friend chose a fruity versus earthy flavor (60.0% vs. 71.7%; $p = .052$), reflecting some mis-matching. There were no interactions between the friend's price and the friend's flavor on the participant's price choice ($p = .758$) or flavor choice ($p = .342$).

In Studies 1-3, participants knew their friend's standing on *both* the vertically-differentiated and horizontally-differentiated attributes. Optimal distinctiveness theory (Brewer 1991) thus raises the alternative explanation that people may match on just one attribute because of optimal distinctiveness reasons. Our account, however, is that matching is dependent on the attributes themselves. Accordingly, our findings should hold even when consumers only have information about their friend's standing on one attribute (vertical or horizontal). Study 4 (N = 378) thus only provided participants with one piece of information about their friend's order (either size or flavor). Study 4 found matching on the vertical attribute but not the horizontal attribute, providing further support for our account.

Finally, Studies 5-6 used different approaches to show that matching on vertically-differentiated attributes occurs because consumers anticipate, and want to decrease, social discomfort associated with mismatching on such attributes.

In sum, consumers match co-consumers on vertically-differentiated attributes (portion size, price) but not horizontally-differentiated attributes (flavor). These findings extend the social influences literature by offering a broad conceptual basis for predicting which attributes are matched.

The Social Path To Satiation: Satisfying Desire Vicariously via Other's Consumption

EXTENDED ABSTRACT

Consumers frequently receive information on other people's food consumption, such as in food commercials and when dining together. Recently, *Mukbang* – a combination of the Korean word for eating and broadcasting – has caught on. People worldwide share “eating show” videos of themselves eating large quantities of food, attracting billions of viewers globally (Evans 2015; Pequenino 2016). How does another's food consumption influence one's own desire for that food? Whereas it may whet one's appetite and signal the positive quality of the food (i.e., increase liking), we explore the possibility that consumers may desire the specific food others just had less momentarily (i.e., decrease wanting) (Garbinsky, Morewedge, and Shiv 2014).

Building on the notion that, as social animals, people experience blurred interpersonal boundaries (Aron et al. 1991; Kelley and Thibaut 1978; Small and Simonsohn 2008), and can perceive others' traits (Goldstein and Cialdini 2007), decision conflict (Schrift and Amar 2015) and ownership (Tu and Fishbach 2015), as partially their own, we propose that other's consumption can make people feel as if they have consumed it too, which in turn leads to lower desire, postponement of consumption and switching consumption. It follows that the degree of perceived self-other overlap matters – *people will experience vicarious satiation only when self-other overlap is sufficiently large*. Crucially, we study attribute-based (rather than hunger-based) satiation, which is sensory-specific (Inman 2001; Larson, Redden, and Elder 2014) and predict *people will desire the food that is similar (rather than dissimilar) in taste to what others consumed less*. Five studies tested the theoretical framework.

Study 1 documented the vicarious satiation effect by having participants watch an adapted “eating show” video, in which the protagonist ate a whole pizza, slice by slice. Participants' desire for pizza changed over time – before watching the video, 1 minute, 3 minutes, and 4 minutes into the video ($F(3, 120) = 8.71, p < .001$; $M_{10} = 3.93, SD_{10} = 1.85$; $M_{11} = 4.12, SD_{11} = 1.85$; $M_{12} = 3.49, SD_{12} = 1.82$; $M_{13} = 3.15, SD_{13} = 1.90$) and followed a linear pattern ($F(1, 40) = 10.78, p = .002$). Moreover, they desired pizza less after than before watching the video ($F(1, 40) = 9.34, p = .004$).

Study 2 used postponement of consumption as a behavioral marker of vicarious satiation. We recruited acquaintances-dyads and presented them with two flavors of candies. We assigned one person (1st mover) to eat one flavor [consumption], or to evaluate its wrapper design without eating it [non-consumption]. We then invited the other person (2nd mover) to eat both flavors and measured his/her consumption order. In support of our hypothesis, more participants postponed consumption of the flavor the 1st mover received when the 1st mover consumed it (73%) than not (46%; $\chi^2(1) = 4.38, p = .036$).

Study 3 used switching consumption as a behavioral marker of vicarious satiation, and explored the similarities between vicarious satiation (for observers) and physiological satiation (for actors). Specifically, observers watched a video of a person either eating [consumption] or counting [non-consumption] M&M's; actors watched the same video and mimicked corresponding actions. We then asked participants to choose between three equally priced gifts: a pack of M&Ms, a pack of Skittles (a different food) or Post-it notes (non-food). We found a main effect that participants chose M&M's less in the consumption conditions (35%) than in the non-consumption conditions (57%; $\chi^2(1) = 9.27, p = .002$), regardless of whether they were observers (vicarious satiation; 39% vs. 60%; $\chi^2(1) = 4.15, p =$

.042) or actors (physiological satiation: 32% vs. 55%; $\chi^2(1) = 5.23$, $p = .022$).

Study 4 shed light on the proposed mechanism—vicarious satiation happens because people treat other's consumption as their own, meaning that the degree of self-other overlap matters. We had participants watch the same eating [consumption] or counting [non-consumption] video as in study 3, and manipulated perceived self-other overlap by informing participants that the protagonist either shares [high self-other overlap] or opposes [low self-other overlap] their political view. We measured participants' desire for M&M's, for something sweet, and for something chocolate after they finished watching the video. A Behavior (consumption vs. non-consumption) x Self-other Overlap (high vs. low) ANOVA on desire for M&M's yielded the predicted interaction ($F(1, 292) = 5.25$, $p = .023$). Specifically, watching another person eat ($M = 2.94$, $SD = 2.03$) rather than count ($M = 3.72$, $SD = 1.97$) reduced desire for M&M's ($F(1, 150) = 5.84$, $p = .017$) but only in the high self-other overlap conditions. When self-other overlap was low, this effect disappeared ($M_{\text{eat}} = 3.25$, $SD = 2.29$ vs. $M_{\text{count}} = 2.93$, $SD = 2.01$; $F < 1$). Desire for something sweet and something chocolate followed the same pattern.

Study 5 aimed to 1) explore whether vicarious satiation can happen when imagination is minimal by providing only text information and 2) document its sensory-specific nature. We had participants read either a daily food journal [consumption], in which a gender-matched person recorded that he/she had lots of Reese's peanut butter cups, or a daily task log [non-consumption], in which the person recorded the tasks he/she performed. We then measured desire for Reese's, for snacks that taste similarly (Snickers bar and M&M's), and for snacks that taste differently (Doritos, Lay's chips, and Goldfish crackers). We found that information about another person's consumption of Reese's (vs. daily tasks) reduced desire for Reese's ($M_{\text{food}} = 2.87$, $SD = 2.06$ vs. $M_{\text{task}} = 3.48$, $SD = 2.25$, $F(1, 220) = 4.46$, $p = .036$) and for similar snacks ($M_{\text{food}} = 2.51$, $SD = 1.72$ vs. $M_{\text{task}} = 3.11$, $SD = 2.04$, $F(1, 220) = 5.57$, $p = .019$; $M_{\text{food}} = 2.43$, $SD = 1.70$ vs. $M_{\text{task}} = 3.11$, $SD = 1.92$, $F(1, 220) = 7.73$, $p = .006$), but not for dissimilar snacks.

Eating is largely a social phenomenon; so much so that people are reluctant to dine alone (Ratner and Hamilton 2015). We identify a social path to satiation and discuss its implications in marketing and social coordination.

Suit Up and Shop: Social Confidence and the Influence of Consumer Attire on Purchasing Decisions

EXTENDED ABSTRACT

We investigate the relationship between formality of dress and purchase intent. Drawing from research on consumer confidence (Bearden, Hardesty and Rose 2001), we argue that when consumers are wearing formal clothing, they are more likely to feel socially confident, or that they have the ability to impress others with the products that they choose to purchase. This enhanced social confidence, which is distinct from other forms of confidence, leads to higher purchase intent in shopping domains that are related and unrelated to clothing.

We expect that formality of dress is an important precursor to social confidence because a primary function of clothing is to communicate one's self to others and generate positive social outcomes. Research has shown that people in formal dress view themselves more positively (Hannover and Kuhnen 2002) and have a greater sense of authoritativeness and competence (Peluchette and Karl 2007; Cardon and Okoro 2009). In this sense, formally dressed indi-

viduals should expect to be viewed positively by others, or socially confident. We expect that they should also be more eager to make purchases, as believing that others will view one's decisions positively reduces the hesitancy associated with making a purchase decision. Although not focusing on social confidence, prior research has shown that when people feel more confident, they perceive less risk and require less information to make a decision (Hisrich, Dornoff, Kernan 1972).

In Study 1, we test our predictions in the behavioral lab. The day before their scheduled session, participants received an email asking them to arrive to the lab dressed formally (sport coat or blazer, slacks or dress) or casually (sweat pants, t-shirts, tennis shoes and flip flops) in exchange for \$5. Undergraduate participants were told that we were collaborating with a retailer to learn about college students' clothing style and the types of items they purchase. They would have the opportunity to spend up to \$30 in a store sponsored by this retailer, which had a variety of college life products (e.g., water bottles, school supplies). Our dependent variable was the number of items participants purchased. We found that participants chose more items in the formal relative to the casual condition ($F(1, 245) = 4.37$, $p = .04$, $M_{\text{formal}} = 10.53$, $M_{\text{casual}} = 8.89$). We also measured perceived economic and social status, financial resource slack, and deservingsness, and ruled these out as alternative explanations.

In Study 2, we examine formal versus casual dress in an online context. To manipulate dress, we use avatars, or computer-based representations of our participants. Participants created an avatar in the image of themselves and were told to select an outfit for this avatar. Those in the formal and casual dress conditions were given options that were purely formal (slacks, dresses, business casual shirts) or casual (athletic pants, sweatshirts and sneakers or flip flops). All participants imagined entering a virtual store as their avatar. Our focal dependent measures were the likelihood participants would buy themselves something and feelings of confidence using Bearden et al.'s Consumer Self-Confidence scale, focusing specifically on the "Social Outcomes Decision-Making" dimension (i.e., "social confidence" $\alpha = .88$). We found that participants were more likely to purchase something for themselves in the formal (vs. casual) dress condition ($F(1, 253) = 7.71$, $p = .01$, $M_{\text{formal}} = 4.53$, $M_{\text{casual}} = 4.02$). This effect was mediated by feelings of social confidence, but not other types of confidence.

In Study 3, we identify type of store as a boundary condition. While in more traditional stores, we predict that formal dress should lead to feelings of being at one's best, in stores where the norm is to dress casually, casual dress may also be consistent with being socially confident, since casual dress is associated with engaging in effort to build or repair. Thus, we conducted a 2 (dress: formal vs. casual) x 2 (shopping environment: formal store vs. casual store) experiment, again using avatars. We also measure feelings of best self, feelings of fit and consumers' desires for self-consistency in addition to our primary dependent measure of purchase likelihood. We found a significant store x dress interaction ($F(1, 395) = 5.52$, $p = .02$). In the formal store, those assigned to formal (vs. casual) dress showed greater purchase intent ($F(1, 395) = 6.77$, $p = .01$, $M_{\text{formal}} = 4.88$, $M_{\text{casual}} = 4.30$). Within the casual store, however, there were no such differences ($F(1, 395) = .51$, $p = .48$, $M_{\text{formal}} = 4.30$, $M_{\text{casual}} = 4.46$). Consistent with predictions, mediation within the formal store condition revealed the predicted mediation within the formal store condition, formal dress \rightarrow social confidence \rightarrow purchase intent.

Finally, in Study 4 we look at whether simply feeling socially confident or actually needing to publicly use a product drives our effect. We assigned MTurk participants to a 2 (formality of dress: formal vs. casual) x 2 (usage objective: public vs. private) experi-

ment. We reasoned that if social confidence is indeed a critical component, the effect of dress should be strongest when individuals are focusing on decisions for social contexts rather than private ones. Participants then imagined that they decided to shop online, in the privacy of their own home (with no one else around) and were shown an online shopping interface. To manipulate the public versus private use of goods, participants were told that they were shopping for new clothes that they would wear exclusively while working from a private home office or a public office. Our dependent measures were purchase intent and social confidence. Results revealed a significant dress x store environment interaction, $F(1, 395) = 5.18, p = .02$. For public use, those dressed formally (vs. casually) displayed greater purchase intent ($F(1, 395) = 4.36, p = .04, M_{\text{formal}} = 4.89, M_{\text{casual}} = 4.44$). For private use, however, there were no differences ($F(1, 395) = 1.27, p = .26, M_{\text{formal}} = 4.18, M_{\text{casual}} = 4.42$). Further analyses replicated our prior mediation paths in the public condition, emphasizing the dependence of our effect on public display.

In sum, across 4 studies, we formal attire enhances the extent to which consumers feel socially confident, which heightens desires for consistency and feelings of belonging, and consequently purchase intent. This can be turned off by shopping in non-traditional contexts where casual clothing is reflective of social confidence, and in contexts where usage is private.

OVERVIEW

Consumers are inherently motivated to have mastery of the environment, which leads them to seek control and certainty. A voluminous literature has shown that situations in which consumers feel out of control or uncertain are threatening to the self (Dow et al. 1992; Kay et al. 2008), which primarily highlights the downside of such states. Yet, low control and uncertainty may not always have detrimental effects on consumer behavior. The four papers of this session address a set of related questions focused on potential benefits of such 'aversive' states.

The first two papers of the session deal with the downstream consequences of low control on consumer belief and choice, differentiating its upsides and downsides. **Han, Samper, and Gershoff** document how a feeling of low (vs. high) control affects consumers' perceptions of two resources: time and money. They find that while incidental low (vs. high) control decreases consumers' money efficacy perceptions, it also *increases* their time efficacy perceptions. This is because time is perceived as more self-representative compared to money. They also show that low (vs. high) control leads consumers to have higher expectations about outcomes when spending time, but lower expectations when spending money. **Min and Schwarz** differentiate two aspects of low control that have been treated as equivalent and subsumed under a generic "control" label: perceptions of unpredictability and low personal control. They show that perceptions of unpredictability (vs. low personal control) give rise to different perspectives on novelty (opportunity vs. risk, respectively), hence thinking about an unpredictable world actually *increases* novelty-seeking whereas thinking about a lack of personal control decreases novelty-seeking.

The second two papers of the session focus on potential advantages of uncertainty in the context of consumer belief and choice. **Cheatham and Tormala** look at the effectiveness of advocacy messages depending on the level of perceived certainty about one's attitude toward an issue (e.g., labeling of GMO foods, banning/taxing of high sugar drinks). They find that consumers who hold less certain attitudes are perceived as actually *more persuasive* than certain advocates, when advocates and recipients have dissimilar (vs.

similar) views. Their work provides evidence that uncertainty can be more persuasive than certainty under some conditions. **He, Carpenter, and Grayson** identify a novel antecedent of preference for authenticity: uncertainty about a product category. They show that authenticity is *more preferred* when consumers are uncertain about a product category than when they are certain and familiar with the category. Authentic options are perceived as more prototypical and representative of the unfamiliar category, thereby providing an opportunity to reduce uncertainty (i.e., learn) about that category. They demonstrate that this learning mechanism is distinct from a risk-reduction account.

Taken together, the combination of the current work contributes to shifting perspectives on the effects of low control and uncertainty by providing convergent support for their favorable effects on consumer belief and choice and demonstrating when and how they can do good. We expect this session to generate significant interest among researchers investigating control, uncertainty, and consumer choice-making and evaluation more broadly.

I Can Do More with My Time, but Less with My Money: The Role of Control on Resource Efficacy Perceptions

EXTENDED ABSTRACT

As consumers, we all use resources such as time and money to obtain the outcomes we want. However, even though a unit of resource should have a fixed objective value, incidental factors may influence how people view their resources (e.g. Soster, Gershoff, & Bearden, 2014) including those in which participants earn and spend real resources and evaluate real products, explore this bottom dollar effect. This research contributes to prior mental accounting research regarding how costs influence decision making (e.g., bundling, coupling, sunk costs). It is important to understand how certain factors impact consumers' evaluation of resources, since such evaluations can further affect consumer expectations and satisfaction. In this paper, we show that while incidental low (vs. high) control increases people's time efficacy perceptions, it decreases people's money efficacy perceptions. Moreover, we find that this change in resource efficacy perception has commensurate effects on consumer expectation and satisfaction.

Since the belief that one has control is integral to the self (Skinner, 1995), incidental events that make one feel low control can be perceived as a threat to the self (e.g. Chaxel, 2016). Past work shows that one way in which people respond to such threats is by becoming defensive, where they reinforce their personal beliefs or engage in compensatory behavior (Hart et al., 2009). Alternatively, the literature also suggests that people can become more conservative, where they become more cautious during decision-relevant information search (Fischer et al., 2011) yet others have found contradictory effects. The present series of 5 studies consistently found that the crucial moderator for these inconsistent findings was whether the induced threat was contextually related to the subsequent decision and information search tasks. Contextual incongruence (e.g., an induction of terrorist threat followed by an economic decision case). Importantly, past work shows that whether people become defensive or conservative in response to a threat depends on the relevance of the subsequent task to the threat itself (Fischer et al., 2011) yet others have found contradictory effects. The present series of 5 studies consistently found that the crucial moderator for these inconsistent

findings was whether the induced threat was contextually related to the subsequent decision and information search tasks. Contextual incongruence (e.g., an induction of terrorist threat followed by an economic decision case. Considering that feelings of low control is a threat to the self, low control could lead to defensive processing for self-relevant evaluations, whereas it could result in conservative processing for non-self-relevant evaluations. A pertinent situation is when consumers are thinking of their time versus money resources. Specifically, the literature on consumer resources finds that people view their time (vs. money) as more reflective of the self (Mogilner & Aaker, 2009; Reed, Aquino, & Levy, 2007) activating time (vs. money, and this could mean that consumers engage in defensive (conservative) processes when evaluating their time (money) resources in response to a threat to the self. Therefore, we predicted that incidental feelings of low (vs. high) control would heighten people's time efficacy perceptions, whereas it would decrease their money efficacy perceptions. We tested these predictions across four studies.

In study 1, we manipulated control by having participants read a purported science article on how effort (high control) or genes (low control) are responsible for people's life outcomes (Cutright & Samper, 2014) what role should products play in helping consumers pursue their goals (e.g., losing weight, maintaining a clean home. Next, we measured people's resource efficacy perceptions using an adopted version of the Instrumentality of Money Scale (Duclos, Wan, & Jiang, 2013). As expected, the data revealed a significant interaction effect ($F(1, 166) = 7.36, p < .01$). Moreover, simple effects analyses showed that low (vs. high) control people felt higher time efficacy perceptions ($F(1, 166) = 3.54, p < .06$), but lower money efficacy perceptions ($F(1, 166) = 3.84, p < .05$). The results provided initial evidence that threats to control differentially affect time vs. money resource efficacy perceptions.

Study 2 investigated the underlying process of our effect. Here, we measured perceived self-representativeness of the resource in addition to manipulating control and measuring people's perceived resource efficacy. First, the results again yielded a significant interaction effect ($F(1, 235) = 8.91, p < .01$). Also, low (vs. high) control people felt higher time efficacy perceptions ($F(1, 235) = 6.37, p < .01$), whereas they felt marginally lower money efficacy perceptions ($F(1, 235) = 2.88, p < .09$). Importantly, as our theory would predict, a mediated moderation model using the PROCESS macro (model 15; Preacher & Hayes, 2004) formal significance tests of indirect effects are rarely conducted. After a brief overview of mediation, we argue the importance of directly testing the significance of indirect effects and provide SPSS and SAS macros that facilitate estimation of the indirect effect with a normal theory approach and a bootstrap approach to obtaining confidence intervals, as well as the traditional approach advocated by Baron and Kenny (1986) showed that perceived self-representativeness of the resource was driving the differential effect of low (vs. high) control on time versus money (95% CI in low control: [0.0189, 0.2164], high control: [-0.0395, 0.1842]).

In study 3, we examined the downstream consequences of biased resource efficacy perceptions on expected outcomes. In the study, participants first went through a control manipulation task and then were instructed to imagine that they had to use either time or money in order to search for a moving company (Saini & Monga, 2008). After reading the scenario, we measured participants' resource efficacy perceptions and also their expectations toward the moving company. First, there was a significant interaction effect of control and resource type on efficacy perceptions ($F(1, 146) = 11.15, p < .001$), where the mean patterns replicated previous results. Moreover, there was a significant interaction effect of control and resource

type on expected outcomes ($F(1, 146) = 8.73, p < .004$), where low (vs. high) control people had higher expectations when spending time ($F(1, 146) = 6.38, p < .01$), but marginally lower expectations when spending money ($F(1, 146) = 2.76, p < .09$). Finally, a moderated mediation using the PROCESS macro (model 8) revealed that the interaction effect of control and resource type on outcome expectations was driven by the interaction effect of control and resource type on efficacy perceptions (95% CI: [-0.2472, -0.0597]).

Finally, study 4 looked at how perceived control affects post-experience satisfaction. We expected that those who spent resources that were perceived as more efficacious would be less satisfied with the same experience. After completing the control manipulation task, participants read a scenario in which they had spent either 4 hours of work (time) or \$ 50 (money) to purchase a restaurant dinner voucher and further read that the actual dinner was a mix of positive and negative experiences. Subsequently, they were asked how likely they would write a positive or negative review for the restaurant. The data again revealed a significant interaction effect ($F(1, 165) = 10.41, p < .002$). As expected, low (vs. high) control led to decreased satisfaction when using time ($F(1, 165) = 3.79, p < .05$), but increased satisfaction when using money ($F(1, 165) = 6.88, p < .01$).

In short, the current paper finds that incidental feelings of control can differentially impact consumers' perceptions of time versus money resources and that control can further affect consumer expectations and satisfactions.

Novelty as Risk and Opportunity: Opposite Effects of Low Personal Control and Perceived Unpredictability on Novelty Seeking

EXTENDED ABSTRACT

Novelty can have two different implications in consumer behavior. Trying out new products can offer consumers opportunities to explore potentially superior alternatives (Hirschman 1980) but can also entail risks of handling uncertainty (Kalish 1985; Schiffman 1972). Since the propensities of consumers to adopt novel products play a critical role in forming brand loyalty (Thompson and Sinha 2008), decision making, and preferences (Bianchi 2006; Hekkert et al. 2003), understanding when consumers regard novel products as positive versus negative carries considerable weight.

One stream of research that investigates consumer novelty-seeking concerns the warm glow effect (James 1961; Titchener 1910) which claims that familiarity is associated with security and safety, thus consumers tend to stick with familiar products when they confront problematic situations (e.g., "chicken soup for the soul"). Low control is one of the detrimental states that consumers are motivated to overcome (Janoff-Bulman 1992). Past research on control showed that consumers who lack personal control show aversion to novel products (Faraji-Rad et al. 2016). However, personal control is only one aspect of control; motivation for personal control fulfills the motivation to overcome perceptions of unpredictability/randomness (Hafer and Bègue 2005) so previous research has treated low personal control and perceived unpredictability as two interchangeable causes of low control (e.g., Rutjens et al. 2013). In this research, we examined whether perceptions of unpredictability and low personal control would have the same downstream consequences on novelty-seeking. In contrast to earlier work, we hypothesized that perceptions of unpredictability would increase novelty-seeking, whereas perceptions of low personal control would decrease novelty-seeking. Six studies confirmed these predictions.

In all studies, participants chose 3 chocolate bars from a set of 6 choice options that consisted of 3 familiar (domestic) and 3 unfa-

miliar (international) chocolate bars. In study 1, participants read a news excerpt (from Friesen et al. 2014) and wrote about an event where they felt like the world is unpredictable (vs. predictable) before choosing 3 chocolate bars (which they received for consumption). Those who thought about unpredictability chose more novel items ($M = 1.15$) than those who thought about predictability ($M = .74$; $t(171) = -2.64$, $p = .009$).

Studies 2A and 2B directly juxtaposed two different aspects of low control: perceptions of unpredictability and low personal control. Consistent with previous findings, participants who wrote about an event where they had a complete lack (vs. sense) of control over the situation (from Faraji-Rad et al. 2016) were *less* likely to choose unfamiliar products ($M_{\text{high-personal-control}} = .99$ vs. $M_{\text{low-personal-control}} = .61$), whereas participants who wrote about the unpredictable (vs. predictable) world were *more* likely to choose unfamiliar products ($M_{\text{predictability}} = .58$ vs. $M_{\text{unpredictability}} = 1.07$) replicating study 1, yielding a significant 2-way interaction ($F(1, 274) = 14.94$, $p < .001$, $\eta^2_p = .052$).

These divergent effects of unpredictability and low personal control highlight that the two constructs are distinct, although they are often treated as equivalent and subsumed under a generic “control” label (e.g., Rutjens et al. 2013). Study 3 added a neutral condition to make comparisons with a baseline. Participants in the neutral condition wrote a short summary about vitamins. This study replicated the 2-way interaction of studies 2A and 2B ($M_{\text{predictability}} = .45$ vs. $M_{\text{unpredictability}} = .95$; $M_{\text{high-personal-control}} = .94$ vs. $M_{\text{low-personal-control}} = .54$; $F(1, 220) = 14.07$, $p < .001$, $\eta^2_p = .06$). In addition, participants in the neutral condition ($M_{\text{neutral}} = .96$) showed as much novelty-seeking as participants in high personal control condition and unpredictability condition (r 's $< .1$), but more novelty-seeking than low personal control condition and predictability condition (p 's $< .004$). This suggests that consumers may perceive the world as generally unpredictable, but their own personal circumstances as controllable.

These findings presumably reflect that different control manipulations give rise to different perspectives on novelty. An unpredictable world requires flexible adaptation and preparation for change, making novel products an opportunity worth exploring. In contrast, familiar alternatives may be comforting in a context where one lacks an opportunity to exert influence. Study 4 explicitly manipulated these perspectives. It replicated all conditions of study 3 while adding conditions that highlighted that new products can be seen as new opportunities (opportunity framing) versus risks resulting in wasted resources (risk framing). The replication conditions reproduced the interaction pattern observed in studies 2 and 3. The frame manipulations produced the expected results in the absence of any control manipulation (i.e., increased novelty-seeking under opportunity framing and decreased novelty-seeking under risk framing). More important, the choices of the participants exposed to unpredictability resembled those under *opportunity* framing, and the choices of the participants exposed to low personal control resembled those under *risk* framing.

These findings highlight that thinking about an unpredictable world differs from thinking about a lack of personal control, despite a long history of treating both manipulations as interchangeable. Whereas an unpredictable world fosters the exploration of novel products, a lack of personal control impairs it. We discuss the conceptual implications for theories of control, highlight the need for distinctions, and note their implications for consumer behavior.

The Surprising Effects of Attitude Certainty on Advocacy and Advocacy Receptivity

EXTENDED ABSTRACT

What drives people to advocate on behalf of their own attitudes? When, and why, do people engage in advocacy and how successful are they when they do? On a daily basis, we are exposed to countless advocacies generated by individuals. One person might advocate for the purchase of fair trade clothing after learning about how garment makers are often underpaid, whereas another might endorse a policy proposal such as the legalization of marijuana based on having recently learned a bit about it. What drives the success or failure of these advocacy attempts? Despite a voluminous literature on attitude change and persuasion, we know relatively little about the psychological drivers of advocacy, and whether the processes that motivate people to advocate also affect the success of their advocacy. One variable that has been studied in this context is attitude certainty (Akhtar, Paunesku, and Tormala, 2013; Cheatham & Tormala 2015; Cheatham & Tormala 2017).

Attitude certainty refers to the subjective sense of conviction with which one holds one's attitude (Rucker, Tormala, Petty, and Briñol, 2014). For the most part, past research has indicated that people are more likely to advocate on behalf of their own views—for example, more likely to try to persuade others—when they feel certain about those views (Akhtar et al. 2013; Cheatham and Tormala 2015; Visser, Krosnick, & Simmons 2003). More recently, Cheatham and Tormala (2017) found that attitude certainty has a curvilinear relationship to advocacy such that low and high certainty participants both advocate more than their moderately certainty counterparts. The current research is designed to further examine this unique relationship. First we will explore the different ways that individuals engage in advocacy across the certainty spectrum. Second we will investigate how these differences affect the receptivity of the advocacy recipient. In other words we will explore how persuasive different types of advocacy are across the certainty spectrum.

Based on the differences in what they do and what they say, we posit that there may be conditions under which low certainty advocacy is more persuasive than high certainty advocacy. We predict that uncertain individuals will be more persuasive than highly certain individuals under conditions of disagreement. Low certainty advocacy is likely much less threatening than high certainty advocacy when individuals disagree. However, if individuals are in agreement they will likely prefer the more certain advocacy because they will be drawn to expressions of confidence and a belief that they are correct.

In study 1 (N=600) we experimentally manipulated three levels of certainty using a novel paradigm. Participants were asked to think of an issue that they were very uncertain, somewhat certain, or very certain about. They were then asked what their attitude and attitude certainty was toward that issue. Finally, participants responded to an open-ended behavioral question asking them what they would say to someone who did not necessarily agree with them. As expected, we successfully manipulated attitude certainty at three levels and found that highly certain advocate messages were significantly longer (more word, more arguments) than either moderate or low certain advocate messages. However, our core interest was in determining the distinctly different forms of advocacy engagement across the certainty spectrum. While an overwhelming majority of participants across the three conditions expressed a clear belief, what they said subsequent to that belief expression was substantively different. Specifically, we found that high certainty fostered significantly more expressions of rational argumentation, moral conviction, judgment of others who disagree, as well as making salient that one's own

opinion is clear and correct. While low certainty fostered significantly more expressions of a desire for conversation, a desire for more information, interest in opposing viewpoints, as well as hedging or qualifying statements.

In study 2 (N=583) we aimed to explore how advocacy across the certainty spectrum was perceived by either pro- or counter-attitudinal others. Participants were first asked to report their attitude and attitude certainty toward an issue from study 1, followed by instructions to read one of the messages written by the former participants, such that each new participant in study 2 read one of the participant's messages from study 1. Participants were then asked to rate those messages on a number of dimensions including receptiveness to the views of the advocate, openness to the views of the advocate, how convinced they were by the message, how interested they were in the message, and how reasonable they felt the advocate was. Importantly, as predicted, all of the above items showed a significant interaction (all $p < .05$) between study 1 certainty condition and initial attitude agreement between advocate and recipient. We found consistent evidence suggesting that when recipients generally agreed with advocates, in other words if the participants' attitude from study 1 aligned with the new participants' attitude in study 2, they had a preference for highly certain attitude advocacy messages; however, this relationship was eliminated or reversed when recipients generally disagreed with advocates.

In sum, using a two-study yoked design, we found that when the advocate and recipient have similar views on an issue, highly certain attitude advocacy is perceived to be more persuasive than moderate or low certain advocacy. When advocates and recipients have dissimilar views, however, low certainty advocacy appears to be seen as more persuasive. This finding suggests that there are contexts in which uncertain advocacy expressions can be more successful than more certain advocacy expressions. This work builds on limited past research showing that uncertainty can be more persuasive than certainty under some conditions (Karmarker & Tormala, 2010). Implications for understanding and eliciting advocacy in consumer contexts will be discussed.

Desire to Learn About the Category Sparks Preference for Authenticity

EXTENDED ABSTRACT

Authenticity as a brand concept has become popular among marketing practitioners; indeed, some view authenticity as fundamental to brand success (The Economist 2015; Gilmore and Pine 2007). Despite the apparent importance of authenticity in marketing practice, a fundamental question remains under-examined in consumer behavior research: what psychological factors drive preference for authentic options? Our research identifies a novel antecedent of preference for authenticity.

Authenticity is often defined as what is real or genuine (Grayson and Martinec 2004). The present research demonstrates that greater preference for authentic options can manifest in unfamiliar product categories, relative to familiar categories. We suggest that in an unfamiliar product category (e.g., Ethiopian restaurants), a natural motive arises to learn about – thus reduce uncertainty regarding – the category. In such situations, consumers have a stronger preference for authentic options than they would in a familiar category (e.g., Italian restaurants) because authenticity is associated with a greater opportunity for category learning. Specifically, we hypothesize that in unfamiliar categories, authentic options are perceived to be more prototypical or representative members of the category. Due to their representativeness, authentic options facilitate greater learn-

ing about what the category is like. Moreover, we distinguish this “learning” account from a “risk-reduction” account. A risk-reduction account predicts that in an unfamiliar category, consumers would prefer a “safe” option, and the perceived typicality of the authentic option may also cause it to be viewed as safer. However, we find that preference for the authentic option persists despite the existence of another, safer alternative in the set.

Experiment 1. A 2 (category: familiar vs. unfamiliar) x 2 (attribute type: regular vs. authentic) mixed design was used to test our hypothesis. Participants (N=97) were randomly assigned to rate a series of attributes for Italian restaurants (familiar) or Tunisian restaurants (unfamiliar). They rated their preference for four “regular” attributes (e.g., service, menu options, etc.) as well as four attributes that connoted authenticity (e.g., chef was trained in Italy [Tunisia], spices imported from Italy [Tunisia], etc.). Participants subsequently rated how authentic each attribute was of Italian [Tunisian] restaurants, how typical, as well as several measures assessing their familiarity with the category ($\alpha=0.95$).

The familiarity manipulation check confirmed that participants were more familiar with Italian restaurants ($M=4.95$) than Tunisian restaurants ($M=1.84$), $t(95)=13.95$, $p<.0001$. The authenticity manipulation check revealed that attributes intended to convey authenticity were indeed rated as more authentic ($M=6.52$) than the regular attributes ($M=4.64$), $p<.0001$. This was true across both the familiar category ($p<.0001$) and unfamiliar category ($p<.0001$).

The core dependent measure of preference showed a main effect of the authenticity factor, $p<.0001$. Overall, regular attributes ($M=5.87$) were more preferred than authentic attributes ($M=5.24$). Importantly, a significant familiarity x authenticity interaction emerged, $p<.0001$. Authentic attributes were more preferred when the category was unfamiliar ($M=5.60$) versus familiar ($M=4.89$), $p=.0001$. In contrast, preference for regular attributes did not differ across familiar ($M=5.98$) and unfamiliar categories ($M=5.76$), $p=.214$.

The proposed mediator of typicality exhibited a familiarity x authenticity interaction, $p<.0001$. Authentic attributes were perceived as more typical in the unfamiliar ($M=5.57$) compared to familiar category ($M=4.69$; $p<.0001$), whereas regular attributes did not differ in perceived typicality ($M_{\text{unfamiliar}}=4.68$ vs. $M_{\text{familiar}}=4.91$; $p=.205$). Moderated mediation analysis revealed that for authentic attributes, typicality mediated the effect of category familiarity on preferences ($b=0.31$, $p<.001$, bootstrapped C.I. [0.19, 0.44]). In contrast, for regular attributes, typicality did not significantly mediate preferences ($b=-0.06$, $p>.05$, bootstrapped C.I. [-0.11, 0]). This provides initial evidence that in unfamiliar categories, authenticity is preferred because it is viewed as more typical of the category, and thus facilitates category learning.

Experiment 2. This experiment distinguished the proposed learning account from risk-reduction. We assessed choice of an authentic option when another alternative in the set was indicated to be more certain (less risky), versus when such indication was absent. Participants (N=202) were assigned to conditions in a 2 (category: familiar vs. unfamiliar) x 2 (certainty information: present vs. absent) between-participants design. Participants read short descriptions of three Ethiopian or Italian restaurants and were asked to make a choice. One of the descriptions was constructed to indicate authenticity: the restaurant's chef was trained in Ethiopia [Italy]. In the certainty-information *absent* conditions, only the descriptions were presented. In the certainty-information *present* conditions, the number of reviews for each restaurant was shown: the authentic restaurant had the fewest reviews (less than 50; least certain), while the safe option had five times more reviews (most certain), and the

other option had an intermediate number. Average rating was held constant. Participants also rated the perceived authenticity, typicality, and certainty regarding each restaurant.

Manipulation checks showed that participants rated the restaurant with the chef as more authentic than the other two options ($p < .001$), and this was true across both categories. The authentic restaurant was also rated as more typical on average than the others ($p < .001$), but consistent with experiment 1, significantly more so in the unfamiliar ($M = 5.77$) than familiar category ($M = 5.25$), $p = .006$. Lastly, the option with the most reviews was rated as more certain or safer ($M = 5.38$) than the authentic option ($M = 4.74$) when review information was present ($p < .001$), and equivalently certain when this information was absent ($M_{\text{certain}} = 4.78$ vs. $M_{\text{authentic}} = 4.88$; $p = .491$).

A logit model of choice with the two factors and their interaction revealed only a significant main effect of category familiarity: a greater percentage of participants chose the authentic option when the category was unfamiliar ($M = 46.0\%$) versus familiar ($M = 32.4\%$). The two-way interaction was not significant ($p = .61$). Thus, preference for authenticity under unfamiliarity persisted despite the presence of a safer option, thereby ruling out a risk reduction account.

The present research demonstrates a novel mechanism – category learning – that drives consumer preference for authenticity. This work deepens marketers' understanding of when consumers value authenticity in products and brands.

SESSION OVERVIEW

Extensive choice research has documented that the way choices are presented can significantly affect consumer decision making (Thaler and Sunstein 2008). Choice architecture (e.g. framing, spatial arrangement of alternatives, etc.) can therefore be used to encourage choices that not only improve consumers' objective well-being (i.e. utility), but also to enhance their subjective appraisal of the decisions (i.e. satisfaction) (e.g., Johnson et al. 2012). In the current session, we seek to explore how changes to the choice architecture of product assortments influence not only which options consumers choose, but also how they perceive the choices. We explore a variety of choice aids, including personalized recommendations, default options, display formats and label structures, and their influence on decision appraisal.

This session seeks to answer two questions: In choices from product assortments, how do various decision aids facilitate the decision making process? How does manipulating different aspects of the choice architecture influence consumers' appraisal of their choices?

The first two papers explore the role of assortment structure on the appraisal of product choices. Häubl, Dellaert, Usta, and Ibrahim explore an ironic effect of personalized product recommendations on consumers' satisfaction with the chosen alternative. In four studies they demonstrate that personalized product recommendations may lead to less satisfaction with their choices when greater choice difficulty outweighs the greater perceived attractiveness of the assortment. They explore the moderating role of assortment size and

propose a "balanced design" to reduce the unintended negative effect. Friedman, Savary, and Dhar examine the default effect in assortments -- specifically, how the number and type of options defaulted affect the number of options chosen. In five studies they establish that due to an asymmetry between selection and rejection criteria, consumers choose more options when less attractive options are defaulted compared to when the most attractive options are defaulted. Importantly, the authors show that default options do not decrease choice satisfaction.

The latter two papers examine the role of fluency in assortment design. Walter, Hildebrand, Häubl, and Herrmann examine how perceptual fluency (vs. disfluency) of display formats influence consumers' product choices. Evidence from three lab experiments and two large-scale field experiments suggest that when an assortment combines both familiar and unfamiliar alternatives, presenting them in an unsystematic (vs. systematic) manner stimulates an exploratory mindset in consumers, and subsequently increases the size of consideration set and promotes the choice of unfamiliar products. Finally, Parker, Rodriguez-Vila, Hamilton, Paul, and Bharadwaj demonstrate how the label structure influences consumers' responses toward food products. In four studies they demonstrate that credence-labels (e.g., organic, gluten-free, hormone-free, etc.) generate less positive responses when applied at the product-level (e.g., organic burrito) than at the ingredient-level (e.g., burrito with organic ingredients), due to increased processing disfluency.

Using a combination of lab experiments and field studies, the four papers examine the underlying psychological mechanisms of the impact of choice architecture and decision aids on choice from product assortments. The insights from these papers may also serve as guidelines for marketers who aim to optimize consumers' well-being both objectively and subjectively.

The Dual Impact of Personalized Product Recommendations on Consumers' Subjective Appraisal of Their Product Choices

EXTENDED ABSTRACT

A common form of decision assistance is to provide consumers with personalized recommendations that screen the available products according to their idiosyncratic preferences. Prior work suggests that such personalized product recommendations benefit consumers by enabling them to identify better alternatives than they would without such assistance (Diehl, Kornish, and Lynch 2003; Häubl and Trifts 2000; Xiao and Benbasat 2007). Intuitively, this increase in decision quality should translate into a more favorable subjective appraisal of the product that is ultimately chosen.

However, providing consumers with a truncated set of alternatives that only includes the most attractive ones tends to also increase the difficulty of identifying the most attractive alternative, which in turn adversely affects consumers' subjective appraisal of their chosen alternative (Dhar 1997; Liberman and Förster 2006).

These two opposing forces are at the center of our conceptual framework of how decision assistance in the form of personalized recommendations affects consumers' subjective appraisal of their

product choices – i.e., choice satisfaction. We present evidence from four studies that were designed to test this dual-pathway framework.

Study 1 demonstrates that personalized product recommendations can both improve objective decision quality and *reduce* choice satisfaction. Across two between-subjects conditions, participants chose a digital music player from a set of eight alternatives that were described on four feature dimensions: sound quality, battery life, memory capacity, and weight. In the *unassisted* condition, the alternatives varied considerably in their attractiveness and were presented in an arbitrary order. In the *recommended* condition, the alternatives were closer in attractiveness than in the unassisted condition and were presented in descending order of attractiveness. For each participant, the utility of each alternative was calculated based on his/her ratings (scale: 0-100) of the importance of the four features. The utility of the chosen alternative was higher in the recommended than in the unassisted condition ($p < .001$). However, despite this positive effect of personalized recommendations on objective decision quality, participants in the recommended condition were significantly *less* satisfied with their chosen alternatives than those in the unassisted condition ($p < .05$).

Study 2 tests the proposed dual-pathway model that captures the opposing effects of personalized product recommendations on objective decision quality and on consumers' subjective appraisal of their chosen alternative. Across two between-subjects conditions, participants chose a hotel from a set of alternatives that were described on five feature dimensions: cleanliness, facilities, location, service, and sleep quality. Participants in the *unassisted* condition were presented with sixteen alternatives that had been selected at random from a pool of 64. Those in the *recommended* condition were presented with the sixteen best alternatives (based on their 0-100 ratings of feature importance) from the same pool of 64. The order of presentation was unique and random for each participant. Consistent with prior findings, the utility of the chosen alternative was significantly higher in the recommended than in the unassisted condition ($p < .001$). Mediation analysis (Preacher and Hayes 2008) revealed both a significant negative indirect effect of recommendation via choice difficulty ($p < .05$) and a significant positive indirect effect via the perceived attractiveness of the presented set of alternatives ($p < .05$), rendering the direct effect of recommendation on choice satisfaction nonsignificant ($p > .05$).

Study 3 examines the moderating role of the size of the presented set of alternatives. We hypothesized that choice difficulty would be lower in smaller recommended sets, which should attenuate the negative indirect effect of recommendations on choice satisfaction via choice difficulty. Participants were randomly assigned to a 2 (condition: unassisted vs. recommended) \times 2 (recommendation set size: large vs. small) between-subjects design, and they were presented with the same choice task as in Study 2. Participants were presented with either sixteen or four alternatives drawn from a pool of 64 hotels. In the *unassisted* condition, the alternatives were selected at random from the pool. In the *recommended* condition, the best alternatives (based on participants' 0-100 ratings of feature importance) were selected. As hypothesized, moderated mediation analysis (Preacher and Hayes 2008) revealed a significant negative indirect effect of recommendation via choice difficulty for the large set ($p < .05$), but not for the small set ($p > .05$). By contrast, the positive indirect effect of recommendation via the perceived attractiveness of the presented alternatives was significant for the small set ($p < .05$), but not for the large set ($p > .05$).

Finally, Study 4 examines whether it might be possible to reduce the negative effect of personalized recommendations on choice satisfaction by presenting consumers with a "balanced" recommen-

dation set that is constructed so as to contain a combination of some attractive alternatives and some less attractive ones. Using the same basic paradigm as in Study 3, participants were presented with sixteen alternatives drawn from a pool of 64 hotels. They were randomly assigned to one of three conditions – the sixteen alternatives were drawn at random (*unassisted*), or they were the sixteen best alternatives ("*good*"), or they were a set of alternatives that covered the spectrum of attractiveness close to uniformly (*balanced*). The results reveal that the utility of the chosen alternative was higher in the "good" condition than in the balanced and unassisted conditions ($ps < .05$). However, perceived choice difficulty was greater in the "good" condition compared to the other two ($ps < .04$). Mediation analysis with pairwise contrasts revealed that the dual-pathway model was supported for the contrast between the "good" and unassisted conditions. However, for the contrast between "good" and balanced, the effect on choice satisfaction is mediated only by choice difficulty ($p < .05$), whereas for the contrast between balanced and unassisted, this effect is mediated only by the perceived attractiveness of the set ($p < .05$). The latter result suggests that the negative effect of product recommendations on choice satisfaction vanished because choice difficulty was about as low in the balanced condition as it was in the unassisted condition.

This research advances our understanding of the psychological forces that govern consumers' subjective appraisal of the product choices they make. The findings identify a significant caveat associated with personalized product recommendations, and they have important implications for the construction of choice architectures for consumer decision assistance.

Purchase Quantity Decisions and Default Effects in Assortments

EXTENDED ABSTRACT

Although most choice research examines how consumers choose a single option from a choice set, many choices in the real world allow them to choose as many (or as few) options as they would like from an assortment or menu of goods. In contrast to the standard theory of choice where the number of options purchased from an assortment depends on the utility and price of each item, we extend the literature on default effects in single choice to explore how the number and type of options preselected or defaulted in an assortment affects the total amount chosen. While prior research has focused on how preselecting a particular option increases preference for that option over a non-defaulted option and the possible mechanisms underlying this finding (Johnson and Goldstein 2003; Choi et al. 2004; Kressel, Chapman and Leventhal 2007), past work does not make a systematic prediction about how many *non*-defaulted options will be chosen when certain other options are preselected.

In the current work, we explore how the number and type of default options will influence the total quantity chosen from an assortment. Consistent with past work that shows that preselecting an option increases the likelihood of choosing that option, we first show that increasing the number of defaulted options linearly increases the quantity chosen. We further research how the total number of options purchased depends on *which* options are defaulted, holding the total number constant. Our main proposition is that preselecting less attractive items increases the total number of items chosen compared to preselecting the most attractive items.

Our results can be explained by a documented asymmetry between selection and rejection criteria. Specifically, consumers have a higher threshold for choosing non-selected items than they do for keeping preselected items (Yaniv and Schul 1997; Levin, Huneke

and Jasper 2000; Huber, Neale and Northcraft 1987). As a result, items in an assortment that might not be attractive enough to actively select but may be sufficiently attractive to keep (or not reject) when already preselected. In contrast, the most attractive items are less likely to be impacted by defaults, because they are likely to exceed even the higher threshold. As a consequence, when less attractive items are preselected, they are more likely to be chosen than when they are not preselected, but preselecting the most attractive items does not increase the likelihood of choosing them to the same extent. As a result, consumers choose more items overall when the less attractive items are preselected than when the most attractive items are.

We test our hypotheses in five studies. Study 1 establishes that there is a significant effect of defaults on the number of items purchased. We presented participants with two assortment scenarios, each with 16 options: a party scenario where they were shopping for snacks, and a home office scenario where they were shopping for supplies. We varied between subjects whether 0, 4, 12 or 16 of the options were preselected. We find a strong and significant linear relationship between the number of preselected options and total number of items purchased for both assortment scenarios: snacks ($b = .17$, $SE = .03$, $p < .001$) and supplies ($b = .15$, $SE = .03$, $p < .001$).

Moreover, in contrast to research that suggests consumers may react negatively to a perceived attempt to manipulate their preferences with defaults (Brown and Krishna 2004), we find that consumers are no less satisfied, and may be marginally *more* satisfied with their choice when options are defaulted, compared to when no options are defaulted.

In studies 2A, 2B, 3 and 4 we test the hypothesis that preselecting less attractive options increases quantity chosen compared with preselecting more attractive options. In studies 2A and 2B, we again use the party snacks and supplies scenarios, with 16 options each, which were all at least somewhat attractive. We pre-tested the options to identify the most and least attractive options. We then manipulated between subjects whether the 4 most attractive or 4 least attractive options were preselected. We find that participants selected more items overall when the least attractive items were preselected compared to when the most attractive items were pre-selected ($M = 8.0$ vs. 6.9 , $p < .001$ for snacks; $M = 7.6$ vs. 6.5 , $p = .006$ for supplies). This result is driven by the number of less attractive items increasing when preselected ($M = 1.7$ v. 0.6 for snacks; $M = 1.8$ vs. 0.4 for supplies) more than more attractive items increase when preselected ($M = 3.4$ vs. 3.0 for snacks, $p(\text{interaction}) < .001$; $M = 3.4$ vs. 2.8 for supplies, $p(\text{interaction}) < .001$).

In study 3, we manipulate which items are attractive by setting certain items on sale. Again we find that people choose more items on average when the less attractive (i.e. full price items) are preselected than when the more attractive (i.e. sale items) are ($M = 7.1$ v. 6.0 , $p = 0.040$). Again the result was driven by defaults increasing full price items ($M = 1.5$ vs. 0.7) more than sale items ($M = 2.3$ vs. 1.9 , $p(\text{interaction}) = .001$). Finally, study 4 tests a charitable giving scenario in which participants could hypothetically donate \$2 to any number of 10 charities. In this scenario, donations for 3 of the charities would be "matched," making them more attractive. We varied between subjects whether the 3 matched (more attractive) charities were preselected, or whether 3 other charities were (less attractive). Again we find that preselecting the unmatched options resulted in fewer charities selected than preselecting the matched charities ($M = 5.2$ vs. 4.4 , $p = .045$). Donations to matched charities were not significantly increased by defaults ($M = 2.1$ vs. 1.9), but donations to unmatched charities were ($M = 1.5$ vs. 0.8 , $p(\text{interaction}) < .001$).

As more retailers begin to add default options to their marketing mix with tactics such as "starter carts" or pre-loaded shopping lists, it becomes increasingly important to investigate the effect of defaults in larger assortments. Our results suggest that preselecting options may be effective in increasing basket size without reducing customer satisfaction, particularly when less attractive items are preselected.

Mixing It Up: The Influence of Unsystematic Product Arrangements on Assortment Processing, Exploratory Search, and Product Choice

EXTENDED ABSTRACT

How best to present product assortments in order to attract consumers' interest and attention is a key challenge for retailers (Mantrala et al. 2009). A common way of arranging a product display entails presenting the most popular, and thus most familiar, alternatives in highly prominent display positions (Nowlis and Simonson 1997; Valenzuela, Raghuram, and Mitakakis 2013), resulting in consumers' attention being directed towards specific alternatives that they tend to already be aware of (Christie and Klein 1995; Downing 2000). This is consistent with findings that greater fluency promotes simplified decision processes by selectively directing consumer attention towards familiar products (Alter et al. 2007; Janiszewski, Kuo, and Tavassoli 2012), and that fluency can reduce consumers' motivation to explore other alternatives (Deng et al. 2016; Janiszewski 1998).

Recent work suggests that perceptual disfluency can act as a metacognitive cue that stimulates the more in-depth processing of information by eliciting a need for cognitive enrichment (Alter 2013; Alter et al. 2007; Graf and Landwehr 2015). In line with these findings, Pocheptsova, Labroo, and Dhar (2010) showed that a difficult-to-read description (i.e., such as one using a grayish font) of an individual product can create perceptions of exclusivity and heightened attractiveness, particularly when the product is unfamiliar.

Against the background of this prior research, we propose that an unsystematic (versus systematic) product arrangement promotes perceptual disfluency. Moreover, we hypothesize that perceptions of disfluency increase consumers' motivation to engage in more exploratory search, resulting in consideration of a larger and more diverse set of products as candidates for purchase, and ultimately promoting the choice of unfamiliar alternatives. We present evidence from three studies that supports this theorizing.

Study 1 was designed to examine the effect of systematic (versus unsystematic) product arrangements on consumers' perceptions of fluency, and to provide initial evidence on how this might affect the motivation to explore unfamiliar products. In cooperation with a large Swiss chain of grocery stores, we selected two stores that were closely matched but differed in one critical respect—whether their assortment of chocolate products was arranged systematically (by brand, flavor, and price) or unsystematically (in a seemingly arbitrary manner). A sample of shoppers ($n = 102$) was recruited in the immediate vicinity of the stores' chocolate displays to complete a short survey. As predicted, shoppers perceived the unsystematic product arrangement to be more disfluent than its systematic counterpart ($p < .01$), and expressed a greater interest in exploring unfamiliar products in connection with the unsystematic than with the systematic arrangement ($p < .05$). In line with our theorizing, a mediation analysis (Hayes 2013) reveals that the effect of unsystematic (versus systematic) product arrangement on consumers' inclination to explore unfamiliar alternatives is significantly mediated by perceptions of disfluency.

Study 2 was a large-scale field experiment across 36 stores conducted in cooperation with a Swiss mobile phone retailer. All stores

used an interactive assortment tracking technology that logged consumers' product search behavior for a total of 21 mobile phones that were arranged in a 3 (rows) x 7 (columns) product display. Each of the 36 stores was randomly assigned to one of four conditions where the 7 most familiar products (identified in a pretest) were presented either (1) according to the retailer's original display format [systematic] (2) grouped together in the top row (salient position; Chandon et al. 2009) [systematic], (3) grouped together in the bottom row (non-salient position) [systematic], or (4) dispersed randomly across the entire product display [unsystematic]. In line with our theorizing, a pretest ($n=82$) showed that the unsystematic product arrangement was perceived as substantially more disfluent than the systematic ones (all $ps < .001$). Moreover, the unsystematic arrangement led to more exploratory product search (all $ps < .05$) and increased customers' likelihood of choosing an unfamiliar mobile phone (all $ps < .05$) relative to the systematic arrangements where the familiar products were presented in salient positions or in line with the retailer's original display format, but not relative to the systematic arrangement where the familiar products were placed in non-salient positions ($ps > .7$). Study 2 provides support for our theorizing based on the in-store behavior of actual shoppers. However, we cannot rule out the possibility of hidden confounding variables in this field experiment, nor the potential alternative explanation that the relocation of familiar products to less salient display positions reduced their likelihood of being chosen (Chandon et al. 2009; Drèze, Hoch, and Purk 1994).

Study 3 was designed to rule out these potential confounds by using a tightly controlled experimental setting. To eliminate the possible influence of prior product/brand familiarity, we created fictitious smart phones and made participants ($n=153$) familiar with a subset of these products in the initial phase of the experiment. For a subsequent consequential choice task, participants were randomly assigned to one of two conditions where the assortment of phones was arranged either in a systematic or unsystematic manner in terms of whether the (now) familiar alternatives were grouped together or dispersed across the display. After a short filler task, participants completed a quiz to assess their memory of product information. The results reveal a significantly higher choice share of unfamiliar products in the unsystematic relative to the systematic product arrangement condition ($p < .05$). A mediation analysis (Hayes 2013) supports our theorizing by showing that this effect is serially mediated by more extensive exploratory search and enhanced recall of information about the unfamiliar products.

This research introduces a novel theoretical perspective on how spatial arrangements of products can trigger perceptual (dis)fluency and affect consumers' shopping behavior. It shows that the perceptual disfluency that is induced by an unsystematic product arrangement increases consumers' motivation to explore a product assortment, ultimately promoting consumers' choice of unfamiliar alternatives. The current work also contributes to our understanding of consumers' reaction to, and adoption of, innovations (Alexander, Lynch, and Wang 2008; Moreau, Lehmann, and Markman 2001), as well as of individuals' preference for unfamiliar or novel stimuli more generally (Wittmann et al. 2008).

Label Structure, Processing Disfluency, and Consumers' Responses to Credence-Labeled Foods

EXTENDED ABSTRACT

For foods, the term credence-labeling refers to products being marketed with claims related to the sustainability (e.g., organic), healthfulness (e.g., GMO-free, gluten-free), and ethicality (e.g., free-range) of the product. Generally, credence-labels signal desir-

able product benefits and consumers use such labels to make quality inferences about food products. In contrast to previous research, this paper investigates the impact of how credence-labels are structured, rather than just the consequences of their mere presence or absence. Specifically, we differentiate between *product-level credence-labels*, which apply to the food product as a whole, and *ingredient-level credence-labels*, which apply to the components that constitute the food item. We predict that credence-labels will generate less positive responses when applied at the product-level (e.g., organic burrito) than at the ingredient level (e.g., burrito with organic ingredients). This prediction is based on the expectation that credence-labels applied at the product-(vs. ingredient) level will be processed more *disfluently* (Alter and Oppenheimer 2009), thereby resulting in less positive attitudes toward the food product.

Studies 1a and 1b demonstrated the basic effect of credence-label structure (ingredient vs. product level) on preferences for foods by measuring the likelihood of ordering a dish at a restaurant. Study 1a asked participants to imagine they were at a restaurant and then randomly assigned to one of two conditions. In the ingredient-level condition, participants were asked to imagine they found a dish called "Our Famous Burger (w/ all organic ingredients)." In the product-level condition, participants were asked to imagine they found a dish called "Our Famous Organic Burger." Participants then indicated the likelihood they would order this dish on a 1 ("very unlikely") to 10 ("very likely") scale. As expected, the likelihood of ordering the dish was significantly higher in the ingredient- (vs. product-) level condition ($M = 7.23$ vs. 5.83 , $p < .001$). Study 1b used an identical study design except it additionally included a control condition in which the dish did not have a credence-label. Additionally, the food type was change to either a burrito or fajitas. In the control condition, the dish was called "Our Famous Burrito [Fajitas]". A 2 (food type) x 3 (credence-label) between-subjects ANOVA revealed neither a main effect of food-type (burrito vs. fajitas) on likelihood of ordering ($F < 1$, NS) nor an interaction between food-type and credence-label structure ($F < 1$, NS). However, the predicted main effect of label structure (control vs. ingredient-level vs. product-level) was significant ($p < .001$). As in study 1, the likelihood of ordering the dish was significantly higher in the ingredient- (vs. product-) level condition ($M = 6.73$ vs. 5.20 , $p < .001$). Importantly, the likelihood of ordering the dish was significantly higher in the control (vs. product-level) condition ($M = 6.51$ vs. 5.20 , $p < .005$), while no significant difference was found between the control and ingredient-level conditions ($F < 1$, NS). Thus, using product-level credence-labels for foods diminished their appeal, as opposed to ingredient-level labels increasing their appeal.

Study 2 tested the underlying process, *disfluency*, by directly measuring the fluency with which participants processed (i.e., the ease with which they understood) the food descriptions and used these measures to test mediation. Participants were asked to imagine they were shopping in the frozen foods section of their local grocery store and then randomly assigned to one of three conditions. In the control condition, participants were asked to imagine they found "Mozzarella Sticks." In the ingredient-label condition, participants were asked to imagine they found "Mozzarella Sticks (all ingredients Hormone-Free, Gluten-Free, Organic)." In the product-label condition, participants were asked to imagine they found "Hormone-Free, Gluten-Free, and Organic Mozzarella Sticks." Participants then indicated how appetizing they found this food product on a 1 ("not at all") to 10 ("very much") scale. Next, participants were asked to indicate their agreement with four statements on 1 ("strongly disagree") to 7 ("strongly agree") scales: (i) *I can easily visualize (mentally picture) this product*, (ii) *I get what this product is*, (iii) *This*

product sounds weird to me (reverse-coded), and (iv) *This product makes sense to me*. Consistent with results of the previous studies, those participants exposed to the product-level credence-label found the mozzarella sticks to be significantly less appetizing than those who were exposed to the ingredient-level credence-label ($M = 7.28$ vs. 5.78 , $p < .001$) and those in the control (no-label) condition ($M = 7.45$, $p < .001$). This fluency measure was then tested as a potential mediator of the influence of credence-label structure on preferences using Hayes's (2013) PROCESS macro for multiple mediation (95% confidence interval; 5,000 bootstrap samples) which revealed that the four-item fluency scale was a significant mediator ($b = .6229$, $LLCI = .3841$, $ULCI = .9311$).

Lastly, study 3 found that the negative influence of product-level credence-labels was mitigated when participants were asked to elaborate on the meaning of the product before evaluating it. Specifically, participants in the elaboration condition were asked to write a short response in a provided text box to the following question before evaluating the food product: *Before proceeding, please describe what you think the burrito described above contains, looks like, and tastes like*. In contrast, participants in the no-elaboration condition were not asked to describe the burrito. As expected, there was a significant interaction between the elaboration factor (yes vs. no) and the label-structure factor (product vs. ingredient) on how appetizing the participants found the food ($p < .05$). While no effect of label structure was found for those who elaborated before evaluating ($M = 7.40$ vs. 7.60 , $F < 1$, NS), the effect documented in the preceding studies was replicated for those who did not elaborate before evaluating ($M = 7.40$ vs. 6.30 , $p < .02$). The same fluency measures used in study 2 were collected in study 3. These revealed that disfluency mediated the above interaction.

In sum, these results demonstrate that while there may be some heterogeneity in consumer's general responses to credence-labels, these responses become more negative overall when credence labels are applied at the product- (vs. ingredient-) level.

Paper #4: The Soul and the Machine: Humanlike Machines and Machinelike Humans

Russell Belk, York University, USA

SESSION OVERVIEW

Advances in digital technologies and artificial intelligence are changing the world. In fact, we have come a long way in less than a decade. Picture this: when Jones is on his way home, the smart thermostat already knows that and turns on the heating system to automatically warm his house. Once he arrives home, he quickly puts some ingredients in the bread-making machine to make some bread for dinner. Then he sits down comfortably on his couch to order a birthday gift for a friend on his tablet. Just a few years ago, it was hard to imagine this mass diffusion of technology in every realm of consumption, from the smart home to automation to touch-sensitive devices.

However, despite the transformational impact on everyday consumption of recent technological progress, we know surprisingly little about human-machine interaction in the marketplace. For example, does interaction with machines shape our identity and consumption experience? Does interaction with humans in turn create an experience for machines?

This special session brings together papers spanning different technological contexts to showcase this exciting research domain. The papers feature research on the Internet of Things, automation, computing interfaces and human-machine interaction. This special session will contribute to the consumer behavior literature by providing timely insights into the value of technology. First, it complements the literature on the consumption experience of technological products. Previous research shows that interaction with technological products can create both positive and negative experiences (Etkin 2016; Mick and Fournier 1998; Wilcox and Stephen 2013). This special session complements this research stream to present these experiences from different perspectives. Second, this special session answers the call to investigate how technological developments may affect people's sense of self (Reed et al. 2012). Recent research suggests that consumers develop digital extended selves (Belk 2013). This special session examines how the rise of more sophisticated technology, such as robotics and artificial intelligence, affects sense of self.

Given the lack of research on these new technologies, new theory is needed in order to define foundational constructs and processes and provide direction for future research. This special session starts

with a theoretical paper on humans and machines interaction. The first paper "Object Experience and Object Consumers" develops a framework to capture how consumers can access object experience with Internet of Things devices in the smart home domain. The second paper "Automation and Identity" investigates how identity can influence preference of automation with empirical data in various consumption contexts. The third paper "Touch-Sensitive Computing Interfaces as Drivers of Experiential Consumption" examines how interaction with computing interfaces can change consumption experience with field and lab data. The final paper "The Soul and the Machine: Humanlike Machines and Machinelike Humans" discusses the fundamental issues concerning how humans can coexist with machines and how technology is revolutionizing the concept of self. Together, these papers will advance our understanding of the technological trends in the marketplace and their significance. This session would be particularly of interest to researchers interested in technology, identity and experiential consumption.

Object Experience and Object Consumers

EXTENDED ABSTRACT

The consumer Internet of Things (IoT) has the potential to revolutionize consumer experience because consumers can actively interact with smart objects. Hoffman and Novak (2016) have proposed using assemblage theory (DeLanda 2006) to conceptualize consumer experience in the IoT, focusing on the smart home domain. In this paper, we draw on that conceptualization to develop a framework for understanding how object experience emerges in the smart home, how consumers can access these experiences, and the implications of object experience for expanding the domains of consumer behavior.

A first step toward object experience is consideration of object ontology. The human-centric approach considers experience from the perspective of the human, and so precludes our ability to evaluate objects as having the capacity to interact with other entities, enabling other objects or humans or constraining other objects or humans. In a position consistent with the object-oriented ontology perspective (Harman 2002) that has recently emerged in consumer behavior research (Canniford and Bajde 2016), we argue that it is not just consumers that have their own ontology; so do objects.

A critical assumption in our approach is that smart objects, as well as the assemblages that form from consumer interaction with these objects, and objects with each other, have meaning on their own and are something more than passive entities that consumers possess with meaning (Belk 1988). Smart objects, possessing their own ontology, equally exist alongside consumers in the relationship. Objects do not exist just for consumers. They engage in interactions on their own and from these interactions, their experiences emerge. But these experiences are very different from consumer experiences.

To develop our conceptualization, we start with three properties that define the ontology of smart objects: agency, autonomy and authority. While it is straightforward to argue that the constructs of agency, autonomy and authority are relevant to consumer behavior, we submit that smart objects in the IoT also possess these characteristics. Drawing on the computer science literature on autonomous agents, smart objects have agency to the extent that they possess the ability for (inter)action (Franklin and Graesser 1996; Latour 2005), having the ability to affect and be affected. Autonomous objects can function independently without human intervention (Parasura-

man and Riley 1997 and independently interact with other entities, serving their own agendas (Franklin and Graesser 1996; Luck and d'Inverno 1995). Smart objects possess authority when they can implement communication and decision-making with other smart objects and with humans (Hansen, Pigozzi, and van der Torre 2007).

We then define object experience as an assemblage that emerges from all object-centric interactions, including the part-whole interactions of the object and the smart-home assemblage of which the object is a part, the part-whole interactions of the object and the various smart home micro-assemblages of which the object is a part, and the within-assemblage interactions of the object with individual smart home components. The main difference between consumer and object experience is that consumers as entities are realized not only through interaction with the external world, but also through interactions inside themselves, whereas objects are only realized through external interactions with other entities (Bryant 2011). However, Bryant (2011) also notes that object realization likely resides on a continuum, so we can argue that even though objects are not living, to the extent that they are smart, they actually can operate on themselves to a certain degree. This suggests that the properties and capacities of a smart object will dictate how it is realized in interaction with other objects and the kinds of experiences it is capable of having. If objects can experience, does this mean they are conscious? Recent work in neuroscience suggests that consciousness can be measured, is graded, and can be found in small amounts even in certain simple systems (Tononi and Koch 2015). Thus, object consciousness can be quantified. However, while many believe machines will eventually achieve consciousness, most think that machine consciousness will not be like human consciousness (Bostrom 2014).

Next, we evaluate how object experience can be perceived by consumers. Because consumers can never have direct access to the exact properties of an object, they can only interact with it in the context of an assemblage. So, experience is constructed from that interaction. We propose that consumers can speculate about object experience through the mechanism of anthropomorphic metaphor (Bogost 2012a). In this approach, anthropomorphism (Epley, Waytz and Cacioppo 2007) is applied as a metaphor where we strive to consider the object's experience not from our own perspective, but by speculating how the object might perceive things from its own, (non-human) perspective.

Finally, we explore the implications of the concept of object experience for consumer research. Marketing scholars tend to view intelligent agents from the perspective of how marketers can use them to improve the effectiveness of their marketing efforts to human consumers (Kumar, et.al. 2016). But, what if instead, we view a smart object as an "intelligent agent" which itself is a consumer that can be understood and marketed to directly? We introduce the idea of "object consumers" to explore what it means to be a consumer. Object consumers can have the equivalent of affective responses, such as when Brad the Toaster (Rebaudengo, Aprile and Hekkert 2012) is only happy when he is making lots of toast. Object consumers can make decisions, such as when Amazon's Dash Replenishment service allows washing machines, pet feeders and printers to re-order laundry detergent, pet food and printer cartridges on their own they are running low (Rao 2015). Objects consumers can participate in consumption such as when, through a smartphone app, smart refrigerators can display the inside of her refrigerator to a consumer at the grocery store and suggest products and recipes contingent on what she already has at home. The consumer IoT is beginning to revolutionize consumption and consumer experience in a broad and growing range of consumer-facing categories. Object experience and how consumers can access it can contribute to a fuller understanding of

the nature of consumer behavior, and its expanding domain, in complex, interactive environments like the IoT.

Automation and Identity

EXTENDED ABSTRACT

Automation is transforming consumption. Innovations such as GPS and food processors perform tasks that would normally require people's skills and effort, allowing us to accomplish more in less time. Whereas anglers in the old days relied on their experience to locate fish, now with a click on a technological device they can know which type of fish is in the areas and at which distance from their boat. Across domains such as food, commuting and entertainment, products are increasingly integrating automated features that improve their efficiency, resulting in higher utilitarian-driven satisfaction.

However, our research documents a drawback of automation for the utility of consumption. Consumers like products not only for their utilitarian-benefits, but also in light of their "non-consumption utility" (Loewenstein 1999). Of particular importance for skill-related consumption, consumers often use products to signal their identities (Berger and Heath, 2007). When consumers are performing tasks to signal their identities, they derive non-consumption benefits from attributing the outcome to their own skills or efforts. By performing a task that would otherwise be performed by the consumer, automation decreases the extent to which consumers can attribute the outcome internally, and in turns reducing the preference for automated products. In seven studies in different domains (e.g., cycling, bread-baking) and with different approaches (correlational, experimental), we test the hypothesis that identity goals lead consumers to forgo automated products in favor of non-automated products. Due to the word-limit, we are going to discuss four studies in details.

Study 1 documents the link between strength of identification and preferences for automation with a manipulation of identity salience. 338 Dutch students were asked to either write for five minutes on what Dutch biking culture (vs. Dutch flower culture) means to them. Then they were asked to read a bike purchase scenario and make a choice whether they want to have a free automated feature which assists the pedalling of the biking task. We found that participants were less likely to choose the free automated feature in the biking priming condition compared to in the control condition ($M_{\text{biking}} = 66\%$, $M_{\text{control}} = 78\%$, Chi-square = 5.79, $p = .016$).

Study 2 extends the findings of Study 1 with a consequential choice. 406 lab participants were asked to finish a coloring task. They could choose either to paint with a color choice automated feature (paint-by-number) or to paint with the colors they choose. Then they were asked questions regarding internal attribution and identification in creativity. Consistent with the hypothesis, stronger identification leads to higher likelihood to choose to paint with the color choice automated feature ($b = .095$, $t(404) = 6.29$, $p < .01$). The desire to attribute outcome mediates the effect of strength of identification on preference for automation (95% $CI_{\text{Attribution}}: [.18; .37]$). Furthermore, the anonymity of the lab settings also suggest that our effect is not limited to observable choices.

Study 3 rules out alternative explanations of expertise and perceived outcomes and provides process evidence that consumers dislike automation because it does not allow them to attribute outcomes to their skills. 403 MTurk participants were randomly assigned to one condition of a 2 (bread baking identity: present vs. absent) x 2 (product: bread-baking machine vs. dough-mixer). Participants were either assigned to imagine that they were a keen amateur baker or given no specific identity instructions. Subsequently, they rated their

willingness to borrow either a bread-baking machine or a dough-mixer on a bipolar scale. These two machines were pretested to present different degrees to which they allow to attribute the bread to the skills of the users. Afterwards, participants answered questions regarding expertise and perceived outcome. As expected, participants in the identity conditions were less (equally) willing to borrow the bread-making machine (dough mixer) than participants in the no-identity conditions (Bread-making machine: $M_{\text{strong}} = .91$, $SE = .18$ vs. $M_{\text{control}} = 1.51$, $SE = .18$; $F(1, 402) = 5.80$, $p = .016$ vs. dough mixer: $p = .74$). Additional analyses reveal that neither expertise nor perceived outcome could explain the findings.

Study 4 aims at showing that strong identifiers' resistance to automation is contingent on products being framed as replacers of skills. If the need for internal attribution drives the documented effect of identification on preferences for automation, automation should be perceived more negatively when framed as replacing the user's skills. When automation is framed as allowing users to deploy their skills, strong identifiers should perceive automation less negatively. 203 lab participants were randomly assigned to one condition of a 3 (no automation vs. skill-replacing automation vs. skill-allowing automation). Participants were shown an advertisement for a cooking product and asked to evaluate its attractiveness. In a between-participants design, we manipulated whether the product was a non-automated cooking set, an automated cooking machine framed as replacing the user's skills, or an automated cooking machine framed as allowing for the user's skills. These products were pretested to show varying degrees to which they are skill-replacing or skill-allowing. Then participants indicated their identification in cooking. As predicted, stronger identification corresponds to higher liking of the product in the no automation condition ($b = .18$, $t(133) = 3.14$, $p < .01$) whereas stronger identification leads to lower liking of the product in the skill-replacing automation condition ($b = -.33$, $t(131) = -4.34$, $p < .001$). Moreover, in line with our predictions about the role of internal attribution, this effect disappeared in the skill-allowing automation condition ($p = .39$).

This paper makes several theoretical contributions. First, despite the prevalence and the growing trend of automated products in the marketplace, consumers' reaction to these products have been understudied. Second, while the consumer identity literature has focused mainly on the product acquisition and display, this research takes an action-oriented perspective and highlights how identity-based consumption relies on consumer being able to attribute consumption outcomes to their skills. Our findings have also important managerial implications. In particular, our work offers actionable insights into a number of important marketing decisions, including targeting, product innovation, and communication.

Touch-Sensitive Computing Interfaces as Drivers of Experiential Consumption

EXTENDED ABSTRACT

This paper explores the idea whether the input-modalities of novel computing interfaces change the psychological process, preference, and actual choices of the person using it. Do changes in the input-modality of a computing interface systematically affect how consumers experience a shopping process, the products they choose in response, and their ultimate shopping expenses? We explore and answer these questions in a series of field studies and laboratory experiments across a wide range of product categories (automobiles, spa packages, and custom-made bikes). The findings of this research reveal that touch-sensitive interfaces relative to touch-insensitive interfaces render the same shopping task more experiential

and less instrumental. This change in consumers' experience has a series of critical downstream consequences such as a greater sensitivity toward the benefits of hedonic product features relative to utilitarian ones, which ultimately drive greater shopping expenses. These results highlight that the malleable factor of input-modalities of computing interfaces can profoundly change how people experience even the same content and how they systematically change consumer's preference in predictable ways.

The conceptual background of the current research is built around recent work on the role of preference modalities and the role of touch as a driver of attachment toward objects (Krishna 2012). A prominent finding in the latter research is that objects that are actively touched, or come into contact with the self, are judged more positively (Olausson et al. 2008). These effects were found to be even stronger for more affect-rich relative to affect-poor stimuli (Shu and Peck 2011). These more direct forms of touch may even persist in the context of more indirect (or mere) forms of touch using touch-sensitive interfaces (Brasel and Gips 2014; Peck, Barger, and Webb 2013). Thus, the central proposition of the current research is that the use of touch-sensitive interfaces promotes more experiential (shopping) experiences during a product configuration task and increase the choice of more hedonic product features, ultimately leading to more higher-priced products.

In Study 1, we examined the influence of touch-sensitive interfaces on actual customers' product configurations in cooperation with a large European car manufacturer. We collected data of $N=95,886$ car buyers over a time-span of 2 years and merged two distinct streams of data. We combined the data of actual car configurations from the manufacturers' ordering system with on-site tracking data logging customers' device information during the car configuration process. In line with our proposition, we find that customers using a touch-sensitive (such as a tablet) relative to a touch-insensitive interfaces (such as a desktop computer) configured significantly more feature-rich cars ($M_{\text{Desktop}} = 19.3$, $M_{\text{Tablet}} = 21.4$, $t(95,884)=9.267$, $p<.001$) which were ultimately higher priced ($M_{\text{Desktop}} = €52,461.82$, $M_{\text{Tablet}} = €61,563.39$, $t(95,884)=18.05$, $p<.001$). Although Study 1 provides initial support for our proposition, the current results are likely to be affected by various self-selection effects of the field data.

Study 2 was designed with the purpose to examine the proposed direction of causality and to assess consumers' subjective experiences during a product configuration task. In cooperation with a European market research company, $N=205$ prospective car buyers were pre-screened to own both a tablet and a desktop PC, and were randomly assigned to configure a car for themselves either using their own touch device or desktop PC. As predicted, the use of a touch-sensitive interface relative to the touch-insensitive interface caused significantly more feature-rich, higher priced cars ($M_{\text{Desktop}} = €40,100.70$, $M_{\text{Tablet}} = €44,566.72$, $t(203)=5.491$, $p<.001$), consisting of significantly more hedonic relative to utilitarian product features (identified by pre-test), as well as a significantly more experiential configuration experience which mediated the main effect on price (95% $CI_{\text{ExpConfig}}$: [687.04; 2230.96]).

Study 3 was designed to rule out a series of alternative explanations by using non-owned devices and holding screen size constant. A total of $N=70$ participants were randomly assigned to configure a bike for themselves in a lab setting, either using a touch-enabled or a touch-disabled tablet (with mouse input). In line with our theorizing, we find that consumers using the touch-enabled tablet perceived the configuration process substantially more experiential ($M_{\text{TouchEnabled}} = 5.66$, $M_{\text{TouchDisabled}} = 4.59$, $t(68)=3.923$, $p<.001$), explaining the significant increase in consumers' choice share of hedonic (relative to utilitarian) product features (as rated by a pre-test; 95% CI_{ExpCon}

fig.: [.03; 15]). This study also ruled out alternative explanations via psychological ownership, processing fluency, and mental simulation.

Studies 4 and 5 were designed to provide an experimental field demonstration and a generalization across product categories respectively. In Study 4, we conducted a field experiment in cooperation with a Swiss day spa. In this study, $N=75$ actual customers configured their preferred day spa package for themselves mirroring the experimental setup of study 3 (random assignment to touch-enabled or touch-disabled tablet). As predicted, the touch enabled vs. disabled tablet caused significantly higher-priced day spa packages ($M_{\text{TouchEnabled}} = \text{CHF } 554.61$, $M_{\text{TouchDisabled}} = \text{CHF } 328.89$, $t(73)=3.658$, $p<.01$), which was mediated by the substantially greater experiential as opposed to instrumental perception of the configuration process (95% CI_{SequMed} : [44.76; 184.94]).

In Study 5, participants ($N=180$) chose for each of 28 product categories whether they would choose a tablet device or a PC with mouse input to configure a product for themselves. Following the binary choice between both devices, consumers rated each product category on a utilitarian vs. hedonic scale based on prior work. A logistic mixed effects model with random intercept revealed that consumers choose multi-touch devices for more hedonic product categories ($p<.01$). However, qualitative interviews revealed that consumers were not aware of the effect that the device itself may have on their purchases.

Overall, the current work contributes to the emerging literature on human-computer interaction and preference modalities in consumer research, highlighting the critical interplay between computing interfaces and human perception (i.e., haptics). Contributing to prior work on consumer self-designs and customization, the current findings also highlight a novel antecedent by revealing that the computing interface consumers use when entering the self-design process can systematically affect their preference for specific product features and how they ultimately experience the process of a product configuration task.

The Soul and the Machine: Humanlike Machines and Machinelike Humans

EXTENDED ABSTRACT

Where does the self reside? What makes us human? Can a robot, like a corporation, become a legal being? Can it become a person? Such questions lie at the heart of this inquiry. They are no longer questions of philosophy or science fiction, but involve very real issues that we will have to deal with in coming decades. Is a robot still a possession or a tool as it becomes more autonomous? Who is to be held responsible if a self-driving car has an accident? Are computers becoming more intelligent than human beings? If computerized robots can learn, reprogram themselves, and reproduce themselves, will they need mere humans? If not, can we humans enhance ourselves enough to keep up with our creations? With biological and genetic enhancements and mechanical and computerized prostheses, can humans in fact approach immortality? Can we, alternatively, upload our consciousness to computers and the devices that house them? And what becomes of the idea of the self as machines become more humanlike and humans become more machine-like (Black 2014; Johnson 2008)?

Consumers are likely to first encounter robots directly in the home, health care facilities, self-driving vehicles, and in service contexts such as retailing, hotels, and restaurants. The robots in these contexts may or may not be humanoid (android if male, gynoid if female), but regardless, they are likely to be anthropomorphized and regarded as human-like (e.g., Aggarwal, and McGill 2007; Belk

2016; Brown and Ponsonby-McCabe, 2014; Goudey and Bonnin 2016; Landwehr, McGill, and Herrmann 2011; Lanier, Rader, and Fowler 2013). They may also potentially be regarded as surrogate selves.

Robot selves frame two changes in the notion of extended self in “The Age of Robots” (Moravec 1994). The first is the prospect that as we acquire personal robots to serve us, we will begin to think of these devices as extensions of our selves, continuing a progression from the extended self (Belk 1988) to the digital extended self (Belk 2013) to the robotic extended self (Groom, Takayama, Ochi, and Nass 2009; Nishio, Watanab, Ogawa, and Ishiguro 2013). Fictional media portrayals help shape our hopes and fears regarding robots and the extent to which we may identify with them (e.g., Barsanti 2014). The second, and potentially more profound prospect is that these robots will evolve from programmed tools to semi-autonomous and autonomous beings that can become non-human legal persons and perhaps moral persons with selves of their own. Robots displaying their own personhood and selfhood go beyond issues of anthropomorphic projection and offer a further catalyst for considering what it means to be a person or a thing. There are even forecasts that we may someday soon marry robots (Levy 2007). Robots, whether as a special object or an emerging subject, prompt us to re-examine our fundamental existential concepts.

A related concept is “the singularity,” the predicted point at which computerized robot intelligence overtakes human intelligence, which according to some will quickly bring about the extinction of the human species, perhaps within the current century (e.g., Barrat 2013; Bostrom 2014; Del Monte 2013; Kurzweil 1999, 2006). Developments pursuing Artificial General Intelligence (AGI), the point at which artificial intelligence (AI) equals human intelligence, is a key goal in the advance of robotics. After that point is reached, the singularity scenario holds that robots, unhampered by biological evolution, would increase in intelligence and strength at an exponential rate leaving us far behind (Barrat 2013).

One human response may be to become cyborgs. Cyborgs (cybernetic organisms) are machine-like humans. Although others described the concept earlier (see Gray, Mentor, and Figueroa-Sarriera 1995), the term was coined by Clynes and Kline (1960) to refer to internal and external bodily modifications needed for a human to survive in space. They began their article by saying that “Space travel challenges mankind not only technologically but also spiritually, in that it invites man to take an active part in his own biological evolution” (26). Norbert Wiener (1948/1965) announced that “We have decided to call the entire field of control and communication theory, whether in the machine or in the animal, by the name of cybernetics...” (11). Recent developments have shifted cybernetics from robots to cyborgs with such as human enhancements as auto-adjusting pacemakers, insulin pumps, and brain-controlled prosthetics. Today its increasing applicability to both entities is one indication of the growing convergence of the two figures. But a basic difference remains: cyborgs are augmented or modified organisms while robots are cybernetic machines.

The figure of the cyborg was brought to prominence by Donna Haraway’s (1985) “A Manifesto for Cyborgs,” and especially in its reproduction as a chapter, in her book *Simians, Cyborgs, and Women* (Haraway 1991). Although Haraway defines the cyborg as “a hybrid of machine and organism,” she also notes that it is “a creature of social reality as well as a creature of fiction” (149). She was more concerned with using the cyborg as a metaphor than a material reality (Best and Kelner 2001; Ranisch and Sorgner 2014). As a metaphorical boundary-straddler, the cyborg that Haraway celebrates is one that collapses dualisms such as “self/other, mind/body, culture/nature,

male/female, civilized/primitive, reality/appearance, whole/part, agent/resource, maker/made, active/passive, right/wrong, truth/illusion, total/partial, God/man" (Kang 2011, 304). Based on a netnographic study, Bhattacharyya and Kedzior (2012) find three threats posed by cyborg technology: humans giving up control to technology; humans using cyborg technology to control other humans; and humans losing the essence of being human by becoming cyborgs. As Robots threaten to gain a soul, humans may be threatened with losing ours.

In assessing such possibilities, I outline questions for consumer research. Key consumer issues involve identity, intimate relations between humans and artificially intelligent robots, interspecies acceptance and trust, and safety and morality. I provide a conceptual understanding of these developments and urge consumer research to address this agenda of issues.

SESSION OVERVIEW

In recent years, there has been a growing appreciation—in academia, government, and industry—for behavioral research on consumer's financial decisions. Although any consumption decision can be said to be "financial" (insofar as it involves money), the stream of consumer financial decision making is specifically concerned with decisions that "have dramatic effects on a consumer's overall financial picture due to the size of a single expenditure [...] or to the accumulated effects of repeating the same pattern [...]" (Lynch 2011). As such, it includes research not only on core decisions regarding financial resources (saving, borrowing, and repaying) but also extends to consumers' budgeting process (when, how and on what should those resources be used or invested). Because of their importance and/or of their frequency, these decisions play a critical role in consumers' welfare, and policymakers are growing increasingly concerned with understanding those decisions, and governments have created "behavioral units" aimed at researching and developing tools to improve consumers' financial behavior.

The four papers presented in the session further our understanding of such consumer financial decisions, and illustrate their importance in areas with strong policy implications. **Homonoff, O'Brien, and Sussman** present the results of a large-scale field experiment in which consumers are provided with information about credit (FICO) scores, and show that giving consumers access to that information has important positive consequences. **Zhang** investigates the consequences of misaligned cash flows (e.g. consumers paid on a bi-weekly basis receiving a "third" paycheck in a given month) and shows that they trigger a significant increase in expenditures. **André, Reinholtz, and Lynch** study the consequences of endowing consumers with a resource that can only be spent on a limited range of products and show that a resource akin to food stamps can paradoxically decrease people's food consumption. Finally, **Gauri, Ma, and Thomas** document how different financial resources (food stamps vs. money vs. credit card) lead to different food choices, with significant implications for consumers' health.

This research offers a broad view of the current issues in consumer financial decision-making research, and have strong connections to policy. First, they are tackling issues on which public institutions have a lever for action, and as such have the potential to inform policy decisions: Should consumers be given more transparent access to their FICO scores? Should bi-weekly payments be discouraged, in favor of weekly or monthly payments? Should the poor be given money, rather than food stamps? Second, they rely on methods high in external validity: the simulations, field experiments, retailer data, and natural experiments used in the projects ensure that the effects documented are ecologically valid, and representative of problems encountered by consumers in their daily lives. Finally, they are authored not only by prominent consumer behavior scholars but also by members of public policy institutes and of the Consumer Financial Protection Bureau (a leading institution in policy-relevant research). For all those reasons, we think that the four papers form a cohesive and important session, which has the potential to appeal to a large audience.

Does Access to FICO Scores Influence Financial Behavior? Evidence from a Field Experiment with Student Loan Borrowers

EXTENDED ABSTRACT

Consumers struggle when making financial decisions. Research consistently documents the costly mistakes individuals make across all domains of household finance, from investment and retirement savings decisions (e.g., Benartzi and Thaler, 2001; Choi, Laibson, and Madrian, 2009, 2011) to mortgage choice (e.g., Huang, Amromin and Sialm, 2007) to debt management (e.g., Gross & Souleles, 2002; Hershfield et al., 2016; Sussman & O'Brien, 2016; Sussman & Shafir, 2011). FICO's recent move to provide people with direct access to their FICO score was intended to empower consumers with the information they need to improve their financial lives. However, the effect of this information on financial behavior remains unknown. In this research, we examine whether and how access to credit score information influences financial decisions among a population of student loan borrowers.

Despite this increased focus and the significant resources invested by policymakers, firms, and charitable foundations, there is little evidence that financial education interventions are effective in improving financial behaviors and financial outcomes. Although consumer financial literacy is positively associated with a range of financial behaviors and financial outcomes (Ameriks et al. 2003; Lusardi & Mitchell 2006, 2007; Stango & Zinman 2009; van Rooij et al. 2012), quasi-experimental studies and randomized controlled trials of financial education interventions typically find no lasting measurable effects (for a meta-analysis see Fernandes, Lynch, Netemeyer 2014; for a review see Hastings et al. 2015).

Alongside efforts to improve financial literacy and financial decision-making, there has been a major push by policymakers, regulators, and firms in recent years to increase consumer access to their credit report information. In this paper, we isolate the effect of viewing the FICO score on consumer financial outcomes drawing on evidence from a field experiment. This intervention differs from more traditional efforts to improve financial literacy in several important ways. First, FICO scores are personalized and are based

on the actual credit behaviors of the individual. Second, FICO scores are concrete and exist on a continuous scale (0-850tk) that makes it possible for consumers to compare their score with others and track their progress over time. Third, participants view at least two “reason codes” alongside their score. These codes are generated by FICO and provide the consumer with personalized information about why their score is what is and, in so doing, provides specific action steps the individual can take to improve their score.

We implemented a randomized experiment using email correspondence between a large student loan lender and their clients. Our analytic sample is comprised of more than 450,000 student loan borrowers. The experimental design randomly assigned borrowers to either a control (no email) group or one of three treatment groups. Those randomly assigned to a treatment group received emails from the lender informing them that their FICO score was online and encouraging them to view their scores. The treatment groups varied in the message that accompanied the login information, with messages that provided (i) no additional information (ii) information about peers successfully managing their finances or (iii) specific steps for successful money management. Emails were sent quarterly starting in June 2015 and continuing through December 2016. To test the impact of viewing scores on financial behavior, we compared within-subject changes across conditions before and after the intervention using administrative data on a range of financial metrics pulled directly from the borrower’s credit report.

Our findings suggest that borrowers in all three treatment groups were significantly more likely to view their FICO scores than borrowers in the control group and that these effects did not differ significantly by message type. Additionally, we observe that viewing FICO score information induced borrowers to take actions associated with improved credit scores. For example, treatment group borrowers were less likely to have past due payments or delinquent accounts on their credit reports relative to those in the control group. At the same time, individuals in the treatment groups were more likely to increase the number of open revolving credit accounts during this period. These actions resulted in a statistically significant increase in FICO scores. Future analyses will examine the effects of the intervention by various subgroups including age, education, and initial FICO score.

Viewing their FICO score appears to induce individuals to take steps to improve their creditworthiness including reconciling delinquent accounts and increasing on-time payments as well as increasing the number of open credit accounts. This is, to our knowledge, the first research project that uses a randomized experimental design to directly examine the impact of providing FICO scores on financial behavior and outcomes. Taken together, our findings coupled with the analytic sample of student loan borrowers who are relatively new to borrowing have important implications for both theory and practice. From a theoretical perspective, the current research adds to our understanding of how we react to new information; from a practical perspective, this research suggests an effective approach for motivating people to make better financial decisions.

Consumption Responses to Pay Frequency: Evidence from “Extra” Paychecks

EXTENDED ABSTRACT

Households who engage in budgeting must manage both their inflow of income and their outflow of expenditures. For many households, however, these two cash flow streams are misaligned—the frequency at which they make their consumption decisions often differs from the frequency at which they receive their pay. This mis-

alignment can result in predictable variation in the amount of income a household receives per “consumption decision period.” Standard economic theory predicts that such variation should not matter—consumption should not respond to anticipated changes in income (Friedman 1957; Modigliani 1988). Whether this implication of the theory holds true has generated significant debate and has given rise to an extensive empirical literature testing for excess sensitivity to anticipated income changes. Results from these empirical studies vary substantially, however, and at present, no consensus exists in the literature on the extent to which households may respond to anticipated income changes or on the mechanisms underlying observed responses.

In this paper, I empirically test this prediction by exploiting variation in monthly income arising from the timing of bi-weekly pay schedules. Bi-weekly workers are paid on a regular two-week schedule and receive 26 paychecks over the course of the year. Because these 26 paychecks must be disbursed over 12 months, bi-weekly workers typically receive two paychecks per month with the exception of two months out of the year, during which they receive three. As a result, the level of wage and salary income that a household receives during these atypical months with three paychecks is higher than during typical months with only two. The timing of bi-weekly pay schedules thus provides predictable variation in monthly income while holding constant both total lifetime income and the environment in which that income is received. This is in contrast to semi-monthly or monthly pay schedules through which workers receive the same income each month.

My focus on the variation generated by bi-weekly pay schedules is motivated by two main considerations. First, this variation in income (and the extent to which there is an “extra” third paycheck) is simply an artifact of evaluating or accounting for income on a monthly basis. For a bi-weekly worker there is predictable variation in monthly income but not in twice-weekly income. While it is not difficult to imagine bi-weekly households thinking or budgeting on a monthly basis, the fact that whether or not a particular paycheck can be considered “extra” is not a priori assumed makes the evidence I provide in this paper even more compelling. Second, in contrast to much of the existing literature, the third paychecks are not referred to as a bonus, special payment, or in any other manner which might induce bi-weekly workers to differentially respond following their receipt. The concern with such special designations is that they may naturally lead households to categorize or evaluate the payments separately from other income. In my setting, the only way in which these third paychecks are “special” is if people choose to evaluate their income at a monthly frequency.

I test for excess sensitivity in months following three paycheck months using panel data from the Consumer Expenditure Survey (CEX). I first identify households whose heads are paid at a bi-weekly frequency and then determine the months during which they receive three paychecks. The empirical strategy takes advantage of the fact that the months during which bi-weekly workers receive three paychecks differ from year to year. For example, a biweekly worker paid in the first week of January in 2008 would have received three paychecks in February and August of that year. In 2009, that same worker would have received three paychecks in January and July. The causal effect of these third paychecks is identified using a difference-in-differences strategy that compares spending responses following a given calendar month in years during which there are three paychecks distributed during that month to responses in years during which there are only two paychecks during that month.

Using this identification strategy, I establish two main empirical results. First, I find that total household spending increases by rough-

ly 31 percent on average in the month following a three-paycheck month and that this effect on spending does not persist in subsequent months. Second, I find that this spending increase is due entirely to changes in durable spending, and specifically new vehicle purchases, with no corresponding response in non-durables. These results are consistent with several other papers in the literature on responses to anticipated income receipt which also find large responses in durable spending (Parker 1999; Souleles 1999; Adams et al. 2009; Parker et al. 2011; Aaronson et al. 2012). These findings suggest that, contrary to the predictions of standard economic theory, households do in fact respond to the variation induced by misalignment between the timing of consumption and the timing of income. I explore several explanations for why I find evidence of excess sensitivity and show that the empirical findings cannot be explained by the presence of liquidity constraints and are instead consistent with households engaging in mental accounting. I finally discuss several policy implications of those findings, such as recommendations for the design of employment contracts, the timing at which welfare benefits should be distributed to recipients, or unintended consequences of tax return policies in the United States.

Can Food Stamps Reduce Food Consumption? The Unintended Consequences of Restricted-Use Funds on Budgeting Decisions

EXTENDED ABSTRACT

A consumer's budget is typically viewed as a single fungible resource (money) from which the consumer allocates money to purchase goods and services. However, less fungible resources—such as gift cards, loyalty points, and coupons—should also be viewed as part of a consumer's budget. This is particularly true in the United States, where close to 15% of the population receives SNAP benefits (food stamps), a resource that can only be spent on non-prepared food products. However, little work has examined how fungibility restrictions impact consumer budgeting decisions. In the present research, we propose a theory of such “restricted-use funds,” and evaluate their impact on consumers' budgeting decisions.

Research on mental accounting has shown that when consumers consider a purchase opportunity of a focal item, they do not compare it to all possible alternatives, but only to a subset of options (Thaler, 1985). Importantly, the greater the categorical similarity between the focal item and the alternative item, the more likely it is to be considered in this subset. For instance, spending \$15 on drinks with friends will likely be contrasted with spending the same amount on a movie ticket, but not with saving the money for a washing machine. This congruency principle applies to income as well, and consumers seek coherence between its sources and destinations. For instance, Reinholz and colleagues (2015) have shown that store-specific gift cards are spent on items that are prototypical of the store (e.g. Levi's gift cards used on jeans rather than t-shirts).

When a restricted-use fund is tied to a product category (as SNAP benefits are to food), we propose that prototypical category members (specific food items) will be intrinsically linked to the fund (SNAP budget). Further, because categories can compete against each other (Chen et al. 2014), we propose that the link between other resources (such as money) and the prototypical members of the target product category will become weaker. We thus predict that consumers will be averse to spending general funds on items which can alternatively be purchased with restricted-use funds. In the context of SNAP, consumers endowed with SNAP benefits should be averse to spending their (non-SNAP) money on food; and since this endow-

ment rarely cover their food needs, they will consume less food than a similar consumer endowed with unrestricted money.

To test this hypothesis, we programmed a simulation to give participants the full experience of a budgeting task with multiple resources. The simulation was divided into four rounds (“weeks”), and each round was further decomposed in three phases: “Recurring,” “Groceries,” and “Misc.” In the “Recurring” phase, participants received their weekly salary, whatever money they had left from the previous period, and paid rent and utilities. No decision is made during this phase. In the “Groceries” phase, participants were asked to pick 14 menus for the week out of three types: “Thrifty,” “Regular,” or “Indulgent.” The total price of the menu choices was displayed to the participants and constitutes our dependent variable. In the “Misc.” phase, participants were given binary choices on non-food spending opportunities (e.g. movie tickets, birthday gift for a friend...).

The critical manipulation took place in the first round: in addition to their paycheck, all participants were given a separate resource called a “Card,” worth \$100. In the “Restricted-Use Fund” condition, participants were only able to use this card in the “Groceries” phase. In the “Control” condition, participants could use this card in both the “Grocery” and “Misc.” phases. As with the salary, any amount left on the card at the end of a round was carried over to the next round. This design allows us to control several important aspects. First, the amount of money that can be spent on food is constant between conditions; the only difference lies in the fungibility of the \$100 “Card.” Second, the weekly salary ensures that participants always have enough money to buy the amount of food that they desire. Finally, the minimum amount of money that participants can spend on food across the four rounds is \$120, which ensures that the restricted-use fund does not fully cover their food needs.

We recruited 103 participants on Mechanical Turk to participate in the simulation. In line with our prediction, participants in the “Restricted-Use Fund” condition spent significantly less money on food each week than participants in the “Control” condition ($M = \$71.05$ vs. $M = \$82.01$, $p < .001$). A week-by-week breakdown of food expenditure revealed a pattern consistent with our theoretical account. In the first week, participants in the experimental condition spent their food-specific fund to buy food, and spent as much as participants in the control condition ($M = \$79.54$ vs. $M = \$84.33$, $p = .136$). However, starting in week 2 (when those participants had to start using their general money), this difference became larger and significant ($M = \$68.22$ vs. $M = \$81.24$, $p < .001$). Since all participants had a similar amount of money that could be spent on food, this difference suggests an aversion to spending unrestricted money on a category that was already covered by a restricted-use fund.

A post-simulation survey administered to the participants revealed interesting differences. First, participants in the experimental condition expressed less discomfort at spending their “Card” on food, but more discomfort at spending their (unrestricted) salary on food, which is consistent with our hypothesized process. Second, consumers had a flawed intuition regarding the influence of the restricted-use fund: Participants in the experimental condition believed that they would have spent less food if they had received unrestricted money in place of their “Card,” but a comparison with the control condition suggests that they would, in fact, have spent more.

Our findings have important implications for the design and public acceptance of food stamps, or other policies aimed at shifting consumption through restricted-use funds (e.g. school supplies or medical allowance). A follow-up study of 200 participants revealed similar results when the cheapest meal options were described as

“unhealthy” rather than “thrifty,” further suggesting adverse effects of restricted-use fund allocations.

Shopping Behavior of Food Stamps Users: The Role of Decision Conflict

EXTENDED ABSTRACT

The food stamps program or Supplemental Nutrition Assistance Program (SNAP) provides economic assistance for low-income individuals to purchase food at grocery stores. In 2014 almost one in every seven – approximately 46 million – people in the U.S. received “food stamps” or supplemental nutrition assistance. In that year almost \$70 billion was spent on food stamps subsidies. The monetary benefit is provided through electronic benefit transfer card (or EBT card), which is an electronic system that allows state welfare departments to issue benefits via a magnetically encoded payment card, which looks and works like a debit or a charge card.

Given the magnitude of the financial outlay, and the size and vulnerability of this segment of customers, scholars, and analysts have called for a better understanding of the shopping habits of food stamps users. In this research, we examine whether the food consumption of food stamps users is more or less unhealthy than that of nonusers of food stamps, and how the mode of payment affects the purchase of unhealthy food items by these shoppers. Are food stamps users more or less likely to buy unhealthy food items? Does their propensity to buy unhealthy food change when they pay using their EBT cards, that look and feel like credit cards? Are they less likely to buy unhealthy food items when they pay for those purchases using cash? Can food stamps users be nudged to purchase more healthy food items if the benefits are disbursed in a more tangible form such as coupons instead of a plastic card resembling a credit card?

To answer these questions, the present research brings together two streams of literature – the literature on judgments and decisions of socially and financially underprivileged shoppers (Bernheim, Ray, Yeltekin 2015; Chandon and Wansink 2007; Mani et al. 2013; van Ittersum et al. 2013) and the literature on effects of mode of payment (Chatterjee and Rose 2012; Feinberg 1986; Hirschman 1979; Prelec and Loewenstein 1998; Prelec and Simester 2001; Soman 2001, 2003; Raghuram and Srivastava 2008; Srivastava and Raghuram 2002).

The form of money has changed radically over the past few decades. Today a majority of retail transactions are carried out through card payments. Although sellers and buyers both have welcomed the cashless economic environment, an emerging stream of research has identified an unintended consequence of cashless payments: they reduce the psychological pain of paying. This reduced pain of paying can, in turn, increase spending and weaken impulse control. Cash payments, in contrast, can strengthen impulse control; the pain of paying in cash can reduce impulsive purchases of unhealthy food products (Soman 2003; Thomas, Desai, Seenivasan 2011). We extend this stream of research by examining the effect of mode of payments on a specific segment of American shoppers – socially and financially underprivileged shoppers who use food stamps for their grocery purchases. We examine whether the effects of mode of payment – cash versus card – vary between food stamps users and nonusers.

We posit that because food stamps users tend to be less health conscious, they do not experience decision conflict – or they experience much less decision conflict compared to nonusers of food stamps – while purchasing unhealthy food products. Thus, food stamps users are more likely to purchase unhealthy products. Fur-

thermore, we also posit that food stamps users’ purchase decisions are less sensitive to the effects of mode of payment.

We test the predictions by analyzing the actual shopping behaviors of around 500 food stamps users and 500 nonusers of food stamps. Specifically, we analyzed the transaction-level data gathered through retail scanners at the point-of-purchase, which includes information about the mode of payment (credit card, food stamps, or cash). This allows us to observe how the unhealthiness of the shopping basket changes with different modes of payment, and whether this change is of similar magnitude for users and non-users of food stamps. This rich dataset allows us to overcome the limitations of self-reports or responses to hypothetical shopping situations and enables us to test our hypotheses across a wide range of products – the top 100 food categories. As such, this research follows a rich tradition of researchers using retail scanner data to test behavioral insights (Briesch et al. 1997; Stiving and Winer 1996; Thomas et al. 2011; Winer 1986).

The results of our empirical analyses support our hypotheses about the role of decision conflict in the purchase decisions of unhealthy food items. Using random effect models to account for individual heterogeneity, we first found that food stamps users’ shopping baskets had a greater caloric density (defined in calories per oz) compared to those of non-users. Furthermore, while non-users of food stamps exhibited a mode-of-payment effect (i.e. were less likely to spend money on high-calorie food items when they paid in cash), this effect was not observed for food stamps users, who purchased as much high-calorie items when they paid in cash as they did when they paid in food stamps. Both the main effect and the interaction were significant at conventional level ($p < .05$). Furthermore, our findings are robust to using the unhealthiness ratings of the food items as an alternative dependent variable.

These results suggest that decision conflict plays an important role in purchase decisions of unhealthy food items and that the experience of decision conflict can be moderated by individual differences (i.e., it is lower for food stamp users) as well as mode of payment (i.e., it is lower when shoppers use plastic modes of payments). We believe that our findings have substantive policy implications (as understanding decision conflict is critical to encouraging better food choices and budgeting decisions as a whole), and promise to offer new insights into the psychology of purchase decisions at the bottom of the pyramid.

SESSION OVERVIEW

Creativity plays an important role in our consumption environments. Being creative not only helps companies generate original and novel business ideas, but also facilitates consumers to solve everyday problems (Burroughs and Mick 2004). Given the importance of creativity, it is not surprising that researchers have explored various factors and cognitive processes that drive creativity, such as cognitive factors (Dahl and Moreau 2002) and motivational factors (Burroughs et al. 2008). This session seeks to provide new insights into creative cognition and explores various novel antecedents from multifaceted perspectives, including physical and mental states, environmental factors and individual consumption experiences that provide important insights that are likely to be of interest to a wide range of audiences.

The previous research has thus far explored various antecedents of creativity that can be broadly categorized into person-based and situational based factors. From a person-based angle, however, research focusing on the potential relationship between consumers' physical and mental states and their creativity is relatively scarce. Two papers in this session intend to fill this gap. The first paper in this session highlights how a person's physical state of being short (or their feelings of being short)—something commonly perceived as a disadvantage in modern society—can lead to positive consequences like enhanced creativity (Jia, Yang, and Deng). The second paper investigates a certain mental state—busyness—and demonstrates how the perception of having many tasks to do can promote creativity (Nowlan and Laran). Together, these two papers show the substantial role that mental and physical states can play in influencing creativity and encourage a deeper understanding of how such states impact consumer behavior.

From a situational-based point of view, the potential role of the physical environment and individual consumption experience in creativity research has received little attention. Thus, the other two papers in this session shed light on these less investigated factors and how and why they might influence creativity. The third paper in this session examines an environmental factor, airflow, and shows that the direction of airflow (facing the source of the airflow vs. facing away from the source of the airflow) can influence creativity by

enhancing people's psychological energy (Izadi, Rudd, and Patrick). Finally, the fourth paper explores the role of individual consumption experience and shows that engaging in a conspicuous consumption experience enhances creative performance (Xu, Mehta and Argo). Together, these two papers extend our knowledge of how situational factors—both those external (airflow) and internal to the consumer (conspicuous consumption)—impact consumer creativity.

Taken together, the four papers (all in advanced stages) in this session provide multifaceted insights into the creativity literature by introducing novel antecedents. As the session integrates diverse research to highlight theoretical developments in this important area, it should be of interest not only to researchers who study creativity, but it is expected to appeal to a broad audience, including those interested in consumer status and consumption habits, physio-environmental factors, time perception, mindsets, and coping mechanisms.

Physically Short, Mentally Flexible? Exploring the Relationship between Stature and Creativity

EXTENDED ABSTRACT

A "height premium" seems to exist in the western society which suggests that taller (vs. shorter) people tend to receive more favorable evaluations and enjoy more social and professional advantages (Judge and Cable 2004). Indeed, research indicates that height is a desirable physical asset and functions as a proxy of power, status, and respect (Agerström 2014). For example, taller individuals are judged as being more attractive, intelligent, and competent (Swami et al. 2008); they are also more likely to be elected as leaders, earn more money, and become more successful in career (Gawley, Perks, and Curtis 2009; Higham and Carment 1992; Jackson and Ervin 1992; Judge and Cable 2004). Being short, however, could be considered stigmatizing and short individuals are perceived as lower in professional status and less competent in social domains (Andreoletti, Zebrowitz, and Lachman 2001).

We investigate how consumers' stature influences their problem-solving capabilities and specifically how a short stature may contribute to creativity. Consumers' physical height can shape their cognition and behavior and one crucial consequence of being short is that short individuals believe that they are more susceptible to external constraints than are taller individuals. That is, short individuals believe that to achieve success, they need to work harder and circumvent more obstacles relative to taller people (Andreoletti, Zebrowitz, and Lachman 2001). Although more disadvantaged compared to their taller counterparts, short individuals may play smart to prevent such a disadvantageous position from holding them back in competition. For example, they can strategically present themselves to counteract the stereotypes associated with being short (Agerström 2014).

Past research suggests that resources for disadvantaged individuals are scarce and opportunities fleeting, and coping with such an adverse social environment improves the executive functioning of shifting (Mittal et al. 2015). Shifting involves switching between different tasks or mindsets flexibly and efficiently, and is a critical component of cognitive flexibility, which underlies abilities such as creativity (Diamond 2013). Extending these previous findings to examining the relationship between physical height and creativity, we propose that inasmuch as short individuals perceive themselves to be in a disadvantageous position, they may cope with the situation (e.g., resource deprivation) by honing their shifting skills and being more

flexible and creative. Specifically, we propose that both a chronic state of being physically short and a situationally induced state of feeling short can promote creativity. We tested our hypothesis in three experiments.

In the first experiment, we assessed creativity using remote associates test (RAT), a well-established measure of creativity. One hundred ninety-one participants took part in the experiment. They were told that they would work on a word association test, in which they were presented with three words (e.g., paint, doll, cat) and asked to think of a fourth word that associated with all these words (house). They worked on ten RAT questions and the number of correct solutions served as our dependent variable (RAT scores). Participants' height was collected at the end of the experiment, among other demographic variables. Analysis showed a significant negative correlation between participants' self-reported height and their RAT scores ($r = -.69, p < .001$), suggesting that shorter participants solved more RAT questions than did taller participants.

In the second experiment, we measured participants' creativity using a scuffed shoe task (Burroughs and Mick 2004). One hundred seventy-eight participants took part in this experiment. They were presented with a scenario in which they found out that their shoes were badly scuffed right before an important social occasion, and they needed to generate as many creative solutions as they can think of to this situation. Their solutions were assessed using a five-point creativity scale (1 = not at all creative; 5 = very creative) and the creativity scores served as our dependent variable. After this thinking exercise, participants' height was collected, among other demographic variables. Analysis again showed a significant negative correlation between participants' self-reported height and their creativity scores ($r = -.15, p < .05$), suggesting that shorter participants generated more creative solutions than did taller participants.

In the third experiment, we attempted to replicate the results of experiments 1 and 2 by manipulating participants' perceived shortness. One hundred and fourteen participants took part in this experiment. To manipulate perceived shortness, we asked participants to role play a short (tall) person, imagining and describing what life would be like for this person. Following this manipulation and a filler task, we assessed participants' creativity. Specifically, participants were asked to come up with as many creative ideas as they could think of for a new type of mattress (Mehta, Zhu, and Cheema 2012). Again, the creativity scores served as our dependent variable. One-way ANOVA showed a significant effect of our shortness manipulation on the creativity displayed by the participants such that those in the short perception condition were more creative than those assigned to the high perception condition ($p < .05$).

To sum up, across three experiments and by employing different creativity measures (e.g., remote associates test, alternative uses test) and both self-reported height and induced state of height perception, we found evidence for our hypothesis that a short stature can make people more creative. To our knowledge, this is first such research demonstrating a relationship between physical height and creativity.

Can Busyness Influence Consumer Creativity?

EXTENDED ABSTRACT

Despite the fact that technology has relieved modern humans from many of their responsibilities, consumers today feel busier than ever before. Prior research on busyness suggests that consumers prefer being busy relative to being idle (Hsee, et al. 2010), and that busy individuals are perceived to be high in status (Bellzza, et al. 2017). However, very little is known about the psychological processes activated by busyness, and how being busy affects consumer behavior.

In this paper, we examine how the perception of being busy affects performance in tasks involving consumer creativity.

Busyness is the perception of having many tasks to complete (Gershuny 2005; Wilcox, et al. 2016). We propose that when an individual is busy, it is harder for the individual to control their thoughts and focus on a specific task. This occurs because the salience of many (vs. few) tasks makes it harder to inhibit thoughts that interfere with the execution of a focal task. Thus, the thought inhibition process that helps people navigate their environment by focusing on information that is relevant to a focal task (Fishbach, et al. 2003; Forster and Liberman 2007; Shah, et al. 2002) is easier to accomplish when the individual does not have many tasks to think about. When the individual perceives that there are many tasks to do, thoughts become less controlled and it is harder to engage in this inhibition process. We propose that this phenomenon increases creativity, and outline four studies that test this framework.

Study 1 sought to test the effect of busyness on task performance across tasks that either did or did not involve creativity. 187 undergraduates listed either three (not busy condition) or ten (busy condition) tasks on their to-do list (Wilcox et al. 2016), before being assigned to generate new names for a pasta brand (creative task) or solve a series of multiple choice analogies (control task). Results indicated that busyness affected performance on the two tasks differentially ($F(1, 183)=4.06, p<.05$). In the creative task condition, busyness ($M=6.36$) led participants to come up with more names that diverged from convention compared to the not busy condition ($M=5.24; p<.05$), but had no effect on the number of analogies answered correctly in the control task condition ($p=.69$).

Study 2 was designed to replicate the effect of busyness on creativity and directly test the proposed mechanism. 159 undergraduates completed the same busyness manipulation as study 1, then either were subtly encouraged not to control which thoughts came to mind (not-controlled thoughts condition), or read neutral text (baseline thoughts condition). Then they came up with a creative way to use bubble-wrap. An ANOVA revealed a busyness by thoughts interaction on the judged creativity of the ideas ($F(1, 155) = 6.83, p<.01$), such that the busy condition ($M=3.77$) came up with ideas that were more creative than the not busy condition ($M=3.16; p<.05$). Additionally, in the not busy condition, the suggestion not to control their thoughts ($M=3.70$) enhanced the creativity of their ideas compared to the baseline condition ($M=3.16; p=.07$).

Study 3 aimed to eliminate the effect of busyness on creativity by restoring participants' ability to control their thoughts. 211 MTurk workers first wrote about their day and how they were busier (vs. less busy) than usual. Next, they were instructed to either think about just one of these activities and block out unrelated thoughts (controlled thoughts condition) or think about their morning routine (baseline thoughts condition). Finally, they came up with a creative way that a company could engage its consumers. A busyness by thoughts interaction emerged on the judged creativity of the ideas ($F(1, 207) = 3.76, p=.05$), such that at baseline, the busy condition ($M=3.47$) came up with ideas that were more creative than the not busy condition ($M=3.15; F(1, 207)=4.10, p<.05$), but no effect emerged when participants were controlling their thoughts ($F<1$). Importantly, in the busy condition, controlling thoughts ($M=3.13$) reduced creativity compared to the baseline condition ($M = 3.47, F(1, 207)=4.08, p<.05$).

Study 4 sought to further support our framework by demonstrating that the effect of busyness on creativity is eliminated among participants who have a high tendency to focus on a single set of thoughts when working on a task. 177 MTurk workers evaluated ads that either led them to think about the tasks they had to do (busy con-

dition) or contained neutral text (not busy condition), before coming up with four creative ways to use a brown paper grocery bag. After answering filler questions, participants then responded to three self-report items measuring their tendency to keep their focus when performing tasks. Responses to these items were averaged ($\alpha=.71$) to form the “focus” individual difference variable. A regression on creativity (flexibility + originality) of the ideas revealed only a busyness by focus interaction ($B=-.13$, $SE=.06$, $p<.05$), such that the effect of busyness on creativity was eliminated as tendency to focus ($M=6.39$, $SD=1.51$) increased (Johnson-Neyman point of transition = 5.74).

In conclusion, four studies demonstrate that busyness boosts creativity. Study 1 rules out the possibility that our effect is driven by a general increase in motivation or task engagement, studies 2 and 3 directly manipulate the proposed control of thoughts mechanism, and study 4 identifies an individual difference variable that eliminates the effect. The findings presented here identify an important psychological consequence of busyness, as well as a novel antecedent of consumer creativity.

The Way the Wind Blows: How Direction of Airflow Influences Creativity

EXTENDED ABSTRACT

Does it matter where you place a fan in an office or store? Can the direction of airflow change how people think? Our research introduces an understudied environmental factor—airflow—and demonstrates that the direction of this airflow can have a profound influence on consumer creativity. We hypothesize that being upwind (i.e., facing the flow of air) versus downwind (i.e., having one’s back to the flow of air) increases consumers’ psychological energy and that this boost in psychological energy has positive consequences for creative performance.

Conceptual Model

Creativity, defined as the production of novel ideas or solutions to problems (Amabile 1983; Moreau and Engeset 2016), not only impacts consumer’s purchase behavior in numerous product categories, but is also highly valued in corporate environments. But despite emerging research that has identified aspects of the physical environment that impact creativity (Mehta, Zhu, and Cheema 2012; Steidle and Werth 2013), the potential link between creativity and airflow (from natural drafts and breezes to ventilation systems and fans) in modern day consumption, shopping, and workplace environments has remained unexplored and is worthy of investigation.

Airflow (i.e., the movement of air in an environment) has three key facets: speed, temperature, and direction. Our research focuses on the last facet—the direction of airflow (upwind vs. downwind)—in consumption spaces. Although the relationship between different facets of airflow and air quality has been studied in building design (Chung and Hsu 2001; Imbabi 2006; Yu et al. 2009), the possible psychological impact of airflow has rarely been explored. The present research aims to extend the extant literature by testing the prediction that facing upwind boosts creativity by enhancing people’s psychological energy.

Psychological energy (i.e., the perceived energy available to the self) is reflected in feelings of aliveness and vitality (Ryan and Deci 2008; Thayer 1989) and depends upon both psychosocial and physical factors (Ryan and Frederick 1997). Given that airflow is an environmental factor people experience physiologically, the literature on physical antecedents of psychological energy is particularly germane to our research. Notably, prior research on environmental factors suggests that experiences that are more sensorially invigorating

can positively influence people’s perceived psychological resources and vitality (Cheema and Patrick 2012). In the present research, we similarly argue that a sensorial and physiologically energizing experience—in this case, the experience of facing upwind—positively affects psychological energy. Namely, due to differences in the density and type of touch receptors present in the skin over various portions of the human body, humans have greater tactile sensitivity on the front-facing (vs. rear-facing) half of their body (Weber 1978). Therefore, we hypothesize that facing upwind (vs. downwind) will amplify one’s psychological energy (as measured by energetic activation, felt vitality, and willingness to expend energy). Moreover, since prior research has shown that increased psychological energy is associated with cognitive flexibility, improved brain functioning, and thus creativity (De Dreu, Baas, and Nijstad 2008; Deci and Ryan 2000), we predict a similar, mediating role of psychological energy in explaining the positive effect of facing upwind (vs. downwind) on creative performance.

Methodology and Results

Five studies tested the prediction that, by enhancing psychological energy, the experience of facing upwind (vs. downwind) would increase people’s creativity. Study 1 provided initial evidence for our conceptual framework, in a field setting (a public park during a kite festival where a natural breeze was present), by examining whether facing upwind (vs. downwind) increased people’s creativity when naming their dream travel destination and increased their likelihood of choosing to undertake a more difficult, energy-taxing task (an indicator of greater psychological energy; Choi and Fishbach 2011; Inoue 2007). Unbeknownst to participants, they were made to stand either upwind or downwind while taking a short survey. As predicted, the results revealed that participants in the upwind (vs. downwind) condition generated more creative travel destinations and exhibited greater psychological energy (i.e., they were significantly more likely to choose to take home instructions for a difficult vs. easy do-it-yourself kite). Moreover, the effect of airflow direction on creativity was mediated by psychological energy.

Studies 2a and 2b were conducted in the lab. For these studies, all participants were placed in identical rooms (with identical layouts and temperature). The only difference was that the fan in each room was positioned to either blow air towards participants or at their backs (the fans, speed of the airflow, and distance from the fans to participants were identical). Study 2a conceptually replicated the prior energy findings: Participants facing upwind (vs. downwind) exhibited greater psychological energy, as they were significantly more likely to choose to perform a more challenging task for an ostensibly upcoming university-organized conference. Building upon these results, study 2b added a “no wind” control condition (wherein a fan was in the room, but blowing toward the wall) and ruled out several alternative explanations. Namely, that our airflow conditions were also manipulating tense arousal (e.g., anxiety) and hedonic tone (e.g., happiness)—constructs that are distinct from psychological energy (Nix et al. 1999; Ryan and Bernstein 2004). Study 2b revealed that although the experience of facing upwind (vs. downwind or no wind) made people feel significantly more psychologically energized, participants in all three conditions reported having an equally positive mood and feeling equally tense. Thus, hedonic tone and tense arousal could not account for our observed effects.

In study 3 (online), participants imagined a scenario where a fan is blowing at their face (vs. back or no fan) and subsequently completed a remote associates task (RAT) to assess their creativity. Results revealed that participants in the upwind (vs. downwind or control) conditions correctly solved more RAT items. Study 4 tested

the full conceptual model (in lab). The results revealed that, as predicted, participants in the upwind (vs. downwind or no wind) condition produced significantly more creative drawings of alien animals and felt significantly more vital and energized. Further supporting our theory, mediation analyses revealed that the creativity exhibited by participants in the upwind (vs. downwind or no wind) conditions was significantly mediated by their feelings of psychological energy.

Can Conspicuous Consumption Experience Affect Consumer Creativity?

EXTENDED ABSTRACT

In the United States alone, consumers spend as much as \$525 billion per year on luxury products (Bev and Zolenski 2011). It has been argued that consumers seek luxury products to signal status and prestige (Han, Nunes, and Dreze 2010). Such frivolous behavior to publicly display one's economic wealth and status is called conspicuous consumption (Veblen 1899). Although previous research has extensively examined consumers' motivation to engage in conspicuous consumption (Rucker, Galensky, and Dubois 2012; Griskevicius et al. 2007), little research has explored the downstream consequences of engaging in such behavior. The current work aims to extend this line of research by examining the effect of conspicuous consumption on consumer creativity. Specifically, we propose that engaging in conspicuous consumption will activate a differentiation mindset, which in turn will lead to higher creativity.

It has been argued that consumption behaviors and products can have ascribed meanings that are generally agreed upon by the members of social groups and general population (Richins 1994). These consumption behaviors then can act as signs, that are interpreted by observers in a given context, to signal consumers' identity and status (Richins 1994). Conspicuous products are costly items that are exhibited publically to impress upon others that one possesses wealth or status (Sundie et al. 2010). Consumption of such conspicuous products provides individuals a means to dissociate themselves from others (Han et al. 2010). For example, the classic monogram pattern or the popular Damier canvas pattern of the luxury brand Louis Vuitton is synonymous with conspicuousness as these well recognized patterns send a clear signal of one's wealth and that such product is beyond the reach of the ordinary (Han et al. 2010).

Extending this line of argument, we suggest that a simple consumption experience of such conspicuous products, that provides consumers a means to dissociate themselves from others, will induce a heightened feeling of distinctiveness or being different from others and activate a unique cognitive process that manifests as a differentiation mindset. We further propose that such differentiation mindset will positively influence consumer creativity. It has been argued that differentiation mindset increases non-conformity and heightens the desire to stand out from others. This in turn enables people to break habitual mental set and think outside of the box leading to higher creativity (IJzerman, Leung, and Ong 2014).

In the first experiment, we aimed to test our focal hypothesis that engaging in conspicuous consumption leads to higher creativity. This experiment manipulated conspicuous consumption through a real conspicuous consumption in which participants were provided with either a Prada or a similar non-branded handbag and were asked to put their belongings in the handbag and walked around with the handbag in a public setting. Then they went back to the lab and completed a creativity task (Torrance 1966). As hypothesized, we observed a main effect of conspicuous consumption experience on originality of the generated ideas ($F(1, 67) = 4.49, p = .038$), such that the ideas generated by the participants in the conspicuous condi-

tion ($M = 3.47, SD = .73$) were judged to be significantly more original than those in the neutral condition ($M = 3.06, SD = .83$).

In the second experiment, we intended to examine our proposed process. Thus, this experiment employed a 2(Consumption experience: conspicuous vs. neutral) x 2(Differentiation mindset: activated vs. control) between-subject design. In this experiment, we manipulated conspicuous consumption through an imagination task and asked participants to imagine using either luxury or neutral products in a public setting. To manipulate differentiation mindset, participants were asked to think about several ways in which they thought they were different from others and then write down how/why they thought so (Kim et al. 2013). In the control condition, participants were simply asked to describe the room they were working in. To measure creativity, participants were asked to come up with a creative idea for a new mattress (Mehta, Zhu, and Cheema 2012). A two-way ANOVA returned a significant interaction between consumption experience and mindset for originality of the generated ideas ($F(1, 190) = 4.39, p = .037$). Under the control condition, we found that conspicuous consumption enhanced originality ($M_{\text{conspicuous}} = 3.56, SD = .70; M_{\text{control}} = 3.17, SD = .83; t(190) = 2.56, p = .011$). However, no difference was observed between conspicuous consumption ($M = 3.46, SD = .78$) and neutral experience conditions ($M = 3.53, SD = .70; t(190) < 1$) when differentiation mindset was induced.

In the third experiment, we examined a key boundary condition. We argue that if conspicuous consumption takes place in a private setting, then the differentiation mindset should not be activated and thus the effect will be attenuated. We employed a 2 (Consumption experience: conspicuous vs. neutral) x 2 (Setting: public vs. private) between-subjects design, in which the participants actually experienced a conspicuous (or neutral) consumption episode, either in a public or a private setting. In the public settings, the manipulation for conspicuous experience was very similar to experiment 1 besides that rather than wearing a Prada bag, participants wore either a Chanel brooch pearl necklace or a pearl necklace without the Chanel brooch. In the private settings, participants stayed in a private room where they could not be observed by anyone. To measure creativity, participants were asked to come up with new ice-cream flavors for Baskin Robbins. A two-way ANOVA returned a significant interaction between consumption experience and setting type ($F(1, 96) = 4.72, p = .032$). Under the public setting, conspicuous consumption enhanced the originality of ice-cream ideas ($M_{\text{conspicuous}} = 4.27, SD = 1.03; M_{\text{control}} = 3.56, SD = 1.16; t(96) = 2.25, p = .027$). However, under the private condition, no difference was observed in the originality score ($M_{\text{conspicuous}} = 3.51, SD = 1.08$) and neutral experience condition ($M_{\text{control}} = 3.81, SD = 1.29; t(96) < 1$).

SESSION OVERVIEW

The company of others often shapes how we process information and act accordingly. In an increasingly connected world, a fundamental question is to understand the varied instantiations of social influence and their accompanying consequences for reasoning and behavior. This session discusses how individual judgment and decisions change as a function of others' presence (Papers 1-2), their attitudes (Paper 3), and their behaviors (Paper 4). Collectively, the selected research illuminate contexts under which social influence can aid as well as harm well-being, while featuring a broad array of human cognition and behavior: reacting to information (Papers 1 and 3), changing experiences (Paper 2) and attitudes (Paper 3), and engaging in repeated actions (Papers 2 and 4).

Jun, Meng, and Johar (Paper 1) begin by examining the effect of evaluating information in a social context on fact-checking. Across a series of incentivized tasks, people fact-checked statements less frequently when they perceived the presence of others (e.g., in group settings or on social media) than when they evaluated the same statements alone. Next, Tu, Yang, and Fishbach (Paper 2) expand on the effects of social presence and highlight one benefit of interpersonal involvement in the form of combating satiation. Specifically, re-consuming familiar activities with those new to that stimuli can restore novelty to otherwise mundane experiences. Kupor and Tormala (Paper 3) turn to the role of others' attitudes by identifying when information is more persuasive in a consumer recommendation context. When the perceived default evaluation is extremely positive, people tend to be more persuaded by moderately positive reviews that deviate from that default. Finally, using large-scale observational data on running activity, Eckles, Nicolaides, and Aral (Paper 4) bring the forces of social influence to the behavioral sphere with an analysis of how habits and disruptions to a performance environment moderate susceptibility to peer effects.

In concert, the above papers call attention to the far-reaching effects of social influence on how people process information, form

attitudes, and change behavior. These consequences may manifest themselves in ways both beneficial and detrimental. On one hand, individuals may derive considerable utility from others' company, as when they re-consume experiences with friends who have not done so (Tu, Yang, and Fishbach) and use peers' behavior to reinforce their own habits (Eckles, Nicolaides, and Aral). On the other hand, the presence of others can suppress willingness to verify information (Jun, Meng, and Johar). People may become swayed by extreme or moderate reviews simply based on the perceived default (Kupor and Tormala).

Bridging insights from different methodological techniques that span various consumption domains (media, product recommendations, experiential activities, exercise habits), this session brings together the latest work on social influence and its consequences for judgment and behavior. With the ease and rapidity of information transmission through social networks, a closer inspection of when people are more susceptible to peer effects can help improve individuals' decisions and experiences. We believe the substantive issues raised here would be especially useful for those interested in social influence, persuasion, information processing, and habits.

Perceived Social Presence Reduces Fact-Checking

EXTENDED ABSTRACT

A recent concern, intensified in the wake of the 2016 U.S. Presidential election, surrounds the circulation of "fake" news and other unverified digital content. As people have grown to rely on social media as an important news source (Pew Research Center 2016), a relevant question is how we scrutinize information in such settings. Across several experiments, people fact-checked less often when they evaluated claims in a (perceived) collective setting (e.g., in a group or on social media) than when they did so alone. Inducing vigilance immediately prior to evaluation increased rates of fact-checking under social contexts.

In Experiment 1 (N=175), MTurk participants logged onto a simulated news website where they evaluated 36 statements described as headlines published by a U.S. media organization. These claims were pretested to be relatively ambiguous, evenly divided in their veracity, and spanned a diverse set of topics. Participants could identify each statement as true, false, or raise a fact-checking "flag" allowing them to learn its veracity. We specified a bonus reward such that individuals received 1/-1/0 points for every correct/incorrect/flagged statement, respectively (e.g., with each point awarding 5 cents). Throughout the task, some participants saw their username displayed by itself (Alone), while others saw 102 other "currently online" participants beneath their own (Group). Respondents flagged (fact-checked) a fewer proportion of statements in the Group compared to Alone condition [$M_{\text{Alone}} = 17\%$; $M_{\text{Group}} = 11\%$].

The incentive structure above implies that an expected-value maximizer would be indifferent between flagging and not flagging. To test whether people are more likely to fact-check in others' presence when doing so is strictly dominant, Experiment 2 (N=215) imposed a reward (+0.25 point) for flagging and featured 37 statements of varying ambiguity. Although overall flagging rates increased, people again fact-checked less in the presence of others [$M_{\text{Alone}} = 26\%$; $M_{\text{Group}} = 20\%$] across all levels of ambiguity.

Experiment 3 investigated whether diffusion of responsibility (Latané et al., 1979) may account for suppressed fact-checking. We presented respondents ($N=165$) with 38 statements about U.S. congressmen/women and introduced a third condition (Group-Distinct) that differentiated participants from others logged onto the forum by displaying their own name in red text alongside 30 others in black (van Bommel et al. 2012). If social presence blunts fact-checking because individuals free-ride on others' efforts, then this behavior should diminish when they feel more personally responsible within a collective setting. Although heightening individual distinctiveness indeed increased felt responsibility for uncovering the truth, this did not prompt greater fact-checking: Those in the Alone condition [$M = 13%$] flagged more than those in both Group conditions [$M_{\text{Group}} = 6%$; $M_{\text{Group-Distinct}} = 7%$].

Experiment 4 ($N=371$) tested whether evaluating information in a social context where others' presence is cued indirectly can impede fact-checking. Participants evaluated the 36 headlines from Experiment 1 in an Alone or Group condition (102 others). We introduced a second factor of platform type: Those in the Traditional News condition completed the task on the simulated forum as done previously, while those in the Social Media condition viewed the same headlines framed as Facebook posts from the focal media organization. Replicating prior results, people flagged less when they saw others (vs. only themselves) on the traditional media site [$M_{\text{Alone}} = 6.4%$; $M_{\text{Group}} = 3.5%$]. On the social media platform, however, this difference disappeared [$M_{\text{Alone}} = 4.4%$; $M_{\text{Group}} = 4.4%$]. So, browsing information in an inherently social context seemed to make participants behave as if they were in a group.

Experiment 5 ($N=308$) found that people need not be co-attending to the same stimuli to be susceptible to the social presence effects observed so far. Regardless of whether other respondents were described as "currently online" (completing the same task) or "previously online" (had already completed it), participants fact-checked less in the company of others [$M_{\text{Current}} = 15%$; $M_{\text{Past}} = 18%$] than when were alone [$M = 24%$].

Might the reluctance to fact-check be compounded by a motive to corroborate one's own beliefs? Participants in Experiment 6 ($N=287$) read 50 (purported) campaign statements from two U.S. politicians. Candidate A's statements reflected a more conservative view, while candidate B's a more liberal one. We further varied the number of others (30 vs. 102 others) to examine the role of group size. Participants flagged less in the presence of others regardless of group size [$M_{\text{Alone}} = 12%$; $M_{\text{Group-Small}} = 8%$; $M_{\text{Group-Large}} = 6%$]. Although people were more likely to accept a statement as true when its view accorded with their own party, political alignment did not affect flagging rates (which instead depended only on social presence), suggesting that the tendency to exercise motivated reasoning may operate independently.

One reason why collective settings suppress fact-checking is that being around others may automatically lower our guards, impairing vigilance more generally. Three pieces of evidence lend some credence to this possibility. First, respondents in a separate study who scored high on chronic prevention (but not promotion) focus—a trait associated with being habitually cautious (Higgins et al. 2001)—appeared less vulnerable to the effect of social presence. Second, people in a group (vs. individual) environment performed worse on a proofreading task. Finally, the last experiment ($N=385$) tested whether promoting a vigilance mindset can increase fact-checking under social settings. Before evaluating statements in either an Alone or Group condition, respondents either were or were not exposed to a vigilance induction shown to increase prevention focus (Higgins et al. 1994). Control participants flagged fewer state-

ments in the presence of others [$M_{\text{Alone}} = 20%$; $M_{\text{Group}} = 12%$]. However, this difference disappeared among those given the vigilance exercises [$M_{\text{Alone}} = 21%$; $M_{\text{Group}} = 23%$], with participants in the Group condition electing to fact-check nearly twice as often.

The experiments above furnish evidence that perceiving the presence of others may reduce people's willingness to fact-check information. Further, these data suggest that others' presence may lower our guards in an almost instinctual fashion, consistent with a "safety in numbers" heuristic (Roberts 1996). Continuing to devise interventions that encourage greater informational scrutiny poses an important challenge towards inspiring a well-informed populace.

Seeing the World Through Others' Lens: When Shared Experience Boosts Novelty

EXTENDED ABSTRACT

Mundane life is filled with repeated activities. Very often consumers take the same route to work, stop by the same coffee shop and interact with the same group of people. Almost by definition, repetition results in a decrease in experienced novelty—people satiate (Coombs and Avrunin 1977). To counteract unwanted satiation, prior research has identified a few intra-personal strategies, such as consuming later and consuming something different. We propose an interpersonal strategy: consume with others who are new to the experience.

Due to our social instinct, we automatically synchronize our behaviors and experiences with other people. When seeing others yawn, we also start yawning (Platek et al. 2003); when witnessing a person being socially rejected, we feel lonely too (Wesselmann, Bagg, and Williams 2009); when reading emotionally laden posts on Facebook, without face-to-face interaction, we can feel how others feel and converge with our friends' emotions (Kramer, Guillory, and Hancock 2014). Building on this line of research, we predict that *when experiencing old stimuli with another person who is new to the experience, people adopt his/her novel perspective, resulting in a more refreshing experience for the self*. This effect is driven by neither the mere presence of others nor the change in experience type (i.e., solo experience vs. joint experience). Hence, controlling for the presence of others, we predict that *people find their experience more novel when experiencing it with another person who has had the experience fewer times*. Importantly, because the degree to which people adopt another person's fresh pair of eyes depends on interpersonal closeness, we predict that *the proposed effect only occurs between close others*. Four studies tested our proposed framework.

Study 1 surveyed people's movie re-consumption experience. Participants recalled the last time they re-watched a movie, rated the novelty of their experience, and indicated whether they re-watched it by themselves or with other person(s). Those who watched with other(s) further rated whether other(s)' have watched the movie more or fewer times than they did (1 = fewer times, 7 = more times). We also collected background variables such as participants' and other(s)' overall liking of the movie. In support of our hypothesis, those who re-watched the movie with others (vs. alone) rated the movie more novel ($M = 5.00$, $SD = 1.22$ vs. $M = 4.57$, $SD = 1.09$; $t(256) = 2.50$, $p = .013$). This is driven by the lower consumption frequency of others relative to self ($M = 2.93$, $SD = 2.05$, $t(196) = 7.34$, $p < .001$; one-sample t -test against 4). Further, controlling for other people's liking of the movie, the fewer times other(s) watched the movie relative to participants themselves, the more novel participants rated their experience ($\beta = .17$, $p = .02$).

Study 2 tested the effect in the Magic Kingdom in Disney World using real-time measures. We surveyed visitors who were with fami-

ly and friends. Participants first evaluated novelty of their experience on that day, and then indicated whether they were a first-time visitor or not. Non-first-timers also rated to what extent it felt like first time. Next, participants indicated 1) how likely they would come back and 2) how soon they would come back. Finally, they answered other questions about the visit, including 1) the (average) frequency of other person(s)' visit, 2) frequency of their own visit, 3) time elapsed since their last visit, 4) time in Magic Kingdom on that day, and 5) group size. Controlling for items 2)-4), the frequency of other(s) visit negatively predicted novelty ($\beta = -.19, p = .02$), likelihood of coming back ($\beta = -.24, p < .001$), how soon people would like to come back ($\beta = -.24, p < .001$), and for non-first-timers, whether it felt like first time ($\beta = -.42, p < .001$).

Study 3 was conducted in the lab for higher internal validity. We presented undergraduate participants with six pictures of their familiar campus scenes and asked them to imagine visiting these places with a group of freshmen (their in-group members) who have "never been to these places before" or "been to these places many times". Participants in the former condition rated the scenes more novel ($M = 4.61, SD = 1.29$ vs. $M = 3.97, SD = 1.01$; $F(1, 130) = 9.95, p = .002$).

Study 4 further tested the process by manipulating closeness, using a 2 (Other's status: without-prior-experience vs. with-prior-experience) \times 2 (Closeness: close vs. distant) between-participants design. Participants first answered a few attitude questions as a part of the closeness manipulation. Next, they watched a short video clip four times, and then watched it one more time with another person who "has not yet watched the video" or "has watched this video for the same number of times." They also learned that this person's answers to the attitude questions overlapped 80% (in close conditions) or 20% (in distant conditions) with theirs. Finally, participants rated the novelty of the last iteration. An Other's Status \times Closeness ANOVA on novelty yielded the predicted interaction ($F(1, 79) = 6.25, p = .014$); participants found the video clip more novel when the other person had no prior experience ($M = 4.52, SD = 2.09$ vs. $M = 3.19, SD = 2.11$; $t(40) = 2.06, p = .046$) only when they felt close to the other person.

Satiation occurs all too often as consumers usually need to experience stimuli repeatedly by themselves. We propose and find support for a social approach to combat satiation—that is, consumers can regain novelty by re-experiencing with a close other who has a fresh pair of eyes. Among other benefits of a social relationship, such as emotional and financial support, friends can enhance our experiences.

When Moderation Fosters Persuasion: The Persuasive Power of Deviatory Reviews

EXTENDED ABSTRACT

When people seek to persuade others to purchase a product, they often review it extremely favorably. Despite the intuitive appeal of this approach, we find that a moderately positive review can sometimes be more persuasive. In particular, when the perceived default evaluation in a given context is extremely positive, moderately positive reviews that deviate from that default can become more persuasive.

Defaults can be created by factors both endogenous (e.g., pre-selected options; Johnson and Goldstein 2003) and exogenous (descriptive norms; Miller and Prentice 1996) to a review context. These defaults often emerge on review platforms, and frequently they are extremely positive. For example, numerous review portals feature pre-selected 5-star ratings (e.g., Merchantcircle.com 2016).

Similarly, perhaps because consumers frequently give services the highest possible rating on many platforms (e.g., Uber, Lyft, etc.), consumers regularly assume that the default review on those platforms is extremely positive (Kane 2014; Quora 2013). We propose that just as people more frequently deviate from a default when they have carefully deliberated about their choice (Huh, Vosgerau, and Morewedge 2014), they may believe that others are more likely to have deviated from a default when those others have carefully deliberated about *their* choice. Furthermore, because greater deliberation increases perceived accuracy (Barden and Petty 2008), people may infer that a deviatory assessment is more accurate, which may thus increase its persuasiveness. This proposed deviation effect suggests that when the default evaluation is believed to be extremely positive, a moderately positive review might be more persuasive (e.g., increase consumers' desire to purchase the reviewed product) than an extremely positive review. We outline four studies below that test this theorizing.

In Study 1, participants imagined that they viewed a 4-star or 5-star rating of a phone on a review platform on which the majority of reviews had 5 stars. Participants perceived the review to be more accurate when the reviewer gave it 4 stars (i.e., when the review was deviatory; $M = 5.14, SD = 1.19$) versus 5 stars (i.e., when the review was not deviatory; $M = 4.55, SD = 1.33$), $t(199) = 3.34, p < .001$. Participants were also more likely to buy the phone when the reviewer rated it 4 stars ($M = 3.52, SD = 1.84$) rather than 5 stars ($M = 2.91, SD = 1.63$), $t(199) = 2.41, p = .017$. Perceived accuracy mediated participants' purchase decisions (95% CI: .12 to .55).

Study 2 examined whether the deviation effect occurs even when the default is not explicit. After a pretest revealed that the majority of MTurkers perceive that the default ride-sharing review is 5 out of 5 stars, a separate sample of MTurkers imagined that they viewed a 4-star or 5-star ride-sharing review. Participants perceived the 4-star (vs. 5-star) review to be more accurate ($M_{4\text{-Stars}} = 5.09, SD_{4\text{-Stars}} = .96$; $M_{5\text{-Stars}} = 4.63, SD_{5\text{-Stars}} = 1.26$; $t(197) = 2.88, p = .004$), and the 4-star review prompted a greater desire to use the ride-sharing service ($M_{4\text{-Stars}} = 5.16, SD_{4\text{-Stars}} = 1.11$; $M_{5\text{-Stars}} = 4.63, SD_{5\text{-Stars}} = 1.35$; $t(199) = 2.65, p = .009$). As further predicted, perceived accuracy mediated participants' behavioral intentions (95% CI: .11 to .60).

Study 3 tested the robustness of the deviation effect with a different manipulation of deviance—deviation from a pre-selected star rating. Study 3 also tested our theorizing that people not only perceive a moderately positive review to be more accurate when the default is extremely positive, but that they also perceive an extremely positive review to be more accurate when the default is moderately positive. Thus, participants read about a reviewer who rated a restaurant 4 (or 5) stars in a review portal that pre-selects a default rating of 4 (or 5) stars. In other words, participants were assigned to one cell in a 2 (Default: Moderate vs. Extreme) \times 2 (Reviewer Evaluation: Moderate vs. Extreme) design. Separate 2 \times 2 ANOVAs revealed interactions on perceived thoughtfulness, perceived accuracy, and desire to try the restaurant ($F_s(1, 396) = 58.75, p_s < .001$): When the default was 5 stars, participants perceived the 4-star (vs. 5-star) review to be more thoughtful, accurate, and persuasive ($F_s(1, 396) = 31.79, p_s < .001$). In contrast, when the default was 4 stars, participants perceived the 5-star (vs. 4-star) review to be more thoughtful, accurate, and persuasive ($F_s(1, 396) = 21.84, p_s < .001$). Moreover, a serial mediated moderation model (Hayes 2013) revealed that the interaction on behavioral intentions occurred because the deviation boosted perceived thoughtfulness, which in turn boosted perceived accuracy (95% CI: -1.80, -.96). These results are consistent with our

theorizing and inconsistent with a variety of potentially competing accounts, which we discuss.

Study 4 further tested the proposed theorizing: If the deviation effect occurs because deviation signals thoughtfulness, then evidence that a reviewer thought carefully about his/her recommendation should moderate the effect. To test this possibility, we presented participants with an 8-star (or 10-star) restaurant review on a website which had a 10-star evaluative default. Participants either read no further information, or read that the reviewer thought deeply about his rating. Separate 2 (Reviewer Evaluation: Moderate vs. Extreme) \times 2 (Thoughtfulness: High Thought vs. Control) ANOVAs revealed interactions on perceived thoughtfulness, accuracy, and desire to try the restaurant ($F_s(1, 396) > 22.53, p_s < .001$): In the control condition, participants perceived the 8-star review to be more thoughtful, accurate, and persuasive ($F_s(1, 396) = 13.37, p_s < .001$). In contrast, when participants learned that the reviewer devoted substantial thought to his review, participants perceived the review equivalently regardless of its deviance ($F_s(1, 396) > .40, p_s > .528$).

Taken together, these results reveal that the perceived default in a review context can play an important role in shaping people's willingness to be influenced by an extreme or moderate review.

Social Influence, Habits, and Disrupted Performance Environments

EXTENDED ABSTRACT

Sedentary lifestyle and the lack of physical activity are leading causes of preventable death globally (Lopez et al. 2001), triggering chronic diseases like obesity, type-2 diabetics and other cardiovascular conditions whose prevalence has become a major health policy challenge. For many people, failure to exercise is unlikely to be due to ignorance or lack of interest. While individuals are frequently motivated to start exercising in order to reduce and reverse different health risks, they often encounter difficulties in forming a sustained behavioral change.

In this research we analyze a unique, granular dataset of individual-level exercise data (primarily running) from millions of users worldwide to (a) measure the regularity of exercise behavior, (b) identify factors that predict a behavior continuing, (c) compare social influence in running for individuals with and without running habits, and (d) estimate the consequences of common disruptions to circumstances cues for habitual behaviors. This work thus uses a large, networked data set and modern causal inference techniques to address central questions in the psychology of habits with applications to interventions—especially social interventions—to influence exercise behavior and adoption of consumer exercise products.

We develop measures of regularity and predictability of behaviors suited to measuring habits in such large observational data sets. Much of the prior work on habits has relied on self-reported frequency and perceived automaticity (Hagger et al. 2015). Prior work on human mobility has measured predictability using discrete time, matrix factorization methods, and entropy of discrete variables (Eagle and Pentland 2009) that are not suited to studying the onset of particular behaviors marked by a time and other, often continuous-valued, contextual variables (e.g., location). For each individual, we fit a Gaussian mixture to the variables describing their behaviors and use the differential entropy of the resulting density as a measure of regularity and predictability of the context for exercise behaviors. This habit measure predicts future exercise behaviors better than mere frequency of prior exercise behaviors: more habitual users are more likely to persist in exercising (and tracking this) in the future.

We additionally compare this measure with other measures from prior work.

We study how individuals with different levels of measured exercise habits respond to disruptions to the performance environment for their behavior. In particular, we use the exogenous shock to the setting for running caused by the end of daylight savings time (DST), the timing and implementation of which varies within our data set (i.e., some countries and states in the U.S. do not observe DST, some locations observe it at different times). Among people who run in the same range of times in the afternoon, people with higher exercise habit measures are more affected by this disruption: they show a larger decrease in average running frequency.

We then estimate peer effects in exercise behavior. We use multiple specifications to increase the credibility of this estimation, including using individual fixed effect to control for time-invariant confounding, using random shocks to peers' running behavior caused by weather (for peers in different cities), and using variations in settings on users' mobile phones that determine their exposure to notifications about peer running. Consistent with prior work (Aral and Nicolaides 2017), we find substantial peer effects in this behavior: peers running causes increases in ego running on that and the subsequent day.

A novel substantive contribution of this work is to examine how peer effects are moderated by habits and the disruption of the performance context for the behavior. Based on prior work, we may expect sudden changes to the everyday environment that disrupt habits to sometimes lead to behaviors that more closely match people's goals. For example, Larcom, Rauch, and Willems (2015) find that a public transport strike caused many commuters to find new routes that were preferable to their old routes. Wood, Tam and Witt (2005) present evidence that disruptions to the performance context for a behavior can cause that behavior to become more consistent with a person's goals. Prior work (e.g., Verplanken and Roy 2015) has found increased effectiveness of interventions following such disruption (e.g., moving). If peer effects occur in part through changes in goals or other attitudes, we should expect that periods of disruption may increase susceptibility to this social influence. Thus, we combine the analyses described above to estimate differences in peer effects on egos with and without strong exercise habits and before and after disruptions. We find, in this work in progress, that these peer effects are moderated by these habit measures and exogenous disruptions.

In summary, this work contributes to understanding habits and when social influence is likely to occur. This has implications for psychological theory and for the design and targeting of interventions (e.g., when to present social information so as to change behavior).

SESSION OVERVIEW

"If you come at four in the afternoon, I'll begin to be happy by three." - Antoine de Saint-Exupery, The Little Prince.

Hedonic experiences are multi-faceted and often consist of a consumption timeline, rather than isolated events. This timeline entails anticipation, the experience itself, and the memories left behind. Consumers also make forecasts about their experiences and relevant features, such as mindfulness and consumption norms. Even within one phase of a hedonic experience, consumers encounter meaningful changes. Further, hedonic experiences do not always occur independently, and the nature of their overlap can affect the overall pleasure consumers derive from the combined engagements.

Thus, timelines of a consumption experience help shape its hedonic value. In this session, we ask, how do consumers evaluate their experiences at different stages on the consumption timeline, and what role do these evaluations play in the total hedonic value of their consumption experiences? Four papers examine how consumers ascribe value to features of the timeline, as well as the psychological processes by which such evaluations affect their hedonic experiences.

The first two papers speak to how consumers value different features of consumption experiences before, during, and after consumption. First, Ksendzova, Norton, and Morewedge examine how consumers view the relative contributions of anticipation, experience itself, and memory to total utility. They uncover a perceived primacy of experience – a belief that experience, regardless of its duration, contributes most to total utility.

Second, when anticipating an experience, consumers forecast their behavior. However, they cannot always properly anticipate key features of an experience. Meyvis and Yoon demonstrate that consumers overestimate the extent to which product quality affects their consumption amount. Specifically, consumers overestimate their mindfulness and the influence of consumption norms, while underestimating the role of visceral factors specific to the experience.

The following two papers zoom into the timeline within an experience itself. Wei and Häubl examine how knowing a pleasurable experience is approaching its end influences the enjoyment of it. Specifically, when consumers perceive low control over the hedonic quality, the passive contemplation of the imminent end reduces the enjoyment of it; however, when consumers perceive high control, it enhances the hedonic enjoyment through motivating consumers to make better usage of their time.

Further, timelines of hedonic consumption may overlap. Focusing on simultaneous consumption of multiple experiences, Smith and Redden demonstrate that holistic processing (vs. analytical processing) enhances the enjoyment of a combined experience, by increasing the perceived complementary and coherence of it.

Taken together, these papers contribute to a better understanding of how consumers evaluate a consumption experience and associated features while moving along its timeline. We approach this topic by discussing different phases of a consumption experience (Ksendzova et al.; Meyvis and Yoon), the time progression within an experience itself (Wei and Häubl), and combined timelines of multiple experiences (Smith and Redden). This session provides insights into the temporal dynamics of consumption experiences and guidance for marketers on optimizing consumers' hedonic consumption.

The Primacy of Experience: Comparing the Contributions of Anticipation, Experience, and Memory to Total Utility

EXTENDED ABSTRACT

In his conceptualization of the total utility provided by an event - the total pleasure or pain it afforded across its anticipation, experience, and recollection, Bentham (1789) envisioned a duration-weighted approach. In his view, the assessment of total utility should account for the intensity of pleasure or pain an event incurred at each moment in time by the amount of time pleasure or pain was incurred, irrespective of phase. Current proposals echo this suggestion, assuming that duration weighting is the optimal way to aggregate the total utility of events – the utility provided by their anticipation, experience, and recollection (Kahneman 1999). These models assume that people perceive utility derived from phases of experiences to carry the same weight, an assumption we test in our studies: do people believe that anticipation, experience, and memory contribute equally to total utility, or are some kinds of utility more impactful than other kinds?

In Study 1a ($N = 99$), we prompted participants to generate examples of three pleasant and three unpleasant experiences lasting five, twenty, or sixty minutes. For each experience, participants then rated the relative contribution of anticipation, experience itself, and recollection (between 0% and 100%) to the total utility provided by that event. A duration-weighting approach would suggest that the utility of experience should contribute less for shorter than longer events. Regardless of event duration, however, participants reported that experience contributes more to total dis(utility) than do anticipation and memory. Additionally, in Study 1b ($N = 100$), we examined events lasting seconds, minutes, hours, and days, and again found participants rated utility from experience to be the primary contributor, regardless of event duration.

Consuming Regardless of Quality: Consumers Overestimate the Impact of Quality Differences on the Amount Consumed

EXTENDED ABSTRACT

Consumers like quality. They often exert substantial effort to identify the highest quality product, and may pay a hefty premium to acquire it. This behavior is often justified as higher quality products result in more enjoyable experiences and increased satisfaction. Naturally, one would assume that this more *enjoyable* consumption would translate into an increased *amount* of consumption. The current research measures people's intuitions about this relationship between quality and consumption amount, and tests how these intuitions compare to the actual impact of quality differences on consumption.

We propose that people tend to overestimate the impact of quality differences on the amount that they consume. Specifically, we suggest that consumers overestimate the mindfulness of their repeated consumption decisions, which in turn leads them to underestimate the influence of visceral factors such as hunger and boredom (Loewenstein, Prelec, and Shatto 1998) and overestimate the influence of consumption norms (e.g., one should [not] consume high [low] quality products) (Kivetz and Tyler 2006). We tested this conjecture in four studies.

In study 1, participants ($N=156$) were given two cups with 31 jellybeans each. They tasted one jellybean of each of the two flavors, after which they indicated how much they liked each flavor and selected the flavor they preferred. Participants then predicted how many of the remaining jellybeans of each flavor they would eat during the rest of the session. They then proceeded with other, unrelated studies. At the end of the session, we measured the number of jellybeans each participant had consumed. As hypothesized, participants predicted that the quality difference would have a greater influence on their consumption ($M_{\text{Preferred}} = 13.4$, $M_{\text{Not Preferred}} = 8.1$) than it actually had ($M_{\text{Preferred}} = 14.0$, $M_{\text{Not Preferred}} = 10.3$; $F_{\text{Interaction}}(1,155) = 5.36$, $p < .05$). Although this suggests that actual consumption was less mindful and discerning than participants anticipated, it is also possible that participants underestimated their desire to seek variety. To rule out this possibility, the next studies varied quality between subjects, which meant that participants only consumed a single jellybean flavor.

In study 2, participants ($N=59$) again tasted one jellybean of two flavors and rated each flavor. They then indicated which flavor they preferred and predicted how many of each flavor they would eat if they were given a cup of 50 jellybeans. After that, they randomly received one of the two flavors to consume during the remaining time in the session. At the end of the session, we measured the number of jellybeans each participant had actually consumed. Participants again overestimated the impact of quality on their consumption; they predicted they would eat significantly more high-quality than low-quality jellybeans ($M_{\text{Preferred}} = 18.9$, $M_{\text{Not Preferred}} = 11.5$), but ended up eating slightly more of the low-quality jellybeans ($M_{\text{Preferred}} = 19.7$, $M_{\text{Not Preferred}} = 22.9$; $F_{\text{Interaction}}(1,57) = 10.75$, $p < .01$).

In study 3 ($N=110$), we extended our investigation to the consumption of cartoons that differed in entertainment value. Participants first saw five cartoons that were randomly drawn from one of two sets of 80 cartoons each. One set of cartoons were pretested to be high-quality (funny), while the other cartoons were pretested to be low-quality (not so funny). To view each cartoon, participants had to enter a short captcha, thus imposing a small cost. Participants next predicted how many of those cartoons they would select to watch (by entering the corresponding captcha) during the next 5 minutes. We

In addition to the perceived contributions of each phase, we examined people's choice between phases of an event in Study 2 ($N=200$). To do so, we first asked participants to generate examples of positive or negative events lasting seconds, minutes, hours, and days. For all listed events, participants then engaged in a thought experiment. Some imagined, for positive events, that they were able to feel pleasure during only one phase of their choosing. Others imagined, for negative events, that they were able to block negative feelings during one phase of their choosing. People more often chose to preserve positive experience and block negative experience, compared to anticipation and memory. Contrary to the duration-weighting approach, the choice of experience did not decrease among shorter events.

Then, in Study 3, we investigated whether people believe that a unit of experience, compared to equal units of anticipation or memory, has greater impact on total utility. We asked participants ($N=100$) to imagine going on an enjoyable date – a date which they hypothetically anticipate, experience, and recall each for three hours. Thus, duration of each phase was held constant. Next, participants imagined that one minute was randomly selected from the three hours of each phase and rated the intensity of that minute. For each phase (in random order), they also rated the intensity of five, fifteen, thirty, and sixty minutes. Although people perceived longer time segments as more desirable than shorter time segments, they rated segments of experience as more desirable than equal segments of anticipation and memory.

Considering that people may think of experience-centric events when judging the utility of phases, we also employed more conservative tests. In Study 4a, we asked one group of participants to name events for which a) anticipation, b) the experience itself, or c) its recollection defines the nature of that event. This procedure yielded a list of 270 events that varied on valence (pleasant and unpleasant) and their defining feature (anticipation, experience, or recollection). We then recruited an independent sample ($N=135$) and randomly assigned each person to evaluate a unique pair of pleasant and unpleasant events with emphasis on one of the three phases. For each event, participants rated the contribution of each phase as a percentage of an event's total utility. They perceived experience to contribute more to total utility than anticipation or memory for most events, and to be at least as important as anticipation and memory for events defined by anticipatory or memory-based components (e.g., giving a speech or a honeymoon). We conceptually replicated these findings in Study 4b ($N=100$), even though participants in this study rated events they themselves generated.

Next, we again examined weighting by choice. In Study 5 ($N=100$), participants generated three pleasant and three unpleasant events defined by anticipation, experience, or recollection. For each example, participants then engaged in a thought experiment. Some imagined (for positive events) that they were able to feel pleasure during only one phase of their choosing. Others imagined (for negative events) that they were able to block negative feelings during one phase of their choosing. For all positive and negative events, participants were in no cases more likely to preserve or block a phase other than experience. Participants chose to preserve positive experience and block negative experience for events defined by their experiential components. More surprisingly, they were also as likely to choose experience as they were to choose anticipation for anticipation-defined events or memory for memory-defined events.

Together, our findings shed light on a lay belief that experienced utility is the primary contributor to total utility, which contradicts the duration-weighted assumptions of class proposals of total utility.

then observed how many cartoons they actually watched from the remaining set of 80 low (or high) quality cartoons. The results replicated the jellybean findings. While participants expected to watch about 11 more cartoons when they were given a high-quality (vs. low-quality) set ($M_{\text{High-quality}} = 31.7$, $M_{\text{Low-quality}} = 20.8$), the number of cartoons they actually watched did not differ between two conditions ($M_{\text{High-quality}} = 27.3$, $M_{\text{Low-quality}} = 28.3$; $F_{\text{Interaction}}(1,109) = 7.14$, $p < .01$).

We have proposed that consumers overestimate the mindfulness of their consumption decisions and underestimate the impact of their visceral states (e.g., hunger and boredom) which are less discerning to the quality of the object being consumed. However, it is also possible that the overestimation of the impact of quality is instead being driven by participants' inadequate accounting for the effects of satiation. While the difference between the two jellybean flavors may be quite apparent initially, this difference may reduce over time as participants get satiated to the flavor they're consuming (DePaoli and Khan 2014). If participants do not take this into account, they may overestimate the impact of quality, especially with prolonged consumption. To test between these two accounts, study 4 measured how predictions and behaviors diverged over time.

In study 4 ($N=141$), rather than asking participants to make a single prediction, we now asked participants to predict about how much they thought they would eat in the first 5 minutes, 10 minutes, 15 minutes, and 20 minutes of the session. Likewise, the actual consumption was also measured four times. Consistent with underestimating the (non-discerning) impact of hunger, but inconsistent with underestimation of satiation, the overestimation of the impact of quality was most pronounced for the *initial* consumption phase. During the first five minutes of consumption, quality had less impact on behavior than participants predicted ($M_{\text{Preferred}} = 5.2$, $M_{\text{Not Preferred}} = 3.5$ vs. behavior: $M_{\text{Preferred}} = 3.7$, $M_{\text{Not Preferred}} = 3.1$; $F_{\text{interaction}}(1,136) = 3.73$, $p = .056$) but this was not the case during the last 15 minutes of consumption (prediction: $M_{\text{Preferred}} = 8.5$, $M_{\text{Not Preferred}} = 6.6$ vs. behavior: $M_{\text{Preferred}} = 5.6$, $M_{\text{Not Preferred}} = 3.8$; $F_{\text{interaction}} < 1$).

Together, these studies indicate that consumers tend to overestimate the impact of quality differences on their consumption amount, an effect that seems to be driven by consumers' underestimation of the impact of (non-discerning) visceral motivations.

The Imminent-End Effect: How the Approaching End of an Experience Affects Enjoyment

EXTENDED ABSTRACT

How does knowing a pleasurable experience is coming to an end influence its enjoyment? The answer was discussed with consumption experiences that entail repeated episodes of a homogenous nature: consumers enjoy a consumption episode more when they know that it is the last one (O'Brien and Ellsworth 2012; Tsai and Zhao 2016). However, the answer is not clear when an experience is non-repetitive and heterogeneous in nature (e.g., vacations, movies, musical performances, and games). Common intuition suggests that the imminent end of a pleasurable experience can have a detrimental effect on enjoyment, particularly. For example, consumers often dread the end of a vacation and feel sad on the last day. The current research introduces a theoretical framework for how and why the imminent end of a heterogeneous experience impacts consumers' enjoyment of it.

We propose that a key factor that governs this "imminent-end" effect is the extent to which consumers feel that they can control the hedonic quality of a consumption experience. This subjective judgment of perceived control is influenced by the nature of the experience and by situational factors. We hypothesize that when perceived

control over the hedonic quality of an experience is low, consumers' enjoyment of it depends on the allocation of undivided attention to the specifics of the experience. This is because, when consumers know that a pleasurable experience is approaching its end, the frequent contemplation of the imminent end interferes with them devoting their undivided attention to the experience, thus reducing their enjoyment. By contrast, when perceived control is high, the imminent end increases the perceived scarcity of the experience, thus motivating consumers to make better use of their time, ultimately enhancing their enjoyment of it (Kurtz 2008). Four experiments provide evidence for these predictions.

Experiment 1 demonstrates the hypothesized interaction between imminent end (yes vs. no) and perceived control (high vs. low) in a 2 x 2 between-subjects design. The imminent end was manipulated through progress bars of different lengths: for the same experience, participants saw a progress bar either progressed to its end (imminent end condition) or progressed to its midpoint (no imminent end condition). The perceived control was manipulated through experiences types: in the low perceived control condition, participants watched an enjoyable video; and in the high perceived control condition, participant played a Tetris game that was pretested to be equally enjoyable. We sampled participants' enjoyment every 30 seconds on an 11-point scale (0-not at all; 10-very much), the *last* measure of which served as the key dependent variable. Results show that the imminent end reduced enjoyment when perceived control was low ($M_{\text{End}}=7.61$ vs. $M_{\text{NoEnd}}=8.14$; $t(359)=-2.13$, $p=.035$), and increased enjoyment when perceived control was high ($M_{\text{End}}=7.51$ vs. $M_{\text{NoEnd}}=6.88$; $t(359)=-2.16$, $p=.032$).

Experiment 2a examines the psychological process underlying the negative effect of the imminent end. To do so, we introduced experience discretization as a moderator. As we predict that an imminent end reduces consumption enjoyment by interfering with consumers' undivided attention, partitioning an experience into discrete segments should facilitate consumers' concentration on the ongoing segment, instead of the distracting information of the imminent end. Experiment 2 employed a 2 (imminent end: yes vs. no) by 2 (experience framing: discretization vs. continuous) between-subjects design, in which all the participants viewed a funny video. In the discretization condition, we partitioned the same video into 30-second segments and told participants to expect to view 5 (imminent end) or 10 (no imminent end) separate videos. When the video-watching experience was framed continuously as a whole, replicating Experiment 1, the imminent end reduced the enjoyment of this video-watching experience ($M_{\text{End}}=7.15$ vs. $M_{\text{NoEnd}}=7.93$; $t(302)=-2.05$, $p=.041$). When the same experience was framed as discrete segments, the imminent end no longer influenced enjoyment of the video-watching experience ($M_{\text{End}}=7.98$ vs. $M_{\text{NoEnd}}=7.37$; $t(302)=1.53$, $p=.13$).

Moreover, a bootstrap analysis ($N=5,000$) found that discretization interacted with imminent end to influence the level of distraction participants had in the video-watching experience ($b=1.39$, $p=.03$), which reduced enjoyment of the video ($b=-.13$, $p=.02$). We also found evidence of distraction in a separate follow-up experiment (2b) with video-watching, such that participants needed to click a button to check how much time left. Participants in the imminent end condition checked the progress bar more often than those in the no imminent end condition ($M_{\text{End}}=7.17$ vs. $M_{\text{NoEnd}}=7.78$; $t(221)=-2.01$, $p=.045$), and enjoyed the experience less ($M_{\text{End}}=5.21$ vs. $M_{\text{NoEnd}}=3.61$; $t(221)=-2.16$, $p=.032$).

Experiment 3 extends this imminent end effect into a new domain—food consumption—and shows how an imminent end can enhance enjoyment, using a 2 (imminent end: yes vs. no) by 2 (se-

lection: yes vs. no) between-subjects design. Participants were asked to sample 5 (imminent end) or 10 (no imminent end) different snacks from a list of 15. In the selection condition, participants chose their preferred snacks and the order to sample them, whereas in the no selection condition, participants sampled a randomly selected set of snacks. The key dependent variable was the enjoyment of the 5th snack. Consistent with results in Experiment 2, when the snack-sampling experience was passive and consisted of discrete segments, the imminent end had no influence on its enjoyment ($M_{\text{End}}=7.41$ vs. $M_{\text{No-End}}=8.18$; $t(158)=-1.68$, $p=.095$). When participants could choose what to consume, the imminent end motivated participants to save the best for the last, thus enhancing the enjoyment of the snack-sampling experience ($M_{\text{End}}=8.88$ vs. $M_{\text{NoEnd}}=8.12$; $t(158)=2.16$, $p=.033$).

To summarize, this research sheds light on how an imminent end influences the hedonic enjoyment of a consumption experience. Evidence from 4 experiments shows that the imminent end reduces enjoyment when perceived control over the hedonic quality of the experience is low, and that the imminent end can increase enjoyment when perceived control is high. These findings add to our understanding of how imminent end shape consumption experiences and can guide managers in creating more enjoyable experiences for consumers.

The Role of Holistic Processing on Enjoyment During Simultaneous Consumption

EXTENDED ABSTRACT

People frequently consume multiple things simultaneously, from eating chips while watching television to listening to classical music while strolling through an art museum. This multi-tasking or multi-consuming is increasing (Nielsen 2010), to the point where 77% of the time spent watching television now also involves the use of another screen (Google 2012). Some samples report 46% of their meals are consumed while watching television (Gore et al. 2003), and television watching while snacking is even more prevalent (French, Story, & Jeffery 2001). Although joint consumption experiences are quite common, little research has explored the calculus for how two separate experiences combine to create overall enjoyment. We draw on research on holistic versus analytic processing styles to propose that enjoyment depends on whether the combined experience is processed in a holistic fashion or an analytic fashion.

Holistic processing involves focusing on the relationship between an object and its field or between components of an object. Analytic processing involves a detachment of an object from its context and the construal of components as independent entities (Nisbett et al. 2001). Interestingly, past research generates conflicting predictions for whether people would enjoy a simultaneous consumption experience more when processing holistically or analytically. On one hand, research on mental accounting suggests that two distinct positive experiences have more hedonic impact than a single one combining them (Thaler 1985; Thaler 1999). This would seemingly predict that expected and realized enjoyment would increase with analytic processing that highlights each contribution to enjoyment. On the other hand, holistic thinkers focus on relationships between objects and are more sensitive to interdependence (Chiu 1972; Masuda and Nisbett 2001), which, for example, results in increased perceptions of fit for brand extensions, especially those with low fit (Monga and John 2007). If these same mental processes increase the perceived complementarity of the multiple consumption objects, or the coherence of the whole experience, holistic thinking may be expected to enhance enjoyment.

We explored these questions in two studies that involved simultaneous consumption of multiple stimuli. We found that people enjoyed and desired simultaneous consumption more when they viewed the experience holistically as an integrated experience (versus analytically processed as multiple distinct components). This holistic approach, and the resulting increased enjoyment, can be encouraged through processing style primes or individual trait differences. We develop process evidence showing that these effects for enjoyment are driven by joint categorization into a single integrated experience, which then makes the components seem more related and hence more enjoyable together.

In study 1, 201 MTurk workers began with a Navon task that primes holistic versus analytic processing (Navon 1977). On the computer, participants were presented with a series of “global” letters made up of smaller “local” letters (e.g., a ‘V’ shape made out of ‘D’s). Over 44 trials, participants were asked to report as quickly as possible whether the stimulus contained either of two focal letters. These target letters were always the global letter (e.g. ‘V’) for participants in the holistic processing condition, and always the local letter (e.g., ‘D’) for participants in the analytic processing condition. Participants then spent two minutes simultaneously watching a montage of Monet paintings and listening to classical music. As expected, participants who were primed to process the combined experience holistically enjoyed it significantly more ($M=75.3$) than participants who were primed to process it analytically ($M=61.72$, $t(96)=3.03$, $p=.003$). They also rated the experience as more of a single coherent experience ($p=.024$), and reported focusing marginally more on the overall experience versus individual parts ($p=.097$). These variables both significantly mediated the increased enjoyment, whether analyzed together, independently, or serially.

In study 2, 179 undergraduate participants watched a video of surfing footage and listened to upbeat instrumental rock music for two minutes. They then rated their enjoyment, several process measures, and then completed the “locus of attention” subscale of the Analysis-Holism Scale (AHS; Choi, Koo, and Choi 2003), which measures tendencies toward analytic versus holistic thinking. It includes items such as “it is more important to pay attention to the whole than its parts” (1 = strongly disagree, 7 = strongly agree). The tendency to focus on stimuli in a holistic way, as indicated by higher scores on the AHS, was associated with more enjoyment of the combined experience ($r=.24$, $p=.001$), more construal of the combined experience as a single coherent experience ($r=.34$, $p<.001$), and more focus on the overall experience versus the individual parts ($r=.34$, $p<.001$). This pattern conceptually replicated the results of study 1. Additional measures revealed that higher scores on the AHS were also associated with an increased perception of complementarity between the two stimuli (measured by three items: complementarity, whether the stimuli made each other better, and whether they belong together; $\alpha=.92$; $r=.33$, $p<.001$), and the perception that attention was paid to both stimuli simultaneously as measured by summing the amount of attention paid to each stimuli ($r=.17$, $p=.02$). A variety of mediation models suggest that holistic processing enhances enjoyment of combined stimuli by increasing the perceived complementarity of the multiple stimuli and coherence of the combined experience.

Holistic processing involves focusing on the relationship between objects (Nisbett et al. 2001), and we show it enhances enjoyment of combined experiences by increasing the perceived coherence between the multiple stimuli. This finding is consistent with research highlighting the benefits of perceived coherence between consumption objects (Rahinel and Redden 2013). However, it is somewhat surprising that enjoyment of combined experiences is higher when

they are construed as a single coherent experience (versus multiple distinct experiences occurring simultaneously) based on mental accounting research suggesting that pleasant experiences should be mentally segregated (Thaler 1999). From a theoretical standpoint, this research brings holistic processing theories to bear on multi-tasking and consumption enjoyment. It also carries implications for both marketers and consumers seeking to maximize enjoyment. Additional studies will be conducted before the conference to examine both the effect of holistic processing on enjoyment for singular experiences, and the potential moderating role of whether the combined stimuli are seen *a priori* as complementary.

SESSION OVERVIEW

Consumers regularly engage in prosocial actions. For example, 62.8 million Americans volunteered 8 billion hours, and over half the population donated at least \$25 to charity in 2014 (Corporation for Community Service, 2015). One important influence on consumers' decisions to give and continue giving is their perceived social impact. People's motivation to help increases when they feel effective in helping others (e.g., Grant et al. 2007); on the other hand, prosocial efforts decrease when consumers believe their help is not (or will not be) effective (e.g., Gneezy, Keenan and Gneezy 2014). However, relatively little is known about how consumers form judgments about the (in)effectiveness of their helpful behavior. In this symposium, we ask, what are some psychological processes by which people evaluate their helping effectiveness? If such judgments of impact are misguided, how can we overcome them?

The first two papers focus on psychological processes in evaluating helpfulness. Ksendzova and Trudel examine how bundling charitable donations with personal benefits affects consumers' judgments of helpfulness. For instance, charities can reward donors with tangible thank-you gifts. These gifts are costly to the charity, but such benefits serve as tokens of prosocial impact – consumers perceive donations paired with personal gains as more helpful than solitary donations of equal or greater value. In the second paper, Olivola and Saccardo find evidence that consumers evaluate helpful actions in isolation rather than by their cumulative benefits. This narrow bracketing leads consumers to more positively evaluate people who are less impactful in their giving. For instance, people judge benefactors more positively when they first allocate more money to a privileged peer but subsequently donate less money to charity, compared to benefactors who give more to charity by withholding money from the privileged peer.

The last two papers provide strategies for overcoming psychological roadblocks to prosociality. For instance, even though charities' overhead costs are not antithetical to their impact, consumers are generally reluctant to cover overhead. Keenan and colleagues find that giving consumers a choice to support overhead helps mitigate this aversion. The option to earmark a portion of their donation toward overhead costs increases not only the amount given toward overhead, but overall giving, suggesting that consumers may feel

more supportive of funding overhead when it is an active choice. Finally, Donnelly and colleagues demonstrate that giving time, compared to giving money, better fosters a feeling of impact when affirming cues are absent. When consumers give time, vividness of the cause and emotional engagement strengthen and, in turn, so does perceived impact. Giving money does not engage the self, making consumers sensitive to vivid markers of impact (e.g., having contact with beneficiaries); in contrast, givers of time can sustain prosocial motivation without such markers.

Together these papers identify factors that influence perceived impact: some misguide consumers' judgment (i.e., donation-benefit bundling and narrow bracketing), but others overturn concerns of low impact and ultimately increase prosociality (i.e., overhead choice and giving time). The findings have important implications for improving prosocial efficacy, and the session should appeal to scholars interested in decision-making, prosocial behavior, and their overlap.

“My Donation is More Helpful if I Benefit”: Personal Gains Signal Impact of Prosocial Spending

EXTENDED ABSTRACT

People want their altruism to be effective - to maximize the prosocial impact of their actions. In turn, perceived helpfulness serves as an important reinforcer of prosocial behavior (Grant et al. 2007), but impact is often difficult to assess (Caviola, Faulmüller, Everett, Savluescu, and Kahane 2014). Instead, consumers rely on various proxies of impact. For instance, information that cues efficient use of resources, such as charities' overhead expenses, can guide donation decisions (Gneezy, Keenan, and Gneezy 2014). Secondly, psychological rewards, such as expressions of gratitude, can affirm helpfulness and fuel prosocial efforts (Grant and Gino 2010).

However, affirming rewards for benefactors can sometimes entail overhead costs that detract from optimal help to the beneficiaries. In the present research, we focus on two contexts in which prosocial behavior is matched with personal benefits that can decrease its efficacy. The first is a situation in which donors receive gifts for their contributions – gifts that incur costs to the fundraising entity. The second context is the purchase of discretionary cause-marketing (CM) products, in which a portion of the price is allocated to prosocial causes. Consumers classify CM spending as prosocial, but CM options can yield lower net donations to the target charity, compared to direct-giving options (Krishna 2011). In both contexts, consumers acquire a costly reward, be it an unintended gift or an intentional purchase. When prosocial spending is bundled with the acquisition of such goods, how do consumers evaluate their helpfulness?

In Study 1, passers-by on a university campus were invited to donate \$1 to a non-profit organization training guide dogs for the blind. Donors ($N=62$) were assigned to one of two experimental conditions: some received a pen, as a thank-you gift for donating, and others did not. Important to note is that all participants were unaware of gift prior to donating. We found that participants who received a pen reported perceived the same \$1 donation as more helpful, compared to participants who did not receive a pen, even when controlling for their affective state (i.e., feeling happy, moral, proud, and compassionate).

Next, we sought to replicate the effect of gains signaling value in a larger sample and extend it to a cause-marketing context. In Study

2 ($N=166$), all participants imagined contributing to the charity UNICEF in one of three ways: donating \$10 and subsequently receiving a mug from UNICEF (gift condition), purchasing a \$10 mug of which the entire \$10 are then donated (CM condition), or simply donating \$10 (control). Despite these donation amounts and total spending being equal across conditions, participants who imagined acquiring a mug, either as a gift or a purchase, rated their contribution as more helpful than participants in the control condition.

Further, in Study 3 ($N=375$), we investigated whether perceived impact is boosted specifically by donations bundled with gains rather than generally coupled with other expenses. Thus, we assigned participants to evaluate one of five donation forms: donations paired with gains (i.e., purchases of mug or a t-shirt), paired bundled with losses (i.e., parking tickets or library fines), or unassociated with either. Again, we held total donation amounts and total spending constant at \$10. As before, participants perceived donations matched with gains as more helpful to the recipient charity than stand-alone donations of the same value. However, donations matched with losses were similar to direct donations in terms of perceived helpfulness.

Subsequently, the aim of Study 4 ($N=402$) was twofold. One purpose was generalizing the effect to another CM purchase frame, in which a portion of sales (rather than a portion of the price paid by an individual consumer) is donated to the target charity. The second was to examine if people may evaluate smaller donations bundled with personal gains as more helpful than larger donations without an associated gain. Participants imagined donating to UNICEF in one of four ways. Some imagined (a) simply donating \$1 and others considered buying a \$10 mug, from which either (b) 10% of the mug price, (c) 10% of all mug sales, or (d) 5% of all mug sales were donated to UNICEF. In all three CM conditions, the prosocial initiative applied to 1,000 mugs and, thus, participants would have contributed (b) \$1, (c) \$1, or (d) \$0.50, respectively. Compared to participants in the direct \$1 donation condition, those for whom the donation was bundled with gaining a mug rated their donations as more helpful – even participants donating \$0.50. Thus, if donations are matched with personal gains, people may feel more helpful while behaving in an objectively less-helpful fashion.

Further, we asked, do gains serve as value reflectors or value tokens? In other words, does perceived utility for others increase alongside utility for the self, or does the mere presence of a personal gain affirm consumers' sense of impact? In Study 5 ($N=283$), we assigned participants to one of three scenarios with a \$5 donation to a local school: simply donating \$5 (control), donating \$5 and receiving 1 chocolate as a gift (smaller benefit), or donating \$5 and receiving 5 chocolates (larger benefit). Participants judged donations bundled with chocolate as more helpful than stand-alone donations but were insensitive to chocolate quantity. Thus, these results support a value-token account.

In conclusion, these findings suggest that personal gains can falsely signal prosocial impact to benefactors, counter to the goal of effective altruism. Investigation of this phenomenon contributes to the body of research examining the cues people rely on to judge prosocial efficacy, as well as biases in prosocial decision-making. Moreover, an open question remains: despite their suboptimal efficacy in the short-term, may such practices help sustain recurring prosocial spending among consumers who, otherwise, would not give directly? Taken together, this research stream has valuable implications for marketing tactics aimed at prosocial engagement, valuation of prosocially-linked products, and the intersection of the two.

Narrow Bracketing in Ethical Trade-Offs

EXTENDED ABSTRACT

Prior research shows that consumers tend to approach purchasing and consumption decisions in isolation (narrow bracketing) rather than as part of a larger set of choices (broad bracketing) (Read, Loewenstein, & Rabin, 1999). Here, we demonstrate that narrow bracketing also affects ethical tradeoffs. Specifically, we show that consumers evaluate decision makers faced with ethical tradeoffs in terms of their isolated outcomes, rather than their aggregate impact. However, when the same ethical tradeoffs are presented in a broad bracketing frame, these consumers indicate a strong preference for maximizing total welfare, contradicting their earlier evaluations based on narrow bracketing.

In our studies, we compare and contrast the moral evaluations of consumers who make decisions that appear unethical in isolation but maximize total welfare, with those of consumers who make decisions that appear ethical in isolation but ultimately produce lower welfare gains.

In Study 1 ($N = 283$), participants read about an individual (the protagonist) from a relatively privileged community who faces two ethical tradeoffs: first, a constrained allocation decision in a laboratory 'dictator game' (DG) study, in which the protagonist decides how much of a starting bonus (i.e., a windfall gain) to send to an anonymous other person from the same privileged community; second, an unconstrained allocation decision, in which the protagonist decides how to spend the money that was earned in the DG study. We independently varied both the first and second allocation decisions, using a fully-between-subjects design. For the first allocation decision in the DG, we varied whether the protagonist decides to keep the entire bonus, share half of it, or send all of it to the anonymous other person. For the second allocation decision, we varied whether the protagonist spends all his/her DG earnings on him/herself OR donates all his/her DG earnings to charity.

After reading one these (randomly assigned) scenarios, participants were asked to evaluate the protagonist on 16 dimensions (using a -5 to +5 rating scale), such as morality, warmth, cooperativeness, likability, etc. These ratings were highly correlated (Conbrach's $\alpha = .99$) and formed a single factor (99% of eigenvalues), so we averaged them to produce a single measure of 'positivity-negativity'. Later in the study (after completing several unrelated questionnaires), participants were asked how they would choose to allocate a sum of money equal to the DG bonus between (i) an anonymous other person from the same relatively privileged community and (ii) charity.

If participants consider the protagonist's two actions in isolation, we would expect their evaluations to 'penalize' an initial decision to keep money in the DG and 'reward' a later decision to donate the money earned in the DG to charity. As a result, protagonists who shared or gave away their DG bonus, then later donated their remaining earnings to charity, would be perceived as having made two ethical decisions, and thus evaluated very positively, despite giving relatively little to charity. By contrast, protagonists who kept all the DG bonus money, but then donated it all to charity, would be perceived as having made an unethical decision followed by a (separate) ethical decision, and therefore not evaluated as positively. If, instead, participants evaluated the protagonist's actions from a broad bracketing perspective, they would realize that the protagonist who keeps the DG bonus money and donates it all to charity ends up having a larger positive impact on total welfare than one who cooperates in the DG then donates the smaller resulting earnings to charity.

We found that protagonists who gave half or all of their bonus in the DG then donated their (smaller) earnings to charity (ethical +

ethical) were evaluated more positively than those who gave nothing in the DG but then donated more to charity (unethical + ethical) ($M = 3.64$ vs. 0.82 , $t(132) = 7.59$, $p < .001$), indicating that participants evaluated these outcomes from a narrow bracketing perspective. Even protagonists who acted altruistically in the DG but then spent their DG earnings (ethical + neutral) were evaluated more positively ($M = 3.18$) than keep-donate protagonists ($p < .001$). However, when the decision problem was presented as a single, aggregate choice (broad bracketing), these same participants overwhelmingly revealed a strong preference for prioritizing charity over the anonymous recipient: 75% indicated that most of the money should go to charity.

In Study 2 ($N = 254$), we replicated this pattern with a 'trust game' (TG) scenario: protagonists who cooperated in the TG (returning half or all of the tripled sum they were sent) then donated their (smaller) earnings (ethical + ethical) were evaluated more positively than defectors who donated more to charity (unethical + ethical) ($M = 3.72$ vs. 0.13 , $t(130) = 10.38$, $p < .001$). Protagonists who cooperated but spent their TG earnings (ethical + neutral) were also evaluated more positively ($M = 3.32$, $p < .001$). Again, presenting the decision problem as a single, aggregate choice led participants to prefer a very different allocation: 79% indicated that most of the money should go to charity.

In Study 3 ($N = 152$), we show that protagonists who share half the bonus in the DG then spend their remaining earnings (ethical + neutral) are evaluated more positively than those who keep the DG bonus money but then anonymously give it all away (plus their show-up fee) to an individual randomly drawn from the same community as the other DG player (unethical + ethical) ($M = 3.39$ vs. 1.20 , $t(101) = 6.04$, $p < .001$), but no more positively than protagonists who earn money from an unspecified lab-study and anonymously give it all away (neutral + ethical) ($M = 3.39$ vs. 3.15 , $t(101) < .6$).

In sum, we find that consumers tend to evaluate ethical tradeoffs using a narrow bracketing frame (by tallying the number of ethical vs. unethical outcomes), which leads them to penalize welfare improving actions that consist of smaller decisions that appear unethical in isolation. When consumers are presented with a broad bracketing version of these same ethical tradeoffs, however, they indicate a strong preference for the welfare maximizing option.

Overcoming Overhead Aversion with Choice

EXTENDED ABSTRACT

Individuals are averse to overhead such that donations decrease as overhead increases, though only when donors' personal contributions are used to cover overhead (Gneezy, Keenan, and Gneezy, 2014). Gneezy et al. (2014) suggest donors are motivated to give based on the impact they feel when they know they are helping the cause directly. As a result, informing donors that an initial large donation has been used to cover overhead costs, making their potential donation "overhead-free", significantly increases giving compared to traditional fundraising techniques. While effective, the "overhead-free" approach simply bypasses individuals' reluctance to donate due to overhead-related concerns rather than targeting the aversion itself.

The current research aims to explore ways to overcome overhead aversion while simultaneously conveying the message that allocating money to overhead is important. Making donations overhead-free attracts a substantially higher fraction of donors compared to a standard solicitation as well as other traditional fundraising techniques (2014). This suggests that in addition to donors that choose to donate despite overhead, there are donors that would donate in the absence of overhead or would donate if they had the option to

direct their entire donation to cause specific programming rather than overhead. In this project, we test whether offering donors the choice to support overhead is an effective tool for overcoming donors' aversion to overhead and ultimately increasing donations.

We posit that offering donors the choice of whether and how to allocate a donation to overhead would be successful for three reasons. First, offering donors the choice to allocate money to overhead allows the option of making the donation overhead-free, thereby attracting donors who are particularly averse to overhead expenses. Second, offering choice will likely capture a subset of individuals who are conscious about the importance of overhead, but have preferences as to the relative magnitude of this type of expenditure. These donors may opt to allocate at least a portion of their donation to overhead, making this strategy overall more successful than the less sustainable strategy of making the donation overhead-free. Third, similar to other consumer contexts where choice has been observed to increase intrinsic motivation, perceived control, and satisfaction (Deci, 1975; Deci and Ryan, 1985), giving donors agency could generally increase donations (see Eckel, Herberich and Meer, 2016).

In Experiment 1 we investigated individuals' beliefs regarding the likelihood that the average donor would donate and how impactful donors would feel if they could choose whether and how to allocate a donation to overhead. In an incentive compatible, within-subjects design participants ($N=56$) read three scenarios regarding an opportunity to donate to the Make-a-Wish Foundation (MAW) in which a) the donation's overhead allocation was fixed (i.e., Control), b) the donation was overhead free (i.e., OH Free), and c) the donor could choose how much of their donation to allocate to overhead (i.e., Choice). Participants were then asked (1) how likely they thought the average individual would be to donate to the MAW and (2) how impactful they thought the average individual would feel if they decided to make a donation, using 5-pt scales for each. We incentivized participants to report beliefs about how an average donor would behave by paying them a bonus if their responses matched the responses given by the majority of other participants in the study.

Results show participants believed donors would be significantly more likely to give in the OH Free ($M=4.35$) and Choice ($M=4.16$) conditions compared to the Control ($M=3.66$; both $p < .001$). The difference between OH Free and Choice was also significant, $p=.04$. Likewise, participants believed donors would feel more impactful in the OH Free and Choice conditions compared to the Control (both $p < .001$).

In Experiment 2 we explored the effect of offering potential donors the choice of how to allocate their donation to a hypothetical charity. This was a 2x2 between-subjects design in which we manipulated overhead level (low OH-5%, high OH-55%) as well as the opportunity for participants to choose how much of their donation they would like to put toward overhead expenses (no option, option) vs. programmatic expenses. Participants ($N=401$) were randomly assigned to read one of four different donation solicitations from Fight Hunger, a hypothetical hunger charity. Participants were then asked if they would donate, (if yes) how much they would donate, and (if in the option conditions) the percentage of their donation that they chose to be used to cover overhead.

Among those that choose to donate, we find main effects of choice—participants donated more on average if they could choose their overhead level ($M_{choice} = 24.11$ vs. $M_{nochoice} = 16.89$, $p=.04$), and if we break down the amount raised by type of expense, overhead vs. programmatic, more money was allocated to programmatic expenses with choice ($M_{choice} = 17.47$ vs. $M_{nochoice} = 11.76$, $p=.05$). Importantly, allowing choice did not negatively impact how much was raised for

overhead. There was no difference, for instance, in the amount raised for overhead between the high OH, no choice and high OH, choice conditions.

In Experiment 3, we tested the effect of choice using a consequential design in which participants worked on a bonus task and had a real opportunity to donate \$3 of their \$10 earnings to MAW. All participants (N=916) were randomly assigned to one of three conditions, similar to Experiment 1 – Control, OH Free, and Choice. Among those that passed a manipulation check, we find a marginal effect of Choice donation likelihood. Participants were more likely to donate \$3 in the Choice (62%) than in the Control condition (54%; $p=.08$). There were no differences between OH Free (61%) and Choice or Control (p 's=.82 and .14, respectively). The average allocated to overhead in the Choice condition was 20% compared to MAW's actual overhead of 21%.

The results of these three experiments suggest that offering choice may be one way to increase the likelihood that donors, who are deterred by OH expenses, will give and how much they give. We aim to bring this intervention to the field to test choice with real donors.

Giving to Receive: Moral Self-Regard and Positive Affect Increase when Giving Time but not Money

EXTENDED ABSTRACT

While consumers devote a considerable amount of their resources toward non-profit helping, they also spend money and time on other people, such as purchasing gifts for family, friends and acquaintances (Gino and Flynn, 2011), and through random acts of kindness (Lyubomirsky et al. 2005).

What, however, does the act of giving time and money say about ourselves? How do consumers view their own prosocial actions in light of their moral identity? And what difference does it make to give money or time to someone in need? In this paper we investigate the effects of giving both money and time on moral identity and positive affect. Our main result is that giving time and money are not perceived as equally moral: consumers experience more moral self-regard, and as a result, more positive affect when they give time than when they give money. Building on previous research, we suggest that giving time leads consumers to reflect on who they are, which impacts their view of their moral self and increases positive affect.

While previous work has provided evidence that moral identity is related to prosocial behaviors (e.g., Aquino et al. 2009), and concepts of time are more closely related to morality (Gino and Mogilner 2014), we extend this work by evaluating how the experience of giving money and time affects moral self-regard. We propose that the process of giving time activates moral self-regard more than giving money, and as a result leads to greater positive affect.

In Study 1 (N=299) participants were asked to reflect on a recent experience where they gave (received) money (time). Participants in the giving conditions were asked to write about a time when they gave some time (money) to someone else. In the receiving conditions participants were asked to reflect on an experience where they received some time (money) from someone else. Following the reflection task participants indicated to what extent the event they described made them feel moral self-regard ($\alpha=.95$; Gino, Kouchaki, and Galinsky, 2015) and to the extent they experienced positive affect ($\alpha=.91$; Gino, Kouchaki, and Galinsky, 2015). We observed a significant interaction between resource and action. Receiving felt equally moral in regards to time and money, but givers felt more moral when giving time than money. With happiness, receivers felt equally happy with time or money, but givers of time were signifi-

cantly happier than givers of money, and this effect was mediated by the increased experience of moral self-regard.

In Study 2 (N=244), participants made a voluntary contribution to a student applying for college and needed assistance with college application essays. Participants were randomly assigned to give money (\$3) to help hire a copy editor who would edit and provide feedback on their statement of purpose, while participants in the giving time condition were asked to donate 10 minute of their time to edit the statement themselves. Givers of time felt more moral self-regard following their donation than those in the money condition, and also experienced greater positive affect. As in Study 1, we find that moral self-regard mediated the differences in positive affect between the giving conditions. One shortcoming of Study 2 is that the giving time condition might be seen as a more direct form of giving relative to the money condition. Given that recent research suggests consumers prefer to give directly to a cause (Gneezy, Keenan and Gneezy, 2014), we sought to tease apart the effect of direct giving in our next experiment.

In Study 3 (N=234), participants were given an opportunity to make a voluntary donation to a local hospital. Based on a pretest, participants in the direct money giving condition were asked to give a dollar to direct service care for patients of the hospital, while those in the indirect money giving condition were asked to give a dollar to overhead costs associated with direct service care for patients of the hospital. In the direct giving of time condition participants were asked to write get well post cards to patients of the hospital, and those in the indirect giving condition were asked to address the get well postcards to patients of the hospital. Impressions of moral self-regard were higher for time participants than money participants, but there was no main effect on directness of giving. With happiness, participants who gave time were happier than money, but there was a significant interaction by directness of giving. While participants were equally happy giving time directly or indirectly, with money, participants were much more happy giving money directly than indirectly. To understand the underlying mechanism as to why participants experience more moral self-regard giving time relative to money, we conducted a mediation and found that giving time is a much more vivid process than giving money, and also engenders more sympathy and greater impressions of making a significant impact to the cause. However, making an impact was significantly related to moral self-regard while vividness and sympathy were not. This suggests that the process of giving time feels more impactful, which in turn make consumers feel moral, making them less sensitive to certain details of the giving process such as contributing to direct service versus indirect service tasks. In turn, we find that impressions of moral self-regard mediate the positive boost experienced by the giving time conditions.

Across three studies we find evidence that giving money and time are experienced differently by consumers, with time engendering much more moral self-regard than money. In turn, consumers feel happier giving their time in part because the process of giving time feels more impactful than giving money.

SESSION OVERVIEW

Life is rife with risk and uncertainty. No one knows what will happen tomorrow; it could be a peace treaty or a declaration of war, and it may bring sun or rain. Despite decades of decision research exploring how consumers contend with risk and uncertainty (e.g., Loewenstein et al. 2001; Gonzalez and Wu 1999; Gneezy, List, and Wu 2006; Kahneman and Tversky 1979; Thaler and Johnson 1990; Tversky and Kahneman 1992; Weber, Blais, and Betz 2002), some fundamental questions remain open: What are “risk” and “uncertainty” in people’s minds? And, how do people learn to make decisions under risk and uncertainty repeatedly?

Papers in this session seek to shed lights on these core questions. The contribution of this session is threefold: Theoretically, we aim to reveal the unexplored drivers of risk-taking behaviors and enrich the literature on consumer decision making under uncertainty. Methodologically, we employ a combination of experimental design, empirical modeling, and neural examination to forge a more nuanced understanding. Practically, we aim to provide data-driven recommendations and advice for marketers and policymakers to better understand and utilize risk and uncertainty.

How do people “feel” about risk? The first paper, by **Kupor, Liu, and Amir**, demonstrates that although risk and uncertainty elicit fear, interruptions (e.g., a phone call) during the decision-making process allow for mere exposure processes to temper this apprehension, consequently increasing individuals’ willingness to take risks.

What do people “think” about risk? The second paper, by **Duke, Mochon, and Amir**, investigates the mental representation of risk and uncertainty. They find that merely introducing probabilities in more conversational, easier-to-visualize formats (e.g., a coin toss) can mitigate both risk aversion in gains and risk seeking in losses.

What does risk look like in the brain? The third paper, by **Sheng, Hsu, and Shiv**, points out that, in the brain, mental accounting matters for risky choices. They find differential loss aversion with endowed versus earned money, and trace neurological activation that may underlie these differences.

How do people work under uncertain incentives? The last paper, by **Shen, Hsee, and Talloen**, examines the effectiveness of uncertain incentives in a field experiment, and models repeated decisions under uncertainty across time.

This session presents four high-quality research papers centered around one important topic: risk and uncertainty in consumer behavior. Each asks interesting questions, takes unique approaches, and provides exciting findings. This session should appeal to a wide audience who are interested in judgment and decision making in general, and risk and uncertainty in particular. Data collection in all papers is complete and all participants have agreed to present, should the session be accepted.

Risks, Interrupted: The Effect of an Interruption on Decisions of Risk

EXTENDED ABSTRACT

Individuals are constantly interrupted. Consider a consumer who is deciding whether to invest her money in a novel risky asset. While she deliberates, she is interrupted by a phone call. When she returns to the decision, will she make a different investment decision than if she had not been interrupted?

When choosing whether to take a risk, consumers do not simply engage in a cold calculus of the probability and severity of the potential outcomes of the risk; rather, fear leads to risk-averse choices. People are most gripped by fear when they face a novel risk (e.g., Loewenstein et al. 2001). We theorize that an interruption in a risky decision can increase risk-taking by reducing the experience of sensory novelty engendered by the decision stimuli. We propose that this occurs because an inherent consequence of an interruption to a risky decision is the introduction of a second exposure to the decision situation, which results in the stimuli appearing less novel and hence less threatening (e.g., Zajonc 1968), and which thereby reduces apprehension and increases risk taking. We test these predictions across six studies, and also differentiate this interruption effect from that of other forms of disruptors and previous effects of interruptions.

Study 1 tests the basic effect. Participants were given \$1.50 (real money), and had the option to invest any portion of this amount in a risk that had a 50% chance of yielding 2.5 times the amount invested, and a 50% chance of a loss of the invested amount. Participants could keep the money they chose not to invest. Participants who were interrupted during the decision invested more money (\$.80) than participants who were not interrupted (\$.67), $t(199) = 2.10, p = .037$.

Study 2 examines the possibility that the observed results may instead be due to degraded processing due to the interruption. To this end, we compare an interruption to cognitive load and time pressure. Further, we compare expected versus unexpected interruptions. If cognitive interference underlies the effect, then an unexpected interruption may exacerbate it by causing more interference; however, our theorizing suggests that it is the repeated exposure inherent in an introduction—regardless of whether that repeated exposure is expected or unexpected—that underlies the current results. Participants chose between a sure \$5, or a risky option that had a 50% chance of \$12 and a 50% chance of \$0. Participants were randomly assigned to one of the above 5 conditions. Condition impacted participants’ choices, $\chi^2(df=4, N=741) = 12.66, p = .013$: Participants in the unexpected (28.8%) and the expected (26.7%) interruption conditions

were equally likely to take the risk ($\chi^2 = .19, p = .663$), were more likely to take the risk than uninterrupted participants (15.4%; χ^2 's > 6.11, $ps < .013$), and trended toward being more likely to take the risk than participants under load (18.0%) and time pressure (18.3; χ^2 's > 2.79, $ps < .095$).

Study 3 tests whether the current effect is due to elongated decision making. Participants decided how much money to invest in a risk that offered a 10% chance of 20 times the amount invested, and a 90% chance of a loss. Participants were randomly assigned to an uninterrupted, interrupted, or elongated duration condition (i.e., 60 seconds, which was the cumulative duration that interrupted participants in a pre-test devoted to making this decision). Condition significantly impacted average investment amount, $F(2, 597) = 4.86, p = .002$. Interrupted participants ($M = 49.56$) took greater risk than uninterrupted participants ($M = 37.65; p = .005$) as well as participants who thought for an extended duration ($M = 38.95; p = .012$), and participants in these latter two conditions took the same amount of risk ($p = .754$).

In study 4 we test the core proposition of our theory—that the interruption effect is driven by reduced sensory novelty upon resuming the decision. We did so by adding a variant of the original interruption condition where we changed the presentation format of the decision (while keeping the informational content the same) when participants resumed the decision. We predicted that this condition would reduce the subjective feeling of familiarity with the decision after the interruption, thereby eliminating the decision interruption effect. Results confirmed our hypothesis—out of a real \$1.50, condition significantly impacted investment amount ($M_{\text{No Interruption}} = .45; M_{\text{Interruption}} = .57; M_{\text{Interruption With Format Change}} = .50$), $F(2, 484) = 2.97, p = .05$.

Study 5 demonstrates that reduced apprehension mediates the interruption effect. Participants made a hypothetical choice between a sure \$50, or a risky option that had a 10% chance of \$1,000 and a 90% chance of a \$50 loss. Participants who were interrupted chose the risky option more frequently (50.6%) than participants who were not interrupted (38.6%), $\chi^2 (df = 1, N = 330) = 4.85, p = .028$. Moreover, apprehension mediated the interruption effect.

Previous research (Liu 2008) shows interruptions reduce focus on feasibility attributes (e.g., probability). Study 6 demonstrates that interruptions increase risk-taking even in contexts where all options are equally feasible (i.e., probable). In particular, participants made a choice between two risks: Option A offered a 50% chance of \$4 and a 50% chance of \$7, and Option B offered a 50% chance of \$0 and a 50% chance of \$18. Although the outcomes in each option were equally feasible (i.e., probable), a pre-test revealed that the prospect of Option B's \$0 evoked more apprehension than the prospect of accruing an amount smaller than the possible maximum. Consistent with our theorizing, interrupted participants (47.1%) chose Option B more frequently than uninterrupted participants (33.3%), $\chi^2 (df = 1, N = 302) = 5.94, p = .015$. Thus, reduced apprehension increases risk-taking even when a reduced focus on feasibility cannot.

Our research sheds light on a fundamental mechanism by which interruptions affect decisions—repeated exposure and its resulting effect on apprehension. Our findings thus have important implications for understanding the dynamic course of risky decisions.

Changing How Probability is Represented Attenuates the Reflection Effect

EXTENDED ABSTRACT

Consumers constantly engage in decisions involving risk and uncertainty, from choosing investments to trying new products. In

general, consumers tend to be risk averse among gains, but risk seeking among losses, a pattern termed the “reflection effect” (Kahneman and Tversky 1979). This asymmetry is typically attributed to diminishing marginal sensitivity—that is, to how individuals process payoffs. In four experiments, we instead focus on how individuals process probabilities, and provide evidence that small changes to how probability is represented can attenuate the reflection effect.

In particular, we contrast probabilities expressed as percentages with those represented by outcomes (e.g., the result of a coin toss) involving processes that can be easily mentally simulated (e.g., the flipping and landing of the coin). Prior research suggests that this mental simulation should make the probabilities feel more concrete and vivid (Taylor and Schneider 1989), and therefore seem more likely (Taylor et al. 1998; Johnson et al. 1993). Further, this change should have a greater influence on the perceived likelihood of low rather than high probabilities, as in our context, the options involving low probabilities also offer more extreme outcomes, which should naturally attract more attention (Bordalo et al. 2012).

Overall, we propose that changing from percentages to easy-to-simulate probability representations should increase the perceived likelihood of risky options. Accordingly, this should increase individuals' willingness to take risks with potential gains, and decrease their willingness to take risks with potential losses. Experiments 1-2 investigate our basic effect, while experiment 3 provides process evidence supporting our theoretical account. Finally, experiment 4 explores a boundary condition.

In experiment 1, participants in the gain (*loss*) conditions chose between a 75% chance of winning (*losing*) \$20, and a riskier 17% chance of winning (*losing*) \$85. The probabilities were represented either as percentages or in an easier-to-simulate format (drawing balls from an urn). Percentage condition participants showed the reflection effect: risk aversion in gains (88% chose the safe option) and risk seeking in losses (36% chose the safe option), $\chi^2(1) = 31.67, p < .001$. However, this asymmetry disappeared in the easier-to-simulate conditions (gains = 52% vs. losses = 61%), $\chi^2(1) = 0.71, p = .40$ (interaction between gain/loss domain and probability representation: $\beta = 2.96, Wald z = 4.84, p < .001$).

Experiment 2 replicates this effect with an option offering certainty. Participants in the gain (*loss*) conditions chose between winning (*losing*) \$20 and a 25% chance of winning (*losing*) \$70. Participants saw these probabilities either as percentages or in an easier-to-simulate format (tossing 2 coins). In the percentage conditions, 90% of gains participants chose the safe option, compared to 21% of losses participants, $\chi^2(1) = 25.04, p < .001$. However, representing probabilities in the easier-to-simulate format again attenuated the reflection effect (gains = 72% vs. losses = 62%), $\chi^2(1) = 0.31, p = .58$ (interaction: $\beta = 3.02, Wald z = 3.19, p = .001$).

Experiment 3 tests our proposed process. Participants in the gain (*loss*) conditions chose between a 70% chance of winning (*losing*) \$8 and a 17% chance of winning (*losing*) \$37. Half of participants saw percentages, and the other half saw the easy-to-simulate probability representation from experiment 1. After choosing, participants reported their perceived likelihood of either the risky or the safe option (scale: 1 = Extremely unlikely to 7 = Extremely likely). The reflection effect again arose in the percentage conditions (81% chose the safe option in gains vs. 41% in losses), $\chi^2(1) = 99.54, p < .001$, and was again attenuated in the easier-to-simulate conditions (gains = 56% vs. losses = 51%), $\chi^2(1) = 1.14, p = .28$ (interaction: $\beta = 1.63, Wald z = 6.52, p < .001$). Furthermore, gains participants perceived the risky option to be more likely in the easier-to-simulate format ($M = 2.85$) than in the percentage format ($M = 2.31$), $t(284) = 4.12, p < .001$, as did losses participants ($M = 3.30$ vs. 2.90), $t(294) =$

2.90, $p = .004$. These shifts in judged likelihood mediated the effect of probability representation on choice in both gains (effect = .19, $SE = .09$, 95% CI : [.06 to .41]) and losses (effect = -.23, $SE = .10$, 95% CI : [-.47 to -.07]). Probability representation had no effect on the perceived likelihood of the safe outcome in losses, $t(275) = -.56$, $p = .58$, and unexpectedly decreased the perceived likelihood in gains ($M = 5.25$ vs. 4.88), $t(230) = -3.12$, $p = .002$, but this did not mediate the effect of probability representation on choice. Thus, experiments 1-3 converge to suggest that easier-to-simulate probability representations make riskier outcomes appear more likely, which promotes risk seeking in gains and risk aversion in losses.

Experiment 4 expands our investigation by identifying a boundary condition. Participants imagined choosing between two health insurance plans, one costing \$300 less/more (depending on condition) than the previous plan, and another whose costs would be determined by uncertain treatment needs (an 83.3% chance of paying \$0 less/more and a 16.7% chance of paying \$1900 less/more). The uncertain probabilities were described either in percentage terms, or based on the outcome of a die roll. Percentage condition participants were again risk averse in gains (75%) and risk seeking in losses (45%), $\chi^2(1) = 28.31$, $p < .001$, and changing the probability representation again attenuated this difference (interaction: $\beta = 1.25$, $Wald z = 3.62$, $p < .001$). However, in this context, it did so through promoting risk aversion in both gains (74%) and losses (73%), $\chi^2(1) < .001$, $p > .99$. Thus, because baseline risk aversion is high in insurance contexts (e.g., Rabin and Thaler 2001), easier-to-simulate probability representations attenuated the risk-attitude asymmetry by promoting risk aversion in *both* gains and losses.

In summary, our experiments illustrate how the renowned reflection effect is quite sensitive to a feature that is easy for marketers to modify: the representation of probability information. Importantly, these results suggest that consumers' risk preferences shift not only when reframing payoffs (e.g., Kühberger et al. 1999), but also when reframing probabilities.

Not All Money is Created Equal: Neural Signature of Mental Accounting

EXTENDED ABSTRACT

Mental accounting describes how individuals compartmentalize their financial activities by a set of mental accounts associate with different propensity of investment or expenditure (Thaler, 1985). Critically, mental accounting violates the principle of fungibility of money: despite of identical economic value, money in one mental account is not psychologically equivalent with money in another.

In so-call "income accounting", substantial evidence exists that decision-makers treat money differently depending on how money was acquired (Thaler, 1999; Levav and McGraw, 2009). For example, O'Curry (1997) found that people were less likely to make frivolous consumption with money earned by overtime work than money received as winnings from a football pool. Similarly, people were more reluctant to purchase a vacation with money earned from work than with money received as a gift (Henderson and Peterson, 1992). More generally, mental accounting has been invoked to explain a variety of behaviors ranging from consumption, to investment, to saving and to borrowing, and has been tested in the context of the laboratory, the household and the market.

Despite this wealth of evidence, a number of fundamental questions remain regarding the nature and even existence of mental accounting. In particular, it remains largely unclear whether mental accounting indeed exists as a set of cognitive processes used by the human mind to record financial transactions, or whether it is a useful

metaphor to describe dynamic changes in a decision-maker's sensitivity to gain and losses in response to past outcomes. Second, in the specific case of income accounting, it is unclear the extent to which how money was acquired affects diminishing sensitivity to gains and losses (risk aversion), or the relative weighting of gains and losses (loss aversion).

To address this question, we used a novel experimental paradigm that comprised of two phases: acquisition phase and investment phase. In the acquisition phase, participants acquired money in two purported accounts, namely, salary account and bonus account, respectively. Specifically, they earned \$20 in the salary account by completing an effortful visual search task, and received \$20 in the bonus account as an endowment effortlessly. Next, in the investment phase, participants made a series of decisions of whether to accept or reject a gamble enabling 50/50 probability of winning vs. losing with money in the two accounts.

We collected both behavioral and neural data using this paradigm, and asked (i) the extent to which how money was acquired in the acquisition phase affected behavior in the investment stage, and (ii) whether the human brain flexibly encodes and processes gains and losses in the investment stage according to how money was acquired in the acquisition phase, as predicted by mental accounting.

Behaviorally, we adopted a prospect theory approach to examine how risk and loss aversion attitudes varied with earned money and endowed money. Specifically, we found that, relative to the baseline model where risk and loss aversion were unaffected by the two accounts, a two-account model where loss aversion was affected by accounts explained choices significantly better. In contrast, this was not the case with a two-account model where risk attitude was affected by the two accounts. Thus, earned money, relative to endowed money, selectively modulated individuals' attitude toward losses as opposed to attitude toward risks.

The validity of the behavioral finding was further examined by the analysis of neural data. First, we calculated the utility of each gamble according to each of the three models and obtained three separate utility for each gamble. Next, we subtracted the utility calculated from the one-account model from the utility calculated from the two-account model with account-dependent loss aversion. Finally, and critically, we searched for neural activity tracing the differential utility independent from neural activity tracing the utility calculated from the one-account model. We found that medial prefrontal cortex, a brain region known for its role in value representation, did not only represent the utility of the one-account model, but also represented the differential utility of the two-account model relative to the one-account model. Thus the brain responds in a manner better predicted by the two-account model than the one-account model.

By employing the novel approach of brain imaging, this study shows that mental accounting is not merely a metaphor, but indeed exists as a set of the neural processes in the human brain. Thus, the concept of mental accounting is not only useful, but also valid, biologically.

Field Experiments on the Effectiveness of Uncertain Incentives

EXTENDED ABSTRACT

Many of the decisions we make are repetition decisions, choosing whether to repeat an activity or not; for example, deciding whether to order another drink at a restaurant after having just finished one, or deciding whether to return to the gym after having worked out yesterday.

Prior behavioral research has identified various determinants of behavioral repetition, such as token size and progress perception. We focus on a factor that has received less attention: incentive uncertainty, that is, whether the financial outcome of an action is certain or uncertain. For example, which pay scheme, a certain per-task pay of \$5 or an uncertain per-task pay of either \$3 or \$5 with equal chances, is more effective at motivating a research assistant to complete a task repeatedly?

We propose that uncertain incentives can lead to more repetitions than certain incentives, even if the uncertain incentive is strictly dominated by the certain incentive, which we refer to as the reinforcing-uncertainty effect. In other words, we predict a positive effect of uncertainty in repetition decisions. We conducted two natural field experiments to test the proposed reinforcing-uncertainty effect.

In one field experiment, we collaborated with a local running club in Hong Kong. Club members participated in a spring running event in which they could earn points by working out on the track. Half of them received 5 points for each lap they completed (certain), and the other half received 3 or 5 points (uncertain). All points they earned could be exchanged for the equivalent amount of Hong Kong dollars into a gift card from a café. At the end of the event, the uncertain incentive scheme made the club members run, on average, about 6.48 extra laps compared to the certain incentive scheme. This experiment shows a positive effect of uncertainty on repetition: People literally ran “the extra mile” (precisely, 1.61 more miles) for uncertainty.

In another field experiment, we replicated the reinforcing-uncertainty effect in repetition decisions with more substantial incentives. The experiment took place on a Hong Kong pay-by-task survey platform (similar to Amazon’s Mechanical Turk) affiliated with a large local public university. In the certain pay condition, for each 10-min survey they were paid HK\$40 (US\$5.13), whereas in the uncertain pay condition they were paid either HK\$20 or HK\$40 with equal chances. These incentive magnitudes were on par with about four times the standard wage of a business-school graduate student working as a research assistant in Hong Kong.

We found that: (a) in terms of “entry,” the uncertain pay did not seem attractive; workers were 20% less likely to show up and take any survey if they were promised an uncertain pay; (b) in terms of “repetition,” the uncertain pay excelled at maintaining an active worker pool; among those who showed up, an uncertain-pay worker, on average, completed 5.65 more surveys (out of 42 surveys) than a certain-pay worker. The contrast between entry and repetition indicates that uncertain dynamic incentives are more effective than certain incentives because people learn about the pleasure of uncertainty resolution through, not before, repetitions.

Together, the two field experiments showed a positive effect of uncertainty on repetition and documented the effectiveness of uncertain incentives with real consequences and in serious decision contexts.

SESSION OVERVIEW

Consumer self-connections to brands have been the focus of extensive research over the last few decades. During this time, it has been well documented that consumers view brands that have been integrated into their self-concept (i.e. self-brand connection [SBC], Escalas and Bettman 2003) differently than well liked brands that are not identity-connected. Such brands can help consumers construct self-identities (McCracken 1989), and symbolize their values and goals (Fournier 1998). Brands that are closely linked to the self are seen as more meaningful than those without an identity-link, and consumers are more likely to form self-brand connections to brands that communicate something meaningful about the self (i.e., are symbolic) than to brands that don't (Escalas and Bettman 2005; 2009).

The current session further explores the idea that self-connected brands are different from those that are not. Each of the four papers provides a unique demonstration of a distinctive effect of self-connected brands, that would not be predicted for well-liked but identity irrelevant brands. For example, people should avoid negative information about well-liked brands, but this effect reverses for high SBC brands (paper 1). Similarly, paper 2 shows that although brand complexity is not always a positive attribute, strongly self-connected brands benefit from being complex. Moreover, brands linked to a tokenized-aspect of identity become devalued (paper 3) and high self-connected brands can actually provide pain insulation (paper 4). The intensive perspective afforded by the current session expands the investigation of identity in brand relationships by demonstrating how the presence of an identity-brand link can result in unexpected and important outcomes. This unique focus on the importance of self-connection to brands encourages interesting, in depth future research questions. For example, panelists may be inspired to ask (1) how increasing customization of products that helps to promote self-brand connections may produce similar effects as presented, and (2) what happens when there is an interaction between multiple self- and brand-identities.

Thus, a wide range of an expected outcomes – information choice, brand evaluations, and experience of pain – are demonstrated to surface when brands and identity(ies) interact. Overall, it seems that when brands are more self-connected, behavior toward the brands are more consistent with the maintenance of a positive self-concept. Whether the behavior be to seek negative, self-relevant information about the brand in order to defend against it (paper 1), to provide better evaluations of brands that enhance (paper 2) versus worse evaluations of brand that threaten (paper 3) positive aspects of the self-concept, or to use self-connected brands to construct a social self-concept as insulation from pain (paper 4), consumer interactions with self-connected brands produce a consistent pattern of self-enhancement outcomes.

Together the four papers in this session will extend and deepen our understanding of the importance of self-connected brands. A focused session such as this, where a broad range of findings support a similar research question, is one of the most effective ways of encouraging diverse thinking as a strategy to solve an interesting question from many sides.

When Ignorance is No Longer Bliss: Seeking Threatening Information About Self-Relevant Brands

EXTENDED ABSTRACT

People often choose to avoid negative information for reasons such as mood maintenance and the protection of self-beliefs, or simply to allow themselves plausible deniability (Golman, Haggmann, and Loewenstein 2016). This avoidant behavior extends to self-relevant negative or threatening information about important matters such as health, finances, and romantic partners (for review see Golman, Haggmann, and Loewenstein 2016; Sweeny et al. 2010). Theorists attribute such avoidant actions to people's desire to avoid information that may require a change in beliefs, demand an undesired action, or prompt unpleasant emotions (Sweeny et al. 2010). Consumers are especially likely to avoid negative information if it elicits negative affect (Luce, Payne, and Bettman 1999). For example, negative emotions were found to drive avoidance of product information even among people who value the information (Ehrich and Irwin 2005). Research has likewise found that consumers distance themselves from brands when they are threatened with negative information about the brand (Aaker, Fournier, and Brasel 2004).

In the current research we propose that the opposite pattern may also occur. When the negative information is about brands with which consumers have a strong self-brand connection, they tend to seek, rather than avoid, that negative information, even though the same self-protection motivations exist. This occurs because when a consumer has a high self-brand connection, the negative information about the brand becomes a potential identity threat that the individual is motivated to deal with. To develop this prediction, we build on prior literature that indicates the need to address an identity threat is more important than other considerations (Aronson 1968). Thus, people are less likely to ignore negative information about a high SBC brand, because that information may threaten their personal identity. This proposal builds on the ideas that people are highly motivated to protect the self (Greenberg, Pyszczynski, Sheldon, and Solomon 1986), but cannot choose an avoidant coping strategy because the information is widely known or available to others (Kunda

1990). Therefore, when dealing with negative brand information that may represent an identity threat, consumers are more likely to choose to try to defend their self-identity by counter arguing the information (Ahluwalia, Burnkrant, and Unnava 2000).

Consequently, we propose that when a consumer has incorporated a brand into their self-identity, resolution of the identity-threat becomes more important than protecting one's mood. Therefore, when people are strongly connected to a brand, (i.e. high SBC) they will seek out negative information about that brand, rather than avoid that negative information. This effect attenuates for low SBC brands. We test this proposal in three experiments.

Overview of experiments: In all studies participants first completed SBC scales (Escalas, 2004) for several brands. They were then presented with a set of article headlines, and told they would have to pick one of the articles to read in depth. One of the headlines always included negative information about the focal brand, and the other articles varied based on study and experimental condition. When the participant chose to read a negative article about the focal brand, we say they are seeking negative information about the focal brand. In study 1, the other articles in the choice set were also negative headlines, but about different brands. In studies 2 and 3, the other articles included a positive headline about the focal brand, and a positive, and negative headline about a neutral brand.

Study 1 investigated the proposed main effect – that degree of SBC will predict choice of negative information about a brand, compared to negative information about other brands. In this study, fifty-three MTurk workers chose one out of three articles with headlines indicating negative information about three different brands for which they had previously completed SBC measures – Nike, Apple, and Lululemon. As predicted, SBC significantly predicted information choice $\beta = .56 (.18)$, $p = .002$. When someone had a higher SBC score for a brand, they were more likely to choose to read the negative information about that brand, rather than another brand to which they were less connected.

Study 2 tested if SBC predicts negative information seeking even when people can choose to read positive information about the focal brand. Specifically, we investigated whether the choice in study 1 resulted from participants wanting to read any information about their high SBC brand, positive or negative. One hundred and sixty-eight undergraduates chose one out of four articles: two about the brand that had received their highest SBC score and two about a pre-tested neutral (high liking, low SBC) brand. Even when they had the option to read about their high SBC brand without incurring a mood cost, participants chose to read negative information about the brand for which they had the highest SBC score (high SBC, negative information = 47.85%, high SBC, positive = 33.45%, low SBC, negative = 4.45%, low SBC, positive = 14.05%). Looking only at people who read about their focal brand, participants were more likely to choose a negative, rather than a positive article, ($X^2(1, N = 117) = 3.8$, $p = .052$).

Study 3 examined our predictions using an experimental design and explored the proposed counterarguing process. 195 undergraduates were randomly assigned to see a set of headlines that included positive and negative articles about either their highest or lowest SBC brand as well as positive and negative articles about the control brand from study 2. After choosing which article to read they wrote a few sentences about their choice article. Results revealed that participants who saw their high SBC brand were more likely to choose the negative information about their target brand compared to participants who were choosing from a set that included articles about their low SBC brand. Further analyses revealed that those

who chose the negative article were more likely to counterargue the information after reading it.

In sum, these findings support the notion that resolution of the identity-threat by seeking information becomes more important than preserving mood when negative information has a self-identity component.

Brand Complexity's Impact on Product Liking and Consumer's Sense of Self

EXTENDED ABSTRACT

The marketing literature describes many ways to design strong brands (Aaker, 2012; Keller, 2001). Many brands have been designed around functional features, such as reliability and safety. But, brands are increasingly designed with more abstract and symbolic meanings. For example, brands are designed with personalities (e.g., Jeep is adventurous while BMW is upscale) and values (e.g., Patagonia is environmentally conscious while Ben & Jerry's is politically active). As a result, many brands that used to be simple in design (Coca-Cola: refreshing taste) are now more complex (Coca-Cola: refreshing, happy, exciting, cool).

The problem is that most marketing managers have been taught to design brands that are relatively simple and unidimensional in design, and that brands need a "unique selling proposition" to be successful. Brand management textbooks provide one identity or trait for which a particular brand stands when talking about successful brands (Keller, 2007). Thus, there is some resistance to building brands that are more complex and incorporate many different functional, abstract, and symbolic meanings.

This leads to our research question: Are complex brands more or less effective in the marketplace? Prior marketing theory would predict that more complex brands would be less effective. In contrast, we predict that more complex brands are more effective. We propose that consumers evaluate complex brands more favorably, and we find that this is because they are particularly good at helping consumers expand their identity.

The objective of study 1 was to explore whether there is a relationship between brand complexity and brand liking. To do so, we selected 2 brands from 3 categories which were similar in most domains (e.g., type of product, price level, country of origin, familiarity), but which differed in their level of liking, using Brand Asset Value (BAV, as measured by Y&R) as a proxy. We measured brand complexity by asking participants to select all of the brand traits and valued that applied to the brand in question, so that the more items selected, the more complex the brand. We also measured brand liking. Separate regression analyses with BAV and brand liking as the dependent measures revealed brand complexity as a significant predictor ($b's > .2$, $p's < .001$).

Past research has shown that brands serve as a way for consumers to construct, clarify, and/or project their identity or self-concept (Ball & Tasaki, 1992; Belk, 1988; Carroll & Ahuvia, 2006). As such, we propose that complex brands are especially helpful in this regard, given the multiple traits and values they embody, from which consumers can draw from in order to build their self-concept. One way in which the process of building one's identity manifest itself is by the expansion of one's concept of self (Aron, Lewandowski Jr, Mashek, & Aron, 2013), so we specifically predict that complex brands will lead to a greater expansion of the self-concept than less complex ones.

In order to test our predictions, we conducted two additional studies with participants recruited from Amazon's Mechanical Turk. In both studies we manipulated the perceptions of brand complex-

ity by presenting all participants with a list of eight brand traits and values, and asked them to pick four, elaborating why they did so. In the control condition the traits and values belonged to one dimension (e.g., excitement), whereas in the experimental condition they belonged to multiple dimensions (e.g., excitement, sincere, environmental concern).

In study 2, participants evaluated a familiar car brand (Toyota). We found a positive effect of brand complexity on brand evaluation, $F(1,64) = 4.0, p = .05$. Additionally, we measured participants' self-expansion with a widely used measure, where participants are asked "Who are you today?" and the number of descriptors they write is used as a measure of self-expansion (Aron et al., 2013). We found that participants in the complex condition had a more expanded self and that this self-expansion mediates the effect of brand complexity on brand liking (mediated effect = .16, $SE = .1, 95\% CI = .02$ to .43).

Recent research has found that experiencing lower self-concept clarity (SCC) predicts less interest in self-expansion (Emery, Walsh, & Slotter, 2015). If too many traits are added to the self-concept too quickly, people's understanding of the self could become unstable. Thus, people with low SCC will be less likely to self-expand, because they risk exhausting an already limited supply of self-clarity. Thus, study 3's objective was to explore SCC as a moderator of the effect of brand complexity on brand liking. To do so, we asked participants to evaluate a familiar soft drink brand (Fanta) and we measured their SCC (i.e., their need to expand their self-concept) as an individual difference. We again found a positive effect of brand complexity on brand evaluation, $F(1,99) = 4.58, p = .04$. Furthermore, we found a significant interaction between SCC and brand complexity ($b = .56, p = .02$). The effect of brand complexity is stronger for those individuals with a higher SCC (+1SD) who thus have a greater need to expand their self-concept (moderating effect = .1.04, $t = 3.26, p < .005$).

From a theoretical standpoint, this research makes significant contributions to the extant body of literature that examines how consumers use brands to help build their identity. Past research suggests that consumers form relationships with brands in order to satisfy their identity needs (e.g., Fournier, 1998). In our research, we uncover a novel brand building tactic that best serves this consumer need, while strengthening the brand. Specifically, we find evidence that, contrary to marketers' wisdom, designing a brand to be multifaceted and thus more complex is particularly helpful in aiding consumers build their identity. This is due to the multiple symbolic meanings, such as traits and values, consumers can draw from when forming connections to these brands. While there is limited research that explores the brand characteristics that are conducive to consumers using brands to help build their identities, none of this past research explores specific actions marketers can take to best serve this purpose.

The Influence of Incidental Tokenism on Attitudes Toward Stereotype-Typifying Products

EXTENDED ABSTRACT

Kanter's (1977) theory of tokenism suggests that individuals whose social identity represents less than 15% of the overall number of people in a group will face negative experiences such as increased visibility and social isolation, which can reduce motivation and performance on tasks. The negative effects of tokenism have been primarily studied in the context of formal organizations where the inclusion of a token may be attributed to higher level symbolic gestures or social pressures (King et al. 2009). However, consumers often find themselves as a token in incidental consumer groups (e.g., the one woman in a group of mostly men in a restaurant). Being

an incidental token in such transient consumer groups cannot be attributed to any kind of intentional planning from a higher authority.

The current research extends tokenism to these less formal and less intentional (i.e., incidental) group contexts, which we refer to as *incidental tokenism*. We propose that being an incidental token makes salient to the consumer the negative stereotypes chronically associated with the tokenized social identity. Since one's own correspondence with negative stereotypes can engender negative affect (Fiske 1982), tokens are expected to report less favorable attitudes toward products that typify negative stereotypes of their tokenized identity in an attempt to avoid conforming to those negative stereotypes.

In study 1, MTurk participants indicated their gender and read that they would be placed into an online group with other MTurk workers. In the token condition all other members of the 10-person group were of the opposite gender of the participant. In the nontoken condition eight members were of the same gender and one was of the opposite gender. In actuality there were no other group members and we displayed fictitious responses to various "getting to know you" questions for each group member. Participants then read brief descriptions of two novels (which were pretested to ensure they corresponded with negative female-gender stereotypes) and subsequently evaluated the books. Participants were explicitly told that these ratings would be confidential and anonymous. As expected, female participants evaluated the romance novels significantly less positively when they believed themselves to be a token versus nontoken group member ($M_{\text{token}} = 3.35$ vs. $M_{\text{nontoken}} = 4.23; F(1, 104) = 8.11, p < .005$). No effect was found for males, as should be the case since the novels did not correspond with negative stereotypes of their male identity.

Study 2 used the same token and nontoken manipulations, but with age (40+ vs. under-40) as the primary identity. Participation was restricted to individuals 40 years of age or older. After the token/nontoken manipulation, participants evaluated the *Buick Lucerne* automobile, which a pretest found to be strongly associated with the negative stereotypes of older individuals. As expected, 40+ year old participants evaluated the *Buick Lucerne* significantly less positively when they believed themselves to be a token versus nontoken ($M_{\text{token}} = 5.49$ vs. $M_{\text{nontoken}} = 6.54; F(1, 54) = 8.35, p < .02$).

Study 3 served two purposes. First, we sought evidence of negative stereotype activation as the process for our effect. Second, we wanted to rule out the possibility that our results could be due to the token identity increasing in salience as a result of being a token. Study 3 used a 3 (Group: gender prime vs. token vs. negative stereotype activation) x 2 (Product: identity vs. non-identity relevant) between-subjects design. Only female participants were used in this study. Gender-prime participants were asked to write about how their gender influenced their decision making and interpersonal relationships. Negative-stereotype participants were asked to describe negative stereotypes associated with their gender. The token manipulation was identical that in studies 1 and 2. Participants then evaluated either one of the books used in study 1 (identity product condition) or a book that was not linked to the female identity (non-identity product). An ANOVA revealed a main effect of product ($p < .001$) and a significant interaction between group and product ($p < .02$). Planned contrasts revealed that participants in the token ($M_{\text{token}} = 3.37$ vs. $M_{\text{gender prime}} = 4.57; F(1, 108) = 11.04, p < .01$) and negative-stereotype ($M_{\text{negative stereotype}} = 3.59$ vs. $M_{\text{gender prime}} = 4.57; F(1, 119) = 7.51, p < .007$) conditions rated the identity-relevant book significantly less favorably than those in the gender-prime condition. There was no significant difference between the token condition and negative-stereotype activation condition ($F(1, 101) = .59; p > .05$). No significant differences were found for the non-identity linked book, as expected.

Study 4 examined the moderating role of self-affirmation. Consistent with research showing that individuals overcome stereotype threats when self-affirmed (Aronson, Fried & Good, 2002), self-affirmation moderated the effect of tokenism on product attitudes. Planned comparisons revealed that in the *no affirmation* condition, token participants evaluated the *Buick Lucerne* significantly less favorable ($M_{\text{token}} = 6.07$ vs. $M_{\text{nontoken}} = 6.80$; $F(1,104) = 4.09$, $p < .04$). Most importantly, in the *affirmation* condition, there was no significant difference between the token vs. nontoken condition ($M_{\text{token}} = 6.68$ vs. $M_{\text{nontoken}} = 6.10$; $F(1, 93) = 2.27$, $p > .05$).

Study 5 found that incidental tokenism on has a negative impact on product evaluations for products that typify the negative stereotypes of the identity as opposed to all identity-related products. Token (nontoken) participants were asked evaluate two identity-linked books—one that typified the negative stereotypes of the identity and one which did not. Results revealed that token participants evaluated the first negative-stereotype-typifying book significantly less favorably than nontoken participants ($M_{\text{token}} = 3.89$ vs. $M_{\text{nontoken}} = 4.59$; $F(1, 270) = 10.45$, $p < .001$). There was no effect for the book that did not typify negative stereotypes.

In sum, across multiple identities and multiple goods, we find that incidental tokens report less favorable attitudes toward products that typify negative stereotypes of their tokenized identity. This decrease in attitudes does not extend to products unassociated with one's identity or identity-linked products that do not correspond to negative stereotypes, and is eliminated when consumers are offered an opportunity to affirm the self prior to giving their attitudes.

Brands as Mitigators of Physical Pain: The Mediating Role of Social Connectedness

EXTENDED ABSTRACT

Why can loved brands mitigate physical pain consumers experience in the lives? Using an experimental-causal-chain design in two separate experiments, this work highlights that feelings of social connectedness explain why loved brands help consumers cope with pain.

Experiment 1

The goal of Experiment 1 was to manipulate close brand relationships and observe the effect on a measure of feelings of social connectedness, attempting to provide the first link of the experimental-causal chain (Spencer, Zanna, and Fong 2005). Participants were randomly assigned to one of two conditions. Participants in the *close brand relationship condition* were asked to self-generate and write about a brand that they loved. Participants in the *control condition* were given a filler task in which they were asked to solve one-digit addition and subtraction problems. Then, participants were exposed to a psychological pain scenario (loss of a loved one) and reported their overall pain on an established six-point scale (Hicks et al. 2001). In between pain measurements, participants were shown their loved brand (or not) and then rated their pain again. To measure feelings of social connectedness, we utilized an established 20-item scale (Russell 1996). A repeated-measures analysis of variance with condition (close brand relationship, control) as between-subjects independent variable, time (T1, T2) as within-subjects independent variable, and pain as dependent variable found a significant interaction effect between time and condition on pain, $F(1, 709) = 80.78$, $p < .001$, $\eta_p^2 = .10$. Both the direct effect of time on pain, $F(1, 709) = 611.74$, $p < .001$, $\eta_p^2 = .46$, and the direct effect of condition on pain, $F(1, 709) = 48.82$, $p < .001$, $\eta_p^2 = .06$, were significant. Independent-samples *t*-tests revealed that participants in the close brand relationship con-

dition exhibited a significantly greater decrease in pain between T1 and T2 ($\Delta = -2.29$) than did participants in the control condition ($\Delta = -1.06$; $p < .001$, $d = -.68$).

Experiment 2

The goal of Experiment 2 was to manipulate feelings of social connectedness and observe the effect on pain, attempting to provide the second link of the experimental-causal chain (mediator \rightarrow dependent variable) (Spencer et al. 2005). We applied an established self-construal manipulation in which the self is defined in terms of social connectedness after either being or not being interdependently construed (Cross, Morris, and Gore 2002). We thus follow extant research that defines the self as an affectively-charged mental representation (Higgins et al. 1986; Markus 1977; Mikulincer 1995), which is why we expected the self-construal manipulation to be a valid proxy for manipulating feelings of social connectedness. Prior to participants' arrival at the lab, we set up the cold pressor apparatus and a laptop with the experimental stimuli. The cold pressor apparatus consisted of a small ice chest filled with water, a small pond pump for water circulation, and two thermometers. The water temperature was monitored constantly and was kept at $6 \pm .5^\circ \text{C}$ by regularly refilling the ice chest with ice cubes. Upon arrival at the lab, participants were randomly assigned to either the interdependent or the independent self-construal condition. We followed pertinent instructions on two self-construal manipulations established in social psychology (Brewer and Gardner 1996; Trafimow, Triandis, and Goto 1991) and widely applied in consumer research (e.g., Loveland, Smeesters, and Mandel 2010; Mandel 2003). We used both manipulations in sequence, as has been done previously (Krishna, Zhou, and Zhang 2008). In the *interdependent self-construal* condition, participants read the story about the Sumerian warrior Sostoras, whose choice would bring *prestige to his family* (cf. Trafimow et al. 1991), and were then asked whether they admired Sostoras (yes, no, not sure). Participants then proofread someone's travel report to France in which all pronouns were plural (e.g., *we, our*) and were asked to count the pronouns (adapted from Brewer and Gardner 1996). Participants then proceeded to the cold pressor task. Participants were then asked to place their left hand in the water for one minute and to keep their eyes on the screen for the duration of the experiment. Immediately after taking their hand out of the water, they were asked to rate their overall pain as was described under Experiment 1. In between pain measurements, participants read the sentence "*We had a great time in France!*" on the laptop screen in front of them. In the *independent self-construal* condition, participants followed the same procedure, except that Sostoras' choice would bring *prestige to himself* and all pronouns in the travel report were singular (e.g., *I, my*). In between pain measurements, participants instead read the sentence "*I had a great time in France!*" A repeated-measures analysis of variance with self-construal (interdependent, dependent) as between-subjects variable, time (T1, T2) as within-subjects independent variable and pain as dependent variable found a significant interaction effect between time and condition on pain, $F(1, 116) = 5.27$, $p < .05$, $\eta_p^2 = .04$. The direct effect of time on pain was significant, $F(1, 116) = 161.76$, $p < .001$, $\eta_p^2 = .58$, while the direct effect of condition on pain was nonsignificant ($p = .931$). Independent-samples *t*-tests revealed that participants in the interdependent self-construal condition exhibited a significantly greater decrease in pain between T1 and T2 ($\Delta = -1.90$) than did participants in the independent self-construal condition ($\Delta = -1.32$; $p = .024$, $d = -.42$).

Discussion

This work contributes to work on the association between *self-brand connections and social inclusion*. In a two-study, multi-

method approach, we reveal that close brand relationships lead to feelings of social connectedness, which in turn provide pain insulation. This finding contributes to and extends prior research arguing that consumers are more likely to develop self-brand connections if strong associations exist between the brand, a reference group, and the consumer's self-concept (Escalas and Bettman 2003). We also expand on work that revealed that lonely consumers establish a goal to belong (Loveland et al. 2010) and magnify research showing that socially isolated consumers (vs. control) are more likely to purchase products symbolic of group membership (Mead et al. 2011).

SESSION OVERVIEW

The theme of this special session relates to the various effects of morality in the marketplace. Expanding on prior research (Gino et al. 2010; Kidwell et al. 2013), the collection of papers identifies novel external and internal factors pertaining to morality—that relate to the consumer and/or the firm—and examines how they influence consumer evaluations/behavior.

In the first paper, Lee, Li and Yeung investigate morality as an external influencer—outside of consumers' internal beliefs—to be utilized by the firm. They test morality as a framing tool, meant to enhance consumer response to public policies. The authors investigate how framing a penalty based incentive (e.g., surcharge) as a moral behavior (e.g., donation) might attenuate negative sentiments associated with the penalty. Counterintuitively, they find morality can backfire as a framing instrument, working against firm policy.

The second paper also looks at morality external to a consumer's inherent beliefs, but researches morality from a more traditional perspective, with the goal of understanding how to enhance moral behaviors. Kelley, Mende and Scott examine how a unique, social influence based, pre-commitment tool and retail policy—that promotes financial incentives—operate as external cues to alter consumers' moral behavior as it relates to engaging in a prosocial cause. This work is significant in that it identifies three external factors—pre-commitment, social influence, and policy—that impact moral behavior.

The third paper by Baskentli, Sen, and Bhattacharya investigates morality from an internal perspective. The authors test how variations in consumers' moral concerns interact with a company's CSR record (strengths vs. concerns) in seven key CSR domains

(Corporate Governance, Diversity, Employee Relations, Community, Environment, Human Rights, and Product Safety) to affect company evaluations. Their central premise is that since CSR actions are inherently moral acts, consumer reactions to the domain of such actions should vary across the different morality clusters.

Finally, Li, Kokkoris and Savani also investigate how consumers' moral beliefs impact attitudes and preferences. Uniquely, they study the impact of internal morality on evaluations of a firm's discriminatory practices (also a moral issue), proposing that some moral ideals are applied to others universally, where everyone is expected to meet the same standard of virtuous behavior. This paper addresses how consumers' morality, as it relates to universal expectations of self-control and obesity, influence consumers' response to pricing policies deemed unfair. The final two papers make important contributions by demonstrating how consumers' internal morality influence firm evaluations among in-domain variables.

Collectively, the four papers raise the key question: What critical factors influence moral evaluations/behaviors in the marketplace? This is important as consumers are often faced with notions of “right” and “wrong.” With reoccurring debates of morality, it is not surprising that consumers struggle to balance their will-power and desires when faced with marketplace decisions. Thus, this special session brings together leading scholars to enhance understanding of (im) moral behaviors, while using diverse methods (e.g., field and lab experiments). We expect this session to encourage broader discussion of morality, expanding researchers' assumptions of what dictates morality in the marketplace.

Reducing Peak-Hour Subway Crowding: Investigating the Effectiveness of Financial Disincentives

EXTENDED ABSTRACT

Subway systems in urban cities are often heavily congested during peak hours. At times, trains are over-crowded to the extent that commuters cannot board them. Many cities adopt travel demand management measures such as time-based pricing to shift demand from peak- to off-peak periods. The most common approach is to offer discounted fares during off-peak periods and position the discount as a reward for early birds. An alternative solution to reducing peak-hour crowding is to impose a peak-hour surcharge and position the differential fare as a loss. Given that people are in general more motivated to avoid losses than to acquire gains (Tversky and Kahneman 1991), a peak-hour surcharge may be more effective than off-peak discounts in shifting demand from peak to off-peak periods. Nonetheless, commuters may display strong opposition to the surcharge policy, making it challenging to implement such a policy. These negative reactions may be explained by either commuters' aversion to heavier financial burdens resulting from peak-hour travel, or their psychological defense against the lack of freedom to choose their own travel time.

The objectives of this research are to examine the effectiveness of a surcharge policy at shifting travel from peak to off-peak periods as well as assess commuters' perception of the surcharge policy. In addition, we aim to develop and test different potential solutions to increase commuters' receptivity toward peak-hour surcharge. Specifically, in our study, we investigated the behavioral and psychological impact of framing the surcharge as a moral behavior by donating the

collected surcharge to charity—varying the proportion of the surcharge donated (50% vs. 100% of the surcharge collected) and the degree of autonomy commuters had in deciding the benefactor of the donation (commuters made their own choice of benefactor vs. the subway company predetermined a specific benefactor). We expected these features of the surcharge donation to reduce opposition in two ways. First, if commuters indeed perceive peak-hour surcharge as unfair to them, such that the surcharge exploits their need to travel to work to obtain financial gains (Nagle et al. 2016), donating the surcharge should negate this perception. Further, having 100% of the surcharge donated may reduce commuter opposition to a greater degree than having only 50% donated. Second, restrictive policies such as surcharge are often perceived as a control over people's choice availability and a threat to their autonomy (Laurin 2012; Laurin et al. 2013). Accordingly, introducing a procedure that could help reaffirm commuters' sense of autonomy (i.e., allowing commuters to choose their donation benefactor) may reduce their opposition to the surcharge policy (Kivetz 2005).

While these two factors—donation and restoration of autonomy—could reduce reactance against peak-hour surcharge, they may paradoxically reduce the effectiveness of the surcharge as a deterrent. In particular, knowing that the surcharge will be donated, commuters may find new meanings in the surcharge and consider the discouraged behavior a socially responsible act. As a result, they may not decrease their frequency of peak-hour travel and may even increase it. Our empirical study also examines this possibility.

We conducted a national randomized controlled trial (RCT) with more than 1,000 commuters across Singapore, randomly assigning these participating commuters to one of six conditions in a 2 (amount of donation: 50% vs. 100%) x 2 (benefactor: self-chosen vs. pre-assigned) + 2 (no-donation + no-surcharge control) between-subjects design. With the commuters' consent, we tracked their travel histories before, during, and after a 6-week intervention period as recorded on their chip travel card. We also captured their attitudes toward the surcharge policy at different points in time during the experiment.

The results of the field experiment demonstrated that peak-hour surcharge effectively reduced the volume of peak-hour travel. However, donation of the surcharge to charity *reduced* the effectiveness of the surcharge in smoothing the peak-hour crowd. Moreover, the donation also failed to reduce attitudinal opposition to the surcharge policy. This result held regardless of how much of the collected surcharge was donated and who had selected the benefactor. A closer examination of the travel patterns in the donation conditions revealed that participants who had revealed less flexibility (vs. those with more flexibility) in their pre-trial travel times were particularly inclined to continue traveling during peak periods, suggesting that these participants were using the charity donation as a justification to retain their status-quo travel patterns. By contrast, travel-time flexibility did not influence commuters' response to the peak-hour surcharge when the surcharge was not donated to charity; that is, how flexible commuters' travel times were did *not* affect commuters' propensity to shift their subway travel to off-peak periods in the no-charity condition.

In summary, our findings indicated that the "pure form" of surcharge (i.e., with the subway company retaining 100% of the collected surcharge) would yield the most promising result from a policy standpoint. Furthermore, besides traveling less during peak hours, commuters in this condition showed a moderate degree of adaptation to the surcharge policy—their attitude towards the surcharge became less negative by the end of the intervention period.

The Ambassador Effect: A Pre-Commitment Technique to Increase Consumer Prosocial Behavior and Loyalty

EXTENDED ABSTRACT

Although incentivizing consumers to engage in sustainable, prosocial behaviors is a moral initiative (Baca-Motes et al. 2013; Goldstein et al. 2008; Smith 2016), altering such behavior is no simple task. Recognizing the positive environmental, monetary, and reputational impact of such an effort, many state legislatures (NCSL 2016) and retailers (Parker 2016; Smith 2016; Target Brands, Inc. 2016) are instituting retail policies meant to encourage reusable bag use and reduce the use of disposable bags. These policies either utilize reward based incentives (e.g., discounts for bringing reusable bags) or penalty based incentives (e.g., plastic bag bans or fees).

Still, it is not clear how consumers might respond to such policies. Thus, we need to understand if consumers are most responsive to reward or penalty based policies, and what can be done to improve the effectiveness of these policies. Expanding work on social influence, sustainability (e.g., Goldstein et al. 2008), and behavioral reinforcement theory (Andreasen 2002; Bickel and Vuchinich 2000; Rothschild 1999), the present research seeks to understand how social influence impacts financial incentives' ability to encourage prosocial behavior. We propose a novel, pre-commitment tool, referred to as the "ambassador effect," that suggests consumers are more likely to engage in subsequent prosocial behaviors if asked to involve another person in the initiative. Even more importantly, we demonstrate that this ambassador effect can enhance the success of penalty based retail policies.

Our proposed ambassador effect emerges in light of extant research on social influence and pre-commitment. Prior work relies on social norms to push prosocial behavior (Goldstein et al. 2008; Schultz et al. 2008), whereas we argue involving another person in a prosocial action leverages anticipated social interaction as a pre-commitment tool. Work on commitment demonstrates engaging in small behaviors aligned with a larger obligation is effective at influencing subsequent behavior (Cialdini 2007; Freedman and Fraser 1966). Pre-commitment's influence on behavior is supported by cognitive dissonance theory's principle of consistency, which suggests that individuals are driven to keep their attitudes/beliefs harmoniously aligned with their current state (Festinger 1957). In our research, we propose that when a consumer agrees (pre-commits) to involve another person in a prosocial action, the social aspect of the pre-commitment causes the consumer to take on an ambassador like role, where they feel obligated to represent and promote the prosocial cause. Due to the consistency principle, the consumer will be motivated to align their subsequent behavior with the ambassador role, increasing prosocial behavior.

We test this hypothesis in the field and lab. In study 1, participants outside of a grocery store completed a short survey in exchange for a free reusable bag. Upon completion, participants in the baseline condition were given one bag, whereas participants in the ambassador condition were given one bag to keep and a second bag to give to another person. Findings show that consumers primed with an ambassador role are more likely to use reusable bags in the future, compared to consumers who were not primed.

An alternative explanation is that these findings are the result of those in the ambassador condition receiving two bags, whereas those in the baseline condition only received one bag. In study 2, we replicate our findings, and rule out the alternative explanation of bag quantity. We add a third condition to the bags factor in which lab participants are told they received two free bags for personal use. We compare the 1 bag and 2 bags condition to the ambassador condition,

finding that the ambassador condition results in greater future reusable bag use relative to both other conditions.

Finally, this paper suggests that the ambassador effect moderates the success of retail policy incentives. In general, we suggest penalty based policies are inferior to reward based policies as reward based policies have no obvious drawback (the individual, retailer, and society all benefit). However, penalty based policies can cultivate consumer opposition as consumers have become accustomed to receiving disposable bags, free of charge, and are likely distressed when fined for a traditionally free service. Moreover, prior research has highlighted several adverse side effects of negative reinforcement such as aggression toward and avoidance of the penalizing entity (Balsam and Bondy 1983). These undesirable effects occur with low intensity penalties as they tend to be less effective (Gneezy et al. 2011; Solomon 1964). Thus, when applying a low intensity loss (e.g., five cent fee), we predict consumers will oppose penalty based policies more than reward based policies.

However, we hypothesize that our ambassador effect will mitigate this opposition to penalty based reinforcement. When the ambassador effect is activated, the need to align a pre-commitment with consistent behavior will attenuate the consumer's rebellion. In addition, the social aspect of the ambassador effect (involving another person) should cause compliance with a prosocial policy to appear more public. Thus, the ambassador effect should enhance receptivity to a penalty based policy as penalty based incentives are more effective when prompting public compliance over private acceptance (Allen 1965; Festinger 1953). Finally, we expect the same moderating effect to spillover onto loyalty toward the retailer employing the policy.

We test our theorizing in study 3, where lab participants were given information about a retail policy stating that, "... retail customers will be [charged/offered] a 5-cent [fee/discount] for each [plastic/reusable] bag they use during check-out." Next, participants were randomly assigned to the baseline or ambassador condition. Findings indicate consumers report high commitment to *reward based policies*, for both the baseline and ambassador conditions. Contrastingly, for *penalty based policies*, participants in the baseline condition revealed relatively low commitment to the policy. Importantly, this low commitment is raised to the level of a reward based policy when a consumer is primed with an ambassador role, attenuating negative effects of the penalty. The same moderating pattern appeared for store loyalty. Moreover, commitment to the policy was found to mediate this change in loyalty.

Altogether, our findings indicate priming a prosocial ambassador is an effective pre-commitment technique that enhances prosocial (moral) behavior, and improves the success of negatively reinforced retail policies.

Consumer Reactions to CSR: Morality Based Differences

EXTENDED ABSTRACT

The CSR actions of a company have been shown to enhance consumers' attitudes, increase purchase likelihood, and improve the company's long-term reputation (Du, Bhattacharya, and Sen 2010). Notably, these CSR actions can fit in one or more of several different CSR domains. Yet, little is known about consumer preferences for specific domains. Prior research points to the importance of domain-specific characteristics in driving consumer response to a company's CSR actions (Kidwell et al. 2013), underscoring the need for a systematic investigation of the role of CSR domains in consumer reactions to a company's CSR record.

In this research, we draw upon moral foundations theory (MFT) to investigate how variations in consumers' moral concerns interact with a company's CSR record in different CSR domains to affect their company evaluations. MFT focuses on the psychological basis of morality (Winterich, Zhang, and Mittal 2012) to identify five moral foundations among which moral behavior varies: 1) harm (minimizing harm to others), 2) fairness (maximizing fairness to all), 3) loyalty (the importance of the in-group), 4) authority (respect for status and hierarchy), and 5) purity (avoiding impure or disgusting acts/entities) (Haidt and Graham 2009). Past research has collapsed these foundations into two superordinate factors; *individualizing*, comprising fairness and harm, and *binding*, comprising loyalty, tradition, and purity (Graham, Haidt, and Nosek 2009). The individualizing dimension is concerned with protecting individual's rights and treating them fairly whereas the binding foundation pertains to preserving the group as a whole (Haidt and Graham 2007). Consumers can be high or low on each of these dimensions, falling thus into four moral concerns clusters: Low Individualizing, Low Binding (LI-LB); Low Individualizing, High Binding (LI-HB); High Individualizing, Low Binding (HI-LB); High Individualizing, High Binding (HI-HB). Our central premise is that since CSR actions are inherently moral acts, consumer reactions to the domain of such actions should vary across the different morality clusters.

We focused on seven CSR domains (Corporate Governance, Diversity, Employee Relations, Community, Environment, Human Rights, and Product Safety) by modifying the generic descriptions of each domain provided by the KLD Indices—the most widely used and comprehensive information source for corporate social performance research (Chen and Delmas 2011). Thus, our study used a 7 (CSR domains; between subjects) \times 2 (CSR record: concerns vs. strengths; within subjects) \times 4 (moral concerns clusters; measured) design. Two hundred nine Amazon Mechanical Turk workers (44.5% female, $M_{age} = 35.32$ SD = 11.52) located in the U.S. participated in this study in exchange for monetary compensation. Participants were randomly assigned to evaluate seven different companies (one for each CSR domain), each with a name that belongs to a South American company, unfamiliar to the U.S. sample. For each company, participants were exposed to a brief description about the company's record on a specific CSR dimension. Over the seven different companies, participants were exposed to all seven CSR domains, with either strengths in four domains and weaknesses in three other domains or, alternately, strengths in three domains and concerns in four other domains. This design allowed us to expose each participant to all seven CSR domains without ever having him/her evaluate the same company on both concerns and strengths in the same CSR domain. After reading each company description, respondents evaluated the company (7-point scale; 1 = very unlikable, 7 = very likable). After evaluating all seven companies, participants completed the 30-item moral foundations questionnaire (MFQ; Graham et al. 2011).

The four moral concerns clusters were created by collapsing five core foundations into two factors; individualizing (the aggregate score on harm and fairness; $\alpha = 0.79$) and binding (the aggregate score on authority, in-group loyalty, and purity; $\alpha = 0.87$). Then, following prior research, we added participants' scores on the individualizing foundations, and performed a median split on our data using these scores. Similarly, we added participants' scores on binding foundations, and performed another median split (Kim et al. 2014). So, participants were divided into four moral concern clusters (LI-LB), (LB-HI), (HI-HB) and (LI-HB) around the respective median values for these measures.

We used a linear mixed-effects model to investigate the differences in company evaluations based on participants' moral concerns cluster, the CSR domain, and companies' record in each domain (i.e., concerns or strengths). We found a significant three-way interaction of CSR domain \times CSR record \times Moral Concerns Cluster ($p < .001$), indicating that participants who belong to different moral concerns clusters react uniquely to a company's CSR record in different CSR domains. To further investigate this three-way interaction, we analyzed the data separately for the two CSR records (concerns vs. strengths). When reacting to concerns, our results reveal that the *Low Binding – High Individualizing* moral concerns cluster dislikes the company more compared to the *Low Binding – Low Individualizing* cluster ($M_{LBHI} = 1.55$ vs. $M_{LBI} = 2.65$; $p = .001$), and compared to the *Low Individualizing – High Binding* cluster ($M_{LBHI} = 1.55$ vs. $M_{LIHB} = 2.34$; $p = .014$) in the Corporate Governance, Diversity, Environment, Human Rights and Product Safety domains. There were no significant differences in the other two domains. Interestingly, we do not obtain similar results in the strengths condition. Our results revealed that the *High Binding – High Individualizing* cluster likes the company more compared to the *Low Binding – Low Individualizing* cluster ($M_{HBHI} = 6.50$ vs. $M_{LILB} = 5.92$; $p = .025$) in the Product Safety and Environment domains ($M_{HBHI} = 6.65$ vs. $M_{LILB} = 5.65$; $p < .001$).

Overall, we find that when people evaluate CSR strengths, those who are high on both individualizing and binding foundations show greater liking towards the company compared to those who are low on both foundations. Interestingly, we do not obtain similar results when individuals evaluate the records of CSR concerns. We find that the *High Individualizing–Low Binding* cluster shows greater dislike towards the company compared to the *Low Individualizing–High Binding* cluster.

How Beliefs about the Universal Potential for Ideal Body Weight Influence Fairness Perceptions of Price Discrimination

EXTENDED ABSTRACT

A newly emerged pricing policy advocates discriminating prices for the same service based on consumers' characteristics; a practice some might deem unfair or immoral. For example, Samoa Air implements a "pay-as-you-weigh" policy, charging its passengers based on their body weight. Such pricing policies, where firms charge different prices to different customer segments, have been called third-degree price discrimination or variable consumer pricing (Kuo et al. 2016). Prior research on price discrimination and fairness has examined the factors that influence consumers' fairness perception (e.g., Kuo et al. 2016; Xia et al. 2004, Wu et al. 2012) and the negative consequences of price discrimination (e.g., Bolton et al. 2010; Campbell 1999; Ferguson et al. 2013). In this research, we investigate how consumers' lay beliefs about body weight affect their attitudes towards price discrimination.

Specifically, we investigate how the belief that only some people versus everyone can achieve an ideal body weight influences consumers' attitude towards price discrimination. This is based on prior research examining people's beliefs that ideal levels of certain traits are found limited only to some people or across all people (non-universal-universal beliefs). For example, Rattan et al. (2012) showed that universal (vs. non-universal) beliefs of intelligence predict increased support for policies that distribute resources more equally across advantaged and disadvantaged social groups. Lay beliefs about the universality of potential have been shown to be conceptually and empirically distinct from lay theories about the malleability or stability of individual traits (fixed-growth beliefs; Murphy

and Dweck 2016), as well as have distinct consequences (Rattan et al. 2012).

We hypothesize that universal (vs. non-universal) beliefs enhance fairness perceptions of discriminating pricing policies (Study 1) via highlighting the benefits for the individual rather than for the company (Study 2). Further, we predict that this effect only occurs when the source of the discrimination is related to body weight and not other types of pricing discrimination, such as discrimination based on the financial situation (Study 3). Finally, drawing upon research showing that people with growth (vs. fixed) beliefs have greater openness to personal improvement (Chiu et al. 1997; Erdley and Dweck 1993; Plaks et al. 2001), we predict that growth belief, as compared to fixed belief, will increase consumers' acceptance of price the discrimination policy among consumers with non-universal beliefs, but not among those with universal beliefs (Study 4).

In Study 1, participants first completed an 8-item measure of non-universal-universal lay beliefs of body weight ($\alpha = .91$). Then, they read a news article about the "pay-as-you-weigh" pricing policy of Samoa Air and indicated their overall acceptance of the policy (fair, acceptable, reasonable; $\alpha = .96$). Results showed that the universal (vs. non-universal) belief was positively related to consumers' overall acceptance of the pricing policy, $\beta = .30$, $t(408) = 6.26$, $p < .001$.

Study 2 replicated the result of Study 1 by manipulating participants' non-universal vs. universal beliefs. Results indicated that participants in the universal condition ($M = 4.03$) had higher acceptance of the policy than those in the non-universal condition ($M = 3.68$), $F(1, 493) = 4.04$, $p = .05$. Moreover, in the universal (vs. non-universal) condition, this effect was mediated by a greater focus on benefits of the policy for the individual rather than for the company (95% CI = .01 to .39).

Study 3 extends the previous studies in three ways. First, we examined the moderating role of the source of discrimination by showing that the above effects do not hold when the discrimination is not related to body weight (e.g., financial situation). Second, we explored downstream consequences in terms of behavioral intentions and word of mouth. Third, we utilized another discrimination context (an insurance company charging premiums based on customers' BMI) to generalize the effect of Study 1 and Study 2. We manipulated the source of discrimination (body weight vs. financial situation) in an insurance scenario and measured non-universal-universal beliefs about weight. Results showed a significant interaction between source of discrimination and beliefs on the overall attitude towards this policy, $\beta = -.39$, $t(168) = -3.37$, $p < .001$. Specifically, universal vs. non-universal beliefs affected the attitude towards discriminatory pricing based on body weight ($M_{\text{Non-universal}} = 3.78$ vs. $M_{\text{Universal}} = 5.29$, $p < .001$), but not based on financial situation ($M_{\text{Non-universal}} = 4.37$ vs. $M_{\text{Universal}} = 4.48$, $p = .71$). Additionally, the pattern of results for buying intention and word of mouth was similar.

In study 4, we examined the moderating role of fixed-growth beliefs. A pretest confirmed that non-universal-universal beliefs are only moderately correlated with fixed-growth beliefs ($r = .36$, $p < .01$). Participants evaluated the insurance company's pricing policy on the set of variables used in study 3 (overall attitude, buying intention, and word of mouth). Additionally, participants completed two measures of non-universal-universal beliefs of body weight and fixed-growth beliefs. Results showed that the universal belief was positively related to consumer's attitude towards the pricing policy, $\beta = .55$, $t(382) = 4.35$, $p < .001$. However, the main effect of fixed-growth belief was not significant, $\beta = .11$, $t(382) = .85$, $p = .40$. More importantly, a significant interaction, $\beta = -.23$, $t(382) = -2.78$, $p = .01$, indicated that, among the universal beliefs, the effect of fixed-growth

belief was not significant ($M_{\text{Universal-entirety}} = 4.40$ vs. $M_{\text{Universal-incremental}} = 4.17$, $p = .49$); in contrast, among the non-universal beliefs, growth beliefs lead to a more positive attitude compared to fixed beliefs ($M_{\text{Non-universal-entirety}} = 2.85$ vs. $M_{\text{Non-universal-incremental}} = 3.52$, $p = .01$). Additionally, the pattern of results for buying intention and word of mouth was similar.

To summarize, our research shows that consumers' lay beliefs about weight, shape consumers' acceptance of price discrimination. Consumers holding universal (vs. non-universal) beliefs are more likely to accept such policies because they view these policies as benefitting the individual more than the company. We further show that this effect is moderated by the source of discrimination and consumers' fixed-growth beliefs. Our findings contribute to research on lay beliefs—in a marketing context—and provide useful managerial insights for price discrimination policies and perceptions of price fairness.

Eleanor Putnam-Farr, Yale University, USA
Rhavi Dhar, Yale University, USA

SESSION OVERVIEW

Understanding when and why consumers fail to engage in beneficial behavior change has important consequences for individual and societal well-being. Key reasons why people are unable to change behaviors often include biases, misperceptions, and habits. The goal of this session is to further explore these key drivers and present novel insights on the rich dynamics that influence behavior change.

This series of four papers explores when and why people fail to engage in beneficial behaviors and considers how to influence both deliberative and automatic thought processes in order to encourage such changes. We collectively demonstrate that consumers' failure to change behaviors is due in part to misperceptions, irrational assumptions, and habits, but that even small changes to seemingly inconsequential marketing variables can successfully promote significant changes with substantial benefits to the self and society.

In the first paper, Lieberman, Amir, and Carmon explore a novel mechanism explaining behavior change failures. Specifically, that the mere perception of a cost to change behavior hinders one's willingness to do so, even when the cost is greatly outweighed by the benefit of the change. The authors further show that the longer consumers engage in an inferior behavior, the lower their likelihood to switch to a superior one.

The second paper expands the focus from the perceived cost of the change to the perceived risks associated with the disfavored behavior. Kristofferson, Morales, McFerran, and Dahl focus on the consequences of misperceiving a behavior as less risky than it truly is and examine ways to alter these perceptions to improve well-being. Specifically, the authors demonstrate that changing the way a sporting event is viewed (i.e., through zoomed-in camera angles) can shift feelings of amusement to sympathy and recalibrate risk perceptions, leading to beneficial changes in behaviors.

Next, Scott and Landy assess why consumers fail to accept drug treatments despite acknowledging that they are the most effective method to improve their current state. The authors show that people dislike drug treatments because they believe using drugs reflects poor moral character, for a wide variety of ailments.

In the final paper, Putnam-Farr and Dhar explore the effectiveness of reminders delivered at the moment of choice versus earlier in the choice process. In a 2-month field experiment encouraging the use of reusable water bottles, the authors demonstrate that triggering upstream consumption decisions, relative to in the moment reminders, was more effective at promoting behaviors that led to sustained habit change, even once the reminders were removed.

Collectively, these four papers provide a fresh understanding of the mechanisms underlying the perpetuation of detrimental behaviors and provide new insights about how to effectively promote positive behavior change. Across several domains, we find that consumers maintain existing negative behaviors because change can be misperceived as costly, viewed as unnecessary, deemed immoral, or overpowered by habit. The authors further demonstrate that manipulating the message framing and timing can overcome these behavior change barriers. We believe this session will have broad appeal, drawing researchers investigating behavior change, influence, risk, habits, health, and judgment and decision-making.

The Mere Cost Effect

EXTENDED ABSTRACT

Much of the research from the social sciences expects that people, all else being equal, will engage in self-serving behaviors. However, when presented with an opportunity to change one's existing behavior to a more beneficial one, consumers often fail to do so. Prior research shows that people prefer to stick with an existing option, the status quo (Samuelson and Zeckhauser 1988), which is often explained by a number of psychological factors, including loss aversion and the endowment effect (Kahneman, Knetsch, and Thaler 1991). We add to this literature by proposing a novel mechanism: the felt cost of a behavior change. Specifically, the mere perception of a cost to change a behavior hinders one's willingness to do so, even when the benefit of the change greatly outweighs this cost, there is no potential loss to the individual, and there is no uncertainty. Across four studies, we demonstrate that participants engaged in a behavior fail to switch to a preferred and more lucrative behavior simply because changing is *perceived* as a cost. Further, the more entrenched one is in a current state, the larger the perceived cost, decreasing the probability of making a behavior change.

In an initial study, we test whether consumers indeed fail to switch from a less preferred behavior to one that is preferred. We also test whether the likelihood to change to an improved state decreases the longer a consumer is engaged (i.e., more entrenched) in a suboptimal behavior. Participants ($n = 273$) are assigned to complete 10 rounds of a task, they begin with a tedious task (transcribing sideways paragraphs) and are given the opportunity to switch to a fun task (word game) either on their third round (low entrenchment) or on their sixth round (high entrenchment). Participants who choose not to switch simply continue transcribing, thus the only cost of switching is the action of clicking one additional button. At the outset of the study, participants tested and rated the tasks; social science research predicts that, given all else is equal, participants will switch to their preferred activity when given the opportunity. However, when provided the option to switch, 24% of participants who preferred the word-game failed to do so! Further, a significantly greater proportion failed to switch in high entrenchment (32%) compared to low

entrenchment (16%), $X^2(1, 195) = 6.93, p = .008$). However, in this study participants did have to click one extra button to switch, requiring they perform an action (Ritov and Baron 1992), whereas if they chose to stay they simply continued transcribing.

In a second study we further equate the cost of switching such that participants have to click on a button to stay or click on a button to switch. Similar to study 1, participants ($n = 882$) were assigned to 10 rounds of a tedious transcription task and given the opportunity to switch to a word-game on their sixth round. Participants either saw the same switching opportunity as in study 1 or a cost-equated switching opportunity where they had to actively click on a button to switch or to stay. Again, 23% of participants who preferred the word-game failed to switch when given the opportunity; this proportion did not differ based on whether participants had to passively or actively make the decision ($p > .4$), supporting our hypothesis that the perceived cost is indeed driven by the switch itself.

A 3rd study provides additional support that enhanced entrenchment decreases the likelihood of switching while also ruling out goal completion (Bargh et al 2001) as an alternative explanation. Participants ($n = 442$) were presented with a similar paradigm as the first 2 studies, but here we set up an infinite horizon such that they were unaware of the length of the study. Participants were given the opportunity to switch from transcribing to the word-game on round 3 (low entrenchment), round 6 (medium entrenchment), or round 9 (high entrenchment), all while remaining unaware of how many rounds they had left. Participants behaved in a manner consistent with the first 2 studies. Across conditions, 21% of participants who preferred the word-game failed to switch, and a significantly greater proportion failed to change tasks in high entrenchment (28%) than in low entrenchment (16%), $X^2(1, 201) = 4.49, p = .034$.

In a final study we generalize to two new tasks and provide a monetary incentive such that participants who fail to switch are financially worse off. Participants ($n = 179$) earned points for their performance on a task, and for each point earned they received an additional entry into a lottery for a \$5 bonus. Therefore, the more points a participant earned, the greater their odds of winning. Participants tested and rated new tasks: dragging a slider to exactly 50 (tedious task) and rating captions for New Yorker cartoons (fun task). Participants learned that the average number of points earned was 10 points on the slider task versus 20 points on the cartoon task. Thus, the cartoon task was financially more lucrative in addition to being rated as more enjoyable than the sliders, $t(178) = 9.3, p < .001$. All participants were then assigned to the tedious task (sliders) and given the opportunity to switch to the more fun and lucrative task (cartoons) halfway through. Yet, even with the clear financial advantage of switching, 44% of participants who also subjectively preferred the cartoon task, chose to remain with the sliders! Participants maintained a behavior that they preferred less *and* made them financially worse off, merely because once on a given trajectory the act of changing a behavior is *perceived* as costly.

Across 4 studies we present a novel mechanism explaining that consumers fail to change their behaviors in part because the act of changing is perceived as costly, even when the benefit of doing so clearly outweighs the mere cost of the change itself. These findings shed light on the reasons why behavior change is so difficult and provide unique insights relevant to a broad audience of practitioners and researchers.

Can NFL Players be Viewed as Victims? How Camera Angles Can Increase Sympathy Towards Athletes

EXTENDED ABSTRACT

In 2015, the top 12 television shows of the fall season were all NFL games and *Sunday Night Football* was the #1 most watched primetime show, averaging 23.7 million viewers per telecast (Chase 2015). The staggering and continual popularity of football stands in stark contrast to the dangerous, and sometimes fatal, injuries that we now know the game can cause its players. Case in point, in a recent study, 96% of NFL players (and 79% of all football players) examined by the Department of Veterans Affairs and Boston University were identified to have chronic traumatic encephalopathy, or CTE, a degenerative disease believed to be caused by repeated head trauma (Breslow 2015; Omalu et al. 2005).

The juxtaposition of high viewership and the potential for severe harm to its players provides an opportune context for examining some of the psychological factors that increase or decrease consumers' support for players. Specifically, the current work examines this issue through the theoretical lens of prosociality, to determine possible ways to increase sympathy towards NFL players. In other words, are there factors that can shift consumers' views of the players to victims in need of help, instead of professional athletes who entertain them?

Previous work in prosocial behavior and value of life has focused primarily on increasing sympathy towards victims in order to increase charitable giving; we contend that many of the same psychological underpinnings apply to the current context. Consistent with prior work that shows people are more inclined to help identified victims than unidentified or statistical victims (Schelling 1968; Jenni and Loewenstein 1997; Small and Loewenstein 2003; Kogut and Ritov 2005a; 2005b), we propose that multiple factors contribute to football players being perceived as unidentifiable. For instance, the uniforms and helmets they wear greatly reduce their individuality on the field (Joseph and Alex 1972), and referring to them by number instead of name also leads to increased dehumanization (Haney, Banks, and Zimbardo 1973). The football context may actually be a stronger test than prior work on identifiable victims: football players do not typically engender much sympathy (given their high incomes and celebrity status) and the degree of behavioral change required may be greater (shifting consumers from a state of enjoyment, rather than apathy).

In the current research, we examine how the camera angles used to broadcast games can change the way consumers perceive players. Specifically, we contend that when consumers view physical contact between football players through a zoomed-in (vs. regular) camera angle, consumers will feel heightened negative emotions that cause them to view players as victims, resulting in changes in attitudes and behaviors. In particular, we demonstrate in 2 laboratory studies that using camera angles to increase negative emotions leads to higher risk assessments of football related injuries, lower attitudes towards the NFL, and decreased support for the game of football.

Study 1 provided an initial test for our hypothesis. Undergraduate participants ($n = 228$) were assigned to one of two between-subject conditions (camera angle: regular vs. zoomed-in). Participants were told they would be watching a video clip and then answering questions about their experience. In actuality, all participants viewed a 40-second clip that highlighted some of the biggest hits of the 2015 NFL season. We digitally edited the clip in the zoomed-in condition such that the moment of contact between the two players was zoomed-in to a level similar to a close-up during a broadcast airing. For internal validity, the audio was removed from both videos. To

assess emotional reactions, participants completed a modified version of the consumption emotions scale (Richins 1997). After completing cover story questions, participants were presented with a series of questions to assess their sympathy towards football players (e.g., *How likely are football players to get seriously injured while playing? How risky do you think football is?*) and their attitudes towards the game (e.g., attitude towards NFL, experienced excitement at seeing extreme hits). Finally, participants were asked to imagine they had a son and answered the likelihood of allowing him to play football (1-7). Supporting our predictions, the zoomed-in clip elicited significantly higher negative emotional reactions than the regular clip ($p < .05$). These heightened emotional reactions in turn increased sympathy towards professional football players (all $ps < .05$), decreased attitudes towards the NFL and enjoyment of watching football ($ps < .001$), and reduced the likelihood of allowing one's own son to play football ($p = .01$).

Study 2 built on study 1 by including a behavioral dependent measure of football support (choice of tickets) and added an additional condition to examine whether other digital edits (i.e., slow-motion) also induce sympathy. Undergraduate participants ($n=126$) were assigned to one of three between-subjects conditions (camera angle: regular vs. zoomed-in vs. slow-motion). In addition to completing the same measures as study 1, participants were given the choice of being entered in a draw for two tickets to a football or basketball game featuring their university team. ANOVA results replicated the emotional reaction and attitude results from study 1 ($p < .05$); the zoomed-in clip elicited stronger emotional reactions and subsequent sympathy than either the control or slow-motion conditions (all $ps < .05$). Notably, the zoomed-in clip also led to a shift in choice of tickets to attend the college basketball vs. football game ($p < .05$). A replication of this study is also in process to better understand the null effects of the slow-motion condition. Preliminary analyses suggest watching an entire clip in slow-motion was generally unpleasant for participants, but additional research is needed.

Several additional studies are also currently in preparation to provide process evidence for the above effects. In particular, we contend that vividness is, in part, responsible for the effects in this particular context. Thus, although Schelling (1968) claimed “the more we know, the more we care,” we propose that for increasing sympathy in this domain, the more closely we see what's actually happening, the more we care and the more likely we are to change our attitudes and behavior.

Good People Don't Need Medication

EXTENDED ABSTRACT

Why might consumers dislike effective drug treatments? For example, why might an alcoholic prefer to quit drinking cold turkey instead of taking Naltrexone, an effective anti-craving drug for alcohol addiction? We demonstrate that consumers sometimes dislike drug treatments, even though they acknowledge that a drug treatment is more effective than treatments in the consideration set. Consistent with a person-centered approach to moral judgment (Tannenbaum, Uhlmann, and Diermeier 2011; Uhlmann, Pizarro, and Diermeier 2015), consumers consider taking a drug as reflective of poor moral character.

In study 1, we examine whether consumers sometimes dislike drug treatments and why that might be the case. In study 1A ($n = 200$), participants considered two treatments for alcohol addiction: Naltrexone (an anti-craving drug) and quitting cold turkey. We measured participants' preferences for each treatment and the perceived efficacy of each treatment. Participants clearly indicated that if they

were an alcoholic, they would prefer to quit cold turkey ($t(199) = 3.36, p = .001, d = .24$), even though they believed using Naltrexone would be more effective ($t(199) = 7.92, p < .001, d = .56$). Additionally, to assess character inferences, participants viewed scenarios about two people who are equally addicted to alcohol. One person chooses to try to quit cold turkey and the other chooses to try to quit by using Naltrexone. Participants judged the person who tries to quit with Naltrexone as having worse character ($t(199) = 5.10, p < .001, d = .36$). These character judgments predicted participants' own preferences for quitting cold turkey over using Naltrexone ($r = .26, p < .001$), even after controlling for efficacy assessments ($r_p = .17, p = .020$). Study 1B ($n = 303$) replicates study 1A in the context of multiple different ailments, including alcohol addiction (Naltrexone vs. cold turkey), nicotine addiction (nicotine gum vs. cold turkey), obesity (diet pills vs. diet), and depression (Prozac vs. trying to stay positive). Across examples, drug treatments were less preferred ($t(303) = 12.96, p < .001, d = .74$), though viewed as more effective ($t(303) = 5.04, p < .001, d = .29$). In scenarios, people who choose drug treatments were viewed as having worse character ($t(303) = 11.16, p < .001, d = .64$). These character judgments predicted participants' own preferences not to use drug treatments ($r = .32, p < .001$) even after controlling for efficacy ratings ($r_p = .11, p = .060$).

In study 2 ($n = 405$), we test whether these character inferences are limited to cases where people caused the ailment they are trying to treat. People may feel they have a duty to “clean up their own mess” instead of relying on drugs. In order to test this hypothesis, we presented scenarios about painkiller addiction in a 2 (Fault: Own, Other) X 2 (Treatment Choice: Drug, Cold Turkey) within-subjects design. In the own-fault scenarios, targets took painkillers recreationally and became addicted, whereas in the other-fault scenarios, doctors prescribed too strong a dose of painkillers to patients, who then became addicted. In both conditions, one person tries to quit using a drug (Methadone) and the other tries to quit cold turkey. Participants judged addicts who choose drug treatments (vs. those who choose to quit cold turkey) as having worse character ($F(1, 404) = 92.51, p < .001, \eta_p^2 = .19$), but this effect was not moderated by whose fault the addiction was ($F(1, 404) = 0.002, p = .967$). Choosing a drug treatment reflects poor character regardless of whether the ailment is your fault.

In study 3 ($n = 408$), we tested whether character inferences are specific to certain types of drugs. In particular, we tested two accounts: a pain-specific account where people don't like drugs that remove pain, and an effort-specific account where people don't like drugs that reduce the effort a person needs to exert. In a within-subjects design, participants considered four addicts: one quitting cold turkey, one quitting with a drug that reduces withdrawal pain, one quitting with a drug that reduces cravings (and therefore effort required to quit), and one quitting with a drug that reduces withdrawal pain and cravings. Contrary to both an effort-specific and a pain-specific account, addicts who took any drug treatment were judged to have about equally poor character regardless of the specific drug (on 9-point likert scale, $M_{\text{no pain}} = 5.82$; $M_{\text{no effort}} = 6.02$; $M_{\text{no pain or effort}} = 5.97$), and all were judged to have poorer character than the addict quitting cold turkey ($M_{\text{cold turkey}} = 6.48, ps < .001$). Choosing a drug treatment reflects poor character regardless of whether the drug targets the pain felt or effort exerted.

In study 4 ($n = 365$), we test whether these character inferences are limited to cases where the drug is fixing a psychological (as opposed to biological) problem. It is possible that people think that psychological cures are best for psychological ailments and biological cures are best for biological ailments. In a study testing this account, participants judged the character of two addicts, one who chooses a

drug treatment and another who chooses a therapy treatment for their addiction. Through random assignment, participants were either told that the addictions were biologically caused or were psychologically caused. In order to ensure that participants were not matching more effective treatments to biological causes, we specified that the drug and therapy treatments were equally effective. Participants judged addicts who took drug treatments as having worse character ($F(1, 363) = 141.75, p < .001, \eta_p^2 = .28$), but this effect was not moderated by whether the addiction was biological or psychological ($F(1, 363) = 0.61, p = .436$). Choosing a drug treatment reflects poor character regardless of whether the ailment is biological or psychological.

Across five studies, we find a robust preference for non-drug treatments. This preference occurs in part because using drug treatments reflects poor character, and these character inferences are not moderated by whether the ailment is your fault, whether the drug alters pain or effort, and whether the ailment is biological or psychological.

Sustaining Sustainable Hydration: The Importance of Aligning Information Cues to Motivate Long Term Consumer Behavior Change

EXTENDED ABSTRACT

The standard theory of consumer choice assumes that customers select the option that has the highest value. In contrast, a vast body of choice research finds that preferences are often constructed in the moment rather determined by a careful evaluation of all available options, leading to systematic biases, such as for the status quo option. (Samuelson and Zeckhauser 1988; Tversky and Simonson 1993) Furthermore, the status quo option in the real world is often a choice that reflects an existing habit and is hence difficult to change (Wood and Neal 2009). We propose that changing behavior away from the status quo option relies on System 1 rather than System 2 processing (Dhar and Gorlin 2013), both in the immediate, when customers are influenced by salience of available options, and in the long term, through prolonged exposure to a change in the underlying contextual cues linked to habits. The current article has two objectives: to explore the most effective way of presenting information that will nudge consumers toward a new desired behavior in the short term, and to measure the persistence of different nudges once they are no longer immediately salient. Even effective treatments tend to quickly wear off once the treatment is no longer present (Gneezy and List 2006; Loewenstein 2005), presenting a challenge for those who wish to understand and influence longer term behavior. Our partner (a large technology company) has a dual goal of increasing water consumption by employees (as opposed to other sugary beverages) while simultaneously reducing the amount of plastic waste. We thus focus on trying to shift people from the practice of grabbing a disposable plastic bottle of water towards refilling of reusable bottles.

While traditional communications literature on behavior change has focused on the persuasive power of relevant information, focusing on System 1 processing suggests that timeliness and salience of the information is more likely to impact the outcome of decisions (Bordalo, Gennaioli, and Shleifer 2013). While timely persuasive information is often effective in the short term (Dale and Strauss 2014; Webb and Eves 2007) however, that registered voters, by registering, have already signaled their interest in voting. The theory presented in this article predicts that impersonal, noticeable messages can succeed in increasing the likelihood that a registered voter will turn out by reminding the recipient that Election Day is approaching. Text messaging is examined as an example of an impersonal, noticeable communication to potential voters. A nationwide field experiment (n

$= 8,053$ or at changing opinions (Cacioppo and Petty 1989), research in habit formation has suggested that changing the environment (Chance et al. 2016; Verplanken and Wood 2006) and identifying situational prompts which can lead to automatic activation of a goal (Holland, Aarts, and Langendam 2006) are more effective in changing long term behavior. Indeed, in our setting, efforts to promote the use of reusable bottles with giveaways and informational campaigns have had limited long-term success, with 58% of employees citing convenience as the primary reason for their continued use of disposable bottles. We thus distinguish between moment of choice reminders, which are delivered at the moment of the desired behavior and focus on changing the salience of different options in the choice set, and reminders which are delivered earlier in the choice process, which focus on environmental cues that can trigger situational activation of a behavioral prompt.

There are two key moments in the hydration decision-making process: the obvious one occurs when people are near water, and its availability can be made salient. (Posavac, Sanbonmatsu, and Fazio 1997) However, targeting communications near the water dispensers misses the window of opportunity to bring a reusable bottle from their desks. Getting them to use a reusable bottle requires targeting the upstream behavior of actually taking the water bottle with them when they leave the desk. Targeting the communications at the desk also links the behavior (refilling a water bottle) to the situational context of the desk area, and may be more effective at changing behavior even without the reminder, if the link between desk and water bottle can become automatically activated.

In a seven week field experiment, we randomly assigned six different office areas to have posters in one of two different locations – either near water dispensers (moment of choice) or near desks (environmental trigger). We used three different posters with slight differences in how the information was presented (e.g., visual vs. text), but there were no differences in outcomes between posters so we combined the different posters and focused on the location of the messages as the manipulation of interest. The focal behavioral outcome was the total amount of water consumption from the water dispensers. We collected three weeks of baseline data, two weeks of poster data, and an additional two weeks of data after the posters were taken down.

Dispensed water consumption during the period the posters was displayed increased an average of 24% across all conditions ($t = 3.06, p = .003$). A full regression model controlling for time and office area effects shows a significant difference between the baseline and poster periods, but no interaction with poster location condition. Posters near water and near desks were equally effective at driving water consumption while salient.

This general positive effect was not unexpected, and we were more interested in potential differences in persistence, where we do see significant differences between location conditions. There was no long term effect on dispensed water in the locations where the posters were displayed near water dispensers, while consumption remained significantly higher than baseline in the locations where posters were displayed near desks (interaction $t = 1.95, p = .05$). On average, putting posters near desks resulted in an additional two gallons per day of water dispensed to reusable containers in the two weeks after posters came down, equivalent to 16 plastic bottles per day from one location. This translates to an 8% reduction in the average daily use of bottles.

Overall, this experiment shows that information presentation can serve as effective reminders for short term and long term behavior change. Posters placed near the moment of choice can trigger salience and are effective at changing short-term behavior. In

order to build new habits and motivate sustainable behavior change, it may be more effective to target upstream triggers in the environment. These upstream reminders are likely to be most effective when they link the behavior to situational cues, allowing the behavior to the environment, rather than the prompt.

Paper #4: How Comparison Standards Influence Tradeoffs Between Absolute And Relative Outcomes

Sokiente Dagogo-Jack, Boston College, USA
Joshua Beck, University of Oregon, USA

SESSION OVERVIEW

It is well-known that people engage in social comparisons (Festinger 1954). Ever since Festinger's seminal paper, this tendency has garnered attention from researchers in several fields, including consumer behavior. Indeed, consumer researchers have shown that social comparisons affect consumers' feelings after viewing advertisements, their evaluations of dynamic pricing models, and their willingness to pay for various goods and services (Haws and Bearden 2006; Richins 1991; Van de Ven, Zeelenberg, and Pieters 2011). To that end, the goal of this special session is to further develop our understanding of the interplay between social comparisons and consumer behavior.

The first two papers in the session explore consumers' misaligned expectations about the social comparisons made by others. Specifically, **Lin, Van De Ven and Utz** find that consumers become more envious of others' experiential (vs. material) purchases, however, they incorrectly expect others to be more envious of their own material purchases. **Givi, Galak, and Olivola** study social comparisons in the gift giving domain. They show that givers expect a recipient's liking of a gift to be influenced by how the gift compares to other givers' gifts, but that a recipient's actual liking of a gift does not change as a function of this consideration. Further, this expectation drives givers to both spend excessively on gifts and skip gift exchanges altogether. **Rosenzweig and Critcher** investigate how social comparisons differentially influence consumer response to apologetic (vs. other) actions of firms. They find that consumers are especially angered by inequitable compensation offered as part of an apology, and that this occurs because apologies trigger prescriptive norms connected to restorative justice, and inequitable remuneration violates those prescriptions. Importantly, they also identify boundary conditions for this effect, which are undoubtedly of great use to marketers. **Dagogo-Jack and Beck** study the relative strength of social (vs. temporal) comparisons. They find that consumers are more influenced by the latter than the former, and that this is because temporal comparisons present a greater potential threat to one's self-concept than do social comparisons

In sum, these papers investigate social comparisons while tying in several important areas of consumer research – material vs. experimental consumption, gift giving, consumer response to firm behavior, and temporal comparisons. This session is likely to be of great interest to researchers interested in any of these areas, as well as to those interested in envy, self-other decision making, prosocial behavior, firm decision making, and the self. Additionally, these papers raise many interesting research questions. For instance, when is it that decision-makers correctly predict the social comparison processes of others? Indeed, it seems that all sorts of decision-makers (e.g., consumers, gift givers, and firms) are misguided in their prediction of the social comparison processes of others (e.g., other consumers, gift recipients, and customers). Thus, a fruitful avenue for future research may be to develop a nuanced framework of when decision-makers are likely (vs. not likely) to be correct in these predictions, and offer prescriptions for how to reduce the former.

Experiential Purchases Trigger More Envy Than Material Purchases do

EXTENDED ABSTRACT

An important distinction in consumer psychology is that between experiential purchases (spending money with the primary intention of acquiring a life experience) and material purchases (spending money with the primary intention of acquiring a material possession). The result of an extensive program of research showed that experiential purchases typically bring more happiness and satisfaction than material purchases do (Gilovich, Kumar, & Jampol, 2015). However, we believe this is not the full picture. Although we think the past findings are convincing that (most) people would have a higher well-being when they were to spend more on experiences than on material goods, we also think that there are situations in which the experiential purchases can have some negative effects - triggering other people's envy (Krasnova, Wenninger, Widjaja, & Buxmann, 2013).

We investigated whether experiential or material purchases are more likely to trigger envy. Prior research on the distinction between experiential and material purchases could lead to both a prediction that experiential purchases would trigger more envy and to the prediction that material purchases would trigger more envy:

Experiential purchases make people happier because they tend to be more closely associated with one's central identity than material purchases are (Carter & Gilovich, 2012). Self-relevance of a social comparison is also an important antecedent of envy: things that are more important to you and are seen as a larger part of your identity are more likely to trigger envy (Salovey & Rodin, 1984). This would thus predict that experiential purchases trigger more envy in others.

Experiential purchases make people happier because it is more difficult to compare someone else's experiential purchase to what one owns oneself, than it is for material purchases (Carter & Gilovich, 2010). The easier it is to make a (social) comparison, the more envy one experiences. This would predict that material purchases elicit more envy.

We therefore test whether it are experiential or material purchases that trigger more envy in three studies. We explore the causes of envy for such purchases (Studies 1 and 2) and whether people are envious for the same things that they think others are envious for.

Studies

Study 1 asked participants to look through their own Facebook timeline, and write down the first post about an experiential and material purchase they could find (in a maximum time period of ten minutes). Among 172 Facebook users, 131 participants found both types of posts, 39 participants found only a post of experiential purchase, and 2 participants found only a post of material purchase. This suggests that posts about both experiential and material purchases are quite common, but experiential purchases are shared more than material ones are. Most importantly, participants reported a higher level of envy when they read the reported experiential post than the reported material post. Self-relevance, the perception that the purchase of the other was also important for oneself, was much higher in the experiential condition than in the material condition. The comparability of experiential purchases was lower than that of material purchases. Furthermore, the effect of experiential purchases on envy was mediated by self-relevance of the topic, not by the comparability.

Study 2 (N = 241) finds that for hypothetical Facebook posts of an experiential or material purchase (of the same price) people report more envy for the experiential purchase. We also again find that an experiential purchase is seen as more self-relevant, and self-relevance (partially) mediated the effect of experiential purchases on experienced envy.

If experiential purchases are more likely to trigger envy, sharing experiential purchases on for example social media can have two possible negative consequences. First, envy is a negative emotion that contains feelings of frustration and in general is an experience that people would rather not feel (Smith & Kim, 2007). Indeed, envy has been found to negatively affect life satisfaction (Krasnova, Widjaja, Buxmann, Wenninger, & Benbasat, 2015) and to increase depression (Appel, Crusius, & Gerlach, 2015). Second, people also dislike being envied by others (Foster, 1972; Rodriguez-Mosquera, Parrott, & Hurtade de Mendoza, 2010; Van de Ven, Zeelenberg, & Pieters, 2010). So if posting about experiences is likely to trigger more envy, the readers of such a message might feel negative and the posters of the message might worry about being envied.

In the third study (N = 332) we test why people quite easily share experiential purchases on social media (see Study 1), even though these posts are likely to trigger envy and people in general do not like to be envied. We replicated again that people who took the perspective of a reader of social media posts indicated that they would experience more envy from experiential posts. However, people who took the perspective from someone *writing* a Facebook post expected that posts about material purchases would actually trigger more envy in others.

Conclusion

People become more envious when they see others display their experiential purchases than when they display their material purchases. However, they expect others to be more envious for material purchases. These effects seem to occur because experiences are more important to people, and more important social comparisons trigger stronger envy (Salovey & Rodin, 1984). Past research has documented many positive effects of experiential consumption (Gilovich et al., 2015), but the current work also shows a negative side effect as it increases envy.

So why do people share experiential purchases so often, if they are likely to elicit envy? One possibility is that people do not necessarily want to be envied, but want to be admired (which is close to, but distinct from, envy, see Van de Ven, 2016, 2017). Another reason is that people hold favourable views over those who spend their

money on experiences (Van Boven, Campbell, & Gilovich, 2010), something we replicate in Study 2 and Study 3.

Two's Company, Three's a Crowd: Givers' Oversensitivity to Other Givers' Gifts

EXTENDED ABSTRACT

Social comparisons are made by consumers every day, and these comparisons constantly influence attitudes, beliefs, and behavior (Festinger 1954). That said, one context in which social comparisons are likely quite prevalent, but which we know little about in terms of social comparisons, is gift giving. That is, at many gift exchanges there are several gifts being exchanged, and thus there is the opportunity for givers and recipients to compare gifts against each other; however, these comparisons and their downstream consequences are yet to be empirically investigated.

To that end, this research investigates whether givers believe a recipient's liking of their gift changes as a function of how it compares to other givers' gifts, and whether a recipient's actual liking of a gift changes based on how it compares to the other gifts the recipient receives. Across several experiments, we find an asymmetry such that givers believe recipients will like their gift more when it compares favorably (vs. unfavorably) to other givers' gifts, but a recipient's actual liking of a gift does not fluctuate in this manner. Further, to avoid giving gifts that they believe will go unappreciated, when givers know others will be giving high (vs. low) quality gifts, they spend more money on gifts and even avoid gift exchanges altogether.

Study 1 serves an initial demonstration of the effect. The study is a 2 (Role: *Giver*, *Recipient*) x 2 (Gift Rank: *Superior*, *Inferior*) between-subjects design. Participants in the *Giver* conditions imagine they and another giver (Jordan) are invited by their friend (Alex) to his/her birthday dinner. Participants in the *Recipient* conditions imagine they invite two friends (Alex and Jordan) to their own birthday dinner. Participants in the (*Giver-Superior* / *Giver-Inferior*) condition imagine they give Alex, who likes wine, two bottles of wine, and Jordan gives (one bottle / three bottles) of the same wine. Participants in the (*Recipient-Superior* / *Recipient-Inferior*) condition imagine they like wine, and that Alex gives them two bottles of wine, and Jordan gives them (one bottle / three bottles) of the same wine. Next, participants in the (*Giver* / *Recipient*) conditions indicate (how much they think Alex likes their two bottles of wine / how much they like Alex's two bottles of wine). The results reveal that participants in the *Giver-Superior* condition thought Alex would like their gift more than participants in the *Giver-Inferior* condition, but participants in the two *Recipient* conditions liked the gift the same (interaction $p < .01$).

Study 2 investigates the extent of givers' misguided beliefs. The study is a 2 (Role: *Giver*, *Recipient*) x 2 (Gift Rank: *Superior*, *Inferior*) between-subjects design. The setup is similar to study 1's, except participants in the (*Giver-Superior* / *Giver-Inferior*) condition imagine they give Alex (one bottle / two bottles) of wine, and Jordan gives (no gift because he/she did not have time to get a gift / three bottles of the same wine). Participants in the (*Recipient-Superior* / *Recipient-Inferior*) condition imagine Alex gives them (one bottle / two bottles) of wine, and Jordan gives them (no gift because he/she did not have time to get a gift / three bottles of the same wine). Next, participants in the (*Giver* / *Recipient*) conditions indicate (how much they think Alex likes their gift / how much they like Alex's gift). The results reveal that participants in the *Giver-Superior* condition, who gave **one** bottle, thought Alex would like their gift **more** than participants in the *Giver-Inferior* condition, who gave **two** bottles,

while participants in the two *Recipient* conditions liked Alex's gift the same (interaction $p < .03$).

Study 3 demonstrates an important economic consequence of this miscalculation by givers. Specifically, study 3 employs two conditions (Gift Rank: *Superior*; *Inferior*). Participants imagine they are planning on getting a friend, who likes movies, two gift certificates to the movies for his/her birthday. Next, participants in the (*Superior* / *Inferior*) condition learn another giver is going to be giving (one certificate / three certificates) to the movies, and then decide whether to purchase two certificates as planned, or to instead purchase five (the cover story was that the theatre was having a sale on a five-certificate package). After choosing, participants indicate how much Alex would have liked two gift certificates if they would have decided to purchase two. As expected, participants in the *Inferior* condition were more likely to upgrade to five certificates than were participants in the *Superior* condition ($p < .001$), and this was mediated by participants in the *Inferior* condition believing their two certificates would be liked less, compared to participants in the *Superior* condition ($p < .001$).

Study 4 demonstrates a second downstream consequence. Specifically, study 4 employs two conditions (Gift Rank: *Superior*; *Inferior*). Participants imagine they purchase an authentic jersey of an average athlete on the local sports team, and are planning on giving it as a "Secret Santa" gift to a coworker who likes sports, at an optional work party. Next, participants in the (*Superior* / *Inferior*) condition learn another giver (who also drew the recipient's name in the Secret Santa) is going to be giving the recipient (a plain white t-shirt with a generic logo of the local sports team on it / an authentic jersey of the recipient's favorite athlete on the local sports team), and then choose whether they will still attend the party and give the recipient his/her gift, or instead go see their favorite band in concert and not give the recipient any gift (the cover story was that another friend invited the participant at the last-minute to the concert, which was at the same time as the party). After choosing, participants indicate how much the recipient would have liked their gift if they would have given it. As expected, participants in the *Inferior* condition were more likely to attend the concert than were participants in the *Superior* condition ($p < .03$), and this was mediated by participants in the *Inferior* condition believing their gift would be liked less, compared to participants in the *Superior* condition ($p < .01$).

The Inequity Penalty: Consumers Show Heightened Sensitivity to Inequitable Treatment in The Context of Apology

EXTENDED ABSTRACT

We live in an era when customer relationship management and loyalty programs have become the norm, employed in industries ranging from air travel to restaurants to cosmetics. Businesses identify their most valuable customers and treat the top twenty percent quite differently than the bottom eighty. For the majority of consumers who do not have privileged status with a company they purchase from, this means they may often be confronted by inequity and often reminded of their relatively low worth as a customer. But while inequitable treatment is most often deployed in the context of rewarding valuable customers, inequitable treatment can also be found in service recovery, when compensating customers who have been inconvenienced or mistreated. In six studies set across three different business contexts, we find that people are especially sensitive to—and angered by—inequitable compensation offered as part of an *apology*.

We hypothesize that this is because apologies activate prescriptive norms associated with restorative justice—specifically the

principle of proportionality—and inequitable remuneration violates those prescriptions. Of course, upward comparisons are often painful (Collins 1996), meaning that even under ordinary conditions consumers should generally feel it is more fair to be treated the same as instead of worse than fellow customers (Soderlund and Collander 2015). But our argument is that this *inequity penalty*—the moral dissatisfaction that consumers have from being treated inequitably compared to equitably—is particularly acute in the context of apology. This is because people are experiencing moral outrage not merely at the inequity itself, but also at the norm violation that inequity represents. Critically, by exploring the conditions that elicit and moderate the impact apology has on people's response to inequitable treatment, we gain insight into how companies can have their cake and eat it too—differentially compensate high status customers without (excessively) angering their broader customer base.

In Study 1, we demonstrate that people are more troubled by inequitable compensation offered in apology for wrongdoing than when that same compensation is provided for a different reason. Participants imagined receiving compensation either for suffering through a long flight delay or in celebration for being part of an airline's millionth flight. Within each of these conditions, participants learned that a frequent flier sitting next to them received either the same (equitable) or greater (inequitable) compensation than they had. While inequity rankled in both conditions, participants were significantly more troubled by inequitable (relative to equitable) compensation when that compensation was offered as part of an apology for the airline's wrongdoing.

Studies 2 and 3 were both designed to rule out the possibility that this heightened 'inequity penalty' was caused by negative experiences (in this case service failures) hyper-sensitizing people to their relative standing or to subsequent slights. In Study 2 all participants imagined taking a cruise to celebrate their anniversary, where they were part of large group of people who contracted food poisoning while on board the ship. Participants who imagined receiving flowers from the cruiseline in compensation for that harm were more upset by the fact that they received a smaller bouquet than first-class passengers than participants who imagined receiving the same inequitably-sized bouquet from the cruiseline as a happy anniversary gift. Study 3 also ruled out the negativity-sensitization hypothesis, but more tightly linked the inequity penalty to our hypothesized mechanism: that it arises in response to a violation of the norms associated with restorative justice. We find that the inequity penalty is heightened specifically when inequitable compensation is offered by a company apologizing for its *own* wrongdoing (e.g. by a hotel whose own fire alarm went off at night), rather than when it accompanies an "empathetic" apology for a harm the company itself was not responsible for (e.g. by a hotel whose guests were woken by a fire alarm in a neighboring building).

Studies 4 and 5 directly test our hypothesis that it is specifically violations of the principle of proportionality that drive the inequity penalty. We do so by manipulating the level of harm that two airline passengers receive, and demonstrate that the inequity penalty is reduced when the amount of harm that those customers have suffered is also unequal. In Study 4, we gain insight into what type of harms people factor into their expectations of proportional restitution. Across measures of both moral wrongness and online word of mouth, we find that the inequity penalty is reduced when consumers are differentially harmed by the firm directly (e.g. suffering different length flight delays), but also when they suffer differential consequences that result the same direct harm (e.g. when both customers experience the same flight delay, but only one misses an important business meeting because of it). In Study 5, we extend this work, de-

termining that companies need not even be aware of the differential consequences their service failures create in order for the inequity penalty to be reduced as a result of them.

Finally, in Study 6, we take lessons learned from studies 2, 4, and 5 to identify ways companies can have their cake and eat it too – differentially compensate high status customers following service failure, without unduly angering their broader customer base. We show that the inequity penalty is reduced both when companies dissociate the compensation from apology (and in fact being explicit that it is being offered to maintain the higher status customer's patronage), or when companies tie differential compensation to differential assumed harm for higher status customers.

Our work breaks new ground in service recovery research, which has almost exclusively studied the effects of compensation and apology separately (e.g. Roschk and Gelbrich 2014; Smith, Bolton, and Wagner 1999; Roschk and Kaiser 2013; Franz and Benningson 2005). What little work addresses these concepts together is focused on whether they are additive or substitutable (Boshoff 2012; Wirtz and Matilla 2004). We take a qualitatively new approach by thinking about how apologies may *constrain* the ways in which people see compensation as just or not. We also offer applied lessons that businesses can implement in their service recovery efforts.

How Comparison Standards Influence Tradeoffs Between Absolute and Relative Outcomes

EXTENDED ABSTRACT

Prior research has demonstrated that two types of comparison standards can influence people's judgments and preferences—other people [i.e., social comparisons (SC); Festinger 1954] and one's own past [i.e., temporal comparisons (TC); Albert 1977]. Typically, individuals are more satisfied by outcomes where they are better (vs. worse) than others (Fox and Kahneman 1992; Klein 1997) and better (vs. worse) than their past (Aronson and Linder 1965; Hsee and Abelson 1991). In fact, people sometimes prefer outcomes in which they are better than others (e.g., you make \$50,000/year; others make \$25,000/year) to absolutely superior outcomes in which they are worse than others (e.g., you make \$100,000/year; others make \$200,000/year; Solnick and Hemenway 1998; 2005). That is, individuals will forgo a better absolute outcome for the sake of being relatively superior to others. Whereas such tradeoffs have been demonstrated for SC, whether similar effects hold for TC is unclear. Furthermore, the relative strength of the two standards remains in question. Although individuals generally prefer improving sequences (Loewenstein and Prelec 1993; Loewenstein and Sicherman 1991), whether such preferences for relative temporal superiority are stronger than corresponding preferences for relative social superiority is unclear. Here, we investigate whether people will be more likely to choose a relatively superior (but absolutely inferior) outcome when comparing themselves to others or when comparing themselves to their past.

In study 1, we sought to determine what proportion of people will forgo a better absolute outcome in favor of being relatively superior to their past (much like they do when comparing to others). One-hundred and sixty participants read ten scenarios in various domains (e.g., income, leisure time, intelligence, physical attractiveness) and made a series of forced choices. In each scenario, participants chose between a situation in which they are better than their past (e.g., you currently make \$50,000/year and used to make \$25,000/year) and a situation in which they are better off in an absolute sense but relatively worse than their past (e.g., you currently make \$100,000/year and used to make \$200,000/year). On average participants preferred

outcomes in which they were absolutely worse off but relatively superior to their past (e.g., choosing \$50,000 over \$100,000) 36.56% of the time, which is significantly greater than zero ($t(159) = 14.69$, $p < .001$). Furthermore, in each individual domain, the proportion of participants who preferred the relatively superior (but absolutely inferior) outcome ranged from 23.75% to 51.25% and was significantly greater than zero (all $t_s(159) > 7.00$, $p_s < .001$). Thus, just as individuals sometimes prefer being better than others to being better off in an absolute sense (Solnick & Hemenway 1998), they sometimes prefer being better than their past to being better off in an absolute sense.

Study 2 built on these findings by directly comparing the effect of TC and SC standards on these tradeoffs. Two-hundred and eighty-seven participants were randomly assigned to one of three conditions and made a series of twelve forced choices that were all framed in terms of TC, SC, or no comparisons. For example, participants in the TC condition chose between a) making \$50,000 when they used to make \$25,000 and b) making \$100,000 when they used to make \$200,000; in the SC condition, participants chose between a) making \$50,000 when others make \$25,000 and b) making \$100,000 when others make \$200,000; in the no comparison (control) condition, participants chose between making \$50,000 and making \$100,000. The key dependent variable was the proportion of relatively superior (but absolutely inferior) outcomes selected (e.g., choosing \$50,000 over \$100,000). A one-way ANOVA revealed a significant main effect of comparison condition ($F(2, 284) = 32.32$, $p < .001$). Participants chose absolutely worse off (but relatively superior) outcomes more frequently in the TC condition ($M = 37.27\%$) than in the SC condition ($M = 20.51\%$) or control condition ($M = 12.15\%$). Notably, simple contrasts revealed a significant difference between the control and SC conditions ($t(284) = 2.71$, $p = .007$), the control and TC conditions ($t(284) = 7.84$, $p < .001$), and the TC and SC conditions ($t(284) = 5.42$, $p < .001$). Thus, it appears that the desire for relatively (vs. absolutely) superior outcomes is stronger when making comparisons to other people than to one's own past.

In study 3, we investigate a boundary condition of the demonstrated effect. We propose that individuals' greater sensitivity to change than to the level of an outcome (Kahneman and Tversky 1979) can account for the stronger preference for relative temporal superiority than relative social superiority. Indeed, TC necessarily involves change (or its absence), whereas SC primarily concerns static levels. Accordingly, factors such as political ideology that reflect individuals' sensitivity to change should moderate the differential effect of TC and SC standards. As liberals are generally less averse to change than conservatives (Jost et al. 2003, 2008), we expect the effect of comparison standard to be attenuated among liberals.

Two-hundred and three participants were randomly assigned to either a TC or SC condition and completed the same choice task from study 2, after which they reported their political ideology (PI) on a 1 (*very liberal*) to 7 (*very conservative*) scale. A linear regression on the proportion of relatively superior choices selected revealed main effects of comparison standard ($b = .06$, $t(199) = 3.35$, $p = .001$) and PI ($b = .02$, $t(199) = 2.20$, $p = .029$), qualified by the predicted interaction ($b = .02$, $t(199) = 2.29$, $p = .023$). A floodlight analysis revealed that the preference for absolutely inferior outcomes was significantly greater in the TC condition than in the SC condition at any level of PI above 2.71 ($b = .08$, $t(199) = 1.97$, $p = .05$). That is, conservatives—who are more threatened by change—were more likely to prefer the relatively superior (but absolutely inferior) outcome when comparing to their past than when comparing to others; however, this was attenuated among liberals.

SESSION OVERVIEW

Consumers choose for others daily: what to pack in a child's lunch, what gift to purchase for a friend, what food to bring to a potluck, or what to order for a partner running late to dinner. These choices are fraught with difficulty: what does the recipient prefer? What does the chooser prefer? What are the consequences—for the recipient, the chooser, and their relationship—of making a poor choice? Despite their ubiquity and complexity, consumer research has neglected such choices (but see, e.g., Sherry 1983). Thus, this session offers conceptual and empirical insight into choosing for others.

To begin, Liu and colleagues develop a conceptual framework that describes choosing for others based on two critical dimensions: whether the chooser is focused on the recipient or the relationship, and whether they have a primary goal to please the recipient. The resulting four choice contexts are gift-giving (relationship-focus, goal to please is primary), absent-recipient (recipient-focus, goal to please is primary), joint consumption (relationship-focus, goal to please is secondary), and paternalistic (recipient-focus, goal to please is secondary).

The three empirical papers in this session fit into and expand on this framework. In three studies, Polman finds that in absent-recipient contexts, consumers gather more attribute and alternative information when choosing for others (vs. themselves). In eight studies, Garcia-Rada and colleagues examine spending on others in the paternalistic context of funerals, and test whether choosers are motivated by pure or impure altruism. In four studies, Moore and colleagues examine how group size and self-construal affect choice in a joint consumption context.

Each empirical paper explores a different choice context from Liu and colleagues' framework. The contexts these papers explore are also the least researched; while there is a large and still-growing literature on gift-giving (Ward and Broniarczyk 2011; Steffel and Le Boeuf 2014), there is less research on choosing for others in absent-recipient, paternalistic, and joint consumption contexts. Further, each paper provides insight into—and helps to refine and expand—Liu and colleagues' framework. Polman's results suggest that information search is a critical outcome of making recipient-focused choices.

Garcia-Rada and colleagues' findings highlight impure altruism as a driver of choice when pleasing the recipient is not a primary goal. Moore and colleagues identify situational and individual factors that affect consumers' degree of relationship-focus and emphasis on pleasing the recipient in joint consumption contexts.

Given their advanced stages, these papers can integrate existing research on choosing for others and generate new research in this area. We expect this session to interest a diverse audience, including consumer psychologists studying social influence, motivation, and decision-making. We hope the session will spur discussion of theoretical and empirical questions for future research, including: 1) beyond outcomes such as search behavior and choice, what are the individual and relationship consequences of choosing for others?; 2) what individual, relationship, or situational factors predict the strength of the chooser's relationship- or recipient-focus?; 3) If choosers are not focused on pleasing the recipient, what secondary goals might they adopt, with what outcomes?

A Conceptual Framework for Understanding Consumer Choices for Others

EXTENDED ABSTRACT

Consumers spend their lives surrounded by others and thus often make choices not just for themselves, but also for others. Yet most consumer behavior research, and the resulting marketing insights, has historically neglected to consider choices for others. Recently, however, consumer behavior researchers have increasingly focused on consumers' choices for others. We consider the remaining gaps in this literature as well as the marketing implications of choosing for others. We do so by developing a new choosing-for-others conceptual framework with two fundamental dimensions.

We propose that thinking about another person in various ways is at the conceptual center of choosing for others. Thus, choosing-for-others situations can be differentiated on two fundamental dimensions—(i) whether the chooser is focused on the relationship between self and other or whether the chooser is focused exclusively on the other person when choosing, and (ii) whether the chooser's primary goal is to maximize the recipient's immediate happiness or to balance this goal against competing interests (i.e., the chooser's own preferences or the recipient's long-term welfare).

With regard to the first dimension, a relationship focus involves high concern with the self-other link, as choosers care considerably about the relational message they convey to the other person through their choice, as well as the relational expectations, dynamics, and implications of their choice (Cavanaugh 2016; Epp and Price 2011; Kelley and Thibaut 1978). In contrast, when consumers adopt a recipient focus, they are much less concerned with the self-other link and the relational implications of their choice (Barasz, Kim, and John 2016; Laran 2010), focusing mainly on the other person's wants and needs instead.

With regard to the second dimension, when a chooser's primary goal is to please the recipient, they consider the recipient's preferences and choose the option that they believe will maximize the recipient's immediate happiness (even if their beliefs about the recipient's preferences are incorrect). By contrast, other situations exist in which beliefs about the other person's preferences are a secondary input to choice, and the goal to please the recipient is not primary. By

secondary, we mean that other concerns, such as what the other person *ought* to receive or what the chooser prefers to choose on his or her own, are similarly important or sometimes even more important than pleasing the recipient. However, this is not to say that the other person's preferences do not matter at all.

Combining these two fundamental dimensions of choosing-for-others results in four "cells". These cells or choice contexts are labeled to correspond to four major, distinct choosing-for-others literatures that can be considered prototypical situations for each cell: gift-giving, joint consumption, absent-recipient, and paternalistic. These labels may not and are not intended to be able to describe every situation that fits into a given cell based on its standing on the two fundamental framework dimensions. However, each context is labeled to improve comprehension, and these labels each represent common, important, prototypical contexts. Furthermore, established literature streams correspond to each label, which facilitates a deeper understanding of the main choice motives in each context and of the choice implications and managerial implications in each context. In our presentation, we will provide an overview of these motives, choice implications, and managerial implications, while acknowledging blurrier cases that are not perfectly described by one of the four labels.

The first cell is labeled the "gift-giving" context. This cell involves a considerable relationship focus (Belk 1979, 1996; Camerer 1988; Lowrey, Otnes, and Ruth 2004; Otnes, Lowrey, and Kim 1993; Ruth, Otnes, and Brunel 1999; Schwartz 1967; Sherry 1983) and pleasing the other person is a primary consideration of the chooser. The second cell is labeled the "joint consumption" context, which consists of making shared consumption choices for self and other (e.g., a shared restaurant choice, a shared vacation destination, or a shared car). This cell also involves a strong relationship focus, but pleasing the other person is not necessarily the primary goal, as the chooser also weighs his/her own preferences. The third and fourth cells are labeled the "absent-recipient" and "paternalistic" contexts. Unlike the gift-giving and joint consumption contexts, choosers in the absent-recipient and paternalistic contexts are more focused on the other person than on the self-other relationship. In the absent-recipient context, which consists of making consumption choices for an able-minded but physically absent recipient (e.g., picking up coffee for a fellow coworker, buying groceries for a spouse), there is a strong recipient-focus, and satisfying the other person's preferences is the chooser's primary goal. In the paternalistic context, on the other hand, the chooser makes consumption choices for another person who is for some reason less *able* to choose (e.g., children, the elderly). In other words, an absent-recipient context (vs. paternalistic context) involves another person who does not have the *opportunity* (vs. ability) to choose. Thus, in the paternalistic context, the chooser considers the welfare implications of each option—in addition to the recipient's preferences—when deciding what to choose.

These four distinct contexts are both theoretically and empirically grounded in their relevance. Theoretically, these four contexts map onto the four main reasons why one consumer would make a choice for another consumer: desire to send a relational signal, sharing of the choice between chooser and recipient, the recipient's lack of opportunity to choose, or the recipient's lack of ability to choose. Empirically, a pilot study shows that this framework parsimoniously captures nearly all contexts in which consumers make choices for others and that each context encapsulates a considerable breadth of situations.

Given that this is a conceptual paper, in our presentation, we would discuss this framework, including the distinct profile of choosers' motives, choice outcomes, and marketing implications within each of the four main choice contexts. Additionally, we would

discuss novel insights of our framework and its generativity for new academic research.

People Make More Informed Choices for Others

EXTENDED ABSTRACT

Consider a recent study that measured how well participants respond to complicated problems, like the classic bat-and-ball problem (Mata, Fiedler, Ferreira, and Almeida 2013). In their examination of these problems, Mata and colleagues discovered that some people were more likely to solve them when the problems belonged to someone else. Why? The authors revealed that because people believe they are less biased than others (Pronin 2008), their confidence in others' ability to identify the correct answer is relatively low, hence they subsequently scrutinize others' choices more. Could this mean that people are "better" (more informed) at making choices for others? We believe so. Specifically, we predict that when making choices for others (vs. themselves), decision makers search for more information.

Several lines of research hint at this idea. For example, some research finds that when people decide for others, their choices are less biased compared to when they decide for themselves. That is, people who choose for others demonstrate less inter-temporal discounting, decoy effect, omission bias, betrayal bias, post-decisional distortion, choice overload, ego depletion, and loss aversion (Gershoff and Koehler 2011; Helgadóttir 2015; Pronin, Olivola, and Kennedy 2008; Polman 2010, 2012a, 2012b; Polman and Emich 2011; Polman and Vohs 2016; Ziegler and Tunney 2012; Zikmund-Fisher, Sarr, Fagerlin, and Ubel 2006).

Research also shows that people sometimes help others more than they help themselves. For example, people behave more assertively and less forgivingly toward transgressors who offend their friends than transgressors who offend them personally (Green, Burnette, and Davis 2008). People also pay more to stop other people's pain than they pay to stop their own (Crockett et al. 2014). In this vein, it would appear as though people occasionally prioritize others' well-being over their own. In support, research has shown that people value their close friends' possessions more than their own (Greenstein and Xu 2015).

Together, these findings suggest that when people choose for others, they may think more about their choices (by considering more alternatives and attributes) than when making their own choices. Entirely consistent with this view, making a choice for someone else has been theorized as an instance of accountability (Tetlock 1992). Further, research by Lee, Herr, Kardes, and Kim (1999) showed that under the sway of accountability, people examine more information, employ multiple search criteria, and employ more compensatory choice strategies.

We therefore tested whether choosing for others increases the extent to which decision makers search for options (*alternative-search*) and pursue information about each alternative (*attribute-search*). We also focused on a theoretically-derived mediator—regulatory focus—which brings to bear a new prediction concerning alternative- and attribute-search. Polman (2012a, 2012b) established that choosing for others puts people into a more promotion- (vs. prevention-) focused state, whereas choosing for the self puts people into a more prevention- (vs. promotion-) focused state. Also, in a nutshell, the literature on regulatory focus reveals parallels with alternative- and attribute-search (Forster and Higgins 2005; Forster, Higgins, and Bianco 2003; Mantel and Kardes 1999; Pham and Avnet 2004; Sanbonmatsu and Fazio 1990; Zhu and Myers-Levy 2007). In our research, we develop a theoretical and empirical link between

self-other decision making, regulatory focus, and alternative/attribute-search, which highlights when and why decision makers pursue more information, and what kind of information they pursue.

In study 1, 124 participants chose between two college courses with ten attributes describing each course. For each attribute, we created three levels and assigned one level of each attribute to each course randomly. Following the initial display of one attribute (for both courses), participants were asked whether they were ready to make a choice or whether they wanted to see another attribute. We found participants making choices for others pursued more attributes than participants making choices for themselves, $d = .81$.

In study 2, 119 participants chose between ten restaurants, where they saw information about one restaurant at a time. Following the initial display of one restaurant, participants were asked whether they were ready to make a choice or whether they wanted to see another restaurant alternative. We found participants making choices for others considered more alternatives than participants making choices for themselves, $d = .54$.

Although the preceding studies provide evidence consistent with our hypothesis, they did not directly examine the trade-off between alternative- and attribute-search. In study 3, we addressed the conflict between alternative- and attribute-search by allowing participants to research information about both alternatives and attributes. In line with our investigation of regulatory focus, we predicted a higher promotion-focus (activated by choosing for others) would lead to trading off attribute information in favor of alternatives, and vice versa, a higher prevention-focus (activated by choosing for the self) would lead to trading off information about alternatives in favor of attributes.

In study 3, 137 participants received three attributes each about three college courses and were asked whether they were ready to make a final choice, or whether they wanted additional information and if so, what kind of information (attribute or alternative). Participants who chose to see more information were shown the requested information (attribute or alternative) until they were ready to make a final choice. We found a significant interaction between target and information type which demonstrates the trade-off between alternative- and attribute-search. Participants choosing for others considered more alternatives than attributes, $d = .62$. In contrast, participants choosing for themselves pursued more attributes than alternatives, $d = .77$.

We carried out two bootstrapping procedures to determine whether promotion/prevention focus mediated the relation between target and alternative/attribute search. For these respective indirect effects, results indicated that the 95% confidence intervals (with 1000 samples) were $[-0.49, -0.10]$ and $[0.24, 0.78]$.

Summing up, our results show that a path to self-help might include a dose of other-help. In fact, it is perhaps no coincidence that when it comes to offering advice, people sometimes say “here’s my two cents” yet when people ask for others’ advice, they might say “penny for your thoughts.” In line with our results, people *can* offer more to others.

The Spirit of Giving: Impure Altruism in Funeral Contracts

EXTENDED ABSTRACT

Giving to others is driven by many extrinsic motives, such as reciprocal and reputational benefits—but its most cryptic drivers are intrinsic, altruistic motives (Falk and Fischbacher 2006; Rabin 1993). People give to others because prosocial giving is pleasurable (Andreoni 1989, 1990), but identifying the source of this pleasure

is difficult. Dictator games can remove reputational and reciprocal motives by making giving private (Haley and Fessler 2005; Nettle et al. 2013) and by anonymizing givers and recipients (Franzen and Pointner 2012; Hoffman, McCabe and Smith 1996). Yet, in almost all cases, giving can still benefit the recipient in some way. Thus, it is unclear whether the pleasure of giving requires that the recipient receives some benefit (i.e., pure altruism), or if pleasure can be derived solely from the act of giving itself (i.e., impure altruism).

Funeral contracts are an exceptional case in which prosocial giving does not benefit the recipient; they are dead. With industry sales of \$14.2 billion per year (McGinley 2016) and an average cost of \$6,500 in the United States, funerals contracts are important financial decisions that must be made by or for almost all persons. Moreover, for most funeral contracts, the recipient does not benefit from executor spending (contracts planned for deceased others), but there are contracts in which the executor is the recipient (contracts planned for the self). Comparing self-planned and other-planned funeral contracts can thus elucidate whether the “warm glow” derived from the act of giving itself influences the spirit of giving. Impure altruism should lead executors to spend more on expenses for others than themselves, particularly on expenses where the amount spent is only clear to the executor.

In Study 1, we used funeral contract data from a U.S. funeral home to test for differences in expenditures between people who pre-planned their own funeral and people who planned a funeral for another person. Total and itemized expenses were collected from 385 funeral contracts prepared between 2012 and 2014 (self-planned funerals=128; other-planned funerals=257). Two samples of funerals planned for others were collected: one matched by age and gender to self-planned funerals, and another randomly sampled from the target years (these groups did not differ and were collapsed in further analyses).

Overall, we find that people spend more on others’ funerals ($M_o = \$6,671.07$) than on their own ($M_s = \$5,779.49$; $b = 471.47$, $SE = 131.00$, $p < .001$), even when controlling for important covariates such as service type, gender, and age of the deceased. Additionally, we explored variation in expense category spending (public vs. private) to disentangle whether reputational effects also drive funeral spending in addition to a feeling of warm-glow. Twenty-four funeral expense categories were deemed public or private (based on the number of people who would notice the amount spent on the item, as indicated by 75 Mturk participants). Applying this categorization to our data, we find that people spend more on both public ($M_{\text{Difference}} = \489.08 ; $b = 246.32$, $SE = 84.41$, $p = .004$) and private expenses ($M_{\text{Difference}} = \257.18 ; $b = 115.00$, $SE = 56.70$, $p = .048$) when planning others’ funerals versus their own. These similar results between public and private funeral expenses address the alternative explanation that reputation or signaling motives drive funeral spending. In two lab studies when participants were assigned randomly to plan their own funeral or a loved one’s funeral, we replicate the self-other spending gap for both burial ($N = 391$) and cremation services ($N = 387$) and show that self-selection does not drive these differences (self-other spending gap: $ps < .001$).

We next ruled out alternative explanations that might drive this self-other difference; participants were asked to read a scenario and make funeral choices, and we manipulated who the recipient was as well as conditions about the funeral. In Study 2 ($N = 765$), we test whether ambiguity about what the deceased would have wanted motivated consumers’ greater spending for others’ funerals; scenarios providing participants with the deceased’s suggested spending amount versus no information about the deceased’s expectations did not differ. In Study 3 ($N = 582$), we refute the explanation that

greater funeral spending for others compared to the self is driven by an expectation of future reciprocity (i.e., spending more on another's funerals to have someone else do the same for you in the future). In Study 4 ($N=580$), we explore whether greater spending for others' funerals is driven by decision makers' expectations of utility from experiencing that recipients' funeral ceremony. Results from this study reveal that funeral attendance did not affect the amount people spent on others' funerals.

Finally, we conducted two additional studies to examine specific drivers of impure altruism (i.e., warm glow) that account for our effect. In Study 5 ($N=799$), we separate two drivers of impure altruism: positive affect felt from benefitting the recipient and utility from the act of giving itself. While funerals constitute a social exchange in which the recipient generally does not benefit due to their status, we test whether decision makers feel that a deceased recipient might still benefit in a supernatural sense. Using scenarios including funeral planning for others who were either alive or deceased at the time of planning, our results suggest that decision makers do not perceive recipients to benefit in a supernatural sense, thus supporting the claim that this prosocial spending on others' funerals is driven by utility from the act of giving itself. Furthermore, in Study 6 ($N=752$), we compare whether decision makers truly engage in greater spending for others' funerals out of utility from giving or due to a moral obligation. Results did not confirm the moral obligation account, further suggesting that greater funeral spending is driven by utility from the act of giving itself.

In sum, this research provides an in-depth look at the understudied and unique context of funeral decisions and the motivations that drive them. We find that people spend more on the funerals they plan for others than themselves, and demonstrate that this self-other gap is robust using archival data and experiments. More importantly, we identify a new driver of impure altruism that motivates prosocial spending when recipients do not receive material benefits: utility from the act of giving.

Wine for the Table: Self-Construal and Choosing for Large Versus Small Groups

EXTENDED ABSTRACT

Imagine that you are out to dinner with friends and you have been tasked with selecting wine for the table. How does the number of friends at dinner, in conjunction with your self-construal, affect your choice? Although recent research has begun to explore how consumers choose for others, little work has examined what role the characteristics of the choice recipient(s) might play in such choices.

The present research proposes that the number of choice recipients, in conjunction with self-construal, will affect consumers' choices for themselves and others. Prior work shows that although individuals have a strong default tendency to focus on themselves (Chambers and Windschitl 2004), making others salient can shift attentional focus towards others (Alicke and Govorun 2005). Importantly, the number of others matters: interacting with a small number of others (e.g., a single other person) increases other-focus, whereas interacting with a larger group maintains individuals' natural self-focus (Barasch and Berger 2014). In addition, research on self-construal suggests that consumers differ in their habitual focus on the self versus others. Independent individuals see themselves as distinct, autonomous beings, leading them to focus relatively more on the self than interdependent individuals. In contrast, interdependent individuals see themselves as inextricably situated within relationships, leading them to focus relatively more on others than independent individuals (Markus and Kitayama 1991).

Combining these ideas, we propose that group size and self-construal will interact to determine choices for others. We focus on joint consumption choices, which have shared outcomes—for example, choosing a t-shirt design to be worn by oneself and other team members, or selecting a happy hour location for a group. In such contexts, the decision-maker must consider not just her own preferences, but also those of others, making the tension between weighing self and others' preferences especially salient.

We propose that when choosing for themselves and a small group of others, independents and interdependents will make choices that account for others' preferences along with their own. When choosing for themselves and a large group of others, however, we expect that independents and interdependents' choice behavior will diverge. Specifically, we expect that while interdependents' other-focus will lead them to continue making choices that account for everybody's preferences, independents will switch to choices that prioritize their own preferences over others. We suggest that this occurs because small (but not large) group contexts heighten the chooser's other-focus—that is, their attention to others.

In study 1A, we primed 297 participants with independence or interdependence and asked them to choose a movie package for viewing with a large or small group of friends. Participants were told that the group's movie preferences were evenly split between drama and western movies. They then chose one of several movie packages with varying numbers of western and drama films. Participants also reported their preferences for both film genres. Choice was predicted by a three-way interaction between self-construal prime, group size, and self-preferences. When choosing for a small group, self-preferences did not drive choice for independents or interdependents ($p > .41$). When choosing for a large group, while self-preferences did not drive choice for interdependents ($p > .50$), they did for independents ($\beta = 0.19$, $t(287) = 3.88$, $p = .0001$): as their preference for western movies increased, so did the relative proportion of western movies in the movie package they chose.

In study 1B, we primed 253 participants with independence or interdependence and asked them to choose one bottle each of red and white wine for dinner with a large or small group of friends. Participants were given a budget and a real wine menu to choose from. They also reported their preferences for red and white wine. Results replicated study 1A: when choosing for a small group, self-preferences did not predict choice for independents or interdependents ($p > .61$). When choosing for a large group, while self-preferences did not drive choice for interdependents ($p > .61$), they did for independents ($\beta = 0.28$, $t(245) = 3.50$, $p = .0006$), who spent more of their budget on their preferred wine (red or white).

In study 2, we examined the mechanism underlying this effect. We primed 276 participants with independence or interdependence and asked them to choose a book deal for their large or small book club. Participants chose one of several deals that contained varying proportions of fiction and non-fiction books, described what they thought reading the books with their club would be like, and reported their book preferences. When choosing for a small group, self-preferences did not predict choice for independents or interdependents ($p > .34$). When choosing for a large group, however, self-preferences predicted choice only for independents ($\beta = 0.22$, $t(266) = 3.68$, $p = .0003$) such that they chose more books of their preferred type (fiction or non-fiction). Supporting an attentional-focus hypothesis, mediation analysis revealed that independents used more other-focused pronouns (i.e., "we") in their written descriptions in small versus large group contexts, and that pronoun use mediated the relationship between group size and choice (CI: 0.0023–0.3686, $p < .05$). This was not true for interdependents ($p > .05$).

Study 3 further tested our process, using wine choices in a small group context. Our prior studies suggest that despite their natural self-focus, small groups draw independents' attention to others; thus, we interfered with their ability to pay attention. We first primed 433 participants with independence and then manipulated cognitive load. Replicating prior studies, when load was low, self-preferences did not predict wine choice ($p > .84$). In contrast, and supporting our hypothesized attention-based process, when load was high, participants chose more expensive wines of their preferred type ($t(429) = 2.99, p < .003$).

We show that group size and self-construal are key factors in predicting consumers' choices on behalf of self and others. In doing so, we identify a context where independents adjust their choices for others—a finding that is in contrast to past work, which has largely shown when interdependents adjust for others (e.g., Morling, Kitayama and Miyamoto 2002).

SESSION OVERVIEW

People generally want to be happy. The extant literature has examined different factors that influence our wellbeing and happiness. Much research suggested that focusing on time and social connections better predict happiness than focusing on money and possessions (e.g. Mogilner 2010; Aaker et al. 2011; Dunn et al. 2011; Dittmar et al. 2014; Ryan and Dzurowiec 2001). Yet, our possessions are essential to our lives (Belk 1988). Thus, it is critical to examine the ways in which possessions can influence different aspects of wellbeing and happiness. Collectively, the four papers in this session study how possessions influence wellbeing and happiness.

In the first paper, Liu, Dalton and Mukhopadhyay suggest that special possessions can *increase* subjective wellbeing. While valuing material possessions may decrease wellbeing in general, focusing on a particular special possession may actually increase subjective wellbeing beyond baseline levels and compared to focusing on multiple possessions taken together. This is because a special possession increases a sense of connectedness, which in turn increases subjective wellbeing.

In the second paper, Tu, Hsee, and Li examine how one can *sustain* happiness by satisfying inherent, as opposed to learned, preferences. Purchasing a product that satisfies inherent (vs. learned) preferences leads to a slower decrease in happiness over time. This is because the happiness gained from satisfying inherent (vs. learned) preferences is less context dependent, and thus longer lasting. This effect also generalizes to the broader domain of improvements in personal life.

In the third paper, Goodman and Lim examine how one *shares* happiness through gift-giving. Despite research suggesting that experiences are more likely to make consumers happy than material goods, consumers are more likely to give material [experiential] gifts to socially-distant [-close] recipients. This is because giving experiential gifts requires greater knowledge about the recipient than giving material gifts.

Finally, Goranson, Ritter, Waytz, Norton, and Gray suggest that wellbeing is unexpectedly high when people are facing the loss of their most valued possession: life. Blog posts of terminally ill patients and the last words of death row inmates are more positive than others would forecast. The blog posts of terminally ill patients also become more positive as death approaches. Thus, facing the prospect of dying, people experience greater wellbeing than others would expect.

This session contributes to answering a very important question: how do possessions influence wellbeing and happiness? Subjective wellbeing is an important but under-researched area of consumer psychology, and the relationship between possessions and well-being is less well understood. The papers in this session highlight the subtle and complex nature of consumer wellbeing by providing insights into the factors that influence the increase, sustainability, sharing, and unexpected experience of wellbeing. We believe this special session on special possessions will attract a large audience with different backgrounds, including researchers of consumer wellbeing, materialism, positive psychology, and emotions, as well as anyone who cares about being happy.

My Favorite Thing: How Special Possessions can Increase Subjective Wellbeing

EXTENDED ABSTRACT

Much research has shown that an emphasis on material possessions negatively affects consumers' wellbeing (Dittmar et al. 2014; Richins and Dawson, 1992; Ryan and Dzurowiec 2001). However, materialistic consumption continues to be central to many consumers' lives, evidenced by the long queues outside of luxury retail stores and the shopping behavior of consumers on Black Friday. In this research, we examine *when* valuing material possessions can increase consumers' subjective wellbeing. Our insight is that focusing on a *particular* possession that is considered special may actually increase subjective wellbeing beyond baseline levels (study 1) and compared to focusing on multiple possessions taken together (studies 2-3).

Extant literature defines "special possessions" as possessions that consumers consider special, valued, and meaningful compared to their other possessions (e.g., Kleine and Baker 2004; Price et al. 2000; Richins 1994). This construct is well-established in the CCT literature, but there is no experimental investigation of its antecedents or consequences. Leading CCT researchers have suggested that special possessions reflect people's connections with the past, future, and others (Price et al. 2000; Wallendorf and Arnould 1988). Based on this work, we propose that special possessions may increase one's general sense of connectedness. Because people's sense of connection to people and things is positively correlated with their happiness (Zelenski and Nisbet 2014), the sense of connection derived from special possessions may increase subjective wellbeing. In what follows, we report three studies that examined the effect of special possessions on consumers' subjective wellbeing and the sense of connectedness as an underlying mechanism.

Study 1 tested the basic effect of recalling a special possession on subjective wellbeing. Participants (N=356) were randomly assigned across two recall conditions: either a special possession or a baseline control condition. Participants in the special possession [baseline control] condition were asked to recall and describe a possession that is special and meaningful to them [everything they did

that morning]. They then reported subjective wellbeing, which was measured using the Satisfaction With Life Scale in all studies (Diener et al., 1985, $\alpha=.85$). Results showed that the special possession (vs. baseline control) condition indeed reported greater subjective wellbeing ($M_{\text{special}} = 4.41$, $M_{\text{control}} = 4.16$, $p < .05$), demonstrating initial support for our basic proposition: special possessions can boost wellbeing above baseline levels. One potential confound in this study is that the two recall conditions pertained to possessions and non-possession. To address this confound, in study 2 we operationally our control condition also using possessions.

In study 2, we aimed to replicate study 1 using a different operationalization: favorite versus all possessions. In particular, we focused on clothing items in this study. Our rationale was that while all possessions include the favorite possession, the average of all possessions taken together should be less special than one's favorite possession. A pretest showed that one's favorite clothing item was indeed more special than all one's clothing items taken together (7-point scale: "special", "valued", and "meaningful"; $\alpha = .94$, $M_{\text{favorite}} = 4.97$, $M_{\text{all}} = 3.78$, $p < .001$). In the main study, undergraduate students ($N=329$) participated for course credit and were randomly assigned across the two recall conditions: favorite versus all. Participants in the favorite [all] condition recalled and described their favorite item of clothing [all clothing items, each on a separate line] that they had purchased in the past five months. All participants then reported subjective wellbeing ($\alpha=.85$). Results showed that the favorite condition reported significantly greater subjective wellbeing ($M = 4.54$) than the all condition ($M = 4.28$, $p < .04$). Moreover, the number of purchases described in the all condition had no effect on subjective wellbeing ($p > .3$), ruling out the possibility that the difference between the two conditions was driven by the number of items recalled. These results conceptually replicated study 1, showing that recalling a special possession generates greater subjective wellbeing than recalling less special possessions.

Study 3 examined our proposed underlying mechanism, a sense of connectedness. The design was similar to study 2, with two key exceptions. First, we included a measure of connectedness after the subjective wellbeing measure as described below. And second, we examined possessions that were received as gifts as opposed to purchased by the recipients themselves. A separate pretest showed that one's favorite Christmas gift was more special than all one's Christmas gifts taken together (7-point scale: "special", "valued", and "meaningful"; $\alpha > .90$, $M_{\text{favorite}} = 5.80$, $M_{\text{all}} = 5.26$, $p < .001$). We conducted the main experiment online one day after Christmas. Participants ($N = 275$) wrote about either the favorite gift they had received, or all the gifts they had received. After describing their Christmas gift(s), participants reported subjective wellbeing ($\alpha=.92$), and completed a 7-point general connectedness scale (adapted from Howell et al. 2011; sample item: "At the moment, I am feeling embedded within the broader world", $\alpha=.95$). Finally, they reported the total number of gifts they had received for Christmas, and demographic information. Results showed a marginal effect of favorite (vs. all) gifts on subjective wellbeing ($M_{\text{favorite}} = 4.87$, $M_{\text{all}} = 4.57$, $p < .10$), and significant effects on the sense of connectedness ($M_{\text{favorite}} = 4.84$, $M_{\text{all}} = 4.42$, $p < .02$). Mediation analyses showed that the sense of connectedness mediated the effect of favorite (vs. all) gifts on subjective wellbeing, controlling for the total number of gifts received (95% CI = .0043, .0483). Thus, an increased sense of connectedness underlies the effect of special possessions on subjective wellbeing.

These results show that valuing material possessions *can* increase subjective wellbeing if consumers focus on the possessions that are most special to them. Additional studies are currently being conducted to further examine the underlying mechanism and bound-

ary conditions. One potential moderator is consumers' tendencies to extend the self to possessions (Ferraro et al. 2012). The effect we observed might be mitigated among consumers who do not identify themselves with their possessions in general. A key implication of these findings is that subjective wellbeing does not derive from owning multiple possessions but, rather, subjective wellbeing derives from imbuing a particular possession with special meaning.

Satisfying Inherent Preferences to Promote Sustainable Happiness

EXTENDED ABSTRACT

We all want to be happy, but the pursuit of happiness seems to be endless. Acquiring and consuming goods and experiences to satisfy our preferences do increase happiness, yet the effects tend to be fleeting. Indeed, maintaining happiness is hard, as evidenced in decades of research on hedonic adaptation (for a review, see Frederick and Loewenstein 1999). Then, is there a recipe for sustainable happiness? We explore this question and suggest that investing resources in satisfying "inherent preferences" (Tu and Hsee 2016) can be a secret sauce.

All preferences are not created equal. Preferences that are rooted in our physiological system and developed early in evolution are more inherent (inherent preferences; IP) than those acquired more recently in specific social, cultural contexts (learned preferences; LP). For example, our preference for a warm ambient temperature, our appetite for delicious food, and our need to belong to social groups are inherent, as they are hard-wired and hold regardless of time and contexts. In contrast, our preference for diamonds, our desire to own luxury products, and our taste for fashion are learned, as they are malleable and vary with time and contexts.

The context-independence nature of IP (inherent preference) suggests that the gain in happiness from an improvement on an IP attribute will last. Conversely, the context-dependence nature of LP (learned preference) suggests that the gain in happiness from an improvement on an LP attribute will exist only when relevant external reference points (e.g., other people's status, one's past status) are salient and constant, and will evaporate when the external reference points change. For instance, whereas the increase in wellbeing when a person gets social acceptance will endure regardless of whether other people get socially accepted, the increase in wellbeing via getting a luxury bag will fade when other people catch up or when one forgets the experience of not owning one in the past.

We conducted two empirical studies to test our theory. Similar to the methodological approach of studying material and experiential consumption (Van Boven and Gilovich 2003), in both studies, we first described our definitions of IP and LP with examples and then tested people's comprehension in some obvious contexts. For example, we asked participants to indicate which preference is more inherent – "the preference for a warm ambient temperature to a cold ambient temperature in winter" or "the preference for earning \$100,000 a year to earning \$80,000 a year." The former is the correct answer. We found that the correction rates are generally high, suggesting that people can intuit and identify the distinction between the two types of preferences.

Study 1 surveyed people about their past purchases, using a 2 (IP vs. LP purchase; between-participants) x 2 (immediate vs. current happiness; within-participants) mixed design. We asked participants to think about a purchase made with the intention to satisfy an inherent (vs. learned) preference. We specified the time frame ("more than two years ago"), the cost ("between \$50-\$500) and the durability of the purchase ("something you still have and are still using"). Partici-

pants recalled such a purchase, described the type of preference they tried to satisfy, and then rated immediate happiness and current happiness due to the purchase. A IP/LP Purchase X Immediate/Current Happiness ANOVA yielded a marginally significant interaction ($F(1, 333) = 3.18, p = .075$); suggesting that the decrease of happiness of IP-oriented purchase ($M_{\text{immediate}} = 4.09, SD_{\text{immediate}} = .96$ vs. $M_{\text{current}} = 3.71, SD_{\text{current}} = 1.07$; $F(1, 191) = 30.25, p < .001$) is smaller than that of LP-oriented purchase ($M_{\text{immediate}} = 4.16, SD_{\text{immediate}} = .85$ vs. $M_{\text{current}} = 3.59, SD_{\text{current}} = 1.11$; $F(1, 142) = 46.06, p < .001$).

Study 2 replicated study 1 in a broader context (i.e., life events) and controlled for immediate happiness, using a 2 (IP vs. LP improvement) within-participants design. We asked participants to recall two improvements in their life within the past 5 years, one satisfying an inherent preference and the other a learned preference. We specified that these two improvements must have had similar immediate impact on their happiness. Participants described two such improvements and rated whether the improvements had a long-lasting effect on happiness. Supporting our prediction, participants rated improvements that satisfied an inherent preference ($M = 4.36, SD = .97$) as having a longer-lasting effect on happiness than those that satisfied a learned preference ($M = 3.56, SD = 1.05$; $t(38) = 3.12, p = .003$).

In sum, this project makes two related contributions. First, it draws a distinction between inherent preferences and learned preferences, a distinction that has potentially profound implications for both theory building and policymaking. Second, it provides initial empirical evidence suggesting that improvements related to inherent preferences produce more sustainable gains in happiness than do improvements related to learned preferences. This insight is important, in light of the fact that most improvements that have been made over the years are only about learned preferences and not about inherent preferences.

When Consumers Prefer to Give Material Gifts instead of Experiences: The Role of Social Distance

EXTENDED ABSTRACT

Gift giving is ubiquitous. It is practiced by consumers of every culture, and researchers from various disciplines have been studying it for decades (e.g., Belk and Coon 1993; Foa and Foa 1980; Mauss 1925). Despite emerging evidence suggesting hedonic benefits to giving experiences (Chan and Mogilner 2016), it seems that consumers prefer to give material gifts. The vast majority of gifts recommended by gift giving gurus are material in nature (e.g., New York Magazine 2015), and in a survey of 100 Americans (via MTurk) we found a vast majority of the gifts—81% of holiday gifts and 66% of birthday gifts—were material in nature. Why are consumers not giving more experiences? And are there times when consumers prefer to give experiences?

We answer these questions by exploring how social distance between gift givers and their recipients influences preferences for giving experiences and material gifts. Based on the interpersonal relationship literature (Berscheid, Snyder, and Omoto, 1989; Kelley et al. 1983), we propose that givers will have less knowledge about individual preferences of socially distant recipients than socially close recipients. Since experiences have been shown to be more unique and more individualized than material goods (Carter and Gilovich 2012; Dai, Chan, and Mogilner 2016), choosing experiential gifts likely requires more knowledge of recipients' preferences to avoid the social risk of giving a poorly liked gift. Thus, consumers will be more likely to give material gifts when they are socially distant from their recipients compared to socially close, and givers will be more

likely to give experiential gifts when they are socially close to their recipients (vs. distant).

Across five studies, we examined the role of social distance on givers' preferences for gift type. In study 1a we asked participants ($N=74$) to imagine that they were choosing a holiday gift for either a close or distant friend and indicate their preferences for ten holiday gifts (five experiential and five material, randomized, and pretested). The social distance by gift type interaction ($F(1,72)=15.02, p < .01, \eta^2=.17$) showed that participants were more willing to give experiences than material gifts for a close friend ($M_{\text{experiential}}=4.20$ vs. $M_{\text{material}}=3.16$; $F(1,72)=8.88, p < .01, \eta^2=.11$), whereas they were more willing to give material gifts than experiences for a distant friend ($M_{\text{material}}=3.01$ vs. $M_{\text{experiential}}=1.93$; $F(1,72)=6.58, p < .05, \eta^2=.08$). In study 1b participants ($N=276$) listed any gift for either a close or distant friend and rated the extent to which the gift was more material or experiential. As expected, participants rated gifts chosen for a close friend ($M=4.36$) as more experiential than those chosen for a distant friend ($M=3.08$; $t(274)=4.13, p < .001, d=.50$) and the effect remained significant when controlling for price of the gift (logged), age, and gender ($p < .001$). We replicated this result in a follow-up study in which a separate group of coders rated the gifts listed by participants ($M_{\text{close}}=3.54$ vs. $M_{\text{distant}}=3.01$; $t(274)=2.80, p < .01, d=.35$).

In study 2, we tested our preference knowledge theory by manipulating perceived knowledge of recipient's preferences. Participants ($N=225$) were asked to write down how well they know (vs. do not know) what their friend likes or dislikes. Next, they listed a gift that they would like to give to their friend and rated whether it was more material or experiential. We found participants were more likely to give experiences when they perceived greater knowledge about a recipient ($M_{\text{high}}=4.44$ vs. $M_{\text{low}}=3.78, t(223)=1.90, p=.06, d=.25$). When controlling for price of the gift (logged), age, and gender, the effect of subjective knowledge became even more reliable ($F(1,220)=4.37, p < .05, \eta^2=.02$).

Study 3 further examined our theory by testing the mediating role of preference knowledge and ruled out joint consumption as an alternative explanation by manipulating whether experiential gifts were shared by givers and recipients. Participants ($N=290$) assessed their preference for the same gifts used in study 1a. Consistent with our previous findings, we found a social distance x gift type interaction ($F(1,285)=21.18, p < .001, \eta^2=.07$). For a distant friend, participants were more willing to give material gifts ($M=3.26$) than experiential gifts ($M=2.44$; $F(1,285)=15.38, p < .001, \eta^2=.05$), whereas for a close friend they were more willing to give experiences ($M=4.09$) than material gifts ($M=3.53$; $F(1,285)=6.78, p < .01, \eta^2=.02$). Most importantly, this two-way interaction was not moderated by shared consumption (three-way interaction: $p > .1$), suggesting that our effects were not driven by shared consumption. Additionally, a mediation analysis on the relative preference difference score revealed a significant indirect effect of social distance on relative gift preference through preference knowledge (95% CI = [.1956, 1.1798]; 5000 samples).

Finally, in study 4, we tested whether providing an opportunity to give experiential gifts with low social risk—gifts that do not require a high degree of knowledge about recipients—eliminates the effect of social distance. The design was similar to study 1a except for the fact that social risk associated with experiential gifts was manipulated. Participants ($N=368$) were presented with either high-risk experiential gifts or low-risk experiential gifts (pretested as different in terms of social risk, $p < .001$, but not in attractiveness, $p > .4$). In the high risk condition, we replicated the interaction effect between social distance and gift type ($F(1,364)=23.75, p < .01$), whereas

in the low risk condition we only found a main effect of gift type ($F(1,364)=15.25, p < .01, \eta p^2=.04$) such that experiential gifts were more preferred than material gifts regardless of the social distance. Together, these results confirmed the proposed moderating role of the social risk associated with experiential gifts.

In sum, this research demonstrated that consumers prefer to give material gifts compared to experiential gifts for distant (vs. close) recipients due to the greater knowledge of individual preferences that is required to give experiential gifts. The results suggest that if firms can provide offerings that lower the social risk of experiential gift giving—thus lowering the knowledge needed to give an experience—then we may find a future where giving experiences becomes more mainstream.

Losing Our Most Special Possession: The Unexpected Positivity of Dying

EXTENDED ABSTRACT

Of all our worldly possessions, our lives are perhaps the most valuable—a fact that can make death seem terrifying. Both death and its inevitability are central to the human condition, inspiring countless poems, books, and plays—as well as substantial psychological research. Much of this research has focused on the general idea of one's own death (Juhl & Routledge, 2016; Kashdan et al., 2014) or reactions to others' deaths (Kastenbaum, 2000; Nelson & Nelson, 1975), rather than the actual experience of dying. What is it like to have only days—or even minutes—left to live?

In this project, we investigate the emotional lives of those about to lose their most valuable possession: those dying via terminal illness or execution. We assess whether their experience differs from how people imagine dying. Becker (1997) suggested that the mere thought of eventual death is so terrifying that ideologies, like religion, can automatically suppress or sublimate these thoughts—an idea borne out by early research (e.g., Greenberg et al., 1990). However, these negative beliefs about dying may be overinflated. Research on affective forecasting suggests that people overestimate the affective impact of negative events because of both focalism—thinking of the negative event in isolation (Wilson, Wheatley, Meyers, Gilbert, & Axsom, 2000) the tendency to overpredict the duration of affective reactions to future events, may be due in part to focalism, whereby people focus too much on the event in question and not enough on the consequences of other future events. If so, asking people to think about other future activities should reduce the durability bias. In Studies 1-3, college football fans were less likely to overpredict how long the outcome of a football game would influence their happiness if they first thought about how much time they would spend on other future activities. Studies 4 and 5 ruled out alternative explanations and found evidence for a distraction interpretation, that people who think about future events moderate their forecasts because they believe that these events will reduce thinking about the focal event. The authors discuss the implications of focalism for other literatures, such as the planning fallacy.”,ISSN:”0022-3514”,”note:”PMID: 10821192”,”shortTitle:”Focalism”,”journalAbbreviation:”J Pers Soc Psychol”,”author:”[{"family:”Wilson”,”given:”T D”}, {"family:”Wheatley”,”given:”T”}, {"family:”Meyers”,”given:”J M”}, {"family:”Gilbert”,”given:”D T”}, {"family:”Axsom”,”given:”D”}],”issued:”[{"date-parts:”[”2000”,5]}]”,”schema:”https://github.com/citation-style-language/schema/raw/master/csl-citation.json”) —and immune neglect—discounting their ability to positively reinterpret negative events (Gilbert, Pinel, Wilson, Blumberg, & Wheatley, 1998; Hoerger, 2012).

Grounding our predictions in these two streams of research, we hypothesize that as people come closer to death, they will view the loss of this most valuable possession more positively and less negatively than those imagining their death in prospect. Revealing that dying is more pleasant than expected may suggest a reassessment of one of humanity's great fears. We compare blogs of terminal illness patients (Study 1) and the last words of death row inmates (Study 2) with forecasts of everyday people imagining themselves facing death. We also examine affect over time in illness blogs (Study 1), and compare death row last words with death row poetry (Study 2). Overall, these investigations will reveal whether death is more pleasant than individuals might think.

Study 1 contrasted the affective tone of blog posts of terminally ill patients ($N = 2,616$) with simulated posts of non-patient participants asked to imagine that they are dying of a terminal illness and to write a blog post about it ($N = 50$). To examine these writings, we used both Linguistic Inquiry and Word Count (LIWC) software and independent coders to rate affect of posts. LIWC analyses revealed that non-patient forecasters ($M = 2.25$) used significantly more negative affect words than terminal patients ($M = 1.70; p = .006$). There were no significant differences in positive affect between terminal patients ($M = 3.43$) and non-patient forecasters ($M = 3.61; p = .52$).

Similarly, independent coders rated blog posts of terminal patients significantly higher on positive affect ($M = 2.65$) than posts of non-patient forecasters ($M = 2.43; p = 0.003$). Coders rated the posts of terminal patients ($M = 2.00$) significantly lower in negative affect than those of non-patient forecasters ($M = 2.36; p < .001$).

As an exploratory investigation, we examined the affective character of terminal patient blogs over time. Multi-level model analyses reveal that positive affect significantly increased as patients approached death ($b = -0.14, p = 0.026$) but negative affect did not increase ($b = 0.008, p = 0.839$).

Our second study examined affect in death row inmates' last statements. Given the results of Study 1, we predicted that inmate last words would be relatively more positive and less negative than non-inmate affective forecasts or poetry written by death row inmates. Last statements of non-inmate forecasters ($N = 117$) and death row poetry ($N = 188$) were compared to those of death row inmates ($N = 396$).

A one-way ANOVA of LIWC ratings revealed significant differences between last words, simulated last words, and death-row poetry in both negative affect ($p < .001$) and in positive affect ($p = .011$). Death row inmates ($M = 2.61$) used a significantly lower percentage of negative affect words in their last statements than in inmate poetry ($M = 5.12$), which both contained less negative affect than in non-inmate forecaster simulated last words ($M = 7.00$). Additionally, positive affect words were higher in last words ($M = 9.23$) and death-row poetry ($M = 10.25, SD = 17.55, 95\% \text{ CI } [8.67, 11.83]$), than in simulated last words ($M = 6.37$).

Independent coder ratings showed a similar pattern of significant differences between last words, simulated last words and death-row poetry in both negative affect ($p < .001$) and in positive affect ($p < .001$). Inmate last words were rated less negative ($M = 1.96$) than death row poetry ($M = 2.19$), with non-inmate forecaster simulated last words being rated as most negative ($M = 2.33$). Additionally, last words ($M = 2.24$) and death row poetry ($M = 2.39$) were rated as more positive than non-inmate forecasters' last words ($M = 2.08$).

In sum, two studies reveal that, when we are about to part with our most valuable possession, we view the loss of our lives in an unexpectedly positive way. Not only do the blog posts of terminally ill patients become more positive as death approaches, but the blogs of near-death patients are less negative and more positive those of

non-patient forecasters. The last words of death row inmates are also more positive and less negative than those of non-inmate forecasters and death row poetry (Study 2). This work has the potential to inform the way we view the loss of this most precious possession – our lives. Our work suggests that death is experienced much more positively than people expect: giving our lives to the Grim Reaper may not be quite as grim as it seems.

Courtney Szocs, Portland State University, USA

SESSION OVERVIEW

The theme of the proposed special session relates to altering perceptions of healthiness through various multi-sensory tools. The collection of papers identifies tools related to the visual, haptic, and olfactory senses that consumers can use to see, touch and smell their way to healthier consumption. In the first paper, Liu, Haws, Scherr, Redden, Bettman, and Fitzsimons focus on visual factors that influence healthiness. They examine the effects of varying the type of food (e.g., chocolates vs. cookies vs. almonds vs. crackers) and the quantity (e.g., ½ serving vs. 1 serving vs. 2 servings vs. 3 servings) on healthiness perceptions. They find that the type of food serves as the primary dimension that dominates healthiness judgments while the quantity of food serves as the secondary dimension that does not critically affect healthiness perceptions.

The second paper focuses on a haptic factor that can influence healthiness perceptions. Specifically, Baskentli, Block, and Morrin examine how the temperature at which a food is served might influence consumers’ calorie perceptions and complementary food choices. They identify a “serving temperature bias” whereby serving a food hot leads to higher calorie perceptions than serving the same food cold. This is because warm foods are perceived as “homelike” and enhance perceptions of hedonic pleasure.

The third paper by Jia, Krishna and Li examines another visual factor that influences healthiness perceptions. They investigate how setting calorie budgets by day (i.e., an “overall approach”) versus by meal (i.e., a categorical approach) influences the total number of calories budgeted and consumed. They find that the categorical approach to budgeting leads to lower total budgets and lower con-

sumption by offering the consumer more opportunities to exercise self-control.

Finally, Biswas and Szocs examine how an olfactory factor related to ambient scent of an indulgent (vs. non-indulgent) food influences consumers’ food choices. They find that children and adults choose healthier options when they have prolonged exposure to an indulgent (vs. non-indulgent) ambient food scent. They attribute their effects to cross-modal sensory compensation whereby olfactory inputs compensate for gustatory pleasure.

Collectively, the four papers in this session identify four novel multi-sensory factors that influence healthiness perceptions. The key question, raised by all the papers as a group, relates to what might be some critical sensory factors that can influence healthful consumption? The proposed special session brings together leading scholars and addresses healthful consumption using diverse methods (e.g., field experiments, lab experiments) and multiple populations (e.g., adults, children). We expect this session to have a broad appeal.

The Primacy of “What” Over “How Much”: How Type and Quantity Shape Healthiness Perceptions of Food Portions

EXTENDED ABSTRACT

Imagine a consumer with a healthy eating goal who is deciding whether to consume a particular portion of chocolate candies. Like most consumers with healthy eating goals, this consumer’s main health goal consists of losing or maintaining weight (International Food Information Council Foundation 2012), such that calories are typically considered the objective measure of health goal impact (Campbell and Warren 2015; Chandon and Wansink 2007; Cochran and Tesser 1996; Huang, Zhang, and Broniarczyk 2012). Given the importance of calories as an objective measure for most consumers’ health goals, there are two main aspects of the food consumed that ought to combine to jointly determine how a given food portion will affect the consumer’s health goals: the type of food and the quantity of the food. However, do a consumer’s judgments of the health impact of a food portion fully factor in both type and quantity, or are they driven more by one dimension than the other?

In this research, we examine the effects of varying food types (e.g., chocolates vs. cookies vs. almonds vs. crackers) and varying food quantities (e.g., ½ serving vs. 1 serving vs. 2 servings vs. 3 servings) on healthiness perceptions. In comparison, the existing food and health literature generally either: (1) separately examines type or quantity; or (2) does not distinguish between type and quantity, instead defining objective healthiness in terms of total calories. We instead introduce an explicit comparison between pursuing health via changing the type versus quantity of a food. Drawing from literature on processing categorical versus continuous attributes (Ha, Park, and Ahn 2009) and by drawing an analogy to research on how people make area judgments of geometric figures (Krider, Raghubir, and Krishna 2001), our main proposition is that for healthiness perceptions, food type is treated as a “primary dimension” (i.e., a highly salient dimension that dominates judgments), whereas food quantity is treated as a “secondary dimension” (i.e., a dimension that does not affect judgments much unless made salient, and, even then, affects judgments less than a primary dimension).

We demonstrate the secondary nature of quantity and the spontaneous tendency to underweight quantity across six studies. Studies 1-3 utilize a visual food diary paradigm with before-after photos of food portions to indicate a snack episode. Study 1 provides initial evidence for our primary-secondary account by showing that consumers' healthiness evaluations of these snack episodes reflect food type differences but are largely insensitive to food quantity differences, even though consumers are able to perceive the quantity differences. Studies 2a and 2b then test process-related predictions stemming from our primary-secondary account by examining two theoretically-motivated ways of increasing the salience of quantity at the time of making healthiness judgments. Study 2a increases the salience of quantity by prompting a joint evaluation mode among participants (González-Vallejo and Moran 2001; Hsee 1996). Study 2b increases the salience of quantity by drawing from expectancy-disconfirmation theory (Bettman 1979; Helgeson and Beatty 1987) to create a condition in which participants evaluate a portion size much larger than would be expected for consumption on one occasion. Studies 2a and 2b show that when the salience of quantity is increased, consumers adjust their healthiness perceptions to account for quantity but only to a small extent.

Study 3 further tests our primary-secondary account by adding emphasis to the actual consumption or eating of (nearly) the entire food portion, finding that consumers continue to treat quantity as secondary. In addition, while our main focus is on healthiness perceptions, Study 3 examines the additional outcome of caloric perceptions and shows that they track less than 1:1 with size perceptions, again suggesting an underweighting of quantity in caloric perceptions.

Study 4 then further tests our primary-secondary account of healthiness perceptions by examining healthiness perceptions when caloric information about food portions is explicitly provided. Study 4 shows that the secondary nature of quantity in healthiness assessments holds even when consumers are provided with caloric information. Study 4 also finds support for our primary-secondary account using direct process measures adapted from Krider et al. (2001).

Finally, Study 5 examines choice implications by examining how consumers instructed to make choices for a healthy lifestyle choose between portions of two calorically dense but differentially healthy foods (chocolates vs. almonds). We find that consumers choose the healthier food type (almonds) even when the size of the almond portion means that the caloric content of the almond portion far exceeds the caloric content of the chocolate candies portion. This finding suggests that the secondary nature of quantity is also reflected in consumers' food choices.

In closing, we provide substantial evidence that although both the types and quantities of foods eaten jointly contribute to weight and overall health, consumers treat type as a primary dimension and quantity as a secondary dimension. Accordingly, a food's type (vs. quantity) has greater impact on perceived health impact, across multiple study designs and stimuli, and even when controlling for caloric content or providing caloric information. Given that healthiness perceptions are an important input to food choice, the tendency towards neglecting or underweighting quantity may have negative effects on those pursuing health goals, especially weight loss goals.

Our findings offer contributions to two main literatures. First, we contribute to the goals literature by showing that even when a change in type or quantity results in exactly the same caloric change, the changes are perceived by consumers to impact healthiness to different extents. This stands in contrast to the existing goals literature, which has to-date treated calories as an objective indicator of health impact given that weight loss is a common health goal. Further, our

research also contributes to the extensive food decision making literature, which has generally used two different choice paradigms (either choice among different food types or choice among different food quantities) to examine the healthiness of food choices. We show that the choice paradigm used affects consumers' perceptions of the healthiness differences between options, suggesting that conclusions from one choice paradigm may not always translate directly to contexts involving the other choice paradigm.

Some Like it Hot: The Effect of Serving Temperature on Perceived Caloric Content and Intent to Purchase Complementary Food

EXTENDED ABSTRACT

Which temperature, hot or cold, to choose for a meal or snack is a common – one might say ordinary-- food decision that consumers make throughout the day, at home as well as at a variety of food retailers. Despite the ubiquity of this decision, no research to date has examined the impact, if any, that consuming a food item served hot, rather than cold, has on consumer inferences regarding its caloric content. Biased caloric estimates have important implications for consumers, as research has shown downstream consequences on obesity (Chandon and Wansink 2007), subsequent and/or concurrent food choices, and overall food well-being (see Chandon and Wansink 2012, and Bublitz et al. 2013).

With this research, we uncover a phenomenon we refer to as the “*serving temperature bias*,” as well as the theoretical underlying source of this bias. The serving temperature bias refers to the notion that people generally believe that a food or beverage served hot has more calories and is more fattening than the same item served cold. Specifically, we show that the serving temperature bias results from a series of sequential linkages. We show that warm foods and beverages are perceived to be prepared with love and that consuming them feels indulgent. We thus build consumer theory by showing that perceived love triggers feelings of indulgence, which is the direct antecedent of perceived caloric content. This research also extends the basis upon which the concept of “psychological warmth” is based. Whereas previous research has suggested this concept arises primarily from the physical holding and cuddling that provides infants with warmth, we suggest it is also based on the warmth emanating from the nourishment (foods and beverages) provided by caregivers early in life. Importantly, we show the existence of a downstream consequence of the serving temperature bias in the form of compensatory consumption.

We begin by providing phenomenon-based evidence of the downstream consequence of the food serving temperature bias in the form of complementary foods or beverages using collected sales receipts from a sandwich shop. Results of this field study revealed that customers who ordered a cold sandwich purchased significantly more complementary items (bag of chips, cookies, beverages) than those who ordered a hot sandwich ($M_{\text{cold}} = 0.79$ vs. $M_{\text{hot}} = 0.33$; $F(1, 121) = 9.48, p = .003$).

In study 2a, we gave participants a sandwich consumption scenario and asked them to imagine consuming the sandwich either hot or cold. Results revealed a significant main effect of serving temperature such that those who imagined consuming the hot sandwich estimated the caloric content to be higher than those who imagined consuming the cold sandwich ($M_{\text{hot}} = 4.71$ vs. $M_{\text{cold}} = 4.13$; $F(1, 103) = 11.11, p < .002$). We also showed the underlying reasons for the serving temperature bias. Results showed that the path from serving temperature (hot = 1, cold = -1) to prepared with love was significant ($B = 0.40, p = .0088$), as was the path from prepared with love to

indulgence ($B = 0.26, p = .0009$) and the path from indulgence to perceived caloric content ($B = 0.23, p = .0021$). In support of our theorizing, a bootstrap analysis of this causal chain yielded a confidence interval that did not contain zero (indirect effect = .0236, $SE = .0150, 95\% CI = .0051$ to $.0728$). Similar to the results observed in the field study, an ANOVA confirmed a significant main effect of serving temperature on complementary food choices such that participants in the cold condition were more likely to order a bag of chips with their sandwich than participants in the hot condition ($M_{hot} = 3.77$ vs. $M_{cold} = 4.62, F(1, 103) = 4.90, p = .029$). Studies 2b, 3 and 4 revealed similar results in actual food consumption settings (i.e., apple cider, chocolate chip cookie, and milk respectively). Through our lab studies we are also able to rule out several alternative explanations (such as effort, satiation, taste, mood, freshness, relevant sensory attributes, and perceived consumption quantity).

Then, in study 5, we show that it is not the initial temperature of the food that matters, but rather the temperature at which it is served that elicits the biased perceptions. To do this, participants were assigned to one of three conditions; hot, cold, or cold-then-hot. An ANOVA with caloric content as the dependent variable was significant ($F(2, 153) = 5.17, p = .007$). Planned contrasts revealed that, as predicted, those in the hot sandwich condition estimated the caloric content to be significantly higher than those in the cold sandwich condition ($M_{hot} = 4.26$ and $M_{cold} = 3.71, t(153) = 3.15, p = .002$) as shown in the previous studies. Importantly, and in support of our serving temperature bias, people in the cold-then-hot sandwich condition also estimated the caloric content of their sandwich to be higher than those in the cold sandwich condition ($M_{cold-then-hot} = 4.09$ vs. $M_{cold} = 3.71, t(153) = 2.16, p = .033$) and equally caloric to those in the hot sandwich condition ($M_{hot} = 4.26$ vs. $M_{cold-then-hot} = 4.09, t(153) = .94, p = .349$).

Thus, in six studies, we provide empirical evidence of the serving temperature bias, demonstrate the underlying reasons (while ruling out several alternative processes) and show the existence of an important downstream consequence of the serving temperature bias in the form of compensatory consumption.

Unpacking Self-Control: When More Categories Lead to Lower Calorie Budgets

EXTENDED ABSTRACT

Research on self-control has documented that people have trouble limiting their consumption across various domains such as eating and smoking (Heatherton and Baumeister 1991). One way to effectively address the problem of overconsumption is to set budgets (Herman and Polivy 2004). In this research, we study how different budgeting approaches result in different total consumption budget, and why they do so. Specifically, we examine two approaches that consumers may employ to set their daily consumption budgets. One approach sets an individual calorie budget for each consumption occasion (e.g., breakfast, lunch, dinner, and snacks; hereafter, called the “categorical approach”). Alternatively, consumers directly set an overall calorie budget (hereafter, called the “overall approach”).

Prior unpacking effects suggest that unpacking an overarching category into its components will increase numeric judgment (Rotenstreich and Tversky 1997; Tversky and Koehler 1994). However, we propose and demonstrate that unpacking, i.e., the categorical (vs. overall) approach, makes consumers set a lower budget – we call this the “Budget Contraction Effect” (BCE). We show that the BCE arises because the categorical (vs. overall) budgeting approach provides multiple opportunities for individuals to exert self-control.

Study 1a was conducted to test the BCE. Participants ($n=294$) were randomly assigned into one of the three conditions. In the *categorical* condition, participants were asked to set calorie budgets for four eating occasions (breakfast, lunch, dinner, and snacks). The budgets that participants set for the four occasions were automatically summed to derive their total daily budget. In the *overall-with-category-information* condition, participants were asked to set a daily calorie budget but were reminded to include their calorie intake for breakfast, lunch, dinner, and snacks. In the *overall-without-category-information* condition, participants were just asked to set their daily calorie intake budget without being reminded of the four eating occasions.

An ANOVA revealed a significant effect of budgeting approach on the calorie budget ($F(2, 291) = 3.06, p < .05$). A contrast analysis further indicated that participants set a lower budget under the categorical approach ($M = 1801.92$ calories) than either the overall-with-category-information approach ($M = 1981.39$ calories; $p = .03$) or the overall-without-category-information approach ($M = 1978.16$ calories; $p = .04$). There was no significant difference in budget between the two overall-approach conditions ($p = .97$). To test the robustness of the BCE, we used natural food groups (e.g., vegetables, grains) as the components in study 1b and replicated the findings of study 1a.

Next, we test the self-control process explanation. We argue that the BCE occurs because (many) consumers want to limit their consumption. Therefore, the strength of consumers’ self-control motivation should moderate the BCE.

In studies 2a and 2b, we test individuals’ internal motivation strength. In study 2a ($n=392$), as well as the later studies, we included only the overall-with-category-information condition to keep the component information constant between the overall and categorical conditions. The proxy for motivation strength was whether participants were dieters or non-dieters. We found that the BCE was observed for dieters ($M_{categorical} = 1756.29$ calories, $M_{overall} = 1950.52$ calories; $F(1, 388) = 5.85, p = .02$) but not for non-dieters ($M_{categorical} = 2082.89$ calories, $M_{overall} = 2195.36$ calories; $F(1, 388) = 1.92, p = .17$).

In study 2b ($n=122$), we manipulated participants’ motivation to control calorie consumption. In the *dieting-is-better* [*exercise-is-better*] condition, participants were told that to lose weight, “eating less” is better than “exercising more.” [“exercising more” is better than “eating less.”] We found a significant interaction between motivation and budgeting approach ($F(1, 118) = 7.10, p = .009$). The BCE was observed in the dieting-is-better condition ($M_{categorical} = 1664.26$ calories, $M_{overall} = 2420.00$ calories; $F(1, 118) = 16.72, p < .001$) but not in the exercise-is-better condition ($M_{categorical} = 2097.65$ calories, $M_{overall} = 2157.04$ calories; $F < 1$).

In studies 3a and 3b, we test the role of the budgeting unit (e.g., calories vs. food points). We predict that the BCE will be stronger when the budgeting unit can activate self-control (e.g., calories) versus not (e.g., food points). In study 3a ($n=386$), half of the participants were asked to set consumption budgets using *calories* as the budgeting unit while the other half of the participants used *food points* as the budgeting unit. We found a significant interaction between budgeting unit and budgeting approach ($F(1, 382) = 4.82, p = .03$). The BCE was observed when the budgeting unit was calories ($M_{categorical} = 1873.98$ calories, $M_{overall} = 2049.00$ calories; $F(1, 382) = 9.01, p = .003$) but not for food points ($M_{categorical} = 27.54$ food-points, $M_{overall} = 25.16$ food-points; $F < 1$).

To further test the role of the budgeting unit, we conducted study 3b ($n=198$) with smokers. Half of the participants were asked to set budgets for “cigarette consumption”, while the other half of the participants were asked to set budgets for “nicotine consump-

tion” from cigarettes. We found a significant interaction between budgeting unit and budgeting approach ($F(1, 191) = 4.21, p = .04$). The BCE was not observed when the budgeting unit was cigarettes ($M_{\text{categorical}} = 12.54$ cigarettes, $M_{\text{overall}} = 11.43$ cigarettes; $F < 1$) but was observed when the budgeting unit was nicotine ($M_{\text{categorical}} = 91.22$ mg-of-nicotine, $M_{\text{overall}} = 122.57$ mg-of-nicotine; $F(1, 191) = 4.59, p = .03$).

In study 4 ($n=89$), we test the behavioral consequence of budgeting approaches. In day 1, participants were asked to set a calorie budget for their food consumption next day. In day 2, participants reported their actual consumption by taking pictures of the food that they ate all day. We found that participants set a lower budget under the categorical versus overall approach ($M_{\text{categorical}} = 1528.36$ calories, $M_{\text{overall}} = 2011.36$ calories; $F(1, 87) = 13.55, p < .001$), and consumed less under the categorical versus overall approach ($M_{\text{categorical}} = 1418.22$ calories, $M_{\text{overall}} = 1649.44$ calories; $F(1, 87) = 5.33, p = .02$). A mediation analysis further revealed that budget set fully mediated the effect of budgeting approach on real consumption.

Our research adds to the literature on unpacking and self-control and has implications for obesity and anti-smoking programs.

The Smell of Healthy Choices: The Paradoxical Effects of Ambient Scent on Children’s and Adults’ Food Choices

EXTENDED ABSTRACT

The obesity rate among children continues to be high (Ogden et al. 2014). Childhood obesity often leads to lifelong medical problems including diabetes, heart disease, and cancer (Weiss et al. 2013), along with social and psychological problems (Puhl and Latner 2007). While physical exercise and even genetic factors can potentially influence obesity, food choices and diet regimens play more influential roles (Livingston and Zylke 2012).

To tackle the high obesity rates among children, regulators/policymakers have implemented restrictive policies to encourage healthier eating, such as by banning sales of “junk food” (Lincoff 2014), sugary sodas (Park 2011), and chocolate milk (Firger 2014) in school cafeterias and vending machines. However, such restrictive policies have often been met with strong resistance and even led to unintended negative consequences, suggesting that subliminal factors might be more effective in influencing behavior (Biswas et al. 2017).

This research examines how one such subliminal factor, in the form of ambient scent, might help to encourage healthier food choices. We focus specifically on how ambient scents related to indulgent (e.g., pizza, cookie) versus non-indulgent foods (e.g., strawberry, apple) influence children’s food choices at school cafeterias. We build on work related to cross-modal sensory compensation which shows that the sensory cortical areas, and particularly the areas related to the olfactory and gustatory systems, are interconnected (De Araujo et al. 2003; Maier, Wachowiak, and Katz 2012) as well as work which shows that exposure to pleasurable stimuli activates reward centers of the brain (Aharon et al. 2001). We propose that when exposed to an ambient scent of an indulgent food item, due to cross-modal sensory influences the reward circuitry of the brain can be satisfied with the sensory olfactory inputs of something tasty and unhealthy, which in turn will reduce the desire for actual indulgent (i.e., unhealthy) foods. We test this hypothesis in five studies.

Study 1a, a field experiment conducted at a middle school cafeteria, examined the effects of artificially diffusing pizza (vs. apple vs. no) scent in the ambience of the cafeteria on schoolchildren’s food choices. The children were exposed to apple, pizza, or no scent as they waited to enter the lunch line. Sales data were obtained from the school administration. The results show that a higher percentage

of healthy items were purchased when the cafeteria had a pizza versus apple ambient scent (78.57% vs. 63.04%; $\chi^2 = 168.33, p < .001$) or versus the control condition of “no scent” (78.57% vs. 62.14%; $\chi^2 = 185.42, p < .001$). There was no difference when the ambient scent was apple versus “no scent” (63.04% vs. 62.14%; $\chi^2 = .47, p = .49$). Study 1b, another field experiment, replicated the effects of Study 1a using a different set of indulgent versus non-indulgent ambient scents (pizza vs. strawberry).

We hypothesized that an unhealthy food related scent would enhance feelings related to a “rewarding pleasant experience” in the reward circuitry of the brain, which in turn will reduce the desire for unhealthy foods. In study 2, we directly tested this proposed mediating effect. In addition, study 2 also examined the moderating effect of hunger. Since hunger tends to enhance the acuity of the olfactory system (Critchley and Rolls 1996), olfactory sensitivity is greater under higher hunger states (Stafford and Welbeck 2011). Hence, we propose that the cross-modal influence of food-related olfactory cues on satisfying gustatory desires related to the brain’s reward circuits would be stronger under high hunger and weaker under low hunger. Study 2 was a field experiment conducted at a middle school cafeteria. Ambient scent was manipulated as in studies 1a and 1b. Study 2 involved participants filling out a short survey. As hypothesized, exposure to cookie (vs. apple) ambient scent led to higher choices of healthier options (53.66% vs. 29.73%; $\chi^2 = 4.56, p < .05$). Mediation analysis using Preacher and Hayes’s (2008) bootstrapped samples (5,000) showed a direct effect of ambient scent on food choices ($CI_{95\%}: .2513, 2.3260$) as well as indirect effects with the effects being mediated by feelings of rewarding pleasant experience ($CI_{95\%}: -.7824, -.0013$). Also, there was a significant effect of ambient scent on food choices (at $p < .05$) for hunger values at 4.51 and above with the effects getting weaker, and attenuated, with hunger levels below this threshold point.

Study 3 examined the moderating effect of duration of exposure to the ambient scent. If as conceptualized, prolonged exposure to the indulgent ambient scent satisfies gustatory cravings, then the effects should hold when an individual is exposed to the ambient scent for a prolonged period as the children were in the field studies. In contrast, brief duration of exposure to the scents should whet the appetite (Wadhwa, Shiv, and Nowlis 2008), leading to priming effects. Study 3 was a 2 (ambient scent: cookie vs. strawberry) X 2 (duration of exposure: prolonged vs. brief) between-subjects experiment. The results of a logistic regression show an interaction effect (Wald $\chi^2 = 8.47, p < .01$). Long duration of exposure to the cookie (vs. strawberry) ambient scent led to greater degree of choice for the healthy option (78.0% vs. 59.74%; $\chi^2 = 4.57, p < .05$). The pattern of results reversed in the case of short duration of exposure to the ambient scents, whereby exposure to cookie (vs. strawberry) ambient scent led to lower degree of choice for the healthy option (55.17% vs. 72.22%; $\chi^2 = 4.08, p < .05$).

Finally, study 4 examines the moderating effect of scent identification capability. UPSIT kits were administered to determine scent identification capabilities. The results of a floodlight analysis demonstrate that the effects of ambient scent on food choices hold for individuals with moderate to high levels of scent identification capability but the effects attenuate for individuals with low scent identification capability.

Overall, across five experimental studies with both children and adults and using a mix of field and lab experiments, we show that prolonged exposure to indulgent food related ambient scents paradoxically enhances preference for healthy food options. These findings have implications for consumer wellbeing and managerial practices.

SESSION OVERVIEW

In 2015, Americans gave over \$370 billion, of which the vast majority came from individuals, which drives an important question – what motivates individuals to contribute to charitable causes? In this session, we focus on perhaps a more intriguing question – what *reduces* individuals' motivation to contribute time and money to or on behalf of charitable causes?

What motivates people to give less than they would give otherwise? What may lead society to devalue prosocial behavior? And, how might opportunities to behave prosocially through giving reduce participation in unrelated activities? Four papers explore these and related questions as they deepen our understanding of individuals' prosocial behavior.

The first two papers examine specific information cues that influence donation behavior, sometimes in counterintuitive ways. **Lupoli, Morvinski and Amir**'s paper challenges established notions that individuals are expected to increase their donation amount, the closer the fundraising campaign is to reaching its goal, and that popularity information positively affects donations. Their paper demonstrates that when the campaign goal has nearly been reached, individuals donate less when they see a large, rather than a small, number of past donors. The paper by **Savary, Li and Newman** examines how different expectations about altruism, which derive from different framing of the donation offering, affect donation decisions. Specifically, they show that a bundle framed as a "donation with a gift," as opposed to "charitable giving," evokes expectations of genuine altruism by causing people to compare the offer to donating without receiving a gift in return, and as a result, they are less likely to donate. The last two papers examine broader aspects of prosocial decisions. **Schwartz, Keenan, Imas, and Gneezy**'s paper demonstrates another situation where threatening one's altruistic self-image can be detrimental. Their work shows that people are less likely to opt-in to activities when they are offered prosocial incentives, where payment for work is donated to charity. Specifically, people avoid this type of

incentives even when they can keep the earnings for themselves due to the guilt associated with potentially saying no to such incentive offers. In the last paper, **Peleg, Lowengart, and Shapira** explore how prosocial behavior is evaluated by society and find that not only the economic value for the beneficiary is considered, but also the amount of self-sacrifice involved in the prosocial activity itself. Such findings may put in question whether social rewards concerns may lead to less effective prosocial responses.

Prior work on prosocial behavior has demonstrated the positive effects of information processing goals on giving, but little is known about how prosocial behavior is negatively impacted by consumers' implicit motives. Taken together, the four papers present novel findings that further our understanding of the mechanisms by which consumers prosocial decisions are constructed.

The session should be of interest not only to researchers who study consumer prosocial-behavior, but also to those who are more broadly interested in decision making, information processing, and incentive scheme optimization. The session incorporates multiple methodologies and speaks to audiences that include theory-inclined academics, consumers, policy-makers, and marketers.

Goal Proximity, Social Information, and Giving: When Norms Backfire

EXTENDED ABSTRACT

The crowdfunding industry has reached over \$34B in 2015 and is growing exponentially (www.crowdsourcing.org). Online fundraisers try to increase donations by providing potential donors with up-to-date information about their campaigns. Two types of information commonly presented are the percentage of the campaign goal that has been reached ("goal proximity"), and the number of individuals who have donated to the campaign. Research suggests that fundraisers would be wise to present these two metrics to potential donors. Indeed, individuals are more likely to donate when campaigns are close to (versus far from) reaching their goals (Cryder et. al. 2013). Likewise, information about the behavior of past donors (descriptive norms) has been shown to increase giving. For instance, people are more likely to give when they learn that a large (versus small) proportion of a population has donated (Frey & Meier 2004). Given the effects of goal proximity and descriptive norms on giving, one might expect these tactics to be at least equally effective when implemented simultaneously. In three studies, we observed a surprising interaction: when campaigns are close to reaching their goals, individuals donate more when there are few (versus many) past donors. We find that both impact concerns and perceived average donation by others drive the observed effect. Individuals may perceive their donation as being more impactful if they learn that few (rather than many) people have donated. In addition, individuals who receive information that a small (rather than large) number of people have donated (holding goal proximity constant), may assume that the average donation is relatively larger, which subsequently, affect their own giving amount. Interestingly, those effects strengthen, or manifest only, when the goal has nearly been reached.

In Study 1 ($N=12,265$ campaigns), we analyzed aggregated data from a popular fundraising website, Kickstarter.com, and found a significant negative interaction between goal proximity and number of past donors on the average amount donated across campaigns.

When campaigns were under 54% complete, there was no relationship between number of donors and giving. However, above 54%, this relationship was significantly (and increasingly) negative. This result held with and without covariates and transformations to account for data skewness.

In Study 2 ($N=571$), we obtained causal evidence for the interaction seen in the Kickstarter data. In this 3(Past Donors: many/few/no-information) \times 2(Goal Proximity: close/far) between-subject laboratory experiment, undergraduate student participants learned that they would be entered into a lottery for \$20, and that, prior to selection of the winner, they could choose to donate \$0-\$20 to a real charity campaign that is committed to saving the lives of malnourished children. They then received the manipulation in the form of a pie chart and written statement explaining that 86% (23%) of the campaign goal had been reached, and that there were 1,023 (23) previous donors (no-information treatment did not specify number of previous donors). Results: There were no main effects of goal proximity or past donors but there was a significant interaction ($F(2, 565)=3.94, p=.02$). When close to the goal, participants in the few treatments donated significantly more than those in the many treatment ($M_{\text{few}}=\$14.06, M_{\text{many}}=\$11.30, p=.01$). The average amount donated by those in the no-information treatment was in between those of the other conditions ($M=\$12.97$). When far from the goal, however, there was no effect of the past donors manipulation on giving. Participants in the many treatment gave slightly more than those in the few treatment but the effect was not significant ($M_{\text{few}}=\$12.08, M_{\text{many}}=\$13.52, p=.19$). The no-information treatment amount was once again in between the other conditions ($M=\$12.27$). Similar results observed when analyzing the probability of giving.

In Study 3 ($N=709$), we examined potential mechanisms for the effect and also tested progress-focus (accumulated versus remaining goal progress) as a potential boundary condition (Koo & Fishbach, 2008). In this 2 (Past Donors: few/many) \times 2 (Focus: accumulated/remaining) between-subjects design study, participants received the same charity campaign and past donors manipulations from Study 2, but everyone saw only the close goal proximity information. We manipulated progress-focus by either presenting (visually and textually) the percentage of the goal already funded (86%)—as was displayed to participants in Study 2—or the remaining percentage left to be funded (14%). Following the donation decision, we measured the perceived impact of donating on reaching the campaign goal using 3 items adopted from Cryder et al. (2013). We also measured other motivations for giving that could potentially account for the effect: perceived average donation, importance placed on campaign, perceived importance others place on campaign, anticipated positive and negative emotions, likelihood of reaching the goal without one's donation, perceived need, and moral responsibility. Results: Replicating Study 2's results, those in the few conditions donated more than those in the many conditions ($M_{\text{few}}=\$13.66, M_{\text{many}}=\$12.11, p<.01$). We observed no main effect of progress-focus, nor an interaction effect, and therefore collapsed across progress-focus. Importantly, a bootstrap multiple mediation analysis containing all potential mechanisms revealed a significant indirect effect of perceived impact on reaching the campaign goal ($\beta = 0.21, 95\% \text{ CI } [0.05, 0.48]$), while no other measure mediated the effect. Analyzing the probability of giving revealed virtually identical results. Together, our results suggest an intriguing phenomenon whereby information about many (as opposed to few) past donors negatively affects giving when the campaign goal is near. This effect is mediated by the perceived impact on reaching the campaign goal such that when the campaign is nearly being reached, information about few (as opposed to many) past do-

nors causes people to think that their donation will have a larger impact, leading them to increase their donation.

This work contributes to theory on goal gradient motivation, norms, and giving by providing the first demonstration that descriptive norms for giving (i.e., many others donated) can sometimes lead to less giving. Our results also have a practical implication: If fundraisers display information about goal proximity, they may be better off emphasizing a small number of past donors (when applicable), at least when the campaign is getting closer to reaching its goal.

Exalted Purchases or Tainted Donations? The Effects of Product Incentives on Charitable Giving

EXTENDED ABSTRACT

The present studies demonstrate a robust framing effect - offers framed as charitable purchases result in more charitable giving than materially identical offers framed as donations with a gift. To explain this result, we suggest that subtle changes in framing give rise to different expectations about altruism. Specifically, when a bundle is framed as a “*donation* with a gift,” it evokes expectations of genuine altruism, and people spontaneously compare the offer to donating without receiving a gift in return. In contrast, when an offer is framed as a “*charitable purchase*,” it is less likely to evoke expectations related to pure altruism and it may be perfectly acceptable (and perhaps preferable) to receive a gift.

Because people find actions that violate their expectations about their own altruism distasteful (Newman and Cain 2014), when the offer is perceived as less than purely altruistic, people are less likely to donate. Therefore, our primary hypothesis is that a charitable purchase should encourage more donations than an otherwise identical offer framed as a donation with a gift. Moreover, these effects should be mediated by differences in people's beliefs about how altruistic they would feel if they accepted the offer. Four laboratory experiments and two field studies provide support for these predictions

Study 1a: 412 participants saw an identical bundle framed as either a Charitable Purchase(CP) or Donation with Gift(DWG). In the DWG condition, the offer was: “Donate and receive a gift in exchange: Currently this organization is seeking donations in the amount of \$3.00. In exchange for your donation, you will receive a thank-you gift of a scented candle” (adapted from Holmes et al. 2002). In the CP condition, it was framed as: “Make a Charitable Purchase: Currently this organization is selling scented candles for \$3.00.” Participants indicated their choice (yes/no). Perceived altruism of the offers was measured on a subsequent page, where people rated the offer along seven dimensions (i.e. Charitable, Helpful, Selfish(r)). As predicted, participants were more likely to accept the offer when it was framed as a CP (61.9%) than when it was framed as a DWG (38.1%, $p < .001$). Participants rated the CP offer as more altruistic than the DWG, $M_{\text{charitablepurchase}} = 75.7, SD = 19.9$ vs. $M_{\text{donation-withgift}} = 65.3, SD = 24.4, F(1, 400) = 22.3, p < .001$). Bootstrap analysis indicates that the measure of perceived altruism fully mediated the framing effect ($\beta = .76, SE=.19; 95\% \text{ CI}=.42 \text{ to } 1.15$).

Study 1b was a conceptual replication using a Likert scale instead of a choice. As before, participants were more likely to accept the offer when it was framed as a CP ($M = 4.6$) than when it was framed as a DWG ($M = 4.1, p = .02$). The CP offer was rated as more altruistic compared to a DWG ($M_{\text{charitablepurchase}} = 78.5$ vs. $M_{\text{donation-withgift}} = 70.6, p = .000$), and perceived altruism fully mediated ($\beta = .21, SE=.06; 95\% \text{ CI}=.10 \text{ to } .33$).

Study 2 used materials identical to 1b, but was conducted in a campus lab and participants completed a thought-listing protocol after the other measure. Again, participants were more likely to ac-

cept the offer when it was framed as a CP ($M_{charitablepurchase} = 5.5$) than when it was framed as a DWG ($M_{donationwithgift} = 4.7, p = .006$), the offer was more altruistic when it was framed as a CP ($\alpha = .89, M_{charitablepurchase} = 77.5$, vs. $M_{donationwithgift} = 64.6, p < .001$) and perceived altruism mediated ($\beta = .21, SE = .07; 95\% CI = .10, .50$).

We hypothesized that when an offer is framed as a DWG, people are relatively more likely to spontaneously compare it to donating and not receiving a gift in return (i.e., “genuine” altruism). To test this, coders blind to condition and hypothesis categorized the thought-listing responses. DWG participants mentioned that the presence of the gift was negative/that they wish they did not receive the gift more often than CP participants did ($P_{donationwithgift} = 33\%$ vs. $P_{charitablepurchase} = 18\%, p = .034$). According to our hypothesis, this in turn should predict rating the offer as less altruistic, which leads to decreased likelihood of accepting the offer. A serial mediation analysis confirms this causal chain, ($\beta = -.25, SE = .18; 95\% BCCI = -.083, .04$).

Study 3 investigates why differences in perceived altruism affect donation likelihood. To do so, we replicate the framing effect documented in earlier studies (using a different charity, gift and donation/purchase amount), and measure three potential mechanisms: *social-signaling*, “If I accepted this offer, other people would see me as”; *perceptions of the organization*, “In light of this offer, I see The Water Project organization as” and *self-signaling*, “If I accepted this offer, I would think of myself as.” Responses to all three measures were on a 7-point scale (1 = Purely selfish to 7 = Purely altruistic). As before, people were more likely to accept the offer when it was framed as a CP ($M_{charitablepurchase} = 4.96, M_{donationwithgift} = 4.44, p = .004$). Only the measure of self-signaling (i.e. how people would perceive themselves) was affected by the framing, and it mediated the effect of framing (DWG vs. CP) on willingness to accept the offer ($.08(.04); 95\% CI = .02, .19$).

Study 4 is a field study, conducted at a farmers’ market. Participants were exposed to an identical product-donation bundle (a bottle of water/\$1), which was framed either as a DWG or CP, depending on condition. People who heard the offer framed as a CP were more likely to accept it ($P_{donationwithgift} = 48.2\%$ vs. $P_{charitablepurchase} = 75.9\%, p = .002$).

Study 5 is a large-scale field study in which door-to-door solicitors approached roughly 1,400 households offering a product-donation bundle (bag of microwave popcorn/\$1.50). The two focal conditions were framed as a DWG (for every \$1.50 donated the participant received a \$0.75 bag of popcorn), and a CP condition (for every bag of popcorn purchased for \$1.50, \$0.75 was donated to charity). Households were 8% more likely to accept the offer in the CP condition (29.19%) than in the DWG condition (21.01%, $p < .05$).

The present studies suggest that the framing of an offer plays a key role in determining how donation-product bundles are interpreted. Specifically, we suggest an important theoretical distinction between offers framed as “donations” versus identical offers framed as “purchases.”

Opting In to Prosocial and Standard Incentives

EXTENDED ABSTRACT

Optimizing incentive schemes to increase effort provision is an important design question for firms and other organizations. However, standard self-benefiting monetary incentives have been shown to backfire in certain contexts (e.g. Gneezy & Rustichini, 2000). To overcome this detrimental effect, prior work has demonstrated that “prosocial incentives” – where individuals work and their payments go to a charitable organization – can be more effective than stan-

dard incentive schemes, particularly when the stakes are low (Imas, 2013; Yang, Hsee & Urminsky, 2014). However, it remains unclear whether prosocial incentives are effective in prompting individuals to participate in an activity or task in the first place.

We examine the effectiveness of prosocial incentives for participation decisions in field and online settings in which the incentivized activity can be avoided; participants can disregard the invitation to do the activity or shut off the browser. In contrast, participants in prior laboratory studies exploring prosocial incentives have already agreed to participate in the activity by showing up; the decision to opt-out is either cumbersome or costly. We also introduce an *optional prosocial incentive* (i.e., individuals can choose to forego the standard incentive and give to charity instead). From the perspective of standard economics, an *optional prosocial incentive* should be appealing because people can select into the task both if they prefer to work for the standard and prosocial incentive. However, from a psychological perspective, this type of incentive may be less appealing than a standard incentive of equal size because individuals prefer to avoid situations in which they may have to directly turn down a charity solicitation (Dana, Weber, & Kuang, 2007); they would prefer to keep the money rather than donate it, but the psychological cost of saying no to the donation request may deter them from engaging with the activity in the first place.

Study 1. In a field experiment, households (N=951) living in a neighborhood with almost no door-to-door recycling collection received an invitation letter to participate in a program to recycle at a nearby drop-off center. In the letter, households were offered one of three levels of cash rewards (\$2.50, \$12.00, or \$25.00), and a message with either a donation option message: “if you prefer, you can also donate this money to an environmental cause” (optional prosocial incentive) or no donation message. One extra condition offered an “acknowledgement” only (no cash or donation option). Our main measure was the proportion of households who recycled with the program. Results: When there was no donation option message, households were 1.1% more likely to recycle for every \$2.50 increase in rewards ($p < .01$). However, when a donation option was included, households were less likely to recycle as the reward increased ($p < .01$) – in fact, at \$25.00, zero households showed up to recycle. The optional prosocial incentive was completely avoided when the incentive was large.

Study 2. Participants (N=1,345) were hired from an online labor market to verify whether a series of URLs were working. After finishing, they received their payment code, so they could leave the task and collect their compensation. They were also invited to participate in an optional bonus task that involved searching for additional images to complete a research database. In this invitation, participants were randomly assigned to either receive a standard incentive for their work, a non-optional prosocial incentive (their work was directly tied to a donation), or an optional prosocial incentive as in the field study (they could choose to donate their standard incentive after finishing the task, or to keep it). There were two levels of payment for their work (£0.01 or £1.00), generating 6 experimental conditions. Results: At the high incentive levels, compared to a standard incentive, participants were less likely to opt-in when an optional prosocial or non-optional prosocial incentive was offered, $OR = 0.59$ and $OR = 0.17$, respectively ($ps < .01$). At the low incentive levels, people were less likely to opt-in for non-optional prosocial incentives than for standard incentives ($OR = 0.46, p < .01$); there was no difference between the optional prosocial and standard incentives. We use a hurdle model to examine behavior at the intensive margin: people worked harder under prosocial incentives (vs. standard) when the amounts were low, consistent with previous evidence. Finally,

we conducted a mediation analysis which showed that reported feelings of guilt partially explained why people were less likely to opt-in when offered a high prosocial or optional prosocial incentive (vs. standard) – Indirect effects: $b=0.059$, 95% CI [0.027,0.115] and $b=0.013$, 95% CI [0.002,0.038], respectively. This is consistent with previous evidence showing that people feel less happy when they have the option to donate their money instead of just receiving it for themselves (Berman & Small, 2012).

Study 3. Using the same setting and invitation as in the previous study, participants ($N=916$) were randomly assigned to either receive £1.00 for searching additional images (high standard incentive), receive £1.00 and have the option to donate 10% of it to charity (partial donation option), receive £0.90 and donate £0.10 (partial donation), or receive £0.90 (low standard incentive). Consistent with the previous studies, we again found that people were less likely to opt-in when they had the option to donate their earnings, even a small part of it ($OR=0.64$, $p=0.02$). We also found that offering a high standard incentive was directionally more appealing compared to offering the partial donation or the low standard incentive, though the results were not significant at the 5% level.

Across studies, our findings suggest that offering prosocial incentives may not be an effective tool to attract people to participate in a task when they have the option to avoid it, i.e. motivating extensive margin decisions. Furthermore, we find that increasing the incentive level does not make the option to donate more appealing, as would be suggested by a standard economic model in which people can self-select into work depending on the type of incentive. Furthermore, our findings suggest that people avoid optional prosocial incentives due to the guilt associated with potentially saying no. These results have implications for contract design and policies aimed at improving selection and recruitment.

The Value of Sacrifice - Relative Evaluation of Prosocial Behavior

EXTENDED ABSTRACT

Consider a case in which two individuals, Alice and Bob, donate money for a noble cause: while Alice donates \$50, Bob donates \$100. Naturally, we may expect that Bob will receive a higher social evaluation for his prosocial act as he donated twice as much as Alice. However, what if it is also known that Alice earns a weekly wage of \$500, while Bob earns \$1,500 per week? Would society then evaluate these acts differently? In this paper, we show that besides evaluating the economic value of one's contribution, society also values the sacrifice per se (i.e., cost) involved in the prosocial behavior even though the benefactor's sacrifice does not help the respective beneficiary.

In previous studies evaluating prosocial behavior and the sacrifice one has to make when the acts are costly, the sacrifice itself is commonly imposed to justify the selfless intentions of the benefactor (Ariely et al., 2009; Berman et al., 2015; A. Gneezy et al., 2012; Olivola & Shafir, 2013) we provide evidence that the prospect of enduring pain and exerting effort for a prosocial cause can promote contributions to the cause. Specifically, we show that willingness to contribute to a charitable or collective cause increases when the contribution process is expected to be painful and effortful rather than easy and enjoyable. Across five experiments, we document this martyrdom effect, and show that the observed patterns defy standard economic and psychological accounts, and identify a mediator and moderator of the effect. Experiment 1 showed that people are willing to donate more to charity when they anticipate having to suffer to raise money. Experiment 2 extended these findings to a

non-charity laboratory context that involved real money and actual pain. Experiment 3 demonstrated that the martyrdom effect is not the result of an attribute substitution strategy (whereby people use the amount of pain and effort involved in fundraising to determine donation worthiness. Moreover, while the sacrifice effect also known as the "Martyrdom Effect" (Olivola & Shafir, 2013) has been studied in the context of prosocial behavior, it has never been compared with the resultant economic value of the prosocial act to the beneficiary. To the best of our knowledge, we are the first to investigate how the trade-off between the economic value conveyed to the beneficiary and the sacrifice of the benefactor affects the social evaluation of prosocial activities. In particular, we are the first to measure this trade-off as it appears in different forms of a contribution (i.e., financial donations and volunteer work). In two studies, we explored the importance of sacrifice signaling in the overall social evaluation, and whether this evaluation changes due to information regarding the beneficiary's needs. We found that society's evaluation of the benefactor's sacrifice accounts for approximately 35 percent of the evaluation of the economic value of the contribution for the beneficiary. Moreover, when the evaluator is being primed towards the beneficiary's need, (i.e., for monetary donations or volunteers), the importance of the said need increases.

In order to measure how prosocial behavior is evaluated by others in the context of self-sacrifice, we conducted two online choice-based conjoint studies. Participants in both studies were asked to choose the most prosocial scenario out of three scenarios characterized by a benefactor's prosocial behavior: offering a monetary donation and volunteering, in addition to information regarding the benefactor's resources (his or her available time and monetary resources). The resources were introduced as a signal for the benefactor's sacrifice. Each attribute (i.e., monetary donation, volunteer work, working hours as a proxy for available time, and income as a proxy for monetary resources) was presented at one of four levels: low, medium-low, medium-high, and high. Each respondent viewed 14 different combinations of the three scenarios and selected what they believed to be the most prosocial one. In Study 1 ($N=465$), we explored prosocial evaluation in a non-informative environment in regard to the beneficiary's needs, whereas in Study 2 ($N=431$), we provided participants with information regarding the beneficiary's specific needs. Participants were informed that a beneficiary needed either a monetary donation (treatment 1) or volunteers (treatment 2).

We analyzed the combined results of both studies by employing a hierarchical Bayes analysis for individual-level estimation. The estimation yielded 0.80 RLH (i.e., root likelihood as model fit), which is significantly above a baseline level (0.33 for a random choice of 1 out of 3 concepts). Specifically, in Study 1, we analyzed the average attribute importance evaluation given by all the respondents and found that the importance of the economic value of the prosocial acts (i.e., monetary donation and volunteer work) summed up to 65% of the overall evaluation compared to 35% of the resources or sacrifice. Furthermore, we calculated the social reward for the interaction between the prosocial behavior and resource at each level (e.g., small donation when income is low). Our results suggest there are two significant trends wherein both a greater contribution and a lower level of available resources are associated with greater social evaluation (all $p<.01$). The results of the non-informative evaluations in Study 2 were not significantly different from the informative evaluation conditions in Study 1. Also, providing information that the beneficiary was in need of money significantly increased the importance of monetary donations. However, information that the beneficiary was in need of volunteers did not increase the importance of volunteer work. Our studies reveal that prosocial behavior is evaluated by

society in a relative manner. That is, not only is the economic value for the beneficiary considered, but also the amount of self-sacrifice involved in the prosocial activity itself. The greater the self-sacrifice involved, the greater is the reward given by society. Moreover, an evaluation might change due to information regarding a beneficiary's needs. Notably, this reward scheme may eventually lead to ineffective prosocial activities. As benefactors may care about the social reward they gain, they may also increase their sacrifice even if it is found to be unnecessary as far as the beneficiary is concerned. These findings might explain ineffective behaviors such as wealthy people who volunteer their time to do simple tasks (e.g., washing dishes at a shelter) or less affluent people who chose to make significant monetary donations. The benefactor's choice to contribute with the scarcer resource will increase that sacrifice and, therefore, the social reward. However, the contribution's value could decrease as far as the beneficiary is concerned, considering the alternative options for contribution.

SESSION OVERVIEW

As the population continues to grow, the world is becoming ever more crowded. Although there is an emerging body of research on crowding in marketing, the majority of it conceptualizes the impact of crowding in terms of various forms of defensive response from the consumer. For example, socially or spatially crowded stores lead to stress (Epstein 1981), an early exit from the store (Eroglu, Machleit, and Barr 2005), a perceived lack of control (Levav and Zhu 2009), and a preference for safety oriented products (Maeng, Tanner, and Soman 2013). In this session, we aim to broaden our understanding of crowding by bringing together four papers exploring new psychological processes and behavioral outcomes. In particular, collectively, the four papers ask if crowding can influence consumer thinking style, and how might this impact behavior and preference?

The first paper by Maeng, Tanner and Wu extends current understanding of crowding by examining its impact on creative performance. Across five experiments, they demonstrate that as individuals become more crowded they increasingly perform worse on creativity tasks. The authors demonstrate that this relationship between crowdedness and creative performance is moderated by crowd composition and an individual's need for arousal, and attenuated for sensation seekers and for crowds perceived positively.

Shifting attention from cognition to product choice, the second and third paper investigate how crowding in a retail setting influences consumer preference. By using both secondary retail data and experimental design, Ding and Zhu show that when consumers are a priori motivated to purchase from a product class, shopping in the crowded (vs. uncrowded) store will make them infer the overall availability of product supply as low and thus increase sales of the most-preferred items. Hock and Bagchi explore consumers' food consumption in crowded versus uncrowded contexts. Their findings suggest that crowding evokes more affective processing because of distraction and consequently makes individuals consume more calories. They also demonstrate that asking participants to focus on

rational thoughts could attenuate the effect of crowding on calorie consumption.

Finally, Zou, Wan, and Yim differentiate social crowding from spatial crowding and test the differential effects on consumers' adoption of anthropomorphized self-service technologies (SSTs). Specifically, they find that anthropomorphized SSTs could help restore control and will be more effective when consumers attribute crowding to spatial reasons. In contrast, when consumers attribute crowding to social reasons, anthropomorphized SSTs will be less effective due to social withdrawal tendency.

To summarize, this set of four papers identifies multiple new insights and novel psychological processes resulting from crowding in a variety of different contexts. We believe this session will attract audiences from diverse background including researchers interested in crowding, consumer cognition, information processing, decision-making, food consumption, and creativity. Findings discussed in this session will advance knowledge about consequences of crowding in retail settings. In addition, we aim to facilitate connections with marketing practice by presenting four papers that are managerially relevant. We also hope that this session will promote future research that could improve our understanding of service management in crowded retail settings.

The Influence of Social Crowding on Creativity

EXTENDED ABSTRACT

Recent research has revealed a wide variety of psychological consequences of being crowded. In this research, we built on the recent findings that being crowded moderates attentional scope and construal level (Maeng and Tanner 2013) and investigated whether social crowdedness might influence an individual's creative performance. In particular, we explored 1) whether being crowded reduces creativity, 2) whether an individual's threshold for arousal activation moderates the influence of social crowding on creative performance, and 3) whether the ways in which crowds are perceived negatively or positively moderates this effect. Our core hypothesis was that, as attentional scope narrows in crowded environments, individuals perform worse on creativity tasks. However, when the crowded individual is sensation seekers or when the crowds are perceived positively, the negative effect of crowding on creativity disappears. We tested these hypotheses in four studies.

Study 1 tested the basic relationship between crowdedness and creative performance. Students participated in the study for extra credit ($n = 193$). In identical rooms, participants were randomly assigned to either crowded (25 participants invited) or uncrowded (3 participants invited) sessions. Creativity was tested using the Guilford "brick uses and consequences" test (Friedman and Forster 2001) with limited time given. As predicted, the participants in the less crowded room generated a greater number of unusual uses of bricks ($M = 5.7$) compared to those in the crowded classroom ($M = 4.8$, $t(191) = -2.21$, $p < .03$). Moreover, coding use uniqueness on a 1-10 scale revealed that ideas in the less crowded room were also more unique ($M = 6.1$) compared to those from the crowded room ($M = 5.6$, $t(191) = -4.74$, $p < .001$).

Study 2 was designed to replicate this core result using a different task. Participants ($n=159$) were once again assigned to either a crowded or uncrowded room as in Study 1. Creativity was measured

using an insight problem-solving task, the “pig in the pen” problem (Schooler, Ohlsson, and Brooks 1993). It presents participants with an illustration of nine pigs in a single square pen, and challenges them (inside 3 minutes) to place them all in individual pens by drawing two additional squares. Consistent with our prediction, participants in crowded rooms were less likely solve the problem (5%) than participants in uncrowded rooms (13%; $\chi^2_{(1)} = 4.18, p < .03$).

The goal of Study 3 was to explore the potential moderating effect of crowd composition. Specifically, we were interested in whether the reduced avoidance motivations invoked by in-group (vs. out-group) crowds would result in an attenuation of the negative effect of crowding on creativity. The study was 2 (crowdedness: crowded vs. uncrowded) x 2 (group identity: in-group vs. out-group) between subject design. Group identity was manipulated using a dot estimation task which has been shown to reliably manipulate group identity (Tajfel et al. 1971). Creativity was measured using the Remote Associates Test (RAT; Mednick 1962). Participants ($n=94$) were given 15s to respond to each of seven problems. An ANOVA on total RAT score yielded a marginally significant interaction between crowdedness and group membership ($p = .07$). Specifically, when the crowd was comprised of out-group members, participants scored significantly lower in the crowded ($M = .19$) than the uncrowded condition ($M = .68, p < .03$). However, when the scene contained in-group members, no difference in RAT score emerged across the crowdedness conditions ($F < 1$).

Study 4 was designed to explore the potential moderating effect of individual differences in stimulation and arousal needs. Researchers have suggested that high sensation seekers (high need for arousal) reduce the intensity of an incoming stimulus, whereas low sensation seekers (low need for arousal) augment the intensity of the stimulus. Thus, we posited that sensation-seeking tendencies should moderate the influence of crowding on creativity. In particular, individuals who have a low need for arousal show reduced creative performance under crowding, whereas the creative performance of those with a high need for arousal are not much influenced by social crowding. The study was 2 (crowdedness: crowded vs. uncrowded) x 2 (arousal need: high vs. low) between subject design ($n=75$). Crowding was manipulated using a picture priming task and creativity was measured with the RAT used in study 3. The sensation seeking scale was administered to measure individual differences in stimulation and arousal needs (Zuckerman et al., 1978). An ANOVA on a total RAT score yielded a significant interaction between crowdedness and sensation seeking ($p < .01$). Specifically, when an individual is low sensation seeking (low need for arousal), participants scored significantly lower in the crowded ($M = 1.0$) rather than uncrowded conditions ($M = 2.28, p < .005$). However, when individuals that are high sensation seeking (have a high need for arousal), there was no difference in the RAT score that emerged across the crowdedness conditions ($F < 1$).

Study 5 explored the role of arousal and valence for the Study 3 findings. Participants ($n=109$) were first presented with a picture of either a crowded or uncrowded scene before being instructed to visualize and describe how they would feel if they were in the scene. These descriptions were later coded for evidence of expressed arousal (activated vs. deactivated) and valence (positive vs. negative). Participants next conducted the RAT as in Study 3. Participants in the crowded condition expressed significantly more activation than those in the uncrowded condition ($p < .001$). An ANOVA on the total RAT score yielded a marginally significant interaction between valence and arousal ($p = .09$). Results showed that participants reported greater arousal and scored more on the RAT when crowding is perceived as positive ($M = 2.67$) rather than negative ($M = 1.66, p$

$< .05$). However, no such differences were found among the participants who reported less activation ($F < 1$). Thus, Study 5 evidences that it is the type of arousal that is activated by social crowding that moderates creative performance.

In conclusion, our research demonstrated the ways in which social crowdedness influence creative performance. Our research has significant implications in many domains including team sizes for new product design or the potential impact of class size on student creativity in educational settings.

The Upside of Social Crowding on Consumer Product Preference

EXTENDED ABSTRACT

Suppose you decide to purchase a “Holiday Truffle Special Box” from a local dessert store that is currently promoting this special box at a discounted price. When you enter the store on your way home, you notice that the store is crowded with consumers. Will this feeling of crowding influence what truffles you choose to include in the special box? Building on the inference making literature (Fantz 1963; Kardes, Posavac and Cronley 2004), the current research aims to investigate how does social crowding affect consumers’ inference about the overall availability of the product class they intend to purchase from, and its consequence on product preference.

Social crowding is ubiquitous in a retail setting. Prior investigations of social crowding caused by higher level of consumer density have mainly demonstrated its negative affective and behavioral outcomes. For instance, previous literature suggests that social crowding activates an avoidance system (Maeng, Tanner and Soman 2013), leads consumers to infer lower social status of other shoppers at the store (O’Guinn, Tanner, and Maeng 2015), increases likelihood of earlier departure from the store (Hui and Bateson 1991) and decreases overall customer satisfaction (Eroglu, Machleit, and Barr 2005; Machleit, Eroglu, and Mantel 2000).

However, a hitherto unanswered question is whether the detrimental impact of social crowding on consumer preference prevails when consumers are a priori motivated to purchase from a product class. We propose that in such situations, social crowding as a salient cue in the retailing environment, can serve as an inferential cue to guide consumers’ choices from a product class they intend to purchase from and that their impact on product choices is mediated by perceived availability of the featured product category. Because high level of customer density often correlates with high demand and low supply, we argue that when consumers are motivated to make a choice among multiple alternatives from a product class, social crowding in a retail store can lead consumers to infer the overall availability of the product class they intend to purchase from as low. As a consequence, feeling socially crowded will increase the choice share of consumers’ favorite item, while broadening the discrepancy between the liking of their most-preferred and less-preferred alternatives. We further investigate three managerially relevant moderators that may attenuate the inferential effect of social crowding on product preference, that is, 1) product supply quantity, 2) inventory replenishment, and 3) assortment size.

A set of five experiments was conducted to investigate these assertions. In Study 1, we employed one secondary retail data to provide initial empirical evidence of social crowding effect on product preference. Among 204 transactions made by real consumers in a café, we differentiated the transactions completed in rush hours and non-rush hours. The results suggest that the market share of best-selling items was significantly higher in the rush hours than in non-rush hours.

Study 2 replicated the findings of Study 1 in a laboratory setting and explored the underlying process by using a 2 (social crowding: crowded vs. uncrowded) between-subjects design. We collected data of this study in the week before Mid-autumn Festival in China. The participants first ranked five mooncake flavors based on their own preference. Then we instructed the participants to imagine shopping in one shop for mooncakes. In the crowded condition, the shop image included twenty consumers. In the uncrowded condition, the shop image only included two consumers with the same display. The participants were further told the shop carried a total of five different mooncake flavors that have been ranked in the beginning of the study and they decided to purchase one mooncake box by selecting and putting four mooncakes into it. As predicted, participants incorporated a significantly higher proportion of their favorite mooncake flavor in crowded condition than in uncrowded condition. And this effect was mediated by perceived availability of supply level about mooncakes.

Across Studies 3-5, we consistently found that social crowding could boost sales consumers' favorite item from a product class when the overall product supply was perceived as depletable. Study 3 manipulated actual product supply quantity and the results suggested that when the actual product supply quantity is not low, consumers exhibited a greater preference for the favorite item in crowded versus uncrowded condition. Conversely, when the actual product supply quantity is low, consumers always preferred for the favorite option, no matter whether the store is crowded or not.

Study 4 validated that inventory replenishment moderated the impact of social crowding on inferred product availability and consumers' choices from a product class. For depletable products, feeling socially crowded (vs. uncrowded) in a shopping context made consumers infer product availability as low, thus enhanced the choice of favorite item. However, when the product inventory was expected to be replenished on a daily basis, social crowding in a shopping context did not influence the inference about product availability and consumer preference.

Study 5 examined the moderating role of assortment size. We found the inferential impact of social crowding on perceived product availability and product choices held when the assortment size was small. However, this impact was alleviated when the retail store offered large assortment size for a product category that consumers intended to purchase from.

To conclude, this research provides novel insights into the upside of social crowding on consumer product preference. In addition, the findings of current research shed new light on the inference making literature by identifying social crowding as an important contextual factor affecting consumer perception of product availability and by providing managerially relevant factors that may moderate the downstream consequences of social crowding on consumers choices.

The Impact of Crowding on Calorie Consumption

EXTENDED ABSTRACT

Imagine it is noon now and you decided to buy lunch at a local restaurant. You walk into the restaurant and find it crowded. Would the level of crowding influence your calorie consumption? Why?

Human crowding is defined as a "group of people gathered together such that the likelihood of an individual's personal space being violated is significantly increased" (Maeng, Tanner, and Soman 2013, 740). In five studies, we demonstrate that crowding leads to higher calorie consumption, because it increases distraction, which hampers cognitive thinking and evokes more affective processing. When consumers process information affectively, they consume

more calories. Thus, we show that when given a choice between several different options from a menu, people select higher-calorie items. Furthermore, when presented with only one option (e.g., trail mix), people eat more of the same food item. Across all our studies, we also rule out differences in specific emotions, actual and anticipated hunger, quality perceptions, explicit scarcity-based beliefs, age, gender, BMI, and dieting behavior.

In Study 1A we use secondary data from a well-known fast food restaurant and analyze 4,730 orders during a regular week (8 a.m. - 9 p.m.). The number of orders in each 10-minute (e.g., 8:00-8:10 a.m.) and 20-minute (e.g., 8:00-8:20 a.m.) interval served as a continuous measure of crowding. A main effect of crowding emerged in both regressions (10-minute: $B = 2.81$, $F(1, 4727) = 4.47$, $p < .04$; 20-minute: $B = 1.41$, $F(1, 4727) = 3.91$, $p < .05$), controlling for hour and weekday. Other ways of looking at the data (e.g., comparing the busiest with the least busy day, isolating lunch times; eliminating outliers) elicit similar results.

In Study 1B we conduct a survey ($N = 97$) at the same restaurant during lunch hours on days that are either more or less crowded. Participants in the crowded condition not only ordered more food ($M_{\text{more crowded}} = 1,059$ cal, $SD = 372$ vs. $M_{\text{less crowded}} = 887$ cal, $SD = 887$), but they also consumed more ($M_{\text{more crowded}} = 1,036$ cal, $SD = 375$ vs. $M_{\text{less crowded}} = 874$ cal, $SD = 303$; $F(1, 89) = 5.44$, $p = .02$). A sequential mediation revealed that consumption was significantly mediated by distraction and processing in sequence (95% CI: .34, 22.08).

In study 2 we manipulate crowding in the laboratory and engage participants in a taste test ($N = 115$). We show that the effects not only emerge when a large number of people aggregate, but also when fewer people are in close proximity. Participants in the higher density conditions—more crowding ($M = 30.25$ grams, $SD = 19.13$) and dense less-crowding ($M = 28.14$ grams, $SD = 20.82$)—consumed similar amounts of trail mix ($F(1, 70) = .08$, $p = .78$), and these were significantly higher than the sparse less-crowded condition ($M = 18.09$ grams, $SD = 17.87$; respectively $F(1, 68) = 6.38$, $p < .02$ and $F(1, 63) = 3.92$, $p = .05$). We also replicate the mediation results of Study 1B.

In study 3 ($N = 107$) we demonstrate that merely evoking a crowded mindset can cause the effect. We showed participants a picture of a non-restaurant scenario that was either more or less crowded, and asked them to imagine being in that scenario. Next, in a purportedly unrelated study, we asked participants to select food from a restaurant's menu. As expected, participants selected food with more calories in the crowded mindset condition ($M_{\text{more crowded}} = 988$ cal, $SD = 549$ vs. $M_{\text{less crowded}} = 784$ cal, $SD = 385$; $F(1, 102) = 5.09$, $p < .03$).

Lastly, in Study 4 ($N = 108$) we employed a 2 (crowding: less, more) x 2 (processing: affective, cognitive) between-subjects design, and demonstrate an approach to attenuate consumption in crowded environments. Participants engaged in another taste test in a room that was either crowded or not. In the affective (cognitive) condition, we asked participants to focus on their emotional reactions (rational thoughts). A significant two-way interaction emerged ($F(1, 101) = 4.53$, $p < .04$). In the affective condition, participants ate more trail mix when the room was crowded ($M_{\text{more crowded}} = 44.93$ grams, $SD = 20.15$ vs. $M_{\text{less crowded}} = 30.33$ grams, $SD = 23.07$; $F(1, 49) = 5.46$, $p = .02$), while no such differences emerged in the cognitive condition ($M_{\text{more crowded}} = 21.63$ grams, $SD = 17.72$ vs. $M_{\text{less crowded}} = 21.13$ grams, $SD = 18.34$; $F(1, 49) = .02$, $p = .88$).

We make several theoretical contributions. We extend the prominent literature on retail atmospherics, which has mostly focused on the effects of subtle cues, such as temperature, color, lighting, or sound. Human crowding, on the other hand, is an omnipresent

factor, but has received relatively little attention. We also show how crowding-induced distractions affect consumption decisions.

Our findings also have practical implications. Obesity is a major problem in most industrialized societies with significant associated medical expenses. Increases in consumption is one of the main drivers of obesity (Chandon and Wansink 2007). Increasing the space of restaurants or food courts could reduce consumers' perceived crowding, which in turn might decrease the risk of overeating. Additionally, as we find, merely evoking a crowded mindset can influence consumption. Therefore, from a public policy standpoint, it may be useful to ask consumers to "empty" their minds before ordering from a menu. Perhaps evoking a more cognitive frame of mind might help lower calorie consumption. Our findings are especially important given that the world's population reached a staggering seven billion in 2007, and is steadily on the rise (United States Census Bureau). Global urbanization will unavoidably increase crowding in public consumption settings. Thus, a better understanding of how crowding impacts food consumption decisions may provide one avenue for a healthier lifestyle.

Social Crowding versus Spatial Crowding: Differential Influences on Customers' Preference for Anthropomorphized Self-Service Technologies

EXTENDED ABSTRACT

Crowding is a ubiquitous phenomenon in many services industries with major negative consumption consequences (Eroglu, Machleit, and Barr 2005; Harrell, Hutt, and Anderson 1980; Hui and Bateson 1991). To cope with some of the problems, such as long waiting line, arising from crowding, self-service technologies (SSTs) are increasingly adopted by firms because they are supposed to help firms improve service productivity and help customers reduce the inconvenience and waiting time caused by crowding (e.g., Dabholkar, Bobbitt, and Lee 2003; Gelderman, Paul, and Diemen 2011; Wang, Harris, and Patterson 2012; Weijters et al. 2007). To encourage more customers, particularly those who prefer to interact with service employees, to use SSTs, service organizations start to imbue anthropomorphic features in the design of SSTs. Both anecdotal and academic evidences suggest that anthropomorphism design makes brands or products more likeable and enjoyable (Aggarwal and McGill 2007; Delbaere, McQuarrie, and Phillips 2011). However, existing research has yet directly examined whether anthropomorphizing SSTs, particularly in a crowded environment, is effective.

We argue that the impact of anthropomorphic design in SSTs on consumer response in a crowded situation depends on consumers' attributions of the crowding. Crowding by definition is a bi-dimensional construct with its attribution to either social or spatial causes (Baum and Koman 1976; Baum and Valins 1979). Social crowding refers to the case when the crowding is mainly attributed to the large number of people whereas spatial crowding is mainly attributed to the inadequacy of physical space. We predict that customers are less likely to prefer anthropomorphized SSTs when they attribute the crowded environment to social reasons rather than spatial reasons due to a social withdrawal tendency. We test the hypotheses with one pilot study and four experimental studies using both student and nonstudent samples from Hong Kong and the United States.

The pilot study provides preliminarily support to our prediction that crowding attribution \times anthropomorphism interaction was significant ($F(1,193) = 3.10, p < .05$) on social withdrawal. Specifically, participants in the social crowding condition experience more social withdrawal when the SST was high (vs. low) ($M_{\text{high anthropomorphism}} = 6.50, M_{\text{low anthropomorphism}} = 5.36; t(1, 193) = 1.98, p < .05$) in anthro-

pomorphism. Furthermore, in the high anthropomorphism condition, participants in the social crowding condition ($M_{\text{social crowding}} = 6.50$) reported a higher social withdrawal than those in the spatial ($M_{\text{spatial crowding}} = 5.46; t(1,193) = 1.79, p = .08$) and low crowding conditions ($M_{\text{low crowding}} = 5.05; t(1,193) = 2.61, p < .01$).

Study 1 examines the interaction effect of crowding attribution and SSTs anthropomorphism on customers' behavioral intentions to use the machines ($F(1, 214) = 18.44; p < .001$). We show that when customers attribute the crowding environment at the canteen to social reasons, their intentions to use the anthropomorphized (vs. non-anthropomorphized) self-ordering machine were lower ($M_{\text{high anthropomorphism}} = 5.96; M_{\text{low anthropomorphism}} = 6.77; t(1,214) = 1.70, p = .09$). When customers attribute the crowding to spatial reasons, they actually indicate higher intentions to use the anthropomorphized (vs. non-anthropomorphized) machine ($M_{\text{high anthropomorphism}} = 7.31; M_{\text{low anthropomorphism}} = 6.47; t(1,214) = 1.76, p = .08$). In the low crowding condition, intentions do not differ across the anthropomorphism conditions. Furthermore, in the high anthropomorphism condition, participants in the social crowding condition ($M_{\text{social crowding}} = 5.96$) report lower (higher) intentions to use the machine when they were in the spatial (low) crowding condition ($M_{\text{spatial crowding}} = 7.31, t(1,214) = 2.82, p < .01; M_{\text{low crowding}} = 4.62, t(1,214) = 2.86, p < .01$). In the low crowding condition, there is no significant difference between the social and spatial crowding conditions but intentions in these two conditions are higher than that in the low crowding condition.

Study 2 extends Study 1 by examining the interaction effect of crowding attribution and SSTs anthropomorphism on customers' attitudinal response ($F(1,140) = 3.90, p = .05$). Again, Study 2 shows that anthropomorphizing the SST backfires if the crowding environment is attributed to social reasons ($M_{\text{high anthropomorphism}} = 6.02; M_{\text{low anthropomorphism}} = 6.73; t(1, 140) = 1.826, p = .07$), but this does not matter when the crowding environment is attributed to spatial reasons. Furthermore, in the high anthropomorphism condition, participants showed less favorable attitudes toward the machine when the crowding environment was attributed to social rather than spatial reasons ($M_{\text{social crowding}} = 6.02; M_{\text{spatial crowding}} = 6.67; t(1, 140) = 1.72, p = .09$). In the low anthropomorphism condition, however, attitudes did not differ between the social and spatial crowding conditions.

Study 3 extends the interaction effect to customers' choices between ATM and bank tellers ($F(1,145) = 3.87, p = .05$) as well as perceived service quality of the bank ($F(1,145) = 6.17, p < .05$). Simple contrast results are consistent with Study 2. Furthermore, by ascertaining the mediated moderation process, we confirm that the interaction effects of crowding attribution and anthropomorphism on customers' choice of ATM over bank tellers (index = .20; CI: .01 to .43) and perceived service quality (index = -.07, CI: -.23 to -.00) are accounted by their social withdrawal tendency.

Study 4 is a field experiment in collaborating with a student canteen with natural customer density and real anthropomorphism design of self-ordering machines and we measure customers' real choice of machines ($F(1, 66) = 5.17, p < .05$). With the actual transactional data from the canteen, we confirm that anthropomorphism design reduces customers' adoption of machines during the rush hours (social crowding) ($M_{\text{high anthropomorphism}} = .28; M_{\text{low anthropomorphism}} = .34; t(1, 66) = 4.73, p < .001$). However, whether the machines are anthropomorphized or not does not matter during non-rush hours (low crowding).

Contrary to the prevailing beliefs on the beneficial effects of adopting SSTs, this research shows that customers in a crowded environment do not always prefer SSTs over human staffs and anthropomorphizing SSTs can backfire especially in a social crowding environment. The findings provide significant implications on

crowding management, and the employment and anthropomorphism design of SSTs for service managers.

SESSION OVERVIEW

When forming impressions or drawing inferences about people and objects, individuals assign greater weight to information seen as diagnostic while ignoring or discounting less diagnostic information. Indeed, diagnosticity, or the extent to which information is seen as indicative of a certain trait or state, is a key construct in theories of judgment, decision-making, and impression-formation (Schwarz et al. 1991; Trope and Liberman 1996).

But while it is clear that perceived diagnosticity plays an important role, less is known about what *determines* whether a cue is seen as diagnostic in a particular context. What cognitive, affective, and motivational factors determine the extent to which choice, for example, is seen as indicative of individual preference? What situational cues determine whether exemplars are perceived as diagnostic of group traits? And might two consistent behaviors sometimes be seen as less diagnostic of individual traits than each behavior in isolation? The current session provides novel insights into these and related questions as it examines the elusive nature of diagnosticity perceptions.

The first two papers examine conditions under which choice is seen as more vs. less diagnostic of individual preferences. **Maglio and Reich** show that whether people believe their decisions are based on affect vs. cognitive deliberation influences the extent to which they perceive those decisions as reflective of their true self. Decisions based on affect are seen as more diagnostic of the true self, which in turn increases decision certainty and makes those decisions more resilient to change.

Sela, Berger, and Kim show that self-control leads people to see their choices as less diagnostic of their true individual preferences. Further, self-control salience undermines the perceived choice-preference link more generally, which may decrease the tendency to view choice as indicative of preference even in unrelated downstream contexts.

The second two papers examine factors that impact perceived diagnosticity more generally, beyond the context of one's choices. **Steinmetz, Touré-Tillery, and Fishbach** find that diagnosticity may depend on an item's arbitrary location within a sequence: compared

with other items (e.g., middle, last, or random), people perceive the first item as more diagnostic of the entire group. As a result, they over-weigh the traits or the performance of the first item when making inferences, predictions, and decisions about the group.

Lastly, **Goldsmith, Hershfield, and Galoni** examine conditions under which two consistent unethical behaviors are, counterintuitively, seen as *less* diagnostic of individual traits than each unethical behavior in isolation. This, in turn, attenuates negative judgments. Thus, two wrongs can be more permissible than one. The findings have important implications for understanding how certain behaviors, such as sexual violence, may be excused in part due to observers' tendency to rely on the perpetrator's intoxication – another unethical behavior – as a discounting cue.

Taken together, these papers provide novel and potentially provocative insights into when and why certain cues are seen as (non)diagnostic. The session would interest scholars who study attribution, impression-formation, choice, and judgment and decision-making more broadly.

Seeing the Self in Choices: How Intuition Creates Attitude Certainty

EXTENDED ABSTRACT

Feeling-based choice – by which people consult their intuitive, gut feelings in processing information in order to make a decision – has witnessed a surge in empirical attention and prescriptive benefits. Evidence continues to mount in favor of feeling-based approaches in the interest of helping consumers arrive at better choices (Mikels, Maglio, Reed, & Kaplowitz, 2011; Pham, Lee, & Stephen, 2012; Slovic, Finucane, Peters, & MacGregor, 2007) Donald G. </Author><Year>2007</Year><Prefix></Prefix><Suffix></Suffix><Pages></Pages><DisplayText>(Mikels, Maglio, Reed, & Kaplowitz, 2011; Pham, Lee, & Stephen, 2012; Slovic, Finucane, Peters, & MacGregor, 2007. The present investigation draws a pointed line from such prior work, proposing that choices made with feelings seem more diagnostic of who one really is, bearing relevance for attitude certainty.

Affective reactions tend to be, among other things, (1) primary, (2) basic, and (3) characteristic of the self. To illustrate:

“Once a cognitive judgment has been made – for example, that at the forthcoming social hour there will be more scotches drunk than bourbons – one can still be persuaded that it may turn out otherwise ... But we are never wrong about what we like or dislike ... It would be much harder to persuade us that we really like scotch better than bourbon, given that we feel otherwise.” (Zajonc, 1980, p. 157)

Divergent from what one thinks, how one feels (e.g., in making a choice) reflects an automatic, innate property of oneself. In other words, affect-based judgments may reveal what recent investigations have termed the true self (Newman, Bloom, & Knobe, 2014; Schlegel, Hicks, Davis, Hirsch, & Smith, 2013). Still, the relationship between feeling-based choice, diagnosticity of consumers' true self, and strong attitudes remains unexamined.

Our account (1) predicts and finds that the use of feelings in choice fosters attitude certainty, (2) offers an account relating feelings to certainty by way of signaling the decision maker's true self, and (3) documents a robust application of feeling-derived certainty to decision making (resilience in the face of negative feedback).

In an initial consideration of the role of feeling-focused choice in attitudes, Study 1 examined whether consumers would prove less

prone to defer choice upon choosing via feelings (versus deliberation). Participants evaluated four (non-alignable) attributes defining two DVD players using either their “deliberative, rational analysis” or their “intuitive, gut feeling” and then selected the one that they preferred before indicating whether they would, in that situation, make that purchase or defer it to a later date. When participants relied on feelings to guide their choice, 90% opted to purchase; when they relied on deliberation, 73% opted to purchase, $\chi^2(1, N = 80) = 4.02, p = .045$. This suggests that feeling-based choice makes people more likely to take action in a manner reflective of holding a strong attitude toward their preferred product relative to their deliberating counterparts.

Study 2 was designed to target both a more direct measure of attitude strength as well as the mechanism by which a focus on feelings might bolster them. Participants evaluated four (non-alignable) attributes defining three smartphones using either their “deliberative, rational analysis” or their “intuitive, gut feeling” and then chose the one that they preferred. Subsequently, to assess whether the choice was diagnostic of their true self, participants reported the extent to which they thought that their chosen smartphone reflected their true self; to assess attitude certainty, participations reported how certain they felt with regard to their choice. Participants who had chosen based on feelings both felt more certain regarding their choice, $F(1, 108) = 8.35, p = .005$, and appraised their chosen smartphone as more evidential of their true self, $F(1, 108) = 4.36, p = .039$, with the latter statistically accounting for the former $\beta = .49$ (95% CI: .05; 1.07).

Having documented a relationship between feeling-focused choice and strong attitudes, as well as pinpointing the diagnosticity of the true self in accounting for this relationship, our next two studies consider how such feeling-derived attitudes might prove resilient when confronted with negative feedback.

In Study 3, participants evaluated four (non-alignable) attributes defining three digital cameras using, as before, deliberation or gut feelings before choosing the one that they preferred. Next, participants were randomly assigned to a feedback condition, asked to envision buying the chosen camera and then seeing a consumer report on it the following day. The positive feedback condition presented a favorable review of the chosen camera; the negative feedback condition presented an unfavorable review. Thereafter, participants reported how much regret they would feel in this scenario. A significant interaction, $F(1, 124) = 6.146, p = .015$, indicated that, when receiving positive feedback, both deliberative and feeling-focused decision-makers feel very little regret, $F < 1$. But, when receiving negative feedback, feeling-focused decision makers felt less regret than their deliberating counterparts, $p < .001$.

Study 4 precludes the alternative account that choosing on the basis of feelings simply elevates mood in the first place, providing a buffer against negative feedback. Accordingly, participants were randomly assigned to evaluate the same set of smartphones from Study 2 on the basis of either deliberation or their gut feelings, then chose the one that they preferred. To assess their feeling state immediately following the making of their choice, participants indicated how they felt (ranging from very bad to very good). Thereafter, they were randomly assigned to a condition in which they received either positive or negative feedback (in a manner identical to Study 3), then again rated their feelings on the same scale as the initial assessment. Prior to receiving the feedback, all participants reported a similarly positive mood, $F < 1$; after receiving the feedback, the patterns of mood ratings diverged. For those who received positive feedback, choosing on the basis of deliberation or feelings witnessed a nearly identical boost in response to the good news, $p = .65$. Upon receiving negative feedback, though, those who had chosen on the basis

of deliberation felt worse than those who had chosen on the basis of feelings, $p = .023$. Thus, there is nothing inherently positive in choosing based on feelings; instead, feeling-focused choice generates a strongly favorable and resilient attitude that is capable of withstanding external rebuke.

How Self-Control Shapes Inferences from Choice

EXTENDED ABSTRACT

Self-control is an important driver of consumer behavior, helping people regulate their choices, attain their goals, and control their emotions. But while it influences choice, could self-control also change choice’s meaning, making it seem less diagnostic of preference?

Decades of research have shown that preference and choice are often intertwined. Choice is often seen as originating from one’s preferences, goals, and values (Markus and Kitayama 2003). In turn, choice is typically seen as an indication of those same inner states, leading people to infer their preferences and valuations by observing their own choice experiences (Bem 1972; Chaiken and Baldwin 1981; Festinger 1957). Picking a Toyota over a Honda, for example, may lead people to infer they like Toyota, and thus increase subsequent evaluation of the brand.

In contrast, we suggest that when the concept of high self-control is salient, people are less likely to draw inferences about their preferences from their choices. We suggest this possibility based on work suggesting that self-control may override, interrupt, and otherwise alter the link between preference and choice (Baumeister, Vohs, and Tice 2007; Muraven, Tice, and Baumeister 1998). Self-control is defined as “restraint exercised over one’s own impulses, emotions, or desires” (Merriam-Webster.com). Self-control can be used to override personal desires in favor of external constraint (e.g., norms or others’ preferences) or override impulses to pursue long-term personal goals (e.g., delay gratification). In both cases, rather than going with their first instinct, consumers exert inhibitory control to do something else.

We argue that this inhibitory control has important implications for the perceived relationship between choice and preference more generally. Specifically, it weakens the notion that choice is driven by preferences, which once activated, may spillover to affect inferences even in unrelated domains. Five experiments test this possibility, examining whether making self-control salient decreases people’s tendency to see their choices as diagnostic of their preferences

In Experiment 1, participants saw five mainstream sedans and chose their preferred option. Then, we manipulated self-control salience using a sentence unscrambling task containing either high self-control words (e.g., discipline, willpower) or low self-control words (e.g., impulse, spontaneous). In this, and all subsequent studies, the self-control manipulation had no effect on which item participants preferred. Finally, we measured the dependent variable: participants’ perception that their car choice reflected their personal preferences and taste.

As predicted, making self-control salient reduced participants’ belief that the car they chose reflected their preferences.

Experiment 2 uses a different operationalization of self-control salience and examines the downstream consequences for brand attitudes. After selecting their preferred car among the same five options used in Experiment 1, participants made unrelated choices, either: (a) self-control dilemmas (e.g., rich vs. lean entrée), (b) choice unrelated to self-control (e.g., apple vs. pear), or (c) neither (the two latter conditions both served as control groups). Finally, we measured how

much participants felt their car choice reflected their preferences, as well as their attitudes toward the brand more generally.

As predicted, making self-control salient through choice dilemmas reduced participants' perception that their chosen car was diagnostic of their preferences, compared with the two control conditions ($F(2,155)=7.34, p<.001$). This carried over to influence brand attitudes ($-.35, [-.67, -.13]$).

Experiment 3 and 4 test the underlying process. If our theory is correct, these effects should be most pronounced among people who generally associate self-control with preference suppression (i.e., going against the self). Experiment 3 tests this possibility. First, participants chose one of several paintings. Second, we manipulated self-control salience by asking participants to describe a past experience where they used self-control vs. chose impulsively. Third, we measured the extent to which participants felt their chosen painting reflected their personal preferences and taste in art. Finally, we measured our moderator, the extent to which participants believed they used self-control primarily to resist their desires (i.e., going against the self) or to resist external persuasion and stick to their true goals (i.e., going with the self). This measure of individual lay-beliefs was unaffected by condition.

In addition to a main-effect of self-control condition ($B=-.42, SE=.18, p<.02$), results revealed the predicted interaction ($B=-.26, SE=.10, p=.01$): among participants who believed self-control meant suppressing desires, recalling self-control made the chosen painting seem less diagnostic of preference ($B=-.83, SE=.24, p<.001$). Among participants who believed self-control meant sticking to one's goals, the effect disappeared ($B=-.007, SE=.23, p=.97$).

Experiment 4 tests the mediating role of choice-preference correspondence perceptions. Participants completed the artwork choice, self-control salience manipulation, and preference measures from Experiment 3. Finally, participants rated the extent to which their choice in the priming task reflected their preference at that time.

Results indicate that making self-control salient through a self-control recall task decreased perceptions that the chosen painting reflected personal preferences ($F(1,188)=4.84, p<.029$). This effect was mediated by the extent to which the decision recalled in the self-control priming task seemed diagnostic of preference ($-.30, 95\% CI [-.55, -.10]$). Recalling self-control in one domain evoked the notion that choice in that particular situation was less reflective of preferences, which in turn decreased the extent to which the chosen painting was seen as reflecting one's preferences.

Experiment 5 extends the findings to the classic "free choice" spread-of-alternatives effect. Following a standard free-choice paradigm, participants ranked ten songs from most to least preferred. Then, they completed the self-control priming manipulation from Experiment 1. Participants in the free-choice condition subsequently chose between their fifth and sixth ranked songs. Participants in the no-choice condition were given their fifth ranked song. Finally, all participants re-ranked the same ten songs they ranked initially.

As predicted, post-choice rank difference between the chosen/received option and the non-chosen option was larger in the choice compared to the no-choice condition, but only under low self-control ($F(1,268)=9.08, p=.003$). Under high self-control, free choice had no effect on spread-of-alternatives ($F(1,268)=44, p=.51$).

Self-control is an important driver of choice, but these findings suggest it also undermines the perceived choice-preference link, making choice seem less diagnostic of one's preferences. These findings further understanding of inference-making, self-control, and the meaning of choice.

Not All Bad Apples Spoil the Bunch: Order Effects on the Evaluation of Groups

EXTENDED ABSTRACT

Imagine waiting in line at a store with five numbered cash registers. When your turn comes, an automated system instructs you to go to "cashier number one, please." You have a terrible experience checking out: the cashier is slow and accidentally charges you twice for the same item. How would cashier number one's negative performance influence your expectations of the other cashiers and of the store in general?

People often make judgments about an unknown group based on information about one member of the group. Smith and Zarate's (1992) exemplar-based model of social judgment posits that representations of specific individuals (exemplars) influence judgments about others from the same group. In particular, similarity along a salient dimension (e.g., race, gender) often determines the extent to which people see an individual as diagnostic of the group. When an exemplar seems particularly diagnostic, people will use their knowledge about her to make inferences about other group members. For example, one might infer that people from a distant country are kind and welcoming based on a conversation with a particularly friendly visitor from that country. Thus, the diagnosticity of a group member can stem from her similarity to other members. The present research explores another, much less studied factor that influences perceptions of social diagnosticity: position in a sequence.

Research on self-diagnosticity shows the position of an action in a sequence influences the extent to which people consider this action diagnostic for inferences about the performer (Touré-Tillery and Fishbach 2012; 2015). We explore whether there are similar order-effects in the perceived diagnosticity of group members, such that the position of a member in a random sequence of members influences how diagnostic she seems. We propose that, due to learned associations between "first" and concepts such as "leader," "best," and "important," people will expect the first group member in a sequence to be the most diagnostic of the group.

Five studies tested this hypothesis. Notably, in all studies, we told participants that sequences were randomly generated, so they would not infer that the first is the best or the leader or the most important (Carney and Banaji 2012). Furthermore, all studies gave participants information about one group member only, and asked them to make inferences about the others. This paradigm allowed us to rule out primacy and recency memory-effects and prevent effects due comparisons among group members (Page and Page 2009).

In Study 1, participants read that the first (vs. middle vs. last) runner of a relay race performed well or poorly depending on the condition, and predicted how well the rest of the team performed. We found participants expected the rest of the team to have performed better when the first (vs. middle/last) performed well, whereas they expected the rest of the team to have performed worse when the first (vs. middle/last) performed poorly. Thus, information about the first (vs. middle/last) runner influenced predictions more, suggesting that the first runner was deemed more diagnostic.

In the next two studies, participant read that the first (vs. middle vs. last) contestant of a cooking competition performed poorly—as a member of a group of five guys collaborating to compete against other teams (Study 2), or competing against each other (Study 3). Participants then indicated how well they expected the other contestants to have performed. Results show participants predicted the other contestants to be worse after reading about the first (vs. middle/last) contestant's lackluster performance. These results indicate that the first (vs. middle/last) contestant was perceived as more diagnos-

tic of the rest of the group, regardless of whether other contestants would lose (Study 2) or gain (Study 3) from his poor performance. Although we made it clear that all sequences were random, in Studies 1, 2 and 3, people might have assumed the other group members could observe one another's performances. Thus, the first (vs. middle/last) member of the sequence would have more influence on the rest of the group, which might account for the observed assimilation to the first member.

We designed Studies 4 and 5 to rule out this alternative explanation. Participants read about a group of five students whose answers to a multiple-choice test were graded in random order by a computer. Using this paradigm, we eliminated the possibility that grading the first group member influenced the grader's perception of the next group member, since people view machines as unsusceptible to such biases. Participants also learned that the first (vs. middle vs. last) student received an unimpressive grade, and indicated their predictions for the other students' performances. In both studies, we replicated the first-as-more-diagnostic effect. In Study 4, participant expected the other students to have received worse grades when the first (vs. middle/last) student performed poorly. In Study 5, in addition to judgments about the other group members, we also assessed behavioral intentions toward the group. Specifically, we asked participants if they would be willing to bet on the group's future performance in an academic competition. We found that when the first (vs. middle/last) student performed poorly, participants not only expected other members of the group to do worse, but also were less willing to bet on the group's future success. Furthermore, expectations about group member's performances fully mediated the relationship between the focal group member's position in the sequence and participants' willingness to bet on the group.

Taken together, these studies show the important role of random position in a sequence in judgments and behaviors related to groups. These findings have important implications for social judgments, including stereotyping and discrimination, judgment of service personnel and the brands they represent. Although we explored our hypotheses in the social context, we expect our findings to extend to evaluations of numbered objects or products presented in bundles or groups (e.g., numbered combo meals at fast food restaurants). Thus, when assigning numbers to groups of employees or product, companies might benefit from assigning the number one to the highest-performing employee or the highest-quality product.

What Two Wrongs Make Alright: Examining the Psychological Factors Underlying the Tendency to Temper Judgments of Intoxicated People

EXTENDED ABSTRACT

The belief that certain crimes are more likely to be committed when one is intoxicated has been supported by academic research and the popular media. However, the direct role that intoxication plays in the personal costs (i.e., criminal sentencing and social judgment) inherent to deviant behavior has yet to become a central part of the conversation. The current research sheds light on this by offering a theoretical framework to predict conditions under which observers' tendency to view an actor's behavior as diagnostic of his disposition will be attenuated if the actor is described as intoxicated (vs. sober). Specifically, we posit that when the behavior is psychologically distant, intoxication will reduce dispositional attributions, which will consequently temper how the actor is judged. We base this prediction on prior work revealing that psychological distance broadens observers' scope of consideration (Liberman & Trope, 1998), which

should allow intoxication to be incorporated as a discounting cue for dispositional attributions.

We present data that supports this perspective drawn from over ten controlled experiments in addition to actual criminal sentencing trials involving over 1,500 inmates. For example, in one experiment, participants were asked to evaluate a hypothetical, psychologically distant other who committed a deviant behavior (i.e., gambling and losing money) while either intoxicated or sober. We then examined observers' tendency to make dispositional attributions about the actor based on his actions in addition to their tendency to negatively judge the actor. Results revealed that when the actor was described as intoxicated observers were less likely to make dispositional attributions based on his behavior, as compared to when he was described as sober ($p < .001$). In addition, participants' judgments of the actor more tempered (i.e., less negative) if he was described as intoxicated ($p < .001$). The effect of intoxication on negative judgments was mediated by a shift in dispositional attributions.

Another experiment replicated and extended these results by manipulating if the actor was intoxicated (vs. sober) and if the behavior that was committed was deviant (vs. socially acceptable). We then measured dispositional attributions and judgments. We observed convergent results for both deviant and socially acceptable behaviors: when the actor was intoxicated his behavior was seen as less diagnostic as compared to when he was sober ($ps < .05$). Further, when the actor was intoxicated, participants judged his behavior less in a more tempered fashion (i.e., less negatively in the deviant behavior condition and less positively in the social acceptable behavior condition) as compared to when he was sober ($ps < .01$). In both conditions, shift in dispositional attributions mediated the relationship between intoxication and judgment.

In subsequent experiments, we assessed if the observed effects would be altered under conditions of psychological proximity. For example, in one experiment we assessed how intoxication affected dispositional attributions and negative judgments of the self following a deviant behavior. In line with our theorizing, when the focal actor was psychologically proximal (i.e., the self) intoxication had no effect on dispositional attributions ($F < 1$). However, participants still judged themselves less harshly for their behavior if intoxicated (vs. sober; $p = .005$). Thus, the previously observed effects of intoxication on judgments of a hypothetical other were replicated for judgments of the self. However, a shift in dispositional attributions did not mediate the relationship between intoxication and negative judgment.

If observers are more likely to incorporate intoxication as a discounting cue for dispositional attributions when the action is more psychologically distant, as we have suggested, factors that promote psychological distance (e.g., the activation of an abstract level of construal, Trope & Liberman, 2010) should accentuate this effect. We tested for this by randomly assigning participants in a 2 (construal level: abstract vs. concrete) by 2 (intoxicated vs. sober) between-participants design. Construal level was manipulated using a temporal focus manipulation (Wakslak, Trope & Liberman, 2006). All participants then read one of the two vignettes about the self-committing a deviant behavior while either intoxicated or sober.

In line with our prior results, under conditions of psychological proximity (i.e., a concrete construal), the intoxication did not affect dispositional attributions for the self ($F < 1$). However, participants judged themselves less harshly for their deviant behavior if intoxicated (vs. sober; $p = .010$). Importantly, however, a shift in dispositional attributions did not mediate the relationship between intoxication and negative judgment.

Under conditions of psychological distance, however, this pattern of results shifted. Here, we observed that when the self was

described as intoxicated the behavior was seen as significantly less diagnostic of the self, as compared to when the self was described as sober ($p < .001$). In addition, when the self was intoxicated, participants judged themselves less harshly for their behavior as compared to when the self was sober ($p < .001$). Finally, a shift in dispositional attributions mediated the relationship between intoxication and negative judgment. Thus, consistent with our predictions, when evaluations were made to feel more psychologically distant (i.e., through the adoption of an abstract level of construal), intoxication was incorporated as a discounting cue for dispositional attributions, and a shift in dispositional attributions explained why intoxication attenuated negative judgments. A test for moderated mediation also supported the notion that a shift in dispositional attributions mediates the relationship between intoxication and judgment among those who construed the behavior as more psychologically distant, and not those who construed the behavior as more psychologically proximal.

The current research provides novel evidence for the role of psychological distance in attribution processes. In doing so, this research provides an important step toward better understanding the factors that inform the costs inherent to committing deviant behaviors, and offers implications for the understanding of attribution theory, self-signaling theory, construal level theory and beyond. In addition, these findings have practical implications for policy makers and others seeking to curtail the incidence of deviant behaviors linked to alcohol consumption.

SESSION OVERVIEW

"I'd like to live as a poor man with lots of money." Pablo Picasso got it right. Only a poor man can truly value having lots of money, because only when one experiences a scarcity of resources does one feel the need to regain resources and appreciate having them.

This special session seeks to provide an overarching look at the impact of resource scarcity, whether experienced in the past, activated in one's mind in the present, or induced to be associated with one's future, on people's decision making and, consequently, their present and future well-being.

Resource scarcity is the extent to which an individual experiences a shortage of resources (Abrams 1992). Recent literature has drawn our attention to the profound effects that experiencing resource scarcity has on people's decisions and behaviors (e.g., Laran & Salerno 2013; Levontin, Ein-Gar, & Lee 2015; Roux, Goldsmith & Bonezzi 2015; Shah, Mullainathan, & Shafir 2012; Sharma & Alter 2012; Zhu & Ratner 2015). This special session aims to build on and extend this previous work by addressing the following overarching question: How does experiencing resource scarcity throughout one's life impact one's judgments and decision making? What are the short and long term effects of experiencing resource scarcity on consumer well-being? Four papers will attempt to answer these questions.

The first paper, by Mittal and Griskevicius, investigates the impact of resource scarcity experienced in the past. They find that experiencing scarcity during childhood prompts people to hold expectations of a shorter life span, which leads them to save less for retirement. The next two papers look at the immediate consequences of experiencing resource scarcity in the present. Specifically, the second paper by Sevilla and Salerno shows that, when individuals are made to believe that certain foods are scarce, they value that resource more, as evident by their overestimation of the food's caloric value. The third paper by Goldsmith, Roux, and Wilson demonstrates how considerations of scarcity heightens people's information-processing abilities by making them better able to identify information relevant to the costs and benefits inherent to different outcomes, and adap-

tively respond to this information to benefit the self. Finally, the last paper explores how associating resource scarcity with one's future influences people's decision-making. Specifically, Ein-Gar, Levontin and Lee find that a scarcity mindset prompts people to put away less money for saving. However, when people are asked to consider their future-self, a scarcity mindset leads them to allocate more money to savings.

Taken together, these four papers provide a panoramic view, from past to future, of how resource scarcity affects our lives and impacts our present and future well-being. Specifically, the first two papers explore how facing resource scarcity can hinder consumer well-being, due to lower perceptions of longevity and increased food valuation. Conversely, the third and fourth papers demonstrate a positive impact of experiencing scarcity, in terms of greater cognitive flexibility and greater saving to benefit one's future self.

Early-life Scarcity, Life Expectancy, and Decision-Making

EXTENDED ABSTRACT

Disparities in financial outcomes stemming from socioeconomic inequalities are a matter of concern for policy makers, researchers, and the society. Yet why people at the bottom of the pyramid respond by behaving in ways that worsen their situation is an unresolved puzzle. A leading reason offered by recent research is that growing up with less leads to certain psychological tendencies that make it difficult to escape poverty (Haushofer and Fehr 2014). However, very little is known about what these psychological tendencies are and what behaviors they affect. Our goal in this paper is to propose one such tendency and to examine its impact on people's financial decisions.

We propose that financial disparities among people from dissimilar socioeconomic backgrounds are a result of differences in their subjective life expectancy – the age up to which people expect to live. Our predictions are derived from life history theory (Stearns 1992), and we conducted three experiments to test our hypotheses. Results show that people's subjective life expectancies are closely tied to their childhood socioeconomic status. Those who grew up in resource-poor environments expected to live up to a significantly lower age as compared to those who grew up in resource-rich environments. Furthermore, in line with recent research, we find that childhood-rooted differences were most strongly evoked in stressful contexts such as when people faced financial threats in their current environment. Finally, we show how differences in subjective life expectations lead to differences in people's financial decisions such as their retirement allocation.

In Study 1 (N=123), we examined our basic prediction that people's life expectancy varies depending on their childhood resources in response to conditions of financial threat. We experimentally manipulated threat by having participants write three indicators that suggest the economy is becoming increasingly unpredictable and that resources are becoming scarcer (Mittal & Griskevicius 2016). Those in the control condition wrote three indicators that suggest the economy is getting better and that resources are becoming abundant. We then measured the age to which people expected to live up to using a slider scale running from 18 to 100 years, and the level of their current and childhood resources (Rindfleisch et al. 1997). As

predicted, there was a significant Condition X Childhood SES interaction ($F(1, 119)=7.45, p=.007$). Results showed that although subjective life expectations for people from different backgrounds were similar in the control condition ($\beta=.02, p=.863$), they diverged in the resource threat condition. Consistent with our predictions, we found that people who grew up in resource-poor environments expected to live to a significantly lower age than people who grew up in resource-rich environments in the resource constraints condition ($\beta=.50, p<.001$). Importantly, these expectations did not vary as function of respondents' current economic conditions.

Study 2 ($N=101$) conceptually replicated and extended the findings from the first study by examining whether people's childhood resources impacted the number of years they thought their retirement would last. Participants arrived in lab in small groups and were randomly assigned to either the resource abundant control or the resource scarcity threat condition. Same manipulations as in Study 1 were used. Next, participants reported the age to which they expected to live up to using the same measure as in Study 1. In addition, they indicated the number of years they expected their retirement savings to last assuming they retired at the age of 67. Consistent with the results from Study 1, there was a significant Condition x Childhood Resources interaction for subjective life expectancy ($F(1, 97)=16.7, p<.001$). Further analyses showed that people who grew up in resource-poor environments expected to live to a significantly lower age than people who grew up in resource-rich environments in the resource threat condition ($\beta=.49, p<.001$). We also found a significant Condition X Childhood Resources interaction for longevity of retirement ($F(1, 97)=9.03, p=.003$), such that threat led people from poor backgrounds to expect to live a significantly less number of years after retirement as compared to people from richer backgrounds ($\beta=.39, p=.005$). A mediated moderation model ascertained that the observed effect of scarcity and childhood resources on post-retirement longevity was mediated by subjective life expectancy (95% CI [.94, 7.59]).

The goal of Study 3 ($N=259$) was to examine whether different life expectations in response to financial threats would influence people's investment allocation decisions. Financial threat was manipulated using the same methodology as in studies 1 and 2. Next, people indicated the average age to which they thought people lived up to. Additionally, they indicated the percentage of their annual salary that they wished to allocate for their retirement. People's responses were recorded on a slider scale running from 0% to 25%. Results mirrored the basic finding from Studies 1 and 2. There was a significant Condition x Childhood Resources interaction for subjective life expectancy ($F(1, 255)=5.6, p<.05$). In addition, there was a significant Condition x Childhood Resources interaction for desired retirement allocation ($F(1, 255)=6.25, p<.05$). Analyses suggested that people growing up poorer expected to live to a significantly lower age than people who grew up in resource-rich environments in the resource scarcity condition ($\beta=.28, p<.001$) and were willing to invest less towards their retirement ($\beta=.18, p<.05$). A mediated moderation model ascertained that the effect of childhood resources and current threat on retirement allocation was mediated by people's subjective life expectancy (95% CI [0.03, 0.48]).

These studies provide important new insights into why people from resource deprived backgrounds might make decisions that paradoxically end up hurting them even more. We show that people's subjective life expectations are shaped by people's socioeconomic backgrounds and play a crucial role in driving their financial behaviors later in life. We believe this work has important implications for public policy and researchers who wish to better understand and

improve decision making among people from disadvantaged backgrounds.

The Food Scarcity Heuristic: People Overestimate the Caloric Content of Scarce Foods

EXTENDED ABSTRACT

Past work has demonstrated that scarce objects are perceived as being higher in value (Brock 1968; Fromkin 1970; Verhallen 1982). This perception may have an evolutionary basis, as in ancient times valuable objects were scarce due to their instrumentality for survival in harsh living environments (e.g. Ellis et al. 2009). Such scarce and valuable items included foods that were higher in caloric content (e.g. Pochron 2005). In this research, we investigate whether consumers make the inverse inference, that foods that are perceived as scarce are also higher in calories. We hypothesize this will occur as items perceived as scarce lead consumers to feel relatively deprived of resources, which makes them overvalue the item and overestimate its calories. Our theorizing is in line with past work showing that when financially deprived, consumers seek scarce items (Sharma & Alter 2012), and with past work showing that consumers tend to devalue items that are not immediately needed (Brendl, Markman & Messner 2003). Furthermore, we also expect that the effect will be attenuated when people are able to consume the target food, as this will reduce their need for resources. Our hypothesis is analog to past research demonstrating that while we know that consumers find scarce items to be more valuable (e.g. Brock 1968; Cialdini 2009), they also believe that all valuable items are scarce. In this case, we demonstrate that while highly caloric items may be seen as intrinsically more valuable (Laran and Salerno 2013), consumers will also infer that all foods they perceive as scarce also contain more calories.

Three studies test our hypotheses. Study 1 used a two (food frame: common vs. scarce) x two (food type: healthy vs. indulgent) mixed design. Food frame was between-subjects while food type was within-subjects. Participants ($N = 169$) were told that the researchers were working with an online food vendor to learn more about people's perceptions of the foods the vendor sells. Participants then read some information about the food vendor that varied by condition. In the common food frame condition, participants read that the foods sold by the vendor were common and widely available. Participants in the scarce food frame condition read that the foods were scarce and limited in availability. Participants were then shown 12 pictures of different food items and asked to estimate the number of calories of each food. Six of the foods were healthy (kiwi, blackberries, avocado, radish, dragonfruit, jicama) and six were indulgent (dark chocolate, honey, red wine, cheese, peanut butter, caramel). To determine whether the effect of the food frame was specific to healthy (versus indulgent foods), an average calorie estimate was calculated for both the healthy and indulgent foods. Results showed a main effect of food frame regardless of food type: participants in the scarce food condition rated the healthy foods as higher in calories ($M = 113.04$) than participants in the common food condition ($M = 93.97; F(1, 166) = 7.61, p < .01$). Similarly participants in the scarce condition rated the foods as higher in calories ($M = 156.16$) than participants in the common food condition ($M = 133.42; F(1, 166) = 6.77, p = .01$). An ancillary study in which we controlled for the potential effect of price perceptions by setting an identical cost/price to the different items regardless of scarcity frame, replicated this same pattern of results.

Studies 2-3 build on study 1 by showing evidence of the underlying mechanism responsible for the effect of food frame on calorie perceptions. Study 2 used a one factor (food frame: common

vs. scarce) between-subjects design. Participants ($N = 136$) read the same food frame manipulation from study 1 and then estimated the amount of calories shown in a picture of a serving of kiwi. After estimating the number of calories, participants indicated their current perceptions of resource availability (e.g., “my resources are scarce”). Results showed that participants in the scarce food condition rated the kiwi as higher in calories ($M = 82.48$) than participants in the common food condition ($M = 67.37$; $F(1, 134) = 4.36, p < .05$). In addition, participants in the scarce condition indicated perceiving their own resources to be more scarce ($M = 5.04$) than participants in the common condition ($M = 4.16$; $F(1, 134) = 6.19, p = .01$). A mediation analysis revealed that perceptions of resource scarcity mediated the effect of food frame on calorie perceptions.

Study 3 ($N = 211$) provided further support for this process in a design where we used cashews as our stimulus and manipulated as opposed to measured resource availability. We manipulated resource availability by introducing a condition where participants were allowed to consume as opposed to just evaluate the scarce item they were exposed to. We hypothesized that allowing subjects to consume the scarce product would mitigate their lack of resources, which in turn would deactivate the effect. Consistent with this prediction, we found that while the effect replicated in the absence of the manipulation ($M_{scarce} = 118.82$ vs. $M_{common} = 71.25$; $t(92) = 3.36, p = .001$), it did not when it was present ($M_{scarce} = 82.95$ vs. $M_{common} = 75.78$; $t(115) < 1, n.s.$)

This research builds on past work on the relationship between scarcity and value (Brock 1968; Cialdini 2009) to show that not only do participants believe that scarce items are more valuable, but that they also attribute a higher caloric content to this type of items. Furthermore, we demonstrate that this occurs because scarce items make consumers feel deprived of resources, and such deprivation leads to the overvaluation and subsequent caloric overestimation of the product.

Acting on Information: Reminders of Resource Scarcity Promote Adaptive Behavior and Flexible Thinking

EXTENDED ABSTRACT:

Past research demonstrated that reminders of resource scarcity prompt the desire to advance one’s own welfare (Roux, Goldsmith, & Bonezzi 2015). We posit that, as a consequence, reminders of resource scarcity increase cognitive flexibility, which facilitates the ability to (i) identify information in the decision environment that informs how one’s own welfare can be advanced (i.e., information relevant to the costs and benefits inherent to different outcomes), and (ii) adaptively respond to this information. We provide evidence for our proposed mechanism across five experiments. We demonstrate that considerations of resource scarcity (vs. control) increase cognitive flexibility (experiment 1) and prompt more flexible information processing (experiment 2). We further show that participants in a scarcity condition (vs. control) are more likely to adapt how they allocate monetary resources (experiment 3) and expend their actual effort (experiment 4) as a function of information in the decision environment. Finally, we provide evidence that consumers reminded of resource scarcity (vs. control) more adaptively integrate external information that bears on the cost and benefits inherent to different outcomes into their tradeoff perceptions (experiment 5).

In experiments 1–4, scarcity was manipulated by asking participants to list things they would be unable to do if certain resources were unavailable (e.g., water; Roux et al. 2015). Participants in the control condition were asked to list things that they could do with the same resources. In experiment 1, following the scarcity manipula-

tion, participants’ cognitive flexibility was assessed using a 7-item measure (Martin and Rubin 1995). Participants in the scarcity condition showed greater self-reported cognitive flexibility ($p = .03$). Experiment 2 provided convergent support for these results using a category inclusiveness task, where participants had to rate the extent to which strong, intermediate, and weak exemplars belonged in a given category; a validated correlate of cognitive flexibility (Isen et al. 1985; 1987). Exposure to reminders of resource scarcity increased category inclusiveness ($p = .02$).

Experiment 3 tested for the consequences of this theoretical mechanism by examining if reminders of resource scarcity also promote the adaptive allocation of resources. Following the scarcity manipulation, participants played one of two economic games: dictator or ultimatum. In the former, allocating very little money to the other player is the best way to advance one’s own welfare. In the latter, allocating too little money can jeopardize one’s chances of earning anything, making it more strategic to incur some cost (i.e. allocate some money to the other player) in order to increase the chances of benefitting from the game (i.e. retaining some money). Therefore, we utilize game-type as a manipulation of information in the decision environment that is relevant for understanding the costs and benefits of expending one’s resources (here, money). Results indicated that participants in the scarcity condition were more likely ($p < .01$) to adapt their resource allocation to game-type than those in a control condition ($p > .6$; interaction: $p = .01$).

Experiment 4 tested for a similar pattern of results in allocations of actual effort. Following the scarcity manipulation, participants were asked to make a choice between either two comparable or two non-comparable options (Cho et al. 2013). Expending one’s effort evaluating comparable options should improve one’s likelihood of identifying the best option. However, engaging in effortful comparisons between non-comparable options is unlikely to yield such results. Therefore, we utilize choice set comparability as a manipulation of information in the decision environment that is relevant for understanding the costs and benefits of expending one’s effort on the product selection task. Results showed that participants in the scarcity condition were more likely to incorporate this information into their effort allocation ($p < .01$): they spent more time evaluating comparable options than non-comparable options; whereas choice set comparability produced no effect on effort in the control condition ($p > .3$; interaction: $p = .02$). These findings from experiments 3 and 4 are consistent with our prediction that scarcity increases cognitive flexibility, which promotes the ability to adapt one’s behavior to tradeoff-related information in the decision environment.

Experiment 5 provided more direct evidence in support of the notion that reminders of scarcity (vs. control) cause people to adaptively integrate relevant external information into their tradeoff perceptions. Participants in the scarcity condition were first asked to recall times when they felt resources were scarce, whereas those assigned to the control condition were asked to list activities they did in the past week (Roux et al. 2015). Next, participants had the opportunity to win an herbal tea of their choosing, with either a high or low probability of winning (between participants). Therefore, we utilize one’s probability of winning as a manipulation of information in the decision environment that is relevant for understanding the costs and benefits of expending one’s effort on carefully evaluating the teas (i.e., the potential benefit is greater if one’s probability of winning is high vs. low). After choosing from a set of twenty teas, participants were asked to rate their agreement with the statement “The benefit I could get from carefully thinking about the teas did not seem worth the effort.” We observed a main effect of the probability of winning, such that the perceived benefit was greater when the probability of

winning was high ($p < .01$). However, consistent with prior results, this was qualified by an interaction between the probability and the scarcity manipulations ($p = .05$): probability of winning affected tradeoff perceptions among participants in the scarcity condition, but not in the control condition. These results support the notion that when the decision environment presents information that is relevant to informing cost-benefit tradeoffs, participants reminded of resource scarcity (vs. control) are more likely to attend to and incorporate that information into their tradeoff perceptions.

In summary, we proposed and found that reminders of resource scarcity promote a cognitively flexible thinking style which allows consumers to (i) identify information in the decision environment that informs cost-benefit tradeoffs, and (ii) adaptively respond to this information. We believe these findings offer theoretical insights into the psychology of scarcity and beyond, in addition to practical insights into when and why resource scarcity might improve decision outcomes.

I Don't Have Now, But I Will Make Sure I Have Later; Saving for the Future Under Resource Scarcity Mindset

EXTENDED ABSTRACT

Based on data from the Federal Reserve, there has been a noticeable uptick in the growth of total savings deposits since the economic crisis in late 2008. However, despite this positive trend of total saving deposits American households are not saving more (Valuepenguin.com). On the contrary, according to the Google Consumer Survey conducted in October 2015, more than 60% of Americans have less than \$1,000 in savings and over 20% of Americans don't even have a saving account. In a recent survey conducted by Banrate.com, only 17% of Americans said they are more comfortable with their savings today versus a year ago, compared with 31% who said they're less comfortable. Individuals in the lowest income bracket are the ones least likely to have an open savings account in the US (Valuepenguin.com).

When people feel financially deprived, they invest effort to attain financial resources (Karlsson et al 2004; 2005 Shah, Mullainathan & Shafir 2012, Sharma & Alter 2012). In particular, perceived financial deprivation is shown to increase preferences for attaining immediate financial resources (earnings) but not for savings (Sharma & Keller 2017). Put differently, individuals who are poor or feel deprived of financial resources tend to save less than those who are rich or feel rich.

In the current research, we propose that a more general resource deficiency or abundance mindset is sufficient to shift people's behaviors related to financial resources. Past research has shown that activations of resource mindsets shifts individuals' motivations between focusing on themselves and their self-resources and focusing on others and other's resources (Levontin, Ein-Gar & Lee 2015; Roux, Goldsmith & Bonezzi 2015). However, people seem to associate putting money aside with feelings of loss rather than abundance (Karlan, Ratan & Zinman 2014). Building on these past findings, the current work show the influence of resource deficiency or abundance mindsets on saving behavior. In particular, we examine the hypothesis that people will save *less* under a resource deficiency mindset than under a resource abundance mindset. However, we also examine how this effect can be reversed. We show how under a resource deficiency mindset people are *more* likely to save if they focus on their future-self rather than their current-self. Past research has demonstrated that focusing on future self can promote savings (Ersner-Hershfield et al 2009; 2011). Counter to intuition, we show that this effect emerges under a resource deficiency mindset We con-

ceptualize this shift in saving behavior as a shift in focus from self to "others" since future-self is more psychologically distant than one's current-self. We conducted two experiments to test our propositions.

Experiment 1: Participants ($n=85$) watched a short video clip of a bag being emptied (resource deficiency mindset) or filled (resource abundance mindset) with different items (Levontin, et al., 2015). Next, participants were asked to imagine that they received a bonus of \$1,000 at the end of the year and could either spend the money on their current-self (a dream vacation, a luxurious restaurant, maintenance expenses), on others (present for a loved one), or on their futures-self (save the money by putting the money in a saving account, put it in the bank for future use). The amount of money allocated to the future-self (savings) served as our DV. Results show that as expected, participants in the resource deficiency mindset condition assigned less of the bonus money to saving ($M=516.93$, $SD=274.93$) than participants in the resource abundance mindset condition ($M=638.84$, $SD=285.90$; $t(1,82) = 1.99$, $p=0.05$).

Experiment 2: In a 2 X 2 design, following the resource mindset manipulation (as in Experiment 1) participants ($n=140$) wrote a letter to themselves, thinking about who they are now (current-self condition) or who they will be in 10 years (future-self condition; van Gelder, 2013). Finally, they completed the bonus task as in Experiment 1. Results show two main effects qualified by an interaction. In the current-self condition, participants in the resource deficiency condition saved *less* ($M=584.933$, $SD=329.033$) than those in the resource abundance condition ($M=669.36$, $SD=306.99$; $F(1,294) = 2.732$, $p=.099$), replicating the results of Experiment 1. However, in the future-self condition participants in the resource deficiency condition assigned *more* of the bonus money to savings ($M=624.25$, $SD=309.91$) than participants in the resource abundance condition ($M=516.33$, $SD=339.07$; $F(1,294) = 3.95$, $p=.048$).

These results offer theoretical and practical insights by highlighting the wide influence of a general (rather than a specific) resource mindset and its effect on saving behavior. Since resource deficiency mindset is easily activated in every-day life (Levontin et al., 2015), savings will only increase if future-self perceptions are also activated prior to savings decisions.

SESSION OVERVIEW

Systematic empirical research on consumer aesthetics used to be “largely ignored by consumer psychologists” (Hoegg and Alba 2008, p. 748), and only emerged in consumer psychology journals in recent years. Aesthetics plays crucial roles in some important aspects of marketing: product creations, package designs, and website layouts, to list a few. As a result, the perception of beauty can serve as an important driver of consumer behavior such as product choices, willingness to pay, quality perception, etc. (e.g., Hoegg, Alba, and Dahl 2010; Page and Herr 2002; Reimann et al. 2010). The purpose of this session is to shed new lights on consumer aesthetics by bringing in new insights and perspectives from recent consumer research. In doing so, we hope to enhance our understanding of how consumers perceive beauty (or the lack thereof) and how they respond to it. The four papers included discuss different aspects of aesthetics and will therefore contribute to a diversified and vivid discussion. The papers are summarized as follows:

In Paper #1, Morgan, Fajardo, and Townsend examine the effect of image-based logos. Contrary to the traditional wisdom that image-based logos should outperform their less aesthetically pleasing and attention-grabbing text-based counterparts, the effect of image-based logos depends *de facto* on brand-awareness. Before brand-awareness is established, text-based logos outperform image-based logos in brand attitude and the likelihood to purchase. Only when brand-awareness is established are image-based logos more effective than text-based logos. Apart from its theoretical significance, this finding is of great importance to the application of aesthetic designs in marketing practices.

Paper #2 by Hagtvedt and Vohs investigates the appreciation of complex and challenging artworks (i.e., high art) as compared to their less complicated counterparts (i.e., low art). The authors demonstrate that whereas low art provides viewers with happiness via process fluency, high art elicits interestingness, which in turn imbues life with meaningfulness. These findings provide a theory that accounts for the appreciation of both low-art and high-art images, and

therefore engender novel insights into our understanding of art appreciation.

In Paper #3, To and Patrick demonstrate the interesting connection between package design and self-brand connections. The authors distinguish between minimalist (clean and simple) and maximalist (ornate and decorative) packaging designs, and argue that while minimalist designs elicit value-expressive attitudes, maximalist designs can give rise to socially-adjustive attitudes. As a result, high(low)-power consumers experience greater self-brand connection when minimalist (maximalist) packages designs are used for the brand, because the brand is perceived to serve a value expressive (socially-adjustive) function.

In Paper #4, Cao, Brucks, and Reimann examine a particular form of aesthetics-pursuing consumer behavior: collecting. Using this context, the authors show that seeking beauty can be more than a form of leisure or entertainment. Specifically, completing a collection can satisfy the very fundamental human desire for control, because collecting's pattern-seeking nature -- also a contributor to the aesthetic experience in collections -- helps satisfy desire for control. This finding identifies a major motive of collecting, and contributes to bridge aesthetic experience and very basic human needs.

Say It or Show It: Logo Aesthetics and Consumer-Brand Relationship Development

EXTENDED ABSTRACT

One of the most fundamental decisions for a brand is whether to have a primarily text- or image-based logo. Aesthetics research suggests that image-based logos should perform better than text-based logos as images are more aesthetically pleasing, attention-grabbing, and easier to process than text (Hsee and Rottenstreich 2004; Carr et al. 1982; Lee, Amir, and Ariely 2009; Townsend and Kahn 2013). However, we find a surprising moderator to the positive benefits of images over text in the brand logo context, brand name awareness.
