Don't Knock The Competition – Knock The Rival: Why Brand Rivalry Creates Message Virality

Johannes Berendt, German Sport University Cologne, Germany

Gavin Kilduff, New York University, USA

EXTENDED ABSTRACT

Despite the existence of multiple competitors in most markets, certain brands seem to have special relationships with each other, typically resulting from a history of competition. These brands often engage in combative exchanges in the media and other communications channels (e.g., Apple-Samsung, Coke-Pepsi). Although the competitive networks brands are embedded in have been shown to be consequential for consumers' psychology and behavior (Paharia, Avery, and Keinan 2014), historic relationships between brands have received little attention. Building upon recent research in social psychology and management that distinguishes rivalry from normal competition, we connect rivalry theory with the storytelling literature, and extend it into marketing. We propose that targeting a rival (vs. a non-rival) competitor in brand communications increases message virality.

Rivalry has been described as a "subjective competitive relationship that an actor has with another actor that entails increased psychological involvement and perceived stakes of competition for the focal actor, independent of the objective characteristics of the situation" (Kilduff, Elfenbein, and Staw 2010, p. 945). The past history between rivals, regardless of the current intensity of competition, is the key characteristic that sets rivalry apart from normal competition (Converse & Reinhard 2016). We argue that repeated competitive interactions between two brands (e.g., advertising battles) will change the way consumers view the brands' relationship. A rival (vs. non-rival) brand relationship is characterized by a narrative, story-like, quality and can thus appeal to actors outside of the rivalry itself, as consumers are inherently attracted to stories and only need minimal information to identify them (Kamleitner, Thürridl, and Martin 2019). Brand rivalries have two key elements of good stories: 1) clearly identifiable and well-known characters (Van Laer et al. 2014) and 2) an interesting, simple plot that is inherent to human beings: conflict (Bohle 1986). Past work has shown that consumers are more likely to engage with content that is interesting, entertaining, and conflictual (Akpinar and Berger 2017; Berlyne 1960) Consumers are also more likely to share ads that contain plots and characters (Tellis et al. 2019). Hence, we expect a positive effect of rivalry on message virality (H1).

We propose that the theoretical mechanism underlying this effect is an increased perception that the brand message is embedded within an ongoing story, or "story embeddedness." Rivalry is an ongoing narrative with the expectation of future episodes. Thus, an interaction between rival brands will be perceived as the next episode of a familiar plot between well-known antagonists. In turn, since stories are easy to follow, entertaining and engaging, they generally produce positive affect and attitudes, and increase willingness to approach and engage (Escalas, Moore, and Britton 2004; Hansen and Kahnweiler 1993). Thus, we predict that the positive effect of targeting a rival (vs. non-rival) on message virality will be mediated by increased perceptions that the message is embedded within a story (H2).

We also propose a moderator of the effect of story embeddedness on message virality. Positive storytelling is more appealing than stories with a negative plot (McCarthy 2008), and negative advertising messages can violate fair play standards, leading to negative consumer perceptions (Jain 1993; Sorescu and Gelb 2000). Thus, perceived story embeddedness will be more likely to cause virality when the competitive message is positive and respectful, rather than purely negative or antagonistic (H3).

To test H1, we analyzed the tweets of six US brands that have a long-standing rivalry (McDonald's-Burger King, Coca Cola-Pepsi, and T-Mobile-Verizon; $N = 1{,}241{,}629$ tweets) during a five-year span. In our model-free analysis, we find that rivalry-related tweets (= those that mention the rival) generate 103.3 retweets on average, while competitive tweets (= those that mention a competitor) generate 16.6 retweets and standard tweets (= all other tweets) 2.95 retweets, respectively. An ANOVA shows that the differences across the type of tweets is strongly significant ($F = 88.03$). Bonferroni pairwise comparisons indicate that rivalry-related tweets generate significantly higher retweets than both competitive tweets (diff: 86.68, $p < .001$) and standard tweets (diff: 100.34, $p < .001$). A zero-inflated negative binomial regression confirms the positive effect of rivalry on virality as compared to standard or competitive tweets, supporting H1.

We next tested our model in an experimental study ($N = 398$). We used a 2 x 2 between-subjects design: brand relationship (rivalry vs. competition) x message framing (respectful vs. disrespectful). H1 was not supported, as there was no direct effect of rivalry (vs. competition) on virality ($M_{Rivalry} = 1.81$, $SD = 1.05$ vs. $M_{Competition} = 1.78$, $SD = 1.14$, $p = .81$). However, in support of H2, there was a positive indirect effect of rivalry on virality via story embeddedness ($b = .11$ [.0440; .1937]). Furthermore, in support of H3, there was a significant interaction effect between story embeddedness and message framing on virality ($b = .29$, $p < .01$). Story embeddedness had a positive effect only in the respectful ($b = .30$ [.1751; .4288]), but not the disrespectful condition ($b = .01$ [-.1146.; .1295]). Using Process model 14, the index of moderated mediation was significant ($b = .20$ [.0745; .1402]). The results hold when controlling for product category involvement, brand usage, brand affect and brand identification.

Our research reveals the value to incorporating rivalry theory into marketing. While past literature shows how small brands can benefit from positioning themselves against big brands (Paharia, Avery, and Keinan 2014), we point out how big brands can use their competitive network to enhance the virality of their communications. While any strong competitor represents a competitive threat, it is the compelling, story-like, nature of rivalry that offers even big brands the opportunity to use the long-time history with a rival to their advantage. Also, we contrast the notion that brands should generally avoid competition. Conventional wisdom suggests that managers prefer weak competitors in order to maximize profits. Our research builds upon a growing body of literature showing positive consequences of intense and longstanding competition for brands. We also reveal an important moderator of the indirect effect on virality via story embeddedness: a respectful (vs. disrespectful) message framing. This provides guidance to practitioners regarding how an attack on the competitor could be framed.

The Impact of Single versus Multiple Narrating Voices in Persuasive Videos

Hannah H. Chang, Singapore Management University, Singapore
Anirban Mukherjee, Cornell University, USA
Amitava Chattopadhyay, INSEAD, Singapore, Singapore

EXTENDED ABSTRACT

Broadcast videos often visually depict a product with one or more narrators providing the voice-over to discuss its features and benefits. Examples of broadcast videos include product videos and video advertising, which have become increasingly prevalent and important in consumer decision making in today's marketplace (Think with Google 2019). Despite the importance of sound and voice on people's behavior, existing research has placed relatively little emphasis on understanding the influence of narrator's voice in effective communications (cf. Dahl 2010).

In this research, we posit that in an initial exposure to a broadcast video, having more voices narrate (in succession) a persuasive message encourages consumers' attention and processing of the message, thereby facilitating persuasion. Having more narrating voices in a broadcast video involve changes in the voiceover. Not only are consumers naturally predisposed to the human voice (Belin et al. 2004), but stimulus change helps capture consumer attention. A change in voice can involuntarily capture attention, even when there are other visual or auditory tasks competing for attention (Cherry 1953; Morton, Crowder, and Prussin 1971). Moreover, as each new voice carries additional (nonverbal) information for the brain to process, the enriched representation of spoken content with more narrator voices should prompt listeners to process the spoken message in a more cognitively effortful manner. Therefore, a change in narrator voices in a broadcast video should help facilitate processing of the spoken message, which in turn boosts persuasion. We termed this "the voice numerosity effect."

We test the hypothesized effect in four studies—two large-scale, real-world datasets (with more than 11,000 crowdfunding videos and more than 1,600 broadcast ads) and two controlled experiments (plus a validation study and a replication)—using a range of consequential dependent measures, decision domains, product categories, and voice-based marcomm. We also examine the conceptualization through three theory-derived boundary conditions.

Study 1 is situated in the context of online crowdfunding (i.e., Kickstarter; Dhanani and Mukherjee 2019), where videos describe new products to potential consumers. We collected and analyzed data from over 11,000 products spanning 2.5 years across 31 categories (under 3 largest supra-categories) on Kickstarter. The dataset includes consequential dependent measures (funding pledged, number of customers, project success; see Fan, Gao, and Steinhart 2020), focal independent variable (number of narrating voices), moderating variable (speech rate), and a range of controls related to visual, audial, linguistic, and project characteristics. We parsed the videos and derived these measures using recent advances in machine learning methods and text mining. Building on prior studies showing that faster speech rate disrupts listeners' cognitive processing (Moore et al. 1986), results showed that having more voices narrate the project message significantly improves project outcomes (all $\alpha_1 > 0$, all ps $< .01$). The effect is both statistically significant and economically important—having an additional speaker, ceteris paribus, is associated with raising $12,795 in additional funds (a 39% increase), getting the support of 118 additional customers (a 38% increase), and a 1.6% increase in the probability of project success (a 6.5% increase). Moreover, the effect is consistently moderated by the rate at which the spoken content was delivered (all $\alpha_3 < 0$, all ps $< .05$), suggesting that cognitive processing is necessary for the hypothesized effect.

Study 2 extends our investigation of the effect to another real-world context of importance to marketing practice: advertising. This study related the voice numerosity effect to consumers' perceived efficacy of ads. We obtained a video ads dataset with human-coded measure of ad efficacy and augmented the dataset by measuring audial and visual characteristics of the ads. Results from over 1,600 ads replicated study 1: having more voices narrate an ad message significantly increases perceived ad efficacy (all $\alpha_1 s > 0$, all ps $< .001$). The effect is consistently moderated by the rate at which the spoken ad message was delivered (all $\alpha_3 < 0$, all ps $< .01$): having more voices narrate an ad message at faster rates relates to lower perceived ad efficacy.

To examine the causal role of voice numerosity, study 3 varied the number of narrator voices in a product video and consumers' processing resources through a distraction task. Results revealed a significant interaction between number-of-voices and distraction ($F(1, 353) = 4.90$, $p = .027$, $\eta^2 = .014$), such that the effect was more pronounced when participants have more processing capacity (low distraction; $M_{1\text{-}voice} = \$44.18$, $M_{5\text{-}voices} = \$47.98$; $F(1, 353) = 5.34$, $p = .021$, $\eta^2 = .015$) than when they have limited processing capacity (high distraction; $M_{1\text{-}voice} = \$44.81$, $M_{5\text{-}voices} = \$43.40$; $F < 1$). A separate pretest established the effectiveness of the number-of-voices manipulation.

Study 4 examined voice numerosity through a consumer characteristic that relates to their natural inclination to engage in effortful cognitive endeavors, known as need-for-cognition (NFC; Cacioppo, Petty, and Kao 1984). The interaction between NFC and number of voices was significant ($\beta = .04$, $t(344) = 2.19$, $p = .029$, $\eta^2 = .014$). A floodlight analysis (Spiller et al. 2013) showed that participants who do not enjoy effortful thinking (i.e., those with NFC scores less than 38) indicated lower WTP for the product in the 5-voice condition than in the 1-voice condition ($\beta_{JN} = -1.04$, SE $= .53$, $p = .05$); in contrast, participants who enjoy effortful thinking (i.e., those with NFC scores greater than 83) indicated higher WTP in the 5-voice condition than in the 1-voice condition ($\beta_{JN} = .72$, SE $= .41$, $p = .08$). A separate pretest provided support for the conceptual rationale that a spoken message narrated by five voices (vs. one voice) was more difficult to comprehend.

Voice-based marketing communications (marcomm) are becoming increasingly popular and important to consumers in the modern marketplace. Our research aims to contribute to extant literatures on sensory marketing and persuasive marketing communication. We identified and showed that number of voices narrating a marcomm message can affect consumer behavior. Our research also aims to offer practical suggestions for designing more effective broadcast videos.

Finding "The One": Effects of Brand Dominance and Type Dominance on Condom Switching Behavior

Yixia Sun, Zhejiang University, China
Tingting Wang, Sun Yat-sen University, China
Anirban Mukhopadhyay, Hong Kong University of Science and Technology, Hong Kong

EXTENDED ABSTRACT

Consistent condom use can effectively prevent against HIV and other sexually transmitted diseases (Catania, Coates, and Stall 1991). However, only 23.8% (33.7%) of sexually active women (men) in the U.S. reported having used condoms the last time they had sex (National Health Statistics Reports 2017). This research takes an innovative perspective to investigate the prevalent lack of condom use —consumers' switching behaviors to find the right condom.

In a pilot study ($N = 495$), we found that (1) having found the right condom ("Have you found one or more condoms that you actually love?" Yes/No) was positively associated with reported condom usage: 61.3% of participants who indicated having found the right condom reported having used condoms at their most recent sexual intercourse, compared with only 27.1% who had not; (2) The pleasure of first-time experience using a condom positively influenced the number of brands (but not the number of types) participants had tried ($B = .10$; $t(493) = 2.96$, $p = .003$) which was positively associated with the likelihood of having found the right condom (Wald(1) = 29.93, $p < .001$). These results implied that a negative condom usage experience demotivated consumers from exploring other condom brands, and reduced the chance of finding the right condom. Without the right condom, they tended not to use a condom on subsequent occasions of sexual intercourse.

The above demotivating effect seems to contradict prior research findings that unpleasant consumption experiences prompt brand switching (Keaveney 1995). In the current research, we argue that consumers are highly risk-averse in using condoms. As condoms are used by a dyad during the highly experiential occasion of sexual intercourse, any uncomfortable feeling may hinder them from reaching climax, potentially ruining the experience for both, and harming the dyad-relationship (Yarber et al. 2004). To mitigate the potential risk of having another bad experience, consumers may switch to low-risk options. We therefore posit that consumers' switching processes for condoms are subject to the joint influences of *brand dominance* (e.g., Trojan vs. Durex) and *type dominance* (e.g., regular vs. dotted). The dominant brand/type, which reflects the majority's choice, signals lower risk than non-dominant counterparts, and this difference is assumed to be greater for brands than for types. Specifically, when a non-dominant brand is unpleasant to use, consumers would simply switch to the dominant brand regardless of the condom type. Contrastingly, when a dominant brand is unpleasant to use, type dominance comes into play: given a non-dominant type, consumers would switch to the dominant type of the dominant brand; whereas given a dominant type, implying that the lowest-risk option within the dominant brand has failed, consumers would switch to a non-dominant brand with a dominant type.

Three studies provided empirical support for the demotivating effect of a negative condom experience (Study 1) and the proposed switching processes (Study 2 & Study 3), and generated practical insights for both consumers and marketers (Study 3).

Study 1

In study 1, following a 2 (experience valence: positive vs. negative) x 2 (product: condom vs. general product) x 2 (type dominance: dominant vs. non-dominant) between-subjects design, we replicated previous research findings for general products – that a negative experience motivated consumers to try the same type of products but from other brands ($M_{positive} = 4.02$ vs. $M_{negative} = 4.37$; $F(1, 791) = 7.75$, $p = .006$). Contrastingly, for condoms, a significant experience valence by type dominance interaction ($F(1, 791) = 23.40$, $p < .001$) emerged, such that a negative experience with a non-dominant type reduced participants' willingness to explore the same type of condoms from other brands ($M_{positive} = 4.72$ vs. $M_{negative} = 3.18$; $F(1, 791) = 43.60$, $p < .001$). This demotivating effect, however, was not evident when the negative experience came from a dominant type ($M_{positive} = 4.41$ vs. $M_{negative} = 4.47$; $F(1, 791) = .08$, $p = .781$). An indirect effect analysis indicated that perceived risk of having another negative experience mediated this three-way interaction (5000 samples, 95% CI: [.46, 1.10]).

Study 2

Study 2 examined consumers' switching processes as a function of brand dominance and type dominance. In a 2 (brand: dominant vs. non-dominant) x 2 (type: dominant vs. non-dominant) between-subjects design, participants imagined that they had a negative condom usage experience, with either a dominant or non-dominant brand/type. Then they selected one condom to use for the next time from 12 combinations, of three brands and four types, that varied on dominance levels. Results revealed that most participants switched to the dominant brand's dominant type (lowest-risk option), except when the negative experience was from the lowest-risk option, whereby participants switched to the non-dominant brand's dominant type.

Study 3

Based on the probabilities calculated in the pilot study and the switching processes revealed in study 2, study 3 built an integrated model to simulate consumers' switching processes to find the right condom and to calculate the average needed switching times (a proxy for number of brands tried). A Monte Carlo Simulation (10,000 iterations) revealed that the average switching times to find the right condom was 3.05 (CI$_{95}$: 3.01, 3.11). This fit very well with the pilot study result that participants who found the right condom tried on average $M = 3.04$ brands, supporting our proposed switching processes. Next, we adjusted the satisfaction rates of dominant/non-dominant brands to see whether and how average switching times might respond. Results showed that the average switching times would drop to 2.00 if both dominant and non-dominant brands could achieve satisfaction rate of 50%, signaling ample room for product improvement. In the current state of affairs, the optimal strategy for consumers to find the right condom is to switch among brands rather than types, and preferably try more than 3 brands.

Discussion

This research contributes to safe sex promotion by identifying the importance of finding the right condom and uncovering the black-box of consumers' switching processes among brands and types. Practically, public health organizations should encourage consumers to try more (>=3) brands rather than types to maximize their chance of finding the right condom. Moreover, consumers may start

with the dominant type of the dominant brand, as consumers in such a situation are more willing to try other brands after a product failure.

The Silver Lining to the Mushroom Cloud: A Netnographic Analysis of Consumers Enjoying Systemic and Existential Risks

Hunter Jones, Aalto University School of Business, Finland

EXTENDED ABSTRACT

To theorize how consumers process systemic and existential risks to market society, this netnography studies doomsday preppers and survivalists, individuals preparing for the breakdown of society by stockpiling resources, acquiring knowledge, and practicing survival skills. While prior research on preppers and the literature on consumers' relationship to systemic and existential risks treats these risks in the intuitive way, as something to be managed and minimized, the paradoxical presence of doomsday optimism suggests the value of further theorization. Unlike previous characterizations, we illuminate how preppers libidinally enjoy systemic and existential risks because the fantasy, through its sacrifice of the relatively safe 'good life', provides them fertile grounds for imagining living exciting, risky lives of action outside the safe confines of modern market-mediated society.

Literature Review

In Beck's (1992) Risk Society, "consumers are forced to self-organize to manage risk, and this… rather than class struggle, becomes the central axiom of modernity" (Young 2010, pg. 261). Extant literature describes how consumers navigate this risk-laden world in diverse contexts (Dreton and Zeyer 2018; Barnhart et al. 2018; Farley 2018) and how factors like gender (Keller and Olson 2018) and political affiliation (Sheppard and Kay 2018) mediate risk perceptions. Moreover, in Risk Society, the status of science is contested, at the same as producing innovations as solutions to new risks themselves fostered by innovation (Ekstrom and Askegaard 2000; Thompson 2005; Wong and King 2007; Humphreys and Thompson 2014). While this research treats systemic risk as something to be managed and minimized, other research notes consumers intentionally seek out bounded market-mediated risks as a source of pleasure, path to self-fulfillment, and means of testing oneself (Celsi et al 1993; Arnould and Price 1993; Scott et al. 2017; Tumbat and Belk 2010).

Despite this attention to market-mediated risk-seeking, consumer researchers have largely ignored consumers who libidinally enjoy threats to the entire market-system itself– the focus of this paper. For some consumers, hyper mediated marketized culture is itself the barrier to living an exciting life of action (Le Breton 2018). Because these risks are not offered through markets and escape from markets is impossible (Kozinets 2002; Arnould 2007), consumers can only imagine them through fantasy. With this gap in mind, we question if prior characterizations of doomsday prepping as "a precautionary desire to be prepared" (Mills 2017, p.7), "an expression of generalized anxiety" (Campbell et al. 2019, p. 798), or an "anticipation of terror… stress and anxiety" (Aldousari 2015, p.33) capture the libidinal stance preppers take towards risk. Widespread presence of excited and optimistic doomsday preppers points to the need for further theorization.

Theory & Methodology

Rather than examining how preppers legitimate their behaviors (see Campbell et al. 2019), this hermeneutic netnography (Kozinets 2015) of a popular American doomsday prepping forum uses a psycho-social approach (Clarke 2002) grounded in Lacanian concepts (Lacan 1998) such as drive, desire, the Real, and Jouissance to uncover the unconscious, libidinal, and dark underside at work.

Findings

Findings part one describes how doomsday preppers construct enjoyable doomsday myths which conveniently promise the undoing of some form of alienation that bars them from unmediated experience and jouissance. In these scenarios, there is a propensity for doomsday optimism. The general narrative goes something like this – the modern age simply cannot go on, eventually something must falter economically, ecologically, legally, or otherwise. However, this is not all bad as society will somehow solve its dilemma through collapse, ushering in a new era, one that is more sustainable, authentic, and real. In this general doomsday mythic structure, America's hardworking, grievously alienated 'everyman,' finds his banal existence violently ruptured by catastrophe, and now has the opportunity to build the world anew which provides undiluted access to the Real and jouissance. Three variations of the general doomsday myth are presented: 1) fantasies of rebirth through violence 2) fantasies of communities and ecosystems of the Real and 3) fantasies of the reconciliation of economic and social life through economic collapse. Overall, part one argues that these doomsday myths follow a similar seductive structure which offers the impossible promise of achieving a non-lacking subjectivity and thus evidences the operation of desire at work (McGowan 2013).

Part two describes four counterintuitive sources of enjoyment produced by doomsday prepping. Specifically, finding 2.1 describes how consumers' doomsday myths produce 'surplus jouissance, or an excess of jouissance independent of use value, through fantasizing about the sacrifice of comparatively safe, comfortable lives today in favor of a risk-laden, post-disaster life. Finding 2.2 describes how a similar surplus jouissance associated with 'knowing' the future is arrived at through the sacrifice both of non-preppers' safety and collective efforts to mitigate risks. In a similar vein, finding 2.3 describes how bricolage and fetishism embed the power of the doomsday myth, representative of the sacred Real, in objects. This fetishism takes the form of an excessive jouissance arrived at through sacrifice of various practical considerations. Finally, finding 2.4 concludes by arguing that preppers' enjoyment stems from the repetition of drive, not the fulfillment of their spoken, conscious desire for risk reduction as prior research suggests (see Campbell et al 2019 and Mills 2017). Rather, we argue that risk reduction is merely an alibi that allows preppers to endure their counterintuitive source of enjoyment: the repetition of drive.

Contribution

We make four primary research contributions. First, we contribute to research on risk and consumption by demonstrating how some consumers libidinally enjoy systemic risks to market society. Second, we introduce and explicate a conceptual vocabulary which distinguishes between 'desire' and 'drive' to describe this paradoxical source of enjoyment. Third, we provide evidence that counterintuitively, it's not consumers' risk assessments which produce desire but desire itself guides the imaginative construction of risk. Finally, we contribute to prior research on the creation of the responsible consumer subject which theorizes responsibilization through governmentality and power (Geisler and Veresiu 2014) by accounting for the role of consumer desire in this process.

Netflix and Cringe: Media Consumption as Transformative Identity-Work

Carly Drake, North Central College, USA
Anuja Pradhan, University of Southern Denmark, Denmark

EXTENDED ABSTRACT

In this study, we articulate how consumers pursue internal conflict as it manifests in experiencing moments of "cringe" while watching television. We explore the phenomenon of "cringe-watching" as a companion/alternative experience to previously studied notions of binge-watching and interrupted escapism (Jones et al., 2020). In so doing, we uncover the transformative identity-work involved in consuming media artefacts in the global marketplace. Leveraging collaborative autoethnography (Ngunjiri et al., 2010) as our method, we challenge the traditional role of researcher as subject, and blur the boundaries between theoretical critique and lived experience. Here, collaborative autoethnography falls under the umbrella of subjective personal introspection (SPI) (Holbrook, 1995) within the consumer introspection theory paradigm (CIT) wherein introspection aids in generating consumer research data (Gould, 2012).

For this study, we watched the show the Netflix show *Indian Matchmaking* and maintained diaries where we individually documented our responses to episodes, which formed 69 pages of data. We then commented on each other's responses to produce collaborative, reflexive research data. Upon finishing our viewings, we conducted separate data interpretations and then together thematically analysed (Miles and Huberman, 1994) the initial findings. By building on non-Western feminist theories, we problematised dualities like researcher/viewer and subject/object, which perpetuate oppressive Western thought present in many media narratives (Davé, 2012). This approach makes visible and recognizable perspectives linked to gender, race, class, and geography that are often ignored in mainstream and scholarly narratives (Mishra, 2013).

Our data reveal an imperative not to abolish dualities but to allow each element to be recognised and understood in a context that often demands clarity. First, by locating and interrogating the past-present duality, we show how media consumption can incite transformative identity-work in multiple ways. Firstly, when cringe related to undesired past-selves emerges as a result of socio-temporal comparison with on-screen characters, acknowledging and accepting our past-selves reveals potential for empathy and self-compassion. Additionally, when publicised intimacies (i.e., media depictions of peoples' private lives) cause viewers conflict, these can simultaneously generate heightened understandings of the show, consumers' insecurities, and in our case, our roles as consumer researchers. For example, we relate to one of the show's contributors, Aparna, who was villainised for being too stubborn or picky on the dating market. We often referred to each other as "Aparna" while emailing about this study, with "Aparnas" representing a form of "sisterhood." By projecting our (subject) insecurities as well as "unfair" and "cringeworthy" treatments on to Aparna (object), we distanced ourselves from visceral experiences and managed self-esteem, or rationalised the validity of our experiences and eventually accepted our (undesired) past-selves as an act of self-compassion.

Secondly, the show blurs the boundaries between the sacred and profane by uncritically depicting instances of women-on-women symbolic violence or misogyny. We find that the cringe arising from these depictions can lead consumers to question the accountability of marketplace actors, like Netflix, who appear to profit from exploiting societal discriminations. Moreover, in *Indian Matchmaking,* religion is foregrounded, but for both non-religious authors, seeing religion in a market context was frustrating. Yet, as the second author writes in a diary entry, "A non-religious person critiquing a show's use of religion just feels too easy, and even wrong." Allowing space for both the sacred and profane allows each element of a duality to exist without a value judgment.

Our research began as a way of mobilising *Indian Matchmaking* as a media artefact for transformative identity-work as an end in itself. We centred conflict in the media consumption experience and demonstrated how cringe can prompt consumers' pursuit of understanding their positions in a globalised world, as well as decolonising ideas around customs such as matchmaking that have been often depicted through the lens of "third world difference" (Mohanty, 1988). By interrogating the subject-object divide, we showed that while such identity-work can be an end in itself, it additionally presents a novel way to understand critical media consumption and generate marketing theory. Thus, our first contribution is to show how consumers' experiences of cringe-watching and attempts at transformative identity-work can be understood as an alternative/companion marketplace phenomenon to previously studied notions like binge-watching.

Additionally, we illustrate the utility of collaborative autoethnography in dimensionalising the complexities, contradictions, and disappointments (Nicotera, 1999) arising from experiences of cringe as related to identity-work. We tease out unexpected outcomes of cringe such as empathy, frustration, self-compassion, and understand limits to our individual feminisms. Thus, as a second contribution, we offer researchers and marketers a novel avenue for studying media consumption while situating the researcher and the researched as epistemologically equal.

Numbers Talk Louder When They are Larger: The Effect of Font Size of Numerical Stimuli on Advertisement Persuasion

Yunzhi Huang, Xiamen University, China
Jun Ye, Xiamen University, China

EXTENDED ABSTRACT

Numerical information plays a crucial role in marketing communication about product price, and product attributes such as volume, effectiveness, performance, etc. Communicating numerical information effectively is important to marketing practitioners. For instance, how to make a twelve-dollar lamp seem cheaper or a 500ml drink seem bigger? This research aims to investigate the effect of font size in displaying numbers on the persuasiveness of advertisements. Specifically, we are interested in examining whether displaying numbers in a larger or smaller font size in advertisements influences the effectiveness of persuasion.

Font size is one of the fundamental factors to be considered in ad design. Big font size of verbal information is believed to draw attention (Wogalter & Leonard, 1999), promotes readability (Rello, Pielot, & Marcos, 2016), and affect individuals' memory and cognition (Mueller, Dunlosky, Tauber, & Rhodes, 2014). Individuals give significantly higher judgments of learning (predictions about the likelihood of remembering recently seen information) to large words than small words, although their real recall performance was equivalent for different sized words (Rhodes & Castel, 2008). Besides, people believe that large word size represents important messages (Luna, Nogueira, & Albuquerque, 2019) and increases fluency perception (Yang, Huang, & Shanks, 2018). Therefore, individuals make biased judgments and inferences towards the content in different font sizes.

However, limited study has investigated the effect of font size of numerical information on marketing communication, except for Coulter and Coulter (2005) and Aggarwal and Vaidyanathan (2016), whose work showed that presenting regular price (a relatively high price) in large font size and sale price (a relatively low price) in small font size accords with the "size congruency effect" (Dehaene, 1989), and thus increase the purchase likelihood. However, these results are based on comparing the font size of different numbers and the numerical stimuli are limited on price information. The effect of font size of numerical stimuli about other product attributes such as attributes and performance on consumers' judgment remains unexplored.

Big font size has been empirically proved to attract attention (Aggarwal & Vaidyanathan, 2016). Then, what downstream outcomes can attention lead to? Information is commonly conveyed for a purpose, thus recipients of the information will go beyond the literal meaning of the message and guess what the information sender intends to express (Hilton, 1995; Kardes, Posavac, & Cronley, 2004). For written information, factors unrelated to message content such as boldface and italics are commonly used to point the emphasis. For example, a bigger font size increases the perceived urgency of warning labels (Adams & Edworthy, 1995). We propose that a bigger font size of numerical stimuli in the ad can raise attention, and consumers would attribute the marketer's motive to deliberately attract attention to their confidence in conveying the message. That is, consumers would surmise a marketer's use of a large font size of numbers in the ad as being confident and conveying strong opinions. Whereas a marketer's use of a small font size of numbers will be perceived as being less confident in his or her opinion.

Some anecdotal evidence proves this assumption. The price tag in the supermarket's promotion ad is always big and salient, while the price tag of luxury goods is normally small and never prominent-

ly displayed. In the former case, price information is advantageous to transmit to consumers. On the contrary, in the latter case, the price information is never a core competence for luxury goods. When consumers perceived strong confidence from the marketer, they are more likely persuaded by the marketing messages. Thus, we hypothesize that increased font size of the numerical stimuli in an advertisement would boost recipients' belief in its implication including the perception of inexpensive price and better product performance, depending on the meaning of the numerical stimuli. Besides, the font size effect on persuasion is mediated by a causal chain: the increased font size would attract more attention, and thus promotes the message strength perception, which in turn boosts persuasive effectiveness.

Three studies were conducted to test our Hypothesis. University students and participants from an online survey platform were recruited for the studies. Study 1A manipulated the font size of the price in a lamp advertisement (small font-size: 16 points; big font-size: 60 points) with the other elements being the same in two conditions. Participants evaluated the perceived inexpensiveness of the lamp and rated the lamp presented with a bigger font size of price less expensive than that was shown with a small font size of price. Study 1B manipulated the font size of the product performance ("Effectively inhibits 99% of bacteria") in a Dettol hand sanitizer advertisement. The font size of "99%" was either 24 points or 72 points. Participants perceived the product to be more effective when the font size of the number claiming the efficacy is big rather than small.

Study 2 used a mobile phone advertisement and manipulated the font size of numerical stimuli of the mobile's parameter (battery capacity, camera pixels, and memory). Participants rated the expected performance of the mobile phone better when the font size of the number is bigger, and the effect is serially mediated by attention and the message strength of the advertisement. We also measured and excluded the alternative explanations of involvement, fluency, and perceived message importance.

Our studies demonstrated that individuals are better persuaded by the advertisement displaying numerical information in larger font size because it can attract more attention, and thus increase message strength. Theoretically, this research extends the literature on font size by examining its effect on ad persuasion and product evaluation in the marketing context. Besides, while the visual marketing literature has examined the effect of light, shape, color, material, and location on consumers' perception (Sample, Hagtvedt, & Brasel, 2020), the font-size effect is an underdeveloped issue in visual design. Thus, the findings also complement visual marketing research. Managerially, our findings suggest that advertisers who aim to covey the advantage of product price and/or product attributes should increase the font size of the numerical stimuli in order the improve the persuasiveness of the advertisement.

The World Needs Re-Balancing: How Consumers Re-Focus Consumption Communities

Jack Coffin, University of Manchester, UK
Emma Banister, University of Manchester, UK

EXTENDED ABSTRACT

There are many different forms of consumption community, but all share a focal brand, practice, or ideology (Thomas et al., 2013). This applies also to consumption collectives that are "noncommunitarian" in nature (Arvidsson and Caliandro, 2016: 730). Consumer researchers have shown how consumption collectives become more heterogeneous by legitimating the value of diversity (Thomas et al. 2013) and how they then demand other collectives become more inclusive also (Scaraboto and Fischer, 2013). Although heterogeneity can be destructive and even disastrous (Parmentier and Fischer, 2015; Kozinets et al., 2017), it can also be managed effectively to enrich consumer culture (Thomas et al. 2013; Preece et al. 2019). Existing studies have generally focused on contexts where the focus of consumption is undisputed – a brand like America's Next Top Model (Parmentier and Fischer, 2015), a practice such as running (Thomas et al. 2013), or an ideology along the lines of inclusivity (Scaraboto and Fischer, 2013). However, such studies provide less insight into cases where consumers feel that this focus of their collective identity is an issue, and where their desire to create and maintain a more heterogeneous culture of consumption necessitates the de-centring of this foci in favour of re-centring another.

Theoretical Foundations

Although existing studies have not addressed this particular empirical problem, they provide theoretical tools and insights. Adopting an assemblage approach (Canniford and Bajde, 2016) enables the study of material and expressive components, working together to allow a consumption assemblage to emerge (Martin and Schouten, 2014), evolve (Thomas et al. 2013), or enervate (Parmentier and Fischer, 2015). Importantly, while not requiring it, it allows for the possibility that one component could become the focus of a particular assemblage. As such, it is plausible that a consumption assemblage could emerge with one focus and evolve to re-focus elsewhere. Indeed, assemblage approaches emphasise the importance of processes, with assemblages always in a state of flux or 'becoming' (Canniford and Bajde, 2016). As such, these approaches facilitate a process theorization (Giesler and Thompson, 2016).

Methodology

Our study is located in Manchester, which has a well-established reputation for celebrating diverse sexualities and genders (Haslop et al., 1998), with a world-famous Gay Village (Binnie and Skeggs, 2004), Pride festival (Hughes, 2006), and local organizations providing specialist services beyond these conspicuous sites and events (Simpson, 2013). Taken collectively, Manchester's LGBTQ+ communities can be framed as an acute case of a culture in flux, with the future of the Gay Village uncertain and the spatial and symbolic trajectories of LGBTQ+ organizations contested. A multi-sited ethnography was conducted (Marcus, 1995, 1998) between 2014 and 2016. Data were collected from *Avant Garde*, an LGBTQ+ running club, *Polari*, an LGBTQ+ theatre group, and *MQC*, the Manchester Queer Choir. The first researcher took notes from meetings, training-sessions, and other events. These were supplemented by photographs, videos, and articles from newspapers and other media. Interviews with members were also conducted, resulting in 31 in-depth transcriptions. Data analysis was conducted throughout the research process (Goulding, 2005), moving from open coding to axial coding, then interpretation and theory-building (Belk et al. 2012). An emergent theme in the data was the role of re-focusing collective identities around novel forms of consumption.

Findings: Emergence, Evolution, Enervation

All three clubs were initially founded as a response to the consumption practices that dominated Manchester's Gay Village and stereotypical 'gay' culture more broadly. Young, gay men in particular were stereotyped by participants as undesirable figures who drunk excessively, went to nightclubs, and lived illicit and promiscuous lives. Historically, these practices have been the focus of the LGBTQ+ collective identities (Kates, 2002, 2004; Visconti, 2008) and markets (Keating and McGloughlin, 2005). All three groups saw their role as providing new social spaces for LGBTQ+ people. These spaces were physically and psychically removed from the night economy of the Gay Village, and offered alternative practices (e.g. running, acting, or singing) to stereotypical LGBTQ+ excessive practices.

Importantly, the stereotype was not considered to be an accurate representation of LGBTQ+ lifestyles, but rather a dominant one that made it more difficult for non-heterosexual individuals to conceive and achieve other lifestyles. The three groups provided material components (e.g. spaces to run or sing) and expressive components (e.g. non-stereotypical representations). They also created imaginative components that facilitated re-assembly (Epp et al. 2014), such as role models. Unfortunately, over time all three groups found themselves refocusing their identities around the stereotypical consumption of the Gay Village, albeit in different ways and to varying degrees. This threatened the collective identity of these groups as alternatives to the stereotype, so all three worked to counterbalance their stereotypical consumption with material, expressive, and imaginative components from elsewhere. In one case (Polari) these counterbalances were not introduced in time and the group disbanded.

Discussion and Conclusion

Our study shows how consumption assemblages can re-focus their collective identities, and explains why consumers and other market actors may be motivated to change focus. Theoretically, it contributes to the literature on communities (Thomas et al. 2013) and other collectives (Arvidsson and Caliandro, 2016), which are usually conceptualised as focused and committed to that focus. While the LGBTQ+ identities of our groups remained consistent, their *consumption* foci were subject to change. Given the intertwinement of consumption assemblages with other assemblages, such as markets (Martin and Schouten, 2014) and brands (Parmentier and Fischer, 2015; Preece et al. 2019), our study also provides theoretical insights into how these might contribute or challenge re-focal activities. There are also a series of practical implications. For managers, this provides the possibility of refocusing markets around new products or brands. For policy-makers, this points to efforts to refocus cultures away from alcohol consumption and other problematic practices (Banister et al. 2019). This study also provides two successful case studies (including one cautionary tale) for pro-active consumers who want to refocus their activities and the collective identities of those who consume like them. However, as the process re-focusing may manifest differently for each consumption assemblage, further focused research is needed.

The Scale Effect: How Rating Scales Affect Product Evaluation

Rahil Hosseini, Universitat Pompeu Fabra, Spain
Gael Le Mens, Universitat Pompeu Fabra, Spain

EXTENDED ABSTRACT

You are wondering whether to watch the latest blockbuster for a movie night at home. Before deciding whether to rent it on your favorite streaming platform or to look for another option, you consult its ratings on two review websites. Website A presents ratings on a 1-to-10-point scale. Website B presents ratings on a 1-to-5-point scale. In this paper, we aim to answer the following question: Which of these two ratings will more strongly influence your consumption decision?

The results of 8 studies suggest that your decision will be more strongly influenced by the ratings from the website that reports ratings on the larger scale (10-point, in this example). More specifically, we measured the relative influences of ratings expressed on 5-point, 10-point and 100-point scales in settings where people evaluate products based on ratings expressed on a relatively *larger* scale (e.g., 10-point or 100-point) and a relatively *smaller* scale (e.g., 5-point or 10-point). We consistently found that ratings expressed on *larger* scales have *stronger* effects on product attitude, willingness to pay and purchase intentions than ratings expressed on smaller scales. We call this phenomenon the '*scale effect.*'

This finding is surprising because people are most familiar with ratings expressed on the 5-point scale and thus these should be more fluently processed (Schoenmüller, Netzer, and Stahl 2019; Schwarz, 2004). This implies that 5-point ratings should more strongly influence product evaluations than 10-point or 100-point ratings.

Ostensibly, the scale effect might be interpreted as a manifestation of the "unit effect" (Bagchi and Davis, 2016; Pandelaere, Briers, & Lembregts, 2011) in the rating domain. According to the unit effect, people neglect the unit of numerical information and are thus sensitive to the numerosity of attribute values (e.g., a distance expressed in centimeters is perceived to be larger than when expressed in meters). Yet, we failed to find evidence for the unit effect in the rating domain.

Our findings suggest that the scale effect results from a default rating aggregation strategy that can be overcome when there is reason to do so. We find that both deliberate and non-deliberate cognition contribute to the scale effect. People report that they find large-scale ratings more informative than small-scale ratings, and this difference in perceived informativeness contributes to the scale effect. This suggests a deliberate component to the scale effect. But even participants who claim they should give equal weights to ratings from both scales are subject to the scale effect. This suggests a non-deliberate component.

Methodology

We analyzed the scale effect in a series of online behavioral studies in which participants evaluated products based on one large-scale ratings and one small-scale ratings. The studies involved single evaluation settings and joint evaluation settings.

Studies 1 to 3 provide evidence for the scale effect. Study 1 (N = 151) provides correlational evidence using real video games and their ratings published by actual review websites. In studies 2 and 3, we manipulated the scales on which ratings were expressed, providing causal evidence for the effect. In Study 2 (N=101), we used a consequential setting; participants evaluated a set of movies and received as payment a voucher to download and own the movie they evaluated the most positively. Study 3 (N = 541) provides evidence

for the scale effect across different scale pairs (5 and 10 points, 10 and 100 points and 5 and 100 points).

Studies 4 and 5 show that differences in rating numerosity are not sufficient to explain the scale effect. Study 4 (N = 152) found that 'unit effect' does not apply to the rating domain and Study 5 (N = 802) found that communicating ratings visually rather than numerically hardly affects the strength of the scale effect.

In study 6 (N = 151), we measured the extent to which the scale effect is produced by a difference in subjective strength of ratings expressed on larger and smaller scales versus differential weighting of the two ratings. We found that the rating scale does not affect subjective strength but affects how ratings are aggregated into a product evaluation.

Study 7 (N = 543) reveals that one reason people give more weight to large-scale ratings is that they find them more informative, suggesting that the scale effect results from a deliberate intent. Moreover, participants who claim they should give the same weights to ratings of the two scales still give more weight to large-scale ratings, suggesting a non-deliberate component to the scale effect.

In study 8 (N = 501), we manipulated perceived rating informativeness by describing them as average ratings based on few or many consumer reviews. When the small-scale rating was described as based on more reviews, the scale effect was reversed.

Conclusion

The finding that product evaluations are more strongly influenced by large scale ratings than small scale ratings is intriguing in light of the recent decisions, by prominent review websites, to change the rating scales they use to report ratings. The classic restaurant guide Zagat abandoned the 30-point scale in favor of the 5-star scale. Similarly, Trustpilot.com, which provides its 'TrustScore' to online businesses, moved from a 10-point scale to a 5-star scale. Both changes consist in abandoning a larger scale for a smaller scale. If consumers are subject to the scale effect, these changes have potentially made these websites less influential.

We conjecture that the scale effect could affect evaluations in other domains that involve the evaluation of options based on the aggregation of multiple pieces of numerical information expressed on different scales such as multi-issue negotiations, recruiting decisions or the selection of providers.

Seeking Security through Liquidity in an Era of Precarity: An Ethnography of Digital Nomadism

Aleksandrina Atanasova, University of Birmingham, UK
Giana M. Eckhardt, King's College London, UK
Katharina C. Husemann, King's College London, UK

EXTENDED ABSTRACT

I imagine 90% of those digital nomads barely make enough to get by. But then again, neither do I, and I have a stable job and an apartment, and all the things society tells you must have. And with those things come expenses. A f***load of them. The last time I had money to spend on a nice vacation or anything really? I don't even remember when that was. And I don't see it changing anytime soon. Maybe what has been romanticized too much for too long is the idea of settling down. Because this idea of a partner, kids, house, a kiss goodbye and a smile before you leave for work does not exist either. At least not for most people. 90% of them also wish they had a different life. Honestly, if I am going to struggle, I'd rather do it in the sun. (Flipflop Poet, YouTube, 2019)

The late modern experience is one of constant change, erosion of stabilities, and disappearance of solid structures and their reliabilities (Bauman 2000; Beck 1992; Giddens 199; Kesselring 2008). Economic uncertainty and professional precarity, alongside environmental decline and global health pandemics, are defining the contemporary moment (Bardhi and Eckhardt 2017; Bauman 2007; Campbell et al. 2020). Life trajectories which for prior generations might have been considered largely solid, predictable and stable (e.g., lifelong career; guaranteed retirement; owned home) are now increasingly uncertain, as the opening quote illustrates. How consumers manage such threats inherent to liquid modernity (Bauman 2000) has been identified as an increasingly important research domain (Campbell et al. 2020). In this study we therefore ask, how do consumers find security and gain a sense of control in precarity?

Prior research suggests that consumers build a sense of security through material possessions and solid consumption such as accumulating objects, consuming familiar goods and products, or achieving solid ideals such as having a family or owning a home (Bardhi and Eckhardt 2017; Weinberger et al. 2017). For many, solid consumption, however, is increasingly becoming a luxury and a resource-heavy indulgence that is out of reach (Bardhi and Eckhardt 2017). For others, solidity can also be a liability (Bardhi and Eckhardt 2017), as modern living gives rise to constellations of risk and uncertainty that demand flexibility and mobility to manage them (Kesselring 2018). Concurrently, it has been shown that, for some consumers, the desire for ownership is waning (Lamberton and Goldsmith 2020), giving way to preference for liquid consumption which promotes flexibility and lightness in lieu of attachment and permanence (Bardhi and Eckhardt 2017). Consumer research, however, has yet to examine how consumer manage to establish security in the long run without ownership, possessions, or safety nets (Bardhi and Eckhardt 2017, 593) or live with enduring insecurity (Campbell et al. 2020).

We explore this gap via a multi-sited ethnography and netnography of digital nomadism – a global lifestyle movement where individuals dispose of most of their possessions and, enabled by widespread Internet access and ease of mobility in a globalized world, serially relocate, often between inexpensive locations, while working remotely (Mancinelli 2020). In contrast to other migrants (e.g., refugees), the digital nomadic way of life inheres lifestyle choices where migration is an escapist and reflexive self-realization project in search of the "good life" (Benson and O'Reilly 2009). This "good life" is often described as the opposite of the insecurity of contemporary (Western) lifestyles; the motivation is to avoid futures foreseen as riddled with economic uncertainty, debt, dead-end jobs or a lonely retirement (O'Reilly and Benson 2009, 4). Our analysis draws on 30 in-depth interviews with digital nomads representing 14 nationalities and various socio-economic levels, although most are privileged in terms of having passports which enable them to live this lifestyle, as well as field notes, photographs and netnographic data.

We find that in an increasingly precarious contemporary context, instead of seeking stability through solidity (possessions, material accumulations, permanence), some consumers paradoxically choose to lean into liquidity as a means to transform and re-imagine their uncertain lived reality and to find security and control. We suggest that when solidity is out of reach or is undesirable, consumers attain a sense of security through lifestyle liquification – a term we introduce to denote a transition in everyday living from prioritization of ownership and rootedness to lightness and detachment. We outline a three-phase process of movement along the solid-liquid continuum (Bardhi and Eckhardt 2017) toward lifestyle liquification as a means to emancipatory construction of control and a sense of security: 1. Relinquishing solidity subsequent to disillusionment with solid ideals and aims; 2. Leaning into liquidity via shifting consumption logics and undertaking reflexive reprogramming of the self; and 3. Legitimizing lifestyle liquification as an alternative pathway to security via marketization and evangelization of liquid living. Each of these phases represents a stage of gradual progression on a continuum from solid to liquid lifestyle orientation, though different consumers may occupy various positions along this continuum at various times.

Our findings challenge established views that security inheres in solid consumption and suggest that for some consumers, solidity can be an unattainable ideal and a source of hardship carrying inherent risks and liabilities. We make several contributions. First, we bring into focus lifestyle liquification as an alternative path to security in times of uncertainty (Campbell et al. 2020), and we show that for many consumers who are increasingly disillusioned with normative life trajectories, idealized solid future goals are no longer aspirational or attainable sources of stability (cf. Weinberger et al. 2017). Second, we extend Bardhi and Eckhardt (2017) by illuminating how and why consumers may choose to move along the solid-liquid continuum in search of different types of utility. Third, we offer a process perspective on consumer lifestyle transformations and expand our understanding on how consumers undertake fresh starts (Price et al. 2018) by materializing pursuits of a better life through liquidity in the face of precarity and uncertainty. Overall, we open new perspectives on how consumers navigate their life projects and draw on different logics of consumption to attain security.

The Impact of Product Anthropomorphism on Price-Quality Judgments: The Mediating Role of Communal Norm Salience

Amogh Kumbargeri, Indian Institute of Management Ahmedabad, India
Arvind Sahay, Indian Institute of Management Ahmedabad, India
Sanjeev Tripathi, Indian Institute of Management, Indore, India

EXTENDED ABSTRACT

Consumers frequently rely on price information to form quality judgment (Kardes et al., 2004). In this research, we pose the question, does product anthropomorphism influence the extent to which consumers use price information to judge quality? Anthropomorphism involves attributing human-like qualities to non-human entities (Epley et al., 2007). Prior research shows that consumers perceive anthropomorphized brands or products as social entities and frequently apply social rules in their interaction with such entities (H. Y. Kim & Mcgill, 2018; S. Kim & McGill, 2011). Relatedly, research in social psychology finds that all social interactions involve some elements of a communal relationship (Mills & Clark, 1982; Clark & Mills, 1993). Taken together, we argue that when consumers interact with an anthropomorphized product, they experience a higher salience of communal relationship norms as compared to when they interact with a non-anthropomorphic product (Aggarwal, 2004; Aggarwal & Law, 2005; Aggarwal & Zhang, 2006).

The key and defining difference between communal and exchange relationship norms is the expectation of *quid pro quo* (Clark & Mills, 1993). In a communal relationship, benefits are provided to the relationship partner based on the partner's needs and without any expectation of a comparable return. On the other hand, in an exchange relationship, benefits are provided strictly with an expectation of a comparable return (Aggarwal, 2004; Aggarwal & Law, 2005). Therefore, we propose that when consumers evaluate anthropomorphic products, they do not expect a strict equivalence between the price and quality of the product. We argue that such an expectation of non-equivalence between price and quality stems from the salience of communal norms of not expecting a comparable return (quality) for the benefit provided (price). Integrating the above arguments and the cited literature, we predict,

Hypothesis 1: *Consumers are less likely to make price-quality judgments for anthropomorphic products as compared to non-anthropomorphic products*

Hypothesis 2: *The salience of communal relationship norms will mediate the effect of anthropomorphism on price-quality judgments*

The research in cultural psychology has refined the broad individualist vs. collectivist classification into two kinds of orientations viz., horizontal (emphasizing equality) and vertical (accepting hierarchy) (Singelis et al. 1995). Specifically, vertical collectivists are mindful of hierarchy in their social interactions as the norms governing such interactions are frequently linked to their place in the social hierarchy (Triandis, 1995). As anthropomorphic products are treated as social entities, we argue that vertical collectivists, driven by their norms of social hierarchy, use price to organize anthropomorphic products hierarchically. Subsequently, for quality evaluation of anthropomorphic products, vertical collectivists are likely to use the same hierarchical order determined based on price. Conversely, such a hierarchical ordering based on price is not applicable for non-anthropomorphic products as they are not perceived as social entities. Stated formally,

Hypothesis 3: *Vertical collectivism reverses the proposed effect of anthropomorphism on price-quality judgments such that anthropomorphism enhances the price-quality judgments for vertical collectivists, but no such increase is seen for horizontal collectivists.*

Empirical Package

Study 1

In Study 1 (N = 119 US adults recruited from Prolific, M_{age} = 30.1 years, SD_{age} = 3.05, 58% female), we tested the focal effect using a two-condition (Anthropomorphism: present vs. control) between-subjects design such that in the anthropomorphism (vs. control) condition, participants saw four anthropomorphic (vs. non-anthropomorphic) products priced low to high. The price-quality judgment was found to be significantly lower in the anthropomorphic condition as compared to that in the non-anthropomorphism condition (M_{anthro} = 6.53, SD = 1.41; $M_{non-anthro}$ = 7.07, SD = 1.47; $F(1,117)$ = 4.13, p = .044, d = .37; H1).

Study 2

For Study 2 (N = 120 US adults recruited from Prolific, M_{age} = 30.7 years, SD_{age} = 3.26, 50% female), we followed a design similar to study 1, and in addition, we measured the salience of communal relationship norms in the context of interaction with the products using a seven-item scale adopted from Aggarwal (2004). Findings revealed that anthropomorphism reduced the extent of price-quality judgments (M_{anthro} = 6.52, SD = 1.79; $M_{non-anthro}$ = 7.14, SD = 1.26; F (1, 118) = 4.82, p = .030, d = .40). Mediation analyses (Hayes 2017, Model 4, 5,000 bootstraps) revealed that the salience of communal norms significantly mediated (indirect effect = .19, SE = .102, 95% CI [.02, .42]) the influence of anthropomorphism on the comparative quality evaluation (H2).

Study 3

Study 3 (N = 208 US adults recruited from Prolific, M_{age} = 30.5 years, SD_{age} = 3.28, 51.4% female), tested hypothesized reversal effect for vertical collectivist consumers as compared to horizontal collectivist consumers (H3). We used a 2 (product-type: anthropomorphic vs. non-anthropomorphic) x 2 (cultural orientation: vertical collectivist vs. horizontal collectivist) between-subjects design for this study. Results revealed that for the vertical collectivists, the price-quality judgments reversed such that for the anthropomorphic product-type, it was significantly higher than for the non-anthropomorphic product-type (M_{VC_anthro} = 5.12 vs. $M_{VC\_non-anthro}$ = 4.57, p = .037).

Study 4

The objective of Study 4 (N = 153 US adults recruited from Prolific, M_{age} = 31.5 years, SD_{age} = 4.01, 47.1% female) was to investigate the behavioral consequence of the influence of anthropomorphism on price-quality judgments in an incentive-compatible choice task involving monetary expenditure. The study used two conditions (product-type: anthropomorphic vs. non-anthropomorphic) between-subjects design. The results revealed that only 44.4% of participants

opted for the expensive variant for the anthropomorphic product-type, whereas 63.6% of the counterparts in the non-anthropomorphic condition did so (χ^2 (1) = 4.042, p = .044).

Contribution and Implications

Our findings have several important theoretical implications. First, we extend the price-quality judgment literature by showing that anthropomorphism moderates the price-quality inference. Next, we bridge the anthropomorphism and the relationship norms literature in identifying communal norm salience as the underlying process. Further, we significantly contribute to the cross-cultural consumer psychology literature in demonstrating how the consumers' cultural orientation moderates the influence of anthropomorphism on price-quality inference. While doing so, we also add to the body of work that studies the impact of anthropomorphism on consumer judgment and acts as a bridge between anthropomorphism, pricing, and cross-cultural consumer psychology literature.

Too Ambiguous for an Algorithm? Anthropomorphic Design of an Algorithm-Based Recommendation Agent Increases the Recommendation Acceptance

Amogh Kumbargeri, Indian Institute of Management Ahmedabad, India
Arvind Sahay, Indian Institute of Management Ahmedabad, India
Sanjeev Tripathi, Indian Institute of Management, Indore, India

EXTENDED ABSTRACT

In the backdrop of burgeoning e-commerce and enabled by the rapid advances in artificial intelligence (AI) technologies, a host of product recommendation agents are now helping consumers search and choose products in the digital marketplace. In this research, we investigate if anthropomorphism enhances the consumers' likelihood of accepting the product recommendation from the algorithm-based recommendation agents.

Anthropomorphism involves imbuing non-human entities with human traits and abilities such as emotions, agency, etc. (Aggarwal & McGill, 2007). Prior research finds that consumers apply their naïve beliefs about human nature while understanding and predicting the behavior of these anthropomorphized entities (Wen Wan, Chen, & Jin 2017; Kwak, Puzakova, & Rocereto 2015). Extending this line of thought, we propose that consumers attribute the uniquely human ability of cognitive flexibility and the consequent ability of ambiguity processing to recommendation agents when they are anthropomorphized compared to when they are not. We define ambiguity processing as the ability to process ambiguous information to achieve desirable outcomes. As cognitive flexibility entails the ability to adapt cognitive processing in an unexpected condition, we argue that cognitive flexibility enables the effective processing of ambiguous information to achieve desired outcomes. In contrast, people characterize inanimate entities such as computers or machines as rigid and inflexible (Loughnan & Haslam, 2007; Montagu & Watson, 1983). Stated formally,

> *Hypothesis 1:* *Anthropomorphic design enhances the perceived ambiguity processing ability of the recommendation agents as compared to the non-anthropomorphic design*

Research exploring product recommendation acceptance behavior documents that consumers believe that an *apriori* knowledge of their requirements, attitudes, and preferences is essential for providing effective product recommendations (Duhan et al., 1997). In contrast, prior research examining perceptions about algorithms finds that consumers believe algorithms do not have the required knowledge about consumers' requirements, attitudes, and preferences (Longoni et al., 2019). In light of the above discrepancy between the knowledge required and the knowledge possessed, we posit that consumers will perceive providing a product recommendation as a task involving ambiguity for the recommendation agents and therefore expect the perceptions of ambiguity processing ability to enhance the perceived recommendation quality and consequently the acceptance of product recommendations provided by algorithm-based recommendation agents. Formally,

> *Hypothesis 2:* *Anthropomorphic design induced perceptions of ambiguity processing ability, increases perceived recommendation quality, which, in turn, increases the recommendation acceptance by consumers as compared to the non-anthropomorphic design of the agent.*

Empirical Package

Study 1

The objective of Study 1 (N = 201 US adults recruited from Prolific, M_{age} 30.4 years, SD = 3.3, 45.8% females) was to provide empirical support for the predicted effect of anthropomorphism on recommendation acceptance. The study employed a single factor (design: anthropomorphic vs. non-anthropomorphic) between-subject design. Post-exposure to the design manipulation, participants read a hypothetical scenario about seeking a recommendation for a restaurant from the focal recommendation agent. Results revealed that the participants in the anthropomorphic condition were significantly more likely to choose the restaurant suggested by the recommendation agent in the anthropomorphic condition (M_{anthro} = 5.38, SD = 1.10) as compared to those in the non-anthropomorphic condition ($M_{non-anthro}$ = 5.01, SD = 1.25, F (1, 199) = 4.641, p = .032).

Study 2

The goals of Study 2 (N = 160 US adults recruited from Prolific, M_{age} = 30.03 years, SD = 1.91, 53.8% females). This study aimed to test for the proposed mediation and rule out two important potential alternative accounts viz., the lack of focus on uniqueness and the inability to understand the process of recommendation. This study employed a single factor (agent-design: anthropomorphic vs. non-anthropomorphic) between-subjects design. Results showed that participants in the anthropomorphic condition (M_{anthro} = 4.45, SD = 1.09) rated the ambiguity processing ability of the recommendation agent to be significantly higher than the those in the non-anthropomorphic condition ($M_{non-anthro}$ = 4.04, SD = 1.04, F (1, 158) = 5.87, p = .017). Mediation analyses (Hayes 2017; Model 4, 5000 bootstraps) documented a significant indirect effect of anthropomorphic design via the ambiguity processing ability on recommendation acceptance (B = .16, SE = .07, 95% CI [.02, .33]). But the mediation by uniqueness focus and understanding recommendation process was found to be non-significant. The findings of this study provided evidence for the hypothesized effect of anthropomorphism on ambiguity processing ability (H1) and the mediation by ambiguity processing ability while ruling out the two alternative accounts.

Study 3

Study 3 (N = 139 US adults recruited from Prolific, M_{age} = 30.1 years, SD = 3.03, 44.6% females) aimed to provide empirical evidence for the complete underlying process by testing for the serial mediation by ambiguity processing ability and perceived recommendation quality. The study employed a two-condition between-subject design (agent-design: anthropomorphic vs. non-anthropomorphic. Similar to the findings of previous studies, participants in the anthropomorphic condition (M_{anthro} = 5.14, SD = 1.11) reported a significantly higher likelihood to accept the recommendation as compared to those in the non-anthropomorphic condition ($M_{non-anthro}$ = 4.72, SD = 1.16, F (1, 137) = 4.62, p = .033). Serial mediation analyses (Hayes 2017; Model 6, 5000 bootstraps) revealed a significant indirect effect of anthropomorphic design via the ambiguity processing ability and the perceived recommendation quality on recommendation acceptance (B = .18, SE = .09, 95% CI [.004, .36]). The findings of Study 3 provided empirical support for the complete mediation model (H2).

Contribution and Implications

Our findings make two fundamental contributions. First, we add directly to the research in anthropomorphism that explores the application of naïve theories about humans to anthropomorphized entities (Wen Wan, Chen, & Jin, 2017; Kwak, Puzakova, & Rocereto, 2015; Yang, Aggarwal, & McGill, 2019) by documenting ambiguity processing ability as a novel downstream consequence of anthropomorphic design. Second, we also contribute to the research on algorithm aversion (Castelo, Bos, & Lehmann, 2018; Longoni et al., 2019; Yeomans et al., 2019; Dietvorst et al., 2015; Diab et al., 2011; Onkal et al., 2009) by identifying ambiguity processing ability as one of the causes that might underlie the larger phenomenon of algorithm aversion.

If Artificial Intelligence Kills Consumers? Decoding the Hot-Cold Organizational Dilemmas from Multivariate Neural Patterns

Jin Ho Yun, Sungkyunkwan University (SKKU), Korea, Republic of

EXTENDED ABSTRACT

Artificial intelligence (AI) has proven to offer tremendous benefits to many consumers and a nation at large. However, what if AI could kill consumers? For example, self-driving vehicles or surgery robots can kill consumers. With the growing AI applications in a gamut of business organizations, this question points out important yet philosophical aspects. As the capability of AI has pervaded into diverse business sectors, the future of AI is disputed having not only its moral concerns but also the possibilities of causing consumer fatalities. The challenge that our society is facing seems rather more philosophical than technical (Greene 2016). Whereas the need for embedding moral codes into algorithms has been much highlighted (Gill 2020; Martin 2019), there remains some philosophical challenges from the organizational leader's perspective. This research addresses this, which specifically pertains to leaders' dilemmas on whether to release such AI-embedded technologies for the sake of receiving the investment offer which can prevent firms' bankruptcy.

In many business cases, leaders often face organizational dilemmas that one has to transgress their moral values to acquire financial advantages in favor of the company. This trade-off consists of weighing certain motives to sustain moral principles against the opportunity of receiving the investment offer. An example includes that the startup leader might devote to pay respect for human lives, despite the fact the organization will face bankruptcy if it cannot receive the investment, while others might shift their focus on receiving the investment. At startup organizations, leaders often face such dilemmas, whereby deciding to release the AI technology (which can kill consumers) can be the only way to prevent bankruptcy and receive the investment. Yet, until now the underlying neural mechanisms of these individual differences in moral decision-making have remained poorly understudied.

Why do organizational leaders vary their immoral actions depending on the outcome of decisions (i.e. releasing AI technology which can kill consumers or cause their discomforts)? Herein, we developed the novel Hot-Cold Organizational Dilemmas, in which each participant evaluated a total of forty decisions on whether to accept the investment offer at the cost of causing consumers' deaths (Hot Dilemmas: HD) or insignificant discomforts (Cold Dilemmas: CD). Participants who acted as organizational leaders at startups, their brains were scanned with functional magnetic resonance imaging (fMRI) to identify multivariate neural patterns that dissociate the psychological processes of HD from CD.

In the MRI scanner, twenty-four participants were presented with forty HD-CD scenarios in random order, with each scenario varied regarding types of AI technologies ranging from self-driving cars, drones, medical AI, judge AI, and robots. In each scenario, they had to decide whether to release new technology which can kill consumers (HD) or simply cause algorithmic errors (CD) (*decision phase*). They then had to indicate whether they will accept any investment amount from the following six options: [None] [$1-2] [$2.1-4] [$4.1-6] [$6.1-8] [$8.1-10] million (*response phase*). They were instructed that one trial would be randomly selected, from the range of $0 to $10, making the task incentive-compatible. Submitting a price means that the participant is willing to accept the investment at cost of killing consumers or causing discomforts. This enabled us with a classification for deontology (do not accept the investment offer) and utilitarianism (accept the offer).

Primary data analyses included the behavioral and multivariate neural pattern results. On average, participants reported significantly higher numbers of counts of making deontological judgments (not accepting any investment offer) in HD (M = 12.83) than in CD (M = 3.58, $F(1, 23)$ = 49.378, p = .000, η^2 = .682). However, this significant difference varied substantially between participants. To further explore any possible scenario effect, the 2 (HD vs. CD) × 20 scenarios (or trials) repeated-measures ANOVA (analysis of variance) was also performed. There was no significant main effect of scenario types (p > .05) as well as the interaction effect between the two main effects. Moreover, the participants took significantly shorter response times in making judgments for the HD (M = 1.98) than they did for the CD (M = 2.18, $F(1, 23)$ = 10.675, p = .003, η^2 = .317).

Individual differences in proportional differences between dilemma types with the classification accuracy were observed by employing the support vector classifiers. First, during the *response phase*, we found a significant positive correlation between the classification accuracy and the proportional differences in deontology (HD-CD) in the ToM (r = .449, p = .028) and cognitive-control masks (r = .502, p = .013). We further found a significant positive correlation between the classification accuracy and the proportional differences in deontology in the left temporal pole (r = .482, p = .017) as well as in the left TPJ (r = .427, p = .037). Second, during the *decision phase*, we found a significant positive correlation between the classification accuracy and the proportional differences in deontology in the left inferior frontal gyrus (r = .452, p = .027) as well as in the left temporoparietal junction (TPJ) (r = .426, p = .038).

Our findings suggest that multivariate patterns in specific regions (i.e., temporal pole, TPJ, and IFG) within the both ToM and cognitive-control mask differentiate between proportional differences in deontology (HD-CD). The Will-Grace hypotheses (Abe & Greene 2014; Greene & Paxton 2009) further support these classification findings: ToM and cognitive control are both needed to make deontological judgments for HD and to make utilitarian judgments for HD. Consonant with Speer et al.'s (2020) propositions, the current results help to reconcile the Will-Grace conflict as cognitive control is not only required to be utilitarian in CD but also needed to be deontological in HD. We thus support that both ToM and cognitive control networks play different roles depending on dilemma types and individual variability.

Collectively, these insights can pave the effective way to develop a transparent and generalizable AI framework for organizational leaders, engineers, policymakers, and consumer researchers. This also has implications for AI-related consumption domains where potential consumers (adopters) need to be aware of *killing AIs* and select morally acceptable AI technologies.

Be Precise or Round it up: How Roundness of Goals Influence Goal Attractiveness and Achievability Perceptions

Sakshi Aggarwal, Indian Institute of Management, Indore, India
Sanjeev Tripathi, Indian Institute of Management, Indore, India
Sudipta Mandal, Indian Institute of Management, Indore, India

EXTENDED ABSTRACT

John (vs. Smith) is *489 (vs. 500)* loyalty points away from achieving the goal.

Intuition suggests that John has an easier goal than Smith. Literature on left digit salience (Thomas and Morwitz 2005; Manning and Sprott 2009) suggest additional reasons to support this intuition. This is consistent with the numerical cognition literature. Since, round (vs. non-round) numbers are typically used for large (vs. small) magnitudes (Thomas *et al.*2010), individuals imbibe a *"precise=small magnitude"* heuristic (Precision effect) (Thomas *et al.* 2010; Yan and Pena-Marin 2017). They judge non-round prices to be *smaller* than round prices of similar magnitude (Thomas, Simon and Kadiyali 2010; Thomas, Morwitz and Pyone 2010).

In the context of our example, we argue that Smith (needs 500 points), would find the goal to be more achievable, than John (needs 489 points).

Research on the fluency of round (vs. non-round) numbers shows that since round numbers are more frequently used (Rosch 1975; Coupland, 2011; Jansen & Pollmann, 2001), round (vs. non-round) numbers are more fluently processed (Kettle and Ha¨ubl 2010; King and Janiszewski 2011). Song and Schwarz (2008) have shown that cognitive disfluency of a task may be misattributed to difficulty in its implementation.

Hypothesis 1: *Non-round (vs. round) goals are perceived to be more (vs. less) difficult to achieve.*

Hypothesis 2: *Non-round (vs. round) goals lead to disfluent (vs. fluent) processing resulting in goals being inferred as more (vs. less) difficult to achieve.*

When individuals think about the effort required to do a single unit of the task, the effect of processing fluency of round goals diminishes, attenuating the effect of non-round (vs. round) goal frames.

Hypothesis 3: *Estimation of effort required per unit task moderates the relationship between the roundness of goal and goal progress perception such that when individuals estimate the amount of effort they are required to invest in doing a single unit of the task, the difference of perceived difficulty between round goals and non-round goals attenuates.*

When individuals focus on the process of attaining the goal (e.g., trying their best), the effect of non-round (vs. round) goal frames attenuate.

Hypothesis 4: *Focus on achieving the end goal (vs. intermediate process of attaining the goal)moderates the relationship between the roundness of goal and goal progress perception such that when the focus is on achieving the end goal, non-round (vs. round) goals will be perceived to be more difficult to achieve. In contrast, the difference between the perceived difficulty of non-round and round goals diminishes when the focus is on the intermediate process of attaining the goal.*

Nine studies validated our hypotheses, all of which were supported. Study 1(A&B) tests H1 in different contexts using a one-way between-subjects design with goal framing (round/non-round goal) as the independent variable. Study 1B included both odd-non-round and even-non-round goal conditions to demonstrate that round goals are considered more achievable than both odd-non-round and even-non-round goals. Study 2 tests H1 in a loyalty points programme context using a one-way between-subjects design. Study3 (A&B) demonstrates that the roundness of the goal influences goal perceptions even when people have already started working towards the goal – demonstrated in endowed progress and intermediate review scenarios. Study 4(A&B) tests H2 in non-marketing and marketing contexts, by showing that fluency of round numbers mediates the effect of roundness of goals on goal attractiveness and achievability perceptions. Study5 tests H3 using a 2 (Goal: Round vs. Non-round) x 2 (Effort per unit estimation: Yes vs. No) between-subjects design by showing that when people are not required to think about the effort it would take to do a single unit of the task, round goals are perceived less effortful than non-round goals but when people are asked to estimate the amount of effort required to do a single unit of the task, the difference between the perceived effortfulness of round and non-round goals attenuates. Study 6 tests H4 using a 2 (Goal: Round vs. Non-round) x 2 (Focus: End goal vs. Process) between-subjects design by showing that when people focus on the end goals, non-round goals are perceived more difficult than round goals but when people focus on the process to achieve the goal and thus when they do so, the difference between the perceived difficulty of round and non-round goals attenuates.

Conclusion

This research contributes to the extant literature on goal progress in multiple ways. The roundness of goal is identified as a novel factor influencing consumers' goal perceptions. Boundary conditions under which the roundness of goal ceases to influence the goal perceptions are demonstrated: estimation of the effort required to do single unit of the task and focusing on the process of attaining the goal. The roundness of the goal influences goal perceptions even when people have already started working towards the goal–demonstrated in endowed progress and intermediate review scenarios. This research may be helpful in setting motivating goals and effective loyalty programs.

Fluency versus Arousal: The Interplay of Two Core Characteristics of Marketing Stimuli

Laura K. M. Graf, Goethe University Frankfurt, Germany
Jan R. Landwehr, Goethe University Frankfurt, Germany

EXTENDED ABSTRACT

Designing marketing stimuli in a way that consumers can process them fluently is a powerful marketing strategy (e.g., Landwehr, Labroo, and Herrmann 2011; Landwehr, Wentzel, and Herrmann 2013; Lee and Labroo 2004; Schwarz et al. 2021). Importantly, however, fluency effects do not occur in a vacuum (e.g., Graf and Landwehr 2015, 2017). For a variety of reasons—regardless of whether due to marketing interventions or contextual factors—consumers may experience different levels of incidental arousal when processing marketing stimuli (e.g., Gorn, Pham, and Sin 2001; Kim, Park, and Schwarz 2010). In the present research, we investigate the hypothesis that heightened incidental arousal works as an attenuator of fluency-based effects on judgments because processing fluency and arousal are two conflicting experiential states. Specifically, we assume that because an elevated incidental arousal level is a signal of effort (Gellatly and Meyer 1982; Gendolla 1998), it is incompatible with high processing fluency (i.e., low effort; Alter and Oppenheimer 2009) and thus attenuates fluency effects. Arousal may inhibit fluency effects at two processual stages depending on how, respectively, when, people integrate their incidental arousal level as well as their fluency experience into their reaction toward the stimulus. In particular, arousal may either reduce people's fluency experience (i.e., fluency attenuation) or it may reduce the impact of the fluency experience on the subsequent judgment (i.e., response attenuation). Four pre-registered experimental studies on different fluency phenomena test the key proposition that arousal attenuates fluency effects and examine the stage in the process model where the moderation occurs (i.e., fluency attenuation vs. response attenuation).

Study 1 examines whether the mediating process via subjective fluency that produces the effect of color contrast of health claims (i.e., stimulus fluency) on the perceived truth of these claims (Graf, Mayer, and Landwehr 2018; Reber and Schwarz 1999) is moderated by arousal. Thus, it uses a 2 (visual color contrast: low vs. high) by 2 (arousal: low vs. high) mixed experimental design where color contrast of 16 health claims is manipulated within-subjects and arousal is manipulated between-subjects. In this study, as well as in Studies 2, 3A, and 3B, we manipulate arousal by showing participants a slideshow of 30 pictures either high or low in arousal (pictures are taken from the OASIS database; Kurdi, Lozano, and Banaji 2017). To test our conceptual model, we conduct a moderated mediation analysis according to Muller, Judd, and Yzerbyt (2005), which shows that subjective fluency mediates the effect of visual color contrast on the perceived truth of health claims and that arousal moderates this mediation such that people draw less on their fluency experience when making truth judgments under conditions of high arousal (i.e., response attenuation).

Study 2 uses a 2 (chair design exposure: 0 vs. 8) by 2 (arousal: low vs. high) mixed experimental design where exposure to 10 different chair designs is manipulated within-subjects and arousal is manipulated between-subjects. The results of a moderated mediation analysis show that arousal moderates the mediating process via fluency that underlies the repeated exposure effect (Landwehr, Golla, and Reber 2017). Specifically, arousal attenuates the influence of the fluency experience on liking (i.e., response attenuation).

Studies 3A and 3B investigate whether the mediating mechanism via processing fluency that intervenes between the manipulation of stock name pronounceability and the perceived safety of investing in the stocks (Alter and Oppenheimer 2006; Song and Schwarz 2009) depends on the level of incidental arousal. Study 3A applies a 2 (stock name pronounceability: low vs. high) by 2 (arousal: low vs. high) mixed experimental design where pronounceability of six stock names is manipulated within-subjects and arousal is manipulated between-subjects. The results of the moderated mediation analysis show that even though subjective fluency mediates the effect of pronounceability on perceived safety, the mediation is not moderated by arousal. Notably, these findings may be the result of the specific stimuli we used. Specifically, as proposed by Schwarz et al. (2021), the fluency effect of pronounceability manipulations on safety/risk judgments is sensitive to the employed stimuli. Indeed, stimulus level-based analyses show that for two out of the six stocks we used (Flinks and Beaulieaux) the pronounceability (fluency) manipulations of the stocks are not associated with their predicted safety/risk scores. Accordingly, we repeated Study 3A and replaced the two inappropriate stimuli for Study 3B. Using this adapted procedure, we find that, as in studies 1 and 2, the positive mediation via subjective fluency is reduced when people are in a state of elevated arousal, and that the interaction between fluency and arousal occurs in the latter stage of the mediating process such that arousal attenuates the influence of subjective fluency on perceived safety (i.e., response attenuation).

In sum, we find across three different fluency phenomena that the mechanism that translates manipulations of ease or difficulty via processing fluency into positive effects on judgments is reduced when consumers have been previously put into a state of high, as opposed to low, incidental arousal. More specifically, we find that arousal attenuates the partial effect of fluency on the resulting judgment (i.e., response attenuation). Our results provide important theoretical implications for the literature on arousal by showing that, in the context of fluency effects, arousal does not work as an amplifier but as an attenuator of the fluency-based evaluative response. With respect to processing fluency, our research introduces a novel boundary condition of fluency effects and extends the feelings-as-information framework (Schwarz 2012) by showing that people not only misread their fluency experience as being part of their reaction toward the stimulus but also their pre-existing incidental arousal level. From a managerial perspective, the current research suggests that in order to leverage the positive effects of fluent marketing stimuli optimally, they should be accompanied by marketing stimuli and/or contextual settings that are low in arousal.

Exploring the Role Grandfathers Play in the Consumer Socialisation of Grandchildren

Ben Kerrane, Manchester Metropolitan University, UK
Katy Kerrane, University of Liverpool Management School, UK
Shona Bettany, Huddersfield Business School, University of Huddersfield, UK

EXTENDED ABSTRACT

This paper investigates the role grandfathers play in the consumer socialisation of children. Studies of consumer socialisation, exploring how children acquire the skills needed to function in the marketplace (Ward, 1974), more usually concentrate on parents' voices and socialisation efforts within the family setting (Kerrane and Hogg, 2013), largely dependent on the adoption of one of a variety of *family communication patterns* (Carlson et al., 1994) and *parenting styles* (Carlson and Grossbart, 1988). Together, these concepts affect the quality of children's socialisation experiences within the family environ (Bao et al., 2007). However, given changes in family life (e.g. the rise of dual-income families, women's greater participation in the labour force, rising divorce rates), grandparents play increasingly visible roles in raising contemporary children. Within the United Kingdom, the site of our study, grandparents spend on average 8 hours per week looking after their grandchildren (Buchanan and Rotkirch, 2018) – findings which are similar across Europe (Di Gessa et al., 2016) and other countries, such as the US (Laughlin, 2013) and China (Ban et al., 2017).

We choose to explore grandfatherhood as: (1) study of the consumption behaviours of individuals heading towards the latter stages of the lifecourse is surprisingly limited (Barnhart and Penaloza, 2013); (2) there is a paucity of research that explicitly investigates grand*father*hood (Mann, 2007); and (3) because the transition to grandfatherhood offers men opportunity to contest and challenge hegemonic masculinity and traditional breadwinner norms (Sorenson and Cooper, 2010) in favour of a more supportive and involved style of intensive grandparenting.

Seventeen grandfathers from the UK were invited to participate in an in-depth interview covering their grandfather experiences. Participants were aged between 58 and 76 years old, having grandchildren aged between 5-17 years. For men of this age group, work had been central to their identity – and they were likely excluded from occupations surrounding caring work (Sorensen and Cooper, 2010). Interviews began by asking grandfathers to discuss their life, both past and present, including key life events/milestones and daily activities/routines (Godefroit-Winkel et al., 2019), before discussing experiences of becoming and being a grandfather. Participants were asked about the everyday nature of their relationship with their grandchildren, how they socialized with their grandchildren, if/how these relationships shaped their consumption, and how these relationships and practices affected their relationship with their adult children.

Our findings reveal reflexive attempts at intergenerational repair. The men made comparisons with their previous life course subjectivities, notably fathering. The grandfather role that the men wanted to perform was often held in sharp contrast to the "*classic breadwinner*" model of fatherhood that they had largely adopted with their own children. For many, this brought a desire for intergenerational repair (Tuffin, Rouch and Frewin, 2010) with the grandfathers highly reflexive of "*the many mistakes*" they felt they had made during their own children's upbringing (manifest by their reported "*absence*" during early childhood.) Consumer goods acted as important transitional objects (see Winnicott, 1953) that participants enrolled to help perform grandfatherhood. Items like sports balls, boardgames and bicycles took on special significance for the men, offering props to help structure grandfather/child time in a way they did not when their own children were young.

However, despite the hands-on grandfatherhood we report, hegemonic masculine values endured. For many of the grandfathers, particularly those who had retired, sport and outdoor activities emerged as particularly gendered pastimes that they were keen to pursue with their grandchildren. Competitive spirit, aggression and a "*take no prisoners*" mentality was imparted from grandfather to grandchild during 'doing' activities (with the weakness of an aging body concealed from children). Grandfathers were also found to dilute/contest parental socialization efforts (e.g. looking after their grandchildren "*on my terms*" in ways which parents felt jeopardized the safety of their child; or undermined parental intentions e.g. buying children items their parents would not/or items parents were encouraging their children to save for).

While we see shifts in hegemonic masculinity (away from breadwinner models of fatherhood in favor of more hands-on grandfatherhood), the legacy of hegemony permeates the grandfather/grandchild dyad in several ways. First, the objects the men used to facilitate their transition to grandfatherhood (e.g. the bike, the ball) are traditional, codified-masculine, goods (offering comfort and stability in a largely new world of care). Whereas these items remained unused by the men with their own children, ghostly objects in earlier family history, they were played with and used as tool to bond with grandchildren. Second, although intensive grandfatherhood was obvious, it was (again, in a highly masculine way) on the men's terms/following their rules – which has important consequences for consumer socialization. The men could support parental socialization efforts, but more usual was the contestation of parental work (subverting parents' best efforts, usually as consequence of the men thinking they knew what was best for their grandchildren/how to make their grandfather workload lighter). This highly gendered reading sheds greater light on existing familial consumer socialization research which largely focuses on parental socialization effort within the family. Such literature fails to both explore 'other' agents which likely play a key role in the lives of contemporary children/socialization itself, but also the ways in which the process of socialization can be disrupted or diluted by 'other' agents, simultaneously.

Effects of Influencer Endorsement of Instagram Ads on Brand Attitudes, WOM Intentions, and Purchase Intentions

Nhat Quang Le, Department of Marketing, BI Norwegian Business School, Norway
Magne Supphellen, Department of Strategy and Management, NHH Norwegian School of Economics, Norway

EXTENDED ABSTRACT

Many firms nowadays are relying on social media influencers to develop brand equity and enhance customers' purchase intentions. Existing research evidence shows that social media influencers can positively affect the behaviors of followers (e.g., Hughes, Swaminathan, & Brooks, 2019). However, our understanding about the role and impact of digital influencer endorsement is still very limited (Torres, Augusto, & Matos, 2019).

In this paper, we aim to contribute to the current literature in two ways. First, we present a novel experimental test of influencer endorsement of Instagram ads in a real setting, involving real influencers, ads, and followers. Marketers pay for ad exposure in the Instagram feed of famous Influencers. Sometimes, the influencers endorse these ads. The question addressed here is whether such endorsements increase the effect of Instagram ads. We focus on an industry where social media influencers are particularly important: the food industry (Demarest, 2020). Second, we examine whether consumer-influencer identification in this context moderates the effects of influencer endorsement. Previous research has shown that followers tend to accept messages from social media influencers who are perceived to be more similar to themselves (e.g., Balabanis & Chatzopoulou, 2019). Furthermore, we propose that the effects of this interaction on customers' attitudes and behavioral intentions occur through a not yet explored mediator: source credibility.

In Study 1, we recruited in total 132 participants (95.5% female, M_{age} = 25-34 years old) through the Instagram account of an influencer (a food blogger with more than 16,000 followers at the moment of data collection). The large ratio of female participants in our sample reflects the true distribution of gender in the population of total followers. The participants were randomly assigned to one of the two conditions: with vs. without influencer endorsement. The endorsement of the influencer was manipulated by adding a short, separate line: "Reklame | innlegg i samarbeid med [brand name]" in Norwegian, which means "Advertisement | in collaboration with [brand name]," before the main text of the advertisement. In both conditions, participants were exposed to identical text of the advertisement with the same picture of a new breakfast (and snack) food. To test our model, we ran a structural equation model (SEM) with the robust maximum likelihood (MLR) estimator using Mplus version 8.0 (Muthén & Muthén, 1998-2017). Our confirmatory factor analysis (CFA) and SEM model both yielded adequate global fit indices. Both convergence and discriminant validity are achieved. Our results show that compared to the non-endorsement condition, people exposed to influencer endorsement had higher scores of attitudes toward the ad ($M_{influencer}$ = 3.72, M_{firm} = 3.62, p = .09), attitudes toward the brand ($M_{influencer}$ = 3.57, M_{firm} = 3.49, p = .06), purchase intentions ($M_{influencer}$ = 3.16, M_{firm} = 3.01, p = .05), and WOM intentions ($M_{influencer}$ = 2.95, M_{firm} = 2.77, p = .05). Further, influencer endorsement had a positive effect on source credibility (b = .25, p = .04), while source credibility exerted positive effects on attitudes toward the ad (b = .39, p = .01), attitudes toward the brand (b = .30, p < .01), purchase intentions (b = .54, p < .01), and WOM intentions (b = .68, p < .01). The total indirect effects of influencer endorsement on consumers' attitudes and behavioral intentions through source credibility were all positive and (marginally) significant (indirect effect on attitudes toward the ad: b = .10, p = .09; on attitudes toward the brand: b = .08,

p = .06; on purchase intentions: b = .15, p = .05; on WOM intentions: b = .17, p = .05). Thus, we conclude that source credibility significantly mediates the effects of influencer endorsement on consumers' attitudes and behavioral intentions.

In Study 2, we recruited a total of 585 participants (99% female, M_{age} = 25-34 years old) through the Instagram of another influencer. This influencer is also a food blogger in Norway with approximately 113,000 followers (at the moment of data collection). Similarly, the participants were randomly assigned to one of the two conditions: with vs. without influencer endorsement. The manipulation of influencer endorsement was similar to that of Study 1. We added two questions to measure consumer-influencer identification. We used the latent moderated structural equations (LMS) method to test the interaction effect between influencer endorsement and consumer-influencer identification (Klein & Moosbrugger, 2000). Our results show that the interaction between influencer endorsement and consumer-influencer identification exerted a positive effect on source credibility (b = .20, p = .03) while the main, direct effect of influencer endorsement on source credibility is also positive and significant (b = .23, p < .01). Furthermore, the positive effect of influencer endorsement on source credibility was reinforced (b = .36, p < .01) when consumers' perceived identification with the influencer is high (i.e., 1 standard deviation (SD) above the mean). When their identification with the influencer is low (i.e., 1SD below the mean), the positive effect of influencer endorsement was reduced and became insignificant (b = .09, p = .26).

In summary, we find that influencer endorsement is indeed an effective way to enhance the effectiveness of advertisements in Instagram feeds. Specifically, the adoption of influencer endorsement would lead to more favorable attitudes toward the ad, the brand, and stronger intentions to purchase and engage in WOM activities. In addition, we also find that source credibility mediates these effects of influencer endorsement: consumers exposed to an ad with influencer endorsement consider the information source more credible than without such endorsement, and higher level of source credibility in turn leads to more positive consumers' attitudes and behavioral intentions. Finally, we prove that the effect of influencer endorsement on source credibility is stronger (weaker) when consumers' perceived identification with the influencer is high (low). Future research might extend our study by testing the model in other contexts such as the entertainment and video games or fashion and beauty industries.

DeepMind: Leveraging Deep Learning to Classify and Interpret Mind Perception in Smart Objects from Unstructured Text

Anouk Bergner, University of St. Gallen, Switzerland, Switzerland
Jochen Hartmann, University of Hamburg, Germany
Christian Hildebrand, University of St. Gallen, Switzerland, Switzerland

EXTENDED ABSTRACT

Perceiving a mind in others is paramount to navigating the world around us. A theory of mind, defined as the attribution and understanding of internal mental states in another entity, is the hallmark of our social cognitive skills, enabling everyday interactions and coordination with others (Goldstein and Winner 2012). The proliferation of AI-enabled smart objects that appear and "behave" increasingly more human-like raises fundamental questions about the role and impact of mind perception in the consumer technology landscape. Recent research on smart object relationships suggests that consumers may form different types of relationships with such objects (Hoffman and Novak 2018; Novak and Hoffman 2018). While some consumers perceive such objects merely as a medium to complete a task, others tend to attribute more human mental states to them, affecting downstream consumer experiences and behavior (Schweitzer et al. 2019; Waytz, Heafner, and Epley 2014; Yang, Aggarwal, and McGill 2020). However, there are limited means to identify the extent of such mind attributions and uncover the emerging formation of distinct consumer-object relationships.

While previous marketing research has successfully employed text analysis for a variety of applications, such as uncovering consumer sentiments (see Berger et al. 2020; Hartmann et al. 2019; Humphreys and Wang 2018 for reviews), no off-the-shelf dictionary (e.g., LIWC, Pennebaker et al. 2015) or alternative text classifier exists to classify the extent of mind perception. Furthermore, compared to traditional text classification tasks, identifying the extent of mind perception from unsolicited reviews is challenging due to the absence of a theory-based mapping of mind perception dimensions and text objects, as well as the subtlety of its signals.

Following recent calls for multi-method approaches and natural language processing (Berger et al. 2020; Schmitt et al. 2021), this research proposes a novel approach to theory development and methodology using unstructured, user-generated text, leveraging the power of deep contextual language models for automated text analysis. Based on a large-scale panel (N=2500, M_{age} = 35.3; 57.4% female) of smart speaker users, in Study 1 we fine-tune and train a RoBERTa language model (Liu et al. 2019). We demonstrate the accurate prediction of mind perception in customer reviews, benchmarking it against traditional text classification methods (random forest, LIWC dictionary). We call this model "DeepMind". Next, we leverage manifold methods to "white box" our DeepMind language model (Rai 2020) and provide a rich set of interpretable linguistic features signaling higher mind perception in customer reviews. Using a multi-method text interpretation approach that employs LDA topic modelling, Lasso regression, and individual term frequency comparisons, we find that high mind perception reviews are characterized by a stronger personification of the smart speaker as well as containing terms that are characteristic of a more communal relationship.

Study 2 aims at establishing ecological validity for our mind perception classifier, DeepMind, by applying it to a large set of unsolicited, smart speaker customer reviews (20k) scraped from a major online review site (amazon.com). To validate the linguistic features of mind perception we leverage LIME (Local Interpretable Model-agnostic Explanations), a recently developed algorithm designed to explain classification predictions by approximating them locally with an interpretable model (Ribeiro, Singh, and Guestrin 2016). Supporting our previous findings, we find that terms related to personification (e.g. "she" and "her") and a more communal relationship (e.g. "family") have a strong impact on predicting high mind perception in customer reviews. This demonstrates how combining a RoBERTa-based classifier with a local interpretable algorithm such as LIME can provide rich insights into linguistic features linked to an underlying psychological mechanism such as mind perception.

The key objective of Study 3 is to demonstrate generalizability of DeepMind by applying it to a completely different category of smart objects (smart vacuum cleaners) and shows that the language model is not only able to correctly identify and generalize linguistic features of mind perception to a novel category of smart objects, but that greater mind perception in these reviews is significantly associated with the same linguistic features as identified in Study 2 for smart speakers.

To the best of our knowledge, this is the first research developing a state-of-the-art deep learning classifier to unobtrusively detect mind perception in smart objects from user-generated text data and leveraging manifold methods to extract and interpret linguistic features of mind perception. The findings of this research highlight the power of deep contextual language models to detect more nuanced variations in text as compared to other classification methods or mere evaluations of consumer sentiment. This research contributes to and extends prior work in marketing, highlighting the importance of automated text analysis to uncover novel behavioral insight (Berger et al. 2020; Humphreys and Wang 2018). Furthermore, the findings of this research contribute to the emerging research on consumer-smart object relationships (Hoffman and Novak 2018; Novak and Hoffman 2019) and technology-augmented choice (Melumad et al. 2020)

The words consumers write provide an unexplored window into their subjective interaction experiences. The current research develops a novel method using deep learning and interpretable machine learning that sheds light onto the nature of these experiences. We hope that the current methodological approach also opens up new avenues in consumer research to leverage the nuanced insights that can be revealed from the systematic analysis of unstructured, user-generated text using deep neural networks and interpretable machine learning.

Let the Weak Lead the Strong: Low-Income Benefactors Motivate Others to Give

Miranda Yin, California Polytechnic State University, USA
Jessica Li, University of Kansas, USA
Jenny Olson, Indiana University, USA

EXTENDED ABSTRACT

Charities often share donor stories in the hope of motivating others to donate (e.g., Fidelity Charitable n.d.). Although consumers generally expect wealthier people to donate more (e.g., Ames, Flynn, & Weber, 2004), little is known about whether such behavior motivates others to donate. We propose that donations from a low-income benefactor elicit greater generosity than one from a high-income benefactor. We further suggest that this effect is driven by perceived altruistic motivations, which enhances feelings of moral elevation (i.e., a warm, uplifting feeling people experience after observing others' human kindness and goodness; Haidt 2000). Research shows that low-income versus high-income donors are perceived as having more altruistic motivations. For instance, Yuan, Wu, and Kou (2018) showed that low-income versus high-income benefactors are perceived as having greater prosocial reputations (e.g., generous, noble). We hypothesize that a benefactor's perceived altruism will lead observers to experience a greater level of moral elevation. Feelings of moral elevation have been shown to enhance consumers' willingness to help others (e.g., Algoe and Haidt 2009). Thus, individuals who see a low-income (vs. high-income) donor should subsequently be more willing to emulate the benefactor's helping behavior by donating.

Across four experiments, we test the following hypotheses:

Hypothesis 1: *Consumers will donate more money after observing a low-income (vs. high-income) benefactor donating to the same charity.*

Hypothesis 2.: *Observing donation behavior of a low-income (vs. high-income) benefactor will lead consumers to experience a greater level of moral elevation.*

Hypothesis 3A.: *The relationship between benefactor income and donations is mediated by feelings of moral elevation among observers.*

Hypothesis 3B.: *The relationship between benefactor income and donations is serially mediated by the perceived motivation of the benefactor (M1) and moral elevation (M2) experienced among observers.*

We further suggest that observers' donation behavior in response to a low-income versus high-income benefactor depends on the benefactor's personal connection with the charity. On average, high-income benefactors tend to be seen as more selfish and less altruistic (Yuan et al. 2018). Thus, when information about the benefactor's personal connection to the charity is present (vs. absent), observers may perceive the high-income benefactor's motives as relatively more altruistic, and hence experience greater moral elevation and subsequently donate more.

Hypothesis 4.: *The effect of benefactor income on donations is moderated by personal connection such that the income effect is attenuated when the benefactor's personal connection is present (vs. absent).*

We test our hypotheses in four experiments. Experiment 1A test H1-H3A. Undergraduate students (N = 258) read a scenario about a benefactor who was portrayed as either high-income, middle-income, or low-income. Results revealed a significant main effect of benefactor income on donation likelihood ($F(2, 255) = 10.27$, $p < .001$). Participants were more likely to donate after seeing a low-income benefactor giving than a middle-income benefactor ($p < .001$) or a high-income benefactor ($p = .002$); the latter two conditions did not differ ($p = .19$). There is a significant main effect of benefactor income on moral elevation revealed ($F(2, 255) = 10.02$, $p < .001$, $\eta_p^2 = .07$). Participants reported experiencing higher levels of moral elevation after seeing a low-income benefactor giving than a middle-income ($p = .007$) or high-income ($p < .001$) benefactor. A PROCESS model (model 4; Hayes 2019) revealed significant indirect effects of benefactor income on donation likelihood via moral elevation (low-income vs. middle-income: 95% CI: .096, .572; low-income vs. high-income: 95% CI: -.837, -.260). This study results support H1-H3A.

Experiment 1B (N=209) includes a control condition where the benefactor's is not specified. Results indicated a main effect of income on donation likelihood ($F(3, 205) = 2.63$, $p = .05$). Participants were more likely to donate in response to a low-income benefactor than a middle-income benefactor ($p = .01$), a high-income benefactor ($p = .02$), or a benefactor with unspecified income ($p = .06$). The latter three conditions did not differ (all $ps > .52$). A similar pattern of effects was found for donation amount. Results also revealed a significant main effect of benefactor income on moral elevation ($F(3, 205) = 6.13$, $p = .001$). Participants experienced higher levels of moral elevation in response to a low-income benefactor than a middle-income benefactor, a high-income benefactor, or a benefactor with unspecified income (all $ps < .02$). No difference was found between any other conditions (all $ps > .13$). Mediation analyses using the Process model revealed significant indirect effects of moral elevation (low-income vs. middle-income: 95% CI: -.165, -.275; low-income vs. high-income: 95% CI: -.702, -.184; low-income vs. control: 95% CI: .115, .976).

Experiment 2 examines the serial mediation presented in H3B. Undergraduate students (N=168) read a scenario about a benefactor who was described as either being low-income or high-income using. Consistently, results indicated a main effect of income on both donation likelihood ($F(1, 166) = 6.25$, $p = .013$) and donation amount ($F(1, 166) = 10.32$, $p = .002$). Participants were more likely to donate/donated more in response to a low-income versus high-income benefactor. Serial mediation models using benefactor income as the predictor, perceived motivation of the benefactor (M1) and the level of moral elevation observers experience (M2) as serial mediators (model 6; Hayes 2019) were significant for both donation likelihood (95% CI: -.537, -.180) and donation amount (95% CI: -1.493, -.422).

Experiment 3 (preregistered) tests H4. MTurk participants (N = 404) were randomly assigned to one condition in a 2 (benefactor income: high vs. low) × 2 (benefactor personal connection: present vs. absent) between-subject design. Results on donation likelihood showed no interaction ($p = .86$) but only a main effect of benefactor income ($F(1, 400) = 5.44$, $p = .02$), such that observing a low (vs. high) income benefactor donating led to greater donation likelihood. For donation amount, results showed a significant interaction ($F(1,

400) = 4.00, p = .046), and a main effect of benefactor income (F(1, 400) = 8.76, p = .003). Consistent with H4, when benefactor personal connection was absent, people donated more money after observing a low (vs. high) income benefactor donating ($p < .001$). No donation amount difference was found when benefactor personal connection was present (p = .50). A moderated serial mediation analyses (model 85; Hayes 2019) using perceived benefactor motivation as the first mediator, moral elevation as the second mediator, and benefactor personal connection as the moderator was significant (95% CI: .002, .030).

Taken together, we show that a low income (vs. high) benefactor is more effective in eliciting donations among observers. The effect is driven by the perceived altruistic motivation of the benefactor and the level of moral elevation experienced among the observers. We further demonstrate that this effect can be attenuated by presenting information about the benefactor's personal connection with the cause. We contribute to research on moral elevation, build upon work examining moral judgments and provide insights to charities about what type of benefactor they should feature in motivating others to donate.

Cleaning with Dustin Bieber: Nicknaming Autonomous Products and the Evolving Relationship with New Technologies

Jenny Lena Zimmermann, University of St.Gallen, Switzerland
Emanuel de Bellis, University of St.Gallen, Switzerland
Reto Hofstetter, University of Lucerne, Switzerland
Stefano Puntoni, Erasmus University Rotterdam, The Netherlands

EXTENDED ABSTRACT

Advances in artificial intelligence and robotics permit today's products to become increasingly autonomous, taking over various consumer tasks and making decisions on their own. The rise of these autonomous products (APs) has translated into new forms of relationships. Products are seen as *collaborators* complementing human skills, as *competitors* substituting human skills, or as *coopetitors* combining both aspects. Since APs possess human-like characteristics, the desire to personify and personalize them evokes more easily compared to conventional products. One way this manifests is by the increased use of nicknames for APs. Consumers discuss online what nickname to choose for their new device (SmarmysPiza 2019) and verbally integrate APs into their social lives by referring to them by their nickname. An analysis of consumer-created Tweets shows that whereas only 1% of Tweets include a nickname for traditional vacuum cleaners, 12% do so for robotic ones. On the company side, several firms such as Husqvarna and iRobot already support the use of nicknames for APs. They highlight nicknames in their communication and provide an option to assign a nickname in their mobile applications. Despite these unequivocal trends, it is unclear how nicknaming influences consumers' perception and use of APs.

Drawing on consumer behavior literature on APs, psychology literature on nicknames in a social context, and findings from organizational management research on coopetition, we propose that, in specific consumer-product relationships giving a nickname can help to regain control over autonomous products, which in turn increases their evaluation. Our theorizing is based on social response theory assuming that people spontaneously apply the same social heuristics used for human interactions to technologies because they possess similar social characteristics (Nass and Moon 2000; Nass et al. 1995). Based on Zhang and Patrick's (2018) definition of brand nicknames, we conceptualize product nicknames as consumer-created substitutes for formal product names, such as "Dustin Bieber" for a robotic vacuum cleaner (Mirani 2020). Psychology literature on nicknames in interpersonal relationships finds that nicknames can emphasize individuality or belonging to a group (Bruess and Pearson 1993). Thus, we expect that the use of nicknames (vs. no nicknames) leads to higher evaluations of APs. As, in social contexts, close relationships are associated with mitigated uncertainties and perceptions of a collective responsibility, we further suggest that the positive effect of using nicknames on evaluation of APs is mediated by perceived control. Moreover, we theorize the effects to depend on the specific consumer-product relationship. Interpersonal relationships are commonly described as cooperative, competitive, or a combination of both, that is, "coopetitive" (Deutsch 1949). According to previous research, coopetition in a social context and between firms is associated with positive effects, such as intrinsic motivation or performance, and it may outperform sole competition or cooperation (Park and Russo 1996; Tauer and Harackiewicz 2004). Combining prior research, we argue that the provision of a nickname might augment team-perception and collaboration in coopetitive settings. Consequently, we assume that nicknaming can foster cooperation as well as motivation in coopetitive environments and lead to a higher feeling of control. Namely, we predict that the positive effect of using nicknames on perceived control over APs is moderated by coopetition in that coopetitive settings enhance the effect.

We tested our predictions across three studies using different samples and study designs (N = 9,577). In study 1, we conducted a large field study with actual customers in collaboration with a distributor of a smart kitchen device. We showed that customers evaluate APs differently when using a nickname for them. 33% of customers used a nickname for their smart kitchen device. Customers using nicknames were more satisfied with their smart kitchen device and used the product more often compared to users that did not use a nickname. In addition, the interaction with the product was described as more collaborative when using a nickname. Next, study 2 experimentally manipulated nicknaming. The study employed a between-subjects design with random assignment to two conditions (nicknaming: yes vs. no) describing the use of a robotic vacuum cleaner. After the manipulation, we measured usage intention and perceived control. We recruited participants through Amazon Mechanical Turk. Participants in the nickname condition were more likely to use the product and perceived to have more control when they created a nickname. Furthermore, a mediation analysis supported the proposed mediation of the positive effect of using nicknames on evaluation via perceived control. Finally, study 3 experimentally manipulated nicknaming a robotic vacuum cleaner and the relationship consumers have with their APs. Participants recruited on Prolific were randomly assigned to one condition of a 2 (nicknaming: yes vs. no) × 3 (relationship: coopetition vs. collaboration vs. control) between-participants design. After the manipulation, we measured product evaluation, perceived control, and perceived collaboration. While in the collaboration and control conditions, nicknaming did not have a statistically significant effect, in the coopetition condition nicknaming lead to higher product evaluations. As expected, perceived collaboration did not differ across the collaboration and coopetition condition. Conclusively, we ran moderated mediation analyses to test our proposed conceptual framework. The results supported the notion that nicknaming APs affects product evaluation via perceived control when experiencing coopetition.

The current research investigates the increasing practice of assigning nicknames to APs in the context of evolving relationships between humans and technology. Overall, our studies demonstrated that using nicknames for APs leads to an increase in perceived control, which in turn increases the evaluation of the product. However, we only found such effects in coopetitive settings, where consumers perceive the AP as a "friendly competitor" that challenges them but still provides a feeling of collaboration. We argue that nicknaming APs can offer an effective counter to the feeling of loss of control that is commonly triggered by product autonomy (de Bellis and Johar 2020; Jörling et al. 2019; Puntoni et al. 2021). We conclude that depending on product category (as some products may be perceived as more collaborative or competitive in general) and context, encouraging the use of nicknames can be a valuable measure for practitioners.

Creatives' Brand Attitudes Affect the Type of Ads They Produce

Cátia Alves, Nova School of Business and Economics, Portugal
Irene Consiglio, Nova School of Business and Economics, Portugal
Luis Martinez, Nova School of Business and Economics, Portugal

EXTENDED ABSTRACT

Consumers and professional creatives often produce creative work for brands, such as new product designs or TV commercials. Several factors influence the production of marketing materials, such as creative managers' leadership style (Mallia, Windels, and Broyles 2013) or the level of collaboration between client and agency (Calderwood, Koslow, and Sasser 2021). However, research has overlooked the impact of creatives' brand attitudes on the outcome of their work. Advertising creatives are consumers themselves; what distinguishes them from other consumers is that brands are also the object of their work.

We investigate how creatives' brand attitudes affect the type of advertisements that creatives produce for a brand. Specifically, we propose that creatives who have negative brand attitudes are more likely to produce functional advertisements, appealing to rationality, and less likely to produce emotional ads, appealing to emotions (Aaker and Norris 1982; Holbrook and Batra 1987; Zarantonello, Jedidi, and Schmitt 2013). We propose that this happens because individuals who dislike a brand believe that their attitudes have a negative impact on their work and that they try to correct for this perceived bias by staying rational and suppressing their emotions. This, in turn, inadvertently spills over onto their creative output. We tested these predictions in four studies, in laboratory and field contexts. All studies were preregistered, except study 2.

In study 1, 201 participants (M_{age} =33.98, SD =12.38; 22.39% male, Prolific) wrote a TV commercial script for their most liked or most disliked fast-food restaurant brand. In this and all other studies, scripts were coded as containing functional (1 = Yes, 0 = No) and emotional elements (1 = Yes, 0 = No), by independent coders (studies 1-2) or the first author (study 4). Participants who worked for a disliked brand were less likely to produce an emotional ad (B = -.490, $\chi^2(1) = 2.715$, $p = .099$) and more likely to produce a functional ad (B = .512, $\chi^2(1) = 2.962$, $p = .085$), as compared to participants who liked their brand. Given the practical importance of our research question, we investigated it in a more consequential context in study 2. Ninety-eight professional creatives (M_{age} = 32.22, SD = 7.45; 59.2% male) from 18 advertising agencies wrote a TV commercial script for their most liked and most disliked brand in counterbalanced order. We found that negative brand attitudes decreased the likelihood of writing emotional ads (B = -.816, $\chi^2(1) = 4.568$, $p = .033$;) and increased the likelihood of writing functional ads (B = .946, $\chi^2(1)$ = 10.375, $p = .001$). Study 3 provided evidence in line with our proposed mechanism. Two hundred eight participants (M_{age} =35.52, SD =11.94; 31.3% male) imagined producing a script for a brand they liked or disliked. Consistent with our hypothesis, participants who imagined working for a brand they disliked (vs. liked) were more likely to believe that their attitudes would have a negative impact on their work, rather than positive (B = 6.013, $\chi^2(1) = 31.923$, $p < .001$) or null (B = 2.584, $\chi^2(1) = 5.870$, $p = .015$). Moreover, participants who disliked (vs. liked) the brand rated staying rational ($t(182)$ = 4.54, $p < .001$) and suppressing emotions ($t(184)$ = 8.46, $p < .001$) as more important strategies to produce a good commercial ($t(161)$ = -7.615, $p < .01$). Finally, in study 4, we addressed the alternative explanation that individuals who like a brand might simply have more positive emotions to express about it as compared to people who dislike a brand. The latter might have fewer positive emotions (or none), and therefore include less emotional content in their scripts. In study 4, 190 participants (M_{age} = 35.4, SD = 13.60; 30.5% male, Prolific) were randomly assigned to a positive, neutral, or negative brand attitudes condition (between subjects). In each condition, participants read a fictitious brand description inducing the intended brand attitudes and wrote a TV commercial for this brand. Negative brand attitudes reduced the likelihood to create an emotional ad, as compared to positive (B = -.820, $\chi^2(1) = 4.835$, $p = .028$) and neutral brand attitudes (B = -.876, $\chi^2(1) = 5.071$, $p = .024$). The likelihood to create an emotional ad was similar between the positive and neutral brand attitudes conditions ($p = .888$). Moreover, negative brand attitudes increased the likelihood to create a functional ad, as compared to positive brand attitudes (B = .629, $\chi^2(1) = 2.993$, p = .084) and neutral brand attitudes (B = .633, $\chi^2(1) = 2.848$, $p = .09$). Participants in the positive and neutral brand attitudes conditions were equally likely to write a functional ad (B = -.004, $\chi^2(1) = 0.000$, $p = .991$). This pattern of results is inconsistent with the alternative explanation that the mere presence or absence of emotions drives the previously observed effects. Indeed, creatives with positive brand attitudes do not include more emotional content in their ad compared to participants with neutral attitudes. Instead, these results are consistent with our proposed mechanism, driven by negative attitudes.

From a theoretical standpoint, we contribute to the advertising literature because we are the first to demonstrate how creatives' brand attitudes affect the type of advertisement that creatives produce. We also contribute insights to the literature on creativity by proposing novel psychological processes involved in projects that creatives dislike. From a practical standpoint, this research challenges the intuitive idea that creatives' negative brand attitudes might affect ad performance negatively (Kover 1995; Phillips, McQuarrie, and Griffin 2014). In fact, choosing a creative that dislikes the brand can be beneficial in situations in which functional ads outperform emotional ads (Chandy, et. al. 2001; Guitart and Stremersch 2021).

"Dream, Love and Cuteness": How Markets Fuel a Diminishing "Girl Culture"

Eva Delacroix-Bastien, Université Paris-Dauphine PSL, France
Sarah Lasri, Université Paris-Dauphine PSL, France
Florence Benoît-Moreau, Université Paris-Dauphine PSL, France

EXTENDED ABSTRACT

Since the Weinstein scandal in 2017, feminist movements have become so popular that they encouraged brands to change their practices. Several things have improved over the past few years: overpricing women's items (a phenomenon known as "pink tax") or objectifying women in advertising have become scarce, and immediately condemned on social media. The children's toys French market is emblematic of this turning point, with the adoption of a charter in 2019, in which brands and retailers signed commitments to end gender stereotypes in product design, promotion and merchandising. We can only welcome these advances, but they should not let us forget that the road to gender equality is still long. Beyond advertising or pricing, Gendered Segmentation (GS) remains common practice, and by relying on stereotypes, it tends to maintain an artificial dichotomy between genders.

In line with feminist sociologist Andrée Michel (1986), we distinguish two kinds of sexisms: explicit and implicit sexism. Explicit sexism refers to clearly unequal or demeaning situations (e.g. an advertisement for vacuum cleaners on Mother's Day). Such sexism is visible and usually quickly condemned. Implicit sexism is more insidious and contributes to a gendered culture that has impacts on several aspects of social life, including self-identity, educational and career aspirations, or leisure activities. In this research, we aim to address this implicit sexism by describing the less visible but still demeaning components of the girl culture conveyed by the Market through GS.

The marketing literature has a long but discrete tradition with gender. Researchers have studied gender to show how men and women react differently to marketing cues (*e.g.* Dahl, Sengupta & Vohs, 2009), to understand life experiences of males and females as consumers (*e.g.* Hutton, 2015) or to criticize gender inequalities produced by the market (*e.g.* Fine & Rush, 2018). Recently, special issues in marketing journals (Journal of Macromarketing (40), 2020; Journal of Consumer Research, 2021) have brought to light the gender field in marketing research and we expect it to grow in the future. Despite this growing interest, the way GS conveys a gendered culture that offers less opportunities for girls than for boys has not been studied by marketing academics. That is the gap we aim to fill with this research.

Since gender identity is mostly constructed during childhood (e.g. Martin, Ruble & Szkrybalo, 2002), we studied two gender-segmented markets dedicated to children aged 6-8 years old: books and clothes. We show that, on both markets, GS relies on stereotyped themes, and that, through texts and images, a diminishing "Girl Culture" is being communicated to children.

To grab the "Girl Culture" and its main characteristics, we built a corpus of products offered by the two major French actors (Kiabi and Hachette), selected not only for their leadership, but also because they practice gendered segmentation. A corpus of book summaries on the one hand and of tee-shirts with a text message on the other hand was constituted and submitted to text-analysis. In the publishing market, we selected two gendered collections by Hachette: "My First Pink Library[1]" (PL) (for girls) and "My First Green Library[2]" (GL) (for boys), targeting 6 to 8 readers. We gathered 55 abstracts from the publisher's website (31 for PL and 24 for GL). In the clothing market, we selected the market leader Kiabi (Xerfi, 2020) and collected all tee-shirts that included a text message from its website. By doing so, we reached a total of 96 girls' tee-shirts and 123 boys' tee-shirts for 3 to 12 years old children. We first ran lexical analyses on the textual data using dedicated software: Iramuteq and Tropes. We then conducted an exploratory content analysis on the T-shirts, in order to analyze texts in their context, and take images and symbols into consideration.

Results are consistent on both markets. We highlight the content of a girl culture in which physical appearance, emotions and fantasy are encouraged. Unlike boys, the messages conveyed to girls do not appeal to strength or competition but to beauty through the lexical field of Physical Appearance. Girls are described as "Little", "Pretty" or "Beautiful", and so are their activities, animals and companions. In addition, girls are invited to spread love, smile and happiness and we can see the importance of emotions and sensitivity in girlhood. Finally, girl culture is a culture of dream and fantasy, where unicorns, magic and fairy tales are omnipresent.

This culture is problematic because it is diminishing in contrast to the themes communicated to boys. When girls are encouraged to be superficial, dreamy and lazy, boys are represented as super-heroes, invited to discover, conquer, protect and save the world. This leads to two very different perspectives: narrow and superficial opportunities for girls, ambitious, dominant and socially rewarded ones for boys.

Clothing is a way to define and communicate one's social identity to others (Feinberg, Mataro et Burroughs, 1992; McNeill et McKay, 2016) and through a focus on appearance, it can influence gender identity development in childhood (Halim et al., 2014, 2018). Books are also significant vectors of gender identity construction (Brugeilles, Cromer and Cromer, 2002). As "sacred" objects, they are rarely criticized even if they frequently convey stereotyped representations of genders (e.g. Brugeilles, Cromer and Cromer 2002; Epiphane, 2007). Our analysis shows that stereotypes are omnipresent on these two markets. The girl culture communicated on everyday consumer products tends to reduce girls to their cuteness, feelings and emotions, but also to an imaginary world far from reality. To increase external validity, it would be interesting to extend the analysis to other publishing and clothing brands, as well as to other markets. To reinforce internal validity, it would be necessary to go further in the content analysis and especially in the text/image articulation. Finally, the appropriation of this Girl culture and its consequences should be studied.

The Role of Perceived Risk and Device Type in Online Crowdfunding Decisions

Sorim Chung, Rochester Institute of Technology, USA
Maria Karampela, University of Strathclyde, UK

EXTENDED ABSTRACT

Background & Literature Review

Online investing platforms (e.g., Robinhood) have grown quickly over the past few years, with online crowdfunding channels having also become popular investment options (Forbes, 2020). Many of those services are available exclusively through mobile apps and websites, and investors' overall service experiences are thus likely to differ as their devices often vary from PCs to smartphones. However, whether and how different devices affect investors' behavior remains largely unknown. To address these gaps, we examine whether device type a influences investors' perceived risk and willingness to invest (WTI) in different online investment conditions.

Risk-taking tendencies often depend on emotional sensitivity (Blekher *et al.*, 2019), and devices with a larger screen evoke stronger emotional responses such as increased excitement (Reeves *et al.*, 2000) and more positive attitudes (Nayler and Sanchez, 2018) toward content displayed. Thus, PCs, of which the average screen size is significantly larger than that of smartphones, may also amplify the level of an individual's perceived risk regarding investment information (H1). Additionally, since perceived risk negatively affects consumers' judgments such as investment options (Mrkva *et al.*, 2020), we propose that using a PC (vs. smartphone) indirectly influences WTI through stronger perceived risk, resulting in lower WTI (H2).

Psychological distance may also play a role in device effects on investment. Previous research has asserted that consumers' perceived psychological distance (e.g., temporal or social distance) should be considered to assess risks accurately (Raue et al., 2015). For instance, temporal distance, such as a delayed investment payoff, leads to stronger perceived risks (Okada and Hoch, 2004), and social distance also has negative effects on consumers' spending decisions (Trope et al., 2007). Thus, we propose that temporal (H3a) and social (H3b) distance from an investment target will amplify the negative indirect effect of H2.

Studies

Method

Three experimental studies were conducted. In Study 1 (*n*=166; men: 58%; age 18–34: 63%), we focused on testing H1 and H2 using a one-way (device type: PC/tablet/ smartphone) between-subjects design. In Studies 2 (*n*=164; men: 68%; age 18–34: 54%) and 3 (*n*=160; men: 65%; age 18–34: 47%), the role of temporal (H3a) and social (H3b) distances was tested in addition to H1 and H2, using a 2(device type: PC/smartphone) × 2 (psychological distance: close/ distant) between-subjects design.

Participants in the studies were randomly assigned to one of the conditions. They read an investment scenario and evaluated their investment interest in a fictitious crowdfunding project (i.e., Studies 1 and 2: face mask projects; Study 3: restaurant projects). In Study 2, temporal distance varied by adjusting return schedules, and social distance in Study 3 varied by the type of restaurant (close: a burger restaurant; distant: a halal food cart). Device identification codes were embedded in the survey to automatically detect and filter device type.

Based on the scenario, participants answered questions on (1) perceived risk (1=not risky at all, 7=very risky; Raghubir and Das, 2010); (2) WTI (1=strongly disagree, 7=strongly agree; α=.88) using a modified scale based on the existing scales (Yang *et al.*, 2019, Baker and Churchill, 1977); (3) perceived temporal distance (1=not very long/soon, 7 very long/soon; α=.70) on a modified scale based on Liberman *et al.* (2007); (4) perceived social distance (1=very close, 7=very distant; α=.89) using the measure based on Kim *et al.*(2008); and (5) demographics.

Results

Study 1. Neither temporal (F(2,163)=.51, p=.60) nor social distances (F(2,163)=2.13, p=.12) significantly differed by device type, hence were controlled. A mediation analysis was conducted using PROCESS macros (Model 4; 50,000 bootstrap samples; Hayes, 2018). We found a negative indirect effect of device type (X: 1=PC; 2=tablet; 0=smartphone) on WTI (Y) through perceived risk (M), and the difference was significant only between PCs and smartphones (b=-.18, 95%CI[-.40, -.02]). The direct effect of PCs was reversed, resulting in higher WTI (b=.66, p=.005).

Study 2. Temporal distance was manipulated successfully (F(1,162)=34.67, p<.0001). The results from PROCESS Model 4 (50,000 bootstrap samples; Hayes, 2018) showed that the proposed indirect effect (H2) of device type (X: 1=PC; 0=smartphone) was significant when temporal distance was controlled for (b=-.10, 95%CI[-.23,-.01]), supporting H2. However, similar to Study 1, controlling for perceived risk, the direct effect of using a PC was reversed, resulting in higher WTI (b=.58, p=.002). A separate analysis (Model 15; 50,000 bootstrap samples) showed that the negative indirect effect of device type (1=PC; 0=smartphone) on WTI was significant in the temporally-distant condition only, supporting H3a.

Study 3. Social distance was successfully manipulated (F(1,158)=39, p<0001). The proposed indirect effect was consistent with that in Studies 1 and 2; the same model used in Study 2 revealed the effect of H2 was consistent when social distance was controlled (b=-.14, 95%CI[-.30,-.005]). However, controlling for perceived risk, the direct effect of PCs was again reversed, leading to higher WTI (b=.71, p=.0004), suggesting an important role of perceived risk. A separate analysis (Model 15; 5,000 bootstrap samples) indicates a similar negative indirect effect, which was significant only in the socially-distant condition, supporting H3b.

General Discussion and Implications

This study presents several theoretical implications. The study is the first to present empirical evidence that device type is a potential cue in online investment environments that affects perceived risk and influences final investment decisions. The findings expand the area of device effect research, which was limited to the effects of device features (screen size; input mode) and non-investment contexts. Our findings also highlight the important role of perceived risk in online investment processes. When risks were involved, PCs led to lower WTI through stronger perceived risks, but when the risks were controlled for, the negative effect was reversed, resulting in higher WTI. These reverse effects imply that using a PC may not always result in lower WTI if the level of risks is controlled for.

Moreover, the findings suggest that crowdfunding investment services should actively monitor their customers' device type condition to optimize business outcomes. However, as the studies were limited to crowdfunding settings, examining field data from different investment services (e.g., stocks, crowdfunding) may add more insights to the findings.

Craving for Density: Residential Mobility Increases Consumer Preference for Color Satiation

Xiao Su, School of Management, Zhejiang University, China
Lili Wang, School of Management, Zhejiang University, China
Yanfen You, University of Massachusetts Amherst, USA

EXTENDED ABSTRACT

With the rapid development of the economy and society, moving has become an essential part of consumer life all over the world (Oishi and Talhelm, 2012). Research has examined how residential mobility affects individuals' self-concept (Oishi, Lun, and Sherman, 2007), their friendship selection (Lun et al., 2012), choices of social networks (Oishi et al., 2013), and civic participation (Kang and Kwak, 2003). However, little is known about how residential mobility might systematically alter consumers' aesthetic preferences.

To answer this question and fill the research void, our research identifies color saturation as an important aesthetic dimension in product choices and documents that residential mobility fundamentally increases consumer preferences for high color saturation in product choices. Specifically, frequent movers always worry about their friendships (Oishi et al., 2013), concern about their income stability (Anam et al., 2008), wonder whether they can get social support (Lun et al., 2012) and are unsure about whom they can trust (Yuan et al., 2021). All these make residential mobility induce a strong sense of uncertainty (Yu et al., 2020; Yuan et al., 2021), which has been provided to be an indicator of lack of personal control (e.g., DiFonzo and Bordia, 2002, etc.). According to compensatory control theory (Kay et al., 2009), consumers often seek to restore perceived control when their sense of control is threatened. Extant research has shown that highly saturated color increases the perceived size of objects (Hagtvedt and Brasel, 2017) and super-sized items are often associated with greater control (Taylor, Noseworthy, and Pancer, 2019) and power (Dubois, Rucker, and Galinsky, 2012). Further, Batra and Ghoshal (2017) find that participants who experience self-threat prefer more saturated colors and this high-intensity sensory consumption has a self-restorative effect. Taken together, we propose that products with high color saturation can serve as a means to compensate for one's lack of control derived from residential mobility.

More formally, we hypothesize that:

Hypothesis 1: *Residential mobility increases consumer preferences for color saturation.*

Hypothesis 2: *Sense of control mediates the effect of residential mobility on consumer preferences for color saturation.*

Across four studies, the present research tests the central premise that residential mobility influences color saturation preference, and explores the underlying mechanism.

Study 1 aimed to provide preliminary evidence that as residential mobility increased, consumers preferred the products with high color saturation more. 109 new university students participated in this study. Participants first indicated how many cities they had lived in before attending the university (Lun et al., 2012). Then, they were asked to indicate their preference for four pairs of products (i.e., computer, mug, luggage, bag; one with relatively high color saturation and the other with relatively low color saturation). Results showed that as participants' residential mobility increased, their preference for high color saturation became stronger ($b = .35$, $t(107) = 2.10$, $p = .039$).

Study 2 aimed to examine the causal relationship between residential mobility and consumers' preference for color saturation. 188 MTurk workers participated. Participants were first randomly assigned to the three experimental conditions: baseline control vs. residential stability vs. residential mobility. They were asked to completed a "simulation task" which was used to manipulate their perceived residential mobility (Lun, Oishi, and Tenney 2012; Oishi et al., 2012). Similar to Study 1, participants then indicated their preference for six pairs of products. Planned contrast showed that participants in residential mobility condition preferred products with high saturation more ($M = 4.79$, $SD = 1.52$) than those in both the residential stability condition ($M = 4.17$, $SD = 1.47$, $t(185) = 2.43$, $p = .016$, $d = .41$) and the control condition ($M = 4.23$, $SD = 1.40$, $t(185) = 2.08$, $p = .038$, $d = .38$). There was no difference between the residential stability condition and the control condition ($t(185) = .23$, $p = .819$, $d = .04$).

In Study 3 we attempted to prove our mechanism that residential mobility reduced consumers' sense of control, which leaded consumers to prefer products with high color saturation. 122 university students participated. Participants were first randomly assigned to two experimental conditions: residential stability vs. residential mobility. The manipulation of mobility was identical to Study 2. Then, they answered several questions in which sense of control (Cutright and Samper 2014) was measured. Afterwards, participants were asked to indicate their preference for three pairs of products. We found the mean indirect effect was positive and significant ($a \times b = .25$ $(.14)$, 95% CI $[.001, .56]$). Residential mobility had a negative effect on sense of control ($a = -.90 (.19)$; $t(120) = -4.69$, $p < .001$; 95% CI $[-1.28, -.52]$), and sense of control negatively predicted preference for product with high color saturation ($b = -.28 (.13)$, $t(119) = -2.20$, $p = .030$; 95% CI $[-.53, -.03]$).

Study 4 attempted to provide further test for the underlying mechanism by manipulating participants' sense of control. 246 university students participated. The study employed a 2 (sense of control: neutral condition vs. boosting condition) × 2 (mobility: residential mobility vs. residential stability) between-subjects design. First, participants either wrote about their daily life (neutral condition) or a time when they felt that they were in complete control (boosting condition). Then, they received the same residential mobility manipulation from Study 2 and 3. After that, participants indicated their product preference. Planned contrasts showed that, in the control condition, residential mobility increased preference for high color saturation ($M_{residential-mobility} = 4.09$, $SD = 1.39$; $M_{residential-stability} = 3.58$, $SD = 1.27$; $t(242) = 2.07$, $p = .040$, $d = .38$). However, when participants' sense of control was pre-boosted, there was no significant difference between the residential mobility and residential stability conditions.

Taken together, these studies provide consistent and convincing evidence that residential mobility reduces individuals' sense of control, which increases their preferences for color saturation in product choices. Our research not only enriches research on residential mobility, color saturation, compensatory control and aesthetic preferences, but also give suggestions to managers that they should consciously identify markets with high residential mobility and customize products with high color saturation for them to achieve higher sales.

Alexa, I Want to Do Good: The Role of Voice Assistants in Encouraging Greater Prosocial Behavior

Smaraki Mohanty, Binghamton University, USA
Iman Paul, Clarkson University, USA
Samuel Bond, Georgia Tech, USA

EXTENDED ABSTRACT

Given the widespread adoption of voice shopping (i.e., shopping using a digital assistant), firms have already started to acknowledge the importance of understanding and managing the customer experience with these devices (Grewal, Roggeveen, & Nordfält 2017). However, only a nascent stream of research has focused on exploring the impact of voice shopping (Munz and Moriwtz, 2019; Dellaert et al., 2020). In contrast to prior work that focused on information processing affecting consumers' purchase journey, we focus on the social cognitive implications of voice assistants as "interaction partners" in a shopping process.

Research has shown that voice assistants with AI-powered technologies are perceived by many users to be social agents with agentic capabilities, mental states, and intentions (Shang et al., 2012). Work in the domain of social presence has shown that the mere presence of others (real or imagined) make consumers to act in accordance with social norms (i.e. acts or behaviors which is considered as appropriate or correct by the society at large, Xu, Mehta and Kelly, 2019) or even affect consumers' purchase behaviors (Dahl, Manchanda and Argo, 2001). Building on these work, we propose that, the agentic and anthropomorphic qualities of the voice assistants have a similar effect of serving as social "others" to their users which activates social norms related to pro-social choices.

In sum, we propose that using voice assistants for shopping evokes perception of social presence which makes social norms salient. Consequently, consumers utilizing a voice assistant for shopping (vs. shopping online using a computer) would be more likely to exhibit pro-social behavior with regards to their purchase and consumption choices. We test our prediction across three studies.

In Study 1, AMT Participants (N=242) were randomly assigned to one of the two different device conditions (voice assistant or computer) through which they could place the order. At the end of the ordering process, all participants were asked to indicate if they would like to add a tip amount (on a 0-100 percentage scale). Afterwards the perception of social presence and social norm was measured on a 9-point scale (1= Strongly Disagree, 9=Strongly Agree). A one-way ANOVA on the amount of tip percentage indicated that participants ordering food using the voice assistant tipped significantly higher percentage than those ordering online using a computer ($M_{\text{voice-assistant}}$ = 12.05, SD = 8.59 vs, M_{computer}= 9.89, SD = 8.64; F (1, 241) = 3.83; p = .05). A mediation analysis using Hayes' (2018) PROCESS macro revealed the expected serial mediation path (Voice assistant → Greater Social Presence → Increased Social Norm → Increased Tipping Behavior) at the 95% confidence interval (CI) (a × b = .71, 95% CI: .30,1.24).

Study 2 examined the impact of using a voice assistant (vs. shopping online using a computer) on the willingness to donate to a charitable cause via rounding up to the nearest dollar during the check-out process. Similar to Study 1, participants who utilized a voice assistant for ordering groceries indicated significantly higher likelihood to donate (i.e., by rounding-up to the nearest dollar) than those ordering online using a computer (M_{computer} = 4.15, SD = 2.39 vs $M_{\text{voice-assistant}}$ = 5.12, SD = 2.15; F (1, 134) = 6.28; p = .01). There was also a significant serial mediation (Voice assistant → Greater Social Presence → Increased Social Norm → Higher willingness to donate) at the 95% confidence interval (CI) (a × b = .28, 95% CI: .11, .53)

Study 3 (N=155 AMT participants) used a brand choice trade-off context where participants were placed in a shopping scenario and asked to make a choice between a brand which was expensive but related to a charitable cause versus a brand which had a price promotion and hence cheaper in comparison. The study utilized a 2 (device used for shopping: voice assistant vs. computer) X 2 (norm reminder: present vs absent) between-subjects design. In the "*Norm reminder: present*" condition, along with the ordering process, participants were explicitly reminded of the fact that donating to a cause is a social norm. This information was not given in the "*Norm reminder: absent*" condition. Towards the end of the grocery shopping process, all participants were asked to indicate the brand they would like to purchase on a 9-point scale item (1=Definitely the one with a price discount of 20%; 9= Definitely the one which donates 20% to the charity). A 2 X 2 ANOVA revealed a significant main effect of the source (F (1, 194) = 6.52, p < .012) and a significant interaction between the source and norm reminder (F (1, 194) = 4.86, p < .029). Consistent with our predictions in the *norm reminder absent condition,* participants who utilized a voice assistant for shopping (vs. using a computer) were more likely to choose the brand that contributed to a cause ($M_{\text{voice-assistant}}$ = 5.41, SD = 3.27 vs, M_{computer} = 3.38, SD = 2.69; p < .006). As predicted, in the social *norm reminder present* condition, however, there was no significant difference in the preference of the brand chosen by participants ($M_{\text{voice-assistant}} =$ 5.14, SD = 3.01 vs. $M_{\text{computer}=}$ 5, SD = 2.88; p < .99).

Implications

In this paper we highlight the novel consequences of the interaction with voice-based smart devices (e.g., Amazon Alexa, Apple Siri, Google Assistant, etc.). This research is among the first to empirically document a "bright side" in the form of subsequent pro-social and charitable behaviors. The possibility that smart devices evoke prosocial shopping norms and behavior represents a powerful societal benefit of their adoption that has not been previously recognized, with potentially profound implications for the cause-related marketing, retail design, and customer journeys.

How Attentional Overload Affects Consumer Preferences

Jeffrey Kang, Cornell University, USA
Manoj Thomas, Cornell University, USA
Dinesh Gauri, University of Arkansas, USA

EXTENDED ABSTRACT

The current work uncovers how subtle attentional cues in retail settings can affect shoppers' purchase decisions. When shoppers buy durable products online, they are often prompted to buy accessories, such as an extended warranty, along with them. We show that merely presenting a warranty decision on a separate screen (vs. the same screen along with the durable) can make shoppers more likely to buy the warranty. We propose that presenting the warranty decision on a separate screen reduces attentional overload, which in turn increases the purchase of accessories. We label this as the *attentional overload effect* and posit that when the main and the accessory product are presented on the same screen, attentional overload reduces shoppers' focus on accessory purchase decisions by screening them out.

In the consumer decision-making process, Mormann et al. (2020) characterize the relationship between attention and choice in four stages: awareness, screening, evaluation, and choice execution. When our attention is overloaded, we filter out less important information (Treisman 1964). By reducing attentional overload, shoppers are prevented from screening out accessory purchase decisions. One way to reduce attentional overload is to present the accessory decision on a separate screen from the focal product decision. Across six laboratory experiments and one archival analysis, we show that merely presenting an accessory decision on a separate screen can increase accessory purchase propensity.

We first identified this attentional overload effect in Study 1 ($n = 599$), where we manipulated in a 2x2 between-subjects design the presentation screen (same screen vs. separate screen) of an accessory product offer and the type of accessory product (protection plan vs. stylus pen) in a hypothetical shopping task for a tablet. We found a significant main effect of presentation screen such that presenting the accessory decision on a separate screen increases its purchase propensity, regardless of the type of accessory ($b = .98$, $p < .001$). Furthermore, using response times as a proxy for attention, we found that log response time mediated the effect of the presentation screen on accessory purchase propensity ($a \times b = .14$, 95% CI = [.06, .24]). Study 1B ($n = 578$) followed up this study by ruling out the possibility that any information increases attentional overload and demonstrated that this effect occurs even in the presence of a distracting advertisement on the separate screen ($b = .53$, $p < .05$).

In study 2A ($n = 900$), we tested the proposed underlying mechanism of attention more directly in a 2x2 between-subjects design manipulating shoppers' beliefs about the importance of the warranty decision (control vs. important) in addition to the presentation screen (same screen vs. separate screen). We expected that giving instructions highlighting the importance of the warranty decision would increase attentional focus to the warranty and thus purchase propensity in the same screen condition, but less so in the separate screen condition. Results indicated that the interaction between presentation screen and decision importance was significant ($b = -.67$, $p < .05$). Giving an importance instruction about the warranty increased warranty purchase propensity to a greater extent in the same screen condition (control = 18%, instruct = 37%, $b = .99$, $p < .001$) than in the separate screen condition (control = 40%, instruct = 48%, $b = .33$, $p = .09$).

Study 2B ($n = 562$) further examined the role of attention by introducing another moderator, a decline button or a rejection-framed response, in a 2 (presentation screen: same vs. separate) x 2 (decline button: absent vs. present) between-subjects design. Prior literature has shown that a rejection-framed option increases deliberation (Sokolova and Krishna 2016). Our prediction was that adding a decline button would increase attentional focus to the warranty decision and therefore increase warranty purchase propensity in the same screen condition, but less so in the separate screen condition. As expected, there was a significant interaction effect ($b = -1.01$, $p < .05$). Adding a decline button increased warranty purchase propensity in the same screen condition (absent = 17%, present = 31%, $b = .76$, $p < .01$) but did not increase purchase propensity in the separate screen condition (absent = 32%, present = 27%).

In studies 3A and 3B, we identified two boundary conditions for the attentional overload. First, Study 3A ($n = 229$) revealed that the attentional overload effect does not occur for products that are unrelated to the goal of purchasing the focal product (e.g. a Polaroid camera offer when deciding to buy a tablet). Second, Study 3B ($n = 418$) investigated the attentional overload effect in a consequential and non-shopping paradigm – a charity donation context. A significant interaction effect was found for presentation screen and familiarity ($b = .25$, $p < .05$). Floodlight analysis (Spiller et al. 2013) revealed that only for high familiarity individuals did presentation screen increase donation propensity.

Finally, Study 4 investigated how purchase setting, a proxy for attentional overload, affects real-world behaviors. According to our theorization, attentional overload of the warranty decision should be higher in online settings compared to brick-and-mortar settings, and therefore sales of warranty should be lower in online versus brick-and-mortar settings. We obtained archival data collected from a club store in a particular state of the U.S. and analyzed transaction-level sales of three durable product categories (TVs, cameras, and tablets) along with any concomitant warranty purchases. In total, we had 257,073 transactions made by 207,053 customers. Consistent with our prediction, warranty sales were lower in online than in brick-and-mortar settings (in-store: 17%, online: 6%; $b = -.98$, $p < .001$).

Critically, this research builds on previous literature in attentional models of choice (Krajbich et al. 2012) by elucidating the bi-directional relationship between attention and choice in a consumer domain. Typically, when the outcome of the choice matters, we pay more attention to the choice. However, we show the reverse association also holds true – when we pay more attention to choice options, that option is chosen. The current work also has important practical implications. We show why separating out secondary purchase decisions using pop-up windows are effective in increasing accessory sales.

Can Markets Be Caring?

Andreas Chatzidakis, Royal Holloway University of London, UK
Giana M. Eckhardt, King's College London, UK
Katharina C. Husemann, Royal Holloway, University of London, UK

EXTENDED ABSTRACT

Care, defined as logics and practices of *maintenance, cultivation and repair of our "'world' so that we can live in it as well as possible"* (Tronto and Fisher 1990, 40), is increasingly provided through markets, whereas the relative prominence of other sources of care provision, such as families/households, communities/neighbourhoods and government, is declining. Accordingly, a substantial body of inter-disciplinary research (e.g., Skeggs 2014; Tronto 2013; Mol 2008; Sandel 2013; The Care Collective 2020) cautions that market norms and logics are incompatible with care values. In this conceptual paper, we draw from our expertise in consumption, markets, and marketing to revisit this premise. We ask, can markets ever be caring, and if so under which conditions? We build upon Tronto's (2013) distinguishing between "caring for", "caring about" and "caring with" logics to review existing marketing and consumer research, and to explore and map out markets' capacity to/for care in each of these three domains. In doing so we also distinguish between mainstream versus alternative market logics.

Caring for refers to "someone or some group notic[ing] unmet caring needs" (Tronto 2013, 22). Care, here, involves looking after the physical and emotional needs of others, and is primarily understood as a hands-on, often dyadic, care giving practice. This type of care occurs often in families or between friends but can also occur in self-care. It is largely seen as incompatible with market logics. For instance, Hochschild's (2003; 2013) work on outsourcing domestic care work doubts the market's capacity to effectively address the care gap at home. On the other hand, research has shown that under certain conditions, market and caring logics may not be incompatible. Marcoux (2009) for example, has shown how some consumers prefer the sense of control and anonymity offered by professional moving companies as opposed to feelings of indebtedness that are common when asking a friend to help.

Caring about has to do with attending to and recognizing specific care needs but not taking direct responsibility in terms of hands-on care provision (Tronto and Fisher 1990). Within consumption, this means making market choices that indirectly enhance the wellbeing of other people, communities, and the planet. An archetypal example would be caring about producers in the global South by buying Fair Trade products or donating in relevant forums (e.g., Hawkins 2018). Yet, many critics argue that caring at a distance is not enough as, somewhat paradoxically, it may work at reproducing individualism rather than a genuine sense of care and interdependence. For example, Chatzidakis, Maclaran and Bradshaw (2021) identify how more radical consumers are averse to mainstream forms of sustainable and Fair-Trade consumerism and prefer instead to participate in small-scale initiatives that directly link them with politically minded producers.

Caring with addresses the more societal and political aspects of care, or in other words how institutions and infrastructures of care provision can be effectively democratized (Tronto 2013). From a consumption perspective, a key concern is access, ownership, and accountability in the provision of "public goods" (Visconti et al. 2010) or items of "collective" consumption (Castells 1977), including health, education, housing but also motorways, parks, and community libraries among others (see Peck et al. 2021). Numerous social critics argue that state-funded models of collective care provision as superior to marketized ones (e.g. Fraser 2016). Research within UK higher education, for instance, has shown how marketization has led to the cultivation of more explicitly consumerist and choice-driven demands and attitudes (Tomlinson 2015). As a result, students are torn between shared commitments or obligations and instrumental concerns (Ibid.).

Alternative market logics. Yet, as mentioned earlier, not all markets are driven by logics of maximised capital accumulation and fierce competition. Markets can be collaborative and mutually supportive, with consumers, retailers, and producers working together to produce positive community outcomes (e.g. Lee, Ozanne and Hill 1999; Weinberger and Wallendorf 2012). Some of these markets do have the capacity to be more democratic, accountable to stakeholders, and to defend common resources (Peck et al. 2021). Platform cooperativism, for example, has emerged within the sharing economy as a way for platform participants to share profits, rather than utilizing gig workers who are typically exploited within sharing economy systems (Schor 2020). However, alternative markets can also be romanticized in terms of their ability to converge market with care-oriented values and logics. For instance, alternative markets are more commonly based on ideas of solidarity and (physical or virtual) community bonding that may not extend to everyone either because of their ability to participate in them or because of potential ingroup-outgroup boundary markers. In the solidarity economies of Exarcheia, Athens for instance, "mainstream" consumers were not always welcomed (Chatzidakis, Maclaran and Varman 2021).

From this analysis, we argue that the relationship between market and care logics can be much more nuanced and multi-faceted than assumed in prior research and introduce propositions to guide future research in this arena. We identify three key dimensions that directly affect the compatibility of mainstream markets with care logics: expectations of (nonmarket) reciprocity and interdependence; existence of asymmetrical vulnerabilities and social-environmental externalities; and centrality of instrumental motives. We also identify moderating dimensions such as need for anonymity and social distance, need for empathy and emotional attentiveness.

Our contribution is four-fold. First, we contribute to an inter-disciplinary debate on the (in)compatibility between market and care logics (e.g., Skeggs 2014; Tronto 2013; Mol 2008; Sandel 2013; The Care Collective 2020) by adding further nuance. Second, we advance research on 'care in consumption' by integrating previously separate research streams (e.g. on familial consumption, environmental consumption, sharing, self-care, and sustainable/ethical consumption) (McInnis 2011). Third, we develop a framework that considers the conditions that enhance or limit the extent to which markets can effectively serve current care needs for our society and the planet. Finally, we offer a series of implications and useful avenues for future research via the propositions.

Don't Show the Price Too Early: How (and When) Uncertainty Improves Perceived Price Fairness

Amin Shiri, Texas A&M University, USA
Xiang Wang, University of Florida, USA
Minzhe Xu, University of Florida, USA
Chris Janiszewski, University of Florida, USA

EXTENDED ABSTRACT

Consumers often see a hidden price and need to engage in an action to reveal it (e.g., "Click here to see the price," "See the price in cart," etc.). Will consumers perceive the same price differently if it is first hidden and then revealed than if it is presented directly? We propose that first hiding a price and then revealing it (vs. directly showing a price) can create uncertainty about the price (i.e., price uncertainty), which in turn, can increase perceived price fairness and purchase likelihood.

Our proposition is based on three streams of literature. First, consumers are aversive to information gaps (i.e., not knowing) and are motivated to reduce an information gap by searching or mentally constructing the missing information (e.g., guessing what the missing information might be; Loewenstein 1994). Hence, we argue that when the price is hidden, consumers tend to predict what the price will be.

Second, prior research suggests that when facing possible negative outcomes, people often "brace for the worst" to reduce potential disappointment when the outcome is realized (Sweeny and Cavanaugh 2012). Since price is usually associated with psychological losses and pain (Rick, Cryder, and Loewenstein 2008; Thaler 1985) and thus often seen as a negative outcome, we further argue that consumers confronting a hidden price tend to cope with price uncertainty by expecting a higher/worse price.

Finally, the literature on price fairness suggests that consumers evaluate the fairness of an offered price by comparing it against their expected price (Kalyanaram and Winer 1995; Monroe 1990), and a smaller difference (i.e., offered price minus expected price) results in a higher level of perceived price fairness (Winer 1988). Consequently, a higher expected price, resulting from price uncertainty, will make the offered price look fairer.

Hypothesis 1: *Price uncertainty (vs. certainty) will increase perceived fairness of the offered price.*

Hypothesis 2: *An increase in the expected price drives the positive effect of price uncertainty on perceived price fairness.*

Furthermore, price is often, but not always, interpreted as a negative outcome. For example, if the context suggests that a price is being hidden because it is too good to be openly disclosed, as in sales events, then consumers may brace for the best and lower their expected price. As a result, in these situations, price uncertainty will reduce the expected price, enlarge the difference between the offered price and the expected price, and make the offered price look less fair.

Hypothesis 3: *The effect in H1 will be reversed when contextual information suggests the price is favorable and encourages people to expect the best.*

Study 1 ($N = 82$ students) tested both the positive effect of price uncertainty on perceived price fairness (H1) and the mediation effect of expected price (H2), using a two-cell (price uncertainty: certain vs. uncertain) between-subjects design. Participants imagined that they were living in an apartment for $600 per month, and needed to decide whether to renew the lease for next year. Those in the certain condition read that their monthly rent next year would be $650, while those in the uncertain condition clicked on a button to log in to the resident portal, waited for six seconds on a loading page, and then saw the monthly rent next year ($650). As predicted, participants in the uncertain condition perceived the $650 monthly rent to be fairer (3.95 vs. 2.93; $F(1, 80) = 8.63$, $p = .004$), because they expected a higher rent next year before seeing the actual rent ($635.72 vs. $607.21; $F(1, 80) = 6.96$, $p = .010$; 95% CI = [.01, .32]).

Study 2 ($N = 296$ Prolific workers) replicated the results of Study 1 in a different product domain (face masks to protect against COVID-19) and found price uncertainty increased purchase intention (45% vs. 36%; $\chi^2(1) = 2.90$, $p = .089$).

Study 3 ($N = 394$ MTurk workers) tested H3 and used a 2 (price uncertainty: certain vs. uncertain) × 2 (discount: present vs. absent) between-subjects design. We created an online shopping scenario where participants were searching for a pair of sunglasses. Those in the discount-present condition learned that there was a 50% discount on a pair of sunglasses, while those in the discount-absent condition did not learn this information. Then, all participants saw a picture of a pair of sunglasses. Similar to our previous studies, price uncertainty was manipulated by revealing the (discounted) price ($75) either right below the product picture (certain condition) or after participants entered a code and spent four seconds on a loading page (uncertain condition). A two-way ANOVA on perceived price fairness revealed a significant interaction effect ($F(1, 390) = 6.98$, $p = .009$): price uncertainty had a positive effect on perceived price fairness in the discount-absent condition (3.98 vs. 3.52; $F(1, 390) = 4.07$, $p = .044$), but a negative effect in the discount-present condition (3.81 vs. 4.20; $F(1, 390) = 2.96$, $p = .086$). Furthermore, expected price showed a consistent pattern: price uncertainty increased expected price in the discount-absent condition ($70.42 vs. $52.22; $F(1, 390) = 12.23$, $p = .001$), but not in the discount-present condition ($49.35 vs. $49.72; $F(1, 390) = .01$, $p = .943$). Finally, expected price significantly mediated the interaction effect of price uncertainty and discount on perceived price fairness, as indicated by a mediated moderation analysis (Model 8; 95% CI = [-.42, -.06]).

Theoretically, this research extends the existing literature on uncertainty, which primarily examined the influence of aleatory uncertainty (e.g., 50% likely to pay $5 and 50% likely to pay $10), by investigating the effect of epistemic uncertainty (e.g., not knowing a price). It also adds to the literature on price fairness by illustrating a novel effect of price uncertainty. Practically, our findings suggest an easy and costless method for marketers to optimize consumers' perceptions of the offered price: creating temporary uncertainty about the price and then resolving it.

Transmitting Craft: Collective Custodianship as Social-Symbolic Work

Joel Mohr, Queen's University, Canada
Peter A. Dacin, Queen's University, Canada
M. Tina Dacin, Queen's University, Canada

EXTENDED ABSTRACT

In this day and age craftwork is being revived (Maciel and Wallendorf 2017), because now more than ever consumers are looking for sources of identity (Moisio, Arnould, and Gentry 2013), emotional value (Fuchs, Schreier, and Van Osselaer 2015), play (Seregina and Weijo 2017), and connections to the past (Türe and Ger 2016) amidst ever increasing alienation and disenchantment. Craftwork requires knowledge and skills (Campbell 2005; Sennett 2008), and consumer research often takes a practice-theoretic approach (Maciel and Wallendorf 2017; Seregina and Weijo 2017; Watson and Shove 2008) to examine how craft practices are transmitted across time through the embodied and routinized enactment of these competencies (Llewellyn 2021). Alternatively, we explore how craftspeople may consciously and intentionally work to transmit their craft.

Craft research implies the potential importance of intentional work in the transmission of craft, which we conceptualize as the craft's continued enactment and reproduction. For one, Sennett (2008) suggests that knowledge transfer between craftspeople is an important transmission mechanism, and that this transfer is optimized when there is a balance between tacit knowledge learned through observation, and explicit knowledge that is consciously and discursively communicated (Sennett 2008). Second, authenticity is the very essence of craft value (Türe and Ger 2016), and it must be maintained for effective craft transmission (Beverland 2005; Campbell 2005). Since authenticity is socially constructed, effortful work (Koontz and Joshi 2017; Peterson 2005) may often be needed to manage various cues regarding the (in)authenticity of craft (Beverland and Farrelly 2010; Grayson and Martinec 2004).

Although prior work provides insight into consumers' intentional craft rejuvenation of family heirlooms (Türe and Ger 2016), less is known about craft transmission within the marketplace. In this work we study craft prosumers, who in addition to creating "use-value" such as play (Seregina and Weijo 2017), also create products of "exchange-value" to sell (Humphreys and Grayson 2008). Studying prosumers provides a unique opportunity to illuminate new, more social insights into craft transmission. For example, a craft prosumer must consider beyond themselves, various "social values and preferences" (Humphreys and Grayson 2008, 973). Moreover, craft prosumers are likely to possess unique motivations for craft transmission, beyond economic-based motivations such as market driving (Maciel and Fischer 2020). In this research we ask, how do prosumers work to transmit their craft across time?

To answer this question, we adopt a social-symbolic work perspective as our theoretical lens (Lawrence and Phillips 2019). Social-symbolic work is "the purposeful, reflexive efforts of individuals, collective actors, and networks of actors to shape social-symbolic objects," (e.g., craft), which are combinations of "discursive, relational, and material elements that constitute a meaningful pattern in a social system" (Lawrence and Phillips 2019, 24, 31). We adopt this perspective because a primary focus of social-symbolic work theory is explicating the "role of intentional action" during the construction of the social world (Lawrence and Phillips 2019, 49). Beneficially, this lens is also complementary to practice theory and prior craft research, as it situates practices as a bridge between social-symbolic work and the social-symbolic objects they are directed at.

To explore our ideas, we studied craft maple syrup in the province of Ontario, Canada. Our data collection included semi-structured interviews with 17 maple syrup craftspeople and one industry leader. Each of these craftspeople "made and designed" their own products (Campbell 2005, 27), and given our study of prosumption, they sold maple syrup in the marketplace. To supplement these interviews, we observed craft prosumers during maple syrup festivals (Bradford and Sherry 2015) at six different farms. We adopted a hermeneutic approach to analyze our data (Arnold and Fischer 1994; Spiggle 1994).

Through our analysis, we find that indeed, although these craftspeople are partly driven by their products' exchange-value, they are true prosumers in the sense that they are primarily motivated to engage in the craft because of the personal value they derive, such as play (Seregina and Weijo 2017), and self-expression (Campbell 2005). Moreover, these prosumers collectively engage in particular types of social-symbolic work with the purposeful intention of transmitting the maple syrup craft across time, both in order to sustain the practice of the craft itself, and for the sake of sharing its value and enjoyment with others. We classify this type of work as collective craft "custodianship" (Dacin, Dacin, and Kent 2019; Montgomery and Dacin 2020).

First, we find that maple prosumers intentionally transfer tacit and explicit craft knowledge through a number of embodied, and discursive, conscious practices, such as teaching, demonstrating, and storytelling. Our data suggests that passion, a sense of responsibility to sustain the craft, and feelings of reciprocity motivate our informants to share their knowledge. Furthermore, we contribute the insight that this process can become cyclical, as it not only replenishes and refines stocks of craft knowledge, but it is enacted through self-expressive, identity-affirming practices that re-enchant and remotivate prosumers. Over time, this cyclical process creates and maintains craft maple syrup communities. Taken together, we contribute a nuanced model of knowledge transfer and acquisition, and integrate disparate streams of consumer knowledge theory that either focus on tacit, or explicit knowledge (Llewellyn 2021).

Our data also shows how prosumers engage in collective custodianship through social-symbolic authenticity work. We find that prosumers collectively manage authenticity threats by discursively framing elements of the craft that they and the community have sustained or have in common as core. Conversely, they redirect attention away from elements subject to authenticity contestations, by framing these as peripheral. The two craft elements most frequently framed as core were the production process itself, and place. Through these findings, we uncover a new mechanism of authenticity management (Grayson and Martinec 2004), illuminate that prosumers actively negotiate which material elements the craft's "indivisible essence" is derived from (Türe and Ger 2016), and reaffirm the sacredness of place (Belk, Wallendorf, and Sherry 1989).

To conclude, we find that craft prosumers engage in collective custodianship, where they intentionally work to transmit their craft across time within their community and the marketplace more broadly, through the mechanisms of knowledge transfer and authenticity management.

Threat Specificity in Fear Appeals and the Role of Perceived Assimilation to Threat

Kamila Sobol, Concordia University, Canada
Marilyn Giroux, Auckland University of Technology, New Zealand

EXTENDED ABSTRACT

Fear appeals are a common communication tactic that intent to motivate compliant behavior by focusing on an undesirable outcome that consumers want to avoid (Latour and Rotfeld, 1997). Past research shows that fear appeals can be effective (Tannenbaum *et al.*, 2015), especially when the communication highlights a personally relevant threat, portrayed as severe and probable (Rogers, 1975; Witte, 1992). This serves to induce perceptions of being at high risk of attaining the distressful outcome, ultimately scaring consumers into action (Pechmann *et al.*, 2003). However, evidence also suggests that fear appeals are not always effective despite meeting these criteria (Merkel *et al.*, 2020; Milne *et al.*, 2002).

We draw from the consumer goal literature to show that fear appeal effectiveness can be optimized by manipulating threat specificity – i.e., extent to which the threat or avoidance goal is framed as a nonspecific versus specific outcome. For instance, a consumer who wants to maintain a youthful appearance can either frame the threat as getting rid of an *aging appearance* (nonspecific) or getting rid of *under-eye lines and wrinkles* (specific). In the current research, we propose that framing the threatening undesirable outcome in a nonspecific (versus specific) way is more likely to motivate compliant behaviors by inducing a sense of assimilation (versus contrast) to the feared outcome. This reasoning is consistent with past findings showing that thinking about the self in a nonspecific (versus specific) way draws attention to the similarities between the different aspects of the self-concept (Forster *et al.*, 2008; Wakslak *et al.*, 2008). The perceived assimilation evokes a sense of urgency to escape the imminent threat, motivating compliant behavior.

Study 1 aimed to confirm that fear appeal specificity impacts consumer motivation to engage in compliant behavior and to examine the mediational role of perceived assimilation. All participants (N=92) initially viewed an ad image depicting a downward perspective of gender-neutral feet standing on the scale. Threat specificity was manipulated by modifying the ad's tagline: "Have you gained a little bit of weight? We can help!" (nonspecific threat), and "Have you gained 5 pounds? We can help!" (specific threat). We then measured perceived assimilation to the undesirable outcome. Finally, to assess compliant behavior, participants reported their willing to pay (WTP) for the gym membership, using a sliding scale: $0-$60/month. The more motivated an individual is to avoid gaining weight, the more they should be willing to spend on the membership. Results revealed that participants exposed to the nonspecific (versus specific) fear appeal reported higher WTP for the gym membership (Mnonspecific=27.64, Mspecific=20.92, t(90)=2.28, p=.025), and reported higher levels of assimilation to the threat (Mnonspecific=4.83, Mspecific=4.23, t(90)=2.20, p=.030). The mediational index (PROCESS: model 4, 5,000 bootstraps: Hayes, 2017) was significant (95% CI=[.26, 5.17]), confirming that perceptions of assimilation mediated the observed effect. These findings support that nonspecific (versus specific) threats in fear appeals motivate compliant behavior by instilling a sense that one is close to reaching the feared outcome, thereby prompting immediate action.

Study 2 aimed to confirm the direction in which nonspecific (versus specific) fear appeals impact responses by adding a control condition, and examine whether threat specificity produced general motivating effects, or whether their motivating effects were limited to the ad's recommended actions. Participants (N=171) were randomly assigned to view one of three versions of the gym ad. The advertisements including the nonspecific and specific threats were the same as in Study 1. The control ad simply included an image of the gym's interior and equipment, void of any reference to a self-relevant threat. Participants were then introduced to a market research survey supposedly designed by a new potato chips brand. They were also given a bowl of chips and told to help themselves to as many chips as they wanted while completing the questionnaire. Amount consumed was calculated for each participant, and served to reflect restraint behavior. Results confirmed that threat specificity impacted self-regulation (F(1,166)=3.32, p=.039). Pairwise contrasts revealed that it was the nonspecific fear appeal that motivated restraint beyond the level of restraint exhibited by participants exposed to the specific threat (Mnonspecific=4.95g., Mspecific=7.12g., t(166)=2.58, p=.026) and control ad (Mcontrol=6.75g., t(166)=-2.57, p=.028). These findings confirm that fear appeals construed in a nonspecific (versus specific) way produce general motivation effects relating to any behavior that aims to avoid the focal threat.

Study 3 aimed to generalize our findings to another threat domain (i.e., illness). Data was collected during the COVID-19 pandemic. All participants (N=164) viewed an image depicting two hands holding each other, one belonging to a sick individual with IV tubes inserted in the wrist. Threat specificity was manipulated by modifying the campaign's tagline: "Wash your hands to prevent sickness" (nonspecific threat), and "Wash your hands to prevent COVID-19" (specific threat). Immediately after ad exposure, we assessed level of motivation to wash hands. Note that we added a relevant moderator to the model: involvement, conceptualized in our study as the extent to which participants were informed about COVID-19. We proposed that threat specificity will have a more significant impact on people who are not actively involved in keeping themselves informed and safe. Using a floodlight analysis (Spiller *et al.*, 2013), we found a significant main effect of threat specificity (t=-2.16, p=.032), as well as a significant threat specificity x involvement interaction effect (t=2.05, p=.042). The difference in hand-washing motivation between the threat specificity conditions was significant for low involvement values. These results confirm that fear appeals focusing on a nonspecific (versus specific) threat effectively motivate compliant behavior, especially among the most susceptible audience.

Our findings make several theoretical and practical contributions. First, by incorporating the notion of threat specificity, we identify a new type of message framing that has the potential to increase fear appeal's persuasive power. We also authenticate the role of perceived assimilation as an alternative mechanism, which broadens our understanding of how fear appeals impact consumer responses. Finally, our results confirm that fear appeals have the potential to help marketers mobilize consumer behavior, especially when the communication highlights a nonspecific rather than specific self-relevant threat.

The Happiness of Withholding Happiness

Bowen Ruan, University of Iowa, USA
Linzhi Yu, Fudan University, China
Bingyan Hu, Mississippi State University, USA

EXTENDED ABSTRACT

Positive life events generate happiness. Unfortunately, the happiness from most positive events fades over time as people pay less attention and adapt to their hedonic benefits (Frederick and Loewenstein 1999; Kahneman and Thaler 2006; Wilson and Gilbert 2008). This work introduces a simple yet costless method that allows people to adapt slower and thus derive more happiness from a positive event—*delaying* sharing the event with others.

We make two main predictions. First, we predict that delaying the disclosure of a positive event will generate more happiness than immediate disclosure. Second, we predict that most people tend to disclose positive events immediately, thereby spoiling the additional happiness they could have obtained from delayed disclosure. While these two predictions seemingly contradict each other, they may both be related to an inherent desire to disclose information, akin to a desire to be known (Kim, Barasz, and John 2021). When people obtain information that others do not have, they experience a strong desire to disclose it, especially if the information is about the self and is positive. Consequently, they act to satisfy the desire (Hofmann et al., 2012) and thus tend to disclose the information immediately.

If the desire is left unsatisfied, however, it draws attention to the desire and related objects (Loewenstein 1996), such as the not-yet-disclosed positive personal event (Lane and Wegner 1995; Slepian, Chun, and Mason 2017). This increased attention allows people to derive more happiness from the event. Furthermore, delaying the disclosure of the event does not mean that the person will *never* disclose it; they can still disclose it, just with a delay. As people anticipate future events and experience utility in the present from anticipation (e.g., anticipating an upcoming vacation can evoke happiness now; Loewenstein 1987), anticipating the eventual disclosure of the positive event—which will be rewarding and pleasant (Tamir and Mitchell 2012; Vijayakumar et al. 2020)—can similarly generate happiness in the moment. Taken together, we predict that delayed (vs. immediate) disclosure of a positive event will generate more happiness.

We report three studies testing our predictions and theory. Study 1 (*N* = 252) asked participants to imagine receiving a dream job offer and had three between-subjects conditions: in the *immediate-disclosure (delayed-disclosure)* condition, participants imagined that they shared the news with someone they named *immediately (seven days)* after they received the job offer; in the choice condition, participants chose to share the news immediately or in seven days, and they predicted which choice would lead to greater overall happiness in the following 21 days. All participants reported their expected happiness for each of the 21 days and indicated how strong their desire to disclose was on days 1, 7, and 8. As predicted, the average expected happiness across the 21 days was higher in the delayed-disclosure (vs. immediate-disclosure) condition, and the strength of the desire to disclose the news mediated this effect. In the choice condition, however, most participants (94%, 75/80) chose to disclose the news immediately versus in seven days, and most (95%, 76/80) predicted that immediate disclosure would lead to greater happiness.

Study 2 (*N* = 137) replicated these findings with a real hedonic experience. Participants in the study learned that they would compete in a math competition in teams of two and that if their team won, they could leave the lab 10 minutes earlier. At the end of the competition, all participants learned that their team won, but that their teammate had not learned the good news yet. Participants in the *immediate-disclosure* (*delayed-disclosure*) condition informed their teammate that they had won *immediately* (*in about 30 minutes*); participants in the choice condition could choose to do so *immediately* or *in about 30 minutes* and predicted which choice would lead to greater overall happiness during the lab session. We sampled participants' happiness and desire to disclose eight times during the lab session. Replicating previous findings, participants in the delayed-disclosure (vs. immediate-disclosure) condition felt overall happier, and the strength of their desire to disclose mediated this effect. Again, in the choice condition, most participants (49/52, 94%) chose to disclose the winning information with their teammate immediately, and most (48/52, 92%) predicted that doing so would make them happier.

Study 3 (*N* = 266) tested our theory with a seven-days longitudinal design and in a gift-giving context. Participants came to the lab on November 7, four days before "Double Eleven," one of the major shopping events in China. They learned that they could send someone a Double Eleven gift prepared by the experimenter. The study had only two between-subjects conditions, with no choice condition. In the immediate-disclosure condition, participants texted their gift recipient immediately about the Double Eleven gift and wished them a happy Double Eleven. In the delayed condition, participants sent their gift recipient a happy Double Eleven text without mentioning the gift; they were also told not to disclose anything about the gift until four days later. On November 11, participants in the immediate-disclosure condition texted their gift recipient another happy Double Eleven; participants in the delayed-disclosure condition did the same and informed their recipient of the gift. We measured participants' daily happiness from November 7 to 13. On November 7, 10, and 11, we also measured their desire to disclose the gift information. During the seven-day study period, participants in the delayed-disclosure (vs. immediate-disclosure) condition felt overall happier, and the strength of their desire to disclose mediated this effect.

These studies provide converging evidence that delayed (vs. immediate) disclosure of a positive personal event can yield more happiness, but that when given a choice, most people would choose immediate disclosure. Practically, our research provides a simple and costless strategy that can boost happiness. Theoretically, our work contributes to research on hedonic decline, interpersonal sharing, prediction bias, and recent research on the innate psychological desire to disclose information.

Analyzing eWOM on Large Social Media Platforms

Denis Utochkin, Norwegian School of Economics, Norway
Ivan Belik, Norwegian School of Economics, Norway

EXTENDED ABSTRACT

Despite WOM's growing importance, much remains unexplored when it comes to electronic word of mouth (eWOM). Prior investigations are often unable to make a distinction between "eWOM as a proxy", i.e., eWOM that is present on a platform, but is never seen by or interacted with by other consumers, and "eWOM as a market influence", i.e., eWOM with which other consumers have engaged (Babić Rosario et al., 2020).

In this study, we propose a method for identifying influential eWOM based on information about consumers' brand attitudes and network positions on large social media platforms. In doing so, we answer the call for more and better ways of identifying consumers which are of particular importance for firms' efforts to facilitate eWOM. We also address the need for separating the wheat of "influential eWOM" from the chaff of "eWOM as a proxy". Finally, we contribute to the growing body of literature that abandons surveys and Likert scales in favour of extracting valuable quantifiable information directly from rich textual data as it naturally occurs (Berger et al., 2020).

Data

Although our approach can be applied, with minimal modifications, to a wide range of social media platforms and online fora, the current implementation is fine-tuned for deployment on Reddit as one of the richest sources of eWOM. Reddit, the self-proclaimed "front page of the Internet", is the seventh largest website in the US and the 18th largest worldwide according to Alexa Internet (2021).

We analyzed twelve of the biggest Reddit communities centered around various brands, platforms, and consumption practices in the video game industry. The dataset we collected includes the entirety of activity in 12 Reddit communities between November 2018 and July 2019 with 19.01 million comments and 1.09 million submissions posted by 1.97 million users. Over the course of our analysis, we "zoom in" on a highly specific portion of the dataset, narrowing down our scope to a subnetwork of 1,613 users.

Approach

Our approach revolves around using natural language processing (NLP) methods and complex network analysis to account for consumers' preferences when modeling diffusion of eWOM across a social network. Every element of the model accepts an input and generates an output based on the data processing routines specific to that element. Brief description of all elements follows.

First, we apply a number of normalization techniques to raw data obtained from Reddit: punctuation removal, conversion to lowercase, and lemmatization (conversion of inflected forms of a word to its dictionary form). Next, we analyze the normalized textual data with Latent Dirichlet Allocation, or LDA, an unsupervised machine learning technique often used for topic discovery (Blei et al., 2003). Additionally, we conduct sentiment analysis with VADER, an algorithm that uses a set of dictionaries and syntactic rules for estimating sentiment (Hutto & Gilbert, 2014). The raw data are then transformed into a graph, or network of Reddit users. Specifically, we transform our dataset into a large-scale directed network (Newman, 2018, p. 110), where nodes in the network are defined as individual Reddit accounts and directed asymmetric links between nodes represent accounts' interrelations.

To see beyond the purely topological features of the network and be better equipped for making predictions about its functioning in real-world conditions, we account for nodes' percolation states (Campbell, 2013; Newman, 2018, p. 569), which we define in the context of the study as the probability of an individual engaging in eWOM about a brand-centric topic and compute based on the user's sentiment about that topic. Finally, we model dynamic propagation of eWOM throughout Reddit by simulating repeated interactions between users in different user network clusters across a series of rounds, and measure the speed of eWOM diffusion for each round.

Results

We test our approach by applying it to one week of activity by 360,495 users in 12 subreddits. In search for the optimal LDA model, we conducted a grid search of various hyperparameter values, estimating C_V coherence, a state-of-the-art synthetic measure of topic model quality (Röder et al., 2015; Syed & Spruit, 2017), for each model. The highest-scoring models were manually inspected for topic interpretability. The final model was able to delineate discussions about various video game consoles. We chose to focus on the topic centred around consoles produced by Nintendo (for illustrative purposes). The resulting network is a fraction of the original, with only 1,613 nodes, but is of considerably higher relevance as it is the result of homing in on a potential topic of interest, made possible by the inclusion of valuable information about the content and emotional valence of discussions occurring within the network. Following the rest of the steps in our model, we were able to identify optimal nodes for producing influential eWOM, outperforming simpler, "naïve" methods.

Conclusion

A key methodological innovation of our work lies in the context-agnostic eWOM diffusion model which is capable of forecasting dissemination of information in a real-world network of users. Our model accounts not only for the overall structure of the communities, but also for attitudes of their members. This approach allows for a more direct investigation of consumer behavior compared to the more restrictive methods such as surveys, small-scale experiments etc. (Berger et al., 2020; Kumar et al., 2018).

Do the Ends Justify the Means? Understanding Moral Reactance to "Poverty Porn"

Shannon Duncan, The Wharton School, University of Pennsylvania, USA
Deborah Small, University of Pennsylvania, USA
Emma Levine, University of Chicago, Booth School of Business, USA

EXTENDED ABSTRACT

Aid organizations and the media often use graphic imagery of people living in poverty as a means of gaining attention, sympathy, and support. Such emotionally evocative imagery is common because it is typically more effective than more affect-poor information (Nisbett and Lee, 1980; Small, Loewenstein, and Slovic, 2007; Small and Verrochi, 2009).

Yet some commentators and philosophers worry these tactics are harmful. In fact, to emphasize their harm, critics have referred to these tactics as 'poverty porn' (Collin, 2009; Dortonne, 2016; Roenigk, 2017; Schaffer, 2016). Criticisms about 'poverty porn' come in different forms. One key concern is graphic images of poverty exploit and objectify those in need. These images, it is argued, define recipients of aid by their suffering—often depicting them at their most vulnerable and heart-wrenching moments. Certain depictions of poverty can also promote negative stereotypes (i.e., all of Africa is poor) and ideas about white saviorhood, for example, by celebrating Western celebrities helping aid recipients in developing countries (Rearick, 2017). Another concern is that these images can portray an exaggerated or even false representation of life under poverty (Roenigk, 2017; Schaffer, 2016).

Because these criticisms vary in kind, we sought to unpack the tactics of 'poverty porn' and to investigate lay perceptions of the abovementioned criticisms. Specifically, we examine if and when people see the ends (i.e., greater support for important causes) as justifying the means (e.g., graphic imagery that may involve exploitation or deception). Across six studies, we isolate specific 'poverty porn' tactics and ask participants to judge their acceptability. We find people are not particularly disturbed by tactics involving exploitation, but they are relatively more disturbed by tactics that involve blatant deception.

In studies 1 and 2, participants judge the appropriateness and acceptability of different poverty porn tactics: 'staging a photograph', 'stereotyping', 'showing an aid recipient's worst moments', 'using a white savior', and 'using an actor'. Across both studies, results indicate participants are significantly more bothered by methods that deceive the audience (i.e., staging a photo or using an actor) than those that are a true representation but may cause some other harm to the group being portrayed (i.e., stereotyping, using white saviors, or showing worst moments). These results run counter to what the media and other experts criticize in their arguments against 'poverty porn' tactics; they typically emphasize the exploitative and objectifying nature of these tactics as the biggest problem (i.e., Collin, 2009; Dortonne, 2016; Rearick, 2017; Roenigk, 2017; Schaffer, 2016).

Study 3 examines the question of whether reactions to these tactics would change if the intent of the advertisement was profit (i.e., self-interest) rather than helping the aid recipients. It's possible harming people living in poverty (through exploitation) in order to help them seems justifiable but harming them in order to increase profitability would seem unjustifiable. We find deception is equally penalized regardless of whether the intent is to provide aid or profit. However, neutral, manipulative, and exploitative advertisements were all rated as significantly less acceptable when the intent was profit. This results in a significant interaction such that the differences between judgments as a function of intent disappear when the tactic is deception. In other words, deception is never justifiable but exploitation and other tactics are more so when there is a good intent.

In studies 4 to 6, we explore why deception is penalized more than other 'poverty porn' tactics. Study 4 disentangles one possible explanation for our effect. It is possible participants judged non-deceptive tactics as more acceptable because they did not view them as particularly harmful. Therefore, in study 4, we make these harms salient by describing them as "problematic: we compare 'poverty porn' tactics that are problematic because they either a) deceive the audience or b) exploit and objectify the aid recipients. We find that even when harms are directly spelled out, participants rate tactics that deceive the audience as less acceptable than tactics that exploit aid recipients.

Our prior experiments focus on deception as one specific tactic that harms the audience (i.e., by manipulating consumers into spending their money in a way they would not have otherwise). In study 5, we test whether consumers are averse to the deception per se, or whether they are averse to the harms associated with it (i.e., manipulation without explicit deception). To do so, we compare deception to non-deceptive manipulation that has identical consequences (i.e., eliciting support). Results show deception is rated as significantly less acceptable than manipulation, indicating consumers are particularly averse to the act of deception, rather than the harm associated with it. Finally, Study 6 attempts to further unpack reactance to deception by separating the intent to deceive from the end result of misrepresentation. We compare advertisements that misrepresent a population's level of need to an equal extent, but differ in their use of deception (e.g., by staging a photo of a person in need versus using a candid photo of one person in need, but neither is representative of the poverty level in the population). We find that the deceptive advertisement is seen as particularly unacceptable, providing further evidence that the act of deception itself taints judgments.

Across 6 studies, we find consumers judge 'poverty porn' methods that deceive the audience as less acceptable than those that exploit or objectify aid recipients. We further unpack when consumers view such tactics as exploitative as well as why deception is uniquely troubling.

Understanding lay perceptions of 'poverty porn,' and deception in particular, has important implications. First, this work bridges philosophy and consumer psychology to foster an understanding of what prosocial marketing tactics will be praised versus admonished by consumers. Second, our work expands our understanding of deception by showing lying for prosocial purposes is not always rewarded (i.e., Lewis et al., 2012; Levine and Schweitzer, 2014; 2015). When it comes to charitable organizations using deception, the ends do not always justify the means.

4D: The Four Dimensions of Anthropomorphism – Manipulations and Measures

Alisa Wu, Columbia University, USA
Pankaj Aggarwal, University of Toronto, Canada

EXTENDED ABSTRACT

Anthropomorphism refers to the tendency to attribute human-like characteristics, intentions, and behaviors to nonhuman objects (Aggarwal and McGill 2007). Extant anthropomorphism research has employed a number of different manipulations to humanize nonhuman objects (name, first-person conversation, etc.). The unstated premise behind employing these different manipulations appears to be that anthropomorphism is a unidimensional construct and that these manipulations all elicit that dimension similarly. Furthermore, prior work on anthropomorphism also employs many different scale items to assess the effectiveness of these manipulations. However, there has been little effort to examine if these different manipulations and different scale items respectively activate and assess one or multiple dimensions of humanness.

This current research endeavors to examine if the different manipulations activate different dimensions of humanness and assess the extent to which the different scale items tap into them. We first conducted a meta-analysis covering 27 published papers with 97 studies that reported complete details of their manipulations and manipulation check items. Results of our systematic review confirm our conjecture that extant papers on anthropomorphism regard anthropomorphism as a unidimensional construct, and that the field seems to be using different manipulations interchangeably. Furthermore, there are no consistent manipulation check items, and once again, there appears to be an assumption that these different items tap into the same unidimensional underlying aspect of humanness.

Study 2 aimed to test if the anthropomorphism manipulations actually make salient different dimensions of humanness. Participants were randomly assigned to one of five different conditions (one control and four anthropomorphism conditions, including name, personality, imagination, and conversation). Participants evaluated a (humanized or objectified) car on 26 anthropomorphism manipulation check questions used across previous studies. An exploratory factor analysis was conducted using principal component analysis (PCA) with varimax rotation to identify different anthropomorphism dimensions. An examination of the RMSEA () and SRMR () showed that a four-factor model was appropriate. The four factors manifested four dimensions of anthropomorphism: The first, *personification* factor, reflects participants' general impression that the product has some humanlike features. The second, *personality* factor, refers to specific personality traits that participants think the product has. The third, *agency* factor, measures the extent to which participants believe that the product has a mind of its own. The fourth, *empathy* factor, assesses the extent to which participants share the product's perspectives and feel connected to it.

Further analysis showed that the four anthropomorphism manipulations resulted in different scores on each anthropomorphism dimension. For the personification and agency dimensions, the imagination and conversation conditions scored higher than the other three conditions (), which didn't differ from each other (). For the personality dimension, the imagination condition scored significantly higher than the other four conditions (). The conversation condition scored significantly higher than the name, personality, and control conditions (), which didn't differ from each other (). For the empathy dimension, the imagination condition scored higher than all the other four conditions () which didn't differ from each other (). In sum, results of study 2 show that different manipulations elicit different dimensions of anthropomorphism, and that different scale items assess these different dimensions more or less successfully.

If different anthropomorphism manipulations manipulate different aspects of humanness, then consumers should respond more or less positively to a brand that employs these manipulations. Study 3 tested this prediction under a scenario of product wrongdoing. All participants read about a new-to-the-market orange juice brand. Participants were randomly assigned to one of the four conditions, including a control and three anthropomorphism conditions (name, imagine, conversation). All participants answered the manipulation check questions as used in study 2 with a few minor changes. Next, participants were asked to imagine that they consumed a pack of the orange juice bought a week earlier, and then got sick about an hour later. Participants then completed a number of brand evaluation measures. A Principal Component Analysis confirmed four anthropomorphism dimensions: personification, personality, agency, and empathy. Replicating the results of (Puzakova et al. 2013), the evaluation of the brand was less positive when it was anthropomorphism (averaged across the four conditions). However, further examination revealed that the results were more nuanced. Although participants' brand evaluations were lower in the name condition compared to control (), the imagination and conversation conditions were not different from the control condition (), suggesting that the specific anthropomorphism manipulations affected whether or not the brand would be penalized. The effect was mediated by empathy: manipulating anthropomorphism through imagination and conversation increased consumers' empathy towards the brand resulting in lower likelihood to punish the brand for wrongdoing.

To further distinguish between the imagination and conversation manipulations, Study 4 employed a hypothetical out-group stationery brand. We predicted that the conversation condition would make the outgroup brand even more of a separate individual since the brand would be 'talking' to the consumer as a distinct entity, resulting in less positive evaluation. However, the empathy associated with imagination manipulation would result in more positive evaluation of the same outgroup brand. The procedure was similar to that of study 3. We recruited U.S. participants and first primed their *American identity* to make the outgroup aspect of the Chinese brand particularly salient (White and Dahl 2007). Results showed that participants in the imagination condition trusted the brand more and evaluated it more positively than in the other two anthropomorphism conditions (). A series of mediation analyses showed that the personification sub-scale mediated the effect of anthropomorphism on brand-related downstream variables.

CONCLUSION

Our research finds that different anthropomorphism manipulations work distinctively by making salient four dimensions of humanness: personification, personality traits, agency, and empathy. We also show that different manipulations result in different downstream consumer reactions to an out-group brand and a product wrongdoing. Furthermore, different scale items are in fact different, tapping more or less successfully into the different dimensions of humanness.

Overall, when anthropomorphizing products and brands, marketers should choose the appropriate manipulation to ensure that the 'right' human dimension is made salient and the 'desired' consumer response received.

Old is Not Always Gold: The Role of Temporal Congruence in Shaping the Downstream Effects of Firm's Longevity

Shweta Jha, Indian Institute of Management, Indore, India

Sudipta Mandal, Indian Institute of Management, Indore, India

EXTENDED ABSTRACT

Marketers often employ a firm's year of establishment to communicate the business's longevity (Desai, Kalra, and Murthi 2008). Prior literature suggests that older firms are evaluated more favorably due to their perceived credibility and quality (Zhang, Kashmiri, and Cinelli 2019), with a firm's longevity acting as an extrinsic cue.

Nonetheless, contrary to the dominant belief that longevity is always beneficial, in this research, we contend that this may not necessarily be so, especially when the benefit offered is incongruent with firm's longevity. For example, we argue that when an older automobile firm offers self-control (e.g., eco-friendly) vis-à-vis indulgence (e.g., luxury) oriented benefits, it may negatively impact purchase evaluation. Likewise, when an older culinary firm offers self-control (e.g., healthy) vis-à-vis indulgence (e.g., tasty) oriented benefits, it is more likely to impact purchase evaluation negatively. Therefore, in this research, we aim to examine how and why consumers associate a firm's longevity with benefits-oriented to indulgence ("taste" and "luxury") vs. self-control ("health" and "eco-friendly") and its downstream effects.

The association of indulgence (vs. self-control) oriented benefits to old (vs. young) firms and its downstream effects can be explained from three perspectives: the consumer, the regulators, and the firm. We suggest that product categories evolve such that the benefits move from the core and basic product needs to indulgent needs and subsequently to self-control needs that are focused on the long-term well-being of the self and the society.

A theoretical backing for this comes from the hierarchy of needs (Maslow 1970), which explains how consumers tend to move from safety needs to rich resources (Kivetz and Simonson 2002) and next toward the self-actualization needs, which are more about self-control (Paschen, Wilson, and Robson 2020). Another theoretical argument for this comes from the product life cycle theory that explains how product benefits evolve over the life cycle of the product category (Vernon 1992).

In a pilot study ($N = 31$), we found that consumer expectations from products shift from the basic needs when the products are introduced to indulgent needs and later to self-control-oriented needs for four existing product categories and two futuristic product categories.

Literature suggests that indulgence-oriented benefit from food is "tasty," a more primitive and tangible consumer expectation. Tasty food is energy-dense containing a higher content of sugar, salt, and various other fatty elements (Breslin 2014; Papies and Veling 2013). As humans evolved, their lifestyles changed. With the shift toward a more sedentary lifestyle and an increase in associated ailments (Larsen 2003), consumers' consciousness of healthy eating habits has also increased. Similarly, the automobile industry's evolution indicates that consumers initially demanded indulgence-oriented benefits (comfort/luxury) and only much later opted for eco-friendliness (Damiani, Deregibus, and Andreone 2009) due to regulatory pressures. Further, the evidence from policymaking and regulation suggests that as product categories have evolved, the policymaking and regulatory intervention has happened at a later stage.

Also, older firms, as such, have in the past offered products that satiated indulgent needs, while younger firms, because of the reasons cited above, are more likely to offer self-control-oriented needs. Though older firms evolve with time, their core offering remains unchanged (Demir et al. 2017). Moreover, older firms have well-defined associations due to their established expertise (Olsen, Slotegraaf, and Chandukala 2014). However, because of their low longevity, younger firms are not perceived to have the expertise; hence, the effect might be weaker.

Additionally, extant literature suggests a negative correlation between taste and health and between luxury and eco-friendliness (Raghunathan, Naylor, and Hoyer 2006; Beckham and Voyer 2014). Therefore, we hypothesize;

Hypothesis 1:   *Consumers associate indulgence (vs. self-control) oriented benefits with old (vs. young) firms.*

Hypothesis 2:   *When the old (vs. young) firm is positioned along indulgence (vs. self-control) oriented benefits, it is highly likely to have a positive purchase evaluation. However, this effect might be weaker for younger firms.*

Due to their longevity, older firms are more likely to have knowledge, experience, and skills in offering benefits that were temporally congruent to these firms' founding time. Prior studies suggest that expertise enhances fit (Choi and Rifon 2012) through the "match-up" effect (Till and Busler 2000). The "match-up hypothesis" (Kamins and Gupta 1994) posits that perceived expertise in offering specific benefits enhances congruence (Lee and Koo 2016) between a brand and its offered benefits, in turn influencing brand evaluation (Gong and Li 2017; Jacob, Khanna, and Rai 2020). Formally,

Hypothesis 3:   *The impact of a firm's longevity and association with indulgence (vs. self-control) oriented benefits on consumers' purchase likelihood is serially mediated by perceived expertise followed by congruence.*

Hypothesis 4:   *The indulgence (vs. self-control) oriented benefits moderate the mediating effect of perceived expertise and congruence on the relationship between the firm's longevity and purchase likelihood.*

We conducted five studies to validate our findings, all of which were supported. Studies 1A and 1B tests H1 using a single-factor (firm's longevity: old/young) between-subjects design for two different product categories. Study 1A established the association with a single attribute for "tasty" and "healthy," whereas study 1B did it with multiple attributes (pre-tested) for "luxury" and "eco-friendly." Unlike studies 1A and 1B, in study 1C, the perceived benefit was the independent variable, and the type of firm (old/young) was the dependent variable. We tested H1 in study 1C using a 2 (firm's longevity: old/young, between-subjects) X 2 (benefits: indulgence – luxury/ self-control - eco-friendly oriented benefits, within-subjects) mixed design. Study 2 tests H2 using a 2 (firm's longevity: old/young) X 2 (benefits: indulgence – luxury/self-control - eco-friendly oriented

benefits) between-subjects design. Finally, study 3 tests H3 and H4 using 2 (firm's longevity: old/young) X 2 (benefits: indulgence – tasty/self-control - health-oriented benefits) between-subjects design and showed a significant moderated serial mediation.

This is possibly the first work to demonstrate that the positive impact of longevity is contingent on the fit with its perceived benefits. It adds to the benefits evolution literature by elucidating the change in benefits offered by firms from basic to indulgence and self-control-oriented benefits. For practitioners, this research emphasizes the need to judiciously exploit a firm's longevity in alignment with the benefits offered.

Experiential Versus Material Purchases: A Cultural Identity Perspective

Xiaodong Nie, Tulane University, USA
Wilson Bastos, CATÓLICA-LISBON School of Business & Economics, Portugal
Zhiyong Yang, University of North Carolina at Greensboro, USA
Narayan Janakiraman, University of Texas at Arlington, USA

EXTENDED ABSTRACT

Researchers are increasingly interested in two domains where consumers spend their discretionary incomes—experiences and material objects. Work in this domain has focused primarily on outcomes—e.g., social relationships, happiness (e.g., Van Boven and Gilovich 2003). In this research, we examine the experiential-material phenomenon from a different angle—that of what *predicts* experiential and material purchases. Specifically, we investigate the potential influence of a consumers' local/global identity on their preference between experiential and material purchases.

One important consequence of globalization is that consumers tend to absorb, to various degrees, two distinct identities (i.e., a local and a global identity), which reflect how strongly they associate with the local and global communities, respectively (Arnett 2002). Individuals with a strong local identity [locals] remain faithful and respectful of local traditions, have strong interests in local events, and identify with people from their local community, whereas those with a strong global identity [globals] favor globalization, view the world as a global village, and identify with people from the whole world. Accordingly, we propose that an important distinction between locals and globals is their different needs for relationship strength—conceptualized as the extent to which individuals desire to strengthen their relationship with others. Specifically, we posit that locals tend to have greater need for relationship strength than do globals. This is because locals often stay in and grow attached to their communities (Strizhakova and Coulter 2019), which motivates them to stay in touch with and ensure the continuity of future contacts. Differently globals view the world as a "global village". They like to form open, mobile, and transient relationship with others (Oishi 2010)—i.e., their relationships are more fluid.

In the context of purchase type (experiences vs. objects), this is relevant because experiences are known to possess stronger socialization aspects. Specifically, experiences are more often consumed with others (Caprariello and Reis 2013) and more conducive to interpersonal interactions via conversations (Bastos and Brucks 2017) than objects. Therefore, experiential purchases should be particularly appealing to people seeking stronger social ties. Thus, we propose that consumers with greater need for relationship strength—locals—will be more likely to acquire experiential versus material purchases. Differently, global's lower focus on relationships strength should make them indifferent.

Study 1. We collected field data to examine our focal prediction. First, the amount displayed in the receipts of shoppers in two different stores were photo-recorded. One of the stores mainly sell an experiential purchase (toys; N=52) and another a material purchase (hats; N=57). Further, we measured participants' local-global identity (Tu et al. 2012). As expected, shoppers with a stronger local identity spent significantly more on toys than on hats (β=0.33, t(105)=2.78, $p<.01$), whereas shoppers with stronger global identity spent statistically indistinguishable amounts (β=-0.03, t(105)=-0.29, p=.77).

Study 2. Keeping the focal purchase constant (a BBQ grill) and manipulating only how it was framed to participants (as an experience versus object), this study manipulates local-global identity to reexamine the focal effect and test the predicted mechanism. Participants (N=228) were randomly assigned to a 2(identity: local vs. global)×2(purchase: experiential vs. material) between-subjects study. We manipulated local/global identity following existing procedure (Ng and Batra 2017). Participants then were presented with information about the grill focusing on either its experiential or material properties. We then measured participants purchase intention and need for relationship strength. As expected, locals reported greater purchase intention for the experientially- (M=4.90) than the materially-framed grill (M=4.06; F(1, 224)=8.87, $p<.01$), whereas globals showed indistinguishable purchase intention ($M_{\text{experientially-framed}}$=4.08 vs. $M_{\text{materially-framed}}$=4.20; F(1,224)=0.16, p=.69). Need for relationship strength mediated this effect (.16, 95%CI [.004,0.414]).

Study 3. This study retests the mechanism with a moderation-of-process procedure. Participants (N=656) were randomly assigned to a 2(identity: local vs. global)×2(purchase: experiential vs. material)×3(benefit-of-relationship-strength: suppressed, control, enhanced) between-subjects design. We expected that enhancing the desire-for-relationship-strength would increase global's preference for experiential purchase as they have a lower need for relationship strength to begin with. However, such effects should not emerge for locals (a "ceiling effect"). Similarly, when the desire-for-relationship-strength is reduced, with locals (but not globals) reducing their preference for experiential purchases. No variation was expected for material purchases given their predominant lack of socialization aspects.

The identity manipulation was the same as in Study 2. Benefit-of-relationship-strength was manipulated by varying the degree of benefit-of-relationship-strengh. Participants in the control condition were asked to review their daily routine and write down their thoughts. Next, participants viewed information about the grill as an experience or an object, as in Study 2, and completed the measure of purchase intention. As expected, when benefit-of-relationship-strength was enhanced, globals showed a greater purchase intention for the experientially-framed BBQ (M=5.04) than in the control condition (M=4.14; F(1,199)=10.19, $p<.01$). Locals showed similar high purchase intention across the two conditions (M_{enhanced}=5.17 vs. M_{control}=5.16; F(1,199)<.01, p=.95). When benefit-of-relationship-strength was suppressed, locals showed lower purchase intention for the experientially-framed grill (M=3.80) than in the control condition (M=5.16; F(1, 190)=20.14, $p<.001$). Globals showed similarly lower purchase intention across the two conditions ($M_{\text{suppressed}}$=3.99 vs. M_{control}=4.14; F(1,190)=0.19, p=.67). No such effect was observed for the materially-framed grill. We also replicate previous findings in the control condition that locals had greater purchase intention toward the experientially-framed (M=5.16) than the materially-framed grill (M=3.79; F(1, 213)=18.70, $p<.001$). However, globals showed no difference in purchase intention across the two conditions ($M_{\text{experientially-framed}}$=4.14 vs. $M_{\text{materially-framed}}$=4.25; F(1,213)=0.14, p=.71).

Consistent with our theorization, globals had a greater need for relationship strength in the benefit-of-relationship-strength enhanced (M=5.36) than in the control condition (M=4.65; F(1, 98)=6.41, p=.01). However, locals' need for relationship strength did not differ across benefit-of-relationship-strength enhanced (M=5.43) and control (M=5.54; F(1, 101)=.35, p=.56) conditions. Additionally, locals had a lower need for relationship strength in the benefit-of-relationship-strength suppressed (M=4.47) than in the control (M=5.54; F(1,

109)=17.90, *p*<.001) condition, whereas globals' need for relationship strength did not differ in the benefit-of-relationship-strength suppressed (*M*=4.79) and control (*M*=4.65; F(1, 81)=.17, *p*=.68) conditions.

The findings in this research contribute to the experiential versus material purchase and identity literatures. We identify a reliable *antecedent* of consumers' inclination to acquire experiential versus material purchases—consumers' local-global identity. This is an important addition to a literature that has noticeably focused on *outcomes* of the two purchase types. Thus, our findings bring a fresh perspective to the experiential consumption literature. Further, we show the critical role of need for relationship strength in explaining consumers' purchase intention for experiential over material purchase. We expect this research to open various avenues for future inquiries in the aforementioned two literatures.

Making Up for Failure: A Simple Nudge to Improve Goal Persistence

Shannon Duncan, The Wharton School, University of Pennsylvania, USA
Marissa Sharif, The Wharton School of the University of Pennsylvania, USA

EXTENDED ABSTRACT

Prior research has found that when small failures occur during goal pursuit (i.e., eating a dessert or skipping the gym) consumers often believe that there is a low chance of reaching their larger goal (e.g., losing weight/staying fit), leading them to completely abandon it (i.e., Cochran and Tesser, 1996; Soman and Cheema, 2004). If feeling like one has failed by engaging in goal inconsistent behavior on the path to goal achievement leads people to be more likely to quit, it may be that encouraging consumers to make up for their failures will increase the likelihood that they reach their goal. We demonstrate that this simple, cost-free nudge can help protect consumers against demotivation due to small failures and improve consumers' overall goal persistence.

In Study 1, we conducted a survey of 303 people on Amazon Mechanical Turk to gauge lay intuitions for the making up for failure intervention in the exercise domain. Results indicated that consumers believed they would be more likely to use and be more motivated to work out by an app that offers a making up for failure functionality than one that does not (likely to use: $t(302) = 5.99$, $p < .001$; motivated to work out: $t(302) = 5.35$, $p < .001$)

In Studies 2 and 3, consumers engaged in real goal behavior. They were given a goal and reported their progress every day for a week using an interface that included a bar graph presenting their progress with one bar per day. Control condition participants simply inputted their minutes studied and viewed their progress. Make-up condition participants were given an additional functionality: they could make up for their past failure. For instance, if they failed their goal on day 2, and did extra minutes on day 3, they were able to reallocate those extra minutes from day 2 to day 3. In Study 2, two hundred and seventy people from Amazon Mechanical Turk participated. Participants were randomly assigned to one of the two experimental conditions: the control or the make-up condition. All the participants were given the same goal: studying a new language for 20 minutes a day using a free app they downloaded on their phone.

Consistent with the idea that encouraging participants to make up for failure helps goal pursuit, participants in the make-up condition ($M = 98.33$, $SD = 64.25$) studied more minutes over the course of the 7-day study than participants in the control condition ($M = 79.61$, $SD = 59.99$; $B = 18.78$, $t(268) = 2.48$, $p = .014$). While daily performance declined over time across the board, there was no interaction between time and condition; the make-up condition always performed significantly better than the control condition ($B = -0.0004$, $t(1515) = -0.003$, $p = 0.99$).

Study 3 was largely the same as Study 2 with a few changes. Two hundred and forty-nine participants were recruited from a large Northeastern university's behavioral lab. In this study, participants were asked to work out for 28 minutes a day using a free app they downloaded on their phone. Participants were randomized into one of three experimental conditions: the control, the make-up, or the frontload condition. This new front-load condition allowed participants to front-load for future failure. For instance, they could work out 56 minutes on day 2 and reallocate those minutes to day 3, allowing them to skip a workout on day 3.

We found that those who were encouraged to make up for their past failure ($M = 89.89$, $SD = 87.39$) worked out marginally significantly more than those in the control condition ($M = 64.29$, $SD = 80.64$; $B = 25.59$, $t(247) = 1.83$, $p = .06$). Unlike the make-up condition, the front load condition ($M = 74.55$, $SD = 99.02$) did not vary significantly from the control condition ($B = 10.25$, $t(247) = 0.74$, $p = .46$), nor did it vary significantly from the make-up condition ($B = -15.34$, $t(247) = -1.11$, $p = .27$). These results suggest *when* consumers are nudged to make up for their failures affects their goal persistence. Unlike in Study 2, there was a significant time and condition interaction ($B = -0.73$, $t(1504.55) = -2.59$, $p = .01$), such that the make-up condition's advantage over the control condition declined over time. The difference in this effect across the two studies may indicate that making up for failure is more effective for shorter or easier goals over time (e.g., 20-minute goal in Study 2 vs. ~30-minute daily goal in Study 3).

Across three studies, we find that encouraging people to make up for their failures is a desirable intervention (Study 1) that can help improve goal persistence (Studies 2 and 3). Our work helps fill a gap in the goals and motivation literature by showing one way that consumers can be encouraged to persist after failure. Furthermore, it demonstrates a simple low-cost nudge that companies can implement to help consumers achieve their goals.

"Yes, I Recall," But "No, I Don't"? – Why Negating (vs. Affirming) Brand Attributes Impairs the Brand's Recall Memory

Sudipta Mandal, Indian Institute of Management, Indore, India
Arvind Sahay, Indian Institute of Management, Ahmedabad, India
Sanjeev Tripathi, Indian Institute of Management, Indore, India

EXTENDED ABSTRACT

Negations, i.e., use of a "no" or a "not" are frequently used to communicate salient brand attributes (e.g., FedEx's advertisement, "When there is no tomorrow," or Kraft's slogan for the DiGiorno brand of frozen pizza, "It's not delivery – it's DiGiorno.") This research examines implications of such "brand-attribute" negation on the recall memory of brands when an attribute is negated. Specifically, we investigate the following: does "brand-attribute" negation impair recall memory of the brand? What is the underlying mechanism leading to such impaired brand recall memory? And, the boundary condition of such effects. We demonstrate that negation activates negation-related semantic concepts, which through a spreading activation mechanism (Collins and Loftus 1975), attenuates consumer's general "judgment of importance" and impairs brand recall memory. We contribute to theories of negation and judgment by advancing our understanding of the mechanism through which negation is construed and processed by consumers.

Consumer researchers have conceptualized the organization of brands and brand-related information (e.g., brand attributes) in memory, using the Human Associative Memory (HAM) theory (Anderson and Bower 2014) that represents declarative knowledge as a network of concept nodes connected by associative links. When a specific knowledge structure is primed, the central node and related nodes are activated. This activation propagates along the links of the network to nodes of all related concepts. Such brand associations influence consumers' product evaluations and choices (Van Osselaer and Janiszewski 2001). Within the HAM tradition, the association strength between a cue (e.g., brand attribute) and an outcome (e.g., brand) and the activation of an outcome in the presence of a cue is strengthened each time the cue and the outcome co-occur.

Research shows that negation is associated with cognitive inhibition and prevents activation of the core concept or schema being negated (Carpenter and Just 1975; Giora et al. 2007; Kaup and Zwaan 2003; MacDonald and Just 1989). Consequently, when a brand's attribute is negated, cognitive inhibition prevents activation of the associative link between the brand and the attribute preventing the two from co-occurring severing the associative link between the brand and attribute nodes, thereby impairing brand memory. Further, since cognitive inhibition is unique to negation, its opposite action, i.e., affirmation, would not impair brand memory. Thus,

Hypothesis 1:   *Brand attribute negation (vs. affirmation) impairs brand recall memory.*

Research has shown that both intrinsic and extrinsic motivation are critical factors that determine how individuals process information and formulate their attitudinal and behavioral responses (Darke, Chattopadhyay, and Ashworth 2006). Thus, memory may be influenced by the consumer's motivation to remember while processing information. In the context of brands, one such intrinsic motivation is brand love (Batra, Ahuvia, and Bagozzi 2012)the authors investigate the nature and consequences of brand love. Arguing that research on brand love needs to be built on an understanding of how consumers actually experience this phenomenon, they conduct two qualitative studies to uncover the different elements ('features'. Brands that

evoke greater "brand-love" vis-à-vis those that do not are more deeply embedded in the consumer's memory, motivating the consumer to remember the brand, irrespective of whether the brand attribute is negated or affirmed. Similarly, an extrinsic motivation, such as a monetary reward, should motivate the consumer to remember the brand, irrespective of brand attribute negation or affirmation. Formally,

Hypothesis 2:   *When a consumer's brand-love is low (vs. high), there is a significant (vs. no significant) difference in brand recall memory under brand attribute negation vs. affirmation.*

Hypothesis 3:   *When consumers are extrinsically motivated by the presence (vs. absence) of a financial incentive, there is no difference in brand recall memory under brand attribute negation vs. affirmation.*

What is the mechanism underlying brand-attribute negation induced impaired brand memory? The HAM model depicts consumer memory as episodic and semantic traces of incoming information comprising schemas or knowledge structures (Kronlund, Whittlesea, and Yoon 2008). We argue that when an attribute is negated, the central and related nodes associated with negation are activated. This facilitates related information processing through 'spreading semantic activation' such that negation-related semantic concepts are stimulated above threshold more quickly than if not primed (Collins and Loftus 1975). This increases the accessibility in memory of specific semantic concepts that negation-related experiences exemplify (e.g., 'oppose,' 'contradict,' etc.) We propose that such cues prevent activation of the associative link between the brand and attribute nodes and exclude such associations from the consumer's immediate scope of consideration. Such exclusion from one's immediate scope of consideration triggers lower judgment of importance toward the negated concept and also induces generally lower judgments of importance in an individual's mind. Being cognitive misers, humans disregard the unimportant and forget under negation. Thus,

Hypothesis 4:   *Accessibility of negation-related semantic concepts mediate effects of explicit negation on consumer's judgment of importance and their brand recall memory.*

Thus, H4 proposes that attribute negation (vs. affirmation), through activation of negation-related semantic concepts, induces lower judgments of importance, leading to impaired brand recall memory. Next, we test our hypotheses.

Five studies validated our hypotheses, all of which were supported. Study 1 tests H1 with real brands that respondents were familiar with, using a one-way within-subjects design with attribute framing (negation/affirmation) as the independent variable. Each attribute emphasized a positive aspect of the brand but was framed either using negation or affirmation. Study 2 tests H1 and H2 with real consumers through a mall-intercept study with real brands using a 2 (brand-love: high/low) x 2 (attribute-framing: negation/affirmation) two-way within-subjects design. Study 3 tests H1 for both

familiar and unfamiliar brands using a 2 (brand familiarity: familiar/unfamiliar) x 2 (action: affirmation/negation) mixed design with familiarity as between-subjects and action, within-subjects. Study 4 tests H3 using a 2 (motivation: high/low) x 2 (action: affirmation/negation) mixed design, with motivation as between-subjects and action as within-subjects. Finally, study 5 tests H4 by showing that the accessibility of negation-related semantic concepts mediates the effect of explicit negation on consumer's judgment of importance and subsequent brand recall memory.

The principal theoretical contribution of our work is in investigating the mechanism leading to brand-attribute negation-induced forgetting. This has implications for brand managers, who communicate essential product attributes through carefully constructed messages. The findings suggest that managers need to communicate attribute information using affirmation rather than negation frames and that judicious use of affirmation (vs. negation) frames to convey the same information may be beneficial to marketers.

The Video-aperitif During Lockdown in France: (Re)Defining Situation and Context of Online Consumption

Thomas Stenger, University of Poitiers, France
Axelle FAURE-FERLET, Le Mans University, France

EXTENDED ABSTRACT

The aperitif is an alcoholic drink taken before a meal as an appetizer, but also a crucial part of the French culture and social life (Corbeau and Poulain 2002). The term *apéro* then refers less to the pre-meal beverage itself than to the moment, social and symbolic aspects of the consumption practice. The aperitif is a moment of food sociability, which can be broken down into four ideal-types: the spontaneous aperitif, the home invitation for only an aperitif, the aperitif invitation as prelude to a meal at home, and the aperitif-dinner (Poulain 2005).

From the very beginning of the first lockdown in France (implemented between March 17 and May 11, 2020), the press has widely reported on a massive phenomenon: online video-apéro, under the terms *Skypéros*, *WhatsAppéros* or even *Coronapéros*, either referring to the platforms or the virus. This research aims to understand this new consumption practice both online and at home (Epp, Schau, and Price 2014) as an opportunity to better distinguish the concepts of consumption situation and context.

The concept of situation has been at the heart of social sciences since Goffman's seminal text (1964) and became central to marketing research (Belk 1974, 1975, Punj and Stewart 1983). The invitation to take better account of the context to avoid the pitfall of micro-social approaches is more recent (Askegaard and Linnet 2011). The situation is determined by the triptych: participants, spatial and material elements, temporal dimensions (Michaud-Trévinal and Stenger 2018). The situation is lived and experienced, subjective. It fundamentally depends on the context (or framework; Goffman 1974).

The context corresponds to the way the situation is lived, to the interpretation structures, to the cognitive patterns, which each person uses to understand the events that occur (Girin 2016). Any experience can intertwine itself to several frameworks–either primary or transformed frameworks (Goffman 1974)–which are related to each other. Primary frameworks can be natural, involving the laws of nature, or social, involving human intentions. The framework is transformed when it resembles a primary framework but has a different meaning. If the transformation is visible and explicit to all participants, it refers to a keying process (e.g., band rehearsal). If the transformation is hidden and intended to distort the interpretation, it is a fabrication process (e.g., mystery shopper).

Three qualitative studies were conducted. At first glance, the results show that video-apéros allow people to "see each other", "get closer" and even "create new links" in the same way as aperitifs. Video-apéros are very much linked to the pandemic context: they allow people to maintain habits despite lockdown– "for me, the video-apéro [...] helps to share things with people close to us with whom we used to have aperitifs before" (Eléonore). This is one of the interests of video-apéros: doing as before, and in a performative way, showing to oneself and to others that everything is fine!

The video-apéros resonate with Poulain's aperitif ideal-types (2005) but goes beyond. On the one hand, *spontaneous video-apéros* are organized following a quick proposal. On the other hand, *scheduled video-apéros* are organized to live an expected moment. They take three different forms: *invitation to the video-apero*, planned to try a new mode of social interaction with colleagues; the *pre-meal video-apéro*, based on the historical principle of appetizers within a closer social circle; the *video-apero dinner*, close to a buffet dinner with friends or family.

However, many frustrations caused by video-apéros tend to keep them away from aperitifs: physical interaction is impossible: "we can't hug each other" (Mireille); verbal or visual interactions are unnatural: "when everyone is talking at the same time, you can't hear yourself" (Bettina); and the restricted and static field of vision causes a certain "weariness".

Finally, for most participants, the video-apéro seems to be nothing more than a copy of the real thing in which the interactants play at having an aperitif: "as if you were going out for real and before going out, you wanted to make yourself a bit prettier" (Aline). And in the absence of interaction rules usually imposed by the hosts, participants are surprised once they realize they have a different idea about the unfolding of a video-apéro: "We were having an aperitif, but she wasn't really having an aperitif" (Gabriel).

The practice of video-apéro reveals a real proximity to the traditional aperitif, but frame analysis of the consumption experience highlights the variety of situations and contexts. On the one hand, the mediatization of the experience, located in distinct places, prevents face-to-face co-presence. On the other hand, the interactants do not necessarily share the same type of space, materiality and food which usually structure consumption situations (Michaud-Trévinal and Stenger 2018). The variety of situations therefore leads to a diversity of consumption experiences.

Framing operations of the consumption experience are also often differentiated. Firstly, participants do not necessarily experience the same type of video-apéro, which leads to ambiguous or even frustrating experiences and to disengagement (Goffman 1974). Secondly, the reference framework is not always shared. For some participants, the video-apéro clearly refers to a primary and social framework: it is an aperitif with a mediated consumption experience. For others, the practice is part of a keying process. The playful dimension of the consumption experience is then prominent, agreeing that one is doing as if while considering that it is not really an aperitif but a copy of the model (Goffman 1974). If all the guests agree, the experience is balanced and the activities are frank. If not, a breakdown is observed. The frustration revealed in our results is symptomatic of participants who would like to privilege a primary social framework but resign themselves to a keying process.

Virtual Reality Promotes Patience for Hedonic Experiences

Ruoou Li, University of South Carolina, USA
Rafay A. Siddiqui, Santa Clara University, USA
Ashwani Monga, Rutgers University, USA

EXTENDED ABSTRACT

Virtual Reality (VR) has become more popular than ever. The global market size for VR was 15.81 billion dollars in 2020 and this number is expected to increase at a compound annual growth rate of 18% in the coming years (Grand View Research, 2021). One common use of VR in marketing is to communicate information about products, especially experiential products, by offering consumers a preview of what they would purchase. For instance, Destination British Columbia, a tourism marketing corporation in Canada, applied VR technology to introduce local travel destinations to potential tourists (Newcomb 2014).

While past research on vividness suggests that VR communication should be more effective (Breugelmans and Campo 2011; MacInnis and Price 1987; Metcalfe and Mischel 1999; Roggeveen et al. 2015), we argue that incorporating VR technologies in marketing practice sometimes decreases the effectiveness of communication. VR refers to a set of technologies that supports immersive experiences in a virtual environment beyond the physical reality (Berg and Vance 2017). Because VR does not simply increase vividness, but in fact fosters a strong sense of physical presence in the virtual environment, or "telepresence" (Kim and Biocca 1997; Steuer 1992), we argue that previewing a real experience through VR can make consumers feel that they have already had part of the experience. This illusion of having already engaged in the experience should make it more difficult for consumers to justify consuming it immediately in real life. Consequently, we predict that consumers will exhibit more patience for an experience after having previewed it through VR (vs. regular video). Importantly, we contend that VR should only lead to greater patience for the real experience when there is a need to justify consumption (i.e., when the experience is hedonic rather than utilitarian; Okada 2005).

We find evidence for this effect in two studies. In study 1, participants were randomly assigned to a 3 (medium: VR vs. regular-video vs. pictures) x continuous (perceived experience type: hedonic vs. utilitarian) between-subjects design. Participants imagined that they were interested in visiting Rome in Italy. In the VR condition, participants watched a 360-degree video about Rome via an Oculus Rift VR headset. In the regular-video condition, participants watched the same 360-degree video on a computer while wearing headphones. In the pictures condition, participants viewed screenshots taken from the same video. A manipulation check confirmed that VR generated a higher level of telepresence than regular-video, and regular-video generated a higher level of telepresence than pictures. We measured patience by asking participants to choose between taking a trip to Rome sooner for a higher price and taking the same trip later for a lower price, with the latter option representing greater patience. We also measured whether participants perceived the experience as more hedonic or more utilitarian (1 = hedonic, 100 = utilitarian). There was a significant interaction between medium and experience type ($X^2 = 7.95$, $p < .05$). A floodlight analysis revealed that compared to the regular video, VR led to more patience when the experience was perceived as more hedonic ($\beta_{JN} = 1.52$, SE = .78, $p = .05$ at 1.52 SD below the mean), but less patience when it was perceived as more utilitarian ($\beta_{JN} = -2.33$, SE = 1.19, $p = .05$ at 1.98 SD above the mean). Additional analyses revealed that compared to the picture condition, regular-video led to less patience when the experience was

perceived as more hedonic ($\beta_{JN} = 1.43$, SE = .73, $p = .05$ at 1.15 SD below the mean), indicating participants became more impatient for the real experience after watching the regular-video than after watching pictures. There was no significance region when comparing pictures to VR. Consistent with prior research on the benefits of vividness, the regular video made participants more impatient compared to the picture condition when the experience was perceived as hedonic. However, supporting our predictions, VR (relative to regular-video) led to a unique effect: greater patience for the experience when it was perceived as hedonic.

Study 2 replicates this effect and shows an important boundary condition: if the preview of the experience is too fleeting, the preview itself will not be sufficient to make consumers feel that they have already had part of the experience. Thus, our effect should only occur when there is sufficient time for consumers to preview the experience. Participants were randomly assigned to a 2 (medium: VR vs. regular-video) x 2 (duration: long vs. short) x continuous (perceived experience type: hedonic vs. utilitarian) between-subjects design. Participants imagined that they were interested in visiting Machu Picchu in Peru. We manipulated medium the same way as in study 1. A manipulation check confirmed that telepresence was higher in the VR condition. Duration was manipulated by showing participants a 7-minute 360-degree video introducing Machu Picchu or a 2-minute version of the same 360-degree video. Both videos featured the same number of destinations and only varied in the details provided about each location and the duration spent on each location. Next, participants answered the measures as in study 1. There was a significant three-way interaction ($X^2 = 5.25$, $p < .05$), and a significant two-way interaction between medium and experience type when the message was long ($\beta = -.03$, $p < .05$). Consistent with our predictions, as the trip became more hedonic, participants were more patient in the VR condition than in the regular-video condition ($\beta = .91$, SE = .44, $p < .05$). When duration was short, the two-way interaction was not significant ($p > .1$), presumably because the fleeting message was not sufficient to make consumers feel that they have already had part of the experience.

Our results contribute to the literature by identifying a special case where a highly vivid presentation of a novel hedonic experience, which can generate a high level of telepresence, leads to patience. Additionally, we offer marketers pathways to attenuate the impact of this effect, such as by making consumers perceive the experiences as less hedonic or providing only fleeting experiences via VR.

The Way We Were: Memories of Extraordinary Group Experiences Impact Cohesion and Well-Being

Zuzanna Jurewicz, Ivey Business School, Western University, Canada
Matthew Thomson, Ivey Business School, Canada
Miranda Goode, Ivey Business School, Canada

EXTENDED ABSTRACT

Every year, millions of dollars change hands in hopes that extraordinary experiences will benefit stressed consumers (e.g., Make-A-Wish). While such experiences promote well-being (Bhattacharjee and Mogilner 2014; Van Boven 2005), little is known about the long-term effects of the special memories (Zauberman, Ratner, and Kim 2009) on the group that shared the experience. To address this gap, we introduce a group-level variable, cohesion, and test hypotheses related to stress, distraction, and group well-being.

Drawing on group and family functioning literature (Mudrack 1989; Olson 2000), we define cohesion as the perception of a group as stable, bonded, and enduring (Friborg et al. 2003). We expect special memories of extraordinary experiences to enhance cohesion because they capture meaningful events shared by the group (Zabriskie and McCormick 2001), which enjoys reliving them (Wildschut et al. 2006). In turn, cohesion is a robust predictor of well-being (Li et al. 2014; Lightsey and Sweeney 2008).

> *Hypothesis 1:* *The positive relationship between more special memories of extraordinary group experiences and well-being is mediated by cohesion.*

We also investigate how stress at the time of the experience influences the relationship between special memories and well-being years later. People with more stress are likely to exhibit greater affiliative behaviors within the group (Taylor 2006; von Dawans, Strojny, and Domes 2021), promoting cohesion during the experience. Memories of these experiences, then, should provide a meaningful reminder of when the group experienced increased cohesion, thereby elevating perceptions of current cohesion and well-being.

> *Hypothesis 2:* *The mediational pathway will be moderated by stress at the time of the experience, such that higher (vs. lower) stress will strengthen (attenuate) the effect of special memories on cohesion and well-being.*

Finally, we examine a feature of extraordinary experiences: distraction, or the degree to which the experience allows the group to escape their daily reality. By buffering the effects of stress (Iwasaki, MacTavish, and MacKay 2005), the distracting extraordinary experience enables highly stressed group members to focus on living through the experience together, allowing them to satisfy affiliative needs (Taylor 2006) and to create memories of cohesiveness (Shaw, Havitz, and Delemere 2008); without this buffer, stress impairs interactions (Webster-Stratton 1990). Thus, we hypothesize a three-way interaction:

> *Hypothesis 3:* *Distraction will moderate the effect of special memories on cohesion and well-being for more (vs. less) stressed individuals, such that extraordinary experiences higher (vs. lower) in distraction will strengthen the indirect effect.*

Study 1

Study 1 addresses H1 and H3 using groups under profound stress: families with critically ill children who partook in an extraordinary experience ('wish') through Make-A-Wish. We surveyed 132 families, asking them to describe their wish and answer questions about the group. Participants completed measures of family well-being (adapted from Hills and Argyle 2002; 7 items, α=.91), cohesion (Friborg et al. 2003; 6 items, α=.83), the extent to which a *memory* of the experience is perceived as special (3 items, α=.94), and distraction (4 items, α=.86)—all of which represent separate constructs. We assessed social support (3 items, α=.83), which captures benefits provided by outsiders (Norris and Kaniasty 1996), as an alternative mediator.

First, we examined the indirect effect of the specialness of memory on well-being through cohesion using PROCESS Model 4 (95% CIs, 5,000 draws [same hereafter]). The effect is significant (β=.12, CI=.01, .53): more special memories are associated with greater cohesion (β=.26, CI=.10, .43), which predicts well-being (β=.46, CI=.25, .66). This effect is concurrent to, but independent of, a significant indirect effect through social support. These results suggest that the link between specialness of memory and well-being is uniquely mediated by cohesion, supporting H1.

Given our high-stress sample, H3 suggests that high-distraction wishes should be associated with greater cohesion. We examine whether distraction moderates the mediated pathway using PROCESS Model 7. With cohesion, the moderation of the mediated pathway is supported (IMM=.24, CI=.05, .42): for less distracting wishes, the indirect effect is significantly smaller (β=.53, CI=.13, .89) than for more distracting wishes (β=.79, CI=.19, 1.34). Distraction does not moderate the mediated pathway with social support. These results provide support for H3. However, study 1 uses correlational data, does not manipulate stress, and includes only extraordinary experiences—issues addressed in study 2.

Study 2

Study 2 examines H1, H2, and H3. We randomly assigned participants (*n*=189) to recall either an ordinary or extraordinary experience with close others (adapted from Bhattacharjee and Mogilner 2014). After writing about the experience, participants completed manipulation checks, followed by measures of cohesion (α=.89), distraction (α=.80), well-being (adapted from Diener et al. 1985; 4 items, α=.89), and stress at the time of the experience (Elo et al. 2003). We measured two alternate mediators: social support (α=.79) and communitas (Arnould and Price 1993; 10 items, α=.89).

The manipulation was successful: individuals in the ordinary (vs. extraordinary) condition reported less special memories (*p*<.01) and less extraordinary experiences (*p*<.01). We expect that recollecting extraordinary (vs. ordinary) group experiences will be associated with increased cohesion and well-being for people highly stressed at the time of the experience, especially if the experience was highly distracting. We examine this three-way interaction using PROCESS Model 11. Cohesion predicts well-being (β=.34, CI=.17, .51) and a significant three-way interaction predicts cohesion (β=.24, CI=.12, .36). For low-stress participants, memories of extraordinary (vs. ordinary) experiences produce significantly more cohesion when the

experiences were *less* distracting (β=.98, CI=.33, 1.63) and significantly less cohesion when they were *more* distracting (β=-.85, CI=-1.50, -.19). For high-stress participants, memories of extraordinary (vs. ordinary) experiences produce significantly more cohesion when the experiences were *more* distracting (β=.96, CI=.27, 1.65) but no effect when they are *less* distracting (β=-.26, CI=-.97, .45). That is, highly stressed individuals benefit from extraordinary experiences only if they provide an escape. This pattern of effects with cohesion remains the same regardless of the inclusion of social support or communitas.

Overall, we contribute to the extraordinary experiences literature by demonstrating that special memories of extraordinary experiences benefit close groups in the long-term by influencing perceptions of cohesion and well-being, particularly for consumers who are highly stressed at the time of undertaking more distracting experiences.

Local versus Global: The Effect of Identity Salience on Impulsive Consumption

Sijie Sun, University of Hawaii at Hilo, USA
Zhiyong Yang, University of North Carolina at Greensboro, USA
Ashok Lalwani, Kelley School of Business, Indiana University, USA

EXTENDED ABSTRACT

Impulsive consumption is highly prevalent in the United States. Hence, an understanding of consumer segments that are more or less likely to consume impulsively as well as factors that strengthen or weaken the tendency can help enhance firm performance. Acknowledging the importance of this phenomenon, previous researchers have identified various factors that influence impulsive consumption, such as self-control (Vohs and Faber 2007) and self-regulation (Verplanken and Sato 2011). However, extant literature has ignored the role of local-global identity in influencing impulsive consumption. Globalization has substantially influenced the world economy, with the world trade of exports and imports of goods and services having increased by 26% from 2008 to 2018 (World Trade Organization 2019), making it timely and important to understand the effect of this variable.

Although prior research has not examined the relationship between local-global identity and impulsive consumption, extant findings seem to suggest that a global (vs. local) identity leads to a greater level of impulsive consumption. Ng and Batra (2017), for example, showed that consumers high in global identity tend to have a promotion focus, whereas those high in local identity tend to have a prevention focus. Since promotion focus is positively associated with impulsive consumption (Sengupta and Zhou 2007), previous research may imply that global (vs. local) identity enhances the tendency of impulsive buying.

However, in sharp contrast to the above perspective, we propose that consumers with a local identity (henceforth, "locals") are more likely to engage in impulsive consumption than those with a global identity (henceforth, "globals"), because they have an accessible constraints mindset, defined "a general cognitive orientation focused on the existence of constraints" (Mehta and Zhu 2016, p. 770). A fundamental difference between a local and a global identity is the focus they place on local vs. global traditions and events. Locals' attention and focus tend to be confined to their local community. In contrast, globals are not bounded to a particular community and are open to diversified experiences and values (Zhang and Khare 2009). Such a difference can be partly attributed to the restrictions that locals have, with respect to access to the outside world. In particular, compared to countries characterized by a global identity, countries characterized by a local identity have more physical and economic constraints, including lower life expectancy, lower level of environmental sustainability, and lower gross domestic product per capita, and have fewer political and civil liberties (Au et al. 2011).

Also, locals (but not globals) tend to be constrained in other aspects of their lives, such as fewer travels and limited media consumption (Arnett 2002). Individuals from more localized countries are limited to local news and events and have restricted access to the news and stories from other cultures; however, those from more globalized countries do not have these constraints and are able to access the stories and news from the rest of the world (Arnett 2002). Previous research also points to a negative association between autonomy and local identity. For example, Singaporean students perceived lower autonomy compared to Canadian students (Rudy et al. 2007), where Singaporeans are higher in local identity than Canadians (Gao, Zhang, and Mittal 2017). The foregoing discussion suggests that local (vs. global) identity enhances the salience of a constraints mindset.

Our core thesis that a constraints mindset mediates the relationship between local-global identity and impulsive consumption relies on the proposed link between constraints mindset and impulsive consumption tendency. We expect this association due to the compensatory role of impulsive buying in mitigating the sense of constraints. Research suggests that consumers who face constraints tend to find it aversive and are motivated to change that state (Mehta and Zhu 2016). For example, when consumers stay in a constrained environment, such as a crowded restaurant, they tend to select and consume more high-calorie food (Hock and Bagchi 2018). Likewise, impulsive purchasing becomes an act of freedom within a restricted situation and relieves people from constraints (Thompson, Locander, and Pollio 1990). Accordingly, we hypothesize that locals have a stronger constraints mindset than globals, which in turn, leads them to consume more impulsively.

We further expect that, when constraints are enhanced by a contextual cue, globals—whose baseline level of constraints mindset is low and have greater potential for increase—should have a higher level of constraints mindset and their impulsive consumption tendency should increase, compared to baseline conditions. However, such a contextual cue is less likely to influence locals, whose constraints mindset (and hence, tendency to engage in impulsive consumption) is already high and has limited room for further increase ("ceiling effect"). Furthermore, locals' baseline constraints mindset is high and has a greater potential for decrease. Hence, a contextual cue that lowers constraints should reduce locals' impulsive consumption tendency. However, globals' baseline constraints mindset is low and is difficult to decrease further using contextual cues ("floor effect"). Hence, their impulsive consumption tendency should be unchanged when constraints are suppressed, relative to the control condition.

Notably, we expect that local-global identity predicts impulsive consumption for vice products, but not for virtue products. A major reason is that vice (vs. virtue) products lead to greater temptation for immediate gratification and thus are more likely to be consumed impulsively (Wertenbroch 1998). Consistent with this reasoning, when examining the relationship between power distance belief and impulsive consumption, Zhang, Winterich, and Mittal (2010; study 3) found that power distance belief affects consumers' purchase of vice products, but not virtue products.

Study 1 provided initial evidence using chronic measures of impulsive consumption tendency and local-global identity. A regression analysis on impulsive consumption tendency, using global-identity and local-identity indices as predictors, revealed a positive effect of local-identity index and a non-significant effect of global-identity index. These results support our prediction that a local (but not global) identity increases consumers' impulsive consumption tendency.

Study 2 tested the effect of local-global identity on impulsive consumption behavior in a real-life setting. Shoppers of a grocery store who agreed to participate were also asked to complete a short survey that contained the measure of local-global identity and demographics. The items on each receipt were classified into two categories: vice products and virtue products. A regression analysis on the amount spent on vice products, using global-identity and local-identity indices as predictors, revealed a positive effect of local-identity

index and a non-significant effect of global-identity index. However, a regression analysis on the amount spent on virtue products revealed no effect of local-identity index or global-identity index. Therefore, using actual consumption data in a real-life setting, local (but not global) identity increases consumers' impulsive consumption tendency, as manifested by the spending on vice products, but not on virtue products.

Study 3 featured a 2 (identity: local vs. global) × 2 (product type: vice vs. virtue) between-subjects design. Participants were randomly assigned to local/global identity conditions. Thereafter, participants answered questions measuring constraints mindset. Further, we used popcorn and salad as the vice product and the virtue product, respectively. Participants were asked to indicate their preferences. A 2 (identity) × 2 (product type) ANOVA on impulsive consumption tendency revealed a significant identity × product type two-way interaction. For the vice-product, locals had a higher impulsive consumption tendency than globals. However, for the virtue-product, there was no difference in impulsive consumption tendency across locals and globals. Also, constraints mindset mediated the relationship between local-global identity and impulsive consumption tendency in the vice-product condition but not in the virtue-product condition.

Study 4 adopted a 2 (identity: local vs. global) × 3 (constraints: enhanced, reduced, unchanged) between-subjects design to demonstrate the moderating role of constraints. Participants answered questions measuring constraints mindset. Further, participants were asked to make a decision of purchasing the ice-cream certificate. A 2 (identity) × 3 (constraints) ANOVA on likelihood of purchasing the ice-cream certificate revealed a significant identity × constraints two-way interaction. We compared the likelihood of purchasing the certificate in the constraints-enhanced and -unchanged conditions among locals and globals separately. For globals, there was a higher level of impulsive consumption tendency in the constraints-enhanced condition than in the control condition. For locals, there was a similar level of impulsive consumption tendency across constraints-enhanced and control conditions. We also compared the likelihood in the constraints-reduced and -unchanged conditions among locals and globals separately. Globals had a similar level of impulsive consumption tendency across constraints-reduced and control conditions, whereas locals had a lower level of impulsive consumption tendency in the constraints-reduced condition than in the control condition. Also, constraints mindset mediated the relationship between local-global identity and impulsive consumption tendency in the control condition (but not in the constraints-enhanced condition or the constraints-reduced condition).

The issues we address in this research have significant implications for the literature on impulsive consumption and local-global identity. Our research represents a first attempt to explicitly examine the effect of local-global identity on impulsive consumption. We are also the first to uncover constraints mindset as a new qualitative difference between local identity and global identity. Because of such a difference, locals and globals exhibit different levels of impulsive consumption. Building upon the "constraints mindset" logic, we identify a contextual factor that sets boundary conditions for impulsive consumption.

Entrusting the Future to Others' Hands: People Delegate Choice to a Decision Device More When Choosing for the Future

Minkwang Jang, University of Chicago, Booth School of Business, USA
Oleg Urminsky, University of Chicago, USA

EXTENDED ABSTRACT

People often face situations where they have to decide in advance what they will get in the future. While much of the extant research on decisions for the future focuses on the outcome of the decision (i.e., which alternative is chosen), another field of research finds that people often also avoid choice, such as by deferring or opting out of choice (Tversky and Shafir 1992; Dhar 1997), going with the default (Dinner, Johnson, Goldstein and Liu 2011), or delegating to another person (Steffel and Williams 2018). However, it is relatively unaddressed how the decision to choose versus leaving choice to other means might be different when people are choosing for the future. In the current research, we examine whether preference for delegating choice differs by outcome timing and propose a novel account of why people might delegate—due to the utility driven from the uncertainty provided by delegation, which can cause an apparent preference reversal when both choice and delegation are delayed.

While choice is inherently valuable (Leotti, Iyengar, and Ochsner 2010), making a choice can also be costly as it can incur cognitive load (Hauser and Wernerfelt 1990) or negative affect, such as regret from potentially choosing wrong (Zeelenberg 1999). Previous research has viewed decision avoidance, including delegation, as a means of eliminating such costs. As the literature on time discounting suggests that the value of the outcome is reduced as a function of how much into the future it is delayed (Samuelson 1937; Urminsky and Zauberman 2015), it is possible that the reduced perceived benefit of the outcome against the cost of choosing leads to delegating the choice more when choosing for future outcomes. While this explanation can also be extended to other means of choice avoidance (e.g., deferral or defaults), delegation is unique in that it offers temporary uncertainty about what they will get, from which people may derive pleasure (Ruan, Hsee, and Lu 2018). Hence, it is also possible that there is direct utility from delegation, over and beyond reducing the cost of choice.

Across five studies (total N=2,023), we demonstrate that people are more likely to delegate choice when the outcome is in the future than when it is in the present and test the predictions of the utility-from-delegation account. In our typical decision task, participants were asked to decide what item to receive (either immediately or in the future), between two alternatives within a consumption domain, varying the domain (e.g., snacks, genres of movies, etc.). For each decision, they chose from among three options: the two alternative consumer goods (i.e., making a choice) and a third option of delegating the decision to an external mechanism (e.g., randomization device, friend, majority rule, or computer algorithm).

Study 1 (N=633) demonstrated our main effect: participants were more likely to select the decision aid option when choosing for the future (27.13%) than for now (16.93%; B=0.10, SE=0.014, p<.001, 95% CI=[0.075, 0.13]). There was no significant difference in the effect of outcome timing on choice to use the decision aid across the different types of decision aids participants were offered (F(3, 1896)=0.33, p=.80), suggesting that preference for delegating future outcomes is more likely to arise from the fundamental benefit that delegation provides. In addition, the preference for delegation scaled with the number of days to the outcomes (study 2, N=320; B=0.001, t(615.6)=6.55, p<.001).

If the increased delegation for future outcomes were mainly driven by discounting of future outcomes, a similar preference should be observed for choosing defaulted options in the future. However, unlike delegation, choosing the default would not create momentary uncertainty. In study 3 (N=320), given the same sets of alternatives as in study 1 but with one of the options designated as the default, the proportion of participants who chose the default did not significantly differ between the immediate and delayed timing conditions in either of the domain conditions (snacks: 57.6% vs. 60.0%, p=.73; movies: 64.2% vs. 59.5%, p=.42), suggesting there is additional utility provided by delegation for delayed options that is not offered by defaults.

Importantly, in study 4 (N=427), the increased preference for delegation for future outcomes persisted even when the timing of the choice (i.e., if they have to choose, when they would be choosing, as opposed to delegating) was delayed into the future as well, so that any perceived costs of choice are also discounted (difference between choice-now condition and choice-later condition: B=-0.038, SE=0.042, 95% CI=[-0.12, 0.048]). Furthermore, in study 5 (N=320), the effect was mitigated when the outcome of the delegation was to be known later, thereby delaying the resolution of the uncertainty provided by delegation (effect of outcome timing with delayed resolution of uncertainty: B=0.036, SE=0.041, p=.38), which is consistent with the utility-from-delegation account.

Our research shows that outcome timing matters in people's preferences for delegation. Importantly, while people prefer to delegate more for future outcomes than for immediate outcomes, the persistence of this preference in the absence of immediate cost of choice suggests that our effect cannot be fully explained by previous accounts of delegation behavior, but rather that delegation may provide direct utility, through momentary uncertainty and its resolution, over and beyond eliminating the cost of choice.

Fairness in Segmentation and Targeting

Elizabeth Friedman, Columbia Business School, USA
Franklin Shaddy, UCLA Anderson School of Management, USA
Olivier Toubia, Columbia Business School, USA

EXTENDED ABSTRACT

Do consumers today believe it is appropriate for companies to target customers based on demographics? Across 10 experiments (N=6,234), we find consistent evidence that perceptions of fairness are lower when advertising specifically targets groups based on race or gender, relative to advertising that broadly engages the general public.

Study 1a employed a 2 (advertising: *broad* vs. *targeted*) × 2 (segmentation basis: *race* vs. *gender*), between-subjects design. Participants read about "a new product" that would "appeal specifically to a particular [race/gender]." A company planned to either "advertise the new product broadly to the general public" (*broad*) or "advertise the new product specifically to that [race/gender]" (*targeted*). We then asked: "How fair is this plan?" Fairness perceptions were lower in the *targeted* condition (M=5.81) than in the *broad* condition (M=7.38, p<.001).

Studies 1b and 1c examined *gender* and *race* as the basis of segmentation, respectively, and were identical to Study 1a, with one exception: participants expressed purchase intentions.

In Study 1b, participants expressed lower purchase intentions in the *targeted* condition (M=3.96) than in the *broad* condition (M=5.46, p<.001). In Study 1c, participants expressed lower purchase intentions in the *targeted* condition (M=4.81) than in the *broad* condition (M=5.68, p<.001).

Study 2a tested whether targeting would be perceived as unfair even when promoted products and services were beneficial. It employed a 2 (advertising: *broad vs. targeted*) × 2 (valence: *beneficial* vs. *detrimental*), between-subjects design. We described a new snack that was "healthy/unhealthy", with (low/high) levels of saturated fat, sugar, and sodium and (many/few) vitamins and minerals." A company believed the snacks would appeal specifically to Black individuals and advertised either "to Black people directly" (*targeted*) or "broadly to the general public" (*broad*). Participants then rated: "How acceptable is this advertising plan?" and "How fair is this advertising plan?" Fairness perceptions were lower in the *targeted* condition (M=5.01) than in the *broad* condition (M=6.21, p<.001). And the lack of an interaction indicated that targeting was viewed as equally unfair in the *beneficial* and *detrimental* conditions (p=.479). A follow-up study (2b) confirmed a similar pattern for gender-based targeting.

Study 2c tested an alternative explanation—that broad advertising has greater reach and thus potentially could feel more equitable. We adapted the *snack* scenario from Study 2a and explicitly told half the participants, that the message would reach "100k customers." If the effect were driven by different inferences about reach, this line should moderate the effect. We replicated the main effect of *broad* versus *targeted* advertising (p<.001), but there was no main effect of reach (p=.589) and no interaction (p=.600).

Study 3 employed a single-factor 2 (advertising: *broad* vs. *targeted*), between-subjects design. All participants first read: "A company has developed a new product, which they believe will appeal specifically to a particular demographic group." The company planned to either "advertise the new product broadly to the general public" (*broad*) or "advertise the new product specifically to that particular demographic group" (*targeted*). We then asked participants

to rate fairness and indicate the extent to which they agreed or disagreed with 10 statements:

1. "The company is limiting access to some people and not others"
2. "The company is making choices on behalf of individuals, instead of letting them choose for themselves"
3. "The company is taking too much control away from individuals"
4. "This plan lets individuals make their own decisions" [reverse-coded]
5. "This plan feels discriminatory"
6. "This plan feels equitable" [reverse-coded]
7. "This plan is inclusive" [reverse-coded]
8. "The company is favoring some people over others"
9. "The company is making assumptions about individuals based on superficial information"
10. "This plan reflects an understanding of unique individual preferences" [reverse-coded]

Fairness perceptions were lower in the *targeted* condition (M=6.56) than in the *broad* condition (M=7.53, p<.001). We next created factor variables by averaging the items that loaded primarily onto each of two factors, which we characterize as "loss of agency" and "discrimination," respectively. A bootstrapped mediation revealed that both simultaneously (and independently) mediated the effect. The remaining studies manipulate these factors directly.

Study 4a employed a 2 (advertising: *broad* vs. *targeted*) × 2 (cofounder/CEO: *Black* vs. *non-Black*), between-subjects design. Participants read that a company had "developed a new line of snacks" that "will appeal specifically to their Black customers." The company planned to "advertise the snacks" either "broadly to the general public" (*broad*) or "specifically to Black people" (*targeted*). The company's CEO was either a "Black entrepreneur" or "non-Black entrepreneur." Finally, participants rated the fairness of the plan. We observed a simple effect of condition when the cofounder/CEO was non-Black (p<.001), and a significantly attenuated simple effect of condition when the cofounder/CEO was Black (p<.001). This attenuation was confirmed by a significant interaction (p=.045).

Study 4b employed a 2 (advertising: *broad* vs. *targeted*) × 2 (product appeal: *race-based* vs. *preference-based*), between-subjects design. Participants read that a company had snacks that it believed would appeal "a particular race (due to their preference for spicy food)" (*race-based*) or "to people who like spicy food" (*preference-based*). The company planned to "advertise the snacks" either "broadly to the general public" (*broad*) or "specifically to people [of that particular race/who like spicy food]" (*targeted*). Finally, participants rated the fairness of the plan. We observed a simple effect of condition in the *race-based* condition (p<.001), and a significantly attenuated simple effect of condition in the *preference-based* condition (p=.018). This attenuation was confirmed by a significant interaction (p<.001).

Study 4c employed a 2 (advertising: *broad* vs. *targeted*) × 2 (reason: *biology* vs. *taste*), between-subjects design. Participants read that for "a new line of snacks…initial testing showed that, due to the taste and texture" (*taste*) or "vitamin and nutrient profile" (*bi-*

ology), they "are better suited to the [preferences/biological needs] of their female customers." The company planned to "advertise the snacks" either "broadly to the general public" (*broad*) or "to women directly" (*targeted*). Finally, participants rated fairness. We observed a simple effect of condition in the *taste* condition ($p<.001$), and a reversal in the *biology* condition ($p=.019$). This reversal was confirmed by a significant interaction ($p<.001$).

Trust Us, We Use AI: Disclosing Information to AI Decreases Consumers' Trust in Brands

Deniz Lefkeli, Koc University, Turkey
Begum Yilmaz, Koc University, Turkey
Zeynep Gurhan Canli, Koc University, Turkey

EXTENDED ABSTRACT

Trust has been traditionally considered as an asset that is gradually built on former interactions with brands (Albert & Merunka, 2013), and it is an important predictor of sharing information. As consumers trust more, they disclose more (Dinev & Hart, 2006; Hoffman et al., 1999). However, in today's world, this route may not be the only route consumers take. Many companies require consumers to share personal information even before they have a chance to build trust. In this study, we explore the reverse relationship between trust and information disclosure, and the consequences of disclosing information to AI (vs humans).

Research has shown that compared to humans, artificial agents are considered as less of social agents (Gray et al. 2007; Lefkeli et al. 2020). Building on these findings, we suggest that when consumers disclose information to agents that are not considered as social counterparts, they infer that there should be other social actors, humans, in this communication episode. In other words, consumers think that AI is only working at the surface level. As actual human beings operate at the background, AI shares consumers' information with other people. Thus, the audience consists of the AI and several people. On the other hand, when they disclose to humans, they think the information will be known by that person, indicating a difference in audience size.

As the number of people that the information is shared increases, consumers tend to disclose less (Barasch & Berger 2014). We propose that broadcasting gives rise to a feeling of exploitation. The larger the audience size with which personal information is shared, the higher the probability of someone taking advantage of the information is. The sense of exploitation decreases consumers' trust in brands (CTB).

In Study 1a, participants (N= 188) were asked to imagine that they called their bank, and shared information regarding their savings with a human (artificial agent) representative. They completed the brand trust scale (Chaudhuri & Holbrook 2001). As predicted, participants in the AI condition trusted the brand less than the ones in the human condition (M_{AI} = 5.07, M_{Human} = 5.57, $F(1, 186)$ = 6.346, p=.013). Study 1b (N=199) replicated these results using a scenario about disclosing contact information to a new brand.

In Study 2, participants (N=302) imagined disclosing their contact information to an artificial agent (vs. human) and reported the anticipated audience size (adapted from Barasch & Berger, 2014) and completed the sense of exploitation scale (Clark & Waddell, 1985). Results revealed that participants in the AI condition trusted the brand less than the ones in the human condition (M_{AI} = 4.04, M_{Human} = 4.54, $F(1, 300)$ = 9.922, p=.002). A serial mediation analysis showed disclosing information to AI increased the anticipated audience size, which increased the consumers' sense of exploitation, decreasing CTB. The direct effect was still significant (β =-.35, p=.012, 95%CI -.61,-.08) and the indirect effects were significant (index=-.16, 95%CI (-.29,-.04))

Employing a 2 (Agent Type: Human, AI) x 2(Audience Size: Narrowcasting, Control) between-subjects design, Study 3 (N=463) provided additional support for the mechanism. Participants in the narrowcasting condition were informed that the information they shared with the agent would not be shared with anyone else. All participants imagined disclosing financial information to their bank and completed the measures of Study 2. There was a significant interaction between agent type and audience size ($F(1, 459)$ = 4.397, p=.037). In the control condition, consumers thought that the information would be shared with less people when the agent was human ($M_{AI-Control}$ = 3.51, SD = 1.73 vs. $M_{Human-Control}$ = 2.76, SD = 1.36). When consumers disclosed information to AI, narrowcasting information decreased the audience size ($M_{AI-Narrowcasting}$ = 2.78, SD = 1.64 vs. $M_{AI-Control}$ = 3.51, SD = 1.73). Replicating our findings, participants in the AI (vs. human) had lower CTB ratings (M_{AI} = 4.85, M_{Human} = 5.51, $F(1, 461)$ = 28.329, p=.000). The interaction of agent type and audience size was not significant. However, when we examined the mediating processes, we found evidence consistent with our hypothesis. Analysis revealed that disclosing information to AI increased the anticipated audience size when narrowcasting information was not provided, which increased the sense of exploitation, decreasing CTB. The direct effect was still significant (β = −.55, p = .000), and the moderated serial mediation model was significant (Index = .183, 95%, CI = -.37, -.01). These findings suggest that informing consumers about the privacy of data is not enough to compensate the negative influence of disclosing information to artificial agents on brand trust.

Study 4 had a 2 (Agent Type: Human, AI) x 2(Medium of Communication: Phone, App) between-subjects design. Participants (N=400) were asked to imagine that they called their bank [opened the application] and provided financial information to a human [artificial agent] representative. Afterwards, they completed the measures of Study 2. Results revealed that consumers trusted brands less when they disclosed information to AI (vs. human) both on the phone ($M_{AI-Phone}$ = 4.59, $M_{Human-Phone}$ = 5.57) and on the app (M_{AI-App} = 5.02, $M_{Human-App}$ = 5.45). Interestingly, consumers who disclosed information to artificial agents on the phone (vs. app) trusted the brand less ($M_{AI-Phone}$ = 4.59, M_{AI-App} = 5.02) Mediation analysis revealed that disclosing information to AI increased the anticipated audience size when consumers do it on the phone, which increased the sense of exploitation, decreasing CTB. The direct effect of agent type on trust was still significant (β= -.69, 95%, CI= -.74 to -.31), and the moderated mediation model was significant (index= .18, 95%, CI= .01 to .39).

We show that algorithm aversion is not limited to the evaluation of the agent; it spillovers to the brands and damages CTB. Consumers may be in need of a human touch especially in the formation of relationships with brands. We also showed for the first time that consumers make attributions about the audience size and sharing information with AI is considered as a form of broadcasting. Brands should create a sense of privacy; however future research can identify the contexts in which broadcasting would be desirable.

The Customization Premium: Consumers Value Custom Bundles More than (Better) Standard Bundles

Alice Moon, The Wharton School of the University of Pennsylvania, USA
Maarten Bos, Snap, Inc, USA

EXTENDED ABSTRACT

When companies want to create value for consumers, one common strategy is to provide additional products/features. After all, adding such utility for consumers can be attractive (Nowlis & Simonson 1996). Consider a cable TV bundle. If the bundle does not include a desired channel (e.g., TBS), customers may not purchase it. Adding channels increases the possibility that bundles "fit" more consumers, allowing companies to capture a greater market share.

But providing more is not always better. Undesirable additions (e.g., a promotional plate when purchasing cake mixes) can decrease purchase likelihood by causing negative inferences about product quality (Simonson, Carmon, & O'Curry 1994) or by creating aversive unused utility (i.e., physical waste; Bolton & Alba 2012).

One potential fix is to ask consumers to customize products. Customization should remove the possibility that a bundle includes undesirable items.

In the current paper, we tested whether (objectively inferior) custom bundles could be valued higher than non-custom bundles. Across 5 studies (N=3,799), we demonstrate that allowing consumers to customize product bundles by removing items can increase valuations, a phenomenon that we refer to as "the customization premium."

Study 1 (N=998) participants were assigned to either the Custom or Standard condition. Participants considered the purchase of a 10-item snack bundle. In the Custom condition, participants removed items they did not want. In the Standard condition, participants instead simply indicated which items they did not want. Then, all participants reported willingness-to-pay [WTP] for their respective bundle.

We established the customization premium: Participants were willing to pay more for Custom bundles (*M*=\$31.61, *SD*=\$16.73) than for Standard bundles that included additional items (*M*=\$28.35, *SD*=\$17.09), $t(996)=3.04$, $p=.002$.

Study 2 (N=507) aimed to conceptually replicate Study 1 with a different bundle (a 10-item cable TV package) and a different measure: choice deferral.

In the Custom condition, participants removed channels they did not want. In the Standard condition, participants instead indicated which channels they did not want. Then, all participants indicated likelihood of purchasing their bundle (versus looking for others).

Conceptually replicating Study 1, participants were more likely to purchase the Custom (*M*=4.10, *SD*=1.82) than the Standard bundle (*M*=3.66, *SD*=1.88), $t(501)=2.65$, $p=.008$.

Studies 1-2 provided evidence for the customization premium. One alternative explanation is that by highlighting items they did not want, Standard participants devalued the standard bundle, rather than Custom participants valuing the custom bundle. *Study 3* (N=1,004) tested whether our effect holds when Standard participants simply reviewed the bundle, rather than considering unwanted items. Furthermore, we attempted to have all participants consider the *same* package.

To do this, we first recruited self-identified Democrats. In the Custom condition, participants removed exactly one item in an 11-item bundle. We expected that most participants would remove the 11th aversive item: FOX News. Participants in the Standard condition instead evaluated a 10-item bundle that did not include FOX

News. Then, all participants reported WTP for their bundle, which we expected would be the same 10-item bundle. Indeed, most participants (68.3%) removed FOX News (but results remained the same in direction and significance level whether including all participants or only those who removed FOX News).

Participants in the Custom condition were willing to pay significantly more for the TV package (*M*=\$20.09, *SD*=\$15.21) than participants in the Standard condition (*M*=\$16.43, *SD*=\$13.10), $t(1002)=4.09$, $p < .001$.

Why does the customization premium arise? We hypothesized that it was because people average (rather than add) their liking for bundle items. Thus, custom bundles (with only liked items) would seem more valuable than non-custom bundles (with liked and disliked items). *Study 4* (N=598) tested this proposed mechanism. Participants were randomly assigned to either the Custom or Standard condition. Participants considered a 10-channel cable TV package. In the Custom condition, participants removed channels they did not want. In the Standard condition, participants instead indicated which channels they did not want (but channels were not removed). Then, all participants reported their WTP for their respective bundle. After reporting WTP, participants rated liking for each channel, which we averaged for bundle liking.

Indeed, we found that liking for Custom bundles was higher (*M*=4.88, *SD*=1.06) than that for Standard bundles (*M*=4.17, *SD*=1.01), $t(590)=8.33$, $p < .001$. Moreover, this mediated the effect of Condition on WTP.

Study 5 (N=898) examined a possible consequence. Though people exhibit the customization premium when presented separately (between-subjects), people likely understand that additional items are more valuable when presented jointly (within-subjects). Ultimately, this should lead people to pay more for standard bundles after first reporting WTP for custom ones. Participants were assigned to either the Custom First or Standard First condition.

In the Custom First condition, participants removed channels they did not want. In the Standard First condition, participants simply indicated which channels they did not want. Then, participants reported WTP for their respective bundle. After reporting this first WTP, participants reported WTP for the other bundle they did not yet evaluate (Custom First participants evaluated the standard bundle; Standard First participants evaluated the custom bundle in which the channels they indicated they did not want were removed).

Examining first WTP only, we again found that participants were willing to pay more for custom (*M*=\$44.49, *SD*=\$25.00) than for standard bundles (*M*=\$41.04, *SD*=\$25.11), $t(896)=2.06$, $p=.040$.

Comparing WTP for bundles within condition, however, people were rational: Participants stated higher WTP for additional items (Custom First participants were willing to pay more for the standard bundle (*M*=\$46.61, *SD*=\$25.78) after reporting WTP for the custom bundle, $t(456)=3.69$, $p<.001$) and lower WTP for fewer items (Standard First participants were willing to pay less for the custom bundle (*M*=\$39.63, *SD*=\$25.02) after reporting WTP for the standard bundle, $t(440)=2.46$, $p=.014$).

Consequently, participants were willing to pay more for the standard bundle in the Custom First condition—i.e., after reporting WTP for the custom bundle—than in the Standard First condition, $t(896)=3.28$, $p=.001$.

Together, these studies demonstrate a novel effect and suggests that offering customization can have considerable benefits for companies' pricing strategies. Future research will explore the contexts in which the customization premium holds.

Precursors and Impact of Mindful Consumption

Sharad Gupta, Delhi School of Business, VIPS-TC, India
Weng Marc Lim, Swinburne University of Technology, Australia
Harsh Verma, University of Delhi, India
Michael Polonsky, Department of Marketing, Deakin Business School, Australia

EXTENDED ABSTRACT

Mindful consumption, defined by Milne et al. (2020, p. 4) as "the application of mindfulness to inform the choices consumers make," has been proposed as an approach that might bring about this change. Undertaking mindfulness and religious practices have often been associated with mindful consumption (Bahl et al., 2016; Harris, 2011; Lim, 2017). Yet, to date, the relationships among mindfulness, religious faith, and mindful consumption remain largely conceptual or descriptive. While some marketers do encourage mindful consumption (e.g., Levi's Buy better, Wear longer" or Patagonia's "don't buy this jacket" advertisements), most marketers do not, thereby resulting in mindless buying. Thus, if marketers or policy makers turn to encourage consumers to undertake mindful consumption (Sheth et al., 2011), it is important to understand the precursors of mindful consumption and effect of mindful consumption appeals on consumer buying (Geiger et al., 2019; Jain & Gupta, 2018; Wamsler, 2019).

This paper contributes (1) to theory, by clarifying whether mindfulness and religious faith encourage mindful consumption, and if they do, whether they are independent, and (2) to practice, by equipping marketers and policy makers with strategies to encourage consumers to practice mindful consumption. We hypothesize -

Hypothesis 1:	*Mindfulness encourages mindful consumption.*
Hypothesis 2:	*Religious faith encourages mindful consumption.*
Hypothesis 3:	*Mindfulness and religious faith correlate and interact to encourage mindful consumption.*
Hypothesis 4:	*Mindful consumption appeals lead to change in consumer buying attributes.*

Methodology

Study 1

Study 1 is a longitudinal experimental research using comparable student samples (n=94, 59% females, all students, 18-24 years, 43 in treatment group and 51 in control group) and analyzed using analysis of variance to establish the effect of mindfulness on mindful consumption using a mindfulness intervention (Kabat-Zinn, 1982) that occur over a period of two months, to ascertain if we could encourage mindful consumption by encouraging consumers to practice mindfulness (H1). The questionnaire administered before and after the intervention consists of adopted items on mindfulness (Brown & Ryan, 2003) and mindful consumption (Gupta & Verma, 2019).

Study 2

Study 2 is a cross-sectional correlational research ($n = 603$, 52% females, all above 18 years, and 47% students), analyzed using SEM with multi-group analysis (MGA) and seeks to test if a) religious faith also encourages mindful consumption (H2), b) possibility of interaction between mindfulness and religious faith (H3), and c) if study 1 findings can be generalized across consumers of different genders, occupations, and household incomes (H1). Participants recruited online using snowball sampling (Basiouka & Potsiou, 2014) complete an online questionnaire with adopted items on mindfulness, religious

faith (Plante & Boccaccini, 1997), and mindful consumption (Gupta, 2019). We changed the last measure for evaluating conceptual replication (Crandall & Sherman, 2016). Most participants have annual income higher than the minimum taxable income (88%), access multiple communication media (96%), participate actively in online social networking (86% spend more than two hours daily) and therefore, suitable for this study on mindful consumption (Gupta, 2019).

Study 3

Study 3 is an online study using MTurk that compares the impact of mindful consumption appeal with that of non-mindful consumption appeal in advertisement on attitude towards the brand, attitude towards the ad, and purchase intention. It randomly collects data from 400 participants out of which 200 see an ad promoting mindful consumption and 200 see the ad without mindful consumption focus.

Results

Study 1

In contrast to the pre-intervention analysis, the post-intervention analysis indicates significant differences between treatment and control group participants, whereby participants in the treatment group report significantly higher mindfulness ($F(1, 78) = 24.27$, $p = .00$; $M_{Treatment} = 4.60$, $S.D._{Treatment} = .54$; $M_{Control} = 3.89$, $S.D._{Control} = .73$) and disposition to mindful consumption ($F(1, 78) = 11.59$, $p = .00$; $M_{Treatment} = 4.59$, $S.D._{Treatment} = .50$; $M_{Control} = 4.21$, $S.D._{Control} = .48$) as compared to participants in the control group. These results suggest that the mindfulness intervention stimulates mindfulness and encourages mindful consumption (H1).

Study 2

For the measurement model having three latent variables- mindfulness, religious faith, and mindful consumption, we ascertain that two approaches for detecting common method variance do not indicate the presence of common method variance (Hulland et al., 2018). Convergent validity (using two ways of CR>.70 and SR weights >.50), discriminant validity (using three methods of AVE>MSV, inter-correlations below .70, and the HTMT ratios below .85), and reliability (CR of all scales >.70) are established (Ab Hamid et al., 2017; Hair et al., 2017; Malhotra & Dash, 2016).

Model fit of measurement and structural models are established through several model fit indices of $χ^2/df<3$, CFI≥ .90, TLI≥ .90, SRMR≤.08, and RMSEA≤.08 (Hair et al., 2017). The structural model (10,000 bootstrap samples) indicates that mindfulness ($β = .27$, $p < .01$) and religious faith ($β = .26$, $p < .01$) significantly influence mindful consumption positively. MGA explores potential differences due to socio-demographics such as gender, occupation, and household income.

Our results offer empirical support to suggest that mindfulness and religious faith encourage mindful consumption without the interaction between religious faith and mindfulness. This finding remains true (1) regardless of gender and occupation, and (2) for low-income and high-income households, but not for middle-income households, wherein religious faith had no impact on mindful consumption. Thus, H1 is supported, H2 is partially supported, and H3 is not supported.

Study 3

We use path analysis using Process plugin (Hayes, 2018) to evaluate multiple mediation and moderation models. Our results offer support to the impact of mindful consumption appeal on different consumer characteristics like attitude towards the brand, attitude towards the ad, and purchase intention.

Discussion

Our multi-study approach examines the relationships between mindfulness, religious faith, and mindful consumption, resulting in three important implications. First, we establish that the impact of mindfulness transcends beyond specific instances of consumption, influences overall consumption, and remains stable across different conceptualizations of mindful consumption. Second, this paper reconciles the extant debate on mindfulness and religious faith. Mindfulness, as a practice, has often been the target of religious criticism (Brown, 2019; Ville & Cotter, 2019), possibly due to the lack of research. The current research addresses this controversial issue with empirical evidence, that mindfulness and religious faith are, in fact, not associated. Finally, we show that mindful consumption have the potential to impact consumer behavior as measured through multiple measures of attitude towards the brand, attitude towards the ad, and purchase intention. We encourage replication studies in other countries that have more Christian-Judaic foundations (like the US), or other Eastern religious foundations (like China) and thus extend these results.

When Identity Comes with Strings: Nonvoluntary Identity Maintenance and Conflicting Identities

Mycah Harrold, Washington State University, USA
Chadwick Miller, Washington State University, USA
Andrew Perkins, Washington State University, USA

First author (woman):	"Good morning. How are you?"
Second author (man):	"Fine, I guess. I just woke up and I have to teach in 15 minutes. So, I rushed in."
First author:	"You just woke up? I have been up for 2 hours getting ready to teach this morning."
Second author:	"Woah. I just rolled out of bed and put on pants and a shirt."
First author:	"That's bull---t."

The first author feels compelled daily to style her hair, shave her legs, and apply make-up. Despite feeling conflict between her feminist identity and the societal expectations surrounding her woman identity, she continues to perform these tasks. In this work, we investigate how holding conflicting identities impacts routine consumption associated with *nonvoluntary identity maintenance* (henceforth, NIM)—consumption practices required to signal/maintain an identity.

Using a behavioral study, a secondary dataset, and three experiments, we are the first to direct empirical attention to routine NIM consumption practices. We provide evidence that consumers who feel obligated to practice NIM but do not hold an identity that conflicts with that maintenance report lower valuations of related products. Ironically, consumers who feel obligated to practice NIM and simultaneously hold an identity that conflicts with that NIM report higher valuations of related products. This effect is mediated by intrinsic motivation and is mitigated when the conflict between the two target identities is eliminated.

Studies

Study 1a

We assigned participants (n=239 women; M_{age}=43.1, SD=16.96; Prolific Academic) to either report how many NIM tasks associated with the woman identity or tasks socially expected but not tied to a specific identity they engaged in regularly. We measured degree of identity conflict and participants made selections from a list of 16 personal care products for a hypothetical subscription box. An OLS regression revealed that the interaction of NIM and degree of identity conflict was a significant predictor of the number of premium NIM products chosen in the subscription box task, b=.25, SE=.10, F (1, 238) = 6.32, p=.013; $\eta^2_{partial}$=.03.

Study 1b

We created a secondary dataset by cataloging the price and type (NIM vs non-NIM) of tagged products posted in one month for 92 Instagram influencers (46 feminists, 46 non-feminists). We observed a significant feminist*product type interaction (**β**=.64, $p < .010$), whereby feminist influencers promoted significantly more expensive NIM-related products than non-feminist influencers.

Study 1c

Women (n=57, M_{age}=24.83, SD=10.8) brought their make-up bags into the lab and sorted the contents into three groups based on how much value (low, high, miscellaneous other products) they placed on each product. An OLS regression revealed that the inter-

action of degree of identity conflict (feminist identity strength) and beliefs that the expectation to wear make-up is the result of coercion from the cosmetics industry was a marginally significant predictor of the number of high value products a woman had in her possession (b=.36, SE=.20, F (1, 56)=3.17, p=.081; $\eta^2_{partial}$=.06).

Study 2

To generalize our effect beyond woman/feminist identities, we recruited gay men (n=196, M_{age}=33.43, SD=12.08; Prolific Academic) because research suggests that they feel physical appearance-related pressures that demand NIM (Siever 1994). We assigned participants to a list of either NIM or non-NIM tasks. We measured intrinsic motivation for the tasks and assessed value placed on associated products. We measured Internalized Homophobia (Herek et al. 1997; Martin and Dean 1987; α=.86) and reverse coded this measure so that a high score represents high identity conflict.

To test whether the relationship between the NIM and degree of identity conflict interaction on valuation of nonvoluntary maintenance products was mediated by intrinsic motivation, we used model 8 of Hayes (2013) PROCESS macro. We observed a significant index of moderated mediation (b=.14, SE=.06, CI 95% [.0379, .2792]). For individuals in the NIM condition, as individuals' degree of identity conflict increased, participants' intrinsic motivation increased (b=.53, 95% CI [.1862, 0.8709]). As intrinsic motivation increased, participants' valuation of NIM-related products also increased (b=.26, 95% CI [.1339, .3859)].

Study 3

We assigned women (n=484, M_{age}=30.76, SD=12.00) to a 2 (identity maintenance: nonvoluntary vs. voluntary) x 2 (identity conflict: eliminated vs. present) x continuous (degree of identity conflict) between-subjects experiment. We manipulated perceptions of shaving one's legs as nonvoluntary or voluntary. We manipulated identity conflict using a writing task where we asked participants to describe why the feminist and women stereotypes are (conflict present condition) or are not (conflict eliminated condition) in conflict. We assessed intrinsic motivation, shaving-related product valuation, and degree of identity conflict.

Using model 12 of Hayes' (2013) PROCESS macro we tested the 2 (identity maintenance: nonvoluntary vs. voluntary) x 2 (identity conflict: present vs. absent) x continuous (degree of identity conflict) impact on product valuations through intrinsic motivation. We found a significant index of moderated mediation (b=.09, 90% CI [.0459, .1668]). Specifically, we observed a positive indirect effect of identity maintenance on product valuation through intrinsic motivation in the conflict present condition when degree of identity conflict was high (+1 SD; b=.15, 90% CI [.0109, .2947]). Importantly, this effect was significant and negative when degree of identity conflict was low (-1 SD; b= -.20, 90% CI [-.3370, -.0724]. In other words, as identity conflict increased for participants who felt that the woman identity and feminist identity are (not) conflicting, we found that NIM increased (decreased) participants' intrinsic motivation for shaving ($b_{interaction}$=.27, 90% CI [.0640, .4715]). As this intrinsic motivation increased, so did participants' valuation of shaving related products (b=.34, 90% CI [.2812, .3929].

General Conclusion

Our research highlights the impact of societal expectations on the identity signaling. We hope that by exposing this type of non-voluntary consumption, consumers may be awarded the ability to choose to spend their money in any purchase category they wish rather than those demanded by societal forces over which they have no control. Thus, we hope that our research is a catalyst for future researchers to investigate and provide solutions to inequalities in consumption expectations.

Insights into Identity Formation: How Differences in Ethical Orientations Predict Affiliation with Individual and Group-Based Identities

Katie Mercurio, California State University, Chico, USA

EXTENDED ABSTRACT

Despite the importance of identity formation within consumer behavior (Klein, Lowrey, and Otnes 2015; Reed et al. 2012; Venkatesh et al. 2010), little research has explored the predictors for the differences in the types of identities with which people prefer to affiliate. Consider two intelligent, ambitious women who live in the United States – one may primarily identify as an American Female while the other might choose to identify as intelligent and ambitious. While the former bases her identity on two group affiliations (females, Americans), the latter bases it on individual attributes. The current research explores a novel predictor for the importance placed by people on such group-based versus individualized identities. Specifically, we assert that whether people care more about group or individual identities is related to differences in their ethical standards of judgment (cf. Love, Salinas, and Rotman 2020).

Extensive prior research, including work on self-construal (Markus and Kitayama 1991), has shown that people differ in their propensity to form group-based versus individualized identities. It is also known that these types of identities are important as they shape consumer decision-making in a variety of contexts such as charitable giving (Freeman, Aquino, and McFerran 2009). Consider a consumer who identifies as being kind and generous while placing little importance on a referent group in designating their self-concept. This consumer is thus likely to decide on giving to a charity due to these individualized identity attributes without experiencing any group normative influence. However, a consumer identifying socially as a Christian would probably refer to the behavior of other Christians or seek to donate to Christian charities when deciding whether and where to donate.

There exist two preeminent standards of ethical judgment in moral philosophy: deontological formalism and teleological consequentialism (Brady 1985; Kant 1785/1998; Reynolds 2006). Formalism is concerned with the duty to follow moral principles and rules (Kant 1785/1998; Love et al. 2020). Given that moral authority of a society may be found in its heritage, tradition, authority figures or group memberships, the rules on which formalists base their moral judgment are likely to be dictated by the groups with which they are affiliated. A formalist will likely draw their moral rules from their nation, religion, or political party and should thus exhibit a stronger identification with these groups. Further, we propose that formalists will be more persuaded by donation requests coming from in-group members and should also be willing to donate more to help those whom they consider part of their in-group than to out-group members.

On the other hand, consequentialism focuses on the consequences of one's actions on other people or on society at large (Love et al. 2020; Reynolds 2006). Since consequentialists do not derive their morality from group norms, we propose that they should be less likely to form group identities. Because they are focused on individual needs, consequentialists should show stronger identification with their individual, abstract-ideal attributes (e.g., kindness, intelligence). Further, we hypothesize that they look inwardly to their individual identities to make donation decisions without caring whether the donation request source or the donation recipient is from an in-group or an out-group.

We propose a positive relationship between consequentialism and individual-identity affiliation and another correlation between formalism and group-identity affiliation. We test these two relationships and their effects on donation decisions in three studies.

In Study 1, 201 US-based MTurk workers completed the Ethical Standards of Judgment Questionnaire (EJSQ; Love et al. 2020) and the Social and Personal Identities scale (Nario-Redmond et al. 2004), in a counter-balanced order. In line with our hypotheses, we found that consequentialism was positively related to individual-identity importance ($\beta = .18$, $p = .009$), but formalism was not. Similarly, formalism was positively related to group-identity importance ($\beta = .48$, $p < .001$), but consequentialism was not.

In Study 2, we examine how activating a giving norm differently affects donation decisions of formalists and consequentialists. Participants (MTurk workers) were presented with an opportunity to donate to a charity. We randomized whether they got to know of this charity from a flyer (control condition) or from their favorite NFL team (group-identity condition). We measured Psychological Commitment to Team (PCT; Mahony, Madrigal, and Howard 2000), as a proxy for NFL team identification. In line with study 1, we found that formalism was correlated with team identification ($\beta = .29$ $p < .001$) but consequentialism was not. We also found a 3-way interaction of consequentialism, formalism, and identity condition on donation amount ($F(1,130) = 7.73$, $p = .005$). Specifically, in the group-identity condition, when consequentialism was low, formalism had a boosting effect on donation ($t(128) = 3.60$, $p < .001$), but not when consequentialism was high. In the control condition, there was no interaction of formalism and consequentialism. Examining PCT as a mediator, we found a significant indirect effect of formalism on donation amount in the group-identity condition ($\beta = .24$, SE = .13; 95% CI: .03, .55) but not in the control condition. The effect of consequentialism on donation amount was not significantly mediated via PCT in either of the conditions.

In Study 3, participants first completed ESJQ and were then asked to donate to a needy child in Middle East (dissociative outgroup) or another part of the world (control). Across both conditions, we found a positive effect of consequentialism on donation intent ($\beta = .12$, $p = .004$) but no main effect of formalism. However, a 3-way interaction ($F(1,585) = 8.72$, $p = .003$) revealed that, in the dissociative-outgroup condition, when consequentialism was low, formalism had a negative effect on willingness to donate ($t(593) = -2.13$, $p < .05$) but a positive effect in the control condition ($t(593) = 3.94$, $p = .001$), and when consequentialism was high, there was no effect of formalism in either condition. Relatedly, consequentialism did not interact with condition.

This research helps explain how moral principles influence the importance placed by people on different identities. Specifically, we show that formalists care more about their group identities while consequentialists are more affected by their individual identities.

The Interactive Effect of Social Crowding and SES on Moral Judgement

Yunhui Huang, The Ohio State University, USA
Ke Zhang, Shanghai University, China

EXTENDED ABSTRACT

Individuals' moral standards can be more flexible than they think (Sharma et al., 2014). Recent research shows that people's perceptions of the ethicality of an immoral action can be shaped by environmental factors incidental to the immoral behavior (e.g., financial constraints, and exposure to variability; Ding & Savani, 2020; Sharma et al., 2014). The research presented herein examines how another prevalent environmental factor, social crowding, interacts with perceivers' SES to influence their moral judgments.

Social crowding is defined as a situation in which a group of people is gathered together so that physical proximity between individuals is increased (Maeng et al., 2013). Prior research has documented a variety of psychological and behavioral consequences stemming from social density (Consiglio et al., 2018; Maeng et al. 2013). In the current research, we predict that social crowding leads to harsher moral judgment for high SES, but not low SES individuals. We argue that it is because an unstable social environment caused by social crowding is particularly threatening to individuals with high (vs. low) SES, who are more likely to become prime targets for immoral or even criminal behavior (Abbink et al., 2011; Zizo, 2003). Therefore, crowding may compel them to judge and even punish unethical behavior more harshly so as to minimize potential transgressions (Ding & Savani, 2020). A set of three studies provides support for our theorizing.

Study 1

Method

We used a large cross-cultural survey (World Values Survey; Inglehart et al., 2014) to examine our hypothesis. 157,875 responses were available from 80 countries and covered 35 years.

Four 10-point items (e.g., "avoiding a fare on public transport"; 1 = never justifiable, 10 = always justifiable, reverse coded) to which more than 90% of participants responded acted as the dependent variable. The World Value Survey collected respondents' relative household income on a 10-point scale, with a higher score indicating a relatively higher income level (1 = lower step, 10 = tenth step), which acted as the moderator. Finally, we used population size of the town in which respondents lived, which was observed and coded by interviewers, as a proxy for social crowding. This item was scored on an 8-point scale (1 = 2,000 inhabitants or fewer, 8 = 500,000 inhabitants or more). We also controlled for variables such as education and employment status.

Results

We z-scored all continuous predictive and control variables and conducted a random-coefficient multilevel regression analysis, with individuals nested within countries and years. The analysis yielded a significant interaction between town size and relative income ($p = .001$). As we theorized, for respondents whose relative income was one SD above the mean, a larger town size was positively associated with harsher moral judgments, $p < .05$. However, for respondents whose relative income was one SD below the mean, such positive association was not supported.

Study 2

Method

This study employed a 2 (crowding: human crowding vs. animal crowding) × continuous (measured SES) between-subjects design. In the human- (vs. animal-) crowding condition, participants were asked to read an article highlighting the growing density of humans (vs. squirrels) in the United States (Sng et al., 2017) and to summarize the main content of this article.

Next, all participants read about four unethical behaviors (e.g., "over-reporting one's travelling expenses") and indicated how justifiable they deemed each behavior along a 7-point scale (1 = never justifiable, 7 = always justifiable; reverse coded). Afterward, participants provided demographic information, embedded in which were three 7-point items assessing their SES (e.g., "I have enough money to buy things I want"; 1 = strongly disagree, 7 = strongly agree; Mittal & Griskevicius, 2014).

Results

We regressed moral judgment on the crowding condition (1 = human crowding, 0 = animal crowding), z-standardized SES, and the interaction between these two variables. The analysis yielded a significant interaction effect, $p < .05$. Specifically, for participants with high SES (i.e., one SD above the mean), human (vs. animal) crowding had a positive impact on how harshly participants judged others' immoral behavior ($p < .01$). By contrast, for participants with low SES (i.e., one SD below the mean), the effect of human crowding on moral judgment was not significant.

Study 3

Method

Participants completed several independent surveys. In the first survey participants responded to four items assessing the crowdedness of their living environment (e.g., "In general, how crowded are the places you usually stay?"; 1 = not at all, 7 = extremely). Next, they were presented with three scenarios (adapted from previous research; Ding & Savani, 2020; Sharma et al., 2014) describing people's unethical behavior (e.g., cheating in an interview). In each scenario, participants made moral judgments of the protagonist by responding to two questions (e.g., "How unethical was [the person described in the scenario]'s action?"; 1 = not at all, 7 = extremely).

Then, participants completed five items that measured their perceived threat level (e.g., "I face many threats these days"; 1 = strongly disagree, 7 = strongly agree), which were adapted from previous literature (Ding & Savani, 2020). Finally, participants responded to the same three items measuring SES as in Study 2, followed by demographic items.

Results

The regression analysis yielded the hypothesized interaction between crowding and SES ($p < .05$). For respondents whose SES were high (i.e., one SD above the mean), crowding led to harsher moral judgments ($p < .001$). Conversely, for respondents whose SES were low (i.e., one SD below the mean), the effect of crowding on moral judgment was not significant.

Next, we examined the mediating role of perceived threat using the SPSS Process Macro (Model 8, Hayes 2012). A 5000-sample bootstrapped analysis showed that the interactive effects of human

crowding (z-transformed) and SES (z-transformed) on moral judgment were mediated by the perceived threat (z-transformed), 95% CI = [.02, .12]. Specifically, the perceived threat mediated the effect of human crowding on moral judgments for respondents with high SES (i.e., one SD above the mean), 95% CI = [.07, .26]; however, the mediation was not significant for respondents with low SES (i.e., one SD below the mean).

Just Teasing: Can Brands Build Strong Relationships by Making Fun of Their Consumers?

Demi Oba, Duke University, USA
Holly Howe, Duke University, USA
Gavan Fitzsimons, Duke University, USA

EXTENDED ABSTRACT

In 2019, Wendy's launched a Twitter campaign (#NationalRoastDay) designed to tease their followers. #NationalRoastDay went viral, spawning positive media coverage, praise by industry experts (Bryan, 2019), and 350,000 new Twitter followers for Wendy's (Beltis, 2018). The popularity of #NationalRoastDay contrasts prior work finding that teasing is (at best) unrelated to brand attitudes (Roehm & Roehm, 2014) and at worst a serious risk of offending consumers and lowering brand attitudes (Warren & McGraw, 2016). How might these opposing viewpoints be reconciled?

We suggest two ways that teasing leads consumers to connect with brands. First, teasing exists on a continuum from antisocial (i.e., provoking) to prosocial. Prosocial teases are teases about non-threatening domains, are common in interpersonal relationships (Kowalski, 2004) and lead to positive outcomes (Haugh, 2011). Thus, advertisements that use prosocial teases should not generate the negative effects that have previously been associated with teasing.

Second, previous research suggests that people anthropomorphize agents when an agents' behavior is unpredictable and resembles a human schema (Epley, Waytz, & Cacioppo, 2007). Consequently, we suggest that brand teasing causes anthropomorphism because teasing is a uniquely human behavior but is unexpected in brand communication.

Combining these ideas, we assert that when brands use prosocial teases, they will benefit from anthropomorphism which leads to improved self-brand connection. However, when brand teases are deployed in more sensitive domains, this positive effect of teasing on consumer-brand relationships should be attenuated.

In Study 1 we analyzed tweets (n=309) from Wendy's on #NationalRoastDay, which included teases and Wendy's normal non-teasing Twitter activity. MTurk workers (N=1533) rated the extent to which tweets from this sample were funny and teasing. Controlling for tweet funniness and the number of followers of the tease target, Teasing was a positive predictor of retweets (β = .315, t(1529)=9.95, p<.001), replies (β = .217, t(1529) = 6.65, p<.001), and favorites (β = .382, t(1529) = 12.57, p<.001). We replicate these findings using Wendy's tweets that did not occur on #NationalRoastDay.

In Study 2 we replicate the observed effect in a controlled experiment. Prolific workers (N= 1147) viewed an online banner ad where Wendy's teased or was merely funny. Participants completed measures of Wendy's. Wendy's was significantly more anthropomorphized when using a teasing (M = 4.81, SD = 1.57) than a funny ad (M = 4.23, SD = 1.63; t(1145) = 6.05, p < .001, d = .36) and that participants reported higher self-brand connection after viewing a teasing ad (M = 2.94, SD = 1.49) vs. a funny ad (M = 2.74, SD = 1.43; t(1145) = 2.32, p = .02, d = .14). Anthropomorphism significantly mediated the effect of ad condition on self-brand connection (B [95% CI] = .29[.19, .39]).

In Study 3, MTurk workers (N=819) watched one of twelve television ads for the food delivery brand Postmates. Then participants evaluated how anthropomorphic Postmates seemed, their level of self-brand connection with Postmates, and how funny and teasing the advertisement was. Controlling for funniness and advertisement dummies, teasing positively predicted anthropomorphism (β = .12, t(805) = 2.95, p = .003) and for self-brand connection (β = .12, t(805) = 3.29, p = .001). Anthropomorphism mediated the effect of teasing on self-brand connection (B[95% CI] = .06 [.02, .10]).

In Study 4, we sought to explore the boundary conditions where teasing no longer leads to positive relationship outcomes by deploying teases in sensitive domains. In a pretest, participants rated romantic relationships as significantly more sensitive than cooking ability. Therefore in Study 4, participants viewed online banner ads for the dating app Bumble. Participants either saw a teasing ad, a purely funny ad, or a neutral control. After viewing the ad participants evaluated anthropomorphism, self-brand connection, and funniness and teasing manipulation checks. When Bumble used a teasing ad, they were significantly more anthropomorphized (M = 3.97, SD = 1.57) than when they used a funny ad (M = 3.62, SD = 1.56) or a control ad (M = 2.96, SD = 1.48; F (2, 642) = 24.03, p <.001, η^2 = .07). We did not observe an effect of condition on self-brand connection (F (2, 642) = .27, p = .76, η^2 = .001). Despite the null main effect, anthropomorphism mediated the effect of condition on self-brand connection: teasing vs. funny (B[95%CI] = .54[.39, .71]); teasing vs. control (B[95%CI] = .54[.38, .70]).

In study 4 we observe the previously established mediation effect of teasing on self-brand connection through anthropomorphism, however, in the more sensitive domain of romantic relationships we no longer observe a main effect of teasing on self-brand connection. Thus far, we have suggested that this observed null effect of teasing on self-brand connection is due to the provoking nature teased used in a sensitive domain.

In Study 5 we test meanness as an offsetting parallel mediator between teasing and self-brand connection. Single Prolific workers (N=444) viewed a teasing or a funny ad for Bumble depending on their assigned condition. Participants then evaluated how mean the advertisement was, as well as how anthropomorphic Bumble seemed, their level of self-brand connection with Bumble. Participants rated Bumble as significantly more anthropomorphized after a teasing message (M = 3.81, SD = 1.52) versus a funny message (M = 3.24, SD = 1.55; F(1,438) = 15.31, p<.001, d = .37). Participants rated the teasing message as meaner (M = 2.42, SD = 1.37) than the funny message (M = 1.62, SD = 1.01; F(1, 438) = 49.25, p <.001, d = .66). As expected, there was no significant difference in self-brand connection between the teasing and funny condition (F(1, 438) = 2.92, p = .09, d = .16). Both anthropomorphism (B[95%CI] = .29[.14, .44]) and meanness (B[95%CI] = -.17 [-.26, -.10]) mediated the effect of condition on self-brand connection.

In summary, we find that teasing consistently leads to increased anthropomorphism over and above funny advertisements and that this anthropomorphism leads to increased self-brand connection. When teases are deployed in sensitive domains however, the effect of teasing on self-brand connection is attenuated by the activation of a secondary 'meanness' mediation path.

'Not Having Enough' Can Safeguard Privacy: Resource Scarcity and Willingness to Share Personal Information

Arani Roy, PhD student, Desautels Faculty of Management, McGill University, Canada
Ashesh Mukherjee, McGill University, Canada

EXTENDED ABSTRACT

Consumers today face several requests to share personal information when they go online. Cookie-requests, registration webforms, location-sharing requests are examples of techniques used by online firms to collect consumer-level data. The reason this consumer-level data is important for firms is because this data helps them understand the consumers better and target efficiently. However, as much as companies attempt to capture consumer-level information, individuals also have concerns about sharing personal data, as misuse of individual-level data following data breaches often occurs online.

Therefore, the question is, what makes consumers share their personal information online? Past research has investigated several factors that contribute to varying levels of information-disclosure. Some of these factors are website-related (e.g., website appearance, Jarvenpaa, Tractinsky, and Saarinen 1999), and some are consumer-related (e.g., age and education, Smit, Van Noort, and Voorveld 2014).

The present investigation extends this literature by identifying a novel driver of consumers' willingness to share personal information, namely the extent to which the consumers' resources are scarce. These resources can be money, time, or a digital resource such as a phone battery. Consumers often feel they don't have enough resources available to them. We hypothesize that this feeling of not having enough can lead to reduced willingness to share personal information.

THEORETICAL DEVELOPMENT

Resource scarcity has been defined as a discrepancy between one's current level of resources and a higher, more desirable reference point (Cannon, Goldsmith, and Roux 2019). This gap in resources or a feeling of not having enough often arises in today's world, such as not having enough money to buy desirable products or not having enough time to go on a vacation.

Extant research in scarcity has explored how resources influence individuals' feelings of security and perceived threat levels. For example, researchers found that people with more money feel more protected from unforeseen events (Johnson and Krueger 2006). Similarly, researchers (Pitesa and Thau 2014) reported that individuals with fewer material resources felt more vulnerable to threat. Taken together, these findings indicate that not having enough resources can make individuals feel less secure and more vulnerable to threats, which then motivates people to generate a coping response to find comfort and security. One such coping response could be exercising increased sensitivity to an external threat.

In the context of online browsing, one of the biggest threats is potential data misuse. Online users are aware of this threat and identify sharing data online as a potential financial and reputational threat (Martin, Borah, and Palmatier 2017). In our research, we envisage that people experiencing scarcity are likely to consider the threat related to potential data-misusage to be higher than the others due to their increased threat sensitivity. Thus, we predict such users to be more reluctant to share information online.

Hypothesis 1:   *Resource scarcity leads to decreased willingness to share personal information (WTSPI).*

Hypothesis 2:   *The relationship between resource scarcity and WTSPI is mediated by perceived threat of data misuse.*

OVERVIEW OF STUDIES

We have tested the proposed hypotheses across three studies. Study 1 was designed to test H1 using a one-factor between-subject design (N=197, 104 male, M_{Age} = 41.57, SD=12.43). We manipulated resource scarcity using an episodic recall task previously used in the literature (Roux, Goldsmith, and Bonezzi 2015). Participants in scarcity condition (control condition) were asked to think of 2-3 times when they felt like they didn't have enough of something (2-3 movies watched). Following the recall task, the participants were asked to imagine browsing a chocolate boutique website named *chocolatedayandnight.com* and were shown a cookie request. After this, the participants indicated their WTSPI. Participants in the resource scarcity condition showed lower WTSPI (M = 3.74, SD = 1.96) than participants in the control condition (M = 4.25, SD = 1.83; $F(1, 195)$ = 3.63, p = .058, h_p^2 = .018) with marginal significance, supporting H1.

Study 2 was designed to test H2 using a one-factor between-subject design (N=130, 79 male, M_{Age} = 37.91, SD=11.73) similar to study 1. We manipulated resource scarcity using a scenario-based task varying money available to participants across conditions. WTSPI was measured using a cookie request on ZARA website.

Participants in the resource scarcity condition showed lower WTSPI (M=2.73, SD =1.37) than participants in the control condition (M=3.21, SD=1.59; $F(1, 134)$=3.59, p=.06, h_p^2 = .026) with marginal significance, which supports H1. We also found that participants in scarcity condition reported a higher perceived threat to data-misuse (M = 4.88, SD = 1.45), compared to participants in control condition (M=4.26, SD=1.69; $F(1, 134)$ = 5.31, p=.018, h_p^2 = .038). Following ANOVA, a mediation analysis (PROCESS model 4, Hayes 2013) supported H2, i.e., that the relationship between resource scarcity and WTSPI is mediated by perceived threat of data misuse, as the 95% CI of the indirect effect through perceived threat as the mediator did not include 0 (.032, .466).

Study 3 was designed to test the underlying mechanism by varying perceived threat of data misuse. A 2X2 between-subject design (N=250, 109 male, M = 45.94, SD = 13.54) was employed to test our prediction. Resource scarcity was manipulated using the same approach as in study 1. Perceived threat was manipulated by comparing food-commerce industry's yearly data-breach number with other industries. WTSPI was measured similarly to study I on the *Chocolatedayandnight* website.

Replicating our previous results, we show that resource scarcity had a significant effect on WTSPI ($F(1, 246)$=7.69, p=.006, h_p^2 =.03). Furthermore, planned contrasts revealed that participants in the high perceived threat-scarcity condition showed lower WTSPI (M=2.63, SD=1.60) than participants in high threat-control condition (M=3.64, SD=1.65; $F(1, 246)$=12.17, p=.001, h_p^2 = .047). However, there was no significant difference in WTSPI between participants in low threat-resource scarcity condition (M=3.03, SD=1.81) and low threat-control condition (M=2.89, SD=1.47; $F(1, 246)$=.21, p=.65, h_p^2 = .001). These findings provide support to our predicted mecha-

nism. We further expect the nature of information disclosure to moderate the main effect.

The current research contributes to the literature on privacy by identifying a novel driver of willingness to share personal info, i.e., resource scarcity, and helps marketers understand when best to request consumers for personal information.

Perceived Financial Constraints and Purchase Happiness

Rodrigo Dias, Duke University, USA
Eesha Sharma, San Diego State University, USA
Gavan Fitzsimons, Duke University, USA

EXTENDED ABSTRACT

Perceived financial constraints are ubiquitous, and research suggests that consumers who feel financially constrained are especially likely to engage in compensatory consumption (Cannon, Goldsmith, and Roux 2019). However, it is unclear whether spending confers greater happiness when consumers feel financially constrained. In seven studies (N = 7,228), we find that perceived financial constraints decrease the happiness consumers derive from spending. This effect occurs because consumers who perceive greater financial constraints are more likely to spontaneously consider opportunity costs when evaluating their purchases.

Opportunity costs refer to the value of alternatives that a person does not choose. While consumers generally neglect opportunity costs (Frederick et al. 2009), those who are resource-constrained are more likely to consider opportunity costs when making decisions (Spiller 2011). We hypothesize that this relationship extends to situations in which consumers evaluate their purchases. This prediction is supported by prior research showing that thoughts about money are more likely to arise spontaneously in the minds of individuals who are financially constrained (Shah et al. 2018).

We further hypothesize that considering opportunity costs will decrease purchase happiness. This proposed relationship is consistent with the finding that satisfaction is reduced when other alternatives are more salient (e.g., Schwartz et al. 2002; Iyengar and Lepper 2000). Thus, we predict that (a) perceived financial constraints will increase spontaneous consideration of opportunity costs when consumers evaluate their purchases, and (b) this will result in lower purchase happiness.

In study 1 (n = 738), natural variation in perceived financial constraints among a nationally representative sample was negatively correlated with purchase happiness across a wide range of purchases ($r = -0.10$, $p = .008$). This effect remained significant after controlling for all the purchase characteristics and demographic variables we collected ($b = -0.09$, $p = .013$). Additional studies suggest that this effect is not due to mood or to financially constrained individuals being less satisfied with life in general.

Studies 2A (n = 1,087) and 2B (n = 1,089) manipulated perceived financial constraints and examined the role of opportunity cost consideration in mediating the effect by explicitly measuring it (2A) and by coding open-ended responses for spontaneous activation of opportunity cost consideration (2B). When financial constraints were made salient, consumers reported lower purchase happiness (2A: $t(1085) = 2.62$, $p = .009$; 2B: $t(1087) = 2.68$, $p = .007$), and this effect was partially mediated by consideration of opportunity costs.

Study 3 (n = 1,488) provided further evidence for the proposed mediator by directly manipulating opportunity cost salience. While increasing the salience of opportunity costs reduced purchase happiness overall ($p = .014$), this effect was attenuated for consumers who perceived greater financial constraints ($p = .412$). This result is consistent with our proposition that perceived financial constraints decrease purchase happiness because consumers who perceive greater financial constraints are more likely to consider opportunity costs spontaneously.

Study 4 (n = 988) demonstrates that the effect is attenuated for planned purchases, a boundary condition consistent with our proposed mechanism. Specifically, this attenuation occurred because (a) perceived financial constraints have a smaller effect on consideration of opportunity costs of planned ($b = .01$, SE = .08, $p = .848$) than unplanned ($b = 0.23$, SE = .08, $p = .004$) purchases, and (b) opportunity cost consideration has a smaller effect on purchase happiness for planned ($b = -0.04$, SE = .03, $p = .181$) than unplanned ($b = -0.21$, SE = .03, $p < .001$) purchases.

Studies 5A-5B tested a downstream consequence: more negative online reviews. We found that because perceived financial constraints decrease purchase happiness, consumers who perceived greater financial constraints write more negative reviews for their purchases. We observed this effect in a unique dataset of consumer reviews on Yelp (n = 852, study 5A, $p = .047$), and in a controlled experiment where we manipulate perceived financial constraints and measured their effect on the reviews consumers write for their purchases (study 5B, n = 986, $p = .014$). This effect emerged both when the content of the review was coded by research assistants and by The Evaluative Lexicon (Rocklage, Rucker, and Nordgren 2018), an automated text analysis software.

To estimate the size of the effect and its robustness across several purchase types, we meta-analyzed our file drawer (25,765 participants; 42 studies). The results suggest an effect size of $r = -0.12$, 95% CI: [-0.14 to -0.10], $p < .001$. This effect was attenuated for purchases that were planned (vs. unplanned), discretionary (vs. necessity), more likely to be used with others (vs. alone), and used frequently (vs. infrequently).

This research demonstrates a novel consequence of perceived financial constraints and shows that financial resources may limit happiness not only by restricting desired consumption, but also by reducing the utility consumers derive from spending.

Understanding Consumers' Well-Being: Moving Consumption from Materialism towards Happy Hedonism

Rita Coelho do Vale, Universidade Católica Portuguesa, Católica-Lisbon School of Business and Economics, Lisbon, Portugal
Rik Pieters, Tilburg University, Tilburg, the Netherlands

EXTENDED ABSTRACT

How many of us never experienced pure pleasure out of owning specific objects? This pleasure might be related with owning an expensive product as a sports car or a technological gadget, but also with possessing rather inexpensive products like a cosmetic that comes in a special wrapping or buying a special type of cookies that come in an exquisite kraft paper box. In fact, many of our purchases are not guided by the functional aspects of the product but instead by the multisensory experience of owning and using the products (Hirschman and Holbrook 1982). And many of these products that elicit pleasure are not conspicuous in nature but rather are related with the satisfaction or value that consumers extract out of small details, such as the rubber-grip handle of the potato peeler or the fact that the colour of the tea shines so nicely through the glass. This suggests that the possession and use of objects, or the consumption of unique experiences, even when not triggered by a specific need, may have a powerful effect on consumer's satisfaction and well-being. But this also suggests that the simple possession of objects or the consumption of unique experiences can have a power effect on consumer's satisfaction and well-being, providing overall a nice feeling (Alba and Williams 2013; Keinan and Kivetz 2010).

This is an interesting proposition because the act of consuming without a specific need, typically associated with materialistic goals is considered by many authors to be associated with negative characteristics/ outcomes (Kasser 2002; Kasser et al. 2014; Richins, 2004). In fact, as stressed by Belk in his seminal work (1985) two of the issues related with materialism that deserved a special look was if (1) materialism is an egoistic trait that impairs altruistic and prosocial behaviors, and (2) materialism would negatively affect interpersonal relationships. In a similar vein, Kasser (2002) argued that consumers high on materialistic values (those who, according to the authors, aim for financial success, aim for social recognition through product owned, and aim for an appealing appearance) tend to exhibit low self-actualization and vitality, high significant levels of depression and anxiety, and alcohol and drugs abuse. In a more recent study Kasser and colleagues (2014) highlighted again a negative relationship between the importance given to materialistic goals and consumers' psychological well-being (mental health).

The hidden assumption in these prior works appears then to be that the act of consuming without need and to achieve specific aspirational goals is something bad, a behavior that people should prevent from exhibiting and that typically impacts negatively on consumers' well-being (Jaspers and Pieters, 2016, Kasser 2016, Richins 2004). However, some consumers may also hold *values* towards hedonism, consuming products for the pleasure of it and reaching *intrinsic* compensation out of those consumption acts (and not *extrinsinc* as proposed by Kasser and colleagues). In fact, hedonism, i.e., the tendency to approach pleasure and avoid pain as ultimate life goals, has had many supporters in the history of the social sciences, but seems to have lost its platform (Bramble, 2016; Monro, 1950).

The present research studies happy hedonism, analyzing its relationship with consumer well-being. Ownership and consumption of products often gives us pleasure over and above the instrumental value of product use. This pleasure can stem from owning an expensive and luxurious product, say a novel technological gadget or a limited-edition product. But the pleasure may also come from owning inexpensive products, such as an insulated transparent tea glass.

We build on the fact that, to our knowledge, there are no validated instruments to assess the likelihood of people that use consumption (of both possessions and experiences) for self-enjoyment and well-being enhancement. We propose then to develop a measurement instrument to assess what we defined as *hedonistic consumption values*, testing its impact of a variety of different measures. This idea that people may consume simply for the pleasure of owning a specific object of experience is especially relevant nowadays because the new generation of millennials seem to be less worried about the ownership of long-term tangibles (as owning a house or an expensive car) as previous generations. Instead, millennials seem to be enthusiasts of the short but highly intense experiences, moving around between occupations, always searching for enjoyable and self-pleasurable consumption moments.

Based on research conducted in the Netherlands and in Portugal, we developed first a short-version scale of hedonistic consumption values, following the basic steps of Richins and Dawson (1992), that we later use to assess the extent to which it relates with other multiple variables as life satisfaction, extraversion characteristics, prosocial behavior, likeability by others, life satisfaction, positive attitude towards life, among many other variables.

We studied this phenomenon across four experimental studies. Study 1 (n=138) goal was the development of a happy hedonism scale, asking participants to generate examples of "happy hedonism" from their own experience, in the form of statements ("items") for a formal instrument. Content analysis of these crowd-sourced items led to a two-facet instrument: enjoyment of consumption independent of its market price, and enjoyment of shared consumption. Study 2 (n = 504) validated the instrument and facet structure vis-à-vis consumer materialism and established its positive association with consumers' well-being. Study 3 (n=159) asked participants to evaluate a materialistic vs hedonistic person and results show that although both persons were presented as heavy consumers/shoppers, hedonic people are perceived to be more concerned about others and to be expected to experience higher well-being than materialistic people. Study 4 (n=259) went one step further and tested for the impact of individuals holding materialistic versus hedonistic characteristics on a battery of personality traits and personality characteristics.

Overall, findings suggest that people that hold hedonistic consumption values may enjoy owning and consuming objects or experiences without this negatively affecting their well-being. Our results also highlight the distinction between happy hedonism and consumer materialism. These findings are a first, small step towards re-appraising the phenomenon of happy hedonism and perhaps towards new theories on the role of consumption in improving people's lives.

Creeping Objectivity: Prior Exposure Makes People More Likely to Believe Claims Are Factual Statements Rather Than Opinions

Daniel J. Mirny, UCLA Anderson School of Management, USA
Stephen A. Spiller, UCLA Anderson School of Management, USA

EXTENDED ABSTRACT

People encounter claims on a daily basis about issues in the world around them. Some claims are objective, they are either accurate or inaccurate, and other claims are subjective, reflecting varying views and opinions. The perceived objectivity of claims has important downstream consequences on collaboration (Liberman et al., 2012), interpersonal conflict (Ross and Ward, 1995), consumer behavior (Spiller and Belogolova, 2016), political polarization (Skitka and Morgan, 2014), and misinformation (Penney, 2020). But perceived objectivity is a malleable construct, affected by how claims are presented. People disagree regarding whether various claims are objective factual statements (subject to verification as true or false) or subjective opinions (not subject to verification) (Mitchell et al., 2018). Previous research has found that prior exposure increases the perceived veracity of objective factual statements (the illusory truth effect) as well as agreement with subjective opinions (the mere exposure effect) (Hasher et al., 1977; Cacioppo and Petty, 1979). The present research bridges these two literatures to investigate the novel question of whether prior exposure affects the perceived objectivity of claims as either objective factual statements or subjective opinions.

Prior work on naïve realism indicates that people sometimes treat their subjective assessments as though they are objective assessments (Griffin and Ross, 1991). Moral objectivity also varies across people, cultures, and modes of social interaction, suggesting that a claim's perceived objectivity is malleable, subject to the way in which it is presented (Goodwin and Darley, 2008; 2012). Given that prior exposure is associated with increased agreement with claims, and strength of agreement is associated with believing that claims are objective, we hypothesize that prior exposure to a claim increases the likelihood of believing it is an objective factual statement rather than a subjective opinion.

In five preregistered experiments (N=3,412 online participants), we find that prior exposure to claims makes people more likely to believe those claims are objective factual statements rather than subjective opinions. These five experiments constitute all of the data we have collected in which we manipulated prior exposure and measured beliefs that the claims were factual statements. All data, materials, and preregistrations are available at https://researchbox.org/44&PEER_REVIEW_passcode=AAOJXL.

We recruited a convenience sample of participants from Amazon Mechanical Turk. All sample sizes were large enough to provide at least 80% power to detect a within-subject difference of at least 0.15 standard deviations. Each experiment was composed of three stages. The first stage was an initial exposure stage, where half of the claims were presented to participants who were then asked to rate the claims for relevance to current events, interestingness, or to categorize them by topic, depending on the particular experiment. The second stage was a filler stage; its primary purpose was to separate initial exposure from our measures of whether participants believed claims were factual statements or opinions. During this stage, we also measured several individual difference variables. The third stage was a classification stage, providing our key measures. Participants were presented with the full set of claims one at a time. Half of the claims were repeated from the initial exposure stage and half of the claims were novel, counterbalanced across participants. Participants were asked to classify claims based on whether they believed them to be objective factual statements or subjective opinions.

For each experiment, we regressed the within-subject difference between percentage of old claims classified as objective factual statements and percentage of new claims classified as objective factual statements on an intercept and a contrast coded variable reflecting the counterbalanced assignment of claim set. When considering pooled analyses across experiments, we accounted for experiment and counterbalancing effects. Across all five experiments, we consistently observe that previously exposed statements are more likely to be classified as factual statements rather than opinions; the pooled effect size was just under a 1 percentage point difference between previously exposed statements and novel statements (exp1:$t(399)$=2.07, p=.039; exp2:$t(601)$=1.94, p=.053; exp3:$t(398)$=1.85, p=.064; exp4:$t(998)$=0.57, p=.566; exp5:$t(1004)$=2.37, p=.018; pooled:$t(3400)$=3.70, p<.001).

Consistent with prior work on the mere exposure and illusory truth effects, we find that claims are more likely to be endorsed (i.e., agreed with when classified as opinions or marked as accurate when classified as factual statements) when participants had been exposed to them during the initial exposure stage than if participants only saw the claim during the classification stage. Difference in endorsement was a significant predictor of difference in classification of claims as objective factual statements rather than as subjective opinions.

We also examined the relationship between individual difference measures and (i) the difference in percentage of old vs. new claims classified as objective factual statements, (ii) the total percentage of claims classified as objective factual statements, and (iii) total percentage of claims accurately classified. Overall, we find none of these individual difference measures moderate the effect of prior exposure on perceived objectivity. Cognitive reflection (a proxy for analytic thinking), political liberalism, and political awareness were positively related to accurate classification of claims.

Across five experiments, we found a replicable influence of prior exposure on the belief that claims were factual statements. Perceived objectivity has important downstream consequences on collaboration, conflict, consumer behavior, political polarization, and misinformation. Moreover, we frequently encounter the same claims multiple times. Sometimes repeated exposure to claims is a result of issues becoming focal points of discussion, debate, or disagreement, and claims reflecting those issues are repeated by our friends, co-workers, and media outlets. Other times repeated exposure to claims may be the result of a marketing or political campaigns or popularized slogans. Repeated exposure to a claim affects the way in which it is processed and understood. We uncover a persistent effect of exposure on perceived objectivity, repeatedly finding that prior exposure to a claim makes it more likely to be classified as an objective factual statement rather than as a subjective opinion, in addition to being more likely to be endorsed. The current research bridges prior findings in the illusory truth and mere exposure literatures, reinforcing the importance of the finding that whether a claim is perceived as objective or subjective is itself a malleable construct.

How Using a Foreign Language Influences Perceived Fairness

Grace Yu-Buck, University of Maryland Eastern Shore, USA
Arul Mishra, University of Utah, USA
Himanshu Mishra, University of Utah, USA

EXTENDED ABSTRACT

Previous research on foreign language has demonstrated that using a foreign language can influence various types of choices or judgements (Costa et al. 2014; Hayakawa et al. 2016). In the current research, we extend the effect of using a foreign language to the fairness domain, which is a hallmark of human beings' ability to maintain their relationships with others (McAuliffe et al. 2017). We propose that when using a foreign language, people are more likely to accept an unfair treatment than when using a native language.

Due to the autobiographical memory (Marian and Neisser 2000), native language (foreign language) words automatically trigger an emotional echo from previous native language (foreign language) experiences. Foreign language, in general, is acquired in less emotional environments, such as classrooms. Hence, successive bilinguals tend to experience words in a native language as more emotionally intense than the same words in a foreign language (Pavlenko 2005). Therefore, when facing unfair offer, people who are using a foreign language have less negative affect than people who are using a native language. This reduced negative affect increases the level of perceived fairness in an unfair situation. The higher level of perceived fairness further increases the likelihood of accepting the unfair offer.

Methodology

Study 1A The Effect of Language Native-Ness on Fairness Expression

This study uses a dataset, which includes 65180 English language written reviews of 309 U.K. hotels, ranging from August 2015 to August 2017. We labeled reviews that were written by reviewers from the countries whose primary natively spoken language is English as reviews written in a native language. All other reviews were labeled as reviewed written in a non-native language.

We used pre-trained word embedding vectors that were trained with the *fastText* algorithm and the Common Crawl corpus. The association between the fairness construct and each review is the dependent variable. We followed the procedure of the DDR method (Garten et al. 2018) to retrieve the numerical values for the review contents and fairness construct. The analysis also included control variables (e.g., the rating score of that review or the rule of law index provided by the World Justice Project).

Our findings revealed that the content of reviews that were written in the native language had stronger association with the fairness construct than reviews that were written in a non-native language.

Study 1B The Effect of Language Native-Ness on Acceptance

A 2 (language: native (Chinese) vs. foreign (English)) between-subjects design was used in this study. 153 Chinese students were randomly assigned to one of the two conditions. Participants in a Chinese university played the Ultimatum Game, as the responder, with a pie of 100 yuan. Participants could either accept or reject the unfair offer they received (i.e., 20 yuan). Results revealed a significant relationship between the native-ness of language and participants' choice. Participants were more likely to accept the unfair offer when using a foreign language.

Study 2 The Effect of Language Native-Ness on Perceived Fairness

Study 2 (N=111) had a 2 (language: native (Chinese) vs. foreign (English)) between-subjects design. Participants from a Chinese university read a scenario about the security deposit of an apartment. We asked participants about how fair they felt the scenario was (1=unfair; 5= fair). The results showed people perceive the unfair treatment in the scenario as fairer when the language is a foreign one.

Study 3A and 3B The Effect of Language Native-Ness on Perceived Fairness and Acceptance

Study 3a (N=109) had a 2 (language: native (Chinese) vs. foreign (English)) between-subjects design. The procedure was similar to study 1b except both perceived fairness (1=unfair; 7=fair) and choice were asked. The results showed that perceived fairness mediates the relationship between native-ness of language and acceptance of the unfair offer. When using a foreign language, participants felt a higher level of fairness, which increased the likelihood of accepting the unfair offer.

Study 3b (N=99) had the same study design as study 3a except the participants' native language was English and foreign language was Spanish. U.S. residents were the participants in this study. The results showed the same pattern as study 3b.

Study 3C The Effect of Language Native-Ness on Perceived Unfairness and Acceptance Intention

Study 3c (N=110) had a 2 (language: native (English) vs. foreign (Spanish)) between-subjects design. Participants were recruited via an online website. We asked them to read a scenario about student loan. Then, participants answered how unfair they felt the scenario was (1=a little bit unfair; 7= very unfair) and how likely they were to oppose against the policy change (1=very unlikely; 7=very likely). The results showed perceived unfairness serves as the mediator of the relationship between language native-ness and acceptance.

Study 4 The Effect of Language Native-Ness on Affect and Perceived Fairness

Study 4 (N=306) had a 2 (language: native (Chinese) vs. foreign (English)) between-subjects design. Participants answered questions of affect (1=very negative; 5=very positive) and perceived fairness (1=unfair; 5=fair) after reading a purchase scenario. The results showed affect mediates the relationship between the native-ness and perceived fairness. When using a foreign language, participants felt less negative affect, leading to a higher level of perceived fairness.

General Discussion

Contributions

First, this research contributes to the foreign language literature. We extended the effect of a foreign language into a new area: fairness. In this research, we used text analysis, economic games, and hypothetical scenarios to explore the effect of foreign language usage on perceived fairness. Second, the current work contributes to the fairness domain. We introduced language native-ness as a new factor that influences people's processing of fairness-related information. Last, we provided an underlying mechanism underlining the relationship between language native-ness and acceptance, affect.

This research could provide evidence to policymakers about how people perceive fairness when they face unfair treatments in different languages. When using a foreign language, people are less sensitive to fairness. Hence, to help people more fully understand some situations, native language versions should be provided. This research also helps managers to understand how consumers may react to unfair treatments.

The Moralization of Debt: Causes and Consequences

Malena de la Fuente, UCLA Anderson School of Management, USA
Franklin Shaddy, UCLA Anderson School of Management, USA

EXTENDED ABSTRACT

People are regularly contacted about time-barred or "zombie" debt (i.e., debt for which the statute of limitations on repayment has expired). They are no longer legally required to repay such debts, and yet the Consumer Financial Protection Bureau (CFPB) estimates that every year debt collectors reach out to millions of people to try to collect (CFPB 2017). Previous research has largely focused on explaining why consumers incur debt in the first place (Hadar, Sood, and Fox 2013; Howard, Hardisty, Sussman, and Knoll 2018; Sussman and Alter 2012; Ulkumen, Thomas, and Morwitz 2008). Other work has explored how consumers manage the repayment of debt once incurred (Amar et al. 2011; Brown and Lahey 2015; Gal and McShane 2012; Gathergood, Mahoney, Stewart, and Weber 2019). The literature, however, has yet to address the important theoretical and practical question: What happens when consumers view the repayment of borrowed money as an ethical duty?

We aim to fill this gap. Specifically, we find that a nontrivial percentage of people (i.e., roughly half, across our studies) exhibit a willingness to pay back debt when it is clear there is no formal, legal, or otherwise binding imperative to do so. And we moreover demonstrate that this propensity for what we call discretionary repayment can be predicted by the extent to which people *moralize* debt—that is, view borrowing as an ethical obligation.

In Pretests A–B (MTurk; *N*=381), we presented participants with scenarios in which they decided whether to pay back delinquent credit card, mortgage, and medical debt, and we made it clear "there will be no negative consequences if you never pay the money back" (for example, because the relevant statute of limitations had expired). Across scenarios, 51% and 42% of participants (Pretests A–B, respectively) nevertheless chose to "unnecessarily" pay back their debt. Propensity to repay was positively correlated with moralization (e.g., "Is paying back debt a moral obligation?"; *p*s<.001).

In Study 1 (MTurk; *N*=466) we asked participants to read news articles that described strategically defaulting on an underwater home mortgage in either moral or economic terms. We then presented a scenario in which participants decided whether to pay back a time-barred credit card debt (see Pretests A–B). Discretionary repayment was higher when participants were first prompted to think about mortgages in moral terms (M=2.97) than economic terms (M=2.41, *p*=.004).

In Study 2 (Prolific; *N*=499) we asked participants to write a short essay about why either morality (*moral* condition) or intelligence (*nonmoral* condition) is important. We presented them with the delinquent credit card scenario (see Study 1). We then asked participants whether they believed their decision said anything about their personal identity. Discretionary repayment was higher in the *moral* condition (M=4.03) than in the *nonmoral* condition (M=3.49, *p*=.011). And participants believed these repayment decisions were more self-diagnostic (M$_{moral}$=4.27, M$_{nonmoral}$=3.76, *p*=.004). Moreover, these attributions mediated the effect (95% CI: [.125, .733]).

In Study 3 (Prolific; *N*=993) we asked participants to write a short essay (see Study 2). We then presented the same credit card scenario from previous studies in the *self-diagnostic* condition. In the *non-self-diagnostic* condition, we asked participants to make the repayment decision as a legal guardian for a grandparent. Discretionary repayment was higher in the *moral* condition when the decision was *self-diagnostic* (M$_{moral}$=4.09, M$_{nonmoral}$=3.49, *p*<.001), but not when it was *non-self-diagnostic* ((M$_{moral}$=2.64, M$_{nonmoral}$=2.65, *p*=.986); interaction: F(1, 989)=5.49, *p*=.019).

In Study 4 (MTurk; *N*=1,115), we manipulated psychological distance between lender and borrower—for example, by manipulating whether a loan was offered by a large international bank (*high* psychological distance) or a local credit union (*low* psychological distance). Participants were less likely to pay back debt when there was more psychological distance between the lender and borrower (*F*(1, 1,176)=17.80, *p*<.001), further implicating self-diagnosticity as the mechanism (e.g., by making the relationship between borrowers and lenders feel less personal).

Finally, in Study 5 (MTurk; *N*=331) we "loaned" participants $5.00, which they "invested" in a stock market simulation, ultimately earning a $2.50 profit. We then told participants they did not have to repay the loan (and thus could pocket a $7.50 bonus), but half of participants were additional told: "Many people use their sense of morality and ethics to guide their financial decision making." Discretionary repayment among these participants was higher (48%) than among those in the control condition (35%, χ^2(1)=5.72, *p*=.017).

In short, while past research exploring the psychology of debt has largely focused on explaining why consumers incur it and how they manage its repayment, we draw from work on morality to demonstrate causes and consequences of treating debt as an ethical obligation.

We also believe our findings yield important practical implications for policymakers. For example, there have been recent calls for regulation of unscrupulous and sometimes even criminally misleading attempts to coerce consumers into settling time-barred debt (Debt Collection Practices 2020), any repayment of which can reflect a "windfall to collectors" (McAllister 2018, p. 449).

In this research, we set out to answer: What happens when consumers view the repayment of borrowed money as an ethical duty? We found that it increases the discretionary repayment of debt by increasing the self-diagnosticity of these decisions. As such, we believe our framework yields numerous implications for marketing theory and practice. For example, this novel psychological insight not only fills an important gap in the consumer financial decision making literature, but also potentially implicates millions of people and billions of dollars.

Undermining Desire: The Persuasive Power of Short-Term (vs. Long-Term) Consequences of Indulging

Paul Stillman, Yale School of Management, USA
Kaitlin Woolley, Cornell University, USA

EXTENDED ABSTRACT

A major struggle facing consumers is how to avoid temptations and instead pursue long-term goals. Consumers want to eat healthier, exercise more, and drink less. Yet they are often tempted by immediate, short-term desires that prevent them from acting in line with these goals (Ariely & Wertenbroch, 2002; Baumeister, 2002; Fujita, 2011; Hoch & Loewenstein, 1991; Hofmann et al., 2008; Myrseth & Fishbach, 2009)2009. Self-control conflicts – dual motive conflicts between superordinate, long-term goals and subordinate, immediate temptations – involve choosing whether or not to engage in behaviors that provide immediate benefits with (often disproportionately large) delayed consequences. For example, eating candy provides benefits in the moment, but harms long-term health, whereas forgoing candy means sacrificing immediate pleasure for improved health in the long-term.

The importance of these conflicts has generated an interdisciplinary research effort to provide a wide array of strategies for overcoming temptations. For one, consumers can focus on the long-term costs that temptations carry (Donnelly et al., 2018). Additionally, consumers can highlight the benefits of the long-term goal (Kuhl & Beckmann, 1985; Mischel et al., 1989), and make the immediate pursuit of long-term goals more enjoyable to increase persistence (Milkman et al., 2013; Woolley & Fishbach, 2016)2016. Thus, focusing on the long-term consequences of temptations or the positive aspects of goal pursuit can motivate consumers.

We suggest an alternative. Rather than focusing on benefits of goal pursuit or long-term costs of indulgence, the present research investigates an often-overlooked component of many temptations: short-term costs. Eating candy, for instance, carries negative consequences that are realized in the short-term – on the order of minutes and hours rather than months and years – such as consequences of a sugar spike and crash (e.g., feeling jittery, losing focus, becoming moody). While long-term costs are believed to be motivating because of their severity, short-term costs may be motivating because they are felt immediately. Specifically, although short-term consequences of indulging are less severe than long-term consequences, we suggest that a focus on short-term consequences can systematically reduce consumers' likelihood of indulging compared with a focus on long-term consequences. We propose that this occurs because short-term consequences undermine the attractiveness of the temptation, making consumers anticipate enjoying the indulgence less.

We tested our hypotheses across eight experiments and three prototypical self-control conflicts: consuming alcohol, high-fat foods, and high-sugar foods. We choose these because engaging in these behaviors has deleterious consequences for consumers' long-term health (Duckworth et al., 2018), and because many consumers struggle with these temptations. First, we find that consumers are less interested in engaging in these unhealthy behaviors when focusing on short-term (vs. long-term) consequences (studies 1a-1c). Further, they are less interested in consuming alcohol or sugary foods when focusing on short-term consequences compared to both long-term consequences or no such focus (study 2a), which holds when making real decisions in an incentive compatible design (study 2b). Holding the consequence of indulging constant (i.e., indigestion), framing the consequences as more (vs. less) immediate further reduced interest in indulging (study 3).

Examining our proposed process, we demonstrate that considering short-term (vs. long-term) consequences reduces indulgence because doing so decreases anticipated enjoyment, a primary driver of these behaviors. As such, reduced anticipated enjoyment mediated the effect of consequence timing on actual choice of a sugary snack in an incentive-compatible design (study 4). As further process evidence, this effect is moderated by the presence of an enjoyment (vs. a charity) goal: focusing on the short-term (vs. long-term) consequences of sugar consumption decreased interest in purchasing candy when consumers held an enjoyment goal, which attenuated when their candy purchases were driven by their goal to support charity (study 5).

Overall, these results provide converging evidence that short-term consequences can undermine the attractiveness of temptation, leading consumers to be less likely to indulge. These results have several practical and theoretical contributions. First, for consumers who would like to indulge less often, our results suggest a readily implementable intervention: consideration of short-term consequences. Second, for marketers of health products, these results suggest that using short-term consequences can sometimes be more effective than comparatively more severe (but less connected) long-term consequences. Third, our results suggest a new avenue for self-control research: targeting the attractiveness of temptations. In other words, rather than focusing on effortful control strategies or situation selection, the present work suggests the utility of making temptation less appealing to begin with.

Consumers often see the world in terms of stark black-and-white tradeoffs. Self-control is no different: we overwhelmingly view indulging in temptation as a tradeoff between immediate and delayed gratification – a tradeoff we too often accept. This black-and-white, good-now/bad-later conceptualization obscures the many consequences that indulgences can carry in the short-term. By sensitizing consumers to these consequences, we can more effectively reduce the attractiveness of temptation, allowing people to better stick to a healthy lifestyle.

Buying More but Paying the Same? Retrofitting an Unplanned Purchase into the Shopping Budget

Liang Huang, Tsinghua University, China
Addison Plummer, University of Arizona, USA
Anastasiya Pocheptsova Ghosh, University of Arizona, USA

EXTENDED ABSTRACT

The majority of consumers strive to control spending yet often make unplanned purchases. Body of literature has studied factors present *before* consumers make an unplanned purchase, such as hedonic motivations (Hoyer 1984) and sales promotions (Suher and Hoyer 2020). We complement this literature by examining what happens *after* consumers decide to make an unplanned purchase. Specifically, we demonstrate that consumers "retrofit" an unplanned purchase into their shopping budgets.

Consumers often use shopping lists to restrict their spending to planned items (Inman, Winer, and Ferraro 2009) and monitor their spending relative to the shopping list. However, consumers often underestimate their spending (Van Ittersum, Pennings, and Wansink 2010) and buy more items than planned (Block and Morwitz 1999). Such estimation inaccuracy has been attributed to consumers' limited cognitive ability for mental calculations (Luna and Kim 2009; Van Ittersum et al. 2010).

We demonstrate that motivational bias can also contribute to spending underestimation. Specifically, we argue that consumers strategically underestimate the price of the planned items on their shopping list, so that they can fit the unplanned item into their shopping budget, justifying the unplanned purchase. As a result, consumers who make an unplanned purchase would report the same total spending as consumers who did not.

Study 1 tested the main proposition with a 3-cell design (control vs. unplanned purchase_toilet_paper vs. unplanned purchase_soap). Participants imagined doing grocery shopping and listed out all the items they plan to purchase. Participants in the unplanned purchase conditions further imagined buying a pack of toilet paper or soap, based on conditions, as an unplanned purchase. All participants estimated the total price for all their purchases in this shopping trip (basket price). Participants who made an unplanned purchase did not estimate a higher basket price than participants who did not ($M_{control}$=57.08 vs. $M_{toiletpaper}$=46.00 vs. M_{soap}=54.27, F(2, 119)=1.44, p=.24), suggesting that consumers did not sufficiently adjust the basket price after unplanned purchases.

Study 2 tested the underlying process with a 2-cell design (control vs. unplanned purchase), by measuring participants' estimates of planned (shopping list) items and total spending separately. All participants imagined buying groceries from a given list and participants in the unplanned purchase condition imagined buying a pack of toilet paper in addition. All participants indicated the price for the total spending, the planned items, and the toilet paper (order counterbalanced). Replicating study 1, the estimated total spending did not differ between conditions ($M_{control}$=62.23 vs. M_{unplan}=59.44, F(1, 153)=1.06, p=.30). Importantly, the estimated cost for planned items was lower in the unplanned condition ($M_{control}$=62.23 vs. M_{unplan}=56.53, F(1, 153)=4.29, p=.04), suggesting that the no difference in total spending was driven by the underestimation of the price of the planned items. The estimated price for the toilet paper was significantly larger than zero and did not differ between conditions ($M_{control}$=7.05 vs. $M_{unplanned}$=6.90, F(1, 153)=.15, p=.70), suggesting that the effect was not driven by the discounting of the unplanned item.

We then test the motivational nature of the observed effect. If the effect is driven by consumers' motivation to "retrofit" the budget, but not driven by their cognitive bias of ignoring the small item price, then consumers should estimate a lower basket price when they subtract an item from the total spending. Study 3 employed a 3-cell design (control vs. unplanned purchase vs. unplanned non-purchase). We constructed two shopping lists based on pre-test. The first list included a pack of KitKat candy, and the second list replaced the candy with peanut butter at a similar price. Participants in the control and unplanned non-purchase conditions were presented with the first list, while participants in the unplanned purchase condition were presented with the second list. Participants in the unplanned purchase condition bought a pack of KitKat candy in addition to the shopping list and participants in the unplanned non-purchase condition missed the KitKat candy that was on the list. The results showed a significant main effect ($M_{control}$=24.37 vs. $M_{unplanned\_add}$=25.75 vs. $M_{unplanned\_subtract}$=20.55, F(2, 296)=8.67, p<.001). Specifically, participants who made an unplanned purchase did not estimate higher total spending than participants in the control condition (p=.29). By contrast, when consumers did not buy KitKat candy, they estimated lower total spending than participants in the control condition (p=.003).

Study 4 tested the motivational bias by varying the time of unplanned purchase. We expect that when an unplanned purchase is made in the early period of a shopping trip and consumers have not yet accumulated planned spending, they would gradually incorporate the extra expense associated with the unplanned purchase into their total spending, resulting in higher estimated spending. The study employed a 3-cell design (control vs. unplanned early vs. unplanned late). All participants shopped by a given list on a computer-simulated shopping task. Participants in the control condition shopped 11 items on the shopping list. Participants in the early unplanned condition purchased a chocolate bar after they shopped the first item from the list, and participants in the late unplanned condition purchased the same chocolate bar after they have shopped ten items from the list. All participants indicated their total spending and the price for the chocolate bar. The results showed a marginal main effect ($M_{control}$=53.44 vs. M_{early}=59.95 vs. M_{late}=55.61, F(2, 438)=2.47, p=.086). Specifically, participants who made the unplanned purchase at the end of the shopping trip did not estimate higher total spending than participants in the control condition (p=.46). By contrast, participants who made an unplanned purchase at the beginning of the shopping trip estimated higher total spending than participants in the control condition (p=.029). Further, there is no difference in the estimated price for the chocolate bar in three conditions (F(2, 438)=.021, p=.98).

This research demonstrates that, when consumers make unplanned purchases, they underestimate the cost of the planned items when calculating total spending. We further show that this estimation bias is driven by consumers' motivation to retrofit the unplanned purchase to the shopping budget and is not explained by price insensitivity. Our work complements prior research by expanding our understanding of how consumers justify unplanned purchases and how motivational bias affects spending estimations.

I Am Authentic and You Said It: Analysing Brand Authenticity on Social Media

Hsin-Hsuan Meg Lee, ESCP Business School, UK
Jakob Engelhardt, ESCP Business School, Germany

EXTENDED ABSTRACT

Being authentic has become increasingly critical for brands to differentiate themselves in a saturated marketplace (Davis et al., 2019). Brand authenticity (BA) has many positive semantic meanings associated with it, such as naturalness, individuality, originality, truthfulness, integrity, and credibility (Napoli et al., 2014; Nunes, Ordanini, & Giambastiani, 2021). Authenticity as a social construct, however, can be contextual and dynamic that is undergoing constant development. In this research, we argue that BA can be seen as an aspect of brand identity, for it is "a unique set of brand associations" that brands aspire to create and maintain (Aaker, 1997).

Many have attempted to conduct text analysis using linguistic cues to classify and identify personalities for individuals and brands (e.g., Hu et al., 2019). Textual cues can convey a great deal of information about the sender and have been proven helpful in distinguishing between personalities (Wang & Chen, 2020). We aim to extend the method into looking at the specific word choices to chracterise BA. Prior research has examined linguistic style to assess the degree of authenticity in text (e.g., Hwong et al., 2017). We suggest that authenticity as a brand identity should be assessed with brand communication, similar to other brand personality traits. What happens when a brand repeatedly claims itself to be authentic?

While the definition of BA can vary, it is agreed that authenticity lies in the eye of the beholder. Most prior studies focus on creating scales and dimensions to measure perceived authenticity by consumers (e.g., Nunes, Ordanini, & Giambastiani, 2021). Consumers look for proofs of authenticity by examining detailed information about the brand, such as ingredients, performance, or communication (e.g., Beverland, Lindgreen, & Vink, 2008; Grayson & Martinec, 2004). However, not all consumers perceive the brand associations as intended.

Especially in social media, much brand meaning and value are co-constructed with the users (Schembri & Latimer, 2016). Some consumers become active content creators by sharing genuine brand-related content and interacting with brand content. The characteristics expressed in the online posts and comments become part of collectively enacted brand identities and associations. Prior research in social media and online communication has observed style matching among users (e.g., Ludwig et al., 2013). If BA can be communicated effectively through verbal cues, it may be expected that the users would also adapt similar words in their comments. This would be one way where brands can manage the co-construction process of the brand identity. There has been no empirical evidence in the literature to prove this to be a feasible approach. Will the consumers buy into the descriptives and portray the brands similarly? We aim to explore the possibility in this study.

Building on the previous effort in extracting human and brand personalities from unstructured textual data, we developed a framework to analyze and compare the perceived and communicated BA. As many of the prior studies established the construct of BA using luxury brands, we tested ours in the similar context. Specifically, we analyzed the branded contents and the users' comments published in 2019 on Instagram for three luxury watch brands (Rolex, Omega, and Audemars Pique). To analyze the textual contents, we developed a dictionary based on the six BA dimensions identified in the previous literature: brand heritage (e.g., Napoli et al., 2014), brand continuity (e.g., Bruhn et al., 2012), originality (e.g., Portal, Abratt, & Bendixen, 2019), credibility, symbolism (e.g., Morhart et al., 2015), and quality commitment (e.g., Ilicic & Webster, 2014). Word vectors that capture the context of a word in a document, semantic and syntactic similarity and the relationship to other words were created. The synonyms and other related words to the keywords per dimension were included so that the variations that occur in ordinary language use can also be represented. In total, the dictionary includes 1754 keywords across all BA dimensions. We then followed a standard process to prepare all the textual data for the text analysis (Palmer, 2010) and used the dictionary to count the frequency and the co-occurrence of each keyword in both the comments and the brand posts.

The results suggest that the dictionary can distinguish the authenticity communication in both the branded messages and the comments. The most commonly communicated BA dimension by the three brands was brand heritage which was not surprising considering the focus on luxury brands. However, the distributions for the rest of the dimensions differ across the three brands. For example, Rolex has quality commitment and originality as the two-second most communicated characteristics. Omega, on the other hand, communicated more on brand continuity and symbolism. The results also show that communicated BA influences the perceived BA at the respective dimensions, albeit with only a small effect.

The result signifies the importance of continuously investigating the perceived brand identities, especially in social media where brand meaning co-construction is inevitable. The main contribution of the research is that text analysis can be a practical tool to monitor and analyze BA conveyed in verbal communication. It can complement the previous attempts in determining BA expressed online (e.g., Shirdastian, Laroche, & Richard, 2019) that were either based on the sentiment analysis using a manual assessment process or focusing on the writing style using existing tools, such as Linguistic Inquiry and Word Count (Pennebaker, Booth, & Francis, 2007).

Future research should consider testing the dictionary on different brands to validate the generalisability of the dimensions. To verify the results, survey research on perceived BA using the previous scales can be helpful. It would also be interesting to use the BA dimensions to predict user engagement and other branding performance metrics to improve the relevance of the textual analysis approach of measuring the BA.

How Time (vs. Money) Salience Enhances Price-Unfairness Aversion

Ritesh Saini, University of Texas at Arlington, USA
Meichen Dong, Valparaiso University, USA

EXTENDED ABSTRACT

Engaging in price differentiation is a profitable proposition. Being able to charge different prices across different customers/times/channels results in significant revenue and profit gain (Phillips 2005). However, there are potential downsides to this price differentiation strategy. Consumers react negatively to being charged prices different from other customers (Feinberg, Krishna & Zhang 2002). Negative downstream consequences of such price-unfairness perception may more than offset any revenue gains attributable to this strategy.

While several papers have dwelled into the issue of price-unfairness, relatively few consumer researchers have examined situational factors which may moderate this phenomenon. In this paper, we examine how the activating time (vs. money) in the consumer's mind can amplify price-unfairness effects.

Consumers often deal with time and money in consumption decisions (Becker 1965). They behave differently when dealing with time than with money (Okada & Hoch 2004). Money is implicitly linked with more market-exchange norms (Vohs, Mead & Goode 2008; McGraw & Tetlock 2005). Merely introducing monetary payoffs in a situation shifts focus from communal to exchange considerations (Kreps 1997, Heyman & Ariely 2004) and dilutes adherence to social norms (Gneezy & Rustichini 2000). In contrast, time leads to lower "value-maximization" concerns and more emotional/social considerations (Liu & Aaker 2008). Gino & Mogilner (2014) demonstrated that priming people to think of time, instead of money, leads to more ethical behavior. Overall, the sense one gets from a holistic analysis of these findings is that time salience leads to more communal concerns, while money salience leads to greater self-interest concerns, value-maximizing and transactional thinking.

Grounded on the above discussion, we propose that time (vs money) salience will activate a more communal (vs exchange) relationship norm, which in turn will lead to enhanced negative reactions to price-unfairness. We further posit that this will happen even across unrelated domains. Five studies have tested the propositions.

Study 1 tested whether time (vs. money) can influence consumer's perception of price-unfairness differently. 223 MTurk participants were randomly asked to think about three activities requiring spending time (vs. money) for their vacation preparation. All participants then read the same price-unfairness scenario where they were told that during the time they met with other tourists in hotel and found out that they were offered a 40% lower price. Following this, their price-unfairness perception was measured. To ensure that our results were not attributable to a perceived value-difference between the time and money conditions, , we measured the subjective value of the time or money spent in the vacation preparation.

Results revealed that time- (vs. money-) activation generates higher perception of price-unfairness ($p = 0.03$). Responses to the subjective resource value question did not show a significant difference among the two resources, ruling out the possibility that the perceived greater value of time explains these results.

Previous research has shown that activating time (vs. money) may evoke variable positive affect (Mogilner & Aaker 2009). This could have caused the observed time-money difference in Study 1. Study 2 examined the proposed effect through a different setting to test this alternate explanation. 218 participants were randomly asked to recall a time that they had to spend money (or time) on fixing a product, which eventually didn't work and they ended up purchasing a new one to replace this broken product. They were then asked to imagine that they later they found out that the same product they had purchased was offered at a 40% lower price to other customers. Subsequent to this, their price-unfairness perception was measured. Similar to Study 1, time/money value perception question was also asked.

As expected, the results revealed that the time (vs. money) activation was more likely to cause stronger price-unfairness perception ($p = 0.004$). More importantly, it ruled out the positive affect as the reason for people to have stronger aversive feelings towards the price-unfairness.

Study 3 tested the underlying process and ruled out other alternative explanations. The manipulation of time and money was evoked by creating a scenario where participants had spent extra time waiting (vs. extra money) to procure front seats at SeaWorld's dolphin show. To induce price-unfairness, they were informed that they were being charged higher prices (vs. back-row customers) for the same snacks. Then they responded to the price-unfairness measure. Along with this, they were asked several questions to measure the proposed underlying mediator and several other potential mediators: (i) communal (vs. exchange) norm activation,(ii) personal connection and (iii) intuitive thinking.

A parallel mediation analysis confirmed that only communal norm activation mediates the relationship between time activation and price-unfairness perception (-0.20, 95% CI [-0.42, -0.06]). The other two accounts were ruled out (personal connection 95% CI [-0.25, 0.01]; intuition measure 95% CI [-0.12, 0.03]).

Study 4 explored a moderating factor. Extant research shows that people may feel less discriminated when a plausible reason is provided to justify the price difference (Ashworth, 2012). In this study, we used 2(time vs. money) × 2(justification-offered vs. justification not offered) between-subject design to test this moderation hypothesis. The results showed that under justification-offered condition, people in time (vs. money) condition were more likely to lower their aversion towards price-unfairness ($p = 0.05$). However, under the "justification not offered" condition, people in the time (vs money) condition still hold greater aversion towards price-unfairness ($p = 0.02$).

Could the results of all our previous studies be driven by some sort of a currency-compatibility effect – because price unfairness is a monetary construct? Along with ruling out this alternate account, study 5 also enhances the generalizability of our finding by examining unfairness-aversion in non-price domain: flight upgrades. Results show that time activation causes people to have a stronger perception about unfairness even in non-price contexts ($p = 0.02$).

Across five studies, we demonstrate that time-activation evokes a communal (vs. exchange) norm which causes consumers to have a stronger aversion towards price-unfairness, and this persists even in non-price contexts. Providing justification of price discrimination moderates this effect.

How Evaluative Nutrition Cues Promote Consumer Response for Unhealthy Foods

Eunjoo (EJ) Han, Pennsylvania State University, Erie, USA
Euejung Hwang, University of Otago, New Zealand

EXTENDED ABSTRACT

Consumers rely on nutrition labels to infer the healthiness of packaged foods, but many find it difficult to interpret them. This has led to the introduction of interpretive front-of-package (FOP) labels which provide the evaluation of the product's overall healthfulness (Newman, Howlett, and Burton 2016). A health star rating (HSR) is a good example of FOP labels; HSR evaluates the healthiness of foods from 0.5 (unhealthy) to 5 (healthy) stars. Placing FOP labels is voluntary; as it is not a mandate, only 16% of HSR-labeled products displays the ratings of 0.5 to 2.5 stars (Mhurchu, Eyles, and Choi 2017). This finding indicates that food manufacturers and marketers are unwilling to place such evaluative nutrition cues for unhealthy foods, presumably because displaying low ratings may undermine sales and brand image. In the current research, we observe how such evaluative nutrition cues influence consumer response to unhealthy foods.

Nutrition labels not only assist consumers in making food choices but also facilitates access to health-related thoughts (Barreiro-Hurle, Garcia, and De-Magistris 2008). This suggests that the exposure to evaluative nutrition cues may offer individuals a greater access to health-related thoughts in unhealthy eating. Offering evaluative nutrition cues for unhealthy foods is also expected to lead consumers to make positive brand inferences. Specifically, the brand's decision to disclose negative product information (i.e., unhealthy) is expected to help consumers generate positive inferences about the brand and its commitment to consumer awareness (e.g., Isaac and Grayson 2017). Further, we argue that the proposed effect will be pronounced for consumers who believe that they are less (vs. more) knowledgeable about nutrition. As consumers lower in subjective nutrition knowledge (hereafter, SK) are more likely to need help in making food choices, they are more likely to appreciate the brand's decision to place evaluative cues on the front of package for unhealthy foods when other brands do not. As only a fraction of consumers believes that they are knowledgeable about nutrition (Goyal and Deshmukh 2018), it is worth investigating whether they exhibit favorable response to unhealthy foods accompanied by evaluative cues.

Study 1 tested the hypothesis by observing individuals' actual product choice. Participants first reported their SK on nutrition (Moorman et al. 2004). We then introduced them to two chocolate granolas from mainstream brands with and without the evaluative cue. They further learned that it is a food manufacturer's decision whether to adopt the cue or not. We then asked participants to choose the brand they want to try between the two options. When the product with (vs. without) the cue was chosen, the response was coded as 1(vs. 0). A logistic regression analysis showed that participants with lower (vs. higher) SK were more likely to choose the product with the evaluative cue ($\beta = -.45$, $\chi^2 = 3.88$, $p = .049$).

Study 2 aimed to offer evidence for the mediating roles of a greater access to health-related thoughts and positive brand inferences. The study was a two-group (Evaluative cue: present vs. absent) between-subjects design, with SK measured on a continuous scale. We first measured participants' SK. Next, as in Study 1, participants imagined a shopping scenario. In the cue-present condition, the product displayed a HSR of 2.0 on the front of package. In the cue-absent condition, participants were not exposed to the evaluative cue. Participants then indicated their willingness to purchase

the product. Subsequently, participants reported the extent to which they made positive inferences about the brand (Kim and Han 2020) and their desire to consider health effects (Bless and Fiedler 2006). We found the hypothesized interaction on purchase intention ($\beta = -.24$, $t(195) = 2.06$, $p = .04$); among participants with lower SK, purchase intention was higher when the cue was present (vs. absent) ($p = .052$). For those higher in SK, purchase intention was not affected by the presence of the cue. On the desire to access health-related thoughts, we also found a two-way interaction ($\beta = .23$, $t(196) = 2.03$, $p = .04$) but failed to find one on positive brand inferences. We revisit this issue in study 3. A bootstrap analysis with participants' access to health-related thoughts as a single mediator (Hayes 2013; Process model 8) revealed a significant mediation effect (.04, 95% CI = .001 to .116).

Study 3 focused on testing the hypothesis in an environment where the role of positive brand inferences is better observed. If positive brand inferences play an important role in the proposed relationship, introducing a factor that makes it unnecessary to make brand inferences should mitigate the observed effects. Thus, we manipulated the labeling into either mandatory or voluntary. The procedure was similar to that of Study 2, but while half of the participants was told the labeling was voluntary, the other half viewed the label and was told it was mandated by law. As predicted, the SK by evaluative cue (voluntary vs. mandatory) interaction on purchase intention emerged ($\beta = -.24$, $t(126) = 1.98$, $p = .049$). Among participants with lower SK, purchase intention was higher when the label adoption was voluntary (vs. mandatory) ($p = .052$). Those higher in SK was not affected by the labeling practice. We also found the hypothesized interactions on the access to health-related thoughts ($\beta = .27$, $t(127) = 1.93$, $p = .056$) and on positive brand inferences ($\beta = -.22$, $t(127) = 2.29$, $p = .02$); both did mediate the proposed relationship (Process Model 8; access to health related thoughts: .05, 95% CI = .005 to .145; positive brand inferences: -.11, 95% CI = -.237 to -.017).

The current research contributes to the evaluative cues literature by demonstrating when and how evaluative cues offering negative product information enhance consumer response. Our work also adds to the new stream of persuasion knowledge literature that consumers are not always skeptical to marketing activities. Our research provides practical implications for food manufacturers that placing interpretive FOP labels for unhealthy foods can be an effective way to improve brand image and sales.

Reserved For You: Implied Selectivity as a New Tool of Choice Architecture

Jon Bogard, University of California, Los, USA
Craig Fox, University of California, Los Angeles, USA
Noah Goldstein, University of California, Los Angeles, USA

EXTENDED ABSTRACT

Imagine you received the following email: "[Name], we know you saw Bob Dylan last time he came to town. He is coming again this summer, and tickets go on sale next week. **As a special opportunity, we have reserved 2 tickets for you to purchase.**" Consider how likely you would be to buy the tickets after receiving this message compared to a more generic message alerting you to the opportunity. We suspect that the simple choice of framing the tickets as *reserved for you* would considerably increase sales.

When consumers see a good as scarce (Lynn, 1989), or when they perceive unmet market demand for some good (Imas & Madarasz, 2020), they come to value that benefit more. Explaining this phenomenon, Imas and Madarasz argue that people's utility for a good is partly a function of their belief that others want that good but cannot acquire it. Likewise, we hypothesized, labeling an opportunity as "reserved" will cause people to infer that they have exclusive access to a coveted opportunity and thus come to value it more. This was recently confirmed in two mega-studies of messages encouraging flu vaccination (Milkman et al., 2021a, b). In this project, we introduce a new, general-purpose social influence tactic to the choice architecture toolkit: the implied exclusivity effect. Here, we test both the effect of "reserved" framing and the proposed inferred exclusivity mechanism across four studies.

Study 1: The Behavioral Science and Policy Association (BSPA) hosted its annual conference in May 2021. BSPA was offering a discount to anyone who registered for the conference before March 2021. For the final three weeks of February, the lead story in BSPA's weekly newsletter was a promotion of this discount. Members of the listserv were randomly assigned to receive one of two messages promoting this early-bird discount:

- **Control**: 2021 BSPA Virtual Conference: Early registration discount. Early bird sign-up discounts are available to subscribers of this newsletter.
- **Treatment**: 2021 BSPA Virtual Conference: Early registration discount reserved for you. We have reserved an early-bird discount for you as a subscriber of this newsletter.

As expected, there was a significant positive effect of the "reserved" language on conference sign-up (p=.02).

Study 2: After completing a decoy task, participants in this study were randomized to see one of two messages: "As an additional thanks, a copy of *Frankenstein* is available [reserved] for you." Participants were then taken to a page where they could either click a button to download an e-book copy of *Frankenstein* or they could advance to the end of the study. Unbeknownst to participants, we observed whether they clicked the button to download the book.

As expected, framing the opportunity for participants to download the e-book as "reserved for you" significantly increased downloads compared to the subtly different "available for you" framing by nearly 10 percentage points (p=.03). It is worth noting a few things about this effect. First, the opportunities are identical, there is just a one-word difference in the *framing* of the opportunity. Second, participants were offered something free—indeed, *Frankenstein* is part of the public domain and thus freely available to anyone who wants it—but not something tangible that they could possess. They were merely offered the *opportunity* to download the book. As such, while participants in the Reserved condition came to value this opportunity more highly than those in the Available condition—as evidenced by their increased take-up—this was a purely psychological effect.

Study 3. While ownership of a discount coupon (as in Study 1) makes no more sense than ownership of a $20 bill, it is possible that participants in Study 2 felt a sense of ownership—either metaphorical ownership of the book, or literal ownership of a digital file—which would be inflating the effects of the "reserved" language. In Study 3, we sought to test the generalizability of this phenomenon by extending it to a domain where formal or legal ownership could not be possible: signing up for a listserv. We replicated the design of Study 2, this time offering participants a chance to join a listserv we started discussing ways to improve your standing as an MTurker and tips for finding good jobs. Once again, this time with a more abstract opportunity, the "reserved" framing caused considerably more participants to sign up for the listserv than the "available" language (p=.003).

Study 4. We hypothesized that part of the effect of framing a benefit as "reserved" is to create the sense that this is a special, coveted benefit that others might seek but the recipient has exclusive access to. In Study 4, we crossed the typical "reserved" or "available" framing manipulation with mention that the offer to join the listserv was reserved [available] for you and "a select group of other workers" (exclusive) or "anyone else who wants to join" (non-exclusive). We hypothesized that "reserved for you" connotes exclusivity whereas "available to you" connotes non-exclusivity. We call these combinations "compatible." However, we expected that reversing these combinations (i.e., "available for you and a select group of other workers" or "reserved for you and anyone else who wants to join") would eliminate the Reserved--Available difference. In fact, that is what we find. The interaction between reserved framing and compatibility is highly significant (p=.004). Further, while there is a significant effect of "reserved" in the compatible frame (b=.21, t=4.13, p<.001), the effect entirely disappears using incompatible language (b=.01, t=0.20, p=.84 *NS*).

Across six studies in multiple domains, we document a phenomenon that framing a benefit as "reserved" for someone substantially increases the chances that they claim the benefit compared to merely informing them that the benefit is available. Moreover, we provide evidence that the effect of "reserved" framing may be driven by an automatic association connoting exclusivity of the offer. From flu vaccines to savings accounts, from gym memberships to financial aid applications, the canonical domains of nudging could all seem to benefit from employing this framing manipulation. As such, we offer this tactic as a new tool of choice architecture.

When and Why Targeted Products for Underserved Consumers Backfire

Ruoou Li, University of South Carolina, USA
Linyun Yang, University of South Carolina, USA

EXTENDED ABSTRACT

Products often fail to accommodate certain consumer groups' needs. In the present research, we refer to consumer groups who have historically felt excluded in the marketplace as underserved consumers, such as women and people of color. However, as the marketplace has become more diverse and consumers have increasingly called for more inclusion, companies have started offering products tailored to underserved segments. While past research suggests that explicitly identifying the target consumer should lead to positive outcomes (Deshpandé and Staman 1994; Forehand and Deshpandé 2001; Forehand et al. 2002), marketplace observations regarding more inclusive products suggest that this strategy often leads to unintended negative outcomes. For example, in June 2020, Band-Aid announced on Instagram their plan to create bandages "for the Black Community." However, to Band-Aid's surprise, their announcement was met with skepticism and ridicule, especially from the consumers they wished to serve.

We propose that because underserved consumers often must use products that fail to fully meet their needs, once they are given (unexpected) attention (e.g., being offered products with features that meet their needs), they may become uncertain about the true intentions behind the positive treatment after being ignored for so long in the marketplace. Specifically, blatantly indicating (relative to subtly suggesting) an underserved group as the target consumer can raise these consumers' suspicions. In turn, these heightened suspicions negatively impact assessments of the company's intentions and ultimately evaluations of the targeted product. Importantly, given that the needs of mainstream consumers are well served in the marketplace (Patrick and Hollenbeck 2021; Perez 2019), we also argue that a blatantly targeted product will not backfire for well served consumers. In addition, we propose that when suspicion mitigating cues are present (e.g., a product creator comes from an underserved consumer group), blatant relative to subtle targeting will be less likely to elicit negative reactions from underserved consumers.

In study 1 (N=83), we tested our predictions with Asian Americans. Because Asian Americans tend to have lower nose bridges (Farkas et al. 2005), they often find that regular glasses slide down their faces. Therefore, we examined Asian American participants' reactions to glasses that solve this problem. Asian American participants were shown an advertisement promoting a pair of glasses. In the blatant (subtle) targeting condition, participants saw the reading glasses labeled as "Asian fit" ("low bridge fit"). In the blatant targeting condition, Asian Americans evaluated the product and brand more negatively ($M_{blatant}$ = 4.22 vs. M_{subtle} = 4.78; $t(81)$ = 2.01, p = .048), felt more suspicious ($M_{blatant}$ = 3.88 vs. M_{subtle} = 2.70; $t(81)$ = -2.99, p = .004), and inferred less positive intentions from the firm ($M_{blatant}$ = 4.68 vs. M_{subtle} = 5.20; $t(81)$ = 2.01, p = .048). Additionally, suspicion and inferred positive intentions mediated the relationship between product targeting and evaluations (B = -.31, 95% CI [-.59, -.08]).

Study 2 (N=401) replicated the negative targeting effect with another underserved consumer group: women. Importantly, we showed that products only backfire when companies target underserved consumers (women) but not when they target mainstream consumers (men). Depending on their gender, participants in the blatant targeting condition saw an advertisement for a tea blend labeled as "Her Tea" or "His Tea" that helps women or men sleep better. All participants in the subtle targeting condition saw the same tea blend advertisement except the product was labeled as "Sleep Tea". Then, participants responded to the same measures as in study 1. We found a targeting x gender interaction ($F(1, 397)$ = 9.89, p = .002) such that women evaluated Her Tea (M = 4.84) more negatively than Sleep Tea (M = 5.51; $F(1, 397)$ = 11.00, p = .001). However, men did not evaluate His Tea (M = 4.91) and Sleep Tea differently (M = 4.72; $F(1, 397)$ = 1.07, $p > .30$). Suspicion and inferred intentions also revealed similar results. Supporting our hypotheses, suspicion and inferred intentions negatively mediated the relationship between targeting and evaluations for women (B = -.19, 95% CI [-.35, -.06]), but positively mediated the relationship for men (B = .13, 95% CI [.002, 28]).

Study 3 (pre-registered; N=876) tested the prediction that the negative targeting effect will be attenuated when the company's founder belongs to the targeted underserved consumer group. Specifically, we should replicate the negative targeting effect with female consumers when the founder of the company is a man but not when the founder is a woman. As in study 2, women in the blatant (subtle) targeting condition saw an advertisement for a tea blend labeled as "Her Tea" ("Sleep Tea") that improves sleep. For those who were in the female (male) founder condition, women read that the product was created by Stephanie (Steve) Wakefield. Then, participants completed the same measures as in previous studies. We found a two-way interaction on evaluations ($F(1, 872)$ = 4.59, p = .032) such that when the company's founder was male, women evaluated Her Tea (M = 4.57) more negatively than Sleep Tea (M = 5.13; $F(1, 872)$ = 15.50, $p < .001$) but when the founder was female, they did not differ in their evaluations ($M_{Her\ Tea}$ = 4.85 vs. $M_{Sleep\ Tea}$ = 5.00; $F(1, 872)$ = 1.41, $p > .23$). Suspicion and inferred intentions also revealed similar results. A moderated serial mediation further revealed that suspicion and inferred intentions only mediated the relationship between targeting and evaluations when the founder was male (B = -.14, 95% CI [-.21, -.07]) but not when the founder was female (B = -.05, 95% CI [-.10, .01]).

Our research makes several important contributions to the literature. First, we distinguish between two targeting approaches, namely blatant and subtle targeting. Our work also highlights how to the extent that underserved consumers view targeted products with distrust, heightened suspicions and negative assessments of a company's intentions can undermine the positive effects of inclusive design in the marketplace. Additionally, we offer a feasible solution to marketers to mitigate this negative effect: marketers can incorporate cues, such as featuring an ingroup product designer, to effectively reduce suspicions among underserved consumers.

Are Critics Credible? Negative Sources are Perceived to be Less Credible

Junha Kim, The Ohio State University, USA
Joseph Goodman, The Ohio State University, USA

EXTENDED ABSTRACT

In today's changing world of alternative facts and fake news, the need to understand the role of source credibility in consumer psychology has only increased. Source credibility, or a source's overall believability, is the combination of expertise and trustworthiness (Petty & Cacioppo, 1981; Petty & Wegener, 1998), and it has important implications for consumers' attitudes, belief formation, and consumption decisions (e.g., Chaiken & Maheswaran, 1994; Petty & Cacioppo, 1984; Sternthal, Dholakia, & Leavitt, 1978). In order to understand the consequences of source credibility, it is important to understand its antecedents—what leads consumers to perceive a source as credible. Although source credibility is one of the most studied variables in the persuasion literature, most of that attention has focused on consequences and less on antecedents.

In this research, we propose and demonstrate that the message itself can affect how a consumer perceives a source's credibility. Traditionally, source credibility and message valence are treated as independent factors that affect message persuasion. However, given the extensive research on valence asymmetries (Baumeister et al., 2001; Fazio et al., 2015) it is possible that the valence itself could affect credibility. On the one hand, negative messages are associated with expertise (Amabile, 1983), which may increase credibility. On the other hand, negative messages may be unexpected and violate norms, thus decreasing credibility. For example, 68% of Yelp reviews are either four or five stars (Yelp, 2020), suggesting that consumers expect positive messages most of times. Negative messages disconfirm such expectations, which may lead consumers to be more skeptical about the source (Ditto & Lopez, 1992; Nickerson, 1998). We propose that this skepticism will lead consumers to infer lower source credibility.

Four studies provide evidence that negatively valenced messages lead consumers to infer lower source credibility than positively valenced messages.

Study 1

In study 1, participants were presented with either positive or negative review of a wine, holding the word count, topic, and consumption vocabulary constant. In the positive message condition, a 5-star review said "smooth, bits of prune, vanilla, strawberry, and cherry are present. Well balanced and with depth." In the negative message condition, a 2-star review said "way too much prune in the palate almost overpowering the bits of vanilla, strawberry and cherry that are also present. Unbalanced and without much depth." Participants indicated their perceived credibility of the source by responding to source credibility measures that tapped into both expertise (e.g. "To what extent do you think this reviewer is an expert?") and trustworthiness (e.g., "To what extent do you think this reviewer is trustworthy?") on 7-point scales. All participants were then presented with another wine and a 5-start review by the same reviewer, and were asked to indicate how interested they would be in trying this second wine. Participants perceived the source less credible when the message was negative (M_{neg}=5.06) compared to positive (M_{pos}=5.33, p=.017). Further, this effect led consumers to be more likely to follow a source's recommendation on a subsequent recommendation (i.e., an indirect effect on interest to follow a recommendation through source credibility, 95%CI=[-.15,-.01]).

Study 2

Study 2 shows that the effect holds regardless of whether the source chose the product. In a 2(message valence: positive vs. negative) x 2(product choice: by-source vs. not-by-source) between-subjects design, participants were presented with a wine review as in study 1 except that additional information also explicitly stated that the product was chosen by the source ("I am delighted [disappointed] that I chose this wine.") or not chosen by the source ("I am delighted [disappointed] that I won this wine from an event."). Again, participants perceived the source less credible when the message was negative (M_{neg}=4.96) than positive (M_{pos}=5.17, p=.016). Further, this decrease in credibility led to lower intentions to follow the source's recommendation (indirect effect 95%CI=[-.10,-.01]). Whether the source choose the product or not did not moderate the effect (p=.882).

Study 3

Study 3 provides further evidence, replicating the effect for multiple products and showing a stronger effect for utilitarian versus hedonic products. In a 2(message valence: positive vs. negative) x 2(product type: utilitarian vs. hedonic) x 3(product replicates of each type) mixed design, participants were presented with one review of each of 6 products. Multi-level linear regression (Judd, Westfall, & Kenny, 2017) showed a significant fixed effect of the message valence on source credibility. Participants perceived the source more credible when the message was positive rather than negative (b=.18, p<.001). There was a significant interaction between review valence and product type (b=.05, p=.010), indicating that the effect was stronger for utilitarian products, but the simple effects were significant for both hedonic (p<.001) and utilitarian products (p<.001).

Study 4

Study 4 tests our theory and identifies a boundary condition in a 2(message valence: positive vs. negative) x 2(expectation: baseline vs. low) between-subjects design. In the low expectation condition, participants expectations for the brand were lowered so that positive reviews would be less expected; participants were told that the product was, "from a brand you've never heard of before. It seems they just entered the market and this is their first and only product." The baseline condition did not receive any information about expectations. Participants perceived the source less credible when the message was negative (M_{neg}=3.92) than positive (M_{pos}=4.24, p=.042), but this was moderated by expectation (p=.003). In the baseline condition, participants perceived the source less credible when the message was negative (M_{neg}=3.60) than positive (M_{pos}=4.41, p=.001) as in our previous studies. However, in the low expectation condition, there was no difference in source credibility perception (M_{pos}=4.07 vs. M_{neg}=4.22, p=.515).

Genernal Discussion

In summary, we find that consumers infer less source credibility from negative messages compared to those that are positive, and this lower credibility decreased a message's persuasiveness. We find this effect across various products and situations. The findings suggest that negative messages may not always be so negative because they can lead consumers to lower the credibility of the message source.

Finally, the findings should caution the overly critical critic, who may be putting their own credibility at risk.

Managing Daily Lives Through A Pandemic: I Shop Therefore I Am

Melika Kordrostami, California State University San Bernardino, USA Minor Outlying Islands
Elika Kordrostami, Rowan University, USA

EXTENDED ABSTRACT

Introduction

Research shows that individuals' behaviors change during a crisis in different ways. A coherent research effort about how a crisis such as a global pandemic impacts an individual's psyche is lacking. Therefore, the goal of current exploratory research is to investigate how people perceive the pandemic and identify their different emotions and thoughts during the pandemic, in addition to coping processes that are used by individuals to manage their lives.

Current research is built upon the self-affirmation theory (Steele, 1988), which suggests that each individual has a self-system to maintain the perceived integrity of the self instead of addressing each particular threat (Steele, 1988). The objective of this system is to sustain a self-concept that is consistent over time and has the capacity to adapt. Based on this theory, individuals have more than one way to respond to threats. They can try to eliminate the threat itself, but also, they tend to make changes in other areas in their lives to diminish the threat (Steele, 1988). These efforts will enhance their perception of self-adequacy in the different areas of their lives, which is the goal of self-affirmation system.

Methodology

A qualitative study design was used to explore consumer feelings and their responses to the pandemic. Interviews were conducted virtually via either Webex or Zoom. Audio-recorded interviews were fully transcribed and the transcripts were coded. Responses within and between respondents were compared through an iterative process until the authors achieved "saturation" (Glaser and Strauss, 1967). Various themes were developed through coding of transcripts.

Results

Results showed that individuals experience various negative feelings through a pandemic such as denial, uncertainty, and anxiety. Also, our results showed that people try to cope with these feelings through some of the following ways: changes in priorities, hope, taking control/being in charge, and self-awareness.

Consumers' feelings at the time of a crisis

Negative events are likely to be met with denial from individuals since they try to avoid thinking about unpleasant consequences (Norgaard, 2006). The results from the interviews in this study showed that most people were involved in implicatory denial by assuming that the COVID-19 pandemic will not have any effect on their lives.

It is clear from the responses that one of the major struggles brought to light by this pandemic is the feeling of uncertainty. Uncertainty is shown to be a powerful cause of stress and anxiety (Badia, McBane, and Suter 1966).

Consumers' coping mechanisms

Change in priorities. Self-affirmation theory posits that individuals tend to take actions that would help them regulate their emotions. Our results showed that consumers might shift their priorities so they can deal with uncertainties and stress.

Hoarding behavior has been linked to mechanisms such as anxiety, depression, and stressful life events (Halperin and Glick, 2003; Frost et al., 2009). For example, one of the interviewees mentioned she felt anxious when she got text messages from her boyfriend and friends that she needs to stock up on products. But after spending a lot of time and money on going to different stores and purchasing an overwhelming number of products, she felt proud of her achievement and felt more prepared for the unknown.

Hope. According to Snyder et al. (1991), hope is defined as "an overall perception that goals can be met" (Snyder et al. 1991, p. 570). Hope is powered by a feeling of agency and control over outcomes and defining pathways to achieve goals (Snyder et al. 1991). This hope is shown in the interviews in terms of believing that there would be a vaccine, that leadership will be more transparent, that communities will get closer, and through becoming more spiritual. Some participants demonstrated hope by trying to *stay positive about the future.*

Taking control/Being in charge. According to Cannon, Goldsmith, and Roux (2019), when consumers feel threatened by losing their personal control, they choose control-restoration techniques to achieve that sense of agency in their life again. At the time of a pandemic, consumers state they are uncertain about several issues. These psychological threats lead consumers to try to take control in other domains to offset the negative effects (Cannon et al., 2019).

Our observations and interviews show control-restoration happens in this period through different activities such as *quarantining themselves* to feel in control of their own health.

Since many consumers do not feel safe shopping in person, they have been compensated by *shopping online* and taking control of their purchase decisions. These effects are also widely reported in the industry.

Self-awareness. In order to manage life during uncertain times, sometimes people assess their own strengths and weaknesses to figure out whether they are fit for a difficult future. For example, our interviewees try to identify whether they are introverts vs. extroverts and how they can manage their *social activities.*

General Discussion

The COVID19 pandemic changed the ways people perceive themselves and their environment in drastic ways. By employing self-affirmation theory, we show how consumers manage their daily lives through a pandemic crisis by taking on different initiatives such as changing priorities by saving instead of spending money, staying hopeful through finding silver lining, maintaining a sense of agency/being in control, and self-awareness. As previous research showed the fluidity of behavior in order to keep balance (Ma-Kellams and Zhang, 2017), our results showed that individuals can focus on behaviors that would put them in a position to manage the pandemic outcomes that would strengthen their sense of self-adequacy and is consistent with self-affirmation theory.

The Rivalry Effect: The Influence of Emotional Intensity and Confrontational Interactions on Purchase Intentions

Diego Alvarado-Karste, Utah Valley University, USA
Blair Kidwell, University of North Texas, USA

EXTENDED ABSTRACT

Rivalries are common among consumer brands and companies. Classic brand rivalries include Coke vs. Pepsi, General Motors vs. Ford, Apple vs. Microsoft, Canon vs. Nikon, and Visa vs. MasterCard. In recent years, new rivalries have emerged, such as Apple vs. Samsung, or Dunkin vs. Starbucks. Notably, rivalries are prevalent across industries and countries. Yet, despite their prevalence, surprisingly, little research has examined how brand rivalries are formed, how they differ from comparative strategies and their subsequent impact on consumer perceptions and choices.

This article explores the dimensions of rivalries and their influence on consumer choices. We make five main contributions. First, we introduce rivalries and its consequences in marketing research. Second, we provide a novel definition of a rivalry and conceptualize it using a model with two dimensions: emotional intensity and confrontational interactions. Third, we develop unique measures for testing rivalries. Fourth, we reveal critical downstream effects of rivalries on consumer decisions. Finally, we uncover the process explanation for the rivalry effects. We show that the rivalry effect on purchase intentions is greater for consumers who have higher needs for external stimulation (NES) and fully attenuated for consumers who have lower NES. These findings suggest that brand rivalries are persuasive because they appeal to consumers' optimum stimulation needs (Raju 1980).

Rivalries

Rivalries have been explored in a variety of fields. However, while past research has attempted to conceptualize and define rivalries, perhaps due to the diversity of research fields, different researchers use a diversity of factors to accomplish their goal. Similarly, there has been little agreement on the dimensions or essential precursors of a rivalry. Due to the lack of a clear understanding of rivalries and their definition, as well as the absence of consistency across researchers of its theorization, in this research, we take a unified approach to provide a parsimonious and operational definition of the construct by exploring its dimensions. Toward this end, a pilot study using an open-ended elicitation procedure was conducted to define a rivalry from a consumer standpoint and develop a brand rivalry scale. We first reviewed rivalries in films and sports and identified the characteristics of rivalries. Then, 119 were asked to define what a rivalry is in their own terms. From their responses, two independent coders blinded to this study chose the responses that were most prevalent among participants. We clustered these items into two dimensions:

Confrontational interactions(CI). That is every event in which one entity engages with an adversary in aims to gain an advantage. CI can have the form of comparative advertising, social media interactions, or point of purchase placement, among others. Thompson (1995) suggests that rivalry confrontations are more predisposed to conflict escalations, which could, in turn, reinforce the rivalry. Furthermore, research demonstrates that narrowly decided conflicts increase rumination, counterfactual thinking, and emotional reactions (Medvec, Madey, and Gilovich 1995; Medvec and Savitsky 1997).

Emotional Intensity (EI). Competition, confrontations, and social comparison have been found to elicit several negative emotions such as anger, resentment, envy and *Schadenfreude* (Feather and Nairn 2005; Feather and Sherman 2002), as well of feelings of threat to social identity (Wann and Grieve 2005), that often result from perceptions of dominance and unfairness within a rivalry (Ambrose and Schnitzlein 2017; Tyler and Cobbs 2015). Other research finds that there are also positive emotions related to competitive relationships, such as pleasure (Converse and Reinhard 2016), and achievement (Abrams and Hogg 1988, 2006). Also, research in sport and political sciences finds that joy (Goldstein 2012; Havard et al. 2013), admiration (Oren 2003), and excitement (Ambrose and Schnitzlein 2017; Tyler and Cobbs 2015) are universal emotions among confrontational relationships.

In this research rivalries are defined as a competitive relationship between two actors built on emotionally intense confrontational interactions. We examine CI, EI and their interaction as possible dimensions of a rivalry. These two factors defining a rivalry can be configured to yield four cells in a 2 x 2 matrix, contained in Figure 1.

Downstream Effects

Rivalries may have an effect on consumers' interest in the rival brands. Luellen and Wann (2010) suggest that sport managers increase rivalry perceptions as a way to increase fan interest and media exposure. Also, according to Madeiro (2007), sport rivalries increase media attention and fan interest, which ultimately leads to more fan expenditure and even changes in stock prices. Moreover, research shows that conflicts and confrontations foster seeking information behavior (Lowry and Johnson 1981), due to increased curiosity, interest and controversy (Berlyne 1960; Chen and Berger 2013).

Similarly, activities that are emotionally loaded are also found to sparkle people's interest (Izard 1977). For example, Allport (1961) suggests that interest and creativity are accompanied by tension and excitement. Furthermore, Koo and Ju (2010) find that emotions such as pleasure and arousal, are correlated with curiosity and interest, which ultimately has an effect on intentions. Also, Oosterwijk (2017) demonstrates that emotional events, especially those high in arousal and negative in valence, increase attention, curiosity and interest, while other research found that disturbing events intensify unpleasant emotions, but at the same time, make people more interested (Turner Jr and Silvia 2006).

Thus, we predict that brand rivalries will increase consumers' interest in the rival brands. Likewise, since interest is the most frequently experienced positive emotion as well as the most prevalent motivational condition (Izard 1977), it is likely that as consumers become more interested in rival brands, their purchase intentions for both brands in the relationship will also surge.

Optimum Stimulation Level

We propose that rivalry effects are driven by consumers' needs to regulate their optimal stimulation level (OSL) (Hebb 1955; Leuba 1955). Raju (1980) suggests that people prefer a certain level of stimulation, which they may find in their environment. When the environmental stimulation is below optimal, individuals will attempt to increase stimulation, and when it is above optimal, they will strive to reduce it (Hebb 1955; Leuba 1955). Therefore, when consumers feel less internally stimulated, they might engage in exploratory behavior with hopes of finding something optimally stimulating.

Overview Of Studies

The rest of this article is organized as follows. Three studies examine the effect of brand rivalries on brand interest and purchase in-

tentions. Study 1 demonstrates the power of the two dimensions in constructing a rivalry and provides support for the mediating role of brand interest in fostering purchase intentions. Study 2 decomposes brand rivalries into its two components - confrontational interactions (vs. non-confrontational) and emotional intensity (vs. lack of emotions) and demonstrates their individual and joint effects on consumer choices. Finally, study 3 investigates the moderating effect of OSL in the effects of brand rivalries on brand interest and purchase intentions.

Study 1

Participants, Design, and Procedure. 115 participants were randomly assigned to one of two conditions (rivalry, indifferent). After answering the brand rivalry scale (6 items, α .96), participants answered questions about their perceived rivalry (3 items, α .98). Then, participants were asked about their interest (3 items, α .89) and purchase intentions (4 items α .93). Finally, participants filled some demographic questions.

Results. A t-test confirmed that the manipulations were successful. A linear regression was performed with confrontational interactions and emotional intensity as independent variables and the perceived rivalry items as the dependent variable. Both factors were significant predictors of rivalries (p < .001) and provided a strong explanation power for rivalries (R^2 = .85, F(2, 114) = 322.06, p < .001). A t-test also confirmed that the rivalry manipulation, which included explicit high emotional intensity and confrontational interactions, fostered greater perceptions of a rivalry than the indifferent manipulation, which contained low emotional intensity and confrontational interactions (M_{rival} = 5.88, SD = .93; $M_{Indifferent}$ = 2.55, SD = 1.94; t = 11.82; p < .001). A one-way ANOVA was conducted with brand interest as the dependent variable. As predicted, the results indicate that the manipulation is significant (M_{rival} = 5.05, SD = 1.24; $M_{Indifferent}$ = 4.53, SD = 1.29; F(1, 113) = 4.85; p < .05).

Study 2

Participants, Design, and Procedure. 237 participants were randomly assigned to one of four conditions about a relationship between two brands (rivalry, plain competition, non-confrontational relationship, and indifference). The manipulations were similar to those in study 1 but included two more quadrants that result from the two rivalry dimensions.

After answering the brand rivalry scale (6 items – 3 for confrontational interaction, α .95; and 3 for emotional intensity, α .94), participants also answered questions about their perceived rivalry (3 items α .97). Then, participants were asked about their interest (3 items α .86) and purchase intentions (4 items α .95). Finally, participants filled demographic questions.

Results. Manipulation checks on confrontational interactions and emotional intensity were significant in the predicted direction. Ratings of perceived rivalry were analyzed using a two-way between-subjects ANOVA with confrontational interactions and emotional intensity as the independent factors. The overall model was significant (R^2 = .59). The analysis revealed a significant main effect for both confrontational interactions (F(1, 233) = 249.98, p < .001), and emotional intensity (F(1, 233) = 68.06, p < .001), as well as a significant interaction of both dimensions (F(1, 233) = 6.48, p = .01). These results provide additional support about how rivalries are formed by both dimensions and their interaction. Also one way ANOVA was conducted with brand interest as the dependent variable, the rivalry condition as the dependent factor. As predicted, the results indicate that the manipulation was significant (F(3, 233) = 9.84, p < .001). Then, a post-hoc analysis with Tukey revealed that brand interest for rivalries (M = 5.39, SD = .80) is significantly higher than the non-confrontational relationship (M =

4.79, SD = 1.25; p = .03), plain competition (M = 4.67, SD = 1.69; p < .001), and indifferent (M = 4.27, SD = 1.27; p < .001) conditions.

Study 3

Participants, Design, and Procedure. 190 students were recruited to participate in a 4 (relation between brands: indifferent, non-confrontational relationship, plain competition, rivalry) x 2 (need for external stimulation: high vs. low) online between-subjects experiment. Participants were first randomly assigned either to the high or the low need for stimulation (NES) conditions. To create the manipulation, we relied on a technique that uses different measurement scales. Then, we measured perceived need for external stimulation by asking participants questions adapted from Raju (1980), (7 items, α .86). After answering the brand rivalry scale (6 items – 3 for confrontational interaction, α .68; and 3 for emotional intensity, α .93), again participants answered questions about their perceived rivalry (3 items, α .98), brand interest (9 items; α .97), and purchase intentions (8 items; α .98). Finally, participants filled demographic questions.

Results. Manipulation checks for confrontational interactions and emotional intensity were found significant in the predicted direction. Also, a t-test confirmed that the need for external stimulation manipulation was significant and in the direction we expected. Furthermore, ratings of brand interest were first analyzed using a two-way between-subjects ANOVA with the relationship between brands and NES as the two independent factors. The model is significant (F(7,176) = 4.46; p < .001). The analysis reveals a significant main effect for the relationship between brands (F(3,176) = 5.98, p < .001), no significant effect for the need for external stimulation condition (F(1,176) = .00, p = .96), and a significant interaction between the two independent factors (F(3,178) = 3.54, p < .02).

Planned contrast reveals that when participants were in the High NES condition, their brand interest was significantly higher when participants were exposed to the rivalry condition (M = 5.88, SD = .28) relative to participants who were exposed to the indifferent condition (M = 3.69, SD = .30; 95% CI [1.38, 3.01], p < .001), the plain competition condition (M = 4.47, SD = .31; 95% CI [.59, 2.24], p < .01), and the non-confrontational relationship condition (M = 4.91, SD = .31; 95% CI [.154, 1.80], p < .01). However, participants in the low NES condition, reported no significant differences in brand interest for the rivalry condition (M = 5.02, SD = .336) in comparison to participants who were exposed to the indifferent (M = 4.70, SD = .30; 95% CI [-.57, 1.20], p = .48), plain competition (M = 4.65, SD = .28; 95% CI [-.50, 1.23], p = .40), and non-confrontational relationship conditions (M = 4.53, SD = .27; 95% CI [-.36, 1.35], p = .26).

General Discussion

Even though brand rivalries are prevalent across product categories, this phenomenon has yet to receive significant attention in consumer behavior literature. In this research, we explored how brand rivalries can affect consumer choices. More specifically, we show that brand rivalries could have a positive impact on consumers' interest and purchase intentions. Consumers' need for external stimulation explains this positive effect.

The results of study 1 provide initial evidence about the effect of emotional intensity and confrontational interactions on the development of rivalries. Furthermore, this study shows that rivalries, established on these two dimensions, have significant downstream effects on consumer choices, fostering brand interest, which ultimately leads to higher purchase intentions. Study 2 deconstructed the two dimensions of a rivalry to examine the individual effect of each dimension in the development of rivalries and replicate the downstream effects found in study 1. In doing so, this study finds that, even though each

dimension on its own is essential, their combination yields into a brand rivalry. Finally, this research also reveals the underlying mechanism of the rivalry effect as a way to regulate consumers' optimum stimulation level. That is, when people have high needs for external stimulation, brand rivalries yield higher interest and purchase intentions. However, when consumers have low needs for external stimulation, the rivalry effects are fully attenuated. This study also replicates the findings of the two previous studies.

Theoretical Contributions

This research makes several contributions. First, it provides the first empirical analysis of the dimensions of a rivalry and is one of the first studies to look at brand rivalries and their effects in marketing. While rivalries have been examined in the past, surprisingly, their psychology and its effects on consumer research are limited.

Also, we demonstrate that brand rivalries have two underlying dimensions - confrontational interactions and emotional intensity - that together generate perceptions of a rivalry. Rivalries are also defined based on these two dimensions as competitive relationships between two actors built on emotionally intense confrontational interactions. This new definition of rivalries, as well as its measures, can help consumer researchers do further investigations of this phenomenon.

This work also unveils the rivalry effects on consumers' brand interest and purchase intentions. Finally, this research explains the underlying mechanisms driving the rivalry effect.

Future Research

Several questions deserve future exploration. First, it would be helpful to understand how rivalries affect consumers in different cultures. It is possible that a past of confrontation and violence in culture may lead to increased interest in rivalries, while cultures without a violent past may have less interest in such relationships.

Research might also examine how brand interest, fostered by rivalries, changes in the future. One possibility is that a rivalry between two brands becomes too familiar and no longer increases brand interest. However, the opposite could also occur. Brand rivalries could foster new confrontations and more emotional intensity, driving consumers to seek more information about the involved brands.

The Effect of COVID-19 Pandemic on Consumers' Online Shopping Behavior

Vahid Rahmani, Rowan University, USA
Elika Kordrostami, Rowan University, USA

EXTENDED ABSTRACT

The rise in online shopping during the pandemic era raises an important question: Other than increasing the tendency to shop online, how else did the Covid-19 Pandemic influence consumers' online shopping behavior? The current research is an attempt to answer this question. In this paper, we argue that the Regulatory Focus Theory (Higgins 1997), the Heuristic-Systematic Model (hereafter HSM; Chaiken et al. 1980), and the insights from the pricing literature could shed light on consumers' online shopping behavior in the pandemic era.

Extant evidence in the literature suggests that priming- or a natural tendency for prevention-orientation will increase the effect of online review volume (rather than valence) on consumers' online shopping behavior (Kordrostami *et al.,* 2020). A global pandemic is likely to prime a prevention-orientation mindset in most consumers. Therefore, we propose that the effect of online review volume on sales may have increased during the pandemic. Similarly, we contend that the pandemic may have rendered online shopping a high-involvement activity. Subsequently, consistent with the HSM theory, we argue that consumers may be more prone to pay attention to a wider range of available information rather than relying on simple heuristics when they engage in online shopping behavior during a pandemic.

Finally, although millions of Americans lost their jobs during the current pandemic, due to the CARES Act and other government-sponsored relief programs, the average income and net wealth of American families significantly increased during the same period (Irwin and Cai, 2021). The evidence in the pricing literature suggests that an increase in the average income may result in a lower level of price sensitivity and a higher willingness to pay premium prices (Kübler et al. 2018). Therefore, we argue that the Covid-19 pandemic may have resulted in a higher willingness to pay a price premium for products.

Method

We followed a multi-step approach to create a representative sample of all of the "Prime" eligible products that were sold on Amazon in men's and women's jeans product categories (N_{women} = 2,000; N_{men} = 2,000). The data set that was created in this process included 4,000 products, 224,000 products/days, and 1,257,088 products/ days/sizes observations from before (September 7 - October 4, 2019) and during the COVID-19 pandemic (September 7 - October 4, 2020).

Model specification

The dependent variable of this study is the sales rank of the products in the "clothing, shoes, and jewelry" category on Amazon. To test the research hypotheses, we devised a hierarchical linear model depicted below:

$$r_{ibd} = \beta_{0ibd} + \beta 1_{ibd}\, y_{ibd} + \beta 2_{ibd}\, X_{ibd} + \beta 2_{ibd}\, X_{ibd}\, y_{ibd} + i_{ibd} + b_{bd} + t_d + e_{ibd}$$

In the above model, r_{ibd} denotes the sales rank of product i, brand b, in day d. Following the guidelines in the literature (Chevalier and Mayzlin, 2006), we transformed the sales rank into the natural logarithm of sales rank and standardized the dependent and all the independent variables in our model. To facilitate the interpretation of the results we multiplied the standardized log-rank by minus 1. y_{ibd} is a dummy variable coded with 2019 as 0 and 2020 as 1. X_{ibd} is the vector of all the independent variables in our model. Finally, we controlled for all the endogenous variation caused by individual product characteristics (i.e., i_{ibd} ranging from 1 to 4,000), the brand name (i.e., b_{bd} denoting brand b in day d; n = 140), and the day of the data collection (i.e., t_d ranging from 1 to 56).

Results

To test the model, we utilized a hierarchical linear modeling analysis. The interaction terms between the year and other variables in the model delineate the changes in consumers' online shopping behavior in 2020 compared to 2019. The interaction between year and online review volume was positive and statistically significant (β = 0.032, p <0.01). In other words, the main effect of volume on sales rank was significantly higher in 2020 than in 2019.

Findings also revealed a significant and positive interaction between year and the number of answered questions (β = 0.031, p <0.001), number of available sizes (β = 0.029, p <0.001), number of available colors (β = 0.028, p <0.001), and number of words in product description (β = 0.269, p <0.001). These findings indicate that a greater amount of available product information resulted in higher revenues during the pandemic than before the pandemic.

Finally, the interaction between the year dummy variable and the average price was positive (β = 0.165, p <0.001). This finding indicates that although the price had a negative effect on sales volume in 2020, the effect size significantly diminished (β_{2019} = -0.400 vs. β_{2020} = -0.235). This counter-intuitive finding reveals that consumers were indeed less price-sensitive during the pandemic than they were before the pandemic.

In summary, the results of this study show that compared to 2019, during the COVID-19 pandemic in 2020, consumers who shopped online for jeans, paid more attention to the available online review information, were more influenced by online review volume, and were less price-sensitive.

Conclusions and Managerial Implications

Our findings offer several imperative practical implications: First, companies should provide extensive product information on their website to satisfy their customers' need for information during a pandemic. Second, companies should encourage their customers (by offering discounts or other promotional offers) to post their honest reviews online. A higher number of reviews could potentially lower the average rating of the product as it reflects a greater variation of consumer experiences. Nevertheless, considering the greater influence of online review volume than valence on consumers' purchase decisions, such strategies are likely to increase sales and revenues during a pandemic. Finally, instead of "diluting" the products to lower their prices during a pandemic, companies should strive to increase product quality and build trust through various promotional campaigns, which may result in higher prices.

Does Customer Loyalty = Faithful Partner? Inferences from Consumers' Relationship with Brands Affect Romantic Attraction

Aybike Mutluoglu, Queen's University, Canada
Laurence Ashworth, Queen's University, Canada

EXTENDED ABSTRACT

Individuals' consumption choices can inform beliefs about their traits and characteristics that are relevant in interpersonal settings, including romantic relationships. For instance, conspicuous luxury purchases can increase romantic attraction, at least when they are being evaluated in the context of a short-term romantic relationship (Sundie et al., 2011). Similarly, men who purchase green products are viewed as more altruistic and, consequently, more desirable as a long-term romantic partner (Borau, Elgaaied-Gambier, & Barbarossa, 2020). Although these findings suggest that particular purchases can influence observers' perceptions about a consumer's suitability as a romantic partner, no research has examined whether a consumer's relationships with a non-personal entity, such as a brand or organization, might also have diagnostic value for observers seeking to understand what this person may be like in a romantic relationship. Therefore, the current work aims to investigate whether aspects of consumer-brand relationships are capable of informing observers' beliefs about consumers' relational qualities more generally.

Existing research has shown that consumers attribute personalities to brands (Aaker, 1997), and form relationships with brands and organizations that have characteristics similar to the relationships they have with other people (e.g., Aaker, Vohs, & Mogilner, 2010; Kervyn, Fiske, & Malone, 2012). Fournier (1998) was one of the first to suggest that brands can be "*viable relationship partners*" and, consequently, that consumer-brand relationships may be guided by the same social norms that guide interpersonal relationships. Considering that individuals are attentive to available cues about the way a potential mate reacts and interacts in their social relationships to form accurate first impressions (e.g., Berger & Calabrese, 1974; Berger, 1979), we propose that the way a potential mate interacts with a brand or organization may be also viewed as indicative of how the same person would act as a partner in a romantic relationship, which, in turn, influence their romantic appeal. More specifically, building on the "*brands as people*" paradigm, we hypothesize that loyal (vs. non-loyal) consumers are perceived as more attractive, mediated by inferences about their likelihood to remain faithful to a relationship partner.

Nevertheless, we still expect observers to be sensitive to factors that influence the diagnosticity of the behavior (loyalty) to draw such inferences. This is because people discount attributions in the presence of information that suggests an alternative explanation for the focal behavior (e.g., Gilbert & Malone, 1995). One feature of consumer loyalty that should influence the diagnositicity of this behavior for dispositional inferences is the distinction between behavioral loyalty and attitudinal loyalty (Dick & Basu, 1994). Consumers may repeatedly purchase from the same brand for reasons unrelated to a genuine commitment to the brand (Jacoby & Kyner, 1973) – for example, a lack of alternatives or for cost or convenience-related reasons. This form of loyalty is also referred to as "*spurious loyalty*" (Day, 1969) because repeat purchase behavior in this case is not motivated by genuine feelings of commitment to the organization and a desire to maintain the relationship, as oppose to attitudinal loyalty. As such, we predict that the observation of behavioral loyalty in the absence of a genuine commitment to the brand should be less likely to enhance a consumer's romantic appeal through inferences of relationship fidelity.

Overview of Studies

We conducted three studies involving a hypothetical scenario about a potential romantic partner. In all scenarios, we manipulated brand loyalty by describing the target as loyal (vs. not) to a particular company. **Study 1** demonstrated the basic effect: Participants reported stronger romantic desire toward the target depicted as a loyal (vs. non-loyal) consumer (4.94 vs. 4.67; $p = .041$). Participants also inferred that the target depicted as a loyal (vs. non-loyal) consumer was more likely to remain faithful in a romantic relationship (5.22 vs. 4.38, $p = .000$), which mediated the relationship between consumer loyalty and romantic attraction [.15, .50].

Study 2 tested if attitudinal loyalty (more so than behavioral loyalty) increases romantic attraction through inferences of fidelity to a relationship partner. Consistent with our theorizing, participants reported stronger romantic desire toward the target if depicted as a loyal consumer who was genuinely connected to the brand (attitudinal loyalty) than either a loyal consumer due to convenience (behavioral loyalty) or not loyal to any brand at all (control) (5.16 vs. 4.59 vs. 4.60; ps = .000). The same pattern was observed for inferences of relational fidelity (5.43 vs. 4.33 vs. 4.32; ps = .000). Mediation analysis showed that attitudinal loyalty increased romantic attraction through inferences of relational fidelity relative to both behavioral loyalty [.34, .67] or the no loyalty (control) [.33,.68]. Behavioral loyalty (vs. control) did not improve romantic attraction through inferences of relational fidelity [-.08, .09].

Study 3 provided process evidence via moderation. As trustworthiness is more important to partner evaluation when assessing suitability for long-term relationships (Fletcher et.al, 2004), we predicted that the effect of consumer loyalty would be greater within observers currently looking for a long-term (vs. short-term) relationship. We replicated the effect of consumer loyalty in the previous studies. More importantly, however, participants' level of interest in a serious, long-term relationship significantly moderated the effect ($p = .023$). There was also a significant moderated-mediation [.01, .08]: Although loyal (vs. non-loyal) consumers were always considered more desirable romantic partners via inferences of relational fidelity, the indirect effect was stronger for participants who were currently interested in a serious, long-term relationship (1-SD-above-mean, indirect effect = .40) than participants who were more interested in a casual, short-term relationship (1-SD-below-mean, indirect effect = .26).

Overall, the current research shows that loyalty to a brand partner may provide interpersonal benefits. Across three studies, we found a stronger romantic preference for loyal (vs. non-loyal) consumers, mediated by participants' inferences of fidelity to a relationship partner. We also found that the romantic advantage loyal consumers possess was mitigated when their loyalty was motivated by reasons other than feelings of genuine connection to the brand (e.g., convenience) and when they were considered in the context of a casual, short-term relationship.

Smartphone Bias: When Consumers Unnecessarily Avoid Smartphones

Vincentia Yuen, University of Miami, USA
Claudia Townsend, University of Miami, USA
Michael Tsiros, University of Miami, USA

EXTENDED ABSTRACT

Smartphones are a ubiquitous part of consumers' lives and increasingly offer the capabilities of a personal computer (PC). Despite this, consumers avoid using them for some decisions. For example, while the advantages of smartphones (e.g., greater portability) facilitate higher traffic to retailer websites (56.2%) than from PCs (34.5%), the conversion to purchase rate for smartphones (2.25%) is less than half that of PCs (4.81%; Charlton 2019). However, to date, there is no clear understanding of why or whether this avoidance is merited.

This research identifies a "smartphone bias"; consumers expect their performance on a smartphone to be worse than on a PC, even in situations where there is no impact of device. We show that the smartphone bias has attitudinal (e.g., decision-making confidence) and behavioral (e.g., choice deferral) consequences.

We proffer that, like many biases (e.g., negativity bias), the smartphone bias is "both multidetermined and overdetermined" (Rozin and Royzman 2001). However, we identify one key driver of the effect, consumers feel that being on a smartphone makes them less thoughtful than being on a PC. Moreover, a pilot study identifies this lower perceived thoughtfulness results from three types of sources: (1) usage situations (e.g., more often use smartphones when in a rush, in public, less for work), (2) physical differences (e.g., screen size, interaction mode), and (3) psychological feelings (e.g., feel more easily distracted and less in control on a smartphone). While these differences exist and, moreover, some of them have been shown to negatively influence behavior (e.g., smaller screens; Ghose, Goldfarb, and Han 2013), we predict and show that consumers overweight the impact of these forces on their decision-making. Then, relying on the lay theory that careful thought leads to more accurate judgments (Barden and Petty 2008; Tordesillas and Chaiken 1999), the result is an incorrectly negative perception of performance on a smartphone. In sum, like many heuristics that may be valid in some situations, consumers overapply this "device-based heuristic," leading to a bias. Formally, we hypothesize:

Hypothesis 1: *A smartphone bias exists such as, all else equal, the device used will influence consumer task evaluation such that consumers on smartphones will predict lower task performance and be less confident than consumers on PCs.*

Hypothesis 2: *Smartphone bias is mediated by lower perceived induced thoughtfulness on smartphones (vs. PC).*

Hypothesis 3: *When actual performance does not vary across devices, smartphone bias will lead consumers to underpredict their performance on smartphones while consumers are more accurate in predicting their performance on PCs.*

We examine this in five studies involving random assignment to device (except 1A) and all using 7-point scales unless otherwise specified. In Study 1A, participants saw information about several sets of earbuds and predicted their performance on a product evaluation task. Even though participants on a smartphone (vs. PC) had higher actual performance ($M_{Smartphone}$ = 6.94 vs. M_{PC} = 5.94 out of

8, $t(160.584)$ = 3.397, p =.001), they predicted their performance to be lower than those on a PC ($M_{Smartphone}$ = 5.11 vs. M_{PC} = 6.09; $t(190)$ = 3.485, p =.001, H1), resulting in an underprediction ($F(1,190)$ = 26.01, p < .001; Wilk's Λ =.880, partial η^2 =.12, H3) .

Study 1B replicates Study 1A and also shows the effect on real choice deferral. Participants on smartphones were more likely to defer choice than those on a PC (27.8% vs. 17.4%; $X^2(1, 287)$ = 4.451, p = .035, H1), despite performing better on the product evaluation task ($M_{Smartphone}$ = 6.85 vs. M_{PC} = 6.11, $t(282.459)$ = 2.905, p =.004).

Study 2 considers product choice rather than evaluation. Participants saw information on dental insurance plans. Those on a smartphone were less confident in choosing and buying an option versus those on a PC ($M_{Smartphone}$ = 4.51 vs. M_{PC} = 5.13; $t(294.096)$ = 3.355, p =.001) and were more likely to defer choice (25.7% vs. 11.3%; $X^2(1, 296)$ = 10.494, p =.001, H1). Also, while there was no difference on actual performance across devices ($M_{Smartphone}$ = 5.94 vs. M_{PC} = 5.56 out of 8; $t(293.998)$ = 1.603, p =.110), smartphone users predicted their performance to be lower ($M_{Smartphone}$ = 4.88 vs. M_{PC} = 5.48; $t(294)$ = 2.600, p =.01, H1), resulting in underprediction ($F(1, 294)$ = 9.210, p =.003; Wilk's Λ =.970, partial η^2 =.030, H3).

Study 3A examines the underlying process (H2). Participants completed two separate studies (order counterbalanced): (1) a micro-investing platforms study and (2) an electronic devices study. For (1), after seeing information on micro-investing platforms, participants rated their confidence in opening a new investment account. For (2), we measured general perceptions of the device, including perceived induced thoughtfulness and alternative accounts (e.g., privacy concerns). As predicted, smartphone participants were less confident than PC participants ($M_{Smartphone}$ = 3.94 vs. M_{PC} = 4.42; $t(295)$ = 2.348, p =.02), which is mediated by perceived thoughtfulness (b = -.69; 95% CI from -.9930 to -.4268), but not mediated by any alternative accounts.

Lastly, Study 3B replicates Study 3A except that half of the participants were first asked to complete an evaluation and choice task of the three micro-investing platforms (thus: 2 device [smartphone vs. PC] X 2 role [predictors vs. performers]) between-subject design. This study reveals that consumers hold the bias, regardless of whether they have performed the task or not and even after performing it. Regardless of performance, those on a smartphone were less confident ($M_{Smartphone}$ = 3.57, M_{PC} = 4.06; $F(1, 440)$ = 7.588, p =.006), and this was mediated by perceived thoughtfulness (b = -.19; 95% CI from -.3231 to -.0916).

By identifying a "smartphone bias," the corresponding device-based heuristic, and the causes of this bias, this research offers an explanation for the difference in decision-making behavior identified across various research disciplines (e.g., marketing, finance). Further, this research contributes to the limited research on mobile consumer behavior consider the difference between smartphones and PCs – the two dominant technology devices – from the point of view of consumers' perceptions of the device. Lastly, this research draws practitioners to the important role of device perceptions in their mobile marketing strategies.

Why Recipients Don't Appreciate Expensive Gifts: The Role of Suspicion

Aybike Mutluoglu, Queen's University, Canada
Laurence Ashworth, Queen's University, Canada
Nicole Robitaille, Queen's University, Canada

EXTENDED ABSTRACT

Gift-givers frequently appear to misunderstand what recipients will appreciate about gifts. One of the more puzzling misunderstandings relates to gift expense. Givers often rely on the signaling value of gift price to convey the importance of their relationship with recipients (e.g., Cheal, 1987; Wang & Van Der Lans, 2018). Yet recipients appear to put little weight on the amount spent (Flynn & Adams, 2009). This is surprising—not just because of givers' misprediction—but because more expensive gifts are both an objectively higher investment and provide greater value to recipients. The current research investigates why recipients seem to put so little weight on this feature of gifts. We argue that recipients are not unresponsive to gift expense per se, but that expensive gifts can sometimes cause recipients to become suspicious of ulterior giver motives, counteracting otherwise positive effects of a more valuable gift.

Gift Expense and Suspicion

Gift-recipients can generate a range of explanations for givers' choice of gift, ranging from attributions of sincere motives (e.g., caring about the recipient) to self-serving motives (e.g., an economic or social reward). Although sincerity may be more likely given the inherent other-oriented nature of gift-giving (e.g., Belk & Coon, 1993), we propose that expensive gifts might also lead recipients to entertain the possibility that givers may possess some ulterior motives other than positive sentiments. Two lines of research support our theorizing. First, givers do sometimes pursue self-serving motives (e.g., Sherry, 1983), such as status, wealth, social recognition, and power (Wolfinbarger, 1990; Hyun, Park, & Park, 2016). Some scholars have even characterized gifts as a form of "*indebtedness engineering*" and a *"polite form of bribery"* (Wolfinbarger, 1990). To the extent that recipients are familiar with these motives – perhaps because they have experienced them themselves – we would expect recipients to sometimes consider these reasons for the gifts they receive.

Second, money—as the universal medium of exchange—is strongly and inextricably associated with the concept of "instrumentality", that is, with getting what one wants (Lea & Webley, 2006). As such, money may be capable of activating self-focused goals. Consistent with this, asking people for monetary donations (vs. donations of time) can reduce donations because it leads people to consider what benefits they will receive in return (Liu & Aaker, 2008). Similarly, monetary donations are perceived as less moral and self-expressive than donations of time (Reed, Aquino, & Levy, 2007). Merely reminding people of money seems to make them more self-focused and less communal (e.g., Vohs, Mead, & Goode, 2006, 2008; Wang, Chen, & Krumhuber, 2020). If money leads people to pursue and do things that benefit themselves, it should also increase the likelihood that people consider self-serving motives to explain others' behaviors. Consequently, we theorize that salient gift expense may activate thoughts about givers' self-focused motives (i.e., cause recipients to become suspicious of that givers have ulterior motives) at least partially counteracting the positive effects of a more valuable gift.

Overview of Studies

Four studies test this idea – three involving a hypothetical gift-exchange scenario and one examining reactions to real gifts. ***Study 1*** tested whether expensive gifts were capable of inducing suspicion in the context of a workplace relationship. Participants imagined receiving an expensive (vs. typically-priced) gift from a colleague who may have deliberately revealed the price. Consistent with our theorizing, expensive gifts made participants more suspicious of ulterior giver motives (4.68 vs. 3.75; $p =.000$).

Study 2 examined whether the effect was limited to the specific context of the previous study. It is possible that ulterior motives may be more salient in a workplace relationship than in other interpersonal relationships, such as a friendship, and when there were indications the giver may have deliberately revealed the price. Consequently, in addition to gift expense, we manipulated whether the gift was between colleagues or friends and whether it was plausible the price was deliberately revealed versus not. Participants were more suspicious of expensive gifts whether from a friend (3.60 vs. 2.90; $p =.000$) or a colleague (4.05 vs. 3.52; $p =.000$) and whether the giver appeared to have deliberately revealed how much they spent (3.82 vs. 3.39; $p =.000$) or not (3.83 vs. 3.03; $p =.000$). In short, Study 2 suggested that gift expense could activate suspicion even in settings where ulterior motives were unlikely to be prevalent.

Study 3 examined suspicion in the context of real gifts. We asked participants to recall a recent expensive (vs. typically priced) gift they had received. Again, participants were more suspicious of expensive gifts (2.15 vs. 1.63; $p =.016$). All three of our initial studies also replicated past findings that gift expense did not directly affect gift appreciation (Flynn & Adams, 2009). Notably, the indirect effect via suspicion was significant in all studies (CIs: *Study 1* [-.28,-.03], *Study 2* [-.12,-.05], *Study 3* [-.20,-.01]), supporting the idea that recipients' apparent indifference to price may, in fact, be a consequence of competing effects of gift expense: the positive investment versus the heightened suspicion.

Study 4 provided an experimental test of the mechanism by manipulating whether givers had given the gift anonymously, which should reduce the likelihood recipients would infer the giver had ulterior motives. A significant interaction ($p =.038$) indicated gift expense had a smaller effect on suspicion when the giver was anonymous. Follow-up analyses revealed that gift expense induced suspicion when the giver's identity was known (4.14 vs. 3.61; $p =.000$) but not when the gift was given anonymously (2.58 vs. 2.59; $p =.947$). Suspicion also mediated the relationship between gift expense and gift appreciation when the giver's identity was known [-.12,-.04] but not when it was anonymous [-.06,06]. Finally, these results held when we included a potential confound in the model: feelings of indebtedness.

Overall, four studies provided evidence that recipients' apparent indifference to gift-givers' monetary investment might be due, at least in part, to suspicion of expensive gifts, which reduces gift appreciation. We contribute to research on gift-giving by shedding light on past findings that have suggested a surprising indifference to an important feature of gifts.

Counterfactual Culpability: Thinking About What You Could Have Done Increases Felt Culpability for Your Action

Maayan Malter, Columbia Business School, USA

EXTENDED ABSTRACT

This paper investigates the causal process underlying the relation between following orders (not having autonomy of choice) and post-outcome feelings of culpability. There is a general understanding in consumer behavior that consumers want and benefit from autonomy of choice (Wertenbroch, et al., 2020), yet there are situations where consumers opt to not choose, and instead prefer to delegate their choice to another person, to an algorithm, or even to chance. Prior research has found that consumers may opt to give up their choice when they anticipate regret for the outcome, want to avoid the negative consequences of responsibility (Steffel and Williams, 2017; Sutan and Vranceanu, 2016), or are conflicted about the tradeoff of potential losses from their choices (Lin and Reich, 2018). In medical decision-making, parents who personally made the choice to end life support for their infants felt worse than when doctors made the decision for them (Botti et al., 2009). Although these parents were conflicted about giving up their autonomy to make this critical choice, Botti et al. found that tragic outcomes reduced parents' desire for autonomy.

Given this preference to relinquish choice, one would expect an actor to feel more culpable for adverse outcomes if they had made the decision themselves rather than simply followed orders. Surprisingly, recent research finds just the opposite, that actors who did not make their own choices and simply implemented the choices of another felt more culpable for negative outcomes than those who were also the decision maker (Malter, Kim, and Metcalfe, 2021). Even though the outcomes were negative, individuals felt relatively better when they made the choice themselves.

The question remains as to why individuals feel more culpable for a negative outcome when they are in a passive role and just dutifully following orders. We follow the metacognition literature and conceptualize choice autonomy as having agency, having "the ability to take intentional action or make choices that influence outcomes, ... or otherwise make things happen in the world" (Bucknoff 2020). In our studies, an actor has high agency if they make the decision and low agency if they simply follow orders. We assume that because low agency actors are randomly assigned to an action option, there is a 50% chance they will be assigned to implement a policy that conflicts with their personal beliefs of which is the better policy. Therefore, we expect:

Hypothesis 1: *Acting against one's own beliefs will increase felt culpability.*

Having to act against one's beliefs will induce upward counterfactual thinking – thinking that a negative outcome could have been better (Rye et al., 2008; Roese, 1994). Counterfactual thinking has been related to moral decisions and blame (Byrne, 2016; Alicke et al., 2008), regret for one's actions and wishing they could be changed (Zeelenberg et al., 1998; FitzGibbon et al., 2021). Therefore, upward counterfactual thinking will mediate the relationship between agency and feelings of culpability for negative outcomes.

Hypothesis 2: *Upward counterfactual thinking will mediate the relationship between acting against one's beliefs and felt culpability.*

To test this theory, we conducted four experiments examining tradeoff decisions that faced American society in 2020 and early 2021: how to safely return to school for Fall 2020, how and when to reopen the economy, and how to allocate scarce vaccine supply. All policy decision scenarios were modeled on the scenarios in Malter et al. (2021) Experiment 5 where participants imagined themselves as a policy maker who must either decide for their community which of two policy options to implement (high agency) or is instructed by their superior which policy to implement (low agency). Note that both policies in the scenarios have a positive and negative aspect which are outlined for the participants, creating a tradeoff decision between competing horizontal values (support the economy vs. support public health). After participants implement the chosen option, they read about a negative outcome resulting from the policy they implemented (the same negative outcome regardless of which policy was implemented) and reported their felt culpability for their actions.

Results from Experiment 1 support H1 that being assigned to act against one's personal beliefs increases felt culpability. Importantly, participants in Experiment 1 were real decision makers who were making this choice for their own children. Experiment 2 replicates Experiment 1 with a larger sample and inferred beliefs (based on political party affiliation). Experiment 2 also tests H2 that counterfactual thinking mediates the relationship between acting against one's beliefs and felt culpability and finds support for this theory. Experiment 3 generalizes the findings from Experiment 2 (school reopening choice) to another context (reopening performance venues). Experiment 4 shows that these findings are not limited to policy decisions that were politically polarized at the time (vaccines) and confirms that the effect reverses for third-person judgements.

These four experiments show that just following orders can lead to more counterfactual thinking about the other option. This finding is important for managers structuring levels of decision making within their organizations. It is also important for society to reassess how we evaluate another person's responsibility and guilt in passive versus active decision-making roles. Although this research focused on the thought process of the low agency participants, future research should investigate why the high agency participants felt lower culpability for outcomes they more directly caused. The findings are also relevant for consumers choosing whether and when to relinquish their autonomy of choice based on expected outcomes. Although distancing oneself from a decision with negative expected outcomes may seem like an easy way out, these findings show that confronting the situation and making the decision oneself may lead to better emotional outcomes for the decision maker.

How to Encourage Sustainable Consumption? A Construal Level Approach to "Concretize" Sustainability with Circularity

Jolie Gutentag, Pepperdine Graziadio Business School, USA
Cristel Russell, Pepperdine University, USA

EXTENDED ABSTRACT

Drawing on construal level theory (Trope & Liberman, 2003), this research shows that framing sustainability as circularity reduces the abstractness of sustainability, which in turn, prompts consumers to behave more sustainably. Four studies document the effects of circular framing on sustainable behavior, including the moderating role of consumers' chronic construal level.

Prompting sustainable behavior with circularity

Construal is a cognitive process that influences people's decisions based on two dimensions: construct construal and individual construal. Construct construal is linked to how distal or proximal something feels from "me, here and now" (Trope & Liberman, 2003) and is a determinant of behavior: abstract construct construal encourages behavior based on values, while concrete construct construal encourages decisions based on feasibility (Trope & Liberman, 2010). Individuals also have distinct chronic levels of construal, which describes how abstractly or concretely they process information (Vallacher & Wegener, 1989). Many people perceive sustainability as abstract because it feels distal: outcomes are uncertain, occur in the future and impact distant places and people. It is possible to influence someone's construal of sustainability and ultimately their sustainable behavior by matching construct and individual construal (Reczek et. al., 2018). This research proposes that circularity, the conceptual basis of the circular economy, is more concrete than the concept of sustainability and as a result, motivates consumers to behave more sustainably.

Research Model and Hypotheses

Based on extant research, we propose that the more concrete the construal of sustainability, the greater the engagement in sustainable behaviors (H1). In addition, individual chronic level of construal is negatively related to engagement in sustainable behaviors such that more concrete individuals engage in fewer sustainable behaviors (H2). We further advance that consumers exposed to a message or intervention with circular framing will have a more concrete construal of sustainability than consumers exposed to a message or intervention without circular framing (H3); that individual chronic level of construal will moderate the relationship between construal of sustainability and engagement in sustainable behaviors (H4) as well as the impact of the circular framing intervention/message on construal of sustainability (H5) such that those effects are stronger for more concrete individuals.

Methodology

Study 1, a cross sectional survey with a national sample, tested H1, H2 and H4. Studies 2 and 3 utilized experimental designs to assess the whole model. Study 4 employed a cross sectional survey to validate whether circular framed marketing messages commonly used in household products are more concrete than sustainably framed messages, and if the effect is stronger for more concrete individuals. All studies were conducted online in the United States.

Results

Study 1 confirmed the need to concretize sustainability. Regression analysis showed that more concrete individuals behaved less sustainably, as predicted by H2. As construal of sustainability became more concrete, engagement in sustainable behaviors also increased, per H1. This main effect was qualified by a significant interaction with individual chronic level of construal but, contrary to H4, the effect was stronger for more abstract individuals.

In study 2, we compared consumers' responses to two between-subjects message conditions: circular packaging claims ("100% Recyclable Packaging and 100% Renewable Ingredients") and sustainable packaging claims ("100% Eco Friendly Packaging and 100% Sustainable Ingredients"), which were validated in a pre-test. This experiment revealed that, although circular framing did not directly affect construal of sustainability, it significantly interacted with individuals' chronic level of construal. Abstract individuals perceived both sustainable and circular framing as equally concrete but, as predicted by H5, circular framing resulted in significantly more concrete message interpretation than sustainable message framing for concrete individuals. In line with H3, more concrete interpretation of the message also led to willingness to pay a higher price for the product. The effect of circular framing on purchase price was mediated through construal of sustainability.

Study 3 also employed a single factorial design with two between-subjects message conditions: an educational video about circularity versus a control video on an unrelated topic. Per H3, the circularity video generated more concrete construal of sustainability, which in turn, per H1, evoked a higher level of donation to charities that support sustainable activities and higher intentions to behave sustainably. One week later, this more concrete construal of sustainability was related to a higher level of reported sustainable behaviors, a lagging effect which was fully mediated sequentially through construal of sustainability and sustainable behavior intentions. Contrary to H4 and H5, these effects were the same regardless of individuals' chronic level of construal.

Study 4 employed an online cross-sectional survey to validate whether circular framed marketing messages used in household products are more concrete than sustainably framed marketing messages (H3), and whether chronic construal also moderates this relationship (H5). Per H3, message circularity was positively related to construal of sustainability and, per H5, we identified an interaction effect: the relationship between level of message circularity and construal of sustainability was stronger for more concrete people.

Conclusion

Across four studies, this research offers encouraging evidence that circularity can concretize consumers' understanding of sustainability and ultimately shift consumption patterns. For marketing messaging and packaging claims, this is valid for more concrete individuals. Reframing sustainability as circularity more broadly with an educational video can motivate more sustainable consumption at all individual chronic levels of construal. Such learnings provide important implications for companies and policymakers in developing strategies to step-change consumer adoption of sustainable behaviors. Our research also makes contributions to theory: we contribute to the body of knowledge that examines ways to prompt consumers to behave sustainably (White et al., 2019) as well as to the stream of research that studies how changing construal linked to sustainability and individual chronic level of construal can impact sustainable

consumption (Goldsmith et al., 2016, Macdonnell & White, 2015, Reczek et. al., 2018) We note that the research should be expanded beyond the U.S. context as well as other messaging formats and contexts. Future research should embrace a greater array of behavioral measures to assess the longer-term impact of circularity framing interventions on consumers' sustainable behaviors.

Exploding Offers: Consumer Response to Time-Limited Promotional Deals

Hyoseok Kim, University of Alberta, Canada
Gerald Haubl, University of Alberta, Canada

EXTENDED ABSTRACT

Promotional offers (e.g., a 10% price discount) vary in the length of their redemption window. Despite the prevalence of such offers in the wild, little is known about how their *duration* affects consumer uptake. At the core of this work is the idea that the interplay between the greater perceived flexibility provided by a longer redemption window and the greater urgency induced by a shorter redemption window is a key driver of consumer response to a promotional offer. We introduce a theoretical framework that identifies circumstances under which longer versus shorter redemption windows are more effective in terms of consumers' uptake of promotional offers. We theorize that consumers' responses to the duration of a redemption window are governed by their action readiness when they encounter the offer (i.e., whether they are in a more deliberative or a more implemental mindset). The essence of our theorizing is as follows. When consumers are in a deliberative mindset, the flexibility of an offer is more important than the sense of urgency it induces, and longer redemption windows thus tend to be more effective than shorter ones. By contrast, when consumers are in an implemental mindset, the urgency induced by an offer is more important than the flexibility it provides, and consequently shorter redemption windows tend to be more effective than longer ones. This interactive effect of mindsets and redemption windows is particularly pronounced when promotional offers are associated with hedonic (vs. utilitarian) consumption. Evidence from five experiments provides support for this theorizing.

Experiment 1A (N=232) provided a first demonstration of the interplay between mindsets and redemption windows in driving promotion uptake. A 2 (deliberative vs. implemental mindset) x 2 (14-day vs. 1-day offer) between-subjects design was used. Deliberative or implemental mindsets were first manipulated in this experiment. To activate a deliberative mindset, participants were asked to list five potentially positive and five potentially negative consequences of switching banks. To activate an implemental mindset, participants were asked to plan the implementation of switching banks and listed five steps required to execute this plan. Next, we presented participants with short (1-day) or long (14-day) redemption window promotions. Then, participants indicated whether they wanted to take advantage of the offered promotion. As hypothesized, participants in a deliberative mindset were more likely to use the promotional offer when it had a longer redemption window (59.9%) than when it had a shorter one (39.6%), whereas those in an implemental mindset were more likely to use the offer when it had a shorter redemption window (61.0%) than when it had a longer one (33.3%, *p*<.001). This pattern of effects was conceptually replicated, in a different different promotion context, in Experiment 1B (N=223; Deliberative-Long=54.3% vs. Deliberative-Short=34.0%, Implemental-Long=41.6% vs. Implemental-Short=62.5%, *p*=.002).

In addition to offering another conceptual replication of the interplay between mindsets and redemption windows, Experiment 2 (N=600) provided direct evidence of the two psychological pathways along which the length of the redemption window affects promotion uptake – one via perceived flexibility and the other via the sense of urgency induced by the offer. The results of a moderated dual-pathway mediation analysis revealed that the positive indirect effect of a shorter redemption window on promotion usage via greater urgency was significantly stronger under an implemental than under a deliberative mindset (b=-.02, SE=.03, CI=[.01, .11]). By contrast, the positive indirect effect of a longer redemption window on promotion usage via greater perceived flexibility was significantly more pronounced under a deliberative than under an implemental mindset (b=.05, SE=.03, CI=[.02, .14]).

Experiment 3 (N=582) examined the moderating role of hedonic vs. utilitarian consumption contexts. The manipulation of deliberative versus implemental mindsets was the same as in the previous experiments. Next, in the hedonic condition, participants were presented with a promotional offer for any Disney Store product. By contrast, in the utilitarian condition, participants were presented with a promotional offer for any HP Ink & Cartridge Store product. As hypothesized, the interactive effect of mindsets and redemption windows on consumer response to promotional offers manifested in hedonic domains (Deliberative-Long=43.4% vs. Deliberative-Short=26.3%, Implemental-Long=27.8% vs. Implemental-Short=45.4%, *p*=.023), but it vanished in connection with utilitarian domains (Deliberative-Long=38.5% vs. Deliberative-Short=25.7%, Implemental-Long=48.7% vs. Implemental-Short=31.3%, *p*<.7).

Finally, Experiment 4 (N=480) demonstrated the interplay between mindsets and redemption windows in an economically consequential setting (involving actual purchases). Moreover, instead of employing a direct manipulation of consumers' mindsets, it used a more ecologically valid approach to activating an implemental (vs. deliberative) mindset in a shopping context by manipulating the extent to which consumers had contemplated their preferences among the available products prior to being presented with the promotional offer. The results showed that, as hypothesized, shoppers in a deliberative mindset were more likely to use the promotional offer when it had a longer redemption window (46.7%) than when it had a shorter one (25.2%), whereas those in an implemental mindset were more likely to use the offer when it had a shorter redemption window (49.6%) than when it had a longer one (33.9%, *p*<.001). In addition, this experiment sheds light on the intertemporal dynamics associated with consumer uptake of promotional offers that arise from the fact that a longer redemption window offers more opportunities for taking advantage of an offer, while at the same providing less of an incentive to do so quickly.

This research advances our understanding of the psychological dynamics that govern consumer response to promotional offers with redemption windows of varying length. It presents and tests a theoretical framework that identifies circumstances under which longer redemption windows tend to be more effective and ones under which shorter redemption windows tend to be more effective.

Do PWYW Labels Affect Internal Reference Prices and Prices Paid?

Olivier Reimann, ZHAW School of Management and Law, Switzerland
Oliver Thomas, ZHAW School of Management and Law, Switzerland
Gunther Kucza, ZHAW School of Management and Law, Switzerland

EXTENDED ABSTRACT

"Pay What You Want" (PWYW) is a participative pricing mechanism (Chandran & Morwitz, 2005) that gives buyers complete control over the price. PWYW is distinctive from other participative pricing mechanisms because sellers have to accept any price, including zero (Kim, Natter, & Spann, 2009). Research has shown that PWYW can be profitable (Kim et al., 2009, 2010), even in the long run (Schons et al., 2014) and across multiple industries (Christopher & Machado, 2019; Kim, Natter, & Spann, 2014; Schröder, Lüer, & Sadrieh, 2015; Viglia, Maras, Schumann, & Navarro-Martinez, 2019). Consumers do not abuse PWYW offers but pay prices significantly larger than zero compared to what one might expect. In some cases, consumers even pay higher prices than a regular fixed price (Gneezy, Gneezy, Riener, & Nelson, 2012; Kim et al., 2009).

PWYW labels are a relatively new extension of PWYW research. Among the different labels used in literature are "Pay as much as you want", "Reduce the price as much as you want" (both Schröder et al., 2015), Rebate What You Want (Atlas, 2015), "Pay What You Think It Is Worth", and "Pay What You Can" (both Cui & Wiggins, 2017). Overall, studies find that different PWYW labels can significantly affect prices paid. However, only "Pay What You Think It is Worth" (PWYT) and "Pay What You Can" (PWYC) have been identified as economically relevant alternatives to the classic PWYW label (Cui & Wiggins, 2017; Saccardo, Li, Samek, & Gneezy, 2015).

Among the moderators investigated in PWYW research, the degree of anonymity in the payment situations received the most attention (Gerpott, 2017). Anonymity refers to whether others can observe the prices paid (low anonymity) or not (high anonymity). Findings on anonymity and PWYW are mixed, which calls for further research on that matter (Dorn & Suessmair, 2016; Gneezy et al., 2012; Jung, Nelson, Gneezy, & Gneezy, 2017; Kim et al., 2009; Kim, Kaufmann, & Stegemann, 2014; Saccardo et al., 2015). Previous research on PWYW and anonymity usually does not reveal the exact phrase(s) used to communicate the PWYW offer to the subjects. Hence, mixed findings could result from inconsistent labels used to communicate the offer within the same study (e.g., no significant effect) or different labels used across multiple studies (e.g., positive vs. no significant vs. negative effects).

In this paper, we address two research questions. First, does the relevance of anonymity for consumers' behavior depend on the PWYW label used? Second, does consumers' IRP depend on the PWYW label communicated? Since previous research indicates that PWYT might be an economically superior alternative to the classic PWYW label, we include PWYT and classic PWYW in our study.

A field experiment in a restaurant was conducted to address the research questions (n = 166, M_{age} = 37, SD_{Age} = 10.88, 41% female). We used a 2 x 2 between-subjects design. The first factor was the PWYW label and used two levels (PWYW, PWYT). The second factor was anonymity which also used two levels (high, low). The restaurant near Zurich in Switzerland, where the study took place, created a new brunch offer just for the study.

The different PWYW labels were implemented by communicating the offer in the restaurant on a menu as *Pay What You Want* or *Pay What You Think It Is Worth* and by training the waiter to ask consumers to *pay what you want* or *pay what you think it is worth*. Each PWYW condition was conducted on a different Sunday. Guests were randomly assigned to one of the two anonymity conditions once they entered the restaurant. The PWYW offers were neutrally advertised as "Set your own price" in promotion material such as flyers and postings on social media to reduce bias.

To implement anonymity, we drew on experiences and suggestions from previous studies (Gneezy et al., 2012; Kim, Kaufmann, & Stegemann, 2014). The low anonymity condition was implemented by asking consumers to pay directly to the waiter at their table. The high anonymity condition was implemented by asking customers to pay in a separate room without supervision. After payment, the staff asked the paying guest to fill out a questionnaire in another separate room. All data used in this study were collected via the self-reported questionnaire. The guest put the questionnaire into an envelope and threw it into a box. The procedure was implemented with the intent to increase perceived anonymity further.

Regarding prices, we observe that total prices paid in the PWYT treatment groups are much higher versus prices paid in the classic PWYW conditions ($price_{PWYT/total}$ = 45.97, $price_{PWYW/total}$ = 33.23). This also applies to anonymous ($price_{PWYT/anonymous}$ = 43.45, $price_{PWYW/anonymous}$ = 32.93) and personal payment situations ($price_{PWYT/personal}$ = 48.16, $price_{PWYW/personal}$ = 33.47). Also, IRP are much higher in the PWYT vs. PWYW conditions ($IRP_{PWYT/total}$ = 47.13, $IRP_{PWYW/total}$ = 37.04), in the anonymous ($IRP_{PWYT/personal}$ = 44.12, $IRP_{PWYW/personal}$ = 37.04) and in the personal payment situation ($IRP_{PWYT/anonymous}$ = 48.16, $IRP_{PWYW/anonymous}$ = 33.47).

We continued our analysis using ANOVA. Regarding prices paid, we find a significant main effect for PWYW labels ($F(1, 132)$ = 41,13, p = .00, η_p^2 = 0.24). but no significant effect for anonymity ($F(1, 132)$ = 1.78, p = 0.18, η_p^2 = 0.01) or the two factors' interaction ($F(1, 132)$ = 1.12, p = 0.29, η_p^2 = 0.01). About IRP, we find a significant effect of the factor PWYW labels ($F(1, 132)$ = 21.61, p = .00), η_p^2 = .14). and the interaction term ($F(1, 132)$ = 9.34, p = 0, η_p^2 = .07). The second main factor anonymity is not significant ($F(1, 132)$ = .01, p = 0.75, η_p^2 = .00).

Overall, our results show that not only prices paid but also the IRP depends on PWYW labels used. Furthermore, in our experiment, anonymity only affected prices paid when the PWYT label was used. When the classic PWYW label was used (consistently), prices paid in high and low anonymity situations did not differ significantly. Further research is required to understand the underlying processes.

Retailers' Response to A Racial Reckoning: Analysis of Corporate Social Justice Communication on Social Media

Olivia Johnson, University of Houston, USA
Whitney Ginder, Georgia College & State University, USA

EXTENDED ABSTRACT

The killing of George Floyd in May of 2020 and the subsequent shootings of other unarmed Black people spurred international protests. Racial equality has emerged as one of the most prominent social values to consumers, and more than half of U.S. consumers believe brands should speak up regarding issues related to equality (Garcia-Garcia et al. 2021). In response to social movements such as this, companies are increasingly engaging in greater brand activism and corporate social justice (CSJ) efforts. Brand activism refers to the efforts of a brand to "promote, impede, or direct social, political, economic, and/or environmental reform or stasis with the desire to make improvements in society" (Sarkar and Kotler 2018, 554). Conversely, CSJ is inclusive of brand activism but incorporates the relationship with the company, its employees, customers, shareholders, and the broader community. Moreover, CSJ focuses on integrating inclusion and equity of oppressed populations at both the macro and micro levels (Zheng 2020).

Companies use a variety of methods to share their support for social and political issues; however, social media has emerged as a critical communication platform where companies can strengthen their brands (Vernuccio 2014) and connect immediately with consumers during a crisis (Eriksson 2018). Some businesses experience difficulties in communicating on social media during a crisis (Li and Li 2014; Parsons 2011) due to consumers perceiving companies' communication as inauthentic. Thus, the purpose of our research is to explore corporations' crisis communication on social media in relation to the racial justice reckoning that occurred in the summer of 2020 following the murder of George Floyd. While there is growing use of CSJ, the academic literature regarding CSJ communication is lacking. Therefore, we sought to answer the following research questions: (1) Of the top 100 retailers, how many made comments on Instagram related to social justice and the Black Lives Matter movement in the wake of George Floyd's murder? (2) What was the content of the social media posts, and what CSJ themes emerged from the data? and (3) What are examples of effective CSJ messaging from retailers, and what are the key components?

To answer the research questions, we employed content analysis. The population consisted of companies included in the National Retail Federation's (NRF) Top 100 Retailers 2020 List (National Retail Federation 2020). The research team collected responses during the first week of June 2020, a week after the murder of George Floyd. A systematic approach was used to analyze the textual content of each message from the 55 retailers who communicated during this time. To analyze the data, we utilized open, axial, and selective coding (Corbin and Strauss 2008). Portions of the responses were deemed as a specific and/or vague acknowledgement and as an action (either external, internal, corporate ability, external safety, internal safety, or inclusivity).

A majority of the messaging included a **vague acknowledgement** where the retailer used words such as *together*, *injustice*, *equality*, *solidarity*, *progress*, and *justice* ($n = 37$, 67.3%), while others also included words such as *action, change, listening, educating,* and *engaging* ($n = 23$, 41.8%). The next largest category used more **specific acknowledgement**. Most prevalently in this category retailers included words denouncing *hatred, racism, stereotyping, bigotry,* and *discrimination* and incorporated more specific terms like *sys-temic oppression, systemic racism,* and *unconscious bias* ($n = 34$, 61.8%). As opposed to the more prevalent use of vague acknowledgement highlighting the need for *justice*, *equality*, and *progress*, fewer companies ($n = 29$, 52.7%) clearly referenced *people of color* or *Black* and *African American* individuals and communities, while even fewer ($n = 19$, 34.5%) explicitly referred to George Floyd or other victims. Only one retailer made specific mention of *police brutality* and *criminal justice reform*. A smaller number of retailers made a commitment to take some type of **action**, with the largest number ($n = 13$, 23.6%) focusing on corporate ability actions (e.g., *commitment to community*, *reopening stores*, and *supporting employees and/or customers*), while a smaller proportion ($n = 10$, 18.2%) committed to taking external action including *donations* and *partnerships*. Additionally, some retailers that committed to taking action also included *internal actions* ($n = 6$, 10.9%) such as strengthening their *diversity, equity, and inclusion (DEI) policies* through better *hiring* and *training* practices and through the use of *internal centers* and *foundations* that improve internal *accountability*. Lastly, retailers committed to actions that would ensure safe and inclusive environments for their employees and customers. Seven (12.7%) retailers emphasized that their stores were *inclusive for all* and *open to everyone*, while a smaller number ($n = 2$, 3.6%) highlighted their focus on ensuring internal safety for their team members.

Finally, to answer research question 3, we identified the vital components of an effective CSJ message. Based on our definition, an effective message included a specific acknowledgement of the issue and actionable items toward employees, customers, stakeholders, and the community. For example, postings from Home Depot and Walgreens contained a specific acknowledgement of the issue by including references to ethnicity, mentioning of the victim's name, and denouncing racism. Additionally, these companies incorporated actionable items both externally and internally and focused on their commitment to the broader community.

To our knowledge, this is the first study to examine messaging related to CSJ. In line with the work of Vredenburg et al. (2020), our findings reveal that some companies demonstrated more effective CSJ messaging strategies that align with authentic brand activism; these retailers used more explicit social justice language and vowed to instigate greater systemic change both internally and externally. On the other hand, most of the analyzed retailers could be perceived as practicing varying degrees of what Vredenburg et al. (2020) referred to as woke-washing whereby they align themselves with social justice issues in a more performative manner rather than committing to integrated change that benefits all stakeholders. True CSJ requires more than mere promises; there must be action that drives solutions for the greater good (Zheng 2020). Therefore, our findings suggest companies are lacking communications approaches that reflect true integration of CSJ, which has important ethical and strategic implications.

The Impact of a Routine Schedule on an Intervention with Working Midlife Adults to Form a Walking Habit for More Sustained Physical Activity

Jane EJ Ebert, Brandeis University, USA
Xin Yao Lin, Brandeis University, USA

EXTENDED ABSTRACT

Despite substantial benefits, most adults are insufficiently physically active (e.g., CDC, 2013). While behavior change is often predicted by motivation-related constructs, such as self-efficacy, actual interventions often fail, and any changes prove hard to maintain (Rhodes et al, 2017). An alternative approach to improve maintenance is to rely on more automatic processes, such as habits, while also identifying contexts that might improve intervention success (Rothman et al, 2009; Sheeren et al, 2017). Habits develop when people perform a behavior repeatedly in a consistent situation, resulting in a mental association between a situation and behavior, resulting in enactment of behavior that is less reliant on explicit motivations and decisions. Globally, individuals' daily schedules often show considerable routine, organized around biological needs (e.g., eating) and social systems (e.g., work; Vagni & Cornwell, 2018). Inserting new behaviors into existing routines can improve habit development (Judah et al, 2013). Therefore, the AIM of the current study is:

To test the impact of this common context, a **routine schedule**, on a physical activity intervention to develop a walking habit. We focus on midlife adults: 1) they are likely to have multiple roles (work, childcare) that impose routine on their schedules, and 2) midlife is a crucial life period to set behaviors for healthy aging (Lachman, 2004).

We conducted a 9-week longitudinal randomized trial (baseline week, 4-week intervention, 4-week follow-up) of a planning intervention to form a daily walking habit with 127 low-activity, working, midlife adults. Outcome variables were weekly measures of habit automaticity (Gardner et al, 2012) during the intervention and at follow-up, and steps measured using accelerometers throughout the study. Participants were randomly assigned to a Consistent context condition or one of two control conditions (Variable context or No plan). To encourage habit development, Consistent context participants planned weekly walking schedules in consistent (recurring) situations. Variable context plan participants planned schedules that varied day-to-day. No plan participants made no plans. All participants received accelerometers, weekly step goals, and similar contact with experimenters. They completed daily, weekly, pre-, post- and follow-up questionnaires, including measures of: schedule, habit, motivation, and demographics.

The planning intervention was successful in forming and maintaining a walking habit. MLM regressions (Condition X Routine X Time) over the intervention, and then during follow-up found that habit automaticity increased for Consistent context participants relative to participants in the control conditions irrespective of schedule routine ($ps < .01$), and their increase in habit from baseline remained at follow-up ($p = .01$).

Having a more routine schedule helped participants who did not make plans (No plan controls) to form a walking habit. Further analyses showed that these effects of routine were mediated by walking in more consistent contexts each week ($\beta=.17$, 95% CI = .0002 to .37), resulting in more habit automaticity.

Similar MLM regressions on steps found that steps increased during the intervention period for participants in *all* conditions, suggesting multiple effects on steps. However, having a routine schedule helped Consistent context participants during the intervention more than participants in both control conditions. Those with more routine schedules walked more (Condition X Routine X Time, $ps < .04$; for Consistent context, simple slopes $ps < .01$). Mediation analyses suggested that having a more routine schedule made it easier each week for Consistent context participants to motivate themselves to walk ($\beta=.04$, 95% CI = .01 to .16).

MLM regressions for the 4-week follow-up period found that participants in all conditions lost steps. However, Consistent context participants benefited to some degree from the walking habits they had formed. Simple slope tests found no significant change during follow-up for participants with a higher level of habit automaticity (+1 SD: $\beta=-.02$, $p=.18$), while steps decreased over time for those with lower levels of habit automaticity (mean habit automaticity: $\beta=-.02$, $p=.02$; -1 SD: $\beta=-.03$, $p=.04$).

The effects of routine on habit automaticity and steps were robust to including other schedule-related variables correlated with routine, such as having a less busy schedule and having a preference for a routine schedule.

In conclusion, we find that a context common for many adults globally, a routine schedule, increased the success of a planning intervention in low-activity working midlife adults. Participants who planned their walking in consistent contexts and had more routine schedules increased their daily walking more with this intervention. In contrast, having a more routine schedule had little impact on the daily walking of participants in two control conditions.

Those who planned walking in consistent context also developed stronger, more automatic, walking habits than those who were asked to plan to walk in varied contexts or who made no plans. In addition, participants who made no plans, but had more routine schedules, seemed to naturally walk in more consistent contexts and so formed stronger, more automatic, walking habit than those with less routine schedules. Finally, the intervention participants who developed a stronger habit also showed some maintenance of steps during the four weeks of following the end of the intervention.

EXTENDED ABSTRACT

The COVID-19 pandemic exacted multiple changes on consumer behavior. One of the most prominent, especially in the early stages, was stockpiling goods such as toilet paper and bottled water. Stockpiling causes logistics and supply chain issues and can divert critical supplies away from those who need them the most. From a consumer perspective, stockpiling can be more than just amassing goods; stockpiling can indicate problematic mental health patterns.

Research across animal and human populations indicates that stockpiling (viz. hoarding) is a response to stress and anxiety during uncertain times (Vickers & Preston, 2014a). Indeed, inducing anxiety and uncertainty in the laboratory increases people's hoarding immediately afterwards (Vickers & Preston, 2014b).

To test the dynamics of stress-induced negative emotions and stockpiling behavior during the pandemic, we took advantage of a unique longitudinal dataset. We tested how loneliness and its interpersonal correlate, anxiety, contributed to stockpiling behavior. Moreover, we tested whether stockpiling was psychologically mollifying, that is, whether it assuaged feelings of anxiety and loneliness over time.

We also tested a potential moderating factor—the degree to which people derive social belongingness from group activities (Gabriel et al., 2017). A new formulation of an old idea (Durkheim, 1912), this measure taps individual differences in collective effervescence. It measures feelings of solidarity and connectedness from large group events, such as festivals, concerts, and somber public events. We focused on collective effervescence for its distinct applicability to the COVID-19 crisis.

We collected an initial wave of data (n =1063) on March 16, 2020, a mere 3 days after the U.S. declared a national emergency due to COVID-19. Time 2 data were collected five weeks later (April 27). Participants who completed both assessments were included in the analyses (n=562, M_{age}=38.98; 45.02% female).

At both time points, participants completed measures of anxiety, loneliness, dispositions toward collective effervescent (Tendency for Effervescent Assembly Measure [TEAM]; Gabriel et al., 2017), and stockpiling of household goods (e.g., bottled water and toilet paper) in the past seven days. Bivariate latent change score models with a structural equation model (SEM) framework were used to fit our data (McArdle 2009).

First, we examined how anxiety at time 1 moderates loneliness at time 1 to influence the change in stockpiling level from time 1 to time 2. The analysis yielded only a significant interaction between time 1 loneliness and anxiety (b = .08, t = 2.36; p = .02). Whereas loneliness at time 1 did not have any influence on change in stocking level (b = -.04, NS) for participants experiencing low levels of anxiety (1 SD below the mean), loneliness predicted an increase in stocking (b = .10, t = 2.31; p = .02) for participants expressing high levels of anxiety (1 SD above the mean). The results suggest that lonely feelings lead to hoarding for people experiencing high anxiety.

Next, we investigated the moderating role of collective effervescence (assessed with TEAM) on the relationship between loneliness and stocking behavior. Specifically, we examined how TEAM at time 1 moderates loneliness at time 1 to influence the change in stockpiling level from time 1 to time 2. The analysis yielded a significant interaction between loneliness and TEAM (b = .03, t = 1.90; p = .06): whereas loneliness did not increase stocking for participants low on collective effervescence (b = .02, NS), loneliness led to higher level of stocking for those high on collective effervescence (b = .10, t = 3.12; p = .002). These results suggest that especially for people who derive utility from large-group experiences, lonely feelings resulted from not being able to do so increases their stocking behavior.

This model also enabled us to examine whether stocking served its intended purposes, that is, alleviating negative feelings such as loneliness and anxiety. To that end, we first examined how the change in loneliness level from time 1 to time 2 was influenced by time 1 stocking level, with TEAM at time 1 as a moderator. The model yielded a significant interaction between time 1 stockpiling and TEAM (b = .03, t = 2.30; p = .02). Stockpiling seems to have opposed effects on the change in loneliness for those who score very high versus low on TEAM. Whereas for participants who score low on TEAM (2 SD below the mean), their change in loneliness level was negatively predicted by their stockpiling at time 1 (b = -.17, t = -2.07; p = .04); for those who score high on TEAM (2 SD above the mean), their change in loneliness level was positively predicted by their time 1 stocking (b = .16, t= 1.92; p = .06). This suggest that for people who do not enjoy large group experiences, stocking up did assuage their loneliness feelings. However, for people who crave large group experiences, stocking up makes them feel even lonelier.

We next examined how the change in anxiety level from time 1 to time 2 was influenced by time 1 stockpiling level, with TEAM at time 1 as a moderator. The model yielded a positive (rather than negative) main effect of stocking (b = .06, t = 2.32; p = .02). Moreover, we observed a significant interaction between time 1 stockpiling and TEAM (b = .04, t = 2.02; p = .04). Whereas for participants who score low on TEAM, the change in their anxiety level from time 1 to time 2 was not predicted by their stockpiling at time 1 (b = .02, NS); for those who score high on TEAM, the change in their anxiety was positively predicted by their time 1 stockpiling (b = .11, t = 3.04; p < .01).

The results of our longitudinal study suggest that loneliness has a positive effect on stocking, especially for people who experience higher level of anxiety and those who enjoy large-group activities. Moreover, our results indicate that negative feelings during the pandemic were not assuaged by stockpiling supplies. To the contrary, for people who thrive in large-group experiences, higher initial stockpiling behavior predicted increased negative feelings across a five-week period.

Don't Play the Scarcity Card: Perceived Scarcity in COVID-19 Vaccine Supplies Reduces Vaccination Priority and Acceptance

EXTENDED ABSTRACT

Introduction

Non-medical interventions have been paramount to curb CO-VID-19 spread, while vaccines against the virus were developed (WHO, 2020). However, even though several successful vaccines were approved worldwide, available doses are insufficient to meet current demand (Torjesen, 2021). How this vaccine scarcity affects individuals' willingness to be vaccinated (hereafter: WTV)? This paper aims to address this important public policy question, as vaccine hesitancy can hinder controlling the pandemic.

While extant literature suggests that scarcity of resources increases demand (Roux et al., 2015; Shah et al., 2012), we argue that this relationship is contingent on two dimensions not fully addressed in the literature: (i) the *beneficiary* of the (scarce) resource and (ii) *access* to the (scarce) resource. The former refers to whether the resource benefits a private actor (e.g., an individual) vs. the general public; the latter refers to whether the resource can be accessed directly vs. one must rely on a 'gatekeeper' (e.g., governmental agencies).

Restricted access to vaccines due to shortages is compounded by the problem of vaccine hesitancy, making it critical to investigate factors that can reduce vaccine acceptance. Vaccine hesitancy is "an attitudinal continuum, capturing doubts regarding the safety, efficacy, necessity and general advisability of vaccination for oneself and one's family" (p. 2540, Browne, 2018). Vaccine hesitancy is fluid and may be affected by a variety of factors, such as trust in healthcare providers (Finkelstein et al., 2020) and high perception of risk related to contagion (Caserotti et al., 2021).

We propose that a key element of COVID-19 vaccine acceptance is the sense of priority of vaccination (i.e., perceived urgency or importance of getting the vaccine for oneself). In health policy research, this concept of priority is often viewed as a "sense of urgency" or reduced interest in selfcare (Barron, 1980; Lacy et al., 2004; Mitchell & Selmes, 2007).

Methods

In two pre-registered experimental studies, we manipulated whether vaccines were scarce or widely available, and tested the effect of scarcity frame on one's perceived priority and WTV (0-100 scales). Participants were told to imagine that they could book an appointment for the following week, regardless of scarcity condition. Based on the extensive scarcity literature, we originally predicted that scarcity would increase WTV. For experiment 2, we revised our theorizing and pre-registered new hypotheses, in an effort to replicate the unexpected findings of experiment 1.

We hypothesized that (i) framing the vaccine as scarce would reduce perceived priority to receive the vaccine, which would consequently reduce WTV; (ii) participants' trust in doctors would moderate the effect of perceived priority on WTV, so that high trust in doctors would "protect" individuals from the deleterious effect that low perceived priority has on WTV; and (iii) participants' objective risk (i.e. those with pre-existing medical conditions) would moderate the effect of scarcity on perceived priority to receive a vaccine, such that individuals in high risk would have higher perceived priority and WTV in the high (vs. low) scarcity condition, while low risk individuals would have lower perceived priority and WTV in the high (vs. low) scarcity condition.

Results

Study 1 ($N = 342$ U.S. undergraduate students, $M_{age} = 20.6$, $SD = 1.65$, 52% female, data collected in Oct/2020) employed a 2 (scarcity: high vs low scarcity) between-subjects design. The scarcity frame (contrast coded: -.5 = low, +.5 = high) reduced perceived priority to be vaccinated ($\beta = -13.72$, SE = 3.40, $t(339) = -4.04$, $p < .001$), while perceived priority increased WTV ($\beta = .75$, SE = .03, $t(335) = 23.59$, $p < .001$). Trust in doctors (alpha = .82) was a significant predictor of WTV ($\beta = 8.62$, SE = 1.72, $t(335) = 5.03$, $p < .001$), and a significant moderator of the effect of perceived priority on WTV. The moderated mediation was significant: coefficient = 1.40, 95% CI = .5517, 2.5201; 10,000 bootstrap samples. (WTV means by condition: scarcity = 60.12, $SD = 33.63$, control = 70.43, $SD = 32.43$, $t(340) = 2.89$, $p = .004$).

Study 2 ($N = 585$, 52.5% female, $M_{age} = 40.23$, $SD = 14.20$, data collected in Jan/Feb 2021 when two vaccines were already available), replicated Study 1 results within a broader U.S. population on Prolific (pre-screened for having objective risk vs. no objective risk to serious COVID-19). This study employed a 2 (scarcity: high vs. low) x 2 (objective risk: high vs. low) between-subjects design. We replicated the moderated mediation model tested in Study 1 (coefficient = .53, SE = .22, 95% CI = .1203, 1.0266, 10,000 bootstrap samples; other coefficients were of similar magnitude of those of Study 1). However, the interactions between objective risk and scarcity frame are not significant predictors of the WTV or priority (both ts < 1), contrary to our prediction. (WTV means by condition: scarcity = 71.72, $SD = 37.58$, control = 78.05, $SD = 33.55$, $t(583) = 2.15$, $p = .032$).

Discussion

Framing COVID-19 vaccines as scarce had unexpected effects on demand, reducing the WTV even for individuals at higher medical risk. This difference in vaccine acceptance could have a significant impact on our ability to reach population immunity for COVID-19. And if population immunity is out of reach, as many have suggested, incremental vaccine acceptance is even more important as each vaccinated person disrupts the chain of transmission. Importantly, behavioral researchers have recently suggested leveraging scarcity of vaccination doses to improve attitudes and intentions to receive a COVID-19 vaccine (Wood & Schulman, 2021). If scarcity has the opposite effect in this context, public health campaigns need to de-emphasize the scarcity aspect.

Addressing the effects of scarcity on demand is common in economic, marketing, or psychology literatures, with a majority of studies suggesting that scarcity increases demand. Building on the relatively meager research on boundary conditions for scarcity resulting in generous, not only selfish behavior, we proposed that scarcity can

have disparate impacts on demand depending on the beneficiary of a particular resource and the access to the resource. Our results illustrate under what conditions perceived scarcity can actually suppress demand for a good.

Beyond a Self-Control Tool: The Effect of Limit Setting on Preference Sensitivity

Xiang Wang, University of Florida, USA
Minzhe Xu, University of Florida, USA
Chris Janiszewski, University of Florida, USA

EXTENDED ABSTRACT

Consumers often experience goal conflict (e.g., leisure-work conflict) when faced with resource constraints (e.g., time constraints). To help consumers manage resources and cope with goal conflict, many apps allow users to set a limit to the resource spent on a conflicting goal (e.g., screen time limit). Will limit setting affect how people allocate resources? Prior research on goal conflict and budgeting mainly focused on resource allocation *between conflicting goals* (e.g., time allocated to leisure versus work; Fishbach and Dhar 2005; Heath and Soll 1996; Larson and Hamilton 2012), while little research has investigated resource allocation *between the options serving one conflicting goal* (e.g., time allocated to each leisure activity; Goldsmith, Friedman, and Dhar 2019).

We hypothesize that setting a limit to the resource spent on one conflicting goal (i.e., the limited goal) increases one's sensitivity to their preference among the options serving that goal. Specifically, limit setting should encourage consumers to *spend a larger proportion* of the resource for the limited goal on their favorite option, if the favorite option is *strongly preferred* over the others, but *not* when the favorite option is *only slightly preferred* over the others. For example, suppose a consumer wants to work more efficiently by reducing smartphone usage. They can set a specific limit on their daily screen time or not. We predict that setting this limit will increase the proportion of screen time spent on their favorite app. However, this effect will be attenuated if they don't have a strong preference for one app (i.e., the favorite app) over the others. We further propose that this occurs because limit setting shifts the opportunity cost people consider when facing goal conflict and resource constraints (Frederick et al. 2009; Spiller 2011). Specifically, when deciding whether to spend resources on an option associated with the limited goal (e.g., whether to open an app), limit setting leads consumers to consider *other options* serving the same goal *(e.g., other apps)*, as opposed to *the other goal (e.g., work),* as the opportunity cost.

Study 1 used 2 (no-limit vs. limit) between-subjects conditions and tested the effect of limit setting when consumers strongly prefer one option serving the limited goal over the others. Participants first ranked eight chocolate truffle flavors based on their preference. After a filler task, participants imagined that they could take four free snacks at their company's cafeteria everyday from Monday to Thursday from two options: carrot & celery sticks and chocolate truffles. The flavor of the chocolate truffles offered on Monday and Wednesday (Tuesday and Thursday) was the one ranked at #7 (#2) in the ranking task, customized for each participant to ensure a strong preference between the flavors. Next, to induce an indulgence-health goal conflict, participants imagined that they decided to limit their consumption of chocolate truffles to prevent weight gain. Then, those in the limit condition set a maximum number of chocolate truffles to eat per week, while participants in the no-limit condition skipped this step. Afterward, all participants indicated the number of chocolate truffles they would take each day from Monday to Thursday. As expected, limit setting increased the proportion of the favorite chocolate truffle each participant selected (i.e., the number of #2-flavor chocolate truffles/the total number of chocolate truffles selected; 62% vs. 73%, $p=.023$), and this effect was driven by increased consideration of the tradeoff between chocolate truffle flavors (3.80 vs. 5.48, $p<.001$; 95% CI=[.03, .16]). We did not find a significant effect

of limit setting on the total number of chocolate truffles taken, perceived goal conflict, or resource scarcity. Controlling for them does not change the conclusions.

Study 2 extended the findings of Study 1 by investigating the effect of limit setting across a larger span of preference strength for the favorite option. The study used 2 (limit vs. no limit) between-subjects conditions and measured preference strength as a continuous factor. Participants imagined experiencing a conflict between work and leisure activities and indicated how they would allocate their limited time among work and different leisure activities. We found a significant limit setting × preference strength interaction ($p=.005$): among participants who strongly preferred their favorite leisure activity over the others, setting a limit to the total leisure time increased the proportion of leisure time spent on the favorite activity; however, the effect was reversed among participants who slightly preferred their favorite leisure activity over the others.

Study 3 used a scenario involving a conflict between work and spending time on fun apps and tested our mechanism using a moderation approach: if our effect is driven by increased consideration of the tradeoff between options serving the limited goal, then the effect should attenuate if this tradeoff is made salient in both the limit and no-limit conditions. Thus, in addition to limit setting (limit vs. no-limit), we orthogonally manipulated tradeoff salience by adding a reminder (i.e., "Spending time on one app might come at the cost of spending time on the other app") or not. As expected, there was a limit setting × preference strength × reminder interaction ($p=.016$): when participants strongly preferred the favorite app, limit setting increased the proportion of screen time spent on that app in the no-reminder condition (64% vs. 72%; $p=.072$), but decreased the proportion in the reminder condition (75% vs. 64%; $p=.026$); however, when preference was weak, limit setting and reminder did not affect the proportion ($ps>.6$).

In sum, three studies showed that limit setting shifts the opportunity cost people consider when facing goal conflicts and thus promotes sensitivity to preferences among options serving the limited goal. Theoretically, this research contributes to the literature on goal conflict and budgeting, and further extends the literature on opportunity cost by investigating a novel antecedent that affects *what type of* opportunity cost people consider (Spiller 2011, 2019). Practically, our findings suggest that marketers can encourage consumers to set a limit to promote the purchase of premium products (when they are consumers' favorites). Moreover, limit setting may increase consumer welfare by encouraging choices that better fit consumers' inner preferences.

Is Brand Activism the New Normal? Scale Development and Application

Nuket Serin, Florida International University, USA
Jayati Sinha, Florida International University, USA

EXTENDED ABSTRACT

In recent years, brands have begun "taking a stand" on social and political issues such as racism, social injustice, LGBTQ equality, or the refugee crisis to influence societal change. As such, brand activism is a newly evolved form of brand communication. Consumer expectations of brands have been evolving rapidly, as brands are expected to profess a more purposeful ethos to society now more than ever before. In the modern marketplace, it has become an increasingly popular trend to see brands promote social movements and fight for issues happening worldwide. For instance, numerous brands, including Nike, Netflix, TOMS, Reebok, started to protest social inequality and racial injustice during the 2020 Black Lives Matter protests (Loyalty Science Lab 2020; Mirzaei 2020). Another recent example is the pushback against the rise of anti-Asian hatred and bigotry following the spread of the COVID-19 pandemic from Asia (Chung 2021). Many brands have started using the hashtag #StopAsianHate on social media to raise awareness and combat racism (Chung 2021; Johannes 2021).

Although this emerging phenomenon has caught the attention of marketing literature in recent years (Bhagwat et al. 2020; Eilert and Cherup 2020; Hydock, Paharia, and Blair 2020; Korschun et al. 2019; Moorman 2020; Mukherjee and Althuizen 2020; Vredenburg et al. 2020), the effects of brand activism on consumer brand perceptions remain a largely unexplored research area. Understanding such effects is critically important because consumer responses to brand activism are diverse and polarized. Additionally, the literature lacks a reliable psychometric instrument to measure the construct of brand activism. Therefore, this research conceptualizes, defines, and develops a brand activism scale from a consumer's point-of-view. Utilizing a multi-method approach including interview and surveys, eight studies were conducted to create a two-dimensional 8-item brand activism scale and to test the scale's validity and reliability. This scale measures how brands can effectively engage in brand activism and be considered activist brands.

The second purpose of this research is to explore the scale's applicability in different brand-consumer relationship contexts throughout various issues such as social equality and racial injustice. Therefore, two additional studies were conducted to explore the scale within its nomological network. Specifically, Study 9a examines the effects of brand activism on consumers' brand evaluation. It also explores whether priming the consumers with a brand activism definition will change the proposed effect. Two hundred nineteen undergraduate students were recruited from a southern US university. Study 9a results support our prediction that consumers have a higher brand attitude when perceiving the brand as an activist than non-activist. Moreover, priming participants with the definition of brand activism did not change the pattern of the results. After controlling for the familiarity and purchase frequency, the results still hold, and patterns were the same.

Study 9b comprised a 2 (brand type: activist brand vs. non-activist brand) x 2 (gender: male vs. female) between-subjects design. A total of 250 participants were recruited from Prolific. Participants were asked to write either one activist or non-activist brand name and explained their reason. Next, participants completed the brand activism scale, manipulation check, willingness to pay a price premium (hereafter, WTP) that was the key-dependent measure in this study (Netemeyer et al. 2004), brand familiarity, and purchase frequency questions. As expected, consumers were WTP a price premium for an activist brand compared to a non-activist brand. A moderation analysis using a PROCESS model 1 (Hayes 2018) also showed that gender was a significant predictor of the relationship between brand type on WTP a price premium. Specifically, consumer's WTP a price premium was stronger for females than males for an activist brand. In contrast, both females and males were less WTP for a price premium in the non-activist condition. The results still held after controlling for the income, purchase frequency, and brand familiarity.

The present research contributes to the marketing and branding literature by presenting novel findings and discussing their associated managerial implications. First, this research makes a significant theoretical contribution by developing and validating a brand activism scale. Developing such a valuable tool to measure the perception of brand activism offers a significant contribution to branding literature. Moreover, brand managers may derive benefit from this research as it will help advance their understanding of brand activism and thus foster more satisfactory consumer-brand relationships. Additionally, from a public-policy perspective, this research may help people from a minority group, and those who suffer from racial inequality or social injustice can feel support from society, leading to increased life satisfaction and wellbeing.

Sharing is Not Always Caring: Enforced Familial Sharing During the COVID-19 Lockdown

Sophie Reeves-Morris, Liverpool John Moores University, UK
Shona Bettany, Huddersfield University, UK

EXTENDED ABSTRACT

Introduction

In Apple's heart-warming Christmas advert, The Surprise (Apple inc., 2019), an image of the family coming together around technology, namely an iPad device, which is promulgated as a force to draw families together; to entertain and appease bored children; and to forge positive and warm intergenerational familial relationships. However, during the enforced togetherness of the COVID-19 lockdown context, the reality for many families challenges the promulgation of these mythological ideals used widely to promote the purchase, consumption and sharing of technology in the household. This paper explores this enforced sharing of technology within families during the constrained home environment resulting from the COVID-19 lockdown context. This pandemic saw consumers increasingly reliant, even dependent upon technology for communications, information-seeking, education, and entertainment (Turkle, 2015a; Sheth, 2020). However, limitations in some households highlight that not all families and/or family members have free and/or equitable access or ownership to enabling devices, despite their heightened necessity, and apparent ubiquity during the COVID crisis. Consideration toward the complexities of family consumption regarding the different roles and identities in the household and the relationships members have with their devices are overlooked in this idealistic image of familial sharing. This work contextualises Belk's (2010) theoretical review of the consumer behaviour of sharing, interrelating considerations toward the pathological attachment family members form to their devices (Melumad & Pham, 2020), ultimately adding to the discussion of Sheth's (2020) paper exploring consumer behaviour and technology use during the pandemic.

Background

The dynamism of the sharing environment can be conceptualised from the literature, understanding that from the parental perspective, sharing devices during the lockdown period can be seen as the pooling of household resources, whereas guardians and children with higher attachment or ownership to devices, are likely to view this as a form of borrowing or lending (this is not dependent on the time period i.e., for a virtual lesson, or the whole lockdown period). From the child perspective, bartering and expectations of reciprocity may be in place and from their view, a sense of commodity exchange is present. In any case, the extension of the use of these devices takes the form of 'sharing in' within the household (expanding the sphere of extended-self by expanding the domain of common property) (Belk, 2010). Belk (2010) identifies this is complex in terms of the attachment we have to this possession, which we know can be quite high (Melumad & Pham, 2020). Thus, this study explores the area of resource allocation and the dynamics of the sharing environment during lockdown.

Method

In exploring the familial environment during the lockdown period, a two phase sequential design was utilised (Weinstein, 2018). Phase one represents the research undertaken to inform this paper, drawing on 48 survey responses completed during lockdown. The phase one survey predominantly consisted of open-ended questions, where some Likert style questions were included, a follow up required participants to reflect and explain why they chose a particular response. This allowed exploration in a more general sense toward the parent/guardians' own technology use, their views on technology use for young children and insight toward how devices were used, shared, and managed within the familial context during the lockdown period. Once ethical approval was given (19/LBS/022), the research took place during lockdown. Social media platform Facebook was used as a recruitment tool. The researcher created a profile specifically for the study. Various 'groups' were approached ranging from those sharing idea's for family/kid's activities during lockdown, more general parenting groups, 'buy and sell' pages for family items, as well as groups which facilitate the donation and receipt of family items to those in need. A thematic analysis was used for the survey.

Findings/Discussion

Our data showed sharing was dynamic within household's during lockdown. The negative parental view of technology use for young children impacted stricter mediation which constructed the demand sharing environment. Those with a more open view, introduced technology earlier reinforcing an open sharing environment during lockdown. Commonalities were found in that increased screen time was not desired. Activities enabled through sharing on highly personalised or economically valuable devices were usually specific, time bound and limited, moving beyond assumptions that possessions are joint within the family. High attachment to the device or the economic activities undertaken can cause conflict within the sharing economy. Similarly, there may be less conflict with less personalised devices, or if the activities undertaken are less likely to be for economic means. The abundance of resources plays a role here, however this is less prevalent than the parental view of technology. This has been summarised throughout a new conceptual framework for understanding the dynamic character of sharing within the familial environment during lockdown. The framework can offer additional insights to the consumption of technology in the family home towards the post-pandemic 'new normal'.

How Does Brand Warmth Influence Consumer Responses to Scarcity Appeals? The Role of Perceived Good Intentions

G. Ceren (Gerry) Aksu, Rutgers University, USA
Gabriela Tonietto, Rutgers University, USA
Alokparna Monga, Rutgers University, USA

EXTENDED ABSTRACT

Scarcity appeals, which advertise the limited availability of products (e.g., "only 10 available"), are one of the most commonly used advertising appeals for product promotions (Middleton 2017). Prior research on the effectiveness of scarcity appeals has primarily examined consumer responses toward the promoted *product*, finding that such appeals tend to increase the perceived value of the product and interest in purchasing the promoted product (Cialdini 2001; Inman, Peter, and Raghubir 1997). Despite the ubiquitous use of scarcity appeals, the effect of such appeals on consumer responses to *brands* has yet to be examined. To fill this gap, we examine the effect of scarcity appeals on brands by investigating the role of brand warmth.

Brand warmth refers to the brands' perceived friendliness, sincerity, trustworthiness, and their good intentions (Kervyn, Fiske, and Malone 2012). Prior research is limited in the role that brand warmth plays in consumer responses to specific brand actions, and the limited research in this domain has focused on prosocial behavior (Gershon and Cryder 2018). Extending this research, we examine the effect of brand warmth on consumer responses to brands using scarcity appeals. The effect of scarcity appeals on product desirability is found to be greater when consumers infer that the scarcity appeal is genuine rather than profit-driven (Lee et al. 2014), and when consumers expect products to be scarce (Mukherjee and Lee 2016). Indeed, persuasion tactics tend to be evaluated more favorably when they are not seen as sales-driven (Campbell 1995; Kirmani and Zhu 2007). Thus, we argue that because high-warmth (vs. low-warmth) brands are perceived to have a well-intentioned nature, consumers should infer that high-warmth (vs. low-warmth) brands have better intentions when using scarcity appeals, as a result, respond more favorably toward high-warmth (vs. low-warmth) brands.

Study 1 followed a single factor (brand warmth: high vs. low) between-subjects design. Participants (N=256) read about a hypothetical electronics store that was described as either warm, or not warm. Next, participants saw a promotion for a portable charger on sale that was scarce ("only 10 available"). Then, participants completed items assessing their behavioral intentions to visit the store, and brand attitudes. As predicted, behavioral intentions were greater and brand attitudes were more positive for the high-warmth (vs. low-warmth) brand following the scarcity appeal (behavioral intentions: $M_{high\text{-}warmth}$=3.40, $M_{low\text{-}warmth}$=2.95, p=.07; brand attitudes: $M_{high\text{-}warmth}$=4.79, $M_{low\text{-}warmth}$=4.08, p<.001).

Study 2 was designed to test the prediction that the effect uncovered in Study 1 is unique to when brands use a scarcity appeal, and does not emerge when brands use just any type of promotional advertisements. The study followed a 2 (brand warmth: high vs. low) x 2 (appeal: scarcity vs. no-scarcity) between-subjects design. Participants (N=614) read about a hypothetical coffee shop that was described as either warm, or not warm. Next, participants saw a promotional advertisement either with the scarcity appeal similar to that in Study 1, or not (lacked scarcity information). Then, participants completed the same behavioral intentions measure used in Study 1. Results revealed a marginally significant interaction (p=.05). Replicating Study 1, for the scarcity appeal, behavioral intentions toward the high-warmth (vs. low-warmth) brand were greater ($M_{high\text{-}warmth}$=3.51, $M_{low\text{-}warmth}$=2.85, p=.002); however, there was no such difference for the no-scarcity appeal (p=.68).

Study 3 was designed to test the proposed underlying mechanism that the observed positive effect is mediated by the perceived good intentions of the high-warmth brand. The study followed a procedure similar to that of Study 2 with the hypothetical footwear brand. Participants (N=388) responded to the same brand attitudes measure used in Study 1, followed by items measuring the perceived good intentions of the brand (e.g., well-intentioned, good-natured). Results revealed significant interactions on brand attitudes (p=.007) and perceived good intentions of the brand (p=.003). Replicating previous studies, for the scarcity appeal, participants had more positive brand attitudes toward the high-warmth (vs. low-warmth) brand ($M_{high\text{-}warmth}$=4.54, $M_{low\text{-}warmth}$=4.21, p=.08); however, the effect reversed for the no-scarcity appeal ($M_{high\text{-}warmth}$=4.36, $M_{low\text{-}warmth}$=4.75, p=.04). Although not predicted, this reversed effect provides even stronger evidence that high-warmth brands benefit over low-warmth brands only when a scarcity appeal is utilized. Moreover, for the scarcity appeal, the high-warmth (vs. low-warmth) brand was found to have better intentions ($M_{high\text{-}warmth}$=4.92, $M_{low\text{-}warmth}$=4.44, p=.004); however, there was no such difference for the no-scarcity appeal (p=.20). Further, moderated mediation analysis (PROCESS, Hayes 2018) demonstrated that the perceived good intentions of the brand mediated the observed positive effect in the scarcity condition (.12, CI [.04, .21]), but not in the no-scarcity condition (-.05, CI [-.15, .03]).

Study 4 was designed to test the proposed underlying mechanism via moderation. To do so, consumers' perceived good intentions of the brand were manipulated by making the profit motive behind using a scarcity appeal salient (vs. not). We predicted that when the profit motive is *not* salient, consumer responses would remain more favorable for a high-warmth (vs. low-warmth) brand. Conversely, when the profit motive is *salient*, this effect should be mitigated, because consumers should no longer infer that the high-warmth (vs. low-warmth) brand has better intentions. The study followed a 2 (brand warmth: high vs. low) x 2 (profit motive: salient, not salient) between-subjects design. Participants (N=444) were presented with a fictitious news article either about how companies use scarcity appeals to increase sales (profit motive salient), or about how companies establish corporate culture to reduce employee turnover (profit motive not salient). Next, participants were exposed to the same brand warmth and scarcity appeal manipulations, and completed the same behavioral intentions measure used in Study 2. Results revealed a significant interaction (p=.02). Replicating previous studies, when the profit motive was not salient, behavioral intentions were greater for the high-warmth (vs. low-warmth) brand using the scarcity appeal ($M_{high\text{-}warmth}$=3.16, $M_{low\text{-}warmth}$=2.71, p=.06). However, as predicted, when the profit motive was made salient, this effect was mitigated (p=.12).

In sum, we show that scarcity appeals influence consumer responses to advertising brands. Specifically, we demonstrate that higher brand warmth boosts consumers' evaluations toward the brand using a scarcity appeal. Moreover, we show that this positive effect is driven by the perceived good intentions of high-warmth brands.

Practice Disengagement: Reconfiguring Systems of Practice in Transformational Consumption Journeys

Larissa Becker, Tampere University, Finland

Grant me the serenity to accept the things I cannot change, the courage to change the things I can, and the wisdom to know the difference.

Serenity Prayer

EXTENDED ABSTRACT

Everyday millions of people wake up determined to change their lives. Some may struggle to abandon a negative behavior (e.g., overeating) while others endeavor to adopt a positive habit (e.g., fitness). In each case, enduring change involves rearranging an array of actions and often takes place throughout a progressive consumption journey (Akaka & Schau, 2019). We argue that these transformations involve reconfiguration of the elements of *social practices* (materials, meanings, and competences) and the *system of practices* that make up a person's life (Shove et al., 2012). Using a practice theoretic lens (Shove et al., 2012), we examine transformational consumption journeys to better understand implications of disengagement from a dispersed practice situated within systems of practices.

Ample research focuses on behavioral change based on individual choice. However, these approaches do not consider how consumption is embedded in practices and in systems of interdependent practices, resulting in limited gains for public policies aiming to promote an individual's singular behavior (Blue et al., 2016; Meier et al., 2017). We argue that changes in consumption are difficult because of the "stickiness" of a practice, which is often due to a practice being embedded within a web of everyday practices. Practices are predominantly studied as discrete entities, and little is known about how they relate to each other and other systems of practices. Furthermore, the enactment of a practice involves habit, routines, and mindless repetition; therefore, disengaging from practices can be rather difficult, and an important topic of investigation (Warde, 2005). To develop novel insight into the systemic, dynamic nature of practices and practice cessation, we pose two research questions: *How do consumers reconfigure practices to disengage from a dispersed practice? What are the outcomes of practice disengagement for the system of practices over a transformational consumption journey?*

The context of our study is compulsive consumers' disengagement from the dispersed practice (Schatzki 1996) of drinking alcohol which is found in an array of integrative practices (holiday celebrations, happy hours). We adopt the view that compulsive consumption can be part of dispersed practices, which themselves are embedded in integrative or complex practices (Schatzki 1996; Warde 2005).

To answer the research questions, we recruited 18 recovering alcoholics in AA groups in Brazil in many stages of the transformational journey (from days to 37 years). We collected data through observation of 13 AA meetings, 29 phenomenological interviews, and 10 diaries (15 days to two months). Data analysis followed a hermeneutic approach with iterations of within-case/across-case analyses to identify patterns in the reconfiguration of systems of practices (e.g., Arsel & Thompson, 2011).

Our findings show that compulsive consumers need to not only disengage from the dispersed practice of drinking alcohol but also enact new practices, change unsupportive practices, and/or disengage from practices where consumption of the substance is encouraged. *Enacting new practices* (e.g., AA and gardening practices) supports the transformational journeys because they can offer prescriptions for recovering alcoholics on how to enact everyday practices, help them overcome temptations, and fulfill idle time when replacing non-supportive practices. The enactment of new practices is supportive for transformation when their elements are aligned. Recovering alcoholics must also *disengage from practices in which the dispersed practice of drinking alcohol is embedded*, such as playing cards and going to bars. Consumers can completely disengage from these practices by physically staying away, giving excuses, or disclosing they are alcoholics. Alternatively, consumers can partially disengage from these practices by enacting them without drinking alcohol. Partial disengagement often entails practice misalignment (e.g., when someone calls them a fanatic in family lunches or when they do not find a football game fun without drinking). *Practice change* happens when practices are enacted without the dispersed practice of drinking alcohol. This can be described as a localized performance of a social practice (Thomas et al., 2020), in which everyone enacting this it accepts the rearranging and/or replacement of its elements. For instance, practitioners can replace alcoholic drinks with a substitute (e.g., grape juice in practices that involve wine). Practice misalignment is not an issue here because these localized performances are enacted by people who "go along" with the change in the practice.

Our data also reveal consumers' transformational journeys are recursive and require constant consideration of the relationship between a focal practice and the systems of practices within which it is embedded. Recovering alcoholics tend to gravitate between two poles: the recovery world and the relapse world. The first is filled with the regular enactment of supportive practices which are compatible among themselves. Conversely, the relapse world is filled with unsupportive practices (e.g., going to bars). When recovering alcoholics gradually disengage from practices in the recovery world, they gravitate toward the relapse world, which is dangerous because one can easily forget the meanings and competences learned in recovery (e.g., they start believing they can drink a beer without consequence). Almost all descriptions of relapse involve this pull towards the relapse world first.

Our study highlights that when consumers disengage from practices that they are used to, routines are disrupted, and they need to adopt other practices to reestablish ontological security (Phipps & Ozanne, 2017). We answer Meier et al. (2017) who call for understanding how disruption in a practice affects other practices and explore challenges consumers face when integrating new practices, which can lead to failure to habituate (Thomas & Epp, 2019). By showing how alcohol consumption is embedded in everyday routines, our study reveals how relationships between seemingly unrelated practices (Meier et al., 2017; Shove et al., 2012) are critical to understanding transformational journeys. Consumers who stop their alcohol consumption must continually consider the manner in which their practice disengagement impacts other practices in a perpetual dance of practice reconfiguration. Moving beyond individual decision-making toward systems of practice offers more meaningful impact to public health policies and interventions deigned to change practices and habits (e.g., Blue et al., 2016; Meier et al., 2017).

How Should I Know? Codifying Brand Practices in Service Encounters

Ignacio Luri, DePaul University, USA
Hope Schau, University of Arizona, USA
Melissa Akaka, University of Denver, USA

EXTENDED ABSTRACT

In response to the pandemic, service providers, such as restaurants, retailers, grocery stores, beauty services, and gyms, radically changed their servicescapes, processes, protocols, and scripts (Benach 2020) altering practices abruptly. Even customers with longstanding relationships and complex customer journeys (Akaka and Schau 2019; Hamilton and Price 2019; Schau and Akaka 2020; Thomas, Epp and Price 2020) with firms were confused. To help consumers understand what services were available and how to interact in physical spaces, brand-related messages were sent out through digital communications and signs were posted on almost any surface possible (doors, walkways, chairs, tables, walls, and elevators). As the pandemic situation morphs and safety standards evolve, it is difficult for service providers to ensure consumers are aware of the most current protocols regarding decreased/increased capacity, mask wearing, vaccine mandates and social distancing protocols - all of which have direct impact on brand experiences (Brakus et al., 2009).

Although our context is a global disruption in service practices, our inquiry is not centered on the pandemic or even on the change of a practice per se. In our study, practice (re)codification takes center stage. Practice codification is the process that links competences and meanings and explains how customers should enact practices in a service context. In a moment when public health concerns demand sweeping practice reforms, practice (re)codification as a phenomenon is necessary. We are addressing how consumers learn to perform particular practices in a service encounter and how service providers encourage consumers to engage in specific, sometimes brand idiosyncratic, ways that support their brand image and enhance the service experience. Our research questions are: 1) how are brand practices codified for consumers in service encounters? And 2) what are the roles of service providers and beneficiaries in codifying brand practices?

We are interested in understanding interactions that involve specialized product knowledge, occur all or in part within physical servicescapes, and engage a variety of actors (e.g., customers, employees, consuming and non-consuming bystanders) in multi-sided interactions that contribute to the shaping of distinct brand experiences. Our empirical analysis focuses on a global coffeehouse, known for a complicated menu, with multiple ordering and fulfillment modalities (coffeehouses, drive-thrus, kiosks, and branded mobile app): Starbucks.

Service encounters are negotiated interactions between service providers and beneficiaries, which are socially constructed and sustained (e.g., Arnould and Price 1993; Bitner 1990; Bitner et al., 1990). Prior research suggests that consumers contribute to shaping service encounters (Arnould and Price 1993) and brands by enacting a variety of brand practices that range from community engagement to customizing and using brands (Schau Muniz and Arnould 2009). For people to comply with service protocols, they must first be codified (Shove, Pantzar and Watson, 2012: 51).

Our data are comprised of firm, third party media and consumer data. Our data collection focused on interviews and branded content that makes reference to service scripts and pandemic protocols, and thus we searched for keywords like "order", "script", "menu," "distancing," "masks," and derivatives. At the customer-level, we include online data from social media, blogs, and forums. We also include three focus groups centered on consumer responses to pandemic era service changes, e.g., masking, social distancing and plexiglass barriers. During our research, data analysis coincided with data collection. The process was iterative, following a hermeneutic approach (Thompson 1997). Initial insights guided the collection of additional data.

Our findings reveal that codification of service encounter practices in Starbucks is the process of encoding the service encounter script and associated props for clear role expectations within the servicescape. We find that at the corporate level, Starbucks fashioned policies, protocols, and signage needed to conduct service encounters in the pandemic. We find codification process involve the roles of encoder and decoder and associated practices, such as scripting, signaling and storytelling (encoder) and observing, trying and interpreting (decoder), respectively. We demonstrate that even brief or short-lived service encounters can be multi-dimensional, with active audience engagement and the potential for role negotiation and role switching within the encounter. Thus, we find that brand practice codification is a recursive and dynamic process that involves multiple actors who take on different roles and are able to switch back and forth within a given service encounter.

Services are central to economic growth. However, to account for service beneficiaries in the service process requires the consideration of how consumers contribute to a service encounter. To better understand consumers' roles in a service encounter we explored the specific practices needed to codify a practice so both service providers and beneficiaries can contribute to value creation in a particular context. Our findings contribute to the understanding of service encounters by identifying multiple avenues for communication of associated competences and meanings. We find that codification of a practice requires multiple actors who engage collections of both encoding and decoding practices. We contribute to our understanding of roles by providing empirical evidence for the dynamics of roles, embedded with sets of practices, and how roles change depending on the practices that are enacted in different contexts. We learn that as contexts evolve so too do the practices, and thereby roles, needed for interaction and, ultimately, value creation.

Practice disruptions have been shown to occur as social structures framing a practice change and evolve (Arsel and Thompson 2011; Goulding et al 2009; Sandikci and Ger 2010) and as threats to individual and societal wellbeing disrupt routines (Campbell et al., 2020; Gonzalez et al 2021; Phipps and Ozanne 2017). Practices that are disrupted must first be re-codified with new encoding of the protocols that foster clear decoding to facilitate timely practice protocol compliance. Further, consumer research has shed light on practice misalignment (Epp et al., 2014; Thomas and Epp 2019) to reveal why practices fail to be adopted within social structures. We offer that the misaligned practices need to be copiously codified in order to locate the misaligned materials, competences or meanings. Once the misalignment is mapped, protocols can be modified to realign the practices.

SESSION OVERVIEW

Language is pervasive. It's how marketers communicate with consumers, consumers communicate with one another, and how people consume news, stories, and information.

But while a burgeoning stream of literature has begun to explore language in consumer behavior, there has been less attention to the role of gender in this process. How do gendered associations with letters or grammar impact how people, or other stimuli (e.g., COVID-19), are perceived? How might cultural items (e.g., music) and online platforms create and reinforce stereotypes and bias? And how by understanding the answer to these questions can we avoid and mitigate potential gender biases in the future?

This session answers these questions and more, as it deepens understanding around these important topics. It integrates various methods (e.g., lab experiments, field experiments, dictionaries, and machine learning), and data sources (e.g., 250,000+ song lyrics and 10 million online reviews) to shed light on gender, language, and their impact on consumer behavior.

First, **Boghrati and Berger** quantify misogyny in consumer culture. While cultural items like songs have an important impact in creating and reinforcing stereotypes and biases, less is known about whether such items are actually biased against women, and how any such biases have changed over time. Natural language processing of over 250,000 songs indicates that lyrics are misogynous, and while such biases have decreased over time, they persist.

Second, **Rathee, Banker, Mishra, and Mishra** examine gender bias in customer reviews. Using word embeddings to analyze over 11 million reviews on platforms like Amazon and Yelp, they find that positive psychographic attributes (e.g., rational and loyal) are more likely to be associated with men and negative attributes (e.g., fickle and lazy) are more likely to be associated with women.

Further, they demonstrate the consequences of such associations for the products women are recommended and ads they are shown.

Third, **Pogacar, Carpenter, and Rahinel** investigate how associations between letters and gender impact the way people are perceived. They find that names beginning with vowels are perceived as more feminine, even when those names belong to men. Further, because women are seen as warmer, people whose names begin with vowels are also seen as warmer. Analysis of U.S. congresspeople's names suggest this may even influence which candidates get elected.

Fourth, **Mecit, Shrum, and Lowrey** examine how grammatical gender might impact responses to things like COVID. In gendered languages like French and Spanish, things like viruses can be referred to in ways that mark them as masculine or feminine (e.g., le or la). They find that such subtle shifts in language can have an important impact. Using feminine marked terms made COVID-19 seem less dangerous, for example, which reduced intentions to be cautious in the future.

Taken together, these papers highlight how language provides insight into a range of important phenomena. The session should be relevant to anyone interested in gender, public policy, technology, judgment and decision making, and social cognition, as well as those who are interested in using natural language processing and language to answer relevant CB questions.

Quantifying Misogyny in Consumer Culture

EXTENDED ABSTRACT

Gender bias is pervasive. Across a range of disciplines (e.g., business, science, and medicine) and outcomes (e.g., hiring, evaluation, and recognition), women are often perceived less favorably and treated less fairly.

One reason bias may be so sticky is that they continually reinforced through culture. Songs, books, and other cultural tastes and practices not only reflect the setting in which they were produced, but also shape the attitudes and behaviors of the audiences that consume them. Song lyrics that are aggressive towards women, for example, or portray them negatively, increase anti-female attitudes and misogynous behavior (Fischer & Greitemeyer, 2006). Lyrics that espouse equality, however, can boost attitudes towards women and encourage pro-female behavior (Greitemeyer et al., 2015). Consequently, one reason stereotypes and biases, as well as attitudes more generally, may be so persistent is that they are continually reinforced by the cultural items (e.g., songs, books, and advertisements) that consumers experience on an everyday basis.

But while such cultural items clearly have impact, their actual nature is less transparent. Consider music. Are song lyrics biased against women? Have they changed over time?

Attempts to answer such questions have been hampered by issues of scale and measurement. While researchers in a range of disciplines have argued about whether music lyrics are misogynist, most perspectives are based on small samples or one genre over a short period of time (Adams & Fuller, 2006; Harding & Nett, 1984). Without more comprehensive data, however, it is difficult to draw strong conclusions. Further, even if one were able to compile such a dataset, quantification would be challenging. Manually coding tens

of thousands of songs would be prohibitive. Finally, because existing analyses rely completely on human judgment, they are susceptible to bias. The same lyrics, for example, may seem more or less misogynistic depending on the gender of the person reading them.

To address these challenges, we use automated textual analysis. We collect over a quarter of a million songs from six music genres over 50 years and use emerging computational linguistic approaches to examine (1) whether women and men are talked about differently in music and (2) whether any such biases may have shifted over time. Further, we examine (3) whether any such biases are driven by male or female artists and (4) whether lyrics seem to impact public opinions about gender.

Data. Our dataset includes 258,937 songs from 1965 to 2018. It includes pop, rock, country, R&B, dance, and rap genres.

Method. We use word embeddings (Mikolov et al., 2013) to examine a subtle form of misogyny; whether women are less likely to be linked with desirable traits (i.e., competence). Word embeddings map words to high-dimensional vectors such that the relationship between vectors captures the semantic relationship between the words. Words that are similar, or used in similar contexts appear closer (Bhatia, 2017).

Competence and warmth are two universal dimensions of social cognition (Fiske et al., 2007). But while women are often perceived as warm (e.g., kind and supportive), they are less often perceived as competent (e.g., smart and ambitious; Fiske et al., 2002). Consequently, we use cosine similarity and word lists known to tap competence (Nicolas et al., 2020), and gender (Garg et al., 2018) to measure the relative association between each gender and competence, and how it changes over time. If a gender word and a competence word occur in similar contexts, their vector representations are close in the word2vec space, which results in a larger cosine similarity score and indicates that the two words are highly associated.

We train a word embedding model for each time period, which allows for separate calculation and comparison of misogyny at multiple points. We take the word vector representation for each word and average the vectors for each gender to obtain a single 300-dimensional vector for men and women at each time point.

Results. Results suggest that while lyrics have become less misogynous over time, they remain biased (Fig. 1). Words related to competence have become more associated with women, from strongly biased towards men to less so ($\beta = -.0002$, $p < .001$). Results remain similar through a number of robustness checks and words related to intelligence (Garg et al., 2018) and warmth.

Drivers of Lyrical Shifts. Ancillary analyses examine the role of artist gender. For male artists, words related to competence ($\beta = -.0004$, $p < .001$) become more associated with women, but for female artists' language shows less evidence of change ($\beta = .0001$, $p = .35$). This is likely due to the fact that female artists' language was less misogynistic to begin with (Fig. 2). Female artists are more likely to associate women with competence overall ($\beta = -.0144$, $p < .001$), and the gender * time interaction ($\beta = .0002$, $p < .001$) indicates that the gender difference decreased over time.

Relationship with Societal Stereotypes. To examine how observed lyrical shifts in lyrics relate to changes in societal gender stereotypes we collect data on all public opinion polls from 1946 to 2018 measuring gender stereotypes related to competence. Results indicate that misogyny in lyrics is strongly correlated with societal stereotypes ($r = .62$). Importantly, lyrical changes are most strongly related to *subsequent* public opinion (i.e., opinion polls that directly follow the time period of lyrics).

Conclusion. These findings shed light on misogyny in music. Lyrics tend to be biased against women, and while these biases have decreased, they persist. Further, they are driven by shifts in the language of male artists (because female artists were less biased to begin with) and such shifts are precursors of subsequent shifts in public opinion.

This work also highlights the value of novel computational linguistic techniques for consumer research. While more and more researchers are starting to use dictionary-based methods, other approaches have received less attention. Hopefully these approaches can unlock a range of interesting questions.

An Examination of the Existence and Cause of Gender Bias in Customer Reviews

EXTENDED ABSTRACT

People increasingly rely upon algorithmically curated feeds that digitally filter information according to their preferences and determine what they see and do not see. This has created information bubbles, or silos where people are served with attitude-consistent news and rarely confront views that run counter to their beliefs, prompting much current debate about the hugely influential role that algorithms play in shaping people's perceptions of the world (Bakshy, Messing, and Adamic 2015; Min et al. 2019). While prior discussions have typically focused on informational bubbles (e.g., regarding news, viewpoints), our research highlights a uniquely consumer-focused problem in the domain of segmentation and targeting. We suggest that similar algorithmic processes involved in microtargeting are giving rise to "consumption bubbles" in which consumers are shown tailored product recommendations and advertisements to match their profiles and predicted preferences. Using 11 million reviews and other large text corpora, our research documents the development of consumption bubbles that are biased against women. Subsequently, in three field studies, we demonstrate gender-prejudiced targeting of female consumers by the major digital ad targeting platforms.

Specifically, we first propose that algorithms learn gender-bias from human-generated text corpora. We define gender-bias as the greater association of negative psychographic attributes (e.g., *impulsive, fickle, lazy*) with women and positive psychographic attributes (e.g., *rational, loyal, creative*) with men. These text corpora are a repository of voluntarily produced thoughts of millions of people, unfortunately capturing implicit societal beliefs including prejudices and biases. Second, we propose that algorithms relying on text corpora to learn consumer preferences then incorporate such bias into filters to offer customized services to users (Caselles-Dupré, Lesaint, and Royo-Letelier 2018; Liu, Joty, and Meng 2015). For instance, if algorithms learn implicit associations from large text corpora that consider men *planned* and women *impulsive*, they may subsequently serve men with financial services ads for *planned* investors while women get ads for *impulsive* investors. Women, therefore, miss out on offers targeting positive attributes as algorithms may not consider women to be *rational, planned* consumers, and the harms of such biased consumption bubbles are exacerbated when combined with firms engaging in predatory advertising (e.g., payday lending or for-profit colleges, that focus on people's vulnerabilities by targeting impatient, isolated consumers; O'Neil 2016). Therefore, we argue that this dark side of consumption bubbles can significantly harm women by limiting access to welfare-improving goods and services online.

In the current work, we build steps to characterize our two propositions. First, we use two word-embedding algorithms, GloVe and word2vec, to examine the existence of marketplace gender-bias. We use Common Crawl and 11 million product reviews from Amazon and Yelp, to ask whether algorithms learn to associate women with negative psychographic attributes that are then leveraged for

customer segmentation. Common Crawl is a snapshot of the contents of the World Wide Web, a text repository of 2.45 billion web pages archived monthly, and is more than 234 terabytes in size. Our analysis indicates that word embedding algorithms indeed learn gender-biased consumer representations from these large text corpora, associating women with more negative and less positive customer psychographic attributes.

Second, using multiple digital ad targeting platforms, we conduct a series of field studies to examine the presence of consumption bubbles in gender-biased product recommendations and ad targeting. In the first field study, we assessed whether algorithms favored delivery to women or men when ads for health services targeted positive versus negative psychographic attributes. We designed advertisements for customers seeking health advice. Our manipulation involved creating two versions of the same advertisement such that one included positive psychographic words (*reliable, rational*, and *resolute*), and the second version included negative psychographic words (*unreliable, fickle*, and *instinctive*). We deployed these advertisements as versions of the same campaign on a large online advertising platform. We used the number of impressions for male and female consumers for each advertisement to analyze the results.

In a second field study, we partnered with an existing company (an aura reader) to evaluate gender-bias in ad delivery. In this study, the ad copy was specific to the business. The advertisements were similar except for the psychographic attribute words, including five positive attributes (*strong, relaxed, jolly, dependable, tough*) and five negative attributes (*fragile, moody, irritable, irresponsible, sensitive*), which were selected by the business. Our results consistently showed that across domains of health services and mental well-being services, ads targeting negative psychographic attributes were delivered significantly more often to women while those targeting positive psychographic attributes were delivered significantly more often to men.

A third field study further examined product search recommendations on common shopping portals. The results demonstrated that shopping search queries provided women with gender-biased product recommendations, resulting in biased consideration sets and choice. Finally, examining Google Books corpus spanning the 20th century helped us understand the decade-by-decade changes in gender-bias over time and enabled us to examine the role of societal interventions such as enhancing educational attainment in creating greater gender equality.

Our findings highlight significant ethical, legal, and policy ramifications for firms. Firms routinely gather insights using algorithms and use these insights in their decisions. If algorithms are influencing so many aspects of decision-making, they should not come with the risk of caveat emptor. Because consumers are largely unaware of how ad-targeting algorithms can limit their access to goods and services, firms need to consider fairness objectives in conjunction with ad efficiency and optimization objectives. Our findings serve to illustrate that the decisions that companies make in designing digital ad campaigns can result in gender-prejudiced delivery of ads. As has been shown within the offline marketplace, the decisions that firms have made in providing limited access to banking, healthcare, and grocery services has resulted in the disenfranchisement of consumers residing in disadvantaged neighborhoods (Allcott, Gentzkow, and Yu 2019; Kirby and Kaneda 2005). As companies increasingly depend upon online platforms to conduct commerce, they must be mindful of how their digital advertising decisions may result in corresponding gender-biased limitations to goods and services, potentially reintroducing historical societal prejudices against women into the digital marketplace.

Aaron is Warmer than Darren: Names Beginning with Vowels Convey Feminine Gender and Warmth

EXTENDED ABSTRACT

Marketing research has examined many linguistic effects of brand names (see Pogacar, Shrum, & Lowrey, 2018). However, less attention has been paid to proper names. People's names carry incredible weigh, prompting first impressions (Rooth, 2010) of perceived intelligence (Young et al., 1993) and attractiveness (Garwood et al., 1980). If a person's name conveys positive characteristics, might this affect marketing outcomes related to the individual, such as political electability?

Perhaps the most important personal characteristic is warmth (Fiske et al., 2007)—trustworthiness, friendliness, likability, and sincerity (Fiske, 2018). Names may communicate warmth linguistically via feminine gender associations. The Stereotype Content Model suggests that warmth is associated with traditional femininity (Fiske, 2010) and linguistically feminine brand names convey warmth (Pogacar et al. 2021). Analysis of the 200 most popular baby names on the U.S. Social Security Administration 2010–2019 list suggests vowel-first names are indeed gendered: girls' names more frequently begin with a vowel than boys' names (30% vs. 21%; $c^2 = 4.26$, $p = .03$).

We test whether names beginning with vowels influence gender and warmth perceptions, and whether vowel-names are associated with the likelihood of a person winning elected office. Four IAT studies, and analysis of U.S. congresspeople's names, show that vowel-names convey femininity and warmth–even when the names belong to men–and male Democrats in congress more often have 'warm' vowel-names than Republican counterparts.

Stimuli names were taken from the U.S. Social Security Administration's list of popular names (except Study 3) and pretested to control for phonetic name gender, numbers of syllables, and familiarity.

Study 1: Vowel—Gender Associations

Four hundred mTurk participants (51% male; M_{age} = 30.07) evaluated either men's names (Andrew; Anthony; Edward; Isaac vs. Caleb; Henry; Marcus; Zachary) or women's names (Anna; Eva; Ella; Isabelle vs. Gabrielle; Leah; Ruby; Sara) in an Implicit Association Test (IAT; Greenwald et al., 1998) by pressing the "E" or "I" key on their computer as quickly as possible in response to stimuli pairings of names ("Vowel Names" vs. "Consonant Names") and gender descriptors ("Masculine" [*Gentleman, Male, Man, Masculine*] vs. "Feminine" [*Female, Feminine, Lady, Woman*]). This produces reaction time measures assessing relative strengths of associations between vowel/consonant names and masculinity/femininity (Greenwald et al. 1998, 2003; Figure 1).

Participants showed a stronger implicit association between vowel-first names and femininity relative to consonant-first names for both men's (M_{IAT} = 0.32, SD = 0.44, $t[196]$ = 10.17, $p < .001$) and women's names (M_{IAT} = 0.20, SD = 0.41, $t[198]$ = 6.78, $p < .001$).

Study 2: Vowel—Warmth Associations

We next test whether vowel-first names are also implicitly associated with warmth. Four hundred participants (52% male; M_{age} = 31.58) were randomly assigned to evaluate the same men's or women's names used previously. "Vowel Names" and "Consonant Names" were paired with "Positive" (*Friendly, Honest, Likable, Warm*) and "Negative" (*Cruel, Dishonest, Hostile, Nasty*) warmth descriptors and their antonyms based on Fiske's (2018) scale items.

The IAT was otherwise the same as Study 1. We collected explicit measures of perceived warmth.

Participants showed stronger implicit associations between vowel-first names and warmth relative to consonant-first for both men's (M_{IAT} = 0.43, SD = 0.50, $t(191)$ = 11.94, $p < .001$) and women's names (M_{IAT} = 0.37, SD = 0.46, $t(193)$ = 11.18, $p < .001$). Explicit measures followed the same pattern (Men's: $t[199]$ = 3.97, $p < .001$; Women's: $t[199]$ = 6.32, $p < .001$).

Study 3: Vowel—Warmth Associations among Unfamiliar Names

We generated a sample of unfamiliar names from a website for expectant parents (thebump.com). Four hundred Prolific Academic participants (46% male; M_{age} = 31.67) were randomly assigned to evaluate either men's (Olin; Oren; Ulmer; Upton vs. Quinlan; Quirino; Waylen; Wilkie) or women's names (Onida; Ursa; Una vs. Quilla; Willa; Wilfreda) as in Study 2.

Participants again displayed a stronger association between vowel-first names and warmth relative to consonant-first names for both men's (M_{IAT} = 0.35, SD = 0.51, $t[193]$ = 9.53, $p < .001$) and women's names (M_{IAT} = 0.27, SD = 0.53, $t[194]$ = 7.26, $p < .001$). Explicit measures of men's names followed the same pattern ($t[197]$ = 2.30, $p = .02$); evaluations of women's names did not differ ($t[201]$ = -1.40, $p = .16$).

Study 4: Vowel—Warmth Associations in Vowel-First versus Vowel-Last Names

The phonetic gender score for quantifying name gender emphasizes the femininity of vowel-*last* names (Barry & Harper, 1995). We therefore test whether vowel-first or vowel-last names have greater influence on perceived warmth by pitting them against each other. Two hundred Prolific Academic participants (51% male; M_{age} = 32.49) evaluated men's names (Alex; Edward; Emmett; Isaac vs. Brady; Henry; Levi; Jonah) because not enough popular women's names had masculine gender scores to generate stimuli. The procedure was the same as in Studies 2-3. Participants displayed a stronger association between warmth and vowel-first names relative to vowel-last names (M_{IAT} = 0.44, SD = 0.46, $t[194]$ = 13.21, $p < .001$). Explicit measures followed the same pattern ($t[199]$ = 3.49, $p = .001$).

Study 5: Vowel versus Consonant Names in U.S. Congress

If vowel-first names convey warmth, this should be relevant for individuals who capitalize on warmth professionally–for instance, elected officials. However, not all political candidates benefit equally from this characteristic–Democrats are associated more with warmth than Republicans (Rule & Ambady, 2010). Chi-square analysis of male U.S. Congresspeople (to control for the greater number of female Democrats) as of March 2021 found that elected Democrats were more likely to have vowel-names than Republicans ($\chi 2$ (2, 358) = 8.34, $p = .015$).

This research shows that names beginning with vowels are associated with both femininity and warmth. This holds for both men's names and women's names, regardless of whether the names are familiar or unfamiliar. The warmth associated with vowel-names may help people achieve professional goals–like winning elected office–when warmth is a valued characteristic. However, one should not judge the warmth of a book by its cover–Darren is likely just as trustworthy and likable as Aaron.

COVID-19 is Feminine: Grammatical Gender Influences Danger Perceptions by Activating Gender Stereotypes

EXTENDED ABSTRACT

Unlike English, which does not assign gender to nonhumans, French is a gendered language, and thus assigns either the masculine article (*le*) or the feminine article (*la*) to all nouns. Remembering whether any noun takes the masculine or feminine gender mark can be difficult, but the situation for COVID-19 is potentially even more confusing because the umbrella term for the virus that causes the disease, coronavirus, takes the masculine gender mark (*le coronavirus*). In this research, across six experiments with speakers of gendered languages (French and Spanish), we investigate whether and how the grammatical gender of COVID-19 influences danger perceptions.

The assignment of grammatical gender to nonhumans is typically semantically arbitrary (Maciuszek and Świątkowska 2019), and gender marks of non-human nouns have nothing to do with the qualities of the objects (e.g., in French, beard (*la barbe*) is feminine, whereas make-up (*le maquillage*) is masculine). However, numerous studies have shown that grammatical gender can act as a perceptual cue that connotes femininity and masculinity (Konishi 1993). The presence of gender markers for nonhuman nouns in gendered languages directs attention to gender distinctions and makes them more salient (Boroditsky, Schmidt, and Philips 2003), and these processes occur nonconsciously (Boutonnet, Athanasopoulos, and Thierry 2012). Thus, stereotypical gender perceptions may be activated by grammatical gender. In terms of gender stereotypes, compared to men, women are perceived as weaker and more passive (Abele 2003; Fiske et al. 2002), whereas compared to women, men are perceived as more violent, aggressive, and destructive (Eagly and Steffen 1986; Rudman, Greenwald, and McGhee 2001). These stereotypical gender perceptions not only apply to humans, but also to entities that have human-like gender cues (Jung et al. 2014).

In Study 1, we tested the hypothesis that activating thoughts about the virus using the feminine gender mark would lead to lower perceptions of danger and lower intentions of taking precautions to avoid contracting the virus in potential consumption episodes compared to activating thoughts with the masculine gender mark. We tested this hypothesis in four separate studies (1a-1d) that were designed to address issues of generalizability and rule out alternative explanations. For Study 1a (French, N=155) and Study 1b (Spanish, N=152), in the masculine grammatical gender condition, the instructions and the questions referred to *le* (Study 1a) or *el* (Study 1b) *coronavirus*, and in the feminine gender condition they referred to *la COVID-19*. Study 1c (N=150) used native English speakers to rule out potential confounds, again with a one-factor design (coronavirus vs. COVID-19). Finally, in Study 1d (French, N=153), we manipulated grammatical gender by whether the instructions and questions referred to *le COVID-19* or *la COVID-19*. Although the masculine form for COVID-19 (*le COVID-19*) is grammatically incorrect, French speakers more often than not mistakenly use it. Thus, the manipulation also has ecological validity.

Results supported our hypotheses (see table 1 for results for all studies): French (Study 1a and 1d) and Spanish (Study 1b) participants in the feminine (vs. masculine) condition thought the virus would be less dangerous in the future and intended to be less cautious in their future behaviors. English participants' perceptions of future danger of the coronavirus and COVID-19 were virtually identical, suggesting that the effects are not driven by differences in danger perceptions independent of grammatical gender.

In Study 2 (N=305), we tested whether stereotypical judgments about the virus would mediate the effect of grammatical gender on

danger perceptions along with a theoretically relevant boundary condition (moderating role of chronic gender stereotypes). The manipulation of grammatical gender was the same as Study 1d (*le* vs. *la COVID-19*).

Replicating the previous findings, results showed that participants in the feminine (vs. masculine) grammatical gender condition perceived COVID-19 to be less dangerous and associated COVID-19 with more stereotypical feminine characteristics. The moderating effect of chronic gender stereotypes on the relationship between grammatical gender and feminine stereotypes about the virus was significant. Probing further, at the mean level of the moderator (chronic gender stereotypes), the effect of grammatical gender on danger perceptions was mediated by stereotypical judgments about COVID-19, and as predicted, the effect was stronger for participants who hold stronger traditional gender stereotypes compared to those who hold weaker stereotypes, the latter of which is not significant.

In Study 3 (*N*=200), we wanted to test whether the results of the previous studies generalize to diseases other than COVID-19. We constructed a set of actual diseases, half of which take the masculine gender mark in French and half take the feminine gender mark, and had participants rate their severity and fatality. We included a comparison condition of native English speakers, whose language does not grammatically mark gender, providing a baseline of perceived dangerousness independent of grammatical gender. A repeated measures analyses showed that only the predicted interaction was significant. French speakers perceived the diseases and health conditions that take the feminine grammatical gender to be less dangerous than the diseases that take the masculine grammatical gender. In contrast, English speakers actually perceived the feminine set to be slightly more dangerous than the masculine set. Thus, French speakers judged the feminine set to be less dangerous than the masculine set more so than did English speakers. Given that English does not grammatically mark gender for non-human nouns, we interpret the difference between French and English speakers as the effect of grammatical gender.

In this research, we demonstrate how a simple linguistic cue–the grammatical gender–affects both perceptions of danger and intentions to engage in precautionary behaviors. Across a series of experiments, we show that COVID-19 is considered less likely to be dangerous when the disease is marked with the feminine (vs. masculine) grammatical gender, and that the grammatical gender effect also generalizes to other diseases as well. To the best of our knowledge, this research is the first to causally demonstrate such downstream effects of grammatical gender on judgment and decision-making.

SESSION OVERVIEW

Narratives are an integral part of everyday life. Consumer share narratives with others through word of mouth, and consume narratives through things like advertisements, books, and movies.

But while it's clear that the creation and consumption of narratives is both frequent, and important, less is known about how narratives work and why some are more impactful than others. Why are some narratives (e.g., movies, tv shows, or even academic papers) more successful? Why is nostalgia marketing so persuasive? What shapes the value of objects featured in narratives? And why are we so drawn to villains?

This session addresses these questions and more, as it sheds light on the nature and impact of narratives. The papers integrate various contexts (e.g., advertisements, movies, and academic papers), research methods (e.g., lab experiments, field studies, and natural language processing), and data sources (e.g., participants at gaming conventions and thousands of stories) to understand what makes narratives engaging and how they shape consumer behavior.

First, **Toubia, Berger, and Eliashberg** examine why some narratives are more impactful. They use natural language processing to represent tens of thousands of narratives (e.g., movies and academic papers) as sequences of points in a high-dimensional space. Then, they extract features of those narratives (i.e., speed, volume, and ground covered) that help explain their success (e.g., why some movies are evaluated more positively).

Second, **Farmer and Nielsen** examine why nostalgia persuades. While some work has suggested that nostalgia works through positive emotions, the authors find that narrative transportation plays an important role. In contrast to other positive appeals, nostalgia sells because it triggers narrative reflection that is immersive and transporting.

Third, **Hamby, Tezer, and Escalas** test a novel mechanism for narratives effectiveness. While prior work suggests that narratives can boost product evaluation through the transfer of positive affect, this explanation has trouble explaining why so many companies have started using meaningful narratives in their communications (i.e., thought provoking content, that may even evoke negative emotions). The authors demonstrate that such meaningful narratives can create value by symbolic transfer of meaning.

Fourth, **Krause-Galoni and Rucker** examine why consumers are drawn to narrative villains. While prior work might suggest interest in villains stems from a desire to experience real-world wishes and therefore may imply sadism or maleficence, the authors suggest an alternative motivation. Rather than allowing consumers to experience something they secretly want, embracing villains allows consumers to distance themselves from life's pressures and to escape from their real-world worries.

Tom van Laer will act as a discussant, integrating themes and work in the space.

Taken together, these papers deepen understanding around narratives and their impact on consumer behavior. While the general notion of narrative transportation has been quite impactful in marketing, this only scratches the surface of the interesting questions and directions in the space. The session should be relevant to anyone interested in narratives, persuasion, emotion, and consumer culture well as those who are interested in using natural language processing and large datasets to understand cultural success.

Quantifying the Shape of Narratives

EXTENDED ABSTRACT

Narratives are a powerful vehicle informing, entertaining, and making sense of the world. But why are some narratives more successful than others? And could a simple set of measures help explain variation in successful narratives across domains?

Narratives have long been described geometrically, as having "shapes", arcs, moving in circles, or covering a lot of ground. But while these suggestions are intriguing, little empirical work has actually measured such shapes or studied their impact. Might certain ways of unfurling a set of ideas increase their success? Might certain ways of structuring movies boost liking, for example, or certain ways of structuring academic papers increase citations?

We use natural language processing and machine learning to address these questions. Using state-of-the-art techniques, we measure the shapes of thousands of narratives from a variety of domains (i.e., movies, TV shows, and academic papers) and test how they relate to success (e.g., evaluations or citations).

We take narratives (e.g., academic papers), break them into approximately equal sized chunks or windows, plot each chunk in a high-dimensional space, and examine the path between chunks. To do so, we use word embeddings (Mikolov et al, 2017), a technique that transforms words into high-dimensional numerical vectors such that the relationship between vectors captures the semantic relationship between words. Each narrative is represented by a sequence of T points, $x_1, x_2, .. x_T$, in the 300-dimensional latent word embedding space.

From these sequences of points, we calculate new measures that characterize the shape of each narrative's path.

Speed. Speed, or pacing, is how quickly a narrative moves between consecutive points. Some narratives are faster, moving from one idea to the next relatively quickly, while others move more slowly. To capture this, we measure how far narratives travel between consecutive chunks. We compute the Euclidean distance between consecutive points: $distance(t) = \|x_{t+1} - x_t\|$. Word embeddings capture semantic similarity (Bhatia 2017), so consecutive narrative chunks that are further away are more likely to discuss different topics or

themes. Normalizing total distance by narrative length generates the narrative's *average speed*:

$$\text{speed} = \frac{\sum_{t=1}^{T-1} distance(t)}{T-1}$$

Rapid changes (i.e., high speed) should make narratives more engaging and exciting (Gergen and Gergen, 1986), but require additional cognitive effort to process and connect (Monahan, Murphy and Zajonc, 2000). Consequently, the excitement that speed generates likely comes at a (cognitive) cost. Consequently, speed may have a positive or negative relationship with success, depending on the context.

While speed is useful, it provides an incomplete picture. Two narratives could cover the same distance with quite different shapes (e.g., one goes out and back, while the other goes out and then out even further). Further, speed focuses only on consecutive points, but the meaning of narratives is often interpreted from the entire path (Bruner 1990).

Circuitousness. To begin to capture these nuances, we also measure *circuitousness*. We identify the shortest path a narrative could have taken, given the first point x_1, the last point x_T, and the other set of points $\{x_2, \dots x_{T-1}\}$ "visited" during the narrative. This optimization problem is a modified version of the well-known Traveling Salesman Problem. After solving this for a given set of points, we quantify the extent to which the actual sequence $\{x_1, x_2, \dots x_T\}$ deviates from optimal. *Circuitousness* is defined as the ratio of actual distance travelled to the shortest possible path. That is

$$\text{circuitousness} = \frac{\sum_{t=1}^{T-1} distance(t)}{length\ of\ shortest\ path}$$

While circuitousness might seem undesirable, given previously explored concepts are easier to process (Monahan, Murphy and Zajonc, 2000), circuitousness may provide the experience of movement or stimulation with reduced cognitive cost.

Volume. To further quantify a narrative's overall path, we also measure its *volume* (i.e., how much ground it covers). We approximate points $\{x_1, x_2 \dots x_T\}$ with an ellipsoid by solving an optimization problem that finds the minimum volume ellipsoid containing all these points (Moshtagh, 2005). Normalizing this by the dimensionality of the ellipsoid provides our measure of the volume of the narrative. Similar to speed, volume presents a tradeoff. Covering a lot of ground allows audiences to see and connect a wide range of topics but may increase the cognitive burden.

Next, we examine the relationship between these measures and narrative success. Examining over **4,000 movies** finds that those that move faster (i.e., travel further in consecutive periods on average) are evaluated more favorably (Table 1, column 1). Examining over **12,000 TV show episodes** finds a similar result (i.e., speed is good; Table 1, column 2). Given that distant points are less similar, they should be more surprising or unexpected, which may be beneficial.

TV show episodes that cover less volume are also evaluated more favorably. While one could interpret this as driven by TV show episodes being shorter than movies, note that volume is normalized by the number of chunks of text, indicating that even for text of the same length, TV show episodes that cover too much ground are evaluated less favorably. This may be driven by what audiences look for when they consume the different mediums. While high volume movies may fit audiences expectations of being transported through a narrative, TV shows may be consumed as a quick diversion, and thus volume may have a more negative effect

Examining citations of almost **30,000 academic papers published in 22 journals** reveals a distinctly different pattern (Table 1, column 3). First, speed has the opposite effect; papers that move faster are cited less. Rapid changes should increase the effort required to

follow an argument which may reduce citations. Second, volume has the opposite effect; papers that cover more ground are cited more. This is consistent with the finding that papers which link disconnected areas of knowledge receive more cites (Uzzi et al 2013). Finally, papers that are more circuitous receive more citations. Consistent with the fact that "spiral" curriculums which revisit similar topics helps students learn (Harden 1999), by repeatedly touching on similar themes, circuitousness may make it easier to integrate disparate information.

Overall, this work measures features of narrative structures and how they are linked to success.

The Story of My Life: How Nostalgia Persuades Through Narrative Transportation

EXTENDED ABSTRACT

To see that nostalgia marketing sells, one only needs to look to advertising's biggest stage, the Super Bowl, where nostalgia was a clear theme in each of the past three years (Maheshwari 2019; Meehan 2020; Smith 2021). In the 2020 Super Bowl, for example, Amazon took people on a time traveling journey from the dusty trails of the Old West to the golden era of R&B in the 2000s. Popular press and industry experts alike are also convinced of nostalgia's persuasive powers (Gross 2018; Miranda 2017; Olenski 2016). Forbes, for example, called nostalgia a "highly effective way for marketers to reach millennials" (Friedman 2016). Industry experts and researchers alike suggest that nostalgia persuades through positive emotions. In this research we propose, and show, that this current understanding of how nostalgia persuades is incomplete.

Building on findings that narrative transportation can result from mental simulation (Nielsen, Escalas, and Hoeffler 2018; Philips 2017), we propose that nostalgia marketing persuades consumers, at least in part, by encouraging them to generate vivid mental narratives of the past that are immersive and transporting. Specifically, we propose that nostalgia marketing persuades by encouraging consumers to reflect on vivid, immersive memories of a nostalgic past in the form of narratives. These nostalgic reflections become so immersive that they can lead consumers to experience a phenomenon known as narrative transportation, a feeling of cognitive and emotional engagement that makes people more receptive to persuasive messages.

This work contributes to theory in three ways. First, we show that people reflect on their nostalgic past in the form of vivid, immersive narratives. We thus expand on prior work highlighting the role of nostalgic reflection (Biskas et al. 2018; Huang, Huang, and Wyer 2016) and provide a fuller, more detailed explanation for why nostalgia has such a powerful effect on consumers. Second, we decouple the experience of nostalgic reflection from the emotion of nostalgia and thus demonstrate that the relationship between nostalgic stimuli and the emotional components of nostalgia is more complex than a simple stimulus response model might suggest (MacKenzie, Lutz, and Belch 1986). Finally, we demonstrate another way in which self-generated mental simulations can encourage narrative transportation (Nielsen et al. 2018), further expanding the scope of potential experiences that take on a narrative structure.

Across six studies (N = 1,148) we show that nostalgia marketing persuades in part by mentally transporting people to a nostalgic past. The first three studies provide evidence that nostalgic stimuli trigger higher levels of narrative transportation than non-nostalgic stimuli. In study 1a (N = 142, MTurk), we find that nostalgic memories ($M_{\text{NostalgicMemory}}$ = 6.12, SD = .88) are more transporting than immersive ($M_{\text{ImmersiveMemory}}$ = 4.63, SD = 1.97; $t(139)$ = 9.47, $p < .001$) or

ordinary memories ($M_{OrdinaryMemory}$ = 3.02, SD = 1.81; t(139) = 4.59, p < .001).

In study 1b (N = 201, MTurk), we directly manipulated two key aspects of memories that make them more nostalgic—warm feelings and a sense of loss—by asking participants who no longer live in their hometown to reflect on their favorite place (warm feelings) versus their least favorite place in either their hometown (a sense of loss) or their current town. Participants in study 1b were most transported when they wrote about their favorite place in their hometown (i.e., memories that are highly nostalgic; $M_{Favorite\_Hometown}$ = 6.91, SD = 1.14; $M_{LeastFavorite\_Hometown}$ = 5.97, SD = 5.97; $M_{Favorite\_Current}$ = 6.50, SD = 1.38; $M_{LeastFavorite\_Current}$ = 6.31, SD = 1.24; two-way ANOVA interaction: F(1, 197) = 4.46, p = .04).

In study 1c (N = 301, MTurk), we showed that advertisements with nostalgic (vs. modern) stimuli—but without a narrative format or instructions to simulate—still evoke more narrative transportation than do their modern equivalents ($M_{Nostalgic}$ = 5.59, M_{Modern} = 4.92; F(1,211) = 63.13, p < .001). We found this effect across multiple ad pairs that featured different products, designs, and nostalgic stimuli.

Studies 2 and 3 provide evidence that nostalgia marketing is persuasive in part because it leads to more narrative transportation, distinct from positive affect. In study 2 (N = 125, Prolific), we find that an ad with nostalgic (vs. modern) stimuli boosts brand attitudes ($M_{Nostalgic\_Ad}$ = 6.48, SD = 1.82; M_{Modern_Ad} = 5.63, SD = 2.56; F(1, 121) = 4.45, p = .037), even when the two ads are identical in design, branding, and messaging. Importantly, we also find that narrative transportation mediates this effect (Hayes 2017; 5,000 bootstrap samples, PROCESS Model 4; I.E. = .51, 95% CI [.02, 1.04]). Study 3 (N = 221, Prolific) replicates this mediation and shows that narrative transportation mediates above and beyond the positive affect elicited by the advertisements (PROCESS Model 4; I.E. = .12, 95% CI [.01, .26]).

In study 4 (N = 158, undergraduate lab) we further contrast the separate effects of narrative transportation and positive affect on persuasion by introducing a cognitive load manipulation to interfere with participants' ability to reflect on nostalgic memories. Consistent with a narrative route to persuasion, we found that under high cognitive load, the nostalgic ad became significantly less persuasive ($M_{NostalgicAd\_LowCogLoad}$ = 6.06, SD = 1.58; $M_{NostalgicAd\_HighCogLoad}$ = 4.86, SD = 1.89; t(154) = -3.05, p = .003) while the modern control ad was unchanged ($M_{ModernAd\_LowCogLoad}$ = 5.12, SD = 1.67; $M_{ModernAd\_HighCogLoad}$ = 5.44, SD = 1.70; two-way ANOVA interaction: F(1,154) = 7.59, p = .007).

Combined, these findings show that that nostalgia marketing does not just persuade through positive emotions, as is commonly described by both practitioners and academics. Rather, we show that nostalgia marketing also triggers vivid narrative reflection on the past that makes messages more transporting and thus more persuasive. These findings suggest that nostalgia can lead to deeper, longer-lasting persuasive effects than purely positive ads. Furthermore, these findings suggest that nostalgia appeals will be more effective than positive appeals in situations where elaboration and immersion are possible.

Significant Objects: How Eudaimonic Narratives Enhance Symbolic Value

EXTENDED ABSTRACT

The consumption of fictional narratives is a sought after, pleasurable experience, as evidenced by the multibillion-dollar narrative-based entertainment industry. However, consumers often seek out narratives that are not necessarily hedonically enjoyable (e.g., *Casablanca* and *Schindler's List*). These narratives contain eudaimonic themes, or those that explore broad life concerns such as significant human relationships, self-development, and societal betterment. Such eudaimonic content is also increasingly featured in advertisements. However, little is known about whether such ads are effective: do they enhance the value of products featured in the ads, and if so, how?

The current research addresses these questions. We build on the model of narrative transportation, or the extent to which the reader is immersed in a narrative. The narrative persuasion process is characterized by emotional engagement, mental imagery, and allocation of attention to the story, and is an inherently enjoyable process (Green and Brock 2000). The hedonically enjoyable aspect of transportation underpins past research on how narratives persuade: through positive affect transfer (van Laer et al. 2014, Escalas 2007).

Alternatively, research in communications posits that eudaimonic stories are consumed for the life lessons and personal insights they provide (Oliver and Raney 2011). Our research proposes that eudaimonic narrative content enhances the valuation of objects depicted in the story because the message transforms these objects into symbols of the meaning featured in the narrative. We assert that this process occurs separately from the hedonic affect transfer process shown in consumer research on narrative transportation (e.g. van Laer et al. 2014).

Our research also proposes that the positive effect of eudaimonic narratives on object value is stronger when an object is central to the narrative plot, where the meaning of a story resides, and after a worldview coherence threat, when consumers are motivated to reaffirm meaning in their lives (Heine, Proulx, & Vohs, 2006). Taken together, this research unravels how eudaimonic narratives create value and contributes to a more nuanced understanding of narrative persuasion.

Thus, the current work makes three main contributions to consumer research on narrative consumption: First, we identify and define eudaimonic thematic content as an influential dimension of narratives, building on prior consumer research (van Laer et al. 2014). Second, we demonstrate the influence of eudaimonic narrative themes on consumers' valuation of an object, adding nuance to the narrative transportation model of persuasion, which focused primarily on hedonic affect transfer (e.g., Escalas 2007). Third, we explicate the process through which eudaimonic narratives persuade. They serve as a symbol-creation mechanism, connecting narrative persuasion research to literature that describes how symbols obtain their meanings (i.e., McCracken 1989).

We accomplish this across five studies, three of which we plan to present at ACR. In the first study, we manipulate eudaimonic theme (present vs. absent), measure symbolic transfer as our proposed mediator, and include hedonic affect as a covariate. We find that participants in the eudaimonic narrative condition are willing to pay more for the focal notebook product (M = \$4.20) than those in the eudaimonic theme absent condition (M = \$3.16, F(1, 122) = 6.40, p = .013, η_p^2 = .050). A PROCESS analysis (model 4; Hayes, 2009) reveals a significant indirect effect of eudaimonic theme on product valuation through product symbolism ($\beta_{indirect}$ = .65, SE = .26, 95% CI = .188, 1.212), controlling for hedonic affect.

The additional two studies we plan to present explore boundary conditions. Study 2 shows that the positive effect of eudaimonic narrative content is conditioned on the centrality of the object to the narrative plot. A 2 (eudaimonic theme: absent, present) x 2 (product-plot centrality: peripheral, central) ANCOVA with raffle tickets purchased as the DV, controlling for hedonic affect, reveals a significant interaction (F(1, 187) = 4.60, p = .033, η_p^2 = .024). Planned contrasts

show that when the focal product is central to the plot, participants purchased more raffle tickets in the eudaimonic theme present condition ($M = 3.71$) compared to the absent condition ($M = 1.86$, $F(1, 187) = 6.70$, $p = .01$, $\eta_p^2 = .035$). However, when the product is peripheral to the plot, there is no effect of eudaimonic theme ($M_{present} = 1.84$ vs. $M_{absent} = 2.14$; $F(1, 187) < 1$, $p > .60$). Additionally, we examine the symbolic meaning transfer mediation process (PROCESS model 8) and find that the conditional indirect effect of eudaimonic theme on raffle tickets through product symbolism is significant in the plot-central condition, $\beta_{indirect} = .98$, $SE = .32$, 95% CI = .428, 1.683, but is not in the plot-peripheral condition, $\beta_{indirect} = .09$, $SE = .24$, 95% CI = -.397, .547. (Index of moderated mediation: $\beta = .88$, $SE = .39$, 95% CI = .214, 1.753.)

Study 3 demonstrates that the positive effect of eudaimonic narrative theme is enhanced for consumers who have experienced a worldview coherence threat. An ANCOVA with product valuation as the DV, eudaimonic theme (present vs. absent) and worldview coherence threat (present vs. absent) as IVs, controlling for hedonic affect, reveals a significant interaction, $F(1, 199) = 4.19$, $p = .042$, $\eta_p^2 = .021$. In the threat present condition, eudaimonic theme presence ($M = \$3.04$) enhances product valuation relative to its absence ($M = \$2.17$, $F(1, 199) = 15.77$, $p < .001$, $\eta_p^2 = .073$). However, without a worldview coherence threat, there is no effect of eudaimonic theme ($M_{present} = \$2.38$ versus $M_{absent} = \$2.62$, $F(1, 199) = 1.25$, $p = .266$, $\eta_p^2 = .006$). Additionally, we examine the symbolic meaning transfer mediation process (PROCESS model 14). The conditional indirect effect of eudaimonic theme on product valuation through symbolic transfer is significant in the threat absent condition, $\beta_{indirect} = .07$, $SE = .05$, 95% CI = .001, .188, but is stronger in the threat present condition, $\beta_{indirect} = .19$, $SE = .08$, 95% CI = .049, .373, as indicated by the index of moderated mediation, $\beta = .12$, $SE = .07$, 95% CI =.006, .284. The results of our studies underscore the richness in the ways that stories create value for consumers, and how this value comes to be captured in objects.

Fictional Villains and Escape from Self

EXTENDED ABSTRACT

The billion-dollar entertainment industry is fueled, in part, by opportunities for individuals to relate to, or even fantasize taking on the role, of individuals very different than themselves. For example, interactive narratives, such as role-playing games (RPGs), allow consumers to influence and become part of a story's events by role-playing as a fictional character (Oh, Lim, and Hwang 2020). Consumers can fantasize playing the part of a hero or a villain, a thief or a king. Creating and marketing these entertainment properties requires an understanding of what drives consumers' character preferences. In this work, we aim to understand when consumers' motivations result in a preference to play villainous characters.

Based on prior research, one possibility is that the only consumers drawn to villains are those with villainous real-world desires. Specifically, some research suggests that those who play villains in games are sadistic themselves (Greitemeyer and Sagioglou 2017). Indeed, the literature suggests a primary motivation for engaging in fantasy is a desire to vicariously experience one's real-world wishes – a motive we label *upward fantasy*. Yet, games and other interactive narratives such as "Grand Theft Auto" that allow consumers to portray the villain are extremely popular (Gilbert 2020; Verma 2020). If all consumers of these games are enacting upward fantasies, that would imply sadism is rampant. In contrast, we suggest a more benign explanation: we propose consumers are often drawn to interactive narratives to fulfill a need for *outward fantasy*. While upward fantasy focuses on approaching real-world goals, outward fantasy represents the desire to temporarily alter, ignore, or avoid one's real-world goals.

We propose that people seek to momentarily distance themselves from their real-world goals to avoid psychological stress. Pursuing important life goals routinely causes psychological strain, or feeling pressured or stressed, which can produce a desire for escape (Baumeister 1991; Carver and Scheier 1989; Connor-Smith and Flachsbart 2007). Forms of entertainment—such as interactive narratives—that allow for outward fantasy may offer a relief from stress by creating a momentary distance from one's real self. Moreover, given that most people want to see themselves as morally good (Blasi 1984; Greenwald 1980), villains—individuals who are "bad" by definition—would be particularly distinct from the real self and therefore should be particularly suited to serve the need for an outward fantasy.

In short, the current work suggests that the desire to portray a villain in an interactive narrative does not necessarily imply real-world sadistic goals. Instead, we propose the experience of psychological strain predicts interest in portraying a villain due to a desire to engage in outward fantasy, or a fantasy that provides full escape from one's real-world worries. This work makes several contributions to the literature on consumption of interactive narratives. First, we propose an alternative explanation besides mass sadism to reconcile assumptions about the use of interactive narratives for wish fulfillment with the massive popularity of villainous games. Second, we introduce novel predictions about the specific narrative content a consumer is likely to prefer, which can inform how and when such products should be marketed. Third, we offer one means of distinguishing when attraction to villains is problematic versus benign, which could help with public policy and interventions aimed at reducing the impact of violent games on real-world violence.

We test these ideas across three studies (N = 903). Study 1 examines whether consumers' feelings of psychological strain predict their interest in portraying a villain in an interactive narrative as well as their likelihood to choose the villain over another character (the hero). The first author programmed an interactive narrative in JavaScript called "Summer Weekend," and participants were offered two different versions of the game: one where they could play as "Heroic Hal," and the other as "Villainous Vic." The dependent measure was consequential in that participants knew their character selection would influence the choices they could make in the game. Participants' feelings of psychological strain significantly predicted increased interest in portraying Villainous Vic ($B = 0.45$, $SE = 0.16$, $t(46) = 2.78$, $p = .008$). This was specific to the villain; psychological strain actually decreased participants' interest in portraying Heroic Hal ($B = -0.32$, SE = 0.14, $t(45) = -2.18$, $p = .035$). Finally, a logistic regression revealed psychological strain significantly predicted the choice of the villain over the hero ($B = 0.61$, $SE = 0.24$, $z = 2.55$, $p = .011$).

Study 2 tests whether the effects in Study 1 replicate for interest in portraying villains from movies. Responses were collected from shoppers checking out at a costume store just before Halloween. Participants indicated their feelings of psychological strain and were also asked their interest in attending a costume party dressed as their favorite movie villain. Consistent with Study 1, psychological strain significantly predicted interest in dressing as a favorite movie villain ($B = 0.49$, $SE = 0.16$, $t(40) = 3.12$, $p = .003$). In contrast, the effect of strain on interest in the hero was not significant ($p > .1$).

In Study 3, we conducted a field study of participants at Gen Con, which is the largest tabletop gaming convention in North America. Participants who played an RPG at Gen Con answered questions

about themselves and the character they created for their game. Feelings of psychological strain significantly predicted how "evil" they made their character, from 1-Purely good to 7-Purely evil ($B = 0.08$, $SE = 0.04$, $t(809) = 2.16$, $p = .031$). The effect was mediated by their motivation to use interactive narratives as outward fantasies (indirect effect: $B = 0.01$, $SE = 0.01$, 95% CI: [0.002, 0.02]).

The results of these studies demonstrate how the concept of outward fantasy can help predict specific content different consumers may seek in interactive narratives. In doing so, it offers insight into when consumers might be particularly interested in entertainment forms that allow them to play a villain. Specifically, rather than villains being a means to fulfill consumers' sadistic fantasies, villains may simply facilitate a momentary reprieve from the psychological stress of trying to maintain one's desired self.

SESSION OVERVIEW

Whether searching for information, sharing word of mouth, or making choices, consumer behavior occurs through different modalities. Consumers can type search queries or use voice assistants like Alexa, email a friend or call them on the phone, communicate through text and images, and make choices over the computer or through their smartphones.

But while modalities, and devices, have only become more ubiquitous, their nature, and how they might impact consumer behavior, is less clear. How might typed versus voice-assisted search, for example, shape the types of information consumers look for? Might speaking versus writing shape the content of word of mouth, and thus its impact on an audience? How might making choices on a smartphone versus PC impact whether consumers choose options more consistent with chronic dispositions? And how does the information people convey through text versus images differ?

This session examines these questions and more, as it works to deepen understanding around how modalities shape consumer behavior.

First, **Melumad** examines how modality impacts what people search for. While until recently search mainly involved typing, today many consumers are increasingly relying on voice-assisted technology (e.g., Siri, Alexa) to engage in goal-directed search processes. Four experiments demonstrate that vocalizing search encourages greater deliberation and self-presentational concerns, which in turn, impact both how consumers phrase queries, and the types of information they search for.

Second, **Berger, Rocklage, and Packard** investigate how modality impacts the content, and consequences, of word of mouth (e.g., sharing opinions of products and services). While word of mouth suggests interpersonal communication through voice, consumers also often communicate through writing. Five studies demonstrate that because the spontaneous (vs. goal-directed) process of speaking involves less deliberation, it increases the emotionality of communication. This difference in language produced, in turn, can increase persuasion.

Third, **Song and Sela** examine how the modality used to make choices can shape what consumers choose. While people vary in their risk tolerance, preferences for vices over virtues, and degree to which they maximize vs. satisfice, such chronic dispositions don't always shape choice. Four studies, however, demonstrate that because smartphones activate private self-awareness to a greater extent than PCs, choosing on a smartphone leads people to make decisions that are more consistent with their chronic dispositions.

Fourth, **Ceylan and Diehl** study how people communicate experiences visually and verbally. While one might imagine that communicators use these two modes as complements, conveying different information through images and words, they find the opposite. People seem to convey the same information in both channels, to make sure important information is clearly communicated.

Taken together, these papers shed light on how modalities shape consumer behavior. Demi Oba will close the session by providing an overarching model that integrates different aspects of modality. The session should be relevant to anyone interested in judgment and decision making, word of mouth, emotion, and choice, as those who are interested in understanding how emerging technologies may shape consumer behavior.

Vocalizing Search: How Voice-Assisted Search Alters Queries

EXTENDED ABSTRACT

Over the past decade, voice-assisted search—such as Amazon's Alexa smart speaker or Google search's dictation feature—has increasingly supplanted traditional online search as a major channel through which consumers seek and gather information. As consumers rely more on voice-assisted technology for search, how might this alter the way they seek information?

In this paper I investigate this question. Drawing upon a variety of literatures including human-computer interaction (e.g., Cowan et al. 2017), psycholinguistics (e.g., Rubin 1987), self-presentation theory (e.g., Goffman 1959), and word-of-mouth (e.g., Berger and Iyengar 2013), I propose a theory of how vocalizing queries systematically affects the process of consumer search, as well as its downstream consequences. In particular, I posit that vocalizing (vs. typing) queries evokes two distinct psychological mechanisms that alter the content of queries. The first is that speaking a query out loud naturally increases consumers' self-presentational concerns (e.g., Chafe and Tannen 1987; Shen and Sengupta 2018), which leads them to seek information in a manner that puts them in a more flattering light, such as trying to appear more knowledgeable or avoiding searching for embarrassing information. Second, because of the "cost" of misphrasing a vocalized query (due to the relative difficulty of editing oneself) when seeking out desired information, consumers deliberate more on their query before indicating it, leading them to provide more specific descriptions of what they are looking for—for example, by naming a specific model/brand of a product. I show that both of these effects manifest in terms of how consumers construct queries for the *same* type of information, as well as the types of information they naturally elect to search for.

I tested these predictions across four experiments. In the first experiment, 700 participants from the Turk Prime panel were given a

specific search goal—here, searching for a product that would allow them to be more productive at home—and were randomly assigned to indicate their queries either by typing into a simulated search engine (e.g., Google) or vocalizing their queries to a simulated voice assistant (e.g., Alexa). After indicating their query, participants responded to a series of questions that measured (1) the degree to which they experienced self-presentational concerns during the task (1-5 scale), and (2) the degree to which they deliberated about their query before indicating it (1-7 scale). After transcribing the audio data (using AWS' "Transcribe" API), all queries were subject to a set of text analyses, including ratings from 1,500 judges from Prolific Academic (blind to condition) who rated six randomly selected queries along two dimensions (1-7 scale): (1) *self-enhancement* – the extent to which the product searched for revealed the consumer's unique personal tastes/preferences; and (2) *description specificity* – how narrowly/specifically the consumer described the product s/he was searching for.

The results supported the Hypothesis. Relative to those in the text condition, participants in the voice condition reported that, when indicating their query, they felt more conscious of how it would come across to others (M_{voice} = 2.24 vs. M_{text} = 1.70; $F(1, 684)$ = 32.91, $p <$ .001), and deliberated more on their queries before indicating them (M_{voice} = 4.37 vs. M_{text} =3.53; $F(1, 684)$ = 28.84, $p < .001$). Next, as hypothesized, vocalized queries were perceived as more self-enhancing than typed queries, with judges rating the products in spoken queries as appearing to reveal more about the participant's particular preferences/tastes (M_{voice} = 3.99 vs. M_{text} = 2.88; $F(1, 2963)$ = 267.75, $p < .001$, η^2 = .08). Likewise, spoken queries were also rated as more narrowly defining what the participant was searching for than typed queries (M_{voice} = 4.42 vs. M_{text} = 4.13; $F(1, 3028)$ = 18.09, $p < .001$, η^2 = .01). Finally, as shown below, a structural-equation model supported the proposed theoretical model.

Three subsequent experiments established the robustness of these effects across a range of domains. Experiment 2 (N=771) conceptually replicated the above findings in a more constrained task where all participants were asked to search for a set of wireless headphones (such that the searched product was held constant across conditions). The results again provide evidence for greater self-enhancement and greater specificity in vocalized search, here reflected in the language that was used to search for the same product (rather than in the types of products themselves): Participants in the voice condition generated queries that made them seem more self-enhancing (M_{voice} = 2.59 vs. M_{text} = 2.34; $F(1, 3134)$ = 24.92, $p < .001$) and contained more specific descriptions (M_{voice} = 4.39 vs. M_{text} = 3.87; $F(1, 4164)$ = 95.13, $p < .001$) as rated by outside judges. Experiment 3 (N=761) then examined whether the tendency for consumers to be more self-enhancing in vocalized search would also manifest in a greater *avoidance* of information that might be embarrassing. To test this, participants were again randomly assigned to vocalize or type their queries, but this time were asked to pose a query about a personal health question. The results provide convergent evidence for differences in self-enhancement, with judges rating vocalized queries as less embarrassing/more shareable than typed queries (LSM: M_{voice} = 5.58 vs. M_{text} = 5.25; $F(1, 3324)$ = 23.62, $p < .001$). In Experiment 4 all participants were asked to search for a product using the same search engine (Google), but were now randomly assigned to type their query (as in the prior studies) or vocalize it as if they were dictating it into the search engine (simulating Google's dictation feature); the results confirmed that the effects were robust to this context, thereby mitigating concerns that the findings were merely an artifact of differences in the norms associated with voice assistants (e.g., Alexa) versus standard Google search.

Expression Modalities: How Speaking Versus Writing Shapes What Consumers Say, and Its Impact

EXTENDED ABSTRACT

Word of mouth is both frequent and important. But might the way consumers communicate (i.e., speaking versus writing) shape the language they use? And, thus, the impact of what they share?

While a great deal of research has begun to examine the behavioral drivers of word of mouth, there has been less attention to how communication modality might shape what consumers share. Sometimes consumers speak to others (e.g., talking face to face or over the phone) and other times they write (e.g., over email or text). Might speaking rather than writing about a restaurant, for example, shape the way consumers talk about it, and, thus, their audience's interest in eating there?

While communication mode may seem inconsequential, we suggest it can have an important impact on word of mouth. Because speaking in the context of conversations is often a more spontaneous process that involves less deliberation than writing, we suggest that it can encourage more emotional language. Indeed, deliberation has been shown to decrease emotion in other contexts (Shiv and Fedorikhin 1999). As a result, communication modality can spillover to impact the persuasiveness of communication. Five experiments test these possibilities.

Experiment 1 provided a test of the basic effect. Participants shared their opinion about a restaurant either orally (i.e., into a microphone) or in writing (i.e., through a computer). To examine generalizability, we also manipulated whether they talked about a restaurant they loved or hated. We transcribed the oral opinions and measured the emotionality of the language produced in each condition using the Evaluative Lexicon (Rocklage, Rucker, and Nordgren 2018). As predicted, regardless of opinion valence, speaking increased the emotionality of the language used.

Ancillary analyses across experiments cast doubt on alternative explanations based on social presence, audience size, ephemerality, synchronicity, arousal, and production time.

Experiment 2 begins to test the hypothesized process through mediation. We measured how much participants deliberated about what to say and whether it mediates the effect of expression mode on emotionality. Speaking again increased emotional language. Further, evidence indicated the effects were mediated by deliberation.

Experiment 3 uses moderation to test the underlying process. If speaking increases emotionality because it decreases deliberation, as hypothesized, then the effects should be moderated by individual differences in spontaneous emotion expression (i.e., emotional expressivity; Kring, Smith, and Neale 1994). Speaking, which involves less deliberation and thus more spontaneity, should be particularly likely to boost emotionality among individuals high in emotional expressivity.

We also use an alternate method of collecting spoken opinions. While speaking into a microphone controls for some possibilities, one could argue that it may seem artificial. To examine generalizability, Experiment 3 has participants leave a voicemail in spoken condition and write an email in the written condition, just as people often do in everyday life.

Analyses revealed the predicted Modality x Emotional Expressivity interaction. Consistent with our theorizing, compared to writing, speaking led emotionally expressive participants (+1 SD) to use more emotion. This difference was significantly mitigated, however, among participants low in emotional expressivity (-1 SD).

Experiment 4 further tests the underlying role of deliberation through moderation. If communication mode influences emotion-

ality via deliberation, as suggested, then encouraging deliberation should mitigate the effect. Encouraging speakers to take time to think about what to say should make them look more like writers and decrease the emotionality of what they share. Consequently, in addition to either speaking or writing, half of them were asked to "take a few moments to organize your thoughts" before sharing them.

Consistent with our theorizing, deliberation moderated the effects. In the control condition, results replicated those found in the first three studies. Compared to writing, speaking increased emotionality. Increasing deliberation, however, mitigated this effect. Taking a moment to think before sharing reduced the difference between speaking and writing.

Experiment 5 tests whether expression mode's impact on emotional language spills over to shape the attitudes of word of mouth recipients. Imagine a friend told you about a movie. Could the fact that they spoke to you, rather than wrote to you, change the emotionality of the language they use to talk about the film, and thus your interest in going to see it?

Participants were randomly assigned the language (i.e., the text) from one of the opinions expressed by a participant from Experiment 2, and based on it, reported how interested they would be in trying the restaurant. In addition, to capture the underlying process, they rated how emotional the description of the restaurant was.

Consistent with our theorizing, expression mode influenced observer attitudes through emotional language. Spoken communication led to more emotional language, which led participants to perceive the review as more emotional, which increased interest in trying the restaurant.

Conclusion Taken together, these results (1) demonstrate that modality impacts emotionality, (2) document the underlying process by which this occurs, and (3) illustrate the downstream effect on the communication audience.

This research makes three main contributions. First, it contributes to the burgeoning literature on psychological drivers of word of mouth. While research has begun to examine why consumers talk about some things rather than others, there has been less attention to how communication mode might impact what consumers share.

Second, this work deepens understanding of the role of language in consumer behavior. We contribute to the growing literature on consumer language (Moore and McFerran 2017), showing that how consumers communicate impacts the emotionality of the language they use.

Finally, research finds large differences between the content of online and offline word of mouth (Fay and Larkin 2017) and suggests that offline word of mouth is more impactful (Keller and Fay 2009). While these effects are likely multiply determined, modality may be a contributing factor. Most online word of mouth is written, but a much larger chunk of offline word of mouth is spoken. Our results suggest this may not only change the content of conversations, but also their impact.

Smartphones and the True Self: How Technology Influences Disposition Expression

EXTENDED ABSTRACT

People differ in their chronic dispositions, and conventional wisdom holds that these often shape behavior (Bargh et al. 1986; Tyler 1947). However, the extent to which dispositional traits manifest in behavior in specific instances varies considerably (Kassarjian 1971; Lewin 1951; Ross and Nisbett 2011; Sirgy 1982), and may depend on accessibility (Higgins 1996), power (Hirsh, Galinsky, and Zhong 2011), social demands (Bargh, McKenna, and Fitzsimons 2002), and culture (Kim and Sherman 2007).

We propose that technology can be an important determinant of behavioral disposition expression. Specifically, compared with personal computers (PCs), we show that smartphone use amplifies the expression of chronic dispositions, such as risk-seeking, self-control, maximizing/satisficing, and political ideology, in choice. We argue that, because smartphones are extremely private and personal, more than any other personal device (Clayton, Leshner, and Almond 2015; Hatuka and Toch 2016; Park and Kaye 2019), using them activates private self-awareness, a state of elevated accessibility of intimate self-knowledge and attention to internal states (Carver and Scheier 1981; Gibbons 1990; Song and Sela 2021). This state of elevated private self-awareness, caused by smartphone use, increases the accessibility and, consequently, the behavioral expression of chronic traits and dispositions. Thus, we predict and find greater correspondence between chronic dispositions and choice when people use their personal smartphone, compared with their PC.

Five studies support this perspective. In Study 1A ($N = 411$), participants used the behavioral lab's desktop computers to complete a personality questionnaire, which included a maximizing-satisficing scale, our focal trait (Nenkov et al. 2008; no device effect on maximizing, $p = .41$). Then, they were randomly assigned to complete the remainder of the session on either their personal smartphone or personal laptop, which they had been asked to bring with them. Participants completed a hotel search task, where they could browse as many or as few options as they wanted before making a final decision. Based on prior research (Ma and Roese 2014; Nardini and Sela 2019), the extent of search is an important manifestation of maximizing vs. satisficing tendencies. Consistent with our theorizing, a device × maximizing trait interaction effect ($b = 1.20$, $p < .01$) reveals pronounced correspondence between dispositional maximizing and search behavior among participants using their smartphone ($b = .95$, $p < .01$), which was attenuated among PC users ($b = -.25$, $p = .45$).

Study 1B ($N = 187$; preregistered) focuses on self-control as the focal dispositional trait. After being randomly assigned to use their own smartphone or PC, participants made a choice between "vice" and "virtue" in one of several domains (e.g., choosing between a delicious pasta and a healthy salad; from Sela, Berger, and Kim 2017). Finally, they completed a personality questionnaire which included a measure of dispositional self-control (Tangney, Baumeister, and Boone 2004; no device effect, $p = .31$). Consistent with our prediction, a marginally-significant device × dispositional self-control interaction effect on choice ($b = .41$, $p = .09$) reveals greater correspondence between dispositional self-control and choice among smartphone users ($b = .72$, $p < .01$) than among PC users ($b = .31$, $p = .016$).

Study 1C focuses on political orientation expression. Participants ($N = 302$) indicated their political orientation (45.5% republicans and 54.4% democrats, no device effect; $p = .20$). After completing filler questions, they indicated their attitudes toward several politically polarizing COVID-19 policies (e.g., fining individuals for violating social distancing rules; Druckman et al. 2021). Supporting our prediction, a significant device × political orientation interaction effect on aggregate policy endorsement ($b = .89$, $p = .02$) reveals greater correspondence between political orientation and endorsement of partisan policies among smartphone users ($b = 3.02$, $p < .01$) than among PC users ($b = 2.12$, $p < .01$).

Study 1D ($N = 141$) used a similar procedure as Study 1A to measure dispositional risk tolerance (scale adapted from Mandrik and Bao 2005; no device effect, $p = .91$). After completing the trait measure, participants indicated the amount of money they would in-

vest in a risky opportunity (Kupor, Liu, and Amir 2017). Consistent with our prediction, a device × dispositional risk-tolerance interaction effect (b = -16.03, p = .02) reveals pronounced correspondence between risk-tolerance and risky/riskless choice among participants using their smartphone (b = -9.11, p = .046), but not among PC users (b = 6.93, p = .19).

One may wonder whether smartphones influence choice by activating chronic self-goals, namely, notions of the "ideal self" (e.g., wanting to be healthy), or – as we hypothesize – knowledge of the "actual self" (e.g., "I am healthy"; Higgins 1987). Study 2 (N = 129) examines this question by measuring both "ideal" (or "ought") and "actual" self-perceptions. We used a procedure from prior research (Higgins 1987; Sela and Shiv 2009) to capture the chronic "ideal" and "actual" self-view related to physical health. Following filler questions, participants were then asked to make a choice in a healthy eating dilemma similar to Study 1B. A marginally-significant device × actual-self interaction (b = .46, p = .08) reveals greater correspondence between "actual" self-view and choice among smartphone users (b = .60, p < .01) than among PC users (b = .14, p = .35). Ratings of "ideal" (i.e., motivated) self-view did not interact with device in predicting choice (b = -.20, p = .57).

Firms and researchers alike routinely measure consumers' personality traits (Graves and Matz 2018; Sunstein 2018) and use them to predict online behavior. The current findings suggest that such "profiling" may prove more predictive of choice when consumers use their smartphones, rather than PC. More broadly, smartphones have had a dramatic effect on consumers' lives, reshaping relationships, habits, and consumption behaviors. We hope that this research advances understanding of some of these effects.

How Do People Communicate Their Experiences Visually and Verbally? More Words and More Pictures

EXTENDED ABSTRACT

With the advent of camera phones, communicating our experiences using pictures has become part of everyday life. For example, 4.5 billion pictures are shared in WhatsApp messages daily (Business Today 2017). In our research, we ask how people use pictures and words to communicate their experiences. Specifically, we ask whether in visual-verbal messages, pictures substitute words for efficiency or whether words are used to emphasize what is communicated in the picture, resulting in redundancy. Lay belief may suggest that "a picture is worth 1000 words" and hence that pictures may substitute text. This would be in line with Grice's Maxim of Quantity that prescribes that communicators need to be brief and efficient (Grice 1975).

Alternatively, people may convey similar information in visual and verbal modalities in a redundant way, to increase the potential relevance of the information to the receiver, and to facilitate processing (Wilson 1993), in line with Grice's Maxim of Relation. Given the dearth of attention and the excess of noise in today's world (Davenport and Beck 2001; Partan and Marler 1999) as well as the relatively low cost of using words and pictures jointly, we expect that, in visual-verbal communications, people will prioritize redundancy (in line with the Maxim of Relation) over efficiency (contrary to the Maxim of Quantity).

Study 1 examined the relationship between pictures and visual words (i.e., words that convey information that pictures could convey also) in the context of reviews, using two large real-world datasets (Yelp and TripAdvisor). We used the *see* words category from the Linguistic Inquiry and Word Count dictionary (LIWC) to determine the extent to which a review included visual words. We found that when writers used more visual words, they were also more likely to add a picture in both the Yelp (β=0.11, t=44.5, p<.001) and TripAdvisor (β=0.05, t=15.9, p<.001) datasets. This held controlling for review, reviewer, and restaurant characteristics. We also found the same relationship for the total number of photos included. These analyses provided initial evidence that pictures and words are positively related.

In **study 2**, we manipulated the number of see words in a product review and tested whether more visual words heighten picture use. This study followed a three-group design. We recruited 598 participants (41.2% female; M_{age}=35.8) on MTurk (preregistration: osf.io/jd23r/). Participants imagined they had written a review of a computer mouse and read "their" 140 words review. Participants in the no-see-words condition read a review that included no words from LIWC's *see* category. In the high-frequency [low-frequency] condition "see" words constituted 30% [10%] of the review. Participants indicated whether they would add a picture when posting this review (Yes=1, No=0). A larger percentage of participants in the high-frequency (86%) indicated that they would include a picture compared to the no-see-words condition (75%), z=3.1, p=.002. Participants in the low-frequency were directionally but not statistically significantly more likely to include a picture with their review (82%) compared with the no-see-words condition (z=1.4, p=.1). This study provided causal evidence that people choose to emphasize redundant information in visual-verbal communications.

In **study 3,** we tested whether people intend to align visual words and pictures at the semantic level (e.g., describing and depicting food), which results in redundancy. We recruited 190 students (52.6% female; M_{age}=19.9; preregistered: AsPredicted #58409). Participants read one of two review replicates that focused on visual aspects of the coffee shop (foam-art, or wall-art). After reading the review, participants chose the picture they would like to post with the review text. In each condition, two out of 10 pictures precisely matched the review text and the remaining eight were from other categories related to the coffee shop experience but not mentioned in the review. Our dependent measure was whether or not people chose one of the two matching pictures. We also measured whether participants believed they selected a picture that conveyed the same information as the text. An overwhelming 92% of participants chose a picture that matched the review text. We did not find any difference between the two review replicates (M=94% in foam-art, M=89% in wall-art). We also found that participants who matched text and picture (M=5.93) reported greater intentions to provide the same information than those who did not (M=3.30), β=1.58, $t(190)$=3.66, p<.001.

While study 3 measured people's intention, **study 4** further examined whether people strive for redundancy by comparing people's internal goal to holding an explicit redundancy or an explicit efficiency goal. We recruited 322 on MTurk (53.7% female; M_{age}=41.3; preregistered: AsPredicted #59195) and randomly assigned them to one of 3 between-subjects conditions (goals: no external vs. redundancy goal vs. efficiency goal). In the redundancy [efficiency] goal condition, participants were told to convey their experience with the goal to communicate thoroughly [efficiently], possibly [without] repeating some of the information that was already conveyed by the picture. In the no external goal condition, participants were not provided a goal. As the key dependent variable, we assessed the extent to which their text referred to the picture. We also measured whether participants believed their text conveyed the same information as the picture. As manipulated, participants in the redundancy-goal condition (M=9.1% of total words) used more picture-related words than participants in the efficiency-goal condition (M=6.4%), β = -2.66, $t(322)$ = -3.68, p < .001. Importantly, and supporting our prediction,

participants in the no external goal condition also used more picture-related words compare to the efficiency condition (*M*=7.9 %), *β* =-1.50, *t*(322) = -2.11, *p* = .03. Further, the no-goal and redundancy-goal conditions used picture-related words similarly frequently, *β* = 1.15, *t*(322) = 1.61, *p* = .11. Participants' stated intention to provide redundant information mirrored these findings.

Taken together, we find that pictures and words go hand-in-hand. We consistently find that people use words describing visual aspects and pictures jointly, in line with Grice's Maxim of Relation, emphasizing relevant information for the receiver. Our research sheds light onto the communicators' side of word of mouth and examines how people use pictures and words in visual-verbal communication.

SESSION OVERVIEW

Consumers nowadays have greater access to important, self-relevant numeric information than ever before. Within the past year alone, they have observed changes in stock prices, health statistics, and election polls expressed in numbers. This increasing abundance of numeric information makes it important to understand how consumers interact with such information. Therefore, this special session presents four papers that are related to numeric judgments and decisions, addressing both how consumers evaluate and generate them.

The first paper by Hu, Gaertig, and Dietvorst examines consumers' perceptions and preferences toward different formats of uncertain time estimates (e.g., the most likely point estimates vs. conservative point estimates vs. range estimates). They find that consumers prefer range estimates to point estimates, unless the ranges are excessively wide. In contexts where early arrivals are preferred, consumers prefer conservative estimates, but when accuracy is better, consumers prefer the most likely estimates. These findings provide practical implications for companies communicating uncertainty in time estimates.

The second paper by Mislavsky and Gaertig studies consumers' responses to predictions made at different time points (e.g., one year vs. one day in advance). They find that—contrary to lay beliefs that early estimates will receive greater credit—consumers give less credit to estimates made too early. This effect seems to arise because consumers acknowledge the role of luck in early predictions, and it does not manifest for incorrect predictions. These results shed light on how consumers evaluate predictions based on the temporal information presented alongside them.

The third paper by Gao, Jung, and Nelson investigates consumers' numeric predictions regarding the effects of various marketing-relevant interventions (e.g., defaults for charitable donations in an online shopping environment) and the accuracy of their predictions. They find that consumers underestimate the effects of defaults on purchasing decisions by large percentage points. They also find that consumers tend to overpredict the effects of interventions in joint evaluations compared to separate evaluations. This research highlights different challenges in accurately predicting prosocial behavior in the marketplace.

The fourth paper by Klusowski, Small, and Goldenberg demonstrates consumers' general, arbitrary tendency to choose even numbers more frequently than odd numbers in quantity decisions (e.g., how many apples to buy for oneself at a grocery store). They find this tendency in both archival shopping data and online survey data. While this tendency largely holds even without round numbers that are multiples of ten, they identify important boundary conditions that attenuate this effect, extending previous research on quantity decisions and numerical cognition.

Together, this session addresses how consumers evaluate or generate numeric judgments and decisions. Specifically, the first two papers examine consumers' responses to information that has been provided to them, and the last two papers investigate their tendencies when arriving at judgments or decisions themselves. Ultimately, this session aims to provide insights into understanding and improving consumers' numeric judgments and decisions—which will become increasingly more important for optimizing their well-being as the amount of numeric information available to them continues to grow every day.

How Should Time Estimates Be Structured to Increase Consumers' Satisfaction?

EXTENDED ABSTRACT

Consumers often encounter algorithmic estimates in inherently uncertain contexts, such as estimated delivery times provided by food delivery apps or estimated arrival times for Uber, Lyft, or Google Maps. When providing time estimates to consumers, companies must decide how to present these estimates and, importantly, whether to communicate the inherent uncertainty of the future. For example, a food delivery app can give customers the most likely delivery time (e.g., "45 minutes"), a conservative estimate (e.g., "55 minutes"), or a range (e.g., "35-55 minutes"). But which format do consumers prefer? In this research, we examine how time estimates should be structured to increase consumers' satisfaction.

In 8 pre-registered studies ($N = 5,816$), participants indicated their satisfaction with time estimates provided by a hypothetical food delivery or GPS app. We presented participants with the estimated and actual arrival times of 20 past orders/trips on the app and then asked them to evaluate the app. This design allowed us to mimic real-world scenarios in which consumers experience a sequence of individual orders/trips and form an overall impression of the app's performance. We generated the apps' actual outcomes from either a normal or log-normal distribution. Across our studies, we manipulated the format of the time estimate (a point or a range) and/or the location of the time estimate in the distribution (accurate estimate or conservative estimate). Each participant always saw the same estimate for all 20 orders/trips. In all studies, participants then reported their subjective liking of the app using a composite scale (liking, informativeness, usefulness, accuracy, trust).

In Study 1 ($N = 698$), participants evaluated a food delivery app. We manipulated whether the delivery estimate was presented as an accurate point estimate ("45 minutes" – the mean of the distribution), a normal range estimate ("35-55 minutes" – the 80% confidence interval (CI)), or a narrow range estimate ("40-50 minutes" - the 50% CI). Participants liked the two ranges significantly more than the point estimate ($ps < .001$) and the liking of the two ranges did not dif-

fer from each other ($p = .571$). We replicated the finding that ranges are preferred to point estimates in 4 additional studies with similar procedures and show that the finding is robust to different domains (food delivery or GPS), different durations (short or long), and different outcome distributions (normal or log-normal). In Study 2 ($N = 599$), we tested a boundary condition: An extremely wide range (99% CI) is liked less than both a point estimate ($p = .026$) and a normal range ($p < .001$), suggesting that consumers like range estimates as long as they are not excessively wide.

Our findings suggest that the choice between a point estimate and a range estimate may involve a tradeoff between accuracy and informativeness (Yaniv & Foster, 1995). While point estimates are informative and easy to understand, they may convey a false sense of certainty regarding the prediction and are more likely to be wrong. In contrast, ranges are more likely to contain the actual outcome, but they are also less informative because they specify a less specific outcome. Our results suggest that as long as ranges are not excessively wide, and hence uninformative, consumers seem to prefer the increased accuracy that ranges provide to point estimates.

One alternative explanation is that ranges are less likely to be perceived as being "late" because, relative to point estimates, fewer outcomes take longer than the upper bound of the range. To address this possibility, we examined consumers' liking of conservative point estimates, which can be just as unlikely to be late as ranges. We additionally manipulated whether the estimates were centered at the mean of the distribution (e.g., a point estimate of "45 minutes" or a range estimate of "35-55 minutes") or the 90th percentile (e.g., a point estimate of "55 minutes" or a range estimate of "45-65 minutes"). In Studies 3-5 (Ns = 801, 998, and 888, respectively), a conservative point estimate was liked less than any range (ps < .001). In addition, when evaluating a food delivery app (Studies 3-4), participants did not penalize conservative estimates for being less accurate on average. In fact, they liked the conservative point estimate directionally more than the accurate point estimate (ps = .164, .024). However, when evaluating a GPS (Study 5), participants were significantly more satisfied with the accurate point estimate than the conservative point estimate ($p < .001$).

We found that this discrepancy between perceptions of time estimates across domains is driven by different perceptions of early arrivals. In Study 7 ($N = 371$), we found first evidence that how satisfied participants would be with an early arrival mediates the domain difference in liking for conservative estimates. In Study 8 ($N = 1,088$), conducted within the food delivery domain, we directly manipulated whether early or accurate arrivals of the food would be better for the consumer, and this moderated the preference for accurate or conservative estimates: When asked to imagine that they order food while still at work and try to get home in time for the delivery (accurate is better condition), participants preferred the app giving an accurate estimate rather than a conservative estimate ($p = .011$). However, those who imagined ordering dessert for delivery while finishing dinner (early is better condition) preferred the app giving a conservative estimate ($p = .004$). The interaction was significant ($p < .001$).

Taken together, our results suggest that in inherently uncertain consumer contexts, range estimates are more appealing to consumers than point estimates, as long as the range is not excessively wide. In addition, in contexts where accuracy is preferred, accurate estimates are more satisfactory than conservative estimates, but when early arrivals are preferred, those conservative errors are no longer punished by consumers. Our results have important practical implications for companies designing apps as apps that provide time estimates to consumers are becoming ubiquitous.

Premature Predictions: Forecasters Get Less Credit For Predictions Made Too Early

EXTENDED ABSTRACT

Many forecasters believe that they will get more credit if they are the first to make a prediction and may feel compelled to make predictions far in advance of an event. However, in six preregistered studies (N=5,444), we find that this intuition is incorrect. Forecasters are given less credit (e.g., are rated as less competent) the farther in advance of an event they make predictions. This is because consumers acknowledge that luck plays a role for very early predictions that turn out to be correct. We also show that this effect does not hold for events that are knowable far in advance. Finally, the effect also exists for future predictions for which the outcome is not yet known.

In Study 1a (N=205), we tested participants' lay theories about prediction timing. Participants were told to imagine making a prediction about a future event and given examples of possible predictions they could make. We then asked how much credit they thought they would get (1=none; 7=a lot) if they made a correct prediction 10 years in advance, 5 years in advance, 1 year in advance, and 1 month in advance (within-subjects). Using a regression analysis with the expected credit as the DV and the number of months in advance (e.g., 5 years=60) as a continuous IV, there was a positive relationship between expected credit and how far in advance the prediction was made, p=.003. That is, they expected more credit for a prediction made 5 years in advance than one made 1 year in advance, and so on. In Study 1b (N=917), we replicate this finding using specific predictions and manipulating prediction timing between subjects.

Despite lay intuitions, in Study 2 (N=992), participants gave others less credit for predictions made farther in advance. We randomly assigned participants to one of four between-subjects conditions. All participants read that they saw an article where an expert made a prediction. We told participants that these predictions were indeed correct and the date that the events occurred. Given the date of the event, the article participants saw was dated 1 month before the event occurred, 1 year before, 5 years before, or 10 years before. To stimulus sample, we showed predictions in 1 of 5 domains. For example, in the "sports" domain, the expert predicted that the Tampa Bay Buccaneers would win the Super Bowl in February 2021. Participants then answered six questions to evaluate the expert's credibility (e.g., "How knowledgeable is this person?") on a 7-point scale. We analyzed the average of these six measures (alpha=.92) using a regression analysis as in Study 1. Collapsing across domains, there was a significantly negative relationship between how far in advance (in months) a prediction was made and the amount of credit that participants gave forecasters, p<.001. That is, forecasters received less credit the farther in advance the predictions were made. This result held directionally for 4 of the 5 domains tested and significantly for 3 of the 5.

In Study 2, we also set out to test a possible mechanism of our effect. Specifically, we examined whether people acknowledge that luck plays a role for very early predictions that turn out to be correct and hence whether participants' perceived epistemicness of the event mediates the relationship between forecaster evaluation and the time frame of the prediction. To do this, we included a set of new questions (α=.77) aimed at measuring participants' perceived epistemicness of the events that we adapted from the short version of the Epistemic-Aleatory Rating Scale (EARS; Tannenbaum, Fox, and Ülkümen 2017). For example, one of the items from the EARS read, "At the time this prediction was made, this outcome was knowable in advance, given enough information." Participants perceived the events as less epistemic (i.e., more determined by chance), the far-

ther in advance the prediction was made, p<.001. When we include participants' responses to the EARS in the regression, EARS entirely mediates the main effect of months in advance on forecasters' evaluations (i.e., the 95% CI did not include zero, 95% CI [-.003, -.001], and the effect directionally, but not significantly, reverses).

The results from Study 2 suggest that we should see an attenuation or reversal of our main effect if the forecasters predicted an event that is reasonably knowable far in advance. We test this in Study 3. We randomly assigned participants (N=1,740) to one of four between-subjects conditions. As in Study 2, participants read about an expert who made a prediction about an event. However, in two pretests, we identified three "short-term" predictions, which participants felt were only knowable one week to one month in advance, and three "long-term" predictions, which participants felt were knowable one year to five years in advance. Participants either read that the prediction was made either one week or one year before the event occurred and answered the same four dependent variable questions as in Study 2. We find a significant interaction between event type (short-term vs. long term) and prediction timing (one week before vs. one year before), p=.019, providing further evidence that the event's perceived epistemicness at the time of the prediction is a primary driver of the amount of credit a forecaster receives for a correct prediction.

Finally, in two additional studies, we find that participants also rate forecasters less positively if they make predictions about events far in the future where the outcome is not yet determined (Study 4). This does not seem to be driven by negative inferences about the forecaster's personality (e.g., that they are arrogant; Study 5).

Our research has substantial implications for the incentives that forecasters face when making predictions. If they have the lay theory that they will get more credit from being the first to "get it right," then they may rush to make a prediction without complete information. With our results in mind, they may now have the incentive to rethink these assumptions and wait to make more informed predictions.

Predicting The Effects of Prosocial Nudges

EXTENDED ABSTRACT

Behavioral science is enchanted by the promise of "nudges". Although nudges have been shown to be effective in a wide range of decision-making, they may also produce null outcomes or even backfire (Hagmann et al., 2019), underscoring the importance of accurately understanding and predicting their effects (DellaVigna et al., 2019).

There is a growing interest in assessing people's predictions of different policy interventions, but the existing investigations yield inconclusive results. Some studies show that people are not good at intuiting and applying nudges (Zlatev et al., 2017) or prediction in general (Dawes et al., 1989), whereas others show that both lay people and experts are quite accurate in their predictions (DellaVigna & Linos, 2020; Jung et al., 2018). The question remains when and how people accurately intuit nudging effects.

Through two pairs of large-scale studies ($N = 23,798$), we examine when and why predictors forecast the presence of intervention effects and whether these predictions align with reality. Furthermore, to probe whether predictions are sensitive to different forms of interventions, we manipulated two types of interventions that involve categorical (e.g., defaulted-in vs. not) vs. incremental (e.g., small vs. large) differences.

We conducted Study 1 ($N = 2,086$) on Amazon Mechanical Turk (MTurk) to examine decisions in a real-effort task where par-ticipants earned bonus by typing "ab"s consecutively (DellaVigna & Pope, 2018). We varied the bonus to be either 2 or 20 cents for every 1,000 pairs of "ab"s typed. Moreover, we defaulted half of the participants to donate the bonus to charity (opt-out) and the other half to receive the bonus themselves (opt-in). Predictors ($N = 503$) predicted the proportion that opted to donate their bonus in each condition.

Defaults were quite consequential. 39.76% of the participants in the opt-out condition donated their bonus to charity, whereas only 14.57% did in the opt-in condition. Predictors intuited this effect but vastly underestimated its size, estimating only a 8.07% difference. Curiously, although the bonus was ten times larger for some participants, participants were equally likely to donate when the stakes were high (26.64%) and low (26.43%). Predictors, however, forecasted a significant effect of stakes size: they predicted a 31.73% donation rate when the stakes were high, and 41.17% when the stakes were low. Predictors seem to be better at intuiting the impact of the categorical (vs. incremental) manipulation.

Participants in Study 1 could compare all experimental conditions when making predictions. It is possible that this joint evaluation mode influenced their predictions (Hsee, 1996). Study 2 tested this possibility by including separate predictors who each evaluated and made predictions for a single experimental condition. If the evaluation mode moderated participants' lay beliefs about intervention effects, we should see differences in predictions between joint and separate predictors.

Study 2 tested consumers' decisions in response to two different forms of prosocial nudges. We conducted a field study in collaboration with a retailer that allows customers to pay any price they wanted for eBooks. Customers ($N = 20,691$) who visited the company's website were randomly assigned to a 2 (default: opt-in vs. opt-out) x 2 (donation proportion: 5% vs. 25%) between-subjects design. Some were defaulted to donate part of their payment to charity (opt-out), whereas others were not (opt-in). Moreover, the donation was either 5% or 25% of the payment.

We recruited a separate sample of predictors ($N = 1,021$) who forecasted the behaviors of customers in the field. Predictors made predictions for all four conditions (joint) or just one (separate). Predictors predicted (1) the proportion of customers who bought a bundle, and among these buyers (2) the average payment, and (3) the proportion who donated.

As in Study 1, predictors correctly forecasted that opt-out choice architecture would increase donations, but they vastly underestimated the magnitude. On average, the change in default created a 43-percentage point difference in donation likelihood (81% vs. 38%), but joint predictors anticipated a 10-percentage point effect, and separate predictors only a 7-percentage point effect. Moreover, there was substantial difference in predictions by joint vs. separate predictors. Donation rate was also influenced by the proportion going to charity, as people were 5 percentage points less likely to donate when a higher percentage went to charity. In this case, joint predictors were correct in both sign and magnitude (a 7 percentage point forecast), but separate predictors didn't forecast this effect at all. Since the incremental difference (25% vs. 5%) is difficult to assess in separate evaluations, it is expected that separate predictors did not predict an effect of donation proportion.

Perhaps most notably, even when the nudge was inert, that did not mean that forecasters anticipated this null effect. On purchase rate, there was no effect of either default or donation proportion. While separate predictors predicted neither effect, joint predictors predicted small negative effects of both. Similarly, on payment amount, there was no effect of either default or donation proportion, and separate predictors again predicted neither. In contrast, joint pre-

dictors predicted small positive effects of both. Therefore, subtler effects (especially those involving incremental vs. categorical differences) tend to elude separate predictions, whereas joint predictors would always predict an effect, for better or worse.

Our studies demonstrate that separate predictors make widely varying guesses about one condition, whereas joint predictors adjust their forecasts based on their lay intuition about the direction and size of the treatment effects, given their initial guesses. But the actual nudging phenomenon is unlikely guided by similar guesses and beliefs. What appears to be accuracy in predictions could be a coincidence between reality and (misguided) beliefs. Therefore, while it may be tempting to conclude that a certain prediction mode produces more accurate predictions, we caution against such interpretation, as accuracy necessarily hinges on the ground truth, which varies from one experimental setting to another (Vivalt, 2015). A more useful and realistic approach, therefore, is to study the systematic, often contextual, influences on predictions (DellaVigna, Otis, & Vivalt, 2020), regardless of their accuracy.

Even Number Prevalence in Quantity Decisions

EXTENDED ABSTRACT

When consumers are deciding the quantity of a particular product to acquire or consume, multiple factors may influence their decisions. Yet, aside from any idiosyncratic, deliberate reasons for choosing specific quantities, consumer may also have a general, arbitrary tendency to choose a certain class of numbers. In this research, we show that consumers choose even numbers more frequently than odd numbers when selecting quantities.

Previous research has shed light on some focal numbers that consumers frequently select. For example, it suggests that consumers often choose one (Geier, Rozin, & Doros, 2006), "round numbers" that are multiples of ten (Baird, Lewis & Romer, 1970; Pope & Simonsohn, 2011), or "prominent numbers" that are powers of ten as well as their doubles and halves (Converse & Dennis, 2018). While this line of work has primarily focused on the prevalence of multiples of five and ten, we propose a much more granular class of focal numbers. Specifically, we show that people choose even numbers more frequently than odd numbers in quantity decisions because the former are more fluent—both in terms of retrieval and processing—across four pre-registered studies.

In Study 1, we used the Kilts-Nielsen consumer panel data to examine whether people are more likely to choose even numbers when shopping for multiple units of an item. To identify contexts in which considering multiple units is the norm, we pre-registered several criteria (e.g., include all products but exclude products for which the mode of the purchase quantities was one). In such contexts, we found that consumers were indeed more likely to buy even quantities than odd quantities. For example, of 51,176 products for which the mode of the purchase quantities was not one, 80% were more frequently purchased in even quantities than odd quantities, which was significantly higher than 50% ($p < .001$).

In Study 2, we used an online survey to test this hypothesis. Specifically, we asked 399 MTurk participants to make 11 quantity decisions across a variety of contexts (e.g., "When you buy apples at a grocery store, how many do you usually buy for yourself at a time?"). These questions specifically preempted potential alternative explanations, such as the evenness of the household size. We found that participants were significantly more likely to choose even quantities than odd quantities in all 11 decisions (Ms = 65-89%; ps < .001). Even when we excluded all round numbers that were multiples of ten—to conduct the most conservative robustness check

against our hypothesis—the proportion of even numbers was significantly higher than 50% in 7 decisions (Ms = 58-88%; ps < .010) and directionally higher in 4 decisions (Ms = 54-57%; ps > .05).

In Study 3, we used an online experiment to demonstrate that this effect would diminish when consumers can fluently retrieve another focal number that happens to be odd. In this experiment, we randomly assigned 397 MTurk participants to either the Control or the Odd condition. In the Control condition, participants indicated how many pieces of sushi they would take at a restaurant offering all-you-can-eat sushi. In the Odd condition, they indicated how many pieces they would take at a restaurant offering free samples of sushi. We expected that in the Odd condition, many participants would fluently retrieve and choose one, following the implicit social norm to take only one free sample per person, and that the prevalence of even numbers would diminish. Indeed, in the Control condition, 59% participants chose even quantities of sushi, whereas in the Odd condition, only 38% did ($X^2(1) = 17.29$, $p < .001$)—driven by the 18% vs. 44% of the participants choosing one in the respective conditions.

In Study 4, we used an online experiment to show that this effect would also attenuate when consumers can fluently process an odd quantity. In this experiment, we asked 398 MTurk participants to imagine deciding whether to buy eight or nine chocolates. We randomly assigned them to either the Control or the Odd condition. In the Control condition, participants saw images of single chocolates. In the Odd condition, they saw images of eight and nine chocolates, each organized within a three-by-three array. We expected that this organization would increase the processing fluency of the odd quantity and hence diminish participants' choice for the even quantity. As expected, we found that in the Control condition, 68% of the participants chose eight chocolates over nine chocolates, whereas in the Odd-set condition, only 49% did ($X^2(1)=14.15$ and $p < .001$).

Overall, this research shows that consumers choose even quantities more frequently than odd quantities and that marketers can harness this tendency by influencing the relative fluency of even vs. odd quantities. This research contributes to consumer research in important ways. First, it shows that consumers' choice for focal numbers (e.g., round numbers, prominent numbers) occurs at a much more granular and concrete level than previously known. Second, it extends the literature on even vs. odd numbers, which has previously focused on a limited set of even vs. odd digits in the context of pricing (Schindler & Wiman, 1989). Third, it broadens the scope of consumer research on numbers from externally generated numeric stimuli (e.g., brand names, King & Janiszewski, 2011; prices, Schindler & Kirby 1997) to internally generated quantities (Converse & Dennis, 2018). These findings should be of importance to both consumers and marketers as they suggest ways to understand and influence consumers' quantity decisions—which has important implications sales forecast, customer satisfaction, inventory management, and many other aspects of marketing (Wansink, Kent, & Hoch, 1998).

SESSION OVERVIEW

Recent years have seen increased worldwide concern over false information and its potential influence political, economic, and social well-being (Vosoughi, Roy, and Aral 2018). False information seems to have infiltrated not only news people read every day but also reviews consumers consult from in their decision processes.

While prior research has started investigating how fake news spreads (Lazer et al. 2018) multiple open questions remain about what causes people to share fake news or reviews and the consequences of doing so for individuals and for the society at large. What personality factors influence peoples' likelihood of spreading fake news or posting fake product reviews? What are the costs and benefits of fake product reviews on customers? How do consumers judge institutions that report inaccurate information? This session addresses these questions and offers insights into how and why false information disrupts the society.

First, **Lin, Zhang and Oyserman** document in 7 studies that collectivism is factor that increases people's beliefs in and likelihood of sharing false news. This is because collectivism motivates people to seek common ground in communication and increases their sense that they are responsible for inferring what a communicator is trying to say. By asking "*How* might this claim make sense?", people who score higher in collectivism are more likely to believe and share fabricated news.

Next, **Reeck and Mazar** explore whether (lack of) dispositional self-control can influence people's morally suboptimal behavior, such as leaving stellar reviews of products they have not used. By using a combination of behavioral and functional magnetic resonance imaging, authors find that self-control tracks individual differences in righteousness when confronting potential conflicts of interest (benefiting the self while harming others), and that this relationship is specific to circumstances in which the proper course of action is ambiguous.

He, Hollenbeck and Proserpio study the market for fake product reviews on Amazon.com. They find that soliciting fake reviews leads to a significant increase in average rating and sales rank, but the

effect disappears after roughly one month. After firms stop buying fake reviews their average ratings fall significantly and the share of one-star reviews increases significantly, indicating fake reviews are mostly used by low quality products and are deceiving and harming consumers.

Ceylan and Weingarten examine how people judge quality of institutions (such as news outlets) that take a corrective action by fact-checking potentially false information and how they further adjust this evaluation in the presence of deviations from true information. They find that consumers use a non-linear adjustment and adjust ratings downward most for the first mistake, then only slightly more downwards for each subsequent mistake after the first.

The papers employ both laboratory and field data to document novel and timely insights into antecedents and important consequences of spread of false information. All papers are at an advanced stage of development with multiple studies completed. We expect this session to generate strong interest among practitioners, researchers studying false information, fake product reviews, and corrections as well as social media and word-of-mouth more broadly.

Seeing Meaning Even When None Might Exist: Collectivism Increases Belief in Empty Claims

EXTENDED ABSTRACT

Four in ten Americans (42%) find astrology scientific (General Social Survey 2018). During the COVID-19 outbreak, 39% of Americans surveyed by the CDC took action based on misinformation, doing things like gargling with cleaning products (Gharpure et al. 2020). The worrisome implication is that people often find meaning and take action based on "empty" claims -- claims that have no regard for either truth or empirical evidence. In an era of social media spreading fake news, understanding why people consistently see meaning in empty claims is critical for developing policies to combat consumption of misinformation. The current research proposes that collectivism, an aspect of human culture that sensitizes people to the importance of connection and fitting in, increases people's vulnerability to empty claims.

We propose that by emphasizing relating with others, collectivism motivates people to seek common ground in communication and increases their sense that they are responsible for inferring what a communicator is trying to say. To do so, people process claims as if they were asking implicitly, "*How* might this claim make sense?" This focus on making sense motivates people to interpret, fill in the blanks, and construct meaning for empty claims, and eventually come to experience empty claims as truthful, meaningful, even profound.

We tested our proposal across seven studies ($N > 16,000$) using a variety of ways to operationalize collectivism and empty claims. In Studies 1 and 2, we examined the association between collectivism and belief in pseudoscience using nationally representative surveys from the U.S. (Study 1) and China (Study 2). We found converging evidence in both countries that the more people endorsed collectivistic values, the more susceptible they were to pseudoscience such as astrology and palm reading (Study 1: $OR = 1.27$, 95% CI [1.21, 1.33], $\chi^2(1) = 86.60$, $p < .001$; Study 2: $= .30$, $F(1, 9636) = 951.27$, $p < .001$, $R^2 = .09$). These positive associations were robust to controlling for gender, race, social class, and religiosity.

In Study 3 we tested the relationship between collectivism and belief in fake news during the COVID-19 pandemic. We showed participants in China (Study 3a) and participants in the U.S. (Study 3b) a mixture of fake and real news about the coronavirus and had them complete a collectivism scale (Oyserman 1993). In both studies, people who scored higher in collectivism believed in COVID-19 fake news more (Study 3a: = .18, $F(1, 276) = 8.93$, $p =.003$; Study 3b: = .20, $F(1, 198) =8.21$, $p =.005$). Belief in fake news mattered. By affecting belief, collectivism increased the likelihood of forming false memories about fabricated news (Study 3a: $ab = .01$, $SE = .005$, 95% CI = [.003, .024]) and people's willingness to share fake news (Study 3b: $ab = .24$, $SE = .07$, 95% CI = [.11, .40]).

In Study 4, we operationalized collectivism as country-of-residence, comparing people in the U.S. and China. Relative to American participants, Chinese participants found more meaning in randomly formed metaphors ($F(1, 438) = 10.70$, $p = .001$, $d = 0.35$) and greater profundity in randomly generated vague statements ($F(1, 438) = 51.98$, $p < .001$, $d = 0.75$. In this same sample, endorsing collectivist values positively predicted meaningfulness (= .25, $F(1, 437) = 26.99$, $p <.001$) and profundity (= .26, $F(1, 437) = 34.84$, p <.001, $R^2 = .07$).

Study 5 documents causality. We used a force-agreement paradigm to manipulate participant's momentary self-perception of being collectivistic. Participants were randomly assigned to either rate their agreement (from 1 = *Slightly agree* to 7 = *Completely agree*) or disagreement (from 1 = *Slightly disagree* to 7 = *Completely disagree*) with six collectivistic self-descriptions. Participants randomly assigned to agree with collectivistic self-descriptions found randomly generated vague statements more profound (Study 5a: $F(1, 286) = 3.47$, $p = .06$, $d = .22$) and believe randomly generated pseudo-scientific news story more (Study 5b: $F(1, 357) = 5.68$, $p = .02$, $d = .26$) than those randomly assigned to disagree with collectivistic self-descriptions.

Finally, Studies 6 and 7 tested the proposed underlying processes: collectivism increases seeing meaning in empty claims because it motivates people to actively fill in the blanks in seeking common ground with the communicator. Study 6 showed that people higher in collectivism were more likely to actively construct explanations of how a novel metaphor might be meaningful ($OR = 1.47$, $t(249) = 2.56$, $p = .01$). This meaning-making process mediated the higher meaningfulness ratings they assigned to the metaphor (indirect effect = 0.22, $SE = 0.09$, $p = 0.01$, 95% CI = [0.06, 0.39]), suggesting that meaning-making underlies the collectivism effect.

Study 7 tested the underlying driver of seeking common ground by manipulating whether a communicator was implied. Participants were led to believe the statements were either human generated or randomly generated (non-human generated). Collectivism was positively related to seeing meaning if a human communicator was assumed ($r(56)= .42$, $p = .001$) and was unrelated to seeing meaning if a human communicator was explicitly excluded ($r(63)= -.08$, $p = .54$). This suggests that people higher in collectivism are more likely to find meaning in empty claims only if they are seeking common ground with an implied communicator.

Taken together, our studies suggest that to satisfy a human need to relate and fit in, people attempt to see what others see by asking themselves "how might this claim make sense?" In doing so, people self-convince. Collectivism increases seeing meaning where none may exist.

The seemingly benign cultural motive to relate is likely a reason why conspiracy theories, fake news, and pseudoscience thrive. A core implication is that to reduce consumption of misinformation, people's tendency to seek common ground needs to be disrupted.

Considering the cultural roots of the tendency to see meaning where none may exist may be one important step to counter the spread of false information in the public sphere.

Neural Mechanisms Promoting Righteousness in Conflicts of Interest

EXTENDED ABSTRACT

Self-interest is fundamental to economic models of human reasoning, which assume that individuals are utility maximizers. Yet people occasionally act against their own self-interest. Sometimes they do so because of external reinforcement, including social scorn and reputational concerns, which promotes seemingly selfless, virtuous behaviors. Sometimes, however, they behave selflessly even when external reinforcements are minimal, as when they leave generous gratuities at restaurants they only visit once (Kahneman, Knetsch and Thaler 1986) or donate organs to strangers (Jacobs et al. 2004). Moreover, people occasionally act against their own interest even when the "proper" response is ambiguous. In circumstances where the proper course of action is difficult to determine and the external consequences of selfish behavior are minimal, what distinguishes people who continue to choose the principled course of action from those who act selfishly?

Conflicts of interest (Cain, Loewenstein and Moore 2004) present a particularly important context for examining righteousness, as they have been shown to undermine a broad range of judgments that consumer rely upon, such as doctors' espousal of self-interested medical guidance (Dana and Loewenstein 2003), and investment recommendations from financial professionals Mullainathan, Noeth and Schoar 2012) at the expense of patient or client welfare. In particular, as the proper course of action becomes more ambiguous, higher-order commitments no longer prescribe a particular action clearly and people's tendency to pursue self-interest becomes more pronounced (Babcock and Loewenstein 2004). Therefore, understanding what predicts who is most likely to act on their self-interest as the appropriate response becomes more unclear is important to avoiding negative outcomes for those who rely on their advice. We examined this question across three primary experiments.

Participants in Study 1 were asked to imagine a purchase that arrived at their home while they were away on vacation. The seller offered a substantial discount if they left a 5-star review of the product within 24 hours, creating a potential conflict between their desire to provide an accurate review and the desire to receive a personal discount. They were given either ambiguous or unambiguous information about the item purchased and asked if they would leave a 5-star review. Participants were more likely to leave a five-star review in the Ambiguous Conflict of Interest condition than the Unambiguous Conflict of Interest Condition, $^2(1) = 6.18$, $p = .013$. Importantly, we observed that several participants were willing to forego their self-interest and decline to leave a 5-star rating despite the tempting refund offer, even when they only had ambiguous evidence that doing so would be inappropriate.

In Study 2, participants were asked to imagine they were purchasing gift cards to a local café for their friends. One friend had ambiguous preferences while the other had clear preferences for which café they preferred. One of the cafés offered a benefit to the participant for buying a gift card, creating a potential conflict of interest where they might choose to buy a gift card to that café in order to receive the benefit, even if it were their friend's less preferred option. Participants were more likely to choose the self-interested option when the recipient's preferences were ambiguous compared to when they were unambiguous (McNemar's Test $p = .011$). However,

even in ambiguous conflict of interest situations, a substantial share of participants eschews private gains, thereby displaying righteous behavior.

To investigate the psychological processes that explain individual differences in righteousness behavior, we next employed a conflict of interest task in conjunction with functional neuroimaging (Mazar, Amir and Ariely 2008). On each of 150 trials, participants (N = 27) viewed an image that contained 100 dots and a vertical line dividing the image into left and right halves. Although participants were instructed to indicate which side contained more dots accurately, they were paid more ($0.10 per response) when they indicated there were more dots on the right than when they responded there were more dots on the left ($0.02 per response). Thus, trials that consisted of more dots on the left, lower paying side represented a potential conflict of interest between giving the correct response or giving an incorrect response in exchange for higher pay (incentivized error trials). As previous research has demonstrated that selfish behaviors are more common in response to ambiguity (Argo and Shiv 2012; Mazar, Amir and Ariely 2008), ambiguity was manipulated such that on half the trials the discrimination was difficult and uncertainty about the correct response was relatively high. Not surprisingly, we find that incentivized responses occurred more frequently than disincentivized responses, $F(1, 26)=21.93$, $p<.001$. Importantly, there was a significant interaction between response incentive and ambiguity, $F(1, 26)=13.016$, $p=.001$. Pairwise comparisons revealed that incentivized responses were provided more frequently than disincentivized responses when the correct response was more ambiguous, $t(26)=5.544$, $p<.001$. This same pattern of results was also observed in error rates, with participants making more selfish, incentivized errors on more ambiguous than less ambiguous discriminations, $t(26)=4.882$, $p<.001$. Overall, participants did allow motives for personal gain to color their judgment, and this self-serving bias was more common when the appropriate response was more ambiguous.

A network of neural regions putatively involved in cognitive control exhibited greater activation in individuals who did not increase their self-interested responding when the proper response was more obscure, including lateral prefrontal cortex, dorsal parietal cortex, and temporoparietal junction. Importantly, these regions discriminated those who responded in a self-serving fashion from those who did not, specifically on trials in which the correct response was more ambiguous, and self-interest was most likely to influence judgments. The parietal regions and temporoparietal junction have been previously implicated in directing attention and other controlled processing (Corbetta, Patel and Shulman 2008). The correlation between lateral prefrontal cortex and righteousness may reflect the role of this region in resolving competition between competing responses, rules, or representations (Botvinick et al. 2001; Kerns et al. 2004; ,acDonald et al. 2000) and resisting temptation by implementing self-control (Hare, Camerer and Rangel 2009; McClure et al. 2004).

Taken as a whole, these findings advocate a central role for self-control in determining who will continue to subvert their own self-interest when the "proper" action becomes more difficult to determine. In light of the present findings, interventions seeking to limit the negative consequences of conflicts of interest should focus on enhancing self-control among those whose judgments they seek to insulate from self-interest.

The Market for Fake News

EXTENDED ABSTRACT

Online markets have from their first days struggled to deal with malicious actors. These include consumer scams, piracy, counterfeit products, malware, viruses, and spam. And yet online platforms have become some of the world's largest companies in part by effectively limiting these malicious actors and retaining consumer trust. The economics of these platforms suggest a difficult tradeoff between opening the platform to outside actors such as third-party developers and sellers and retaining strict control over access to and use of the platform. Preventing deceptive or fraudulent actions is key to this tradeoff. Third-party participants may have strong incentives to manipulate platforms, such as increasing their visibility in search rankings via fake downloads (Li et al., 2016), increasing revenue via bot-driven advertising impressions (Gordon et al., 2021), manipulating social network influence with fake followers, manipulating auction outcomes, defrauding consumers with false advertising claims (Rao and Wang 2017; Chiou and Tucker 2018; Rao 2018), or manipulating their seller reputation with fake reviews (Mayzlin et al. 2014; Luca and Zervas 2016). We study this last form of deception or fraudulent activity: the widespread purchasing of fake product reviews. Fake reviews may be particularly harmful because they not only deceive consumers into purchasing products that may be of low quality, they also erode the long-term trust in the review platforms that is crucial for online markets to flourish (Cabral and Hortacsu 2010; Einav et al. 2016; Tadelis 2016). Therefore, if user feedback and product reviews are not trustworthy, in addition to consumers being harmed platform values may suffer as well.

We study the effect of fake reviews on seller outcomes, consumer welfare, and platform value. Despite this practice being unlawful, we document the existence of a large and fast-moving online market for fake reviews. This market features sellers posting in private online groups to promote their products and solicit willing customers to purchase them and leave positive reviews in exchange for compensation. These groups exist for many online retailers including Walmart and Wayfair but we focus on Amazon because it is the largest and most developed market. We collect data from this market by sending research assistants into these groups to document what products are buying fake reviews and the duration of these promotions. We then carefully track these products' outcomes on Amazon.com including posted reviews, average ratings, prices, and sales rank. This is the first data of this kind in that it provides direct evidence on both the fake reviews themselves and on detailed firm outcomes from buying fake reviews.

Our research objective is to answer a set of currently unsettled questions about online rating manipulation. How does this market work, in particular, what are the costs and benefits to sellers from buying fake reviews? What types of products buy fake reviews and how effective are they? Are consumers ultimately harmed by fake reviews or are they mainly used by high-quality products, that is, should they be seen more like advertising or outright fraud? Do fake reviews lead to a self-sustaining increase in sales and organic ratings? These questions can be directly tested using the unique panel nature of our data.

We first employ research assistants to construct a random sample of approximately 1, 500 products observed soliciting fake reviews over a 9-month period. We find a wide assortment of product types in many categories, including many products with a very large number of reviews at the time we first observe them buying fake reviews. These products also tend not to have especially low ratings, with an average rating slightly higher than comparable prod-

ucts. Almost none of the sellers purchasing reviews in these markets are well-known brands, consistent with research showing that online reviews are more effective and more important for small independent firms compared to brand name firms (Hollenbeck 2018). We then track the outcomes of these products before and after the buying of fake reviews using data collected from Amazon. In the weeks after they purchase fake reviews, the number of reviews posted increases substantially. Their average rating and share of five-star reviews also increase substantially: Ratings increase by .08 stars on average, and the average number of reviews posted per week increases by 7, roughly doubling the number of reviews they receive compared to before soliciting fake reviews. We also observe a substantial increase in search position and sales rank at this time. The increase in average ratings is short-lived, with ratings falling back to the previous level within 2 to 4 weeks, but the increase in the weekly number of reviews, sales rank, and position in search listings remain substantially higher more than four weeks later. We also track the long-term outcomes associated with the buying of fake reviews. We find that the evidence primarily supports the consumer harm view. We track outcomes after the last observed post soliciting fake reviews and find that ratings tend to fall as soon as the seller stops buying reviews. Finally, we document some facts regarding how the platform regulates fake reviews. We see that a very large share of reviews is deleted by Amazon. The bulk of deleted reviews are those that are posted within one to two months of the fake review solicitation that we observe, but they are deleted with an average lag of over 100 days, thus allowing the short-term boost in average ratings and number of reviews that we document. Altogether our results suggest that while Amazon's review deletion policy should reduce the long-term harm to consumers from fake reviews, it is inadequate because there is enough of a short-term boost in sales and ratings that firms find it advantageous to participate in this market, and there is a clear consumer harm as shown in the subsequent increase in one-star reviews.

The Impact of Mistakes on Perceived Quality

EXTENDED ABSTRACT

Recent years have seen an uptick in the spread of fake news (Vosoughi, Roy, and Aral 2018). Alongside this rise, researchers and practitioners are developing best practices for how to correct peoples' beliefs or mitigate the extent to which consumers believe untrustworthy headlines (e.g., Clayton et al. 2020; Lewandowsky et al. 2012; Pennycook, Cannon, and Rand 2018).

One such method to address inaccurate headlines is fact-checking (e.g., Snopes; Jun, Meng, and Johar 2017), in which sites or users identify mistakes and how truthful headlines or articles are. However, in the presence of mistakes, how do consumers update their beliefs about the quality and trustworthiness of news outlets and journalists? That is, how do consumers judge the quality of news outlets with no mistakes, one mistake, or multiple mistakes?

We examine how consumers adjust their evaluations in the presence of deviations from news verification. One possibility is that consumers apply a consistent decrease in quality for each mistake they learn about (which we call the *linear punishment* model). Another possibility is that consumers use a non-linear adjustment and adjust ratings downward most for the first mistake, then only slightly more downwards for each subsequent mistake after the first (which we call the *purity* model). This outcome, reminiscent of past judgment and decision-making models (Einhorn 1970; Einhorn et al. 1972) is observed in a series of four studies and is consistent with punishing violations of purity (see Graham, Haidt, and Nosek 2009).

In study1, we examined how people adjust their ratings of quality of the news outlets in the presence of mistakes. Participants (N = 298) read a series of five nonpolitical headlines (e.g., SpaceX launch, CO_2 emissions) meant to avoid people trying to adapt the message to prior beliefs (Lord, Ross, and Lepper 1979). After each headline, participants learned nothing about the headline (no-info), that all the information was verified (control), that there was a numeric mistake (one numeric), that there was a non-numeric mistake (one non-numeric), or that two details (the numeric and non-numeric mistake) were incorrect (two-mistakes). These conditions were counterbalanced across the five headlines; each participant saw one headline from each condition in a random order. After seeing each headline and the corresponding information for that condition, participants rated the accuracy of the headline (1 = Not at all accurate, 7 = Completely accurate), and were randomly assigned to rate either the journalist or news outlet (between-subjects) on five dimensions: competence, effort into researching the news, quality source of news, trust, and willingness to read more (-50 = Completely disagree, 0 = Neither agree nor disagree, +50 = Completely agree). These statements held together and were averaged into one quality index.

The pattern of results was consistent with the purity model. First, the manipulations were successful: the perceived accuracy of the numeric and non-numeric mistake conditions were not significantly different from each other but were lower than that of the control and no-info conditions but were both higher than in the two-mistakes condition. Second, the drop in the quality index was greater when going from control to either of the mistake (numeric, non-numeric) conditions than from either mistake condition to the two-mistakes condition (ts > 3, ps < .01) for both the journalist and the news outlet conditions. Thus, study1 provided initial evidence that the difference in quality between no mistakes and one mistake is greater than that of one mistake to two mistakes.

In the second study, we replicated the findings from study one but with slightly different conditions. That is, participants (N = 194) read five headlines that had no information (no-info), were verified (control), or were disputed and had one mistake (one-mistake), two mistakes (two-mistakes), or three mistakes (three-mistakes). Participants were also randomly assigned into one of two conditions: they rated either an unspecified journalist or a journalist from their preferred news outlet (which participants reported at the beginning and was piped into the questions) on the same measures from the first study. This manipulation did not interact with the results and will not be discussed further. Consistent with the first study, the drop in the quality index from the control to the one-mistake condition was greater than that of the drop from the one-mistake to the two-mistakes condition (ts > 3, ps < .01). The same difference between the one and two-mistakes conditions and the two and three-mistakes conditions was lesser in magnitude (ts < 1, ps > .3).

In the third study (N = 195), we tested whether the results were contingent on severity of the mistake. That is, do any mistakes lead to the aforementioned results, or will people temper their judgments when the mistakes are trivial (e.g., identifying small typos that do not change the meaning of the headline)? When mistakes were meaningful as in other studies, we replicated the aforementioned results (p < .001), but not when the mistakes were perceived to be trivial (p > .5; interaction p < .001).

In the final study (N = 266), we tested whether the attribution for why the mistake was made influenced reactions to mistakes. Participants were randomly assigned to one of the three mission conditions: the news outlet wanted to get it right and had a responsibility to correct errors (ethics), they wanted to get it first and had a responsibility to deliver news fast (speed), or no-mission. The design of headlines

and fact-checking information was similar to earlier studies. Indeed, people judged the news outlet in line with the purity model in the speed and no-mission conditions. However, in the ethics condition, they adjusted their quality judgments linearly and the drop in quality from control to one-mistake reduced significantly compared with other two conditions (interaction $p < .001$).

Collectively, our findings suggest that while fact-checking is important, consumers adjust their quality judgments downwards as a function of number of mistakes using a purity model.

SESSION OVERVIEW

Each passing day seems to bring about a new political conflict. From provocative online posts to controversial commercials, we often need look no further than the marketplace to see the influence of our political divisions (Horst 2018). Yet, despite its growing ubiquity in consumer behavior, there is still much we do not know about the influence of politics in the marketplace (Keller 2020).

This session takes a comprehensive look at the role of politics in marketing by examining its influence at three levels – consumers' political ideology, brands' political activism, and companies' political influence through lobbying. Each perspective brings its own questions and insights. Specifically, does political ideology shape consumers' satisfaction with the products and services they consume? Why has consumers' political ideology influenced perceptions of threat during the COVID-19 pandemic? When brands take controversial political stances, who expresses outrage and who stays silent?

And, how do consumers view companies' political lobbying behavior? This session answers these and other questions as it deepens our understanding of how and why politics influence marketplace dynamics.

To begin, **Ordabayeva and colleagues** investigate how and why political identity influences customer satisfaction with the very same product. Across 9 studies, they find that conservatives tend to express greater satisfaction with the products and services they consume. This is due to conservatives' (vs. liberals') greater belief in free will, which leads them to trust more in their consumption decisions.

Lisjak and colleagues examine a seeming paradox: conservatives are often more vigilant to threats, and yet resistant to interventions during the COVID-19 pandemic. The authors find that conservatives' desire to signal bravery helps explain this discrepancy. Conservatives are more likely to believe that visiting public places during the pandemic signals bravery, which predicts them taking fewer precautions.

Rocklage and Rucker analyze 300 million tweets from 110,000 Twitter users to forecast who, when, and how consumers react to brands' controversial political stances. They find a bleak outlook for brands: consumers who tend to form and express negative attitudes readily express outrage. However, opposite of what brands would hope, those on the positive end are surprisingly silent. Moreover, consumers who are predisposed to base their attitudes on emotion are quickest to react during a controversy.

Paharia and colleagues find that not only do consumers have a sense of which companies lobby the government or not, but also that this knowledge can lead to lowered satisfaction and likelihood of purchasing from those companies. Indeed, the authors find that consumers view political lobbying as unfair and potentially indicative of lower product quality.

By examining politics' effect at all three levels – consumer, brand, and company – the session answers the call for examining and bridging political divisions. It also identifies useful insights for consumers, brands, companies, and policy makers. This session will be of interest to researchers seeking to understand how politics influence consumer behavior from multiple perspectives. In addition to attracting the growing number of scholars interested in political ideology, the session will also draw those studying customer satisfaction, attitudes, language, word of mouth, emotion, and branding.

How Political Identity Shapes Customer Satisfaction

EXTENDED ABSTRACT

A growing literature examines how political identity shapes consumers' preferences for products and marketing campaigns. Yet, it is unclear how political identity shapes individuals' satisfaction with the products and services they consume, despite the significant implications of customer satisfaction for post-purchase behavior (consumption quantity, usage, re-purchase, recommendation, loyalty), wellbeing, and sales.

We propose that, compared to liberals, conservatives may be more satisfied with the products and services they consume. We propose this may happen because conservatives (vs. liberals) hold a

stronger belief in free will – that individuals exercise free will and autonomy over their actions – which, in turn, may boost conservatives' (vs. liberals') trust in their decisions (including decisions to consume certain products and services). Our predictions build on several literatures. First, although belief in free will is widely prevalent, individual factors may shape the strength of these beliefs (Carey and Paulhus 2013; Zheng et al. 2016). We posit that political identity is one such factor. Specifically, conservatives tend to emphasize the role of personal responsibility, whereas liberals focus on external sociocultural factors, to explain individual outcomes (Jost et al. 2008; Skitka et al. 2002) – this may contribute to conservatives' (vs. liberals') stronger belief in free will. Second, perceiving personal causality behind actions increases individuals' feelings of efficacy and confidence about the outcomes of these actions (Bandura 1980; Botti and McGill 2010) – hence, belief in free will may boost individuals' trust in their decisions and actions. Third, higher confidence in one's actions or decisions may motivate individuals to process and perceive decision outcomes and experiences in a way that confirms prior beliefs – i.e., that one's decision was sound in the first place (Simon and Spiller 2016; Snyder and Swann 1978).

We therefore predict that conservatives' (vs. liberals') higher trust in their decisions, stemming from their stronger free-will belief, may result in higher customer satisfaction. This prediction goes beyond recent findings on conservatives' (vs. liberals') lower tendency to engage in customer complaints (Jung et al. 2017). Specifically, dissatisfying consumption experiences do not result in complaints most of the time, and complaints do not necessarily reflect customer (dis)satisfaction (Day and Landon 1977; McGraw et al. 2015). Furthermore, we document the wide-ranging downstream consequences (repurchase, recommendation, sales) and boundary conditions (low choice availability, overwhelmingly positive consumption experience) of the novel political identity-satisfaction link.

Nine studies test our predictions using primary and secondary data, real and hypothetical behavior. Studies 1-4 use controlled experiments and Studies 5A-D use field data.

Study 1 (N = 412) examined the phenomenon and its mechanism. After indicating their political identity (1 = extremely liberal, 9 = extremely conservative; Jost 2006), participants recalled a product that they had purchased within the past two years, reported their satisfaction with the product (1 = very dissatisfied, 11 = very satisfied; 1 = extremely dissatisfied, 7 = extremely satisfied), product price, and how long ago they had made the purchase. Afterwards, participants indicated their belief in free will (7 items; e.g., "People have complete control over the decisions they make"; Paulhus and Carey 2011), trust in decisions (3 items; e.g., "I can trust my ability to make good decisions"), and additional constructs (heuristic processing, need for closure, market efficiency, cognitive dissonance, dissonance reduction, fluency, expectations of and commitment to decisions). Political conservatism (vs. liberalism) led to higher customer satisfaction ($p < .001$), due to free-will beliefs and trust rather than alternative process specifications or constructs. In this and subsequent studies, controlling for purchase price and purchase age (reported by participants), as well as purchase hedonism (vs. utilitarianism) and positivity (vs negativity) (coded by research assistants) did not impact the results.

Studies 2A-B examined the process behind the political identity-satisfaction link while controlling for actual consumption experience. Study 2A (N = 291) manipulated ideology by prompting participants to recall a prior interaction with someone who was much more liberal or conservative than them (Ordabayeva and Fernandes 2018). We measured free-will beliefs and decision trust (in random order using abbreviated scales) as well as satisfaction with a "how-

to" video that participants watched in the context of the study. Satisfaction was higher in the conservative than in the liberal condition ($p = .017$). This effect was serially mediated by free-will beliefs and decision trust. Study 2B (N = 202) further corroborated the role of free-will beliefs and decision trust (vs. alternatives) in mediating the effect of measured political identity on satisfaction with the controlled video from Study 2A.

Study 3 (N = 442) measured political identity and then weakened (vs. not) free-will beliefs through an article that argued against (vs. for) the existence of free will (Alquist et al. 2013). Weakening free-will beliefs attenuated the effect of political identity on customer satisfaction (same task as in Study 1; interaction: $p = .022$; ideology effect in the high free-will condition: $p = .052$ and in the low free-will condition: $p = .162$).

Study 4 (N = 412) tested the moderating role of valence of the consumption experience. After indicating their political identity, participants recalled a product purchase that turned out very well or very poorly, and they indicated their product satisfaction. The political identity-satisfaction link was attenuated for a very positive prior experience (interaction: $p < .001$; ideology in the negative experience condition: $p < .001$; positive experience condition: $p = .660$).

Studies 5A-D examined real-world settings to boost managerial relevance. Study 5A documented a positive link between online customer reviews of local restaurants and localities' political ideology, particularly (vs. less so) when many (vs. few) restaurant options were available. Study 5B revealed a positive link between political conservatism and travelers' satisfaction with the services of an actual airport. Study 5C showed that conservatives' (vs. liberals') higher satisfaction with healthcare insurance led to their higher repurchase (re-subscription) and recommendation intentions. Study 5D documented higher actual sales reported by B2B companies with more conservative (vs. liberal) customers.

Political Ideology, Desire to Signal Bravery, and Vigilance against Health Threats

EXTENDED ABSTRACT

American citizens' responses to COVID-19 have differed by political ideology, whereby conservatives have been less likely to wear masks and wash hands than liberals (Reuters/Ipsos Poll 2020). This resistance is surprising, given the large body of evidence that conservatives tend to engage in more health-related behavior than liberals, especially against infectious disease (Terrizzi et al. 2013).

We propose that conservatives' propensity to engage in health-related behavior depends not only on their vigilant motivation, but also on their psychological desire to signal bravery. When a tradeoff exists between following one's vigilant tendencies and the desire to project bravery (e.g., in the context of COVID-19), conservatives' likelihood to engage in health related behavior may depend on how proximal the health threat is. We define threat proximity as the perceived closeness of the danger to the self (Cole et al. 2013). We propose that when threat proximity is low, conservatives may be less likely to engage in health-related behavior than liberals in an effort to signal bravery. Consistent with this possibility, people living in Southern conservative (vs. other) U.S. states were sometimes willing to incur personal health costs, such as experiencing minor electric shocks, to project bravery (Cohen et al. 1996). However, when threat proximity is high, we suggest that conservatives will revert to their natural vigilant state, and be as likely to engage in health-related behavior as liberals.

Study 1 used secondary data to examine the effect of political ideology and threat proximity on state-level Google searches of vigi-

lance against COVID-19 (coronavirus symptoms, COVID-19 prevention, medical face mask, N95 mask, hand sanitizer, gloves, social distancing, and food supplies; from 0=no search volume to 100=max search volume in a state; α = .69). We scored each state on conservatism, following Ordabayeva and Fernandes (2018). The measure of threat proximity was the cumulative number of coronavirus deaths per 100K population in each state. The results revealed the predicted ideology × threat proximity interaction on vigilance-related searches (p = .025). Floodlight analysis showed that under low threat proximity, conservative states were less likely to search for vigilant terms than liberal states (111 deaths per 100K population and lower, $p \leq$ .05), but not under high threat proximity.

Study 2 tested the causal effect of threat proximity and political ideology on vigilance. Student participants (n = 173) read a news article about the death of an actual COVID-19 victim. Following Mandel, Petrova and Cialdini (2006), we manipulated perceived threat proximity by describing a victim who was a dissimilar other (73-year-old man with medical conditions; low proximity) or a similar other (college student with no medical conditions; high proximity). Next, participants indicated whether they intended to (1) purchase virus protection products (e.g., medical masks); (2); stock up on food; and (3) purchase crime-protective products (α=.72). Participants reported their political ideology using a single-item scale (1 = "extremely liberal" to 9 = "extremely conservative"; Jost et al. 2007). The ideology × threat proximity interaction was significant (p = .022). While in the low threat proximity condition, conservatives reported lower intentions to engage in vigilant behavior than liberals (p = .002), they did not differ in the high threat proximity condition (p = .904).

Study 3 (n = 412) tested the mediating role of the desire to signal bravery. We measured retrospective actual vigilant behavior by asking participants to indicate the extent to which thus far they (1) had purchased virus protection products, (2) had purchased enough food and household supplies, (3) had been wearing masks in public, and (4) had been practicing social distancing (α = .88). As a measure of threat proximity, participants indicated (1) how many people have tested positive, and (2) how many people have died from COVID-19 in their county. We measured political ideology as in study 2. We measured desire to signal bravery by asking participants to indicate their agreement that visiting public places during the COVID-19 pandemic is a sign of (1) personal strength and (2) bravery and courage. Lastly, to show that the effects of bravery persisted above and beyond the role of partisan media consumption, we measured how frequently participants watched (1) CNN and (2) Fox News. We observed the critical political ideology × threat proximity interaction (p < .001). Floodlight analysis revealed that under low threat proximity, conservatives were less likely to engage in vigilant behavior than liberals (5.88 and lower on the 1-to-7 threat proximity scale, $p \leq$ .05), but not under high threat proximity. A moderated mediation analysis (Hayes 2013; Model 15) revealed that desire to signal bravery mediated the effect of ideology on vigilance under low threat proximity (CI = -.179, -.044), but not under high threat proximity (CI = -.008, .061). These effects remained significant after controlling for the role of partisan media consumption.

So far, we tested our framework in the context of COVID-19. As a first step to examine the generalizability of these findings in different contexts, we conducted a survey (n = 550), in which participants indicated their agreement with statements measuring preference for signaling bravery in the face of a health threat: (1) If I ever injured my foot, I would never walk in public with a walking stick. I would just deal with it. (2) If I get a concussion in a game with friends, I try to shake it off and continue the game. (3) It looks really weak when people who are on bikes or motorcycles wear a helmet even on quiet residential streets. Finally, we measured political ideology as in study 2. Conservatives (vs. liberals) reporter grater preference for bravery in the face of health threat across all three contexts (b's: .10 - .12, p's: .013 - .045). The results remained significant after controlling for gender.

These findings suggest that public health leaders could increase conservatives' precautionary behavior by (1) using bravery appeals and (2) highlighting threat proximity.

When Brands Become Activists: Who Reacts and How?

EXTENDED ABSTRACT

Brands serve numerous roles – from providing products to bolstering consumers' identity (MacInnis and Folkes 2017). Despite this, an unswerving principle for most brands is to remain publicly neutral on political issues (Swaminathan et al. 2020). Taking a side risks alienating large segments of consumers. And yet, prominent brands have recently broken this rule (Horst 2018). In three consecutive years, Budweiser, Nike, and Gillette all spent millions of dollars on advertising that took positions on polarizing political issues.

Despite these recent events, most marketers struggle with even a basic understanding of who reacts to these stances, when they react, and the opinions they express (Swaminathan et al. 2020). We use a novel approach that combines attitude theory with computational linguistics and real-world big data to provide insight into these dynamics.

Specifically, prior research treats each attitude as its own entity, disconnected from that person's other attitudes. For example, people's attitude toward their toaster is treated as unique from their attitude toward racial injustice. Yet, we propose there may be individual differences in people's predisposition toward forming and expressing both positive attitudes (vs. negative) and emotional attitudes (vs. cognitive). Put simply, understanding consumers' propensities toward certain types of attitudes may serve as a means to understand who responds when brands take polarizing stances in advertising.

Hypothesis. Regarding valence, consumers who are predisposed toward negative attitudes may be most likely to express outrage (e.g., Bizer et al. 2011). In contrast, consumers predisposed toward positive attitudes may express support for the brand (e.g., Abelson et al. 1982). Thus, consumers' valence tendencies may predict who will respond to a controversial stance by brands. We also explored the possibility of a negativity bias, whereby negative attitudes may be stronger predictors than positive (e.g., Rocklage, Pietri, and Fazio 2017).

In addition, research suggests that attitude emotionality may predict how *quickly* consumers will react to these controversies. On the one hand, research indicates that attitudes that are formed via a more thoughtful, reason-based approach are particularly strong (Petty, Haugtvedt, and Smith 1995). This may lead consumers to react quickly when they perceive a political stance either in line or against their attitudes. On the other hand, those who base their attitudes more on their emotional reactions may be quicker to react given the ability of emotion to spur behavior (e.g., Rocklage, Rucker, and Nordgren 2021). We test these competing Hypothesis.

Given the brands' stances were political, we also examined how the political ideology of each consumer moderated these results. Finally, we assessed the additional consequences of these tweets by examining whose tweets were retweeted and therefore spread further.

Field studies. We first identified three advertisements where brands took a political stance that evoked widespread controversy:

advertisements on immigration (Budweiser), racial injustice (Nike), and the Me Too movement (Gillette).

For each brand separately, we then identified all consumers who tweeted about that brand in the year *prior* to each advertisement. Identifying a set of consumers prior to the controversy decreases bias in the sample as it allows for the unique ability to assess not only who reacts to the controversy, but also who stays silent and *does not* attack or defend the brand.

We scraped all of each consumer's tweets in the year prior to each event. Across the studies there were approximately 110,000 consumers and 300 million tweets. To measure individual differences in attitudes, we first removed any tweets that mentioned the brand. We then quantified the average valence and emotion (vs. cognition) of each consumer's attitudes via their tweets using the Evaluative Lexicon, a validated computational linguistic tool for measuring attitudes (Rocklage, Rucker, and Nordgren 2018). This provided us with the average valence and emotionality of each consumer's attitudes in the year prior to the controversy. We used these individual differences to predict how consumers reacted on Twitter during the controversies. We measured consumers' political ideology using a validated latent space model (Barbera et al. 2015).

Results. For each controversy, we used logistic mixed modeling to predict whether a consumer tweeted about the company during the week of the controversy. We also controlled for consumers' general propensity to tweet by including the total number of tweets that consumer made in the year prior to the controversy.

Across controversies, the more consumers were predisposed to form and express negative attitudes, the more likely they were to react to each controversy as it broke in real time for Budweiser, Nike, and Gillette. This was moderated by ideology: negative conservatives were particularly likely to tweet given the companies tended to take liberal stances. These same results indicated those predisposed to form and express positive attitudes as well as liberals were noticeably silent and did *not* come to the support of brands.

How did these consumers react when they tweeted? The more negative and conservative consumers were, the more negative they were toward the brand. This same effect indicates that positive and liberal consumers tended to tweet positively toward the brand, though, as overviewed previously, they were less likely to tweet in general.

Regarding emotionality, we found that the more that consumers tended to form and express their attitudes based on emotion (vs. cognition) as an individual difference, the quicker they were to tweet when the controversy broke. More emotional consumers tweeted closer to when the advertisement was released from each brand. Emotional liberals and conservatives were equally quick to react.

Finally, conservatives' tweets were retweeted more, thereby having the consequence of spreading negativity further.

Summary. These real-world field data indicate that brands should expect consumers who are predisposed to form and express negative, emotion-based attitudes to be overrepresented on social media, quicker to react, and to react negatively. Tweets from negative consumers were also more likely to spread. Finally, brands should not necessarily expect to have consumers come to their support.

Consumers' Responses to Firms that Engage in Government Lobbying

EXTENDED ABSTRACT

Lobbying, defined as "expending resources in an attempt to sway government officials to make decisions beneficial to the lobbying firm," is a tactic firms use to manage their regulatory environ-ment. Firm-lobbying has been shown to provide strong returns estimated by some at 22,000% (Alexander, Mazza, and Scholz 2009). Recent findings reveal that $325 million in lobbying investments by *Fortune* 100 firms accounted for $338 billion in federal contracts in return (Andrzejewski 2019). Accordingly, the high returns to lobbying make it unlikely that firms will halt this practice.

In this research we consider how consumers respond to lobbying. News about company lobbying is often present in the news (e.g. the Associated Press has a unique web page dedicated to news about lobbying). Therefore, we propose that consumers' exposure to information about corporate activities such as lobbying can incidentally impact purchase intentions. In this research, we find that consumers disapprove of firms that lobby compared to firms that do not lobby (or when no lobbying information is provided). We find this effect is driven by a cognitive mechanism and an emotional mechanism. From the cognitive side, consumers perceive that lobbying firms offer inferior products. Such inferences may be based on an intuitive understanding of regulatory capture theory, where firms are incentivized to focus more on securing favorable treatment from government, than they are focused on satisfying customers. As regulatory capture theory explains, firms use lobbying to derive competitive advantages from benefits such as subsidies, monopolistic or favorable competitive conditions (barriers to entry, access to new markets), protective tariffs, and fixed prices (Stigler 1971). From the emotional side, consumers feel that lobbying is an unfair act, where companies may be seen as bending the rules in order to secure unfair advantages. Past research has shown that consumers are highly sensitive to fairness (Bolton, Warlop, and Alba 2003). Accordingly, we propose that consumers will disfavor lobbying firms because they believe these firms are acting in an unfair manner. We further predict this effect of fairness will be stronger for liberals who care more about fairness compared to conservativse (Graham, Haidt, and Nosek 2009).

In a pretest with a sample of 505 U.S. participants our goal was to first determine how accurate participants would be about company lobbying activities. The study quizzed respondents on the extent to which ten well-known firms lobbied (five-point Likert scales). We compared respondent scoring with actual company lobbying spending disclosed. Within the companies featured, we posed paired-comparisons of close competitor firms and asked whether one lobbied more, less, or about the same. On this task respondents were 71% accurate.

In Experiment 1, with a sample of 225 participants recruited from a U.S. executive MBA program, our purpose was to demonstrate the effect of customer lobbying for a currently owned product. To increase realism, and control for product experience participants were asked about the mobile phone they currently owned (Apple, Samsung, HTC, Google, and LG). Participants were then randomly assigned to a no lobbying condition or a lobbying condition where they read news of lobbying disclosures for their phone brand. Participants report lower satisfaction when they were told the brand lobbied than when they were told the brand did not lobby (M=5.75 vs. M=5.34, t(223)=3.34, *p* = .001). Results for purchase intentions follow a similar pattern (M=5.5, vs. M=5.13, F(1, 223)=2.22, *p* < .03). These results did not change when including brand as a covariate in the analysis.

In Experiment 2, we considered quality and fairness as mediators, and attempted to attenuate the negative effects of lobbying. In addition to being told whether a company lobbied or not (through a news article headline), participants in Experiment 2 were given information about whether the company was alone in their lobbying activities (self-interested), or whether they were lobbying alongside a customer group (customer-interested). Three-hundred and ninety

nine U.S. participants were randomly assigned to condition in a 2 × 2 between subjects design with lobbying (lobbying vs. no lobbying mention) and intention (self-interest vs. customer-interest) as between-subjects factors (industry replicates: pharmaceutical and electricity). We found a significant interaction ($F(1, 395)=8.79$, $p < .005$). In the company-interest conditions, participants indicated lower purchase intention when the company lobbied compared to when there was no mention of lobbying ($M_{lobby}=2.96$ vs. $M_{no\ lobby}=3.84$; $F(1, 395)= 29.49$, $p < .001$). However in the customer-interest conditions, there was no significant impact of lobbying behavior on purchase intention ($M_{lobby}=3.86$ vs. $M_{no\ lobby}=4.03$; $F(1, 395) = 1.02$, n.s). Fairness and quality evaluations were significant mediators in the company-interest conditions (fairness evaluations: -.45, CI: -.66, -.27; quality evaluations: -.12, CI: -.23, -.05). Neither were significant mediators of lobbying in customer-interest conditions (fairness: -.02, CI: -.21, .15; quality: .02, CI: -.06, .1).

In experiment 3, our goal was to determine whether the negative effect of lobbying on purchase intention would vary based on consumer groups with varying concerns for fairness. We predicted that liberals, who carry greater fairness concerns, would exhibit a stronger disfavor of lobbying firms compared to conservatives who care about fairness less. 268 U.S. liberals and conservative participants (prescreened) were randomly assigned to a lobbying condition or a no lobbying condition for an automobile brand. We found a significant interaction between lobbying and political orientation ($F(1, 264)=11.97$, $p < .001$). Examining the interaction very liberal participants indicated lower purchase intentions when the brand lobbied compared to when there was no lobbying ($M_{lobby}=2.76$ vs. $M_{no\ lobby}=4.86$; $F(1, 264)= 106.59$, $p < .001$). However, for very conservative participants this negative effect of lobbying was weakened ($M_{lobby}=3.43$ vs. $M_{no\ lobby}=4.52$; $F(1, 264) = 24.64$, p<.001). The negative mediating effects of fairness were significantly stronger for liberals (liberals fairness evaluations: -1.52, CI: -1.92, -1.17; conservatives fairness evaluations: -.9, CI: -1.19, -.64; index of moderated mediation: .62, CI: .28, 1.02). There was no difference in the negative mediating effects of quality between conservatives and liberals (liberals quality evaluations: -.15, CI: -.3, -.05; conservatives quality evaluations: -.11, CI: -.24, -.02; index of moderated mediation: .03, CI: -.08, .19).

Paper #4: Risky but Alluring: The Unexpected Increase in Risk Taking During the COVID-19 Pandemic

Claire Tsai, University of Toronto, Rotman School of Business, Canada

Ying Zeng, University of Toronto, Rotman School of Business, Canada

SESSION OVERVIEW

The COVID-19 pandemic presents a unique opportunity to examine how consumers deal with novel and emerging risks related to safety, finances, and health. Not only are consumers faced with the uncertain health risks of a new virus, but also with incorporating new restrictions and safety measures into their daily routines (Habersaat et al., 2020; Sheth, 2020). In addition, financial insecurity has amplified the risks associated with making these choices.

From whether to go to the grocery store to whether to visit elderly relatives to whether to go into an in-person job, previously mundane decisions have become constant risk assessments (Hakim et al., 2021). Consumers must make daily decisions about what risks they are willing to take, how they will respond to risks in the environment, and how they expect those around them to react to risks (Budd et al., 2020). While the extremity of the situation is unique to the pandemic, the insights into consumer behavior gleaned from studying the pandemic have applications to improving understanding of risk-related behavior under pressure, in general. The papers in this session examine how consumers' experiences during the COVID-19 pandemic impacted their risk tolerance and how the impact varied across types of consumers.

From the beginning of the pandemic, consumers' attempts to reduce COVID risk have had a major impact on their choices about when to shop, what to buy, and how to behave. Consistent with the desire to minimize COVID risk, **Urminsky and Bergman** find widespread support for retailers having strict COVID-19 safety requirements among consumers despite consistent underprediction of this support by both managers and consumers. Most people desire to avoid risk themselves but fail to recognize that others share this desire. Using survey and Nielsen Homescan data, **Orhun and Ur-**

minsky document behavior consistent with avoiding shopping risk, particularly stockpiling durable goods and decreasing trips to the store. However, poorer people, who were often more impacted by the pandemic, were less likely to stockpile and did not reduce shopping frequency as much.

The last two papers explore differences in how attitudes toward non-COVID risks were impacted by the pandemic. **Tsai and Zeng** find increased (non-COVID) risk-taking behaviors in populations that were more directly affected by the pandemic compared to those who were less affected and argue that this increase is due to heightened boredom among these populations. Furthermore, **O'Leary, Sussman, and Trueblood** demonstrate that pandemic-induced financial hardship was associated with a higher willingness to engage in risk-taking behaviors.

Taken as a whole, these papers collectively demonstrate the varied risk responses to the pandemic as well as the heterogeneity observed in risk preferences. Beyond the COVID-19 pandemic, these findings can help further our understanding of the way that danger and deprivation more generally impact how people think about risky choices for themselves and others.

The Masked Majority: Underprediction Of Widespread Support for Covid-19 Safety Policies

EXTENDED ABSTRACT

Mask wearing is a key intervention to reduce COVID-19 transmission risk, especially indoors (Brooks et al., 2020; Eikenberry et al., 2020; Khanh et al., 2020). However, lack of a centralized pandemic strategy in the US resulted in uneven mask policies, requiring firms to decide how strictly to require and enforce mask-wearing, and leaving consumers to assess risk based on limited policy information. Norm-formation regarding mask-wearing hinged on potentially inaccurate beliefs about others' preferences. Individuals often under-predict how risk averse others will be (Faro & Rottenstreich, 2006; Hsee & Weber, 1997). Perceptions about mask policy adherence could also be obscured by vocal minority opinions that skew policy decisions when businesses believe that more people oppose masks than actually do (Halbeslehen et al., 2004; Oliver, 2014).

In four pre-registered studies, we investigate whether support for strict COVID-19 prevention policies is underestimated, across business types, information sources (stated policies and viral videos), and types of policies (required mask-wearing and vaccination). We consistently find that people strongly favor organizations with strict COVID-19 prevention policies, such that the risks of losing customers and of negative consumer perceptions are higher for lax policies (e.g., recommended mask-wearing) than for strict policies (requiring and enforcing mask-wearing). Nevertheless, customers and managers underestimate support for strict policies.

In study 1, (N=546), made repeated choices between two airlines, one that required masks and one that recommended masks, with differences in ticket prices varied across the choices. Participants then predicted how many participants out of 100 chose each airline when tickets were equally prices. Across all price pairs, participants chose the stricter option 69% of the time (SD=35.11). When choosing between equally-priced options, the majority of people selected the stricter airline option (69.78%). However, the same respondents under-predicted how many people would choose the stricter option

(M$_{prediction}$=59.83%, error=9.95%, bootstrapped 95%CI of difference: [-13.55,-6.22], p<0.001). Thus, consumers preferred a stricter policy but were not aware that others did as well.

In study 2, we examine the accuracy of a sample of retail managers (N=93, study 2b) because they are often the employees responsible enforcing store policies (Corkery, 2020; Repko, 2020; Segarra, 2020) in predicting the preferences of a nationally-representative sample of consumers (N=498). We tested consumers' preferences (and their beliefs about other consumers' preferences) in five between-subjects scenario conditions (bakery, pharmacy, movie theater, hair salon, and gym). In each condition, participants chose between visiting one of two equally convenient businesses that required vs. recommended mask-wearing or choosing not to patronize either business. Consumer participants then estimated how many other consumers out of 100 would choose each option. The manager participants likewise estimated how many participants out of 100 made each choice in all five scenarios. Consumers also rated each business on perceived warmth and competence (Kervyn et al., 2013). Consumers mostly selected the stricter mask-required option (73%, Z=106.44, p<.001; vs. 15% lax option or 12% abstaining). Both consumers and managers significantly underpredicted how many consumers chose the stricter option overall (M$_{consumer\ prediction}$=55%, error=-18.65, p<.001; M$_{manager\ prediction}$=49%, error=-23.74p<.001). Overall, managers were not better than laypeople at predicting the preferences of consumers.

In study 3 (N=200), participants watched two videos filmed at actual Walmart stores, one depicting strict enforcement and the other depicting non-enforcement. Participants chose between shopping at the strict-enforcement or non-enforcement store, or choose not to go to either store. Participants then estimated how many participants out of 100 would choose each option. Participants also assessed the warmth, competence, trustworthiness and caring of each store.

Respondents preferred the stricter store over the lax non-enforcing store (70.1% vs. 29.9%, χ²(1,N=134)=21.8, p<.001), and rated the strict store significantly higher on warmth, competence, caring, and trust (all ps<.02). Instead of harming a store's reputation, videos depicting strict enforcement resulted in more choices of that store and beneficial brand perceptions of the business, compared to a video showing nonenforcement. Nevertheless, respondents underpredicted the degree to which other consumers would share an overall preference for the stricter store (M$_{prediction}$: 39.9% vs. 54.3% actual, error=-14.43, p<.001). Overall, these results suggest that the negative impact of non-enforcement on consumer preferences is systematically underestimated.

In study 4 (N=197), participants chose between having a surgical procedure at a hospital that required employees to be vaccinated against COVID-19, or at a hospital that that recommended employees be vaccinated or not having the procedure at either hospital but enduring pain, holding constant convenience and insurance coverage. Participants then estimated how many other participants out of 100 would choose each option. To examine the potential consequences of beliefs about descriptive norms regarding staff vaccination policies on word of mouth (Anderson, 1998; Buttle, 1998), participants were then told that their friend is going to have a procedure at the opposite hospital than the one the participant selected, and asked whether they would warn the friend about each hospital's vaccine policy.

The majority of respondents selected the stricter vaccine-requiring hospital over the lax non-requiring hospital (77.04% vs. 19.89%, χ²(2,N=196)=176.8, p<.001; 3.06% delayed). Respondents rated the hospital with the required-vaccine policy significantly higher on warmth and competence (ps<.001). Respondents again underpredicted the preference for the stricter hospital (M$_{prediction}$=63.76% vs.

77.04% actual, error=-12.28%, p<.001). Controlling for own choice, weaker perceived descriptive norms (i.e., a lower estimated percentage of people the respondent expected to agree with them) predicted a lower likelihood of warning a friend about the hospitals' policies (b=0.004, SE=0.001, p<.001). Overall, these results demonstrate not only underestimation of the majority-preference to get treatment at a hospital that requires employees to be vaccinated, but that underestimating the descriptive norm predicts less willingness to engage in word-of-mouth behavior.

These four studies demonstrate that consumers and managers consistently underestimate support for COVID-19 prevention measures, reinforcing a climate in which individuals and businesses hesitate to advocate for strict policies, and impeding the establishment of crucial social norms, with consequences for public health.

Grocery Spending and Stockpiling During the COVID-19 Pandemic

EXTENDED ABSTRACT

Consumer inertia has been widely documented, with consumers purchasing tending to be relatively stable over time. However, the 2020 COVID pandemic in the United States was an unprecedented shock to consumer behavior. In this paper, we investigate the nature of changes in consumer grocery shopping behavior during the pandemic and how consumers differed in their response.

During the initial weeks of the 2020 COVID pandemic in the United States, consumers faced an uncertain and stressful future. In March, a patchwork of school closure and stay-at-home orders went into effect over a three-week period in the majority of U.S. states. Grocery shopping, typically a routine activity, became a challenge of providing for one's self and one's family in the face of uncertainty about the availability of supplies and about future needs, as well as unprecedented economic insecurity. In this paper, we investigate how consumers changed their food purchasing behaviors during the early weeks of the pandemic and the lock-down period that followed. Differences in consumers' responses could impact their preparedness to face the pandemic, including their access to beneficial nutrition and their potential for food insecurity while isolating. Therefore, we investigate how populations already at-risk for food insecurity, particularly low-income households, differ in the extent to which their shopping behavior changed.

Using both original survey data (N=722) and Nielsen Homescan panelist purchase data, we find dramatic changes in U.S. households' grocery shopping behavior during the pandemic and substantial discrepancies in those changes across households of different demographics. During the "initial-response" period in early March we see substantial increases in both shopping trips (increasing by 7% - 8%) and spending on food and beverages (by 25% - 32%) compared to the same periods in 2019, consistent with stockpiling. During the subsequent "lock-down period" through the end of April, consumers sustained an increased level of spending on food and beverages (an average 13% increase compared to the same period in 2019), while making fewer shopping trips than usual (an average of 10% reduction). As a result, during the lock-down period, consumers' spending per shopping trip ballooned to levels 30% higher than usual.

Both survey data and shopping data suggest that these spending changes varied by type of food. Specifically, survey respondents reported initially increasing purchases for foods that they perceived as more storable and more of a necessity. Subsequent spending increases focused on foods perceived as healthy, tasty and necessities. Purchase data confirms that the spending changes prioritized rela-

tively nutritious foods that store well. These results held when controlling for demographics.

Food insecurity has been on the rise since the pandemic began. For example, Feeding America, a national organization serving 200 local food banks, reports that 98% of their client food banks had reported higher demand since the beginning of the pandemic, and two-thirds reported reduced inventory (Gundersen et al., 2021). Even prior to the pandemic, lack of liquidity constrained grocery shopping flexibility for lower-income households (Orhun & Palazzolo, 2019). Consistent with the view that lower-income households lacked the liquidity to effectively stockpile, spending data reveals that lower income shoppers did not increase food spending to the same degree as higher-income households during the pandemic, and what they did spend did not shift towards the storable, high-nutrition ingredients that high-income households were stocking up on. Survey data further finds that households that reported experiencing greater food insecurity in 2019 increased their spending less at the start of the pandemic.

These findings suggest that low-income consumers have in fact not adapted their grocery shopping to meet changing needs during the pandemic as much as the wealthier families were able to. Overall, our results raise the possibility that for millions of low-income American families, the coronavirus pandemic may also have created or exacerbated food-insecurity issues. Our results regarding the differences in the composition of food purchased by low-income households during the pandemic also suggest that in addition to potentially insufficient food, lower income households that do have enough food may still be at greater risk of lower nutritional quality in the foods they are able to buy.

Risky But Alluring: Severe COVID-19 Pandemic Influence Increases Risk Taking

EXTENDED ABSTRACT

Decision under risk has been one of the most lively and interdisciplinary topics in judgment and decision-making (Fox et al., 2015; Loewenstein et al., 2001). Despite the rich literature on this topic, it does not provide a clear theoretical prediction about how an extreme exogenous shock such as the COVID-19 pandemic might influence consumers' general risk attitude in their daily lives. The present research addressed this issue.

A series of four studies (two preregistered) showed that compared with consumers who were less severely affected by the pandemic, those who were severely affected indicated *greater* risk taking toward a set of risky activities across social, health/safety, financial, ethical, and recreational domains (30-item DOSPERT scale, Blais & Weber, 2006; Weber et al., 2002) or on a single-item risk-taking scale (study 4:"please indicate your willingness to take risks in general;" Dohmen et al., 2011).

The difference in risk taking cannot be attributed to individuals' risk perception because across studies, the perceived risk of the same activities among the severely affected group was either *lower* or *similar* to that of the less severely affected group, showing a counterintuitive risky-but-alluring effect. Data showed that this paradox could be explained by elevated boredom levels and perceived benefits of risky activities among those who were severely affected.

Pandemic influence was measured using a factual scale such that a participant would be categorized as *severely affected* if they or any of their household members encountered at least one of the following situations due to the epidemic: (1) substantially reduced income; (2) confirmed as infected or being hospitalized; (3) experienced mandatory quarantine; and (4) other applicable situations.

Although these situations are different in nature, they share one thing in common: cause individuals to be even less likely or able to engage in common, lower-risk activities such as dining out, not to mention higher-risk activities such as skydiving (Meta-analysis confirmed that the effect of pandemic influence did not vary by these situations.)

Study 1 (MTurk) established the risky-but-alluring effect and showed that severely affected participants ($N = 122$) were more likely to engage in risky activities ($M = 3.75$) than those who were less severely affected ($N = 94$, $M = 2.94$, $t(214) = 6.43$, $p < .001$). However, the mean risk-perception level did not vary significantly between those who severely affected ($M = 3.51$) and those who were less severely affected ($M = 3.58$, $t(214) = .79$, $p = .43$). Linear regression showed that pandemic influence remained a significant predictor of risk taking ($p < .001$) when risk perception was controlled for, ruling out risk perception. To verify which group was driving the effect, we used a pre-pandemic group (i.e., the unaffected group, $N = 120$) who completed a similar survey in Summer 2019 as a comparison benchmark. Results showed that the pre-pandemic participants (the unaffected group) were less risk taking ($M = 2.51$) than both the severely affected group (Tukey's $t(333) = 11.01$, $p < .001$) and the less severely affected group (Tukey's $t(333) = 3.55$, $p = .001$). However, compared to the unaffected participants ($M = 3.28$), risk perception was *higher* among both the severely affected ($M = 3.58$, $t(333) = 3.75$, $p < .001$) and the less severely affected participants ($M = 3.51$, $t(333) = 2.69$, $p = .021$), further suggesting the effect of pandemic influence on risk taking cannot be attributed to risk perception.

Study 2 (234 university students in Canada) replicated study 1 and showed that severely affected participants were more likely to engage in risky activities ($M = 2.65$) than the less severely affected ones ($M = 2.51$, $t(232) = 2.16$, $p = .032$), and the effect remained significant after controlling for risk perception ($p < .001$). Mediation analysis showed a significant indirect effect of pandemic influence on risk taking through state boredom, but not through positive or negative affect.

Study 3 (206 MTurkers) replicated the risky-but-alluring effect and showed that the effect remained robust after controlling for risk perception, demographics and subjectively perceived pandemic influence, suggesting that our categorization of pandemic influence would still predict risk taking independently from people's perceptions. In addition, data showed that perceived benefits from taking risks mediated the effect of pandemic influence and ruled out factors related to risk perception including perceived severity and perceived chance of negative outcomes.

Study 4 (206 MTurkers once again replicated the key finding using the DOSPERT scale and the singles-item measure of willingness to take risks). A serial mediation showed that the indirect effect of pandemic influence on risk taking through boredom and perceived benefits was significant. One might argue the severe pandemic influence was driven by participants' chronic individual difference in risk taking because more risk taking leads to careless behaviors toward COVID-19 and thus severe pandemic influence. We ruled out this reversed inference by showing that people perceived themselves to be similarly careful toward COVID-19 ($M_{severe} = 5.66$, $M_{less\ severe} = 5.41$, $t(204) = 1.19$, $p = .24$) and reported taking similar actual safety measures ($M_{severe} = 8.22$, $M_{less\ severe} = 7.80$, $t(204) = .91$, $p = .36$). Together, these results suggested that the severely affected participants experienced a higher boredom level, expected more benefits from taking risks, and thus reported greater risk taking.

This research adds to the literature on decision under risk, especially the role of perceived benefits, as well as literature on public reactions toward long-lasting emergency states. It also has policy

implications on targeted interventions and aid plans, as well as methodological implications regarding data collection during the COVID-19 pandemic.

Jobloss and Risky Decision Making

EXTENDED ABSTRACT

Few events are as detrimental to consumer well-being as a job loss (Lucas et al., 2004; Wanberg, 2012). One of the many destructive impacts of the COVID-19 pandemic has been the associated job losses. In April 2020, the unemployment rate in the United States reached 14.7%, equivalent to 23.1 million people, higher than at any time since the Great Depression. The magnitude of these layoffs underscores the importance of understanding job loss and related consequences.

One pervasive feature of consumer behavior is the trade-off between risks and rewards (Kahneman & Tversky, 1979; Taylor, 1974). From deciding whether to invest in the stock market to deciding whether to purchase a new brand of blender, nearly every decision that a consumer makes involves some amount of risk. Given the centrality of risk to a wide range of consumer decisions, understanding the circumstances, such as job loss, that influence risky decision-making is critical.

The relationship between job loss and risk preferences has not been widely studied, but prior research has examined this relationship in the context of other components of a person's financial well-being (Griskevicius et al., 2013; Guiso et al., 2018; Haisley et al., 2008; Haushofer & Fehr, 2014; Tanaka et al., 2010). While some researchers find that financial well-being is positively associated with risky decision-making (Dohmen et al., 2011a; Guiso & Paiella, 2008; Haushofer & Fehr, 2014; Tanaka et al., 2010), others find that financial well-being is inversely associated with risky decision-making (Gabrielyan & Just, 2020; Griskevicius et al., 2013; Haisley et al., 2008). These two sets of findings suggest competing Hypothesis for the relationship between job loss and risky decision-making. The former would predict that people who have recently lost their job should become more risk averse while the latter would predict they should become more risk-seeking. In the present research, we undertook a systematic investigation of this relationship.

In Study 1, we developed a novel laboratory manipulation of job loss. We examined whether participants assigned to a job loss condition were more likely to make risky decisions than participants assigned to a control condition. At the start of the experiment, participants were told that they would complete 80 trials of a decision-making task where they would earn wages based on their decisions. Participants were also told that while completing the task, they might lose their ability to earn additional money. For participants in the job loss condition, they lost the ability to earn money after trial 40. Our first measure of risky decision-making was an incentive-compatible risky decision where participants could choose either keep the bonus payment that they had earned during the task or they could choose to invest their winnings in an investment with a 50% chance of doubling their bonus and a 50% chance of losing their bonus. Our second measure of risky decision-making was a hypothetical lottery decision where participants could choose to gamble hypothetical winnings of $100,000 between $0 and $100,000 in $20,000 increments in a gamble that offered a 50% chance of doubling the amount they gambled and a 50% of losing half the amount they gambled. Participants in the job loss condition were more likely to choose to gamble their bonus than participants in the control condition (Odds Ratio = 2.64, 95% CI = [1.48, 4.83], z = 3.24, p = 0.001) and chose to gamble more of their hypothetical earnings than participants in the control condition (b = 0.31, 95% CI = [0.03, 0.58], t = 2.20, p = 0.029). These results are consistent with the hypothesis that a job loss leads to increases in risky decision-making.

In Study 2, we examined the relationship between job loss and three types of risk-related outcomes (two in the financial domain and one in the health domain) using a cross-sectional survey administered to 32,368 participants (17% of whom report job loss). Our three outcomes are decisions in a gambling task (e.g., 10% chance of $100 versus 100% chance of $50), lottery ticket purchases, and hypothetical COVID-19 health-related risky decisions (i.e., social distancing). In addition, we assessed whether recency of job loss was associated with the magnitude of risky decision-making. If individuals who have recently lost their job are more risk-seeking than those who lost their job further in the past, this would suggest both that risk-preferences are tied to recent job loss rather than to longer-term unemployment and also that job loss leads to risk-seeking rather than the converse.

We find that job loss (1=lost job, 0=did not lose job) is positively associated risky choices on the gambling task (B = .28, 95% CI = [.25, .32], t = 17.90, p<.001), lottery ticket purchases (B = .37, 95% CI = [.34, .40], t = 23.11, p<.001), and health-related risky decision-making (B = .25, 95% CI = [.22, .28], t = 15.73, p<.001). These findings persist after controlling for income, education, socioeconomic status, and employment-related covariates. In addition, the recency of job loss (1= did not lose job to 8 = lost job < one week ago) is associated with risky decision-making on the gambling task (B = .14, 95% CI = [.12, .15], t = 24.03, p<.001), lottery ticket purchases (B = .15, 95% CI = [.14, -.16], t = 26.92, p<.001), and health-related risky decision-making (B =.12, 95% CI = [.11, .14], t = 22.05, p<.001) such that participants who have lost their jobs more recently prefer greater risk. Importantly, we find that each of these relationships between job loss and risky decision-making are partially mediated by self-reported financial fragility and negative affect. In supplemental analyses, we find evidence for these same relationships with a hypothetical stock investment outcome.

Our results have important implications for consumer behavior and consumer well-being during times of financial crisis. Although our results suggest that the relationship between job-loss and risk-taking may be time-limited, even brief shifts in risky decision-making could lead people to engage in riskier behaviors (e.g., gambling, unhealthy eating) with consequences that extend beyond the short-term.

The Meaning of Minimalism: What Consumers See in Minimalist Aesthetics (And What They Don't)

Chair: Linda Hagen, University of Southern California, USA

Kate E. Min, Wheaton College, USA

Paper #3: Differential Effects of Minimalist Visual Branding on Expected Utilitarian and Hedonic Capacity
Linda Hagen, University of Southern California, USA

SESSION OVERVIEW

Over the past decade, minimalist aesthetics have resurged in popularity (e.g., Cook 2019; Sokol 2012). This trend is evident in consumer interest in a minimalist *lifestyle* (e.g., phenomena like the "Tiny House" movement, "capsule wardrobes," and Mari Kondo); the popularity of minimalist *product aesthetics* (e.g., brands like Muji, Everlane, and Apple); and the trend of minimalist *marketing aesthetics* (e.g., Starbucks' logo growing more minimalist; McDonald's' "picto" campaign; or Public Goods' visual branding).

Although it is well-known that visual aesthetics meaningfully influence consumer evaluations (e.g., Hagtvedt and Patrick 2008; Hoegg, Alba, and Dahl 2010; Reimann et al. 2010; Townsend 2017) and qualitative consumer research has studied advertising creatives' beliefs about minimalism (Prajecus et al. 2006) as well as how consumers strategically downsize to become more minimalist (Mathras and Hayer 2019), virtually no quantitative consumer research has examined consumer reactions to minimalist aesthetics in the marketplace. This Special Session fills this gap by first empirically deriving consumers' conceptualization of minimalism and then experimentally studying consumers' positive and negative reactions to one fundamental dimension of minimalism: minimalist aesthetics.

First, **Wilson and Bellezza** showcase a comprehensive, multi-method approach to studying what minimalism means to consumers and identify three key dimensions that define minimalism: a preference for (i) owning few possessions, (ii) a sparse, minimalist aesthetic, and (iii) mindfully curating possessions. They introduce the Minimalist Consumer Scale, which captures these dimensions and predicts consumer behavior, including the look of people's actual living spaces (rated by independent coders), home décor preferences, and willingness to forego free gifts. The subsequent two papers focus on the minimalist aesthetic dimension of consumer minimalism and investigate when minimalist aesthetics are beneficial—and when they are not.

Min, Anderson, Liu, and Min examine minimalist (vs. complex) *product* aesthetics, and in particular, how preference elicitation method influences whether people prefer minimalist or complex product design. They find minimalist and complex design are often similarly preferred in choice, which is determined chiefly by individual taste. However, minimalist design is devalued in willingness-to-pay, which is governed by production cost considerations. Ac-

cordingly, framing minimalist design as the result of effort-intensive paring-down can boost minimalism's merit in WTP.

Finally, **Hagen** investigates minimalist (vs. complex) *packaging/branding* aesthetics and how they shape expectations about product attributes. She finds that (equally attractive) minimalist (vs. complex) design enhances expected utilitarian capabilities, driven by greater perceived focus on essentials, but diminishes expected hedonic capabilities, driven by perceived lack of stimulation. As a result, utilitarian (vs. hedonic) purchase goals boost choice of products with minimalist (vs. complex) packaging design.

Minimalist aesthetics are under-studied. Expanding our theoretical and substantive understanding of it is important—not just because it is pertinent to current marketing practice, but also because of its implications for sustainability (e.g., focus on reducing waste; potential for less resource-intense production; promise of longer product lifespan due to design timelessness). This session begins to offer such insights, by sharing novel research and inviting discussion (led by aesthetics expert **Claudia Townsend**).

Consumer Minimalism

EXTENDED ABSTRACT

American consumerism is often characterized by overt materialism, opulence, and an insatiable desire to acquire. This celebration of accumulation, however, has often been accompanied by an embrace of simplicity and austerity in consumption. More recently, minimalism has risen to the forefront of consumer culture, with many people embracing notions of decluttering, sparse living spaces, and reduced consumerism.

Nonetheless, the concept of minimalism is not presently well-defined or concretely understood. To address this gap in the literature, we define consumer minimalism by identifying three key dimensions of the construct (i.e., number of possessions, mindfully curated consumption, and sparse aesthetic) and develop the twelve-item Minimalist Consumer Scale assessing these dimensions. A series of studies, using samples from a variety of populations (*N*=3,342), demonstrates the validity and reliability of the tridimensional Minimalist Consumer Scale, situates the measure conceptually and empirically within a broader nomological network of related constructs (e.g., voluntary simplicity, frugality, green values, materialism), and documents the scale's ability to predict relevant consumer behavior.

Construct Development. To develop consumer minimalism, we used an approach aligned with grounded theory (Glaser and Strauss 1967). This process involved collecting and aggregating data from various sources before engaging in open-coding, selective coding, and theoretical coding (Urquhart 2012). First, we collected an abundance of qualitative data relating to minimalism from popular press and media—including books, television shows, news and media outlets, store visits, and Google image searches. We also joined over twenty minimalist-themed private Facebook groups to survey self-ascribed minimalists (*N*=96) and recruited lay consumers via Amazon Mechanical Turk (*N*=200).

Next, we analyzed our data using a bottom-up open-coding procedure to create a list of conceptual categories found in the data, followed by a selective coding process organizing the codes into higher-order concepts and a theoretical coding procedure relating the

higher-order selective codes to each other (Urquhart 2012). This process resulted in our identification of consumer minimalism's three fundamental dimensions: number of possessions, mindfully curated consumption, and sparse aesthetic. This process also allowed us to identify the nature of the construct of minimalism as a consumer value and to theoretically distinguish minimalism from adjacent constructs.

Scale Development. We generated an initial pool of 150 items (50 items per dimension). After eliminating ambiguous and repetitive items, eleven faculty and Ph.D. students evaluated a revised pool of 105 items for clarity and representativeness of the defined dimensions. Based on the judges' ratings, we retained 45 items. These items were formatted into seven-point Likert-type response scales (1=Strongly Disagree, 4=Neither Agree nor Disagree, 7=Strongly Agree) and rated by a sample of American Prolific Academic respondents (N=422; 51% female, M_{age} = 32.2). We evaluated the items based on interitem correlations, average corrected item-to-total correlations, and average factor loadings, as well as clarity of meaning and face validity. These analyses resulted in a final set of twelve items, four items per dimension (see Table 1). A subsequent series of exploratory and confirmatory factor analysis validated each of the scale items and tri-dimensional structure. All three factors had high alphas (all $\geq$ .86), and the alpha for the full scale was α=.88.

Scale Validity & Reliability. We assessed the discriminant and convergent validity of the Minimalist Consumer Scale by examining its relationship with other related existing constructs and its precursors—including voluntary simplicity, frugality, GREEN consumer values, experiential buying, product retention, materialism, fashion orientation, and distinction. American Amazon Mechanical Turk respondents (N=621; 54.3% female; M_{age}=39.5) completed scales assessing each of the constructs. As expected, the Minimalist Consumer Scale was positively and significantly related to voluntary simplicity (r=.26, p<.001), frugality (r=.46, p<.001), GREEN consumer values (r=.32, p<.001), and experiential buying tendency (r=.21, p<.001). The relationships with materialism (r=–.31, p < .001) and product retention tendency (r =–.26, p<.001) were negative and significant, while the Minimalist Consumer Scale was not significantly correlated with fashion orientation (r=.02, ns) or distinction (r=.04, ns). The results of this survey provide evidence for the expected discriminant and convergent validity of the scale.

We then demonstrated the scale's known-groups validity by showing that members of minimalist Facebook groups scored significantly higher on our scale than members of reading Facebook groups (N=104; 96% female; M_{age}=47.8). Moreover, we confirmed our scale's test-retest reliability in two samples (163 graduate students, 39.3% female; M_{age}=28.1, and 393 participants recruited through Prolific Academic, 45.5% female, M_{age}=33.2) with different time lags between collections: one week and five weeks.

Next, we assessed the predictive validity of the scale across three studies. First, participants completed our scale and uploaded photos of rooms in their homes (N=112; 43.8% female, M_{age}=41.2). Three independent research assistants, blind to the purposes of the research, rated the images on the three dimensions of consumer minimalism. Scores on the Minimalist Consumer Scale significantly predict the extent to which consumers' actual home environments reflect the three dimensions of minimalism. Second, we showed that scores on our scale significantly predict preferences for minimalist (vs. non-minimalist) apartment interiors (N=200, 50.5% female, M_{age}=40.2). Finally, we showed consequences in a hypothetical consumption choice scenario, demonstrating that higher scores on the Minimalist Consumer Scale predict lower interest in receiving

products—even when the products are all presented as part of a free giveaway (N=203, 55.8% female; M_{age}=39.9).

In sum, we demonstrate that consumer minimalism is a unique construct situated within a broader nomological network of related constructs, such as voluntary simplicity and frugality, but not fully captured by any of them. We identify three core dimensions of minimalism—number of possessions, mindfully curated consumption, and sparse aesthetic—that unify the variegated displays of minimalism observed in the marketplace and validate a scale for measuring consumer minimalism.

The Unwillingness to Pay for Minimalist Product Aesthetics

EXTENDED ABSTRACT

Products with minimalist aesthetics have proliferated alongside products with more visually complex aesthetics (Cook 2019). Given the prevalence of minimalist aesthetics in the marketplace, and the robust influence of aesthetics on consumer judgments and choices (e.g., Hagtvedt and Patrick 2008; Hoegg, Alba, and Dahl 2010), we investigate which aesthetics consumers prefer in products. Specifically, we examine whether, when, and why the preference for minimalist versus complex aesthetics varies based on how preferences are elicited.

Whereas standard economic theory assumes procedure invariance, past research documents that preferences are often reversible, context-dependent, and constructed as elicited (e.g., Bettman, Luce, and Payne 1998; Lichtenstein and Slovic 1971; Tversky and Thaler 1990). Building on this literature, we suggest that preference elicitation mode influences the weight that consumers place on their personal aesthetic tastes versus their beliefs about the product's production costs.

Four pre-registered experiments identify a robust preference reversal: minimalist products are more preferred when preference is elicited via choice versus WTP. This reversal occurs because WTP reflects consumers' beliefs that minimalist (vs. complex) products have lower production costs, whereas choice is more reflective of consumers' personal aesthetic tastes.

Experiment 1A (N=300) documents the preference reversal effect when both goods' identical manufacturer suggested retail price (MSRP) is displayed. In this and all experiments, participants were first randomly assigned to an elicitation mode condition (choice vs. WTP). Participants in the choice condition chose between the minimalist and complex version for each set of goods, with no preference as a third option, whereas participants in the WTP condition indicated their maximal WTP for each good. We classified WTP participants as preferring the option for which they indicated a greater WTP (those who indicated equal WTP were classified as indifferent). In this and all experiments, indifferent participants were excluded consistent with prior research (Slovic, Griffin, and Tversky 1990). As hypothesized, participants were more likely to prefer the minimalist good in choice (45.5%) than in WTP (11.4%); χ^2=40.09, p<.001.

Experiment 1B (N=402) replicates the reversal using an incentive-compatible design. Participants in the choice condition were entered into a raffle to receive the product they choose and participants in the WTP condition had WTP elicited via the incentive-compatible Becker, DeGroot, and Marschak (1964) mechanism. Participants expressed greater preference for the minimalist good in choice (44.0%) than in WTP (19.5%), χ^2=23.76, p<.001.

Experiment 2 (N=252) tests whether the reversal is mediated by a differential situational focus on production costs, visual appeal, or both, using parallel mediation. After expressing their preference,

participants responded to the two mediator measures, which gauged a situational focus on production costs and a situational focus on visual appeal. WTP (vs. choice) promoted a situational focus on production costs, which predicted preference for the complex (vs. minimalist) good—mediating the preference reversal (b=-.54, SE=.11, z=-5.15, p<.001). By contrast, choice (vs. WTP) promoted a situational focus on visual appeal; a focus on visual appeal did not in turn exert a systematic influence on preference for the minimalist (vs. complex) good, (b=.0007, SE=.16, z=.005, p=.996), reflecting that consumers vary on which kind of aesthetic they find more visually appealing.

Experiment 3 (*N*=602) tests whether framing the production value of the minimalist (vs. complex) design as higher eliminates the preference reversal in a 2(elicitation mode: choice vs. WTP) × 2(relative production value of the minimalist design: lower [add-on frame] vs. higher [reduction frame]) between-subjects design. Participants evaluated minimalist and complex versions of a website design purportedly created by the same web designer. The minimalist design was framed as the result of an effortful paring-down process in the reduction frame, as opposed to a lack of building up elements in the add-on frame. Choice participants indicated their preference between the minimalist and complex versions of a website design, whereas WTP participants indicated which they would be willing to pay more for. All participants responded on a 9-point scale. The interaction between elicitation mode and relative production value of the minimalist design was marginally significant (Wald $\chi^2(1)$=3.18, p=.074): the effect of elicitation mode on preference was only significant in the add-on frame (Wald $\chi^2(1)$=15.79, p<.001), but not in the reduction frame (Wald $\chi^2(1)$=2.16, p=.142).

Overall, we identify a novel preference reversal as a function of product design aesthetics. In doing so, we add to understanding preferences for product minimalism—a popular yet not well-understood aesthetic dimension. We show that elicitation mode—by shifting consumers' relative focus on their personal aesthetic tastes versus their beliefs about the product's production costs—is one important determinant of expressed preference for minimalist design in consumer goods.

Differential Effects of Minimalist Visual Branding on Expected Utilitarian and Hedonic Capacity

EXTENDED ABSTRACT

Beyond being popular in product design, a minimalist visual aesthetic has become increasingly prevalent in visual branding (e.g., Sokol 2012), and highly aesthetically appealing examples of both minimalist and complex marketing aesthetics co-exist across diverse product categories—from chocolate to personal care, wine to household cleaners. Visual aesthetics clearly shape consumer evaluations (e.g., Hagtvedt and Patrick 2008; Reimann et al. 2010; Townsend 2017), yet the consequences of minimalist (vs. complex) marketing aesthetics have not yet been studied in detail. This paper examines when and why a minimalist (vs. complex) marketing aesthetic is advantageous.

Much of the aesthetics literature would suggest that higher aesthetic appeal positively shapes various product inferences (e.g., Reimann et al. 2010; Townsend and Shu 2010; Wu et al. 2017). In contrast, we propose that—independent of aesthetic appeal—minimalist (vs. complex) visual aesthetics specifically convey *higher utilitarian* capacity, but *lower hedonic* capacity, as a function of perceived product richness.

Five pre-registered experiments document consistently that minimalist (vs. complex) aesthetics enhance expected performance but diminish expected enjoyment. This pattern is driven by minimalist (vs. complex) design suggesting a more focused, but less stimulating, product.

Experiment 1A (*N*=201) tested if minimal (vs. complex) packaging design conveys superior utilitarian capacity, but inferior hedonic capacity. Participants evaluated a shampoo whose packaging featured either a minimal or complex version of a black-and-white shapes or of a multi-colored zigzag design (using two designs for robustness). Note that in this and all other studies, stimuli pre-tested as differentially minimalist but equally aesthetically appealing (except for Experiment 2B, which controls for aesthetic appeal differences)—therefore, aesthetic appeal or liking cannot explain results. Participants rated, in random order, their impression of the shampoo's utilitarian (e.g., effective) and hedonic capabilities (e.g., enjoyable), plus perceived expensiveness as a potential covariate, on 7-point scales.

Participants expected higher performance for the shampoo with minimalist (vs. complex) design (F(1, 199)=14.31, p<.001), but lower pleasure for the minimalist (vs. complex) shampoo (F(1, 199)=39.30, p<.001). All results held independent of perceived expensiveness.

Experiment 1B (*N*=202) extended these findings to a different product (sunscreen) and different designs (minimal and complex versions of a blue flecks base design), while providing additional product information (e.g., price) and measuring perceived uniqueness as a different potential covariate. All findings replicated, and were independent of perceived uniqueness.

If minimalist (vs. complex)-looking products promise higher utilitarian but lower hedonic value, a consequence should be that they will be preferred more strongly when consumers pursue utilitarian (vs. hedonic) goals. Experiments 2A&B tested this prediction with hypothetical choice (using lab-controlled packaging designs) and real choice (using real products available in the marketplace).

In **Experiment 2A** (*N*=401) participants adopted a utilitarian or a hedonic goal for purchasing hand soap (between-subjects) and then evaluated two hand soaps: one with a minimalist packaging design and one with a complex packaging design (within-subject). To disguise our focus on minimalism in this within-subject design, participants were shown minimal and complex versions of different designs: either a minimalist version of an art-deco design and a complex version of a doodle design, or the opposite combination. They rated utilitarian and hedonic capabilities and chose which product they would buy, in random order.

Participants expected higher performance for the minimalist (vs. complex) soap (F(1, 399)=119.43, p < .001), but lower pleasure for the minimalist (vs. complex) soap (F(1, 399)=243.18, p<.001). These expectations translated into choice: goal predicted product preference ($\chi^2(1$, N=401)=81.78, p<.001), such that a utilitarian goal made people more likely to choose the minimalist soap (80.1%) than the complex soap (19.9%; p<.001), but a hedonic goal fully reversed this preference pattern (minimalist: 35.5% vs. complex: 64.5%; p<.001).

Experiment 2B (*N*=400) extended this finding to consequential choice behavior (20% chance to win chosen product) and to a college sample. We used a real minimalist soap and created a complex counterpart in the same color scheme, labelling the two soap bottles with two real brand names (counterbalanced). Students happened to find the minimalist (vs. complex) soap more aesthetically appealing, which we control for in the analyses.

Participants again expected higher performance, but lower pleasure, for the minimalist (vs. complex) soap, which again shaped choice: goal predicted choice ($\chi^2(1$, N=363)=11.26, p=.001), such

that for a utilitarian goal people were more likely to choose the minimalist soap than the complex soap, but for a hedonic goal this preference significantly diminished (by roughly 20%), as signified by χ^2. Controlling for aesthetic appeal differences revealed an unsurprising positive effect of aesthetic appeal on choice, but more importantly, a persistent and *strengthened* effect of goal on choice (B=.82, SE=.25; p<.001; Exp(B)=2.27).

A replication with an adult sample who happened to find the complex soap more aesthetically appealing replicated these results and yielded the same crossover as Experiment 2A.

Experiment 3 (N=400) tested the proposed mechanisms driving the pattern of results, specifically, that minimalist design diminishes perceived arousal potential (which is known to be hedonically engaging, e.g., Kaplan et al. 1972) but boosts perceived focus on essentials (which we hypothesize enhances utilitarian value). Participants evaluated a nutritional breakfast shake whose packaging featured either a minimal or complex version of a geometric pattern.

Participants rated utilitarian (e.g., healthy) and hedonic (e.g., delicious) capabilities as well as how focused-on-essentials and how stimulating the product appeared. Participants expected higher performance for the minimalist (vs. complex) breakfast shake (F(1, 398)=13.06, p<.001), which was mediated by enhanced perceived focus-on-essentials (F(1, 398)=34.78, p<.001; B=.46, SE=.08, 95% CI [.32, .62]). They also expected lower pleasure for the minimalist (vs. complex) breakfast shake(F(1, 398)=39.42, p<.001), which was mediated by diminished perceived stimulation (F(1, 398)=44.04, p<.001; B=−.42, SE=.07, 95% CI [−.57, −.28]).

In sum, minimalist and complex visual aesthetics are beneficial in different contexts, depending on whether consumers seek functionality or fun. These insights advance our theoretical understanding of minimalist aesthetics and offer implications for branding.

SESSION OVERVIEW

A rise in global awareness and environmental concerns is evident in recent decades, leading consumers to buy fewer products that cannot be reused or recycled (Pew Research Center 2019). Nevertheless, prior research has identified a gap between consumers' purchase intentions of environmentally friendly products and actual purchases (Block et al. 2016; Brough et al. 2020; Tezer and Bodur 2020; White et al. 2019). This session brings together four papers that examine what hampers sustainable choices and identify consumers' beliefs about environmental consumption, in an aim to mitigate this gap. These research streams provide novel perspectives on sustainable consumption, involving well-powered and well-developed field, laboratory, and online experiments.

The first two papers investigate factors that potentially decrease sustainable consumption. In the first paper, **Goor and Zwebner** show that effort decreases the likelihood to choose environmentally friendly products over conventional products. They find that this preference arises because exerting effort makes consumers feel deserving and focused on self rather than on others.

In the second paper, **Lee and Winterich** investigate the "price entitlement effect," and show that upper-class consumers are more likely to purchase high-priced products that involve social costs but hold consumer benefits. This effect is driven by feelings of entitlement and is mitigated when consumers choose for others (vs. self).

The final two papers examine perceptions of environmentally friendly products. Further addressing price inferences of sustainable products, in the third paper, **Haltman and Donnelly** demonstrate a bidirectional green = expensive heuristic. They find that consumers perceive environmentally friendly products as expensive, and that perception holds even when products are sustainable by default but lack explicit green attributes.

Finally, in the fourth paper, **Guo and Lamberton** compare consumers' perceptions of sustainable processes and sustainable materials. They find that sustainable processes increase purchase interest compared to sustainable materials, as choosing the former products helps consumers envision a better future.

Taken together, these four papers highlight the importance of consumers' beliefs concerning sustainable consumption, and reveal potential antecedents that may hinder environmentally friendly behaviors. Thus, this session focuses on timely and compelling problems, develops useful theories, and offers pragmatic solutions that hopefully promote consumers' engagement in environmentally friendly consumption, addressing what the world needs now.

Effortlessly Green: When and Why Effort Impacts Environmentally Friendly Consumption

EXTENDED ABSTRACT

Choices between environmentally friendly products and conventional products are commonplace in consumers' lives (e.g., Mazar and Zhong 2010; Turdel 2019). In recent years, increasing global awareness and concerns about the environment have led to remarkable market growth of environmentally friendly products (BCG Report 2020). As a result, understanding the drivers of consumers' environmentally friendly choices is more important than ever. This work addresses a recent call for research on the antecedents of sustainable consumption (Trudel 2019) by demonstrating that consumers' effort may lower their preference for environmentally friendly products, producing what we call *the effortlessly green phenomenon*. Furthermore, we find that this effect arises because exerting effort makes consumers feel deserving and focused on the self rather than on others. This work contributes to consumer psychology literature that seeks to identify the drivers of environmentally friendly consumption (e.g., Ebeling and Lotz 2015; Irwin and Baron 2001; Luchs et al. 2010; Peloza et al. 2013), and to research that focuses on effort that has demonstrated its impact on consumers' decision making (e.g., Labroo and Kim 2009; Kivetz 2003; Luce et al. 1999; Schrift et al. 2011) but has yet to examine the impact of effort on consumers' deliberation between conventional and environmentally friendly options. Using a mixed-method approach, combining actual purchases on an e-commerce platform, field studies, and incentive-compatible lab studies, we show that high (vs. low) effort reduces consumers' preference for environmentally friendly products across consumption contexts and consumer populations.

A pilot study provides evidence for the effortlessly green phenomenon in a natural setting, using actual sales data from a large e-commerce website (which includes millions of transactions made during 10 months across the U.S.). As a proxy of effort we used time of day: A pre-test confirmed that consumers' effort was higher in the evening (7pm-11pm) compared to the morning (7am-11am; $p<.001$). As expected, effort was associated with a decline in environmentally friendly purchases ($p<.001$): In the evening (vs. morning) consumers were less likely to purchase environmentally friendly products ($M=0.033\%$ and $M=0.042\%$, respectively).

Study 1 was conducted at a fitness studio to examine the effect of physical effort on preferences for environmentally friendly products. Gym-goers who purchased a cold drink at the studio's cafeteria were given the choice of a conventional plastic straw or an environmentally friendly cornstarch straw. The straws were identical in quality, shape, and texture, and were placed in containers labelled "regular straws" and "ecological straws." For 16 summer days, a research assistant who was blind to the hypothesis documented 106 purchas-

ers of cold drinks who used a straw (50% of the purchases were made after a workout). Consumers showed a general preference for environmentally friendly straws (70.1% chose the ecological straw), yet, importantly, they were *less* likely to choose the environmentally friendly straw *after a workout* (56.6%) compared to before a workout (84.9%; χ^2=10.26, *p*=.001).

Study 2 tested the effect in a controlled lab setting using a cognitive effort task and an incentive compatible design. One-hundred and forty undergraduates read an act from Hamlet. In the high (vs. low) effort condition, they were given a difficult (vs. easy) task of identifying words in the text. As a token of appreciation, participants entered a raffle to win a water bottle of their choice: either an environmentally friendly water bottle or a leak-proof water bottle. Participants were less likely to choose the environmentally friendly product after exerting high effort (54.93%) compared to low effort (71.01%; χ^2=3.878, *p*=.049), supporting the effortlessly green conjecture.

In Study 3, we included a baseline (i.e., control) condition and explored the mediating role of sense of deservingness. Participants (*N*=581; Mturk) imagined that they were on their way home after an 8am-to-4pm workday. They were randomly assigned to one of three conditions. In the high (vs. low) effort condition, participants imagined they had a busy and effortful (vs. easy and relaxing) day. In the control condition, they had a typical day. Then, they indicated their preferences (on a scale from 1 to 7) for a ride home on a fuel train and a environmentally friendly electric train. The effect of effort on product preference was significant (*F*(2,578)=9.47, *p*<.001): high effort reduced participants' preference for the environmentally friendly train (*M*=3.11, *SD*=2.19) compared to low effort (*M*=4.06, *SD*=2.20, *p*<.001, *d*=.433) and control conditions (*M*=3.60, *SD*=2.18, *p*=.029, *d*=.23). Furthermore, low effort increased the likelihood of choosing the environmentally friendly train compared to the control condition (*p*=.043, *d*=.208). Importantly, the effect of effort on deservingness was significant (*F*(2,578)=17.77, *p*<.001): high-effort increased deservingness (*M*=4.80, *SD*=1.87) compared to low effort (*M*=3.70, *SD*=1.80, *p*<.001, *d*=.60) and control (*M*=4.20, *SD*=1.88, *p*=.002, *d*=.32). Low effort reduced sense of deservingness compared to the control condition (*p*=.008, *d*=.27). Sense of deservingness mediated the effect of effort on preference for environmentally friendly products (model 4 in PROCESS, Hayes 2013; *a×b*=-.33, *SE*=.06, 95%CI=[-.44,-.22]). Notably, the effect of effort on guilt was not significant (*F*(2,578)=1.34, *p*=.263) with no significant simple effects comparing each pair of conditions (*p*s>.105).

Finally, Study 4 demonstrated the egocentric nature of the underlying mechanism. Participants (*N*=402; Mturk) were randomly assigned to high (vs. low) effort conditions and imagined the same workday scenario as in Study 3. Then, they indicated their preferences for a ride home on a fuel train or an environmentally friendly electric train. A serial mediation analysis (model 6 in PROCESS, Hayes 2013) revealed that sense of deservingness increased self-focus (e.g., "focus on myself rather than on others"; "my own needs are more important than others' needs"), which, in turn, reduced the preference for environmentally friendly products (*a×b*=-.20, *SE*=.13, 95%CI=[-.11,-.03]). Sense of deservingness alone (95%CI=[-.01,.15]) as well as self-focus alone (95%CI=[-.10,.055]) did not mediate the effect of effort on environmentally friendly consumption, highlighting the unique egocentric nature of the mechanism underlying the effortlessly green phenomenon.

Our work is the first to demonstrate the implications of consumers' everyday effort on environmentally friendly product choices. The findings add useful insights to marketing theory and practice.

The Price Entitlement Effect: When and Why High Price Entitles Consumers to Purchase Socially Costly Products

EXTENDED ABSTRACT

Although many consumers indicate they prefer products offering social benefits such as green products (Haws, Winterich, and Naylor 2014), these consumer attitudes are not always reflected in purchases (Carrington, Neville, and Whitwell 2010). Consumers still purchase products with social costs such as non-green products when the products provide benefits such as convenience or performance (Luchs et al. 2010; Ottman et al. 2006). This research investigates who purchases products with consumer benefits but social costs, explicating when and why.

Oftentimes consumer benefits of socially costly products come at a higher price, due to higher costs of materials, production, and environmental harm (e.g., Schwepker Jr. and Cornwell 1991). Though both paying a higher price and social costs are general deterrents for product purchases, we demonstrate upper-class consumers are more likely to purchase a product with consumer benefits but social costs when it has a higher price, driven by feelings of entitlement, which we term 'the price entitlement effect'.

Entitlement refers to individuals' perceptions that they deserve better outcomes than others, which can be activated by situational factors (Campbell et al. 2004; Ding et al. 2017). We suggest that upper-class consumers will feel greater entitlement for the benefits from purchasing a socially costly product when the product price is perceived as higher than those of alternative options. Upper-class consumers are more likely to feel entitlement based on the higher price of a product due to the more prevalent exchange orientation (Berkowitz and Friedman 1967; Muir and Weinstein 1962) arising from their self-focused mindset (Kraus, Côté, and Keltner 2010).

Studies 1A-1C explored the proposed price entitlement effect in various contexts. Study 1A (two-group [price: same vs. higher] design) examined choice of convenient, but environmentally harmful plastic utensils. Participants imagined being at home ordering food for lunch. After participants selected the food items, they were asked to select any extra items they want. The first extra item was plastic utensils priced at either $.05 (same) or $.15 (higher) depending on the price condition. The second extra item was the salt and pepper in paper packets priced at $.05. A two-way interaction between price and social class (measured) on choice of plastic utensils revealed that when the price of plastic utensils was higher, social class increased choice, but when the price was same, social class did not affect choice. Also, for upper-class participants, choice was greater when the price was higher (vs. lower). As a comparison, choice of salt and pepper was not influenced by social class or price. Study 1B (two-group [price] design) examined products with other types of social costs (noise). After reading a news article about how noise from their home can bother their neighbors, participants considered two home exercise programs that varied in social costs (noise) and consumer benefits. The two-way interaction between price and measured social class indicated that social class increased choice of a more socially costly option when the price was higher than the other option ($15/$12), but this effect did not occur when the price was same ($15/$15). For upper-class participants, choice of the socially costly option was greater when the price was higher (vs. lower). Study 1C (2 [price] × 2 [social class] design) manipulated subjective social class and replicated the price entitlement in the choice between green versus non-green bathroom cleaner options.

Study 2 (two-group [price] design) examined actual product purchase. Participants received two dollars to spend on a purchase and considered two Purell hand sanitizer options, which varied in

environmental harm and consumer benefits, inferred from ad appeals highlighting greenness versus performance. The interaction between price and measured social class on choice was replicated: social class increased actual purchase of the unsustainable option only when it was higher-priced ($1.50/$2.00) (vs. same-priced; $1.50/$1.50), and price increased purchase of the unsustainable option by upper-class participants.

Study 3 (two-group [price] design) examined the mediating role of entitlement perceptions. After reading a news article making salient environmental cost of synthetic fabric, participants considered a shopping scenario involving a backpack made of synthetic fabric. The interaction effect of price (same vs. higher) and social class on purchase intention of the backpack was significant with a pattern identical to earlier studies. Importantly, the moderated mediation via entitlement was significant.

Study 4 identified necessary conditions for the effect in a 2 (salience of social cost) × 2 (salience of product benefits) between-subjects design. The positive effect of social class (measured) on purchase intention for a higher-priced product occurred only when the product involved salient social costs and consumer benefits but not in other conditions, suggesting that price entitlement by upper-class consumers occurs only when the product involves salient social costs and product benefits.

Finally, Study 5 examined a boundary condition for the price entitlement effect. Because entitlement is a self-focused process and not experienced on behalf of others, when consumers are considering what others should do, the price entitlement effect should be mitigated. As predicted, a three-way interaction between social class (measured), choice target (self vs. other), and price (same vs. higher) was significant on choice of socially costly option (home exercise context same as study 1B). The interaction of price and social class was significant only when consumers were making a choice for the self (vs. others).

Together, these findings demonstrate that social class increases the perceptions that a higher price entitles consumers to purchase a product that offers personal benefits but generates social costs. This price-entitlement effect is mitigated when consumers are induced to think what others should do, which reduce entitlement for personal benefits and lead consumers to purchase more socially beneficial products.

Cost of Sustainability: The Green = Expensive Heuristic

EXTENDED ABSTRACT

While sustainable products are marketed with the intention of attracting consumers who believe the product will be better for the environment, there's a growing body of work that's demonstrated a number of other potential inferences. For example, Luchs et al. (2010) showed that there can be consequences for sustainable attributes, wherein for certain product categories environmentally friendliness can actually signal inferior quality. On the other hand, recent work by Tezer & Bodur (2020) demonstrated that sustainable attributes can result in increased enjoyment of a consumption experience. Even still, beyond positive and negative attribute inferences, there's more nuance to consider. As Gershoff & Frels (2015) show, even the centrality of the green attribute itself can affect the resulting perceptions of how sustainable a product actually is.

With all of the work that's been dedicated to understanding sustainability appeals, it's surprising that there have been, to our knowledge, no papers on the topic of price inferences related to sustainability. This lack of empirical evidence is especially stark when considering that there's been a growing emphasis on understanding

the "attitude-behavior gap" of intentions for consumers to act sustainably, and the failure to follow through (White et al. 2019). Seeing as how price is often a driving factor in purchase decisions, it's an important consideration for marketers when deciding how to position their goods. Prior work has largely been built on the assumption that sustainable products are seen as more expensive by consumers, but has failed to consider the nuance of that sentiment. In the work that follows, we seek to address this gap.

Acknowledging that it's arguably an intuitive premise, that sustainable products command a premium, we extend our findings by also considering two previously unexplored Hypothesis related to this lay theory. First, we seek to demonstrate that the lay theory is bidirectional, and the explicit absence of ethical attributes leads to inferences of affordability. This is a particularly interesting consideration for marketers, as it's a technique that's not been traditionally used, and may be effective for price-conscious shoppers. Second, we demonstrate that neutral product labeling (i.e., labels without explicit ethical attributes) are viewed to be relatively sustainable, and therefore more expensive, by default.

To test for the existence of a green = expensive lay belief, two initial studies were run to demonstrate that, ceteris paribus, altering the perceived sustainability of a product alters price perceptions. The first of these studies used a box of disposable cutlery, which was either shown to have a sustainability grade of 'A' or a grade of 'C.' A manipulation check for perceived sustainability yielded a significant result, wherein the product with an 'A' grade was seen as significantly more sustainable than the product with the 'C' grade ($F(1, 197)=5.82, p<.001$). Further, the product with an 'A' grade was predicted to be significantly more expensive than the product with a 'C' grade ($F(1, 196)=9.68, p<.001$). We then ran the same manipulation with a different product to show that the effect is robust across product category, product type, and that the effect holds for both disposable and non-disposable items. The same experiment, run with picture frames, yielded consistent results; the 'A' rated product was seen as both significantly more sustainable, ($F(1, 154)=23.74, p<.001$) and was predicted to be significantly more expensive ($F(1, 154)=14.27, p<.001$).

Having demonstrated the existence of the lay theory, we turn our attention to our other proposed Hypothesis, regarding an unsustainable = affordable intuition, and a baseline assumption of sustainability for neutrally labeled products. For the former of these predictions, we designed an experiment to measure perceptions of a notebook that was either advertised as being sustainable (made from 100% recycled material), specifically unsustainable (made from 0% recycled material), or control (no information related to recycled material given). A one-way analysis of variance (ANOVA) run on the manipulation check of perceived sustainability yielded a significant difference between the three conditions ($F(2, 440)=207.86, p<.001$). A planned contrast post hoc comparison using a Bonferroni Correction indicated that the unsustainable 0% recycled notebook ($M=2.53, SD=2.01$) was seen as significantly less sustainable than the control notebook ($M=4.03, SD=1.11$), which was seen as significantly less sustainable than the 100% recycled notebook ($M=5.97, SD=1.03$). An ANOVA on price inferences also yielded a significant difference between conditions ($F(2, 440)=14.85, p<.001$). Supporting our hypothesis, planned contrast using a Bonferroni Correction showed that the unsustainable notebook ($M=3.68, SD=1.58$) was seen as significantly less expensive than the control notebook ($M=4.07, SD=1.18$), which was seen as significantly less expensive than the 100% recycled notebook ($M=4.58, SD=1.48$).

In order to elaborate on the results of the previous study, we designed an experiment to understand how the lack of any specifi-

cally provided sustainability information is perceived in comparison to products labeled as sustainable. Specifically, we used a between-subject design, and altered the environmental attributes of a computer monitor, described to have been made with 0%, 10%, 90%, or 100% renewable energy, or with no information given (control). An ANOVA run on price inferences ($F(4, 502)=24.92, p<.001$), and sustainability inferences ($F(2, 440)=148.93, p<.001$), both yielded significant differences between groups. A planned contrast post hoc comparison showed that, compared to the computer monitor that used 0% renewable energy ($M=2.55, SD=1.76$), the computer monitor without sustainability information given ($M=3.68, SD=1.07$) was seen as significantly more sustainable. The rest of the contrasts were also significant, except for the comparisons between the 90% monitor ($M=6.03, SD=.81$) and the 100% monitor ($M=5.71, SD=1.13$). Further, the computer monitor that used 0% renewable energy ($M=3.49, SD=1.38$) was seen as significantly more affordable than the one with no sustainability information given ($M=4.06, SD=1.17$). This provides support our other hypothesis that, without any sustainability information given, consumers infer that a neutral product is relatively environmentally friendly, and relatively more expensive as a result.

To our knowledge this is the first work to empirically demonstrate the sustainable = expensive lay belief, show that it is bidirectional, and show that even when not mentioned, products are seen as relatively sustainable and relatively more expensive by default.

Sustainable Processes vs. Materials: Which Matters, and Why?

EXTENDED ABSTRACT

Many brands consider sustainability an important product feature due to consumers' awareness of environmental impacts in their consumption (White, Habib, and Hardisty 2019). However, the nature of sustainability can vary: While prior research typically operationalizes sustainability as the amount and type of sustainable raw materials used in products (i.e., sustainable materials; Olson 2013; Winterich, Nenkov, and Gonzales 2019) it is also possible for firms to be sustainable by altering their energy usage or resource waste during the manufacturing process (i.e., sustainable processes; (Ljungberg 2007; Davim 2013). As both may involve substantial costs, offering clear guidance on the importance of these different aspects of sustainability matters (Luchs et al. 2010). Which matters most to consumers, and why? Is investing in both types of sustainability justified by potential increases in consumer preference?

Drawing on the construal level theory and temporal frame matching research (Trope and Liberman 2010; Pounders, Lee, and MacKert 2015; Spassova and Lee 2013), we argue that there is a natural temporal fit between sustainable processes (vs. materials) and long-term environmental benefits, making products with sustainable processes more appealing. Specifically, since sustainable materials are visible and tangible, they may lead to more concrete thoughts, and in turn, heightened short-term orientation. By contrast, sustainable processes are invisible and intangible, potentially leading to more abstract thoughts, and in turn, heightened long-term orientation (Goldsmith, Newman, and Dhar 2016). Therefore, because of the temporal (mis)match between sustainability features and environmental values, we predict that sustainable processes (vs. materials) will allow individuals to project more environmental values in the future. Envisioning a better future prompts consumers to feel more motivated to choose sustainable products (Winterich and Haws 2011).

In experiment 1, 369 Prolific participants (M_{age} = 36.50, M_{income} = \$67,082; 194 females) were randomly assigned to one of five conditions: control (without mentioning sustainability features), conventional ("100% virgin fiber and 100% conventional manufacturing process"), sustainable materials ("100% recycled fiber and 100% conventional manufacturing process"), sustainable processes ("100% virgin fiber and 100% eco-friendly manufacturing process"), and dual sustainability (i.e., both sustainable materials and processes). Participants indicated their purchase likelihood of a Gucci shirt on a two-item seven-point scale (i.e., "Overall, how likely would you be to buy this Gucci shirt?" "Overall, how much do you like this Gucci shirt?"; 1 = "Not at all" and 7 = "Very"; ρ = .78; Haws, Winterich, and Naylor 2014).

Results revealed a significant main effect of condition ($F(4, 364)$ = 7.86, p <.001). As expected, participants' product purchase likelihood was lower in the conventional materials (M = 3.69, SD = 1.85) versus control (M = 4.45, SD = 1.81, p = .05) condition, suggesting that making consumers aware of non-sustainable practices has an adverse effect. However, pairwise comparison showed that participants were more likely to purchase this Gucci shirt made with sustainable processes (M = 4.75, SD = 1.39) versus sustainable materials (M = 3.88, SD = 1.70; p = .02). Interestingly, the difference between sustainable processes and dual sustainability (M = 4.96, SD = 1.52) conditions were non-significant – sustainable processes alone seemed sufficient to boost purchase likelihood.

Experiment 2 replicated these findings using a dichotomous-choice dependent measure. Participants (N = 189 on Prolific, M_{age} = 34.86, M_{income} = \$94,772.75; 107 females) were randomly assigned to choose from one of three pairs of Patagonia fleeces: Pair 1 (conventional vs. sustainable materials), Pair 2 (conventional vs. sustainable processes), and Pair 3 (conventional vs. dual sustainability). Binomial tests revealed that more participants chose the sustainable versus the conventional option (Pair 1: $N_{conventional}$ = 21, $N_{materials}$ = 38, p = .04; Pair 2: $N_{conventional}$ = 4, $N_{processes}$ = 60, p < .001; Pair 3: $N_{conventional}$ = 11, N_{dual} = 55, p < .001). However, binary logistic regression results showed that sustainable processes (vs. materials) significantly increased the likelihood of choosing the sustainable product (Pairs 2 vs. 1: B = 2.12, SE = .58, Wald $\chi^2(1)$ = 13.13, p < .001; Pairs 3 vs. 1: B = 1.02, SE = .43, Wald $\chi^2(1)$ = 5.64, p = .02). Again, there was no benefit of dual sustainability over sustainable processes alone.

Experiment 3 replicated previous findings and tested the underlying process. Participants (N = 363, Prolific, M_{age} = 32.56, M_{income} = \$75,779.70; 202 females) were randomly assigned to one of four conditions: conventional, sustainable processes, sustainable materials, and dual sustainability. After indicating their purchase likelihood of an American Eagle Outfitters' hoodie in the same scale as Experiment 1, they completed the following potential mediation measures in randomized order: innovativeness (e.g., "This hoodie is highly innovative"), perceived luxuriousness (e.g., "This hoodie is a luxury/necessity for everyone"), future outlook (e.g., "The future seemed bright"), self-expressiveness (e.g., "This hoodie helps ascertain my self-identity"); adapted from Grewal, Mehta, and Kardes (2004). Again, participants were more likely to purchase the hoodie with sustainable processes (processes: M = 5.08, SD = 1.35; dual: M = 5.31, SD = 1.35; processes vs. dual: p = .30) versus sustainable materials (M = 4.38, SD = 1.51; ps < .01). Mediation analyses (PROCESS model 4) with all potential mediators simultaneously showed that the effect of sustainability feature on purchase likelihood was only mediated by individuals' future outlook (indirect effect$_{[processes\ vs.\ materials]}$ = 1.86, CI$_{20,000bootstrapped}$ = [.53, 3.63]; indirect effect$_{[dual\ vs.\ materials]}$ = 1.90, CI$_{20,000bootstrapped}$ = [.51, 3.74]).

Overall, we find that sustainable processes (vs. materials) make individuals feel more positive about the future, which leads to higher sustainable consumption tendency. We also find that adding sustainable materials to sustainable process has neither an additive nor multiplicative effect. Future research will attempt to further quantify the bonus that sustainable processes provide, such that firms may be able to determine the optimal investment in both – as well as the malleability of sustainability features in terms of their temporal nature.

SESSION OVERVIEW

Consumers often share consumption with others: for example, they order a shared platter with a colleague, watch a movie with a friend, and merge their bank accounts with a spouse. How does such consumption-sharing affect consumers' interpersonal relationships with their partners? Prior research examines how relational consequences affect people's decision-making in joint consumption decisions (Liu, Dallas, and Fitzsimons 2019; Simpson, Griskevicius and Rothman 2012). For instance, research has found that consumers trade off their own and partners' preferences to maintain relationships (e.g., Dzhogleva and Lamberton 2014; Etkin 2016; Wu, Moore and Fitzsimons 2019). Our four papers further examine relationship considerations in consumption sharing—in particular, we examine consumers' motivation to increase or reduce relationship closeness when they share consumption. Our first two papers examine how consumption sharing can increase relationship closeness (**Garcia-Rada and Kim; Olson, Rick, Small and Finkel**) when sharing an experience or a resource, and our final two papers examine how consumers avoid excessive relationship closeness when sharing a product or an experience (**Xue, Lin and du Plessis; Kwon and Liu**) in the context of friendships, romantic relationships, and work partnerships.

Garcia-Rada and Kim examine how sharing extraordinary experiences can help sustain the well-being of a close relationship. Across four experiments, they find that the perception of shared time scarcity increases consumers' preferences for extraordinary experiences, as consumers believe these experiences will strengthen relationships. **Olson and colleagues** examine how sharing a resource (i.e., merging bank accounts) can improve relationships in romantic relationships. Employing a long-term intervention, they show that newlywed couples assigned to merge finances fared better (greater relationship quality, financial harmony) as they transitioned to married life than those assigned to maintain separate accounts or to a no-intervention condition. As the first papers suggest that consumption sharing strengthens intimacy in relationships, the next papers

examine when this intimacy may be considered excessive, and how this affects co-consumption choice. **Xue, Lin and du Plessis** examine how male consumers avoid excessive relationship closeness when sharing oral consumption (e.g., food or drink) with other men. Because consumption sharing reflects relationship intimacy, men are concerned that sharing consumption with other men would violate heterosexual standards; they are thus less willing to share food or drink with same-gender partners than women. Finally, **Kwon and Liu** look at how consumers manage too much relational time together during experience sharing (e.g., going shopping or traveling to a city with a friend). Although consumers desire some amount of social time together, they find that people also desire some solitary time in shared social consumption experiences to ease social exhaustion in a relationship.

Our papers use diverse methodologies and theoretical perspectives to study how consumption sharing affects relationship closeness and relevant consumer behavior. Furthermore, our papers shed light on multiple domains of consumption sharing (product sharing, experience sharing, resource sharing) in a variety of relationship types (romantic couples, work colleagues, friends). Thus, each contributes uniquely to consumer research while offering practical implications for marketers and consumers. Our session should appeal to a broad audience at ACR.

Shared Time Scarcity and the Pursuit of Extraordinary Experiences

EXTENDED ABSTRACT

Time with partners, friends, and family is becoming increasingly scarce in this era when consumers often juggle many responsibilities. Situations such as having demanding work schedules, becoming new parents, and being in long-distance relationships are a few of many examples when consumers do not have *enough* time to engage in leisure activities with loved ones. What kind of shared experiences do consumers choose when they perceive their time with a relationship partner as scarce (versus abundant)?

We extend prior work on relationship maintenance strategies (e.g., Rusbult et al. 2001) to suggest that prioritizing extraordinary experiences when one perceives shared time as scarce is a behavioral relationship maintenance mechanism. Given that extraordinary experiences are perceived as more unusual (Bhattacharjee and Mogilner 2014), memorable (Zhang et al. 2014) and exciting (Aron et al. 2000), we predict that when consumers perceive their time with a relationship partner as scarce (versus abundant), they prioritize the extraordinariness of a shared activity over other factors such as convenience and quantity. This effect is driven by a person's belief that extraordinary experiences will help maintain the well-being of a close relationship. We test these predictions in four experiments.

Study 1 is a field experiment conducted on a social media platform to demonstrate the main effect: feelings of shared time scarcity led to preferring extraordinary experiences (AsPredicted.org # 24194). Using the platform's A/B testing feature, we randomly assigned Boston residents to seeing one of two ads—evoking time abundance or time scarcity with loved ones. The ads included a link to a blog post describing extraordinary experiences in Boston and the number of clicks served as our dependent measure. Our ad reached 25,148 users and had a total of 35,848 impressions. Most importantly, more people clicked on the ad when they felt that their time with

their loved ones was scarce (8.85%) versus abundant (7.50%; $\chi^2(1)$ = 15.26, $p < .001$).

Study 2 employs a writing task to manipulate perceptions of shared time scarcity and examines the psychological mechanism (AsPredicted.org # 47141). Participants currently in a romantic relationship ($N = 393$ Prolific Academic workers; 46% male; M_{age} = 35.35 years, $SD = 11.50$) were first asked to write about how the COVID-19 pandemic had reshaped their relationships and now they had more (*time abundant*) or less (*time scarce*) time to spend with their romantic partner. After, participants indicated the extent to which they thought it was important to select an extraordinary experience for an upcoming date with their partner (1 = Not at all; 7 = To a great extent); participants also indicated the extent to which they thought it was critical for the success of the relationship that they thought about their partner frequently (self-focused relationship maintenance motivation item) and that their partner thought about them frequently (partner-focused relationship maintenance motivation). Participants in the *time scarce* condition indicated that it would be more important to select an extraordinary experience for an upcoming date ($M = 4.70$, $SD = 1.70$) than those in *time abundant* condition ($M = 4.35$, $SD = 1.72$; $t(391) = 2.08$, $p = .038$). Importantly, a mediation model of the relationship between shared time and extraordinary experiences with both relationship maintenance motivation items as parallel mediators revealed a significant indirect effect through the partner-focused maintenance motivation item ($ab = 0.14$, SE = 0.07, 95% CI_{Boot} [0.02, 0.31]) but not through the self-focused one ($ab = 0.05$, SE = 0.06, 95% CI_{Boot} [-0.06, 0.17]).

Study 3 employs a consequential choice to demonstrate that when facing shared time scarcity, consumers prioritize the extraordinariness of the experience over its quantity. Participants ($N = 100$; 31% male; $M_{age} = 21.55$ years, $SD = 5.77$) who came to the university lab were first randomly paired with another participant and engaged in the relationship closeness induction task (Sedikides, Campbell, Reader, and Elliot 1999). Then, dyads were randomly assigned to one of two conditions: those in the *time abundant* condition were informed that they would have two more interactions with the same partner while those in the *time scarce* condition were informed that they would have only one more interaction with the same partner and a second interaction with a stranger. Participants chose between one gourmet chocolate (extraordinary experience) and two regular chocolates (ordinary experience) to share with their current partner during the next interaction. The percentage of participants choosing the extraordinary option was significantly higher in the *time scarce* condition (80%) than in the *time abundant* condition (63%; $B = 0.92$, $SE = 0.47$, *Wald* = 3.81, $p = .051$, $Exp(B) = 2.51$).

Study 4 involves a 2(shared time: abundant vs. scarce) x 2(relationship maintenance goal: weak vs. strong) between-subjects design to demonstrate that consumers prioritize extraordinariness over convenience when facing shared time scarcity (AsPredicted.org # 55725). Participants ($N = 799$ MTurkers; 47% male; M_{age} = 40.77 years, $SD = 13.10$) were shown information of two restaurants for an upcoming dinner with a colleague. They reported their preference by moving a 100-point sliding scale with end-points "definitely the convenient restaurant (i.e., place close to their work)" and "definitely the unique restaurant." Consistent with our relationship maintenance account, we find that relationship goal moderated the effect of shared time on choice of restaurant ($F(1, 795) = 6.30$, $p = .012$). In the strong relationship goal condition, participants in the shared time scarce condition preferred the unique restaurant ($M = 56.12$, $SD = 37.43$) more than participants in the shared time abundant condition ($M = 48.21$, $SD = 38.37$; $F(1, 795) = 4.71$, $p = .030$). In contrast,

in the weak relationship goal condition, there was no difference in participants' preference for the unique restaurant ($p = .171$).

In conclusion, we demonstrate that evoking shared time scarcity motivates consumers to seek out extraordinary experiences as a means to sustain the focal relationship. These findings advance our understanding of the antecedents of experiential choices in close relationships.

Common Cents: Merging Bank Accounts Preserves Marital Quality among Newlyweds

EXTENDED ABSTRACT

Are romantic partners better off keeping their money in separate accounts or pooling their money into a joint account? *A priori*, the answer is not obvious. On the one hand, pooling money might lead to uncomfortable revelations and contentious conversations. On the other hand, opening a joint account might help to cultivate a "communal" mindset among partners (e.g., by turning "your money" and "my money" into "our money"). Prior work suggests marriages are happier when characterized by stronger communal mindsets, even in the early stages of relationships (Clark et al. 2010). Some non-experimental research demonstrates a positive correlation between merging finances and relationship quality (Addo and Sassler 2010; Garbinsky, Gladstone, and Mogilner 2019; Kenney 2006; van Raaij, Antonides, and de Groot 2020), an intriguing association with ambiguous causality. Even with longitudinal elements, these studies retain ambiguity about whether joint accounts improve marital quality or whether happier couples are more likely to merge their financial lives.

As the first causal investigation of its kind, we conducted a longitudinal field experiment to examine the influence of banking arrangements over time. Specifically, we randomly assigned 230 engaged or newlywed couples to merge their finances in a joint bank account (Joint Condition), to keep their finances in separate accounts (Separate Condition), or to a condition where they received no banking instructions (No-Intervention Condition). We conducted six waves of data collection across the first two years of marriage; this time window is known as the *connubial crucible*, a critical period during which couples' relational dynamics "foreshadow their long-term marital fate" (Huston et al. 2001). Couples earned up to $250 ($125 per partner) for completing one intake survey and five follow-up surveys.

Across the three experimental conditions, we anticipated the greatest attrition in the Joint Condition because those couples were required to exert the most effort to comply with instructions; all couples entered the study with a separate account structure (i.e., an eligibility requirement unbeknownst to participants), so couples in the Joint Condition were the only ones required to deviate from the status quo. To address this asymmetry while still producing approximately equal numbers of participants across conditions, we randomized more participants to the Joint Condition. Specifically, for every seven couples, we randomly assigned three to the Joint Condition, two to the Separate Condition, and two to the No-Intervention Condition. In accord with expectations, 34% of couples in the Joint Condition, 12% in the Separate Condition, and 6% in the No-Intervention Condition failed to complete any follow-up surveys after the intake survey (i.e., couples lost to attrition). We revisit this (anticipated) selective attrition issue when discussing robustness checks below.

We preregistered key elements of our data-analytic plan on Open Science Framework (https://osf.io/ycem7/), where we also share complete model specification, example syntax, ancillary analyses, and robustness checks (https://osf.io/2m7sv/). Importantly, we

pre-registered guidelines for determining compliance with study instructions. We coded Joint and Separate Condition couples as having strictly complied with our instructions (i.e., they fully transitioned to joint account(s) in the Joint condition or fully remained with separate accounts in the Separate condition), liberally complied (e.g., opening a joint account but still using separate accounts in the Joint condition), or not complied. We used dyadic growth curve modeling (Kenny, Kashy, and Cook 2006) and multilevel conditional process modeling (Bauer, Preacher, and Gil 2006) to examine intervention effects on relationship quality (e.g., "My relationship with my partner makes me happy"; Funk and Rogge 2007) and financial harmony (e.g., "When it comes to our finances, my partner and I see eye-to-eye"; Rick, Small, and Finkel 2011) over two years.

The results provide clear evidence that couples randomly assigned to the Joint Condition fared better as they transitioned to married life. Namely, the trajectory for Joint couples was significantly more positive than the trajectory for either Separate or No-Intervention couples. Simple slopes analyses revealed that while couples in the No-Intervention and Separate Conditions exhibited significant declines in relationship quality over time (i.e., a pattern commonly observed in longitudinal studies of newlyweds' relationship satisfaction; Huston et al. 2001), couples in the Joint Condition did not. After two years, couples in the Joint Condition exhibited significantly greater relationship quality than couples in the other two conditions, which did not differ. Subsequent multilevel mediation analyses revealed that Joint couples experience relatively positive relationship outcomes, in part, due to increases in financial harmony over time.

We also performed a series of robustness checks to examine how sensitive our results are to different data-analytic decisions (e.g., potential sex differences; controlling for demographic covariates including income, age, race, and education; using liberal vs. strict compliance rules). We draw substantively similar conclusions across all checks. We also anticipated (and subsequently observed) the greatest attrition and non-compliance in the Joint Condition (i.e., these couples had to exert the greatest effort to comply with experimental instructions). In addition to oversampling this condition, we compared relationship quality and financial harmony at study entry across participant groups as a function of compliance. We observe no significant differences between Joint compliers and Joint non-compliers, Joint compliers and Separate compliers, or Joint compliers and Non-Intervention compliers. Collectively, our results suggest that, on average, merging finances helps couples preserve marital well-being as they transition to marriage.

Too Close for Comfort: The Adverse Role of Heterosexual Standards in Male Dyadic Consumption Sharing

EXTENDED ABSTRACT

Due to the rigidity of traditional male gender roles, self-identified men feel pressured to adhere to traditional gender norms (Bosson et al. 2005; Bosson and Michniewicz 2013; Brough et al. 2016). Although legal and social acceptance of LGBTQ+ rights has grown lately (King 2021; Masci et al. 2020), self-identified men may maintain an internalized traditional gender norm that "true" men should behave in ways that convey unambiguous heterosexuality (Herek 1986). We argue that, even if they do not endorse such norms, men (vs. women) feel uncomfortable showing intimacy with same-gender others because it violates heterosexual standards. As sharing consumption has been shown to reflect intimacy (Argo et al. 2008; Miller et al. 1998) and even romantic attraction (Alley et al. 2013), we hypothesize that self-identified men (vs. self-identified

women) believe that sharing consumption with same-gender others would violate heterosexual norms (due to its romantic connotations), leading them to avoid consumption sharing. We show how this adversely affects men's consumption choices, leading them to give up desirable options, choose less variety than they want, order bigger portions than needed, and pay a higher price to have their own individual consumption.

In study 1 (N=200 dyads), we tested the basic hypothesis in a field setting using a 2 (dyad gender: male vs. female) × 2 (tea option: one big bottle to share vs. two separate bottles) design, in which we asked dyads to choose between green tea and water. The green tea option was presented as either one big bottle to be shared or two separate bottles. Male dyads chose green tea less often when it had to be shared (28.00%) than when it did not (62.00%), B=−1.43, SE=.43, $p<.001$. However, female dyads did not differ in the green tea choice between the shared (39.22%) and separate condition (48.98%), B=−.40, SE=.40, $p=.326$; $B_{interaction}=−.26$, SE=.15, $p=.079$.

Study 2 (N=401) used a 2 (participant gender: male vs. female) × 2 (dyad gender composition: same- vs. opposite-gender) design to test whether men are less willing to share with other men (rather than simply other people). Participants imagined dining with a same or opposite gender friend and indicated how likely they would be to propose splitting two desirable dishes rather than picking one for themselves. Men were less likely to suggest sharing ($M=2.40$) than women ($M=3.20$) when dining with same-gender partners, $t(397)=−4.30$, $p<.001$; this did not occur for opposite-gender partners ($M_{male}=2.75$, $M_{female}=2.74$), $t(397)=.05$, $p=.958$; $t_{interaction}(397)=−3.06$, $p=.002$. Furthermore, anticipated heterosexual norm violation mediated the effect of participant gender on sharing for same-gender pairs, $CI_{95}=[−.963, −.500]$, but not for opposite-gender pairs, $CI_{95}=[−.296, .130]$, moderated mediation $CI_{95}=[−.949, −.344]$.

Study 3 (N=400) (pre-registered) used a mixed-subject design to test whether men's aversion to consumption sharing is internally endorsed—that is, if they believe they should avoid sharing consumption. Participants indicated how much they think they should share and how much they actually would share a dish that is too big with a same-gender friend. Men believe they should share ($M=3.54$) more than they actually would share ($M=3.25$), $t(398)=3.70$, $p<.001$, and as much as women believe they should share ($M=3.70$), $t(398)=−1.29$, $p=.199$. Women, on the other hand, did not display a difference in their belief about what they should do ($M=3.70$) and what they would actually do ($M=3.73$), $t(398)=.32$, $p=.750$; $t_{interaction}(398)=−2.84$, $p=.005$. This suggests that although men realize that adhering to this gender norm of not sharing consumption with other men is undesirable, they may still be uncomfortable violating such gender norms.

Studies 4a (N=990) and 4b (N=1177) (both pre-registered) examined the moderating role of situation romanticness, further testing the role of anticipated heterosexual norm violation. In study 4a, participants imagined dining with one (romantic condition) or two (unromantic condition) same-gender friend(s), and indicated how likely they would be to suggest sharing appetizers rather than ordering one for themselves. Men were less likely to share with one man ($M=3.72$) than two men ($M=3.96$), $t(986)=−2.60$, $p=.010$; however, women did not show this effect ($M_{one}=4.34$, $M_{two}=4.31$), $t(986)=.40$, $p=.692$; $t_{interaction}(986)=−2.12$, $p=.034$. Anticipated heterosexual norm violation mediated the effect of the number of dining partners on sharing for men $CI_{95}=[−.273, −.030]$, but not women $CI_{95}=[−.065, .080]$, moderated mediation $CI_{95}=[−.301, −.016]$.

In study 4b, participants chose between sharing a dish (either with or without romantic connotation) with a same-gender partner, or ordering a half portion at a per-volume price mark-up for them-

selves. Men were less likely to share the romantic dish [chocolate-covered strawberries] (M=3.90) than the unromantic dish [fries] (M=4.09), t(1173)=−2.08, p=.038; however, women did not show this effect ($M_{romantic}$=4.48, $M_{unromantic}$=4.34), t(1173)=1.78, p=.075; $t_{interaction}$(1173)=−2.74, p=.006. Anticipated heterosexual norm violation mediated the effect of food romanticness on sharing for men CI_{95}=[.181, .440], but not women CI_{95}=[−.012, .110], moderated mediation CI_{95}=[.122, .400].

Study 5 (N=120 dyads) tested a theoretical extension that if forced to share consumption, men would do so in a way to avoid further intimacy. We predicted that men would avoid exchanging bodily essence (i.e., saliva) when sharing food, which has been shown to further levels of intimacy (Alley 2012; Rozin et al. 1995). We asked dyads in-lab to share and finish an individual sticky snack by both biting out of it. Male dyads (vs. female dyads) felt that sharing the snack by both biting out of it would violate heterosexual standards (M_{male}=3.24; M_{female}=2.47), t(118)=3.26, p=.001, leading men to avoid contamination (e.g., by tearing the snack with their hands) marginally more (26.53%) than women (14.08%), B=.79, SE=.47, p=.093. Anticipated heterosexual norm violation mediated the gender effect on contamination avoidance, CI_{95}=[.030, .220].

Practically, our research underscores important consumer behavioral and well-being consequences of the pressure to adhere to heterosexual standards in male consumers. Theoretically, our research contributes to a broader understanding of gender roles in consumer behavior (Brough et al. 2016; Dzhogleva and Lamberton 2014; Gorlin and Dhar 2012; Liu et al. 2019, 2020; Nikolova and Lamberton 2016) by examining *when* consumers prefer to share a product over consuming individually.

Shared-Solitary Combined Experiences: The Desire for Some Solitary Time in Social Consumption Experiences

EXTENDED ABSTRACT

Hedonic consumption experiences are often shared with close others. Indeed, much research has compared shared experiences with solitary experiences, showing that shared experiences amplify enjoyment of hedonic consumption activities and are thus often preferred to solitary experiences (Caprariello and Reis 2013; Raghunathan and Corfman 2006; Ramanathan and McGill 2007; Ratner and Hamilton 2015). The present research asks: how can marketers and consumers structure optimal social experiences? In particular, does consumers' robust preference for shared experiences for hedonic consumption activities always persist?

We propose that as the actual or perceived duration of experience increases, consumers' default preference for entirely shared experiences reduces in favor of "shared-solitary combined experiences"—experiences wherein some time is spent with others and some time is spent solitarily. We further propose that this shift occurs because of a desire to mitigate anticipated social fatigue.

We focus on experiences for which entirely shared experiences are often normative: hedonic consumption experiences occurring within typical reasonable durations for spending entirely with a friend (i.e., less than one day), such as a shopping trip at the mall or a trip to a city. We report six experiments (all pre-registered).

Experiment 1 (N=572) had a 2(duration: short vs. long)×2(choice set: "shared vs. combined" vs. "shared vs. solitary") between-subjects design. Participants imagined making plans for relatively short (2-hour) versus long (6-hour) mall shopping experiences with a friend and indicated their preferred experience type, either between shared versus solitary experiences or between shared versus combined experiences, where combined experiences would

have equal proportions of shared and solitary time. Analysis revealed a significant interaction (p=.040). In the "shared vs. solitary" choice set condition, choice shares did not differ between the duration conditions (short$_{shared}$:88% vs. long$_{shared}$:87%; p=.875). By contrast, in the "shared vs. combined" choice set condition, choice shares differed between the duration conditions (p<.001). Preference for shared experiences reduced in favor of combined experiences as duration increased (short$_{shared}$:83% vs. long$_{shared}$:64%). Experiment 2 (N=631) further tested the role of duration but examined preferences from a choice set with all three types of experiences (shared, combined, solitary). Again, the choice shares of experience types differed between the short versus long duration conditions (p<.001). Choice of shared experiences decreased as duration of experiences increased (short$_{shared}$:77% vs. long$_{shared}$:65%), shifting towards combined experiences (short$_{combined}$:17% vs. long$_{combined}$:32%). Choice of solitary experiences was relatively low (short$_{solitary}$:6% vs. long$_{solitary}$:3%).

Experiment 3 (N=224) tested the underlying role of anticipated social fatigue and the generalizability of the effect to a different context: traveling to a city with a friend. Participants wrote about making plans for a trip that would last either a short (2-hour) or long (8-hour) duration. They then chose their preferred experience type between three options (shared, combined, solitary). Next, participants indicated their motive to address anticipated social fatigue (3-item; α=.67). As pre-registered, we focused on comparing the choice of shared versus combined experiences to simplify analysis (as few participants ever chose the solitary experience). Generalizing the key effect to this different hedonic consumption context, preference for shared experiences reduced in favor of combined experiences as duration of experience increased (short$_{shared}$:94% vs. long$_{shared}$:72%; p<.001). This shift was mediated by heightened motives to address anticipated social fatigue for long (vs. short) experiences (95%CI[-.65,-.09]). An alternative account based on the motive to address variety-seeking was not supported (95%CI[-.19,.22]).

Experiment 4 (N=604) used a consequential choice task where participants chose which trip agenda to receive. Rather than manipulate actual experience duration, we held experience duration constant and framed a particular length of time (eight hours) as short or long, addressing the alternative explanation that constraints associated with budgeting specific time periods account for the effects. Participants were first randomly assigned to write about how eight hours is either a short or a long amount of time to spend with a friend. They then considered making plans for either a short or long 8-hour trip with a friend to a nearby city and chose between three travel agendas: an agenda containing activities to do with a friend (shared experience), an agenda containing activities to do by themselves (solitary experience), or an agenda containing some activities to do with a friend and some activities to do by themselves (combined experience). Participants received their chosen agenda. Results (focusing on comparing the choice of shared vs. combined experiences; pre-registered), showed that when the duration was long (vs. short), preferences for an agenda shifted from shared experiences towards combined experiences (short$_{shared}$:80% vs. long$_{shared}$:67%; p<.001). The shift was again mediated by higher motives to address anticipated social fatigue (95%CI[-.19,.22]).

Experiments 5a (N=211, undergraduate lab sample) and 5b (N=606; online panel sample) had a similar manipulation as experiment 4. However, rather than a 3-option choice set, participants chose their preferred agenda type for their social trip (8-hour) from a 5-option choice set. We systematically varied the proportions of shared-solitary time elements, such that the choice set included two additional agendas featuring variants of combined experiences: combined experiences with relatively more shared time (shared

6-hour+solitary 2-hour) and combined experiences with relatively more solitary time (shared 2-hour+solitary 6-hour). Results of experiments 5a-5b revealed that choice of agenda for shared experiences decreased as the duration increased (short$_{5a}$:68% vs. long$_{5a}$:50%; p_{5a}=.007; short$_{5b}$:67% vs. long$_{5b}$:39%; p_{5b}<.001), shifting towards combined experiences with a relatively larger proportion of shared time (short$_{5a}$:25% vs. long$_{5a}$:37%; p_{5a}=.075; short$_{5b}$:23% vs. long$_{5b}$:29%; p_{5b}=.109) or combined experiences with equal proportions of shared and solitary time (short$_{5a}$:5% vs. long$_{5a}$:12%; p_{5a}=.064; short$_{5b}$:7% vs. long$_{5b}$:24%; p_{5b}<.001). Few participants opted for combined experiences with a relatively larger proportion of solitary time (0%-6%) or for solitary experiences (1%-2%). Altogether, these findings suggest that consumers viewed the trip as primarily social experience—into which they would like to incorporate some (no more than half) solitary time.

Overall, this research proposes and systematically examines a novel experience structure—shared-solitary combined experiences—diverging from prior work focusing on entirely social or entirely solitary experiences. This work identifies how to structure optimal social experiences by demonstrating that consumers view combined experiences as a potential solution for enjoying social experiences while relieving potential social fatigue.

SESSION OVERVIEW

Words have tremendous power. The world has witnessed how words can either harm and divide, or heal and unite. What brands say (and when they say it), can have a major impact on how consumers perceive their brands. For instance, while some brands have expressed support this year for issues such as racism, COVID-19 vaccinations, and climate change, others have stayed silent or provided opposing views. In line with the conference theme, *What the World Needs Now*, this session offers novel insights into how language impacts brand perceptions.

If the CDC is planning a communications campaign to encourage the public to receive COVID-19 vaccines, this session could offer insights for more effective communication. First, the message source matters (Pyrah and Wang). If the message comes from the CDC directly, it would be more effective if it avoids using informal language such as slang, because the audience expects formality and authority in messages from brands and institutions. However, the CDC can also encourage the public to share their vaccination experiences on social media. In such social media posts, the use of informal language, such as slang, may help people connect with each other. Second, if the CDC plans to use user-generated content in social media to help convince individuals to get vaccinated, then it may consider using moderately typical influencers (i.e., moderately typical brand consumers), because the public will consider all vaccinated people as more similar (i.e., homogenous) when the influencers are not too typical or too atypical (Junqué de Fortuny and Lee). When analyzing online chatter about related topics, the CDC can also examine and suggest influencers to increase the use of unfamiliar words if their posts are negative (Li and Kronrod). Last but not least, stereotypical perceptions about countries can help new brand names acquire instant brand personality. Whereas Pfizer has a foreign sounding brand name (German) and may hence inherit particular personality traits

associated with the country of origin (e.g., rigorous, love of order), Moderna may elicit other country-of-origin associations.

This set of papers opens new avenues of research on how consumer linguistics impacts brands. Overall, these papers offer insights into distinct aspects of language (the use of slang, a holistic view of influencer content, the familiarity of words, and the sounding of brand names) and its impact on consumer perceptions of brands and their messages. Due to the increasing importance of branding and the burgeoning work on consumer linguistics, this session is likely to have a broad appeal to the ACR audience and attract researchers interested in branding, consumer linguistics, and word-of-mouth. More importantly, this session answers the important call of the conference theme, *What the World Needs Now,* with language and brand perceptions being at the forefront of many issues around the globe. The papers represent an advanced stage of completion and offer a multimethod approach. Overall, they comprise 13 studies employing text analysis of online content, a large-scale survey, and experiments. We anticipate that this session will provide novel insights and spark important questions.

Brands that Use Bae: Does Slang Help Brands?

EXTENDED ABSTRACT

Firms often employ slang in their marketing messages, such as Mountain Dew ("Mountain Dew is the bae") and Burger King ("This whopper bruh"), to connect with their target customers (Aaker, Brumbaugh, and Grier 2000), However, the impact of slang on persuasive messaging is unclear. We theorize and show that the use of slang by brands violates consumers' expectations, ultimately harming brand attitudes.

Slang refers to a fluid set of words and phrases that individuals use to establish social identity, cohesiveness with a group, or with a trend or fashion in society (Eble 1996). Two defining characteristics of slang are its informality and sociability. Slang moves discourse in the direction of informality (Dumas and Lighter 1978; Moore 2014), and is socially motivated, to establish one's social identity (Eble 1996) or form camaraderie (Kiesling 2004).

We propose that slang in marketing messages affects brand attitudes in different ways depending on the source of the messages—sent by brands or fellow consumers. In brand messages, consumers desire formality and professionalism (Bullard and Snizek 1988), and when these qualities of formality fall short, perceptions of brand quality diminish (Ofir and Simonson 2001). Additionally, the use of slang assumes a particular familiarity between communicators (Dumas and Lighter 1978), and overly friendly behaviors by unfamiliar others can be met with skepticism by consumers (Main, Dahl, and Darke 2007; Sela, Wheeler, and Sarial-Abi 2012). On the other hand, consumer messages are informal in nature (Westbrook 1987) and socially motivated (Dubois, Bonezzi, and De Angelis 2016; Syn and Oh 2015), matching both the informality and sociability characteristics of slang. Thus, we propose that the use of slang will be inappropriate in brand messages, leading to less favorable brand attitudes. However, the use of slang in consumer messages should be more acceptable.

We test our Hypothesis across 5 studies. In study 1, we showed that in brand messages, the use of slang (versus not) leads to less favorable brand attitudes. Undergraduate students (N = 301) viewed

a tweet that either contained slang or not (slang words validated in a pre-test). Participants reported less favorable attitudes in response to the tweet with slang ($M = 3.82$) than when the tweet did not contain slang ($M = 4.39$; $p < .001$).

In study 2, we tested the interaction effect of slang use and slang source on brand attitudes. Undergraduate students (N = 180) were randomly assigned to a 2 (slang use: present vs. absent) x 2 (message source: brand vs. consumer) between-subjects design. Participants read a product review that either contained slang or not and that was sent from either a brand or a consumer. After reading the review, they reported their brand attitudes. A significant interaction ($p < .05$) revealed that when the message source was a brand, the use of slang lead to less favorable attitudes ($M_{present} = 4.16$, $M_{absent} = 5.25$, $p < .001$). When the message source was a consumer, there was no difference in attitudes ($M_{present} = 4.88$, $M_{absent} = 5.23$, $p > .18$).

In study 3, we sought to extend our results to real purchase behavior. Community members (N = 102; recruitment was halted because of COVID-19 health concerns) were recruited and assigned to the same design as used in study 2. Participants viewed a product description about ChapStick and had a chance to purchase lip balms with their own money. Participants bought fewer lip balms when brand messages used (vs. didn't use) slang ($M_{present} = .48$, $M_{absent} = 1.00$; $p < .034$). Such difference was not found when the message source was a consumer ($M_{present} = .46$, $M_{absent} = .22$; $p > .15$).

In study 4, we tested our mediator through expectancy violations. MTurk participants (N = 503) were randomly assigned to the same 2 (slang use: present vs. absent) x 2 (message source: brand vs. consumer) between-subjects design. After reading a tweet, participants reported their brand attitudes and expectancy violations (adapted from Bettencourt et al. 1997) in a counterbalanced order. A significant interaction ($p < .05$) revealed that the use of slang by a brand negatively impacted brand attitudes ($M_{present} = 5.24$, $M_{absent} = 5.67$, $p = .003$), but there was no difference when the source was a consumer ($M_{present} = 5.86$, $M_{absent} = 5.91$, $p > .8$). The same pattern of results emerged for expectancy violations. As predicted, expectancy violations mediated the relationship of slang use and slang source on brand attitudes (95% CI [-.38, -.13]).

To pinpoint expectancy violations as the mediator, we tested our process with a moderation approach (Spencer, Zanna, and Fong 2005) in study 5. Consumers have different expectations for brands with certain personalities (Aaker, Fournier, and Brasel 2004). The use of slang is congruent with the traits of *exciting* brands (daring, spirited, up-to-date), but incongruent with the traits of *sincere* brands (honest wholesome, and warm; Aaker 1997). Therefore, the use of slang should be more (less) appropriate for brands with an exciting (sincere) personality. Undergraduate students (N = 285) were randomly assigned to a 2 (slang use: present vs. absent) x 3 (brand personality: exciting vs. sincere vs. control) between-subjects design. We manipulated brand personality following previous researchers (Aaker et al. 2004; results from a pre-test confirm a successful manipulation). Participants viewed a brand's social media post and reported their brand attitudes. A significant interaction ($p < .05$) revealed that the use of slang negatively impacted attitudes for the control brand ($M_{present} = 3.58$, $M_{absent} = 4.85$, $p < .001$) and the sincere brand ($M_{present} = 3.60$, $M_{absent} = 4.25$, $p = .027$). However, as predicted, for the exciting brand, there was no difference in attitudes ($M_{present} = 3.87$, $M_{absent} = 4.09$, $p > .44$).

Overall, we find that the use of slang by brands violates consumers' expectations and, hence, harms attitudes. However, because expectations for consumer messages differ, the use of slang is more acceptable in consumer messages. Unless a brand has a particular

personality (i.e., exciting) that aligns with the use of slang, this research serves as an important caution against its use by brands.

Influencer Typicality and Brand Reference Group Associations

EXTENDED ABSTRACT

A wealth of research (e.g. Bearden and Etzel 1982, Escalas and Bettman 2005, Berger and Heath 2007, White, Argo and Sengupta, 2012) has explored how reference group associations can influence consumer behavior. However, less is known about how cultural meanings are transferred to brands (e.g. how brands gain reference group associations, e.g. Batra 2019). Given the development of an economy of consumer influencers (Khamis, Ang, and Welling 2017; Marwick 2015; Senft 2013) and the digital "megaphones" (McQuarrie, Miller, and Phillips 2013) that consumers now enjoy in social media, the potential for the creation of reference group associations has never been greater. In this project, we explore how influencers might transfer reference group meanings to brands, by analyzing consumer descriptions of brands after exposure to influencer content.

We leverage research on stereotype change (Hewstone and Hamberger 2000; Maurer et al. 1995) to predict how influencer content can strengthen or change the meanings associated with a brand. An important variable affecting stereotype change is the *perceived typicality* of the person relative to their group (Weber and Crocker 1983). While prototypical individuals strengthen existing stereotypes (e.g. a football player who is dumb), atypical individuals may be able to change stereotypes (e.g. a football player who is a smart). Furthermore, highly atypical individuals (e.g. a football player who is a Rhodes Scholar) can lead to "subtyping," whereby they are seen as "exceptions to the rule" and may even strengthen pre-existing associations about a group (Taylor 1981). As brand reference group associations have also been described in terms of stereotyping (Grubb and Hupp 1968; Levy 1959; Sirgy 1982), we extend insights from the stereotype change literature to the topic of branding, reference groups and social media.

We designed a survey inspired by Tucker (2015), constructing a set of 125 Instagram posts published by social media influencers (averaging 150,000 Instagram followers) about one of 25 major brands. The set of posts was constructed from a major influencer networking site, and we selected the top five posts per brand (averaging 5,000 likes) based on number of likes per post. After participants viewed a post[1], we asked them to provide five nouns and five adjectives describing the type of person who wears the brand. Subsequently, for each text entry provided, we asked participants to indicate whether the word or phrase was characteristic of people who wear the brand (1 = Very uncharacteristic, 7 = Very characteristic) to capture reference group "association strength". To capture the perceived typicality of the influencer, we asked participants whether the influencer in the post was typical of someone who wears the brand (1 = Highly atypical, 7 = Highly typical). Finally, to explore the perceptions held regarding the homogeneity of a brand's consumers, we asked "how similar to each other are people who wear this brand" (1 = Extremely dissimilar, 7 = Extremely similar). All items were adapted from the stereotype change literature.

We found that influencer typicality is associated with a brand's perceived homogeneity ($\beta = .082$, $t = 4.78$, $p < .001$), and that this relationship is actually quadratic ($\beta = .074$, $t = 9.31$, $p < .001$). Second, we found that typicality is associated with reference group associa-

---

1   Note that a subset of our participants did not view influencer posts and served as a baseline condition upon which we could compare main survey participants' responses

tion strength (β = .083, t = 6.48, p < .001), and that this relationship is also quadratic (β = .043, t = 7.39, p < .001). Using Hayes' MEDCURVE, we found evidence of curvilinear mediation. The linear effect of typicality on perceived homogeneity was significant (β = .083, t = 4.77, p < .001), as was the quadratic effect (β = .074, t = 9.31, p < .001). Also, the effect of perceived homogeneity on association strength was significant (β = .149, t = 10.65, p < .001). Yet typicality remained significant on both linear (β = .071, t = 5.61, p < .001) and quadratic effects (β = .032, t = 5.54, p < .001) after accounting for the intervening role of perceived homogeneity.

We considered the text responses provided by our participants. For each participant, we computed two measures capturing the tightness of reference group associations: the degree of differences among a participant's responses (termed "embedding variation"), and the number of reference group categories mentioned by the participant. These measures were constructed by associating each participant's individual words or phrases with a unique ConceptNet word embedding vector (Speer, Chin and Havasi 2018). For the second measure, we employed a Weighted Dirichlet Process Gaussian Mixture Model to link each response to one of 100 overarching reference group clusters, and we took a greater number of clusters mentioned to reflect a more diverse set of brand associations held by the participant. By employing Hayes (2017) PROCESS Model 6 in two separate exercises, we found that typical influencers generated greater perceptions of homogeneity, which increased participants' strength of reference group associations and ultimately reduced participants' embedding variation (effect = -.0013, SE = .0004, LLCI = -.0020, ULCI = -.0006) and the number of clusters participants described for the brand (effect = -.0054, SE = .0022, LLCI = -.0098, ULCI = -.0013).

Overall, these findings suggest that when influencers post on social media, their perceived typicality for the brand can shift the perceived homogeneity of a brand's consumers, strengthening or changing the groups that come to mind for the brand. Furthermore, at certain levels of atypicality, influencers may begin to lose their ability to increase perceived homogeneity and weaken reference group associations. Finally, a word embedding analysis revealed that typical influencers can tighten brand associations by increasing the likelihood that participants will think of brand descriptors that are both more similar and representative of fewer reference group categories. In short, this work bridges cultural theories in consumer research (e.g. McCracken 1989), insights on stereotype change, and novel methods in computer science, to better characterize the effects of influencer content on brand reference group associations.

The Role of Word Familiarity in Positive and Negative WOM

EXTENDED ABSTRACT

Word of Mouth (WOM) has a significant influence on product evaluations and purchase decisions (Park, Lee, and Han 2007; Trusov, Bucklin, and Pauwels 2009; Mauri and Minazzi 2013). Extending current research, we focus on the influence of word familiarity on these processes.

As language is developing, novel, unfamiliar words keep emerging and appearing in WOM. Therefore, it is important to understand the role of word familiarity in the effect of WOM. Familiarity is defined as knowledge regarding something/someone following previous encounters with that something/someone (Bridger, Bader, and Mecklinger 2014; Zajonc 1968). On the one hand, familiarity leads to positive attitudes and liking because of the pleasure with the familiar (Zajonc 1968, 1980; Alter and Oppenheimer 2008; Garcia-Marques, et al. 2010). On the other hand, excessive familiarity elicits boredom and disliking (Kronrod and Lowrey 2016), while unfamiliarity can increase the feeling of interest and novelty (Kashdan and Silvia 2009; Turner and Silvia 2006). Extended to language, these mixed results beg the question: how will familiar and unfamiliar language in WOM influence readers?

Importantly, WOM can be positive or negative. Previous research suggested that linguistic familiarity has a different effect within positive and negative contexts (Kronrod and Lowrey 2016). We build our predictions relying on this notion and on the finding that when processing negative information, people are more diagnostic and attentive (Lee, Park, and Han, 2008; Homer and Yoon 1992; Maheswaran and Meyers-Levy, 1990), and tend to collect and expect new information (Noguchi, Gohm, and Dalsky, 2006). In contrast, in positive contexts, people tend to use heuristic processing and more holistic top-down thinking (Bless, 2001; Erber and Erber, 2001; Fiedler, 2001). In other words, people in negative situations are more likely to be in an information seeking mindset, compared with positive contexts.

Based on the differences in mindset between positive and negative contexts, we predict that unfamiliar words have a replenishing effect on attitudes when processing negative WOM, because these words fit with consumers' diagnostic and detail-oriented processing of information, and their information-seeking mindset. However in positive WOM, these effects are attenuated. Thus, we predict that word familiarity interacts with WOM valence, such that:

Hypothesis 1: *unfamiliar words in negative WOM lead to higher attitudes and purchase intention, compared with familiar words. In positive WOM this effect is attenuated.*

Mediation of information seeking mindset. In this work we also investigate information seeking mindset as a potential underlying mechanism. Prior literature showed that unfamiliar words are viewed as novel stimuli (Kashdan and Silvia 2009; Turner and Silvia 2006), and that novel stimuli are consistent with states of seeking novel information (Berlyne, 1954, Loewenstein, 1994). Thus, we suggest that the reason that unfamiliar words replenish the effect of negative WOM on attitudes is that they are consistent with the increased information seeking mindset in these contexts. Formally,

Hypothesis2: *Information Seeking mindset mediates the interaction effect of word familiarity and WOM valence on attitudes.*

We test our Hypothesis across four studies that examined the effect of word familiarity on consumer decisions in positive and negative WOM. **Study 1** is a text analysis of a thousand online Amazon reviews for various products obtained from an online source available for academic use. We found a significant interaction between word familiarity and WOM valence ($p = .046$), such that for negative reviews, unfamiliar words increase helpfulness ratings ($M_{unfamiliar} = 4.84$, $M_{familiar} = 2.79$, $p = .001$), whereas for positive reviews, word familiarity does not matter ($M_{unfamiliar} = .98$, $M_{familiar} = .70$, $p = .66$). In **Study 2a**, participants read an online product review for a backpack which used familiar (e.g., bright, weak) or unfamiliar (e.g., glistening, frangible) words, and indicated purchase intentions. Supporting H1, we found that unfamiliar words in negative WOM lead to higher purchase intention ($M_{unfamiliar} = 2.67$, $M_{familiar} = 2.03$, $p = .039$). However, the effect of word familiarity was not significant in positive WOM ($M_{unfamiliar} = 4.03$, $M_{familiar} = 4.13$, $p = .75$). **Study 2b** replicated this interaction effect with a different product (a film) and WOM type (a tweet). In negative WOM, unfamiliar words lead to

higher purchase intention ($M_{unfamiliar}$ = 3.76, $M_{familiar}$ = 2.96, p < .001), whereas this effect is not significant in positive WOM ($M_{unfamiliar}$ = 4.61, $M_{familiar}$ = 4.35, p = 0.19). **Study 3** tested the interaction effect with a different product (a jacket), and also tested the potential mediator of seeking more information. Supporting H2, the moderated mediation analysis showed that seeking information mediates the interaction effect of word familiarity and WOM valence on purchase intentions (B = .2832, SE = .0791, 95% CI: [.1373, .4536]). We also explored attitude certainty as the potential mediator, and the results showed that in positive WOM, unfamiliar words significantly reduce attitude certainty ($M_{unfamiliar}$ = 4.34, $M_{familiar}$ = 4.80, p < .000), which is consistent with our theory.

This research extends the literature on the way WOM influences consumer decisions, as well as the research on familiarity, by analyzing the different effects of word familiarity in positive and negative WOM. Using valence as a moderator contributes to our understanding of the way WOM aspects can have a different effect depending on the valence of the text. We also identified information seeking as a mediator that can explain how word familiarity works when reading positive and negative WOM about products.

From a practical standpoint, this research can help marketers and managers make better predictions about future sales based on WOM and design better marketing plans based on the understanding of what textual characteristics make up the most influential WOM. It also provides insights for sellers about how to understand the effects of negative WOM. Marketers could take our findings into consideration when solving questions about the most influential WOM or considering ways to promote their products.

Country Brand Personality DNA: Creating Instant Brand Personalities for New Brands

EXTENDED ABSTRACT

This research introduces "Country Brand Personality DNA" – the unique combination of four personality traits associated with a country – and explores the way this unique DNA can be "inherited" by brand names that sound like they originated from a particular country. Drawing from literature on branding, country of origin, and country stereotypes, we test how foreign sounding brand names can trigger associations with their country of origin, eliciting associations with a specific set of personality traits that are associated with that country.

Literature on brand personality has established that people associate specific personality traits with brands (Aaker, 1997). Literature on country of origin (COO) shows that consumers have certain expectations of products, such as quality, depending on their COO (Bilkey and Nes 1982; Johansson, Douglas and Nonaka 1985; Maheswaran 1994). Extending these literatures, and using the DNA metaphor, we suggest that countries have a "Country Brand Personality DNA" - a unique and identifiable combination of four personality traits that are associated with the country. Just like the four chemical bases that make up the genetic code that is stored in DNA, we suggest that brand names that sound like they originated from a particular country "inherit" that country's personality DNA, resulting in consumers associating the unique combination of that country's four DNA traits with the brand. This inheritance occurs through the process of instant activation of stereotypical personality traits associated with the country. Thus, a country can act as a "parent" to the "child" brand by passing down its own distinct personality DNA to the brand name that sounds like it came from that particular country.

We therefore predict that: 1. People are able to associate a set of four personality traits uniquely with particular countries; 2. Con-

sumers associate similar traits with brand names that sound like they came from these countries. Thus, a brand name that resembles a particular country-of-origin language should carry the perceived DNA (four personality traits) of its parent country.

We conducted three studies to test our predictions. We examined the combinations of four personality traits that are associated with two different countries: France and Japan. **Study 1** was designed to test the prediction that countries have a Country Brand Personality DNA – a unique combination of four Core Genes (personality traits); 203 participants rated 29 personality traits on the extent to which they could represent France, or Japan, if these were people. Results of this study suggest that the Country Brand Personality DNA for France consists of the following traits: *Glamorous, Sophisticated, Elegant and Romantic.* As for Japan, we found the following traits: *Reliable, Intelligent, Stable and Dignified.* These traits loaded on the same one or two factors in a factor analysis, and had the highest ratings of the extent to which they were considered representative of their respective countries.

Next, **Study 2** tested the prediction that brand names that sound like they originate from a certain country "inherit" the Country's Brand Personality DNA, that is, the four personality traits uniquely associated with that country. 392 participants ranked the 29 personality traits from Study 1 on the extent to which the traits accurately described each of four fictitious brand names (2 French sounding and 2 Japanese sounding). Subsequently, participants guessed the COO for each of the four brand names. 195 participants guessed the country correctly, and analyses were conducted with this sub-sample. Results showed, as predicted, a significant overlap between the human traits that participants assigned to each of the brand names and the four traits of the corresponding country's Brand Personality DNA. Specifically, the four DNA traits of France were rated as significantly more representing the French brand names than the Japanese brand names, and vice versa. Finally, **Study 3** aimed to provide further support to our theory by testing whether typical French or Japanese human first names evoke the same associations with the four unique personality traits as the countries and the foreign sounding brand names did in Studies 1 and 2. The study followed the same procedure as Studies 1 and 2, except that participants rated typical French and Japanese human names (e.g. François and Fujiko). As expected, participants associated typical foreign first names with a similar set of four personality traits as we found in Studies 1 and 2, representing their COO Brand Personality DNA.

In summary, results suggest that countries possess a personality DNA – a unique combination of four personality traits, and that when brand names are recognized as being from a particular country, they "inherit" the country's DNA, such that they evoke these same personality traits as those associated with the country itself. Our study is the first to identify inheritable country personality traits and to link them to branding, thereby contributing to existing research on branding, and informing brand managers on the use, process, and outcomes of foreign brand naming. Consequently, this work provides a new and promising avenue for branding managers and entrepreneurs: Utilizing the new Country Brand Personality DNA model as a marketing tool could allow marketers, brand managers, and entrepreneurs to create brand names that can instantly evoke a strong brand personality, which could help improve the efficacy of branding and marketing strategies of firms worldwide.

SESSION OVERVIEW

Marketers constantly strive to create messages that persuade consumers, and customers communicate with each other to influence their choices and behavior (e.g. word-of-mouth). Researchers have long studied the factors that affect attitudes and persuasion, concentrating for the most part on message content and the message source's characteristics and identity. The four research projects in this session find that the structural elements of a message—beyond its content—can have an impact on persuasion. Specifically, all of these papers study how different types of message construction characteristics—from linguistic cues, to the number of arguments contained in persuasive communications—drive consumers judgments by shaping perceptions of the message source.

Maimone, Karmarkar, and Amir examine how the *linguistic structure* of a statement can elicit different cognitive processes that affect recipient judgments. For example, a politician's seemingly equivalent statements "I will not accept any form of bribery" and "I will not tolerate any form of bribery" bear subtle structural differences that can lead voters to experience different levels of processing speed and judgment confidence. The authors additionally show that such differences impact attitude certainty toward the message source more then toward the message content. Their findings provide a new theoretical framework relating message structure and consumer judgments, impacting settings ranging from product claims to political speech.

Packard and Berger study how using present versus past tense to describe things impacts persuasion. People often pay little attention to verb tense when sharing their opinions (e.g., "That movie is/ was great!"). Employing field data and experiments, the authors find that present (vs. past) tense increases audience perceptions of how helpful the information is, and how much they think they'll like the product. This happens not because of something related to time itself (e.g., information currency, memory, usage over time) but instead, perceptions of the source's certainty about the topic.

Hussein, Catapano, and Tormala examine whether overjustification in a message can influence perceived source bias. They find

that compared to communications with a small or moderate number of arguments (e.g., 2 or 3), messages including a large number of arguments (e.g., 15) increase perceptions of source expertise but also increase perceptions of source bias. These perceptions have competing effects on downstream consequences such as recommendation adherence and future interactions with the source.

Finally, **Fan, Rucker, and Jiang** study how states of personal power exert a bi-directional influence that shapes consumer behavior regarding the type of communications people send as well as the type of communications they prefer to receive. Specifically, they find that a high-power state reduces consumers' need-for-justification and lowers the degree of support put into communications. However, they nevertheless prefer others do so. Consequently, consumers in high-power states are less persuaded by others' communications with a low degree of support (e.g., feeling-based arguments, more concise language).

Overall, these four papers provide a new and insightful glance on the importance of several structural aspects of communication, and how they can influence consumers' judgments, experiences, and source perceptions.

The Impact of Linguistic Structure on Judgment Confidence and Source Attitudes

EXTENDED ABSTRACT

Past research has shown how numerous facets of message content and message source characteristics are key factors in persuasion and attitude change (e.g., Karmarkar and Tormala, 2010; Petty and Cacioppo, 1986; Priester and Petty, 1995; Tormala and Petty, 2004). In this work we add another dimension to our understanding of persuasive communication. We demonstrate the message's *linguistic structure* itself can affect people's judgment confidence related to the message. Imagine, for example, a campaigning political candidate giving a speech that includes one of the two following statements:

Statement 1: "I will not tolerate any form of bribery."
Statement 2: "I will not accept any form of bribery."

While equivalent in sentiment, their structure bears a subtle difference that can be described as an interaction of their *concept polarity* and their *statement framing*, which we describe below.

Generally speaking, statements have *claim types* that can be affirmations (I will tolerate) or negations (I will not tolerate). Related to this, Mayo et al. (2004) defined *concept polarity* as the "reversibility" of a concept. A concept is uni-polar if expressing its opposite requires negating the original concept (e.g., "tolerate", "not tolerate"). A concept is bi-polar if people express its opposite by using an antonym (e.g., "accept", "reject"). Negations of uni-polar concepts engage a cognitive process they call *Schema-Plus-Tag*. For example, when reading the uni-polar negation "I will not tolerate any form of bribery", people process "I will tolerate" first (Schema), and then process 'not' (Tag). In contrast, negations of bi-polar concepts involve a *Fusion* process. So, "I will not accept any form of bribery" triggers antonym retrieval, and it is processed as "I will reject".

We provide some of the first evidence showing that Schema-Plus-Tag and Fusion have downstream consequences on judgments. In real life, people aren't passive listeners; they judge whether or not the messages they receive are truthful (Gilbert, 1991). This judgment can be influenced by their prior beliefs on this topic, and people

can feel more or less confident about their judgments of veracity. A voter's judgment of the truthfulness of our politician's statement— together with the claim type—determines the *statement framing*. Specifically, when the voter's belief is congruent with the statement, they will judge it to be true; when their belief is incongruent with the statement, they will judge it to be false. We identify three conceptual classes of statement framing: 1) belief congruence with an affirmation claim type results in an *Affirmation frame*, 2) both belief congruence with a negation claim type and belief incongruence with an affirmation claim type result in a *Negation frame*, and 3) belief incongruence with a negation claim type results in a *Double Negation frame.* So, if a voter believes the politician's statement "I will not tolerate any form of bribery" to be true, that combines a negation claim type with a congruent belief, leading to a Negation frame. If, the voter believed the statement to be false, we would have a negation claim type and an incongruent belief, leading to a Double Negation frame.

Our research takes the novel approach of interacting our three classes of *statement framing* with *concept polarity*. We propose that, when people hold beliefs about a message, bi-polar Negation frames (not bi-polar negation claim types) engage the Fusion process, while all the other combinations engage Schema-Plus-Tag. This framework allows us to predict that statements engaging Schema-Plus-Tag will be faster to process, will lead to greater confidence about the truthfulness of the statement, and will lead to stronger attitudes than those engaging Fusion.

We tested our Hypothesis across three pre-registered experiments (AsPredicted links: Study 1 http://aspredicted.org/blind. php?x=824t8w, Study 2 http://aspredicted.org/blind.php?x=p7fk3a, and Study 3 https://aspredicted.org/blind.php?x=y2ti7q). Study 1 (N = 270) examines participants' response time and their judgment confidence when judging twelve pre-tested Trivia-like statements as true or false (repeated-measures). As predicted, we find that statements engaging Schema-Plus-Tag lead to shorter processing times (in milliseconds, $t(1619.36) = -2.63$, $p = .009$) and greater confidence (9-point Likert scale, $t(1715.02) = 3.54$, $p < .001$) than those engaging Fusion. Study 2 (N = 280) investigates how this effect might impact attitudes emerging from a persuasive message in a political domain. As predicted, statement structures engaging Schema-Plus-Tag lead to stronger attitudes (7-point Likert scale, $t(278) = 2.99$, $p = .003$) about the politician's claim than the same content using structures engaging Fusion. Study 3 (N = 1048) then disentangles whether these structural differences impact the recipient's attitude toward the message content, the message source, or both. This experiment replicates the main effect finding that Schema-Plus-Tag engagement leads to stronger attitudes ($F(1, 1044) = 14.14$, $p < .001$) in a marketing context involving a reviewer's product recommendations. Furthermore, we find a significant interaction ($F(1, 1044) = 7.44$, $p = .006$) demonstrating that this effect is stronger for attitudes towards the message source (the reviewer) than the message target (the product).

Overall, this paper offers new insights related to designing persuasive messaging in consumer and policy domains by improving our understanding of how communication's linguistic structure impacts judgment.

The Persuasive Present (Tense)

EXTENDED ABSTRACT

Word of mouth is both frequent and important. Consumers talk about products they like, books they enjoyed, or experiences they've had, and such interpersonal communication has a significant impact on evaluations, choice, and purchase.

But word of mouth can vary in the tense used to share information. Someone who saw a movie, for example, could say "I like that movie" (i.e., present tense) or "I liked that movie" (i.e., past tense). Similarly, someone could share their attitude about a vacation destination by saying "the beach is beautiful" (present tense) or "the beach was beautiful" (past tense).

While these might seem like subtle variations, could they impact how helpful the information seems and its persuasive impact? And if so, why?

Analysis of over 500,000 online reviews across two major websites and two experiments begins to address these questions. We suggest that present tense should make information seem more helpful, and be more persuasive, because it communicates a sense of certainty. While past tense indicates that something was true, or that someone had a specific experience with a product or service at a particular point in time, present tense suggests something broader. That this opinion may be true more generally. This is consistent with suggestions that present tense may be used rhetorically for states that are "always in effect, always happening" (Fahnestock 2011, 155). Consequently, when a speaker uses present tense, it suggests they are confident enough to make an assertion (Austin 1962; Searle 1969). Not just that something was, but that it is. This increased sense of certainty, in turn, should make the audience find the information more helpful, and make them more likely to take action based on it (Karmarkar and Tormala 2010; Price and Stone 2004).

Study 1 analyzed over 100,000 Amazon book reviews to examine the relationship between verb tense and helpfulness. For each review, we collected how many people rated it as helpful or not, and used part-of-speech tagging to identify the presence of verbs, and whether they were past or present tense.

As predicted, reviews that used more present tense were seen as more helpful ($b = .09$, $p < .001$). This relationship persists including a range of controls (i.e., review length and valence, number of helpfulness ratings, product price and rating, review themes captured using a topic model, and a variety of other language features; $b = .03$, $p < .001$) and whether present tense verbs are treated as a proportion of words or a simple count.

While this initial result is intriguing, one could wonder whether it was due to something specific to the product category examined. Alternatively, maybe it only holds for things that are consumed once, or products but not services. To test these possibilities, Studies 2, 3, and 4 examine alternate product domains.

Across three different product categories present tense was more helpful (Study 2 (music), N = 164,435; $b = .13$, p < .001; Study 3 (consumer electronics), N = 157,649; $b = .04$, $p < .001$; Study 4 (restaurants on Yelp), N = 103,659; $b = .01$, $p < .001$). In all cases, results are robust to inclusion of the controls used in Study 1.

Study 5 tested the causal impact of tense on persuasion as well as the hypothesized process. Participants (N = 118) imagined hearing about a book, and we manipulated whether the source used past or present tense ("The plot was [is] interesting."). As our dependent measure, we asked how much participants thought they would like the book.

Consistent with the field data, shifting word of mouth from past to present tense increased persuasion (5.29 vs. 4.71; F(1, 116) = 8.22, $p = .005$).

To test the hypothesized process, we collected a two-item measure of communicator certainty (certain, confident; r = .67; Karmarkar and Tormala 2010). Consistent with our theorizing, a bias corrected mediation model (PROCESS model 4; Hayes 2018) found

that perceived certainty mediated the effect of tense on persuasion (indirect effect = .12, 95% CI [.03, .22]). Using present tense made the communicator seem more certain (b = .25, p = .015) which increased persuasion (b = .47, p < .001).

This pattern of results was replicated using perceived helpfulness as the outcome measure (as in the field data studies), and using different stimuli. Ancillary analysis revealed that time-related factors (e.g., memory, recency) can't explain the results.

Study 6 further tested the hypothesized process through moderation. If present tense boosts persuasion because it makes communicators seem more certain, then providing another cue of source certainty should mitigate the effect ("mediation-via-moderation"; Bullock, Green and Ha 2010).

Participants (N = 358) were randomly assigned to condition in a 2 (Tense: past vs. present) x 2 (Certainty: baseline vs. cued) between-subjects design. Tense was manipulated using the stimuli from Study 5. For participants in the certainty cue conditions, we added the word "definitely" so it read "The plot definitely was [is] interesting." Manipulation of perceived certainty was supported (F = 4.04, p = .045).

In addition to main effects of tense (F = 5.57, p = .012) and certainty (F = 5.35, p = .021), results of a 2 x 2 ANOVA revealed the predicted interaction (F = 6.32, p = .012). In the baseline condition, consistent with our prior studies, moving from past to present tense boosted persuasion (5.54 vs. 5.02; F = 12.05, p < .001). Supporting the hypothesized role of perceived certainty, however, boosting certainty through an alternate cue mitigated the effect ($M_{Present}$ = 5.52 vs. M_{Past} = 5.54; F = .01, p = .914).

In conclusion, while a great deal of research has examined word of mouth, and word of mouth always involves a verb tense, there has been little attention to how tense might impact consumer behavior. Six studies, looking across the lab and field, demonstrate that present tense increases helpfulness and persuasion, and does so because it makes communicators seem more certain. The work sheds light on word of mouth and deepens understanding around how language impacts consumer attitudes and perceptions.

15 Reasons Why You Should Attend This Talk: How Overjustification Increases Source Bias and Source Expertise

EXTENDED ABSTRACT

Consumers generally believe that more is better in persuasion—and for good reason. Past research has found that providing more justification for one's position can lead to more favorable persuasion outcomes (Petty & Cacioppo 1984; Pelham et al., 1994; Wallace et al., 2020). For example, giving nine, compared to three, cogent arguments in favor of one's position has been found to result in greater attitude change (Petty & Cacioppo 1984). But is more always better in persuasion? We propose that providing greater justification for one's position is a double-edged sword: On the one hand, it can cast the source as having greater expertise. On the other hand, it can cast the source as more *biased*; that is, as having a vested interest in a specific outcome or a skewed and slanted perspective (Wallace et al., 2020). These two forces—greater perceptions of expertise and greater perceptions of bias—can have competing influences on downstream consequences, such as recommendation adherence and interest in future interactions with the source.

Across three studies, we manipulated the amount of justification (e.g., number of arguments) provided by the source to be either low or high, and tested how it influenced perceived source bias, source expertise, and downstream consequences (e.g., recommendation adherence and interest in future interactions with the source). We found that providing greater justification for one's position (e.g., more arguments) increased perceptions of both source bias and source expertise (Studies 1-3). Moreover, these two forces worked in conflict. Providing more justification for one's position led to higher perceived expertise, which increased recommendation adherence and interest in interacting with the source, but also led to higher perceived bias, which *decreased* those outcomes (Studies 2-3). These results were robust to different manipulations of justification amount (the number of arguments within a message and the total number of messages) and were observed across domains (public health communications and restaurants reviews).

In Study 1, we provided participants (N=502) with a persuasive message that contained a high or a low number of arguments and measured their perceptions of the source's expertise and bias. Participants were told that they would read a message from another participant, who was instructed to write as few or as many messages as they would like. Participants were then shown a message advocating for wearing masks in public that contained either twelve or two arguments. Next, participants rated the source on bias (e.g., how biased does the person who wrote these arguments seem?) and expertise (e.g., how knowledgeable do you think the person who wrote these arguments is on this issue?). Results indicated that participants who saw twelve arguments rated the source as more biased (M=3.38, SD=1.95) and more expert (M=5.25, SD=1.27) compared to participants who saw two arguments (M_{bias}=2.79, SD_{bias}=1.74, b=.59, t(500)=3.58, p<.001; $M_{expertise}$=4.38, $SD_{expertise}$=1.39, b=.87, t(500)=7.26, p<.001).

In Study 2, we investigated how perceptions of expertise and bias might have competing effects on downstream consequences, such as interest in future interactions with the source. Study 2 followed the same procedure as Study 1 with two changes: First, we measured interest in future interactions with the source (e.g., how willing would you be to read the source's thoughts on other issues?). Second, we added another condition containing six arguments. Thus, participants were assigned to read either two, six, or twelve arguments. For brevity, we collapse across the two- and six-arguments conditions. Replicating the results from Study 1, we found that participants who saw a high number of arguments rated the source as more biased (M=3.18, SD=1.85) and more expert (M=5.03, SD=1.33) compared to participants who saw a low number of arguments (M_{bias}=2.88, SD_{bias}=1.64, b=.29, t(700)=2.06, p=.04; $M_{expertise}$=4.52, $SD_{expertise}$=1.31, b=.51, t(700)=4.81, p<.001). Next, we examined the effect of number of arguments on interest in future interactions with the source. Perceived bias and expertise had opposing effects on this outcome. That is, we found a suppression effect (b=.037, t(700)=.32, p=.75) such that there was a negative effect through perceived bias (indirect: -.047, SE=.024, 95% CI [-.094, -.005]) and a positive effect through perceived expertise (indirect: .15, SE=.037, 95% CI [.077, .22]).

In Study 3, we extended these findings to online reviews and manipulated overjustification using the number of reviews posted. Participants (N=400) were asked to view the Yelp page of a new restaurant. In one condition, participants saw one review recommending the restaurant. In the other condition, participants saw ten reviews written by the same source all recommending the restaurant. Participants were then asked to provide a star rating of the restaurant, to report their interest in trying out the restaurant, and to report their interest in reading reviews about other restaurants from the same source. Participants were also asked to rate the source's perceived bias and expertise. Participants in the ten-reviews condition saw the source as more biased (M_{bias}=5.06, SD_{bias}=1.94) and more expert ($M_{expertise}$=4.94, $SD_{expertise}$=1.25) compared to participants in the one-review condition (M_{bias}=3.52, SD_{bias}=1.39; b_{bias}=1.54, t(372)=9.23, p<.001; $M_{expertise}$=4.43, $SD_{expertise}$=1.14; $b_{expertise}$=.51, t(372)=4.13, p<.001). These per-

ceptions again had opposing effects on downstream outcomes. That is, there was a suppression effect on participants' ratings of the restaurant (b=-.09, t(372)=-1.08, p=.28), interest in trying the restaurant (b=.14, t(372)=.87, p=.39), and interest in reading more reviews from the same source (b=-.25, t(372)=-1.63, p=.10). For all three outcomes, this suppression reflected a positive effect through perceived expertise and a negative effect through perceived bias.

In sum, giving more justification for one's position (e.g., more arguments or messages) is a double-edged sword. It casts the source as more of an expert, but also makes the source seem more biased, and these perceptions have opposing implications for persuasion-relevant outcomes. Implications for persuasion theory and practice will be discussed.

Power Decreases Consumers' Efforts to Support Their Own Position but Increases Their Demand that Others Do So

EXTENDED ABSTRACT

Modern marketing communications between consumers and companies, as well as among consumers, are both highly visible and influential when it comes to consumers' decisions and behavior (Keller and Libai 2009; Taylor 2003). Academics have aimed to understand how various properties of these communications are influenced by environmental factors (e.g., social density, self-construal; Berger and Iyengar 2013; Chen 2017; Moore and McFerran 2017) and motivational tendencies (e.g., persuasive intent, self-enhancement; De Angelis et al. 2012; Rocklage et al. 2018). Yet, in spite of this growing body of knowledge, our understanding of the ways that psychological states shape people's communication remains limited. To help fill this gap, this work explores how a pervasive psychological state—power—affects consumers' construction of, preference for, and response to communications.

On one hand, we predict that a high-power state reduces consumers' need-for-justification and subsequently lowers the degree of support they put into their own communications. This is presumably because that the feeling of powerfulness enhances consumers' perceptions of self-efficiency and assertiveness in decision making (e.g., Anderson and Galinsky 2006; See et al. 2011) and consequently reduces their need to justify they decisions and actions to others. We focus on one consequence of the reduced need-for-justification, that is consumers in a high-power state will put less emphasis on and effort into supporting the position in their communications—or what we term "degree of support." It can be manifested in various representations: *reduced effort in information search*, *lower reliance on rational-based arguments*, and *more concise language*.

On the other hand, high-power states lead to a heightened sensitivity to asymmetric control and can produce a double-standard for the self and others (e.g., Magee and Galinsky 2008; Rucker et al. 2012). Thus a state of high power might lower the extent to which consumers feel they need to justify their position to others, yet they may nevertheless prefer others to do so. Consequently, consumers in high-power states are less persuaded by others' communications with a low degree of support.

Power and Degree of Support Sought As Message Senders

The first study (N = 180) investigated our basic hypothesis that the feeling of powerfulness decreases the degree of support that consumers put in their communication. We randomly assigned participants to one of three power conditions (high vs. low vs. baseline). We first manipulated participants' feeling of power through a recall task (Galinsky et al. 2003; Rucker and Galinsky 2008). Next, all partici-

pants were given two consumption scenarios (one positive and one negative) and were asked to write a review aimed at a popular customer-review website. Degree of support in the form of message length was calculated by counting the number of words. Participants in the high-power condition wrote shorter reviews compared to their low-power counterparts and participants in the baseline condition. And we did not observe a similar difference between low-power and baseline conditions.

Study 2 (N = 200) provided direct process evidence by showing the mediating roles of need-for-justification. Power was manipulated through an imagination task (adopted from Rucker et al. 2011). Next, participants were invited to express their thoughts in support of having the innovation day and share them via Facebook later. We provided them some relevant information to inform or support their arguments. We measured how many pages (from 0 to 7) that participants actually read and how long each participant persisted in this search task. Finally, we measured their perceived need-for-justification via three items (Hsee et al. 2003). Results showed that participants in the high-power condition exerted less effort searching for information (standardized and combined the number of pages participants actually read and the time duration in the task) than those in the low-power condition and this effect is mediated by need-for-justification.

Power and Degree of Support Sought As Message Recipients

The last two studies illustrated the bidirectional effects of power on communication by showing high-power consumers are less persuaded by others' communications with a low degree of support.

Study 3 (N = 335) used 2 (high power vs. low power) × 2 (message type: feeling-based vs. rational-based) between-subjects design. After the same power imagination manipulation, participants evaluated an advertisement for blood donation (one ad emphasized benefits of blood donation through feeling-based arguments vs. another the ad emphasized benefits of blood donation through feeling-based arguments, Cesario et al. 2004). Previous research has shown that rational-based arguments are perceived as more elaborated and more evidence-based than feelings-based arguments (Hong and Chang 2015; Kahneman and Frederick 2002). The results demonstrated that high power participants were less persuaded by feeling-based (vs. rational-based) messages and low power consumers did not show this difference.

Study 4 (N = 317) replicated the effect with a real incentive-compatible behavior. It is a 2 (high power vs. low power) × 2 (concise information vs. detailed information) between-subjects design. Power manipulation was same as in Study 3. Participants were given an opportunity to bid for a box of six assorted color highlighters (Roux et al. 2015; Wertenbroch and Skiera 2002).

Degree of support was manipulated via the length of marketing information provided in ads. As expected, participants in the high-power condition bid lower prices for the highlighters accompanied by concise (vs. verbose) product information. Participants in the low-power condition did not show this difference.

In summary, the present work demonstrates how a fundamental and pervasive psychological state, power, affects consumers' construction of and response to communications. Different from past research has examined the effects of power on communications from a unidirectional perspective, we found that power exerts a bi-directional influence that shapes consumer behavior with regard to the type of communications people send as well as the type of communications they prefer to receive. Finally, the present findings provide implications to marketers seeking to design effective marketing communications.

I'd Rather Die by My Own Hands

EXTENDED ABSTRACT

Attribution theory (e.g., Heider, 1958) and self-serving bias (e.g., Shepperd et al., 2008) predict consumers prefer to attribute positive events to internal factors (e.g., their own personality or skills), and negative events to external causes (e.g., chance or other people). We hypothesize that there are instances in which consumers prefer to be responsible for negative outcomes. Consider, for example, being involved in a fender bender accident with your own car. Would it be more painful if you had made a mistake at the wheel, or if a friend of yours had done so? Or imagine performing a math task—if you pick the correct answer, you win $100,000, otherwise, you get $0. Now imagine a wrong answer is picked, so you forgo the opportunity to win $100,000. Would you rather have picked the wrong answer yourself or that a third person picked the wrong answer for you? Although attribution theory and self-serving bias predict consumers would rather attribute such negative outcomes to others, we show consumers would prefer owning them. We call this the "I'd Rather Die by My Own Hands" (DBMOH) preference.

We consider three potential explanations for this preference: *overplacement*, *impact bias*, and the *isolation effect*.

Overplacement—a variety of overconfidence—denotes consumers' belief to be better than others (Moore and Healy, 2008). Consumers may prefer getting negative outcomes by themselves because they believe that—despite how the outcome turned out—they had maximized their probability of success. If this was the underlying mechanism, we should observe DBMOH preferences only among those who exhibit *overplacement*.

Impact bias is the tendency to overestimate the affective impact of future events. Past research on *impact bias* shows that individuals' affective forecasts are influenced by the intensity of past instances that come to mind, and the ease with which these instances are recalled (Morewedge, Gilbert and Wilson, 2005). Consumers may be able to recall only not-so-negative events when thinking about past instances in which they got a negative outcome by themselves, and recall more negative ones when thinking about instances in which they got a negative outcome because of someone else's actions. If this was the underlying mechanism for DBMOH preferences, consumers should recall *less* negative instances, and *less* easily, when thinking about getting negative outcomes by themselves than by somebody else.

Isolation effect is the tendency to disregard common characteristics and instead focus on characteristics that distinguish choice alternatives from each other (Tversky, 1972). When eliciting DBMOH preferences by choice (i.e., in joint evaluation mode; Hsee, 1996), the negative outcome information is common to all options, whereas the agent—oneself versus somebody else—is the characteristic that distinguishes the choice options. Focusing on agency, consumers may hence exhibit DBMOH preferences, as they prefer personal control. According to this explanation, consumers in separate evaluation mode should focus equally on the valence of the outcome and on the agent, causing DBMOH preferences to vanish.

In five pre-registered experiments, we demonstrate DBMOH preferences and test their underlying mechanism.

In Study 1 (N = 231; https://aspredicted.org/blind. php?x=qs6az5), we tested the DBMOH preference, and addressed the *overplacement* account. The majority of participants preferred obtaining a negative outcome caused by themselves (51.1%) over somebody else having caused it (13.4%; $\chi^2(1)$ = 50.8, p < .001)[1]. As a test of *overplacement* driving this preference, participants indicated who they thought would have had a higher chance of getting a positive outcome on a bipolar scale ranging from "definitely someone else" to "definitely myself". We repeated our analysis excluding participants who indicated that they themselves had had a higher chance of getting a positive outcome (N = 135). Contrary to *overplacement* driving the results, DBMOH preferences still prevailed ($\chi^2(1)$ = 33.9, p < .001).

Study 2 (N = 69—two independent RAs agreed 32 participants did not perform the task correctly; https://aspredicted.org/blind. php?x=44tm6b) was designed to test *impact bias* as underlying DBMOH preferences. Participants described their past experiences of negative outcomes—one caused by themselves (Self condition) and one by someone else (Other condition)—and indicated how negative, difficult to recall, and recent each memory was. In the Self condition, participants reported recalling both *more* negative ($t(68)$ = 5.18, p < .001) and easier to recall ($t(68)$ = -2.80, p = .007) outcomes/memories than those in the Other condition, speaking against *impact bias* as the underlying mechanism for DBMOH preferences. A sentiment analysis run on participants' descriptions of their experiences corroborated these findings. (Memories did not vary in recency across conditions.)

In Study 3 (N = 444; https://aspredicted.org/blind. php?x=fa5am3) we manipulated the evaluation mode to test whether the *isolation effect* may cause DBMOH preferences. As predicted, in joint evaluation mode we replicated DBMOH preferences as participants reported that they would be *less* dissatisfied with the negative outcome when it was caused by themselves than by somebody else

---

[1] Participants preferred obtaining the negative outcome caused by themselves (51.1%) also over caused by chance (35.5%; $\chi^2(1)$=6.48, p=.011).

(t(146) = -2.91, p = .004). In separate evaluation, in contrast, dissatisfaction with the negative outcome did not differ across conditions (t(295) = -0.52, p = .604). These results suggest that DBMOH preferences could be driven by the *isolation effect*.

Study 4 (N = 389; https://aspredicted.org/blind.php?x=gj2kv8) further tests the *isolation effect* account. We hypothesized that evaluating the negative outcome *after* a positive one would cause people to focus not only on agency, but also on outcome valence. As predicted, when people evaluated the negative outcome first, we replicated the DBMOH preference (t(189) = -2.5, p = .012), but when they evaluated the negative outcome after having imagined the positive, the DBMOH preference vanished (t(198) = -0.4, p = .659). Studies 3 and 4 show the *isolation effect*—which makes people focus on agents of outcomes when all outcomes have the same valence—underlies the DBMOH preference.

Finally, Study 5 (N = 326; https://aspredicted.org/blind.php?x=hf5we9) replicates the null result in separate evaluation mode in a consequential setting (t(206) = -0.24, p = .810), suggesting the "I'd Rather Die by My Own Hands" effect is effectively a misprediction.

Information and Control: What is the Value of Knowing about an Undesirable, Unavoidable Future?

EXTENDED ABSTRACT

Rapid technological developments in the medical field, including direct-to-consumer genetic testing and artificial intelligence, make it increasingly easy to know in advance the likelihood of developing specific health conditions, including life-threatening and untreatable ones. We examine the psychological consequences of knowing, versus not knowing, about the occurrence of an undesirable, unavoidable future. Research suggests that such advance knowledge has potential advantages after the event has occurred, because it may allow consumers to prepare for it and increase perceived personal control (Folkman et al. 1986); it also has potential disadvantages before the event has occurred, because it can decrease emotional well-being and foster negative anticipation (Galak and Meyvis 2011; Harris 2012). Nevertheless, current trends in direct-to-consumer genetic testing indicate that people prefer to know in advance. We therefore hypothesize that consumers are hyperopic in this domain (Kivetz and Keinan 2006): they value more uncertain, future psychological advantages of advance knowledge more than less uncertain, current psychological disadvantages. We study this phenomenon with hypothetical scenarios, real data, and consequential lab studies.

In the first two studies participants imagined going to the doctor for an annual check-up and learning about a new genetic test that reveals with certainty the presence of a mutation associated with a disease that causes blindness. They were then asked whether they would take the test to learn whether they have the mutation (1a; N=291) and whether they would take the test in advance of developing the symptoms assuming they had the mutation (1b; N=292). The majority chose to take the test and to take it in advance; in both cases, the main reason was to be prepared.

Study 2 (N=485) examines the consequences of advance knowledge on general affect, life satisfaction, and perceived control. We used the same scenario as in study 1a and manipulated whether participants learned in advance that they would develop the disease, because they received a positive test, or not, because they did not test. In the first part of the experiment, participants in the Test condition imagined how they would feel over the year after testing, whereas participants in the Baseline condition did not read any scenario and simply reported their feelings over the next year. Participants who imagined testing positive felt worse on all measures than those in the Baseline condition. In the second part, participants in the test condition imagined developing the symptoms whereas those in the Baseline condition imagined developing the same symptoms and taking the test that confirmed the illness. Participants in the Test condition (those who knew in advance) reported feeling and coping no better than those in the Baseline condition (those who knew after developing the symptoms).

Study 3 (N=182) tests for external validity and hedonic adaptation. We ran a survey with asymptomatic members of several Huntington's Disease (HD) associations. HD is a neurodegenerative disease that usually develops around mid-age; a genetic test can predict HD with certainty in advance of developing the symptoms. Participants reported whether they had tested and answered questions like those in Study 2. Those who tested positive, who knew in advance that they would develop HD, did not score higher on affect, satisfaction, and control than those who did not test; not surprisingly, they scored lower on the same measures than those who tested negative. We used the time elapsed since testing as a continuous proxy for knowledge: contrary to hedonic adaptation, those who had known for a longer time felt worse than those who had known for a shorter time. In addition, the longer the time, the worse those who tested positive scored on all measures relative to those who tested negative.

Study 4 (N=173) tests this effect in the lab. Participants were told that they would perform two tasks: the first online and the second in the lab. Before they were given any information about these tasks, they were asked to schedule the second task within three days from the first. Next, participants in the Future Known condition were informed about both tasks: watching a video online (a neutral, present event), and eating a disgusting yogurt in the lab (an undesirable, unavoidable future event). Participants in the Future Unknown condition were informed only of the first task and told that they would learn about the second task when they came to the lab. Future Known participants reported lower satisfaction, affect, and control while watching the video (before the undesirable event had occurred) than Future Unknown participants; the two groups did not differ on the same measures taken after eating the yogurt (after the undesirable event had occurred). In addition, we measured the time elapsed between the first and the second task and found that the longer Future Known participants had known about the unpleasant future event, the less satisfied, happy, and in control they felt with their present life in general. Despite these results, which conceptually replicate our previous findings, a follow-up study (N=198) showed that the majority of participants would like to know in advance whether they would eat a disgusting yogurt so that they could prepare.

To test for participants' ability to forecast the consequences of knowing in advance, Study 5 (N=196) illustrated study 4's procedure and asked participants to predict how they would feel after knowing or not knowing in advance about the undesirable future task. Participants correctly predicted most of the consequences of advance knowledge, both before and after the undesirable event has occurred; however, they incorrectly predicted that advance knowledge would make them feel more in control after the event's occurrence.

Consumers prefer knowing in advance about an undesirable, unavoidable event, despite correctly predicting that this knowledge hurts or does not improve their psychological well-being before and after the event has materialized; however, they incorrectly predict that it increases personal control after the event has materialized. These results indicate a hyperopic tendency, such that people value the future advantages of advance knowledge more than its current

disadvantages. This tendency can be counterproductive, because future advantages are more uncertain than current disadvantages.

A Dark Side of Hope: Why People Cling onto Losing Stocks

EXTENDED ABSTRACT

Consumers often sell winning stocks too quickly and hold on to the losing too long (Shefrin & Statman, 1985; Odean, 1998), despite this "disposition effect" being irrational. Stocks that did not perform well in the past tend to do poorly in the next period, so it would be rational to sell the losing stocks and keep the winning stocks (Baberis & Xiong, 2017). We examined the question: Why do people keep their losing stocks, given it is not optimal to do so?

We propose that people cling on to losing stocks in hope of these bouncing back and them breaking even. This explanation was first suggested, but not investigated, in the seminal article by Shefrin and Statman (1985). The hope explanation also fits well with several theoretical accounts of the disposition effect such as prospect theory (Kahneman & Tversky, 1979), mental accounting (Thaler, 1985), regret aversion (Shefrin & Statman, 1985), and self-control (Thaler & Shefrin, 1981).

Hope is "*the desire for a positive outcome and a belief in the possibility of this outcome*" (Luo et al., 2021), and it emerges in difficult situations (Bruiniks & Malle, 2005; Bury et al., 2016). Seeing a drop in stock price is such a situation. Kahneman and Tversky (1979, p. 287) already realized that a "person who has not made peace with his losses is likely to accept gambles that would be unacceptable to him otherwise". The pain of loss leads to a hope to break even which can erase the possibility of losing, and thus people keep their losing stocks. Indeed, people make decisions as if they could achieve what they hope for (Goldsmith & Amir, 2010). We hypothesized that: hope is positively correlated with the inclination to keep losing stocks (hypothesis1); losing (vs. not-losing) leads to a stronger hope to break even, but not hope to make a profit (hypothesis 2), and a stronger inclination to keep (hypothesis 3); reducing hope decreases the inclination to keep (hypothesis 4). We examined this in a newly developed paradigm. We found support for hypothesis 1. Trait hope (Study 1a) and state hope (Study 1b) correlated with the likelihood of keeping losing stock. Study 1a ($N = 147$, $M_{age} = 35.95$) used Snyder et al.'s (1991) hope scale. Study 1b ($N = 294$, $M_{age} = 36.10$) used a new self-developed four-item trait hope scale (based on Luo et al., 2021). In these studies, participants read a scenario in which their stock invested a year ago has lost value and were asked their inclination to keep the stock. We found positive correlations across Studies 1a ($r = .15$, $p = .06$) and 1b ($r = .12$, $p = .04$). In Study 2 ($N = 145$, $M_{age} = 37.69$), participants read that their investment lost value, and they indicated whether they hoped that the stock price would increase and whether they would keep or sell their losing stocks. State hope and the inclination to keep correlated ($r = .43$, $p < .001$).

We found support for Hypothesis 2 and 3 in Study 3 ($N = 345$, $M_{age} = 20.26$), using a three-group (condition: losing, "3€" control, "5€" control) between-subjects design. Participants read that the value of the stock they bought last year changed from 5€/share to 3€/share; In the two control conditions they read that the stock value stayed at 3€/share or 5€/share. We introduced two control conditions to examine whether it is the experience of loss, and not the height of the stock prices, that influences people's willingness to keep. Participants indicated both their hope to break even and their general hope that the stock would be worth more than before (i.e., hope to win more). Subsequently, participants indicated their inclination to keep. As predicted, losing (vs. not-losing) indeed leads to a stronger hope to break even ($M_{losing} = 5.43$, $SD = 1.10$; $M_{3€control} = 2.46$, $SD = 1.14$, $F(1, 342) = 363.54$, $p < .001$; $M_{5€control} = 2.40$, $SD = 1.33$, $F(1,342) = 342.63$, $p < .001$) and stronger inclination to keep ($M_{losing} = 4.56$, $SD = 1.56$; $M_{3€control} = 3.63$, $SD = 1.56$, $F(1, 342) = 23.06$, $p < .001$; $M_{5€control} = 3.83$, $SD = 1.77$, $F(1,342) = 14.73$, $p < .001$). Exploratory mediation analyses revealed that the hope to break even mediates the effect of losing on people's inclination to keep stocks (Losing vs. "3€" control: $B = -.77$, SE $= 0.25$, 95% CI[-1.28, -0.31]); losing vs. "5€" control: $B = -.75$, SE $= 0.25$, 95% CI[-1.27, -0.29]).

We found support for Hypothesis 4 in Study 4 ($N = 758$, $M_{age} = 31.91$). A 2 (losing vs. losing & reduced hope) + 1 ("3£" control) between-subject design was used. We used the control condition to show a baseline of inclination to keep. The results revealed that indeed when hope is reduced, people's inclination to keep decreases significantly ($M_{losing} = 4.65$, $SD = 1.67$, $M_{losing\&reduced\_hope} = 4.04$, $SD = 1.86$, $t(755) = 3.80$, $p < .001$). Moreover, the losing & reduced hope condition is as likely as the control condition to keep the stocks ($M_{control} = 3.78$, $SD = 1.79$, $t(755) = 1.62$, $p = .11$).

This series of studies provides support for the idea that hope can drive people's decision to keep losing stocks. Furthermore, the results also demonstrate that the hope to break even, but not the hope to win more, explains the effect. Finally, the results show that reducing one's hope decreases people's willingness to keep their losing stocks, and can as such be used as an intervention preventing people from making such suboptimal decisions. We believe the current research importantly adds to the disposition effect literature, by showing the role of hope as a potential explanation of the effect.

People Behave as if they Anticipate Regret Conditional on Experiencing a Bad Outcome

Many decisions involve uncertainty. Managers determine whether to invest in risky personnel restructurings, doctors choose between costly procedures with differing success rates, and intelligence analysts evaluate how likely expensive initiatives are to prevent terror attacks. Normative theories of decision-making propose that people make these decisions by first considering the probability of both good and bad outcomes, and then weighing the consequences of each outcome by those probabilities. Of course, a large literature on risky decision-making suggests that decision-makers often inaccurately weigh both probabilities and outcomes (Baron and Hershey 1988; Kahneman and Tversky 1979). In addition, counterfactuals—possible alternative outcomes—influence how people make risky decisions (Kahneman and Miller 1986; Roese 1997). For example, negotiators are more risk-seeking and less likely to accept an agreement when they expect to receive counterfactual information about a competing firm's offer (Larrick and Boles 1995). Models that incorporate the effects of such counterfactuals on decisions are known as regret models (e.g., Loomes and Sugden 1982).

Formal models of regret assume that decision-makers accurately predict the probability of experiencing regret ("What is the proportion of *all* outcomes I could have improved if I had acted differently?"). We demonstrate that decision makers instead anticipate regret conditional on experiencing a bad outcome ("What is the proportion of *bad* outcomes I could have improved if I had acted differently?"). This biased anticipation leads to risk preferences that violate normative standards.

In our studies, participants indicate their valuation of changes in probabilistic lotteries (e.g., how much they would pay to increase their chances of winning a lottery from 20% to 30%). This design, adapted from Lewis and Simmons (2020), keeps the size of probability changes constant (e.g., a 10 percentage point increase) while varying starting probabilities (e.g., increases from 20% to 30% or

from 70% to 80%). Keeping the size of probability changes the same necessitates that one's objective chances of experiencing regret also change by the same amount. However, 10% increases in one's chances of winning a lottery can have very different effects on the proportion of bad outcomes. Increasing a 10% chance of winning to a 20% chance eliminates 1/9 of losing outcomes, while increasing an 80% chance of winning to a 90% chance eliminates 1/2 of losing outcomes. Thus, if people indeed anticipate regret conditional on bad outcomes, these identical changes in chances—which have different effects on the proportion of bad outcomes—will be valued very differently.

This illustrates our primary hypothesis: Valuations of changes in chances are best described by a model that assumes decision-makers anticipate regret conditional on obtaining a *bad* outcome (as opposed to *all* outcomes). In contrast with existing theories in psychology and economics—including regret theory (Loomes and Sugden, 1982) and prospective outcome bias (Lewis and Simmons, 2020)—our conditional regret model predicts that participants' valuations of changes in chances follow a convex pattern. This shape follows directly from our theorizing: As starting probabilities increase, changes in chances lead to ever-larger proportional decreases in bad outcomes (and therefore, higher valuations).

In Pilot Studies 1-3 (N=487) participants answered a series of questions that elicited their willingness-to-pay (WTP) to increase their chances of winning ~30 probabilistic lotteries (e.g., "*How much are you willing to pay to change a 20% chance of winning \$10 to a 30% chance?*"). Our conditional regret model—with the percent reduction of bad outcomes as a predictor—better fit the data than models that used absolute chances in chances or ending win chances after the change as predictors (all $ps < .001$). Ultimately, participants valued normatively identical absolute changes very differently (going from an 80% to 90% chance to win \$10 was valued roughly three times more than going from a 10% to 20% chance).

Study 1 extended on the pilot studies in two primary ways. First, we tested if this pattern held when participants' valuations were incentive-compatible. Second, we included additional trials with higher starting probabilities. This allowed us to better chart participants' valuations at these probabilities, where changes have the most pronounced effect on bad outcomes. Again, we replicated the convex pattern of valuations observed in the pilot studies: our conditional regret model better predicted participants' valuation than competing models (all $ps < .001$). Further, for trials that have starting probabilities below 70%, participants were *risk-averse*: On average, they paid less than the expected value of the change in chances. But for trials that had starting probabilities above 70%, participants were *risk-seeking*.

Study 2 (N=2421) tested our mechanism directly. A frame that drew participants' attention towards the proportional decrease in bad outcomes implied by changes in chances ("decrease chances of losing by ½") does not affect participants' valuation of a change, implying it may already be applied. On the other hand, a frame that drew attention away from the proportional decrease in bad outcomes ("increase chances of winning by 1/8") full eliminated our effect, suggesting that participants do not spontaneously apply this frame.

In several ancillary studies, we find that the biased anticipation of regret leads to non-normative choices. For example, participants given the opportunity to decrease their likelihood of becoming ill prefer a less-effective drug (but which decreases a larger proportion of bad outcomes than an alternative). We conclude by discussing how our conditional regret theory can offer a psychological explanation for existing findings (such as the certainty effect), while also

illustrating the clear applicability of our model to decision-making in medical, investment, and insurance contexts.

SESSION OVERVIEW

Not all decisions are one and done. Consumers make thousands of decisions each day, some of which span the same overarching purchase (e.g., car add-ons or customizations), and many of which will span across multiple domains (e.g., clothing, food) or be repeats of previous purchases. While these decisions may only be somewhat interrelated on their face, in reality, much work has suggested a great intertangling of how earlier and later choices relate. Later decisions in a sequence may be prone to fatigue effects (Levav et al. 2010), earlier purchase decisions can affect later ones (Dhar et al. 2007), and whether choices are bracketed close together temporally can influence preference (Read et al. 1999). Further, consumers may schedule or select into sequences of decisions that improve or decline in quality (Loewenstein and Prelec 1993) or acceptability (Gino and Bazerman 2009).

While decades of literature have investigated separate ordinal position effects or sequential decision-making, there remains myriad unanswered questions. How does a choice being multi-stage or not influence what alternatives consumers pick? How does an unrelated prior purchase (or failure to purchase) influence later purchase likelihood? How do consumers transition into (and what will help them transition out of) dishonest behavior? How does a structure of a previous experience (i.e., increasing or decreasing enjoyment) influence how consumers build subsequent experiences? The present session answers these questions and more.

First, **Smith** and **Spiller** show in six studies how decisions in a first stage can be influenced by later stages of decisions. That is, the choice share of an option relative to its alternative increased when that alternative became a multi-stage choice (i.e., first A vs. B or C, then choose between B and C)– even if the subsequent choice between B and C involved a dominated decision. Second, **Amir**, **Morvinski**, and **Weingarten** present twelve studies regarding how initial purchase decisions in unrelated domains can influence subsequent purchases in unrelated domains. They also report how later ordinal positions across unrelated decisions have lower purchase rates. Third, **Reeck**, **Mazar**, and **Ariely** provide evidence across

three studies about how behavior can tip into continuous dishonesty in ethical decisions. However, they also find costly pre-commitment and making salient one's actions can curb this what-the-hell effect. Finally, **Dutton** and **Diehl** illustrate in three studies that when structuring a series of experiences, those who initially plan an experience to proceed with a decreasing trend (i.e., most enjoyable pieces first) regret their decision more (relative to increasing trends) and are more likely to plan their next experience as an improving sequence.

Importantly, this session ties into the conference theme of "What the World Needs Now" by examining how consumers can keep ethical and design optimal experiential and purchase sequences as countries turn to a new normal. These four papers will appeal to both practitioners and researchers who study judgment and decision-making, time, dishonesty and ethical decision-making, retailing, and experiences and experiential consumption. These papers employ both laboratory and field data, and all papers have at least three studies completed.

Consumers Undervalue Multi-Option Alternatives in Two-Stage Choice

EXTENDED ABSTRACT

Only rarely does a consumer's full decision process conclude at the moment of choice. Instead, each node in a decision tree typically leads to more decisions. Sometimes these choice sequences are implicit, as when choosing a home implies choices among where to eat, where to shop, and who to visit. Other times they are explicit, as when choosing a restaurant implies choosing items from a menu or choosing to watch TV implies choosing a show. Even this narrower case of explicit multi-option alternatives is ubiquitous. Multi-retailer gift cards, airline choices, food/drink tickets (e.g., at fairs/festivals), and game tokens (e.g., at arcades) all constitute multi-option alternatives.

There are two competing Hypothesis regarding how consumers might misvalue multi-option alternatives relative to the best sub-option (i.e., the normative baseline). Consumers might value a multi-option alternative more than the maximum value of its component options due to the fact that the multi-option alternative enables choice (Brehm 1966; Bown, Read, and Summers 2003; Mochon 2013; Shin and Ariely 2004). Alternatively, consumers might undervalue a multi-option alternative if they use a weighted average of the values of the components (Brough and Chernev 2012; Chernev and Gal 2010; Gaeth, Levin, Chakraborty, and Levin 1991; Yadav 1994; Shenhav and Karmarkar 2019; Weaver, Garcia, and Schwarz 2012; Troutman and Shanteau 1976). Only two prior papers have directly examined this question (Le Lec and Tarroux 2020; Spiller and Ariely 2020). In both of these cases, the studies considered WTP (rather than choice) in particular contexts (internet surfing options and media of exchange). Both sets of authors found evidence consistent with the weighted-averaging process.

Here, we seek to better understand how consumers integrate across options in a choice set when deciding among such multi-option alternatives. We ran six preregistered studies in two domains: consumer goods and incentivized risky gambles. In each study, participants made (at least) two types of choices: control choices and

test choices. In the control choices, participants chose between two single-option alternatives (e.g., A vs. B). In the test choices, participants chose between a single-option alternative (e.g., A) and a multi-option alternative (e.g., B or C, where the value of B is greater than the value of C). Choosing this multi-option alternative allowed the participant to make a (later) choice between B and C. In some studies, the dominance relationship between B and C was engineered to be more (vs. less) transparent. For example, a more transparent dominance relationship might be: B: win $4 if you roll a 1 or 2 or 3 on a die; C: win $4 if you roll a 1 on a die. Alternatively, a less transparent dominance relationship might be: B: win $4 if you flip heads on one coin; C: win $4 if you roll a 1 on a die.

We compared choice proportions for A between test and control choices to test for the presence of undervaluation. In all studies (1, 1b, 2, 2b, 2c, 3), participants chose A significantly more often when it was contrasted with a multi-option alternative (B or C) than when it was contrasted with the highest-valued option from the multi-option alternative (B) (paired t-tests, all ps < .001). In other words, adding C (as a component option with B) made people less likely to choose "B or C" than they were to choose B. Moreover, the difference in value between B and C is predictive of the size of the effect; as the value of C gets worse relative to the value of B, participants show a greater degree of undervaluation (clustered-SE regression; Study 1: p < .001; Study 1b: p < .001; Study 2: p = 0.07; Studies 2b, 2c, and 3 did not allow suitable tests of this hypothesis).

In Study 3, we also examined the information acquisition patterns of participants via a custom mouse-tracking interface. Mouse-tracking revealed that participants who spent more time on A in test choices demonstrated a greater degree of undervaluation (r(207) = 0.27, p < .001). In addition, participants who attended more to the dominated option (C) in a test choice were less likely to choose the multi-option alternative (b = –1.70, SE = 0.24, p < .001). However, participants spent less time on the dominated option (C) when the dominance relationship between B and C was more transparent (M = 0.01, 95% CI = [0.002, 0.02], t(207) = 2.46, p = .01). Participant choices mirrored this attentional shift; undervaluation was reduced when the dominance of B was more transparent (M = –0.03, 95% CI = [–0.06, –0.01], t(208) = –2.76, p = .006), and participants with greater mouse-tracking differences between high- and low-transparency decisions showed greater differences in choice behavior between high- and low-transparency decisions (r(206) = 0.13, p = 0.06).

We also ruled out several alternative explanations. One alternative explanation is that participants do not want to have to make an additional choice later on. We ruled this out by requiring our participants to acknowledge that they would make the same number of choices in the study, regardless of what they chose in any particular trial. Moreover, in comparing the test choices (e.g., A vs. B or C) to dominated-option choices (e.g., A vs. C), we found that participants chose the multi-option alternative (B or C) more often than its worst component option (C) (M = 0.18, 95% CI = [0.15, 0.22], t(175) = 10.93, p < .001). This demonstrates that people do not have an extreme aversion to making future choices. We also address inattention as an alternative explanation for our results. Using a variety of attention checks, we show that our effect does not diminish – and if anything, gets stronger – when we exclude inattentive participants from our analyses.

Across all of our studies, participants regularly sacrifice a chance at maximizing their subjective value by inappropriately integrating the value of less-attractive options. Overall, this work contributes to our understanding of multi-stage consumer decision-making and how consumers assess and integrate the overall value of multi-option alternatives.

A Reference Value Theory of Sequential Choice

EXTENDED ABSTRACT

Consumers make many purchase decisions in daily life across multiple domains, be it whether to buy candy, whether to purchase a book, or whether to pick up an extra flash drive for a conference. However, despite these decisions being nominally unrelated, is it possible that the decision for one purchase might have an impact on the subsequent decisions? Notably, in other contexts, the order in which decisions unfold matters. For example, parole decisions become harsher the later in the day they are (up until lunch; Danziger et al. 2011), and people become more likely to pick defaults in voting or customization decisions later in a sequence or after difficult decisions with many options (Augenblick and Nicholson 2016; Levav et al. 2010).

We build a reference-value theory of sequential unrelated purchase decisions. We argue that across even unrelated purchase decisions, consumers carry a reference point based on the acceptable expected value from prior purchases decisions. Concretely: each purchase consumers face may fall into one of three categories: something to definitely reject, something to definitely buy, or something that consumers could see themselves being willing to buy or not to buy. We contend that following a purchase decision, consumers may update their beliefs about what is or is not an acceptable range of outcome value based on whether they bought or did not buy the previous good (see also Hogarth and Einhorn 1992; Schrift et al. 2018). That is, after making a purchase, consumers may widen their standard for what an acceptable degree of value is for subsequent purchases, and after rejecting a purchase, consumers may narrow their standard for what is an acceptable degree of value.

According to this theory, we suggest there is a prior purchase effect by which following an initial purchase, people may be more willing to make subsequent purchases, and following a rejection, people may be less willing to make subsequent purchases. However, due to a stronger impact of rejections (relative to purchases) on updating (see Baumeister et al. 2001), we further expect a negative ordinal position effect: purchase rates in later ordinal positions in a sequence should, on average, be lower. Importantly, we are able to unite insights from previously-unrelated streams of research on how prior purchases influence future purchases (Dhar et al. 2007) and how turning down initial opportunities spurs rejecting further opportunities (Tykocinski et al. 1995) within one theory in the context of unrelated purchases.

In field data from Fiverr, Inc consisting of six months of customer transaction data, we find initial evidence of a prior purchase effect and a negative ordinal position effect when looking within shopping trips spanning multiple different unrelated categories (e.g., podcast editing, programming) constructed over eight-hour intervals (or six-hour intervals for robustness). That is, relative to the purchase probability for a customer with no prior purchases, the likelihood of subsequent prior purchases increased when customers have a prior purchase. Further, we observed evidence consistent with a negative ordinal position effect: the purchase rate declined across each ordinal position (first, second, third, fourth).

In a preregistered incentivized laboratory study (N = 728), we replicated the findings from the field. Participants made a series of three purchase decisions in one of six counterbalanced orders for three goods: a portable charger, a flash drive, and chocolates. Further, to ensure the study was incentive-compatible, one in every fifty

participants had one of their purchase decisions enacted at random. Descriptively, consistent with a prior purchase effect, we find that conditional on making a first purchase, people are more likely to make a second purchase; similarly, conditional on not making a first purchase, people are more likely not to make a second purchase. Consistent with a negative ordinal position effect, we find that the purchase rate declined over ordinal positions. These results held analytically in binary logistic regressions. Further, we replicated these results in a preregistered non-incentivized study (N = 588) that expanded the number of decisions to six goods over three.

Further, consistent with the importance of the reference value from an initial decision, manipulating the attractiveness of the initial decision influenced the emergence of the negative ordinal position effect. That is, in a large study (N = 1608), we manipulated the attractiveness of the first good participants saw (a Bone Conduction Waterproof Bluetooth headset) to be unattractive (1-star), mildly attractive (3.5-stars), attractive (4.5-stars), or very attractive (5-stars). All participants, following making a purchase decision for this headset, saw a common choice for a 4-star coffee cup. Consistent with the manipulation, participants were more likely to purchase the headset as its rating increased. On the other hand, the purchase rate for the coffee cup was negatively related to the attractiveness of the initial headset. When regressing the two decisions onto ordinal position, the initial rating, and the interaction, we observed a significant interaction by which there was a negative ordinal position effect for the 3.5-star, 4.5-star, and 5-star conditions. Yet, in the one-star condition with a low initial purchase rate, we observed a reversed negative ordinal position effect. That is, the purchase rate of a second good declined as the initial good became more attractive such that the negative ordinal position effect only held with attractive initial purchases.

We also address bracketing explanations of the results (i.e., that people merely bracket the otherwise-unrelated purchase decisions together) in two ways. We run preregistered studies in which either a) the study (N = 715) was framed as either three different studies with three different consent forms (meant to bracket each good narrowly) or one study as before, or b) there was a temporal delay with a filler task for some participants meant to separate the decisions and potentially attenuate the aforementioned results (N = 822). Neither study design found an interaction with bracketing, instead observing prior purchase and negative ordinal position effects. Seven other replications similarly find evidence for a prior purchase effect and negative ordinal position effect while ruling out other alternative explanations.

"What-the-Hell:" Dishonest Behavior Can Escalate to Continuous Ethical Transgression

EXTENDED ABSTRACT

The marketplace and the workplace are characterized by abundant temptations to behave dishonestly. For example, consumers overstate tax deductions, fib about returning items unused, or download pirated music files from sharing servers. Consumers are often victims of others' immoral transgressions as well, from doctors prescribing medicines produced by pharmaceutical companies they receive benefits from to financial advisers steering investors towards options with high commissions without disclosure of their conflicts of interest. Employees may also engage in dishonest acts, from taking credit for others' work to stealing office supplies for personal use to violating professional codes of conduct. Despite the fact that honesty is a universal value (Schwartz 1994) and many of us have strong beliefs about our own morality (Bem 1972), it is easy to deviate occasionally from the path of honesty. However, each individual lapse may not occur independently, and previous ethical transgressions may compound to make future transgressions more likely. In the present paper, we consider whether these infractions are momentary lapses of ethicality from which people quickly recover or if acts of dishonesty beget subsequent acts of dishonesty. Specifically, after repeated transgressions the nature of behavior might transition so that dishonest behavior becomes a pervasive and persistent pattern. After the first few exaggerations on one's tax forms, does one at some point start inflating all subsequent potential deductions? Do we gingerly download a couple songs, only to at some point find ourselves downloading whole albums unabashedly?

If our transgressions were just isolated bumps on an otherwise honest path, the cumulative effect of our dishonest acts would simply equal their individual magnitudes. But, if there exists a tipping point beyond which the behavior becomes a pervasive pattern, then the cost of our transgressions could be much higher, since each additional transgression would also increase the likelihood of an escalation of dishonesty or eschewing honest behavior altogether. If such a tipping point exists, do people understand the risks of repeated temptations for dishonesty and try to avoid them—even if doing so is costly?

Particularly relevant to our focus on the context of a series of opportunities to be dishonest is research on the cheat-at-the-end effect (Effron, Bryan, and Murnighan 2015) and the slippery slope effect (Garrett, Lazzaro, Ariely, and Sharot 2016; Gino and Bazerman 2009; Welsh, Ordonez, Snyder, and Christian 2015). Building on this recent body of work in behavioral ethics research, we consider the very extreme, end result of facing a series of opportunities to cheat over time. That is, the present work moves past this prior research by seeking to document a transition to uncontrolled unethicality, that is continuous maximal cheating. Establishing whether such a "What-the-Hell" (WTH) effects extend to the domain of morality is of central importance. Previous demonstrations of the WTH effect have typically occurred in domains in which behavior largely only impacts the self, such as eating, personal spending, or substance use (Cochran and Tesser 1996; Polivy 1976; Soman and Cheema 2004). Preventing a transition to uncontrolled, maximal unethical actions, however, is of collective importance, as people's unethical actions can have negative impacts on other people. At the same time, there are reasons to anticipate that such WTH effects may not emerge in the moral domain, given the widespread desire to maintain a positive moral-self concept.

The present experiments examine the ethical WTH effect in a task featuring repeated temptations to cheat. Across three incentive-compatible physical laboratory studies, we demonstrate that a subset of people eventually succumb to continuous cheating.

Study 1 (N=36, within-ss manipulation of temptation) establishes the WTH Effect in a continuous decision-making task, showing that 52.8% of participants eventually transitioned to continuous cheating.

Study 2 (N=79, two between-ss conditions: payment feedback vs behavior feedback, within-ss manipulation of temptation) replicates the effect and tests for the role of self-perception in counteracting the WTH effect. Critically, we found that the feedback manipulation significantly impacted the extent to which participants switched to continuous cheating, $\chi^2(1) = 11.86$, $p = .001$, as participants who viewed their responses were much less likely (10.3%) than those who viewed their earnings (45.0%) to exhibit the effect. Even for those participants who did exhibit the WTH effect, those who viewed their actual responses made significantly less money, $t(20) = 2.56$, $p = .019$, and transitioned to WTH behavior marginally later, $t(20) = 1.81$, $p = .086$, than those who viewed their earnings. Thus, making

one's behavior salient during task performance appeared to counteract the tendency to switch to continuous cheating.

Finally, study 3 (N=78, within-ss manipulation of temptation) replicates the effect and tests costly pre-commitment (option to choose to avoid future exposure to repeated temptation) as a means to encourage honesty and rehabilitate those who have transitioned to continuous cheating. Again, we found evidence for a WTH effect. Specifically, 19.2% of participants showed a switch to continuous cheating. More importantly, 56.4% of participants chose to sacrifice earnings to remove subsequent temptation.

The present findings are consistent with previous theories explaining the emergence of the "What-the-Hell" effect in other behavioral domains such as dieting. Survey responses in experiment 2 reveal that those who exhibit the WTH effect know the ramifications of their actions. Both those who do and those who do not transition to continuous cheating view the behavior as similarly unethical and inappropriate, indicating that the effect does not emerge due to complete moral disengagement or a redefinition of what honesty entails.

We document the emergence of continuous cheating following repeated ethical same-domain transgressions, such as illegally downloading multiple songs. Given that in our daily lives we face repeated temptations to be dishonest, and that dishonesty is very costly to societies, the implications of our and future related research may be substantial for policy aimed at preventing people from falling prey to the WTH effect in the context of ethical decision making. Our findings suggest that pre-commitment and making one's actual actions salient represent two means to curb the negative effects of the WTH effect, and we are hopeful that future work will uncover others.

I'll Do it Differently Next Time: How Consumers Structure Repeated Experiences

EXTENDED ABSTRACT

Experiences are important for consumer well-being (Gilovich and Kumar 2015) and are an important contributor to the economy. We focus on one type, *consumer-structured experiences*, which contain unique components that people combine to create an overall experience. Consumers decide the specific components, then arrange them in a sequence. We focus on repeated consumer-structured experiences (i.e., when at least one component has been experienced previously). Consumers find enjoyment in repeated experiences (O'Brien 2019) and popular press has documented the importance of repeat experiential customers (Olson 2013). Further, firms often offer incentives such as season passes and loyalty programs to increase their repeat customers. Despite this, little is known about consumers making repeat decisions when it comes to experiential purchases.

Novel components, and therefore experiences are characterized by uncertainty. Uncertainty may cause people to choose declining sequences (Frederick and Loewenstein 2008), hence, people may be more likely to choose improving sequences for repeated experiences that have less uncertainty. Further, consumers may use their assessment of an initial experience as a diagnostic for a subsequent similar experience (Wilson, Meyers, Gilbert 2001; Feldman and Lynch 1988). Past research suggests that the experience sequenced influences the assessment of the experience (Ariely and Zauberman 2003). If consumers believe that their initial sequencing resulted in an unfavorable experience, they may regret their sequencing decision (Zeelenberg 1999), and change their sequencing type in a repeated experience.

We predict that 1) repeated components are more likely to be structured in an improving sequence and 2), increasing levels of regret predict a consumer's likelihood to change the way they structure a repeated experience. We test these predictions in three studies.

Study 1 provides evidence that prior experience with experience components predicts improving sequences. M-Turk participants (N=202) imagined going to a food market that offered sample-sized portions of up to ten different food items. Participants rated how appealing each item was on a 7-point scale anchored at "not at all appealing" (1) and "extremely appealing" (7). They then indicated which items they wished to taste (at least one and up to ten). Finally, those who selected at least two items (N = 153) indicated their preferred tasting order. To assess prior exposure, participants indicated whether they had previously eaten each food item.

To determine sequencing type of sequence, we estimated individual regression coefficients for each participant by regressing the appeal rating of each selected component on the order in which the participant wanted to experience each component. Based on their individual-level regression coefficients, we classified participants as having created an improving (regression coefficients > 0) or declining (regression coefficients < 0) sequence. Participants were classified as creating a sequence with equally appealing components when their regression coefficients were equal to 0. As expected, we find that the more repeated the experience (i.e., the more items someone has tasted in the past), the more likely participants were to create an improving sequence (0=improving, +1=declining, b=-.19, $X^2(1)$=4.11, p=.04).

In study 2, we manipulated the repeatedness of the components. Undergraduate students (N=200) were randomly assigned to a 2-cell design (completely/partially repeated). Participants rated nine different art pieces that could be a part of an online art gallery using the same scale as study 1, then ranked their appeal relative to each other. For their initial experience, participants were shown their first, third, sixth, and eighth ranked paintings in a declining sequence based on their rankings (i.e., from their most preferred to least preferred painting).

Participants then imagined returning to the online art exhibit. Those in the completely repeated condition saw the same four paintings as in the initial experience. Those in the partially repeated condition were shown two paintings from their initial experience (first and eighth ranked) and two that had not been part of their initial experience (second and seventh). Participants indicated the order in which they wished to view the paintings. People who completely repeated the experience were more likely to change the way they structured their experience to an improving sequence (26%) than those who repeated the experience only partially (13%, $X^2(1)$=4.62, p=.03).

In Study 3, we explored how regret of an initial experience affected the structure of the repeated experience. Undergraduate students (N=175) rated then ranked nine jelly bean flavors the same way they did in study 2. They were shown their second, fifth, and eighth ranked jelly beans, and indicated their preferred tasting order. They ate each jelly bean, then reported their enjoyment of each jelly bean on a 7-point scale. After eating all three jelly beans, participants reported their regret of their chosen sequence a 7-point scale anchored at "do not regret at all" (1) and "regret a great deal" (7). They then were asked to indicate the order they wished to taste the same three jelly bean flavors in a subsequent experience.

We focus our analysis on participants who created an improving or declining sequence (N=167). Those who created a declining sequence reported more regret (M=2.62) than those who created an improving sequence (M=1.83, $F(1,165)$=9.05, p<.01).

To assess sequencing preferences of the repeated experience, we regressed the enjoyment of each jelly bean on their repeated tast-

ing order. Interestingly, while 18% people who initially created an improving sequence changed their repeated experience to a declining sequence, a greater proportion (44%) of people who initially created a declining sequence changed the way they structured the repeated experience (to improving). A McNemar test showed that these differences were significant ($X^2(1)=15.19$, $p<.001$). As expected, the more participants regretted their initial experience, the more likely they were to change the way they structured their repeated experience: $b=.30$, $X^2(1)=8.42$, $p<.01$.

This research is the first to examine how an initial experience can affect the way in which a subsequent experience is structured. We find that repeated experiences are more likely to be structured in an improving sequence. This may result from consumers' negative assessment of their initial experience, and a desire for a more positive repeated experience. Future work will examine the role of consumer lay beliefs on repeated experiences.

SESSION OVERVIEW

New technologies and predictive systems powered by Artificial Intelligence (AI) are being developed by organizations and governments across the world. Today, AI pervades the private and public sector, with profound implications for consumer welfare, the economy, the judicial system, labor markets, and many other core public functions spanning healthcare and education. Yet, the social impact of AI remains unclear. How do consumers respond to AI making decisions pertaining to criminal justice and the provision or core public services? What are AI's blind spots and biases, and can they be mitigated? Can AI be used to deliver persuasive messages that promote social welfare?

Overall, *this symposium brings together a diverse and interdisciplinary set of researchers from marketing, law, computer science, and psychology to present evidence examining the many facets of the social impact of AI.* By showcasing insights from various disciplines and empirical methodologies, this symposium answers the call for multi-method and interdisciplinary submissions.

Specifically, these are topics covered: perceptions of AI algorithms in the criminal justice system and in the provision of core public services; implicit bias embedded in facial recognition technologies, and whether this bias may be mitigated; how to design AI algorithms to maximize well-being.

The first two papers present novel insights with respect to people's perceptions towards AI in the public sector. **Yalcin et al.** investigates how people perceive algorithms (vs. humans) in justice systems. In collaboration with legal scholars, the authors demonstrate that individuals trust algorithmic (vs. human) judges less and have lower intentions to go to court when algorithms adjudicate. They also reveal that trust for algorithmic judges is especially penalized when cases involve emotional complexities (vs. technical complexities).

Continuing the theme of examining perceptions towards AI in the public sector, **Longoni, Cian,** and **Kyung** examine the inferences and generalizations that people make when learning of AI (vs. human) errors in the provision of public services. Studies cross different types of public services show that people mentally represent groups of AI versus humans in fundamentally different ways, and generalize algorithmic errors at a higher rate than human ones. This effect has detrimental downstream consequences for propensity to access public services and trust in the legitimacy of core public institutions.

The third paper by **Wang** and **Rahman** uses a different methodological approach (machine learning) to examine how facial recognition algorithms make recruitment and promotion decisions, and the potential bias that may ensure from these decisions. Leveraging machine learning, the authors introduce the concept of algorithmic *face-ism* in facial recognition systems—the notion that algorithms unfairly express an inherent preference for specific facial morphologies and show that this bias persists even after controlling for other common algorithmic biases.

Finally, **Castelo, Chalaguine** and **Häubl** test the possibility to leverage AI and design persuasive chatbots. The authors build an actual chatbot to deliver persuasive messages and test its efficacy in increasing people's willingness to get the COVID-19 vaccine. The author will also provide a tutorial on how to build and implement persuasive chatbots—a tool that should prove greatly useful for the larger ACR community.

Perception of Justice by Algorithm

EXTENDED ABSTRACT

AI technologies have increasingly been used the justice system to review legal case files, predict legal outcomes, and even make judicial decisions. Accordingly, many governments (e.g., Estonia, Netherlands) and international organizations (e.g., the Council of Europe) have been formulating policies related to the application of AI in courts. To our best knowledge, however, no research has looked at consumers' perceptions towards algorithmic judges. In collaboration with law scholars, we examine how interacting with algorithmic (vs. human) judges affects the extent that people trust them, and their intentions to submit their cases to a local court. Finally, to examine whether there are any potential advantages of algorithmic (vs. human) judges, we explore individuals' perceptions of cost and speed of the judge.

Existing research has documented that individuals rely less on algorithmic (vs. human) decision-makers (Longoni et al. 2019). In line with these findings, we expect consumers to trust algorithmic judges less compared to human judges as well as having lower intentions to submit their cases to a local court. In addition to the effect of

the decision-maker, extant work suggests that the type of task algorithms and humans are given might impact consumers' perceptions (Castelo et al. 2019). One classification that is often used is whether a task is emotional or cognitive in nature. Previous work suggests that non-human entities are perceived as capable of thinking, but not feeling (Rai and Diermeier 2015) and that consumers express more favorable attitudes towards algorithms when tasks are framed as requiring cognition than emotion (Waytz and Norton 2014). Building on these papers, we test whether consumers trust algorithms and humans differently depending on the nature of a legal case. We propose that algorithmic judges will be trusted even less when cases involve emotional complexities (vs. simple vs. technical complexities).

Two studies (*N*=1,822) tested our predictions. In each study, we gave participants a general background of a divorce case and randomly assigned them to the judge (human vs. algorithm) that would take their case. We then manipulated the type of the case: low vs. high emotional vs. high technical complexity. Participants in the low complexity condition were given a straightforward case description, whereas we added details to complicate the case in the remaining conditions. Specifically, we either added technical (e.g., unequal shares of property) or emotional details (e.g., psychological problems). Importantly, we measured participants' trust towards their assigned judge by aggregating four items (1= unfair/biased/not trustworthy/unpredictable; 9= fair/unbiased/trustworthy/predictable). To test whether consumers' perceptions have consequences for their intentions, we also measured participants' willingness to submit their cases to the local court (e.g., "How likely would you be to submit your case that will be resolved by the AI/judge to the local court?", 11-point scale). Finally, to examine whether there are any potential advantages of algorithmic (vs. human) judges, we included two exploratory measures, namely, perceived cost (1= *cheap*; 9= *expensive*) and speed (1= *slow*; 9= *fast*) of the judge.

As predicted, both studies revealed a significant main effect of the judge type (see Table 1 for the details): participants perceived the human judge to be more trustworthy than the algorithmic judge, replicating the general algorithm aversion documented in the literature. Importantly, we also found a statistically significant effect between type of the case and type of the judge in both studies: participants trusted the algorithmic judge even less when the case was high in emotional complexity compared to cases that are not complex and high in technical complexity (see Figure 1). Looking at the downstream consequences of these perceptions, both studies showed a strong main effect of the judge type, revealing consumers' strong aversion to algorithmic judges. The interactive effect of the type of judge and case on consumers' perceptions of trust, however, did not spill over to their intentions to submit their cases. Finally, looking at the exploratory measures we included, people perceived some advantages in algorithmic (vs. human) judges, as they were perceived to be faster and cheaper.

Our interdisciplinary work provides novel insights on the impact of algorithms on consumer judgment and decision-making. First, we document algorithm aversion in an important domain, judicial decision-making, that has not been shown. We also document the impact of case complexity on perceived trust of algorithms and humans and show that trust for algorithmic judges drops especially when legal cases involve emotional complexities. From a practical perspective, we raise important questions for governments, policymakers, legal firms, and societies in general. Our findings indicate that despite some positive aspects of algorithms (i.e., perceived speed and cost), policymakers should expect strong pushback from citizens against courts' adoption of algorithms in adjudication.

Algorithmic Entitativity and the Overgeneralization of Algorithmic Errors

EXTENDED ABSTRACT

Artificial Intelligence is transforming the deployment of core public services. Despite popular belief that the public administration relies on antiquated procedures, automation in the public sector is well underway in the United States. AI decision systems are being deployed to supplant traditional decision-making in many public sectors, from government benefits, to justice, policing, social services, education, and health (de Sousa et al. 2019). For instance, AI algorithms are used to allocate a variety of public benefits, from Medicaid to Medicare, food stamps, unemployment, and Social Security disability.

The spread of AI to the public sector is advocated on the promise of reducing costs and improving service quality, ultimately making agencies more effective and citizens more satisfied. Despite technological improvements, these AI systems are fallible, and might commit errors. In the recent years, the press has reported a number of algorithmic errors in the provision of public services. A key question, then, is how the public responds to AI making errors in the provision of public services. What inferences and generalizations do people make when learning of AI (vs. human) errors? That is the basis of these generalizations? And what are the downstream consequences for the perceived legitimacy of our core institutions?

We answer these questions in a series of experiments (*N*=2442) across a range of public services using both convenience and nationally representative U.S. samples. These experiments show that people manifest *algorithmic transference*—the propensity to generalize algorithmic errors at a higher rate than human errors: when observing an algorithm or a person err, people are more prone to infer that another algorithm, but less so another person, will make the same error. Rather than reflecting generalized algorithm aversion (i.e., preference for humans over algorithms), algorithmic transference stems from a perceptual process that we term *algorithmic entitativity*. People spontaneously perceive and mentally represent a group of algorithms as a group of greater entitativity (i.e., homogeneity and intragroup similarity) than a group of humans. Ultimately, generalization of algorithmic errors has detrimental downstream consequences for propensity to access public services and institutional legitimacy.

Table 1 summarizes our empirical testing. We tested our predictions across several types of public services on both convenience (Amazon Mechanical Turk) and representative U.S. samples (Lucid, Prolific). All of the domains employed are based on actual uses of AI algorithms in the provision of public services.

Experiments 1A-1C provide evidence of algorithmic transference—a higher generalization of algorithmic than human errors to other group members—across three different domains using real news articles. Participants read brief news articles describing the commission of an error in the allocation of disability benefits (1A), calculation of social security benefits (1B), and pre-trial risk assessment (1C). Between-subjects, we manipulated whether the target error was made by an algorithm or by a person. We then measured inferential generalizations via performance (probability estimates that another agent of the same group—algorithm or person—would make the same error) and inferential evaluations (attitudes towards another agent of the same group employed by a different institution). These experiments showed algorithmic transference—greater propensity to generalize algorithmic than human errors.

Experiment 2 offers preliminary evidence of algorithmic entitativity. Participants read brief descriptions of either 6 algorithms or

6 people carrying out various tasks in the public sector and then were asked to evaluate their perceived entitativity. As predicted, people perceived algorithms as having greater group entitativity than humans.

Experiments 3A and **3B** tested the prediction that algorithmic transference stems specifically from algorithmic entitativity via mediation while controlling for error base rates. Study 3A examined the mediational role of algorithmic entitativity on inferential performance, and study 3B on inferential attitudes. We assessed entitativity as perceptions of intra-group similarity and group cohesiveness. In both studies, while controlling for the base failure rate for algorithmic and human errors, algorithmic entitativity mediates the effect of algorithmic transference.

Experiment 4 tests our process account via moderation: attenuating algorithmic entitativity eliminates algorithmic transference. In addition to manipulating agent as an algorithm or person, we manipulated group entitativity by specifying that the erring agent and the target agent shared few similarities, were different from each other, and did not belong to one cohesive group. An algorithm aversion account would predict a main effect where people always infer that other algorithms are more likely to err than other humans. However, an algorithmic entitativity account predicts that reducing entitativity will eliminate algorithmic transference. This is what we find.

Finally, **Experiments 5A** and **5B** tested the negative downstream consequences of algorithmic transference for institutional legitimacy, where perceived institutional legitimacy was mediated by the extent of algorithmic transference.

This research makes theoretical contributions to literatures on psychological responses to automated systems (Castelo et al. 2019; Gill 2020, Granulo et al. 2020; Leung et al. 2018; Longoni and Cian 2020) and to perceptions of algorithmic errors (Dietvorst et al. 2015; Dzindolet et al. 2002). Our research is unique in identifying algorithmic entitativity, a critical perceptual process that characterizes how people mentally represent a group of automated agents—as having a greater entitativity than a comparable group of humans. Our perspective is novel because it is rooted on representational processes at the group-level (i.e., how a collection of automated agents is mentally represented) rather than on lay-beliefs at the individual-level (i.e., what an individual automated agent is presumed capable of doing), as in most prior research. Second, we identify novel inferential implications of this representational process: algorithmic transference. As a type of inferential judgment, algorithmic transference is also novel, given that prior research on automation has largely assessed choice (to rely or reject automated agents) rather than inferences at the group-level. From a substantive perspective, if thoughtfully deployed, AI has the potential to improve the public sector by allowing public institutions to more effectively deliver to their statutory duties and meet rising expectations of responsiveness (Calo and Citron 2020). However, our findings highlight how the premature or unregulated spreading of AI technologies to the public sector might undermine legitimacy of the very institutions it is meant to modernize.

Uncovering and Mitigating Algorithmic Bias in Decision-Based Facial Recognition Systems

EXTENDED ABSTRACT

The use of facial recognition systems (FRS) has increased dramatically in the past decade. Governments, companies, and consumers are integrating FRS to make critical decisions, such as whom to interview (Ryan 2020), hire, trust (Abrams 2016), and even arrest (Hill 2020). Concern over algorithmic bias in these systems, however, is also growing (Lambrecht & Tucker 2019). Recent studies, for example, consistently document lower facial recognition rates for females and racial minorities (Srinivas et al. 2019). However, existing research has not systematically evaluated the objectivity of decision FRS.

To address this gap, we first implemented a leader detection algorithm (Stoker et al. 2016) similar to the ones employed in job-screening systems (Ryan 2020). To evaluate the algorithm, we hand-collected a dataset of leaders, professors, and actors using the judgment sampling method, an industry standard procedure in data collection. Our preliminary analysis shows that the sampling method did not mitigate the effects of covariates, which persisted in virtually all later stages, leading to algorithmic focus bias. Heeding the call to conduct more explainable machine learning (Kroll et al. 2016) and to unpack the "black-box" of decision FRS models, we employed adversarial machine learning techniques and composite rendering of facial images and found that the leader detection FRS indeed "focused" only on covariates such as lighting, clothing, and hairstyle differences. In some cases, blocking facial information actually improved prediction power.

Second, we compared the sample of leaders against the sample of professors and actors using apparent age, attractiveness, and transient facial features extracted using Face++ API. Apparent age was significant after excluding individuals outside 30 to 80 years of age, showing that a person who appears to be relatively younger based on facial image is more likely to be a leader. Attractiveness was also significant, indicating that a person who is less attractive is more likely to be a leader than others. Smiling was significant, even though we aimed to collect neutral facial images. In other words, the results indicate it is more likely that the person in a facial image is a leader if that individual is smiling.

Third, because the judgment sampling method failed to eliminate covariates such as attractiveness and apparent age, we employed propensity score matching, a method commonly applied in econometrics to simulate experimental settings (Caliendo & Kopeinig 2008). Using matched samples we trained and tested a leader prediction model using the Face++ attributes again. The AUC scores of logistic regression prediction after matching (N per class = 600) were 0.532 for leaders vs. professors and 0.533 for leaders vs. actors. The scores dropped to approximately chance level, indicating successful matching based on the given attributes.

Fourth, we employed a deep neural network (DNN) models to see if it could filter out the effects of (transient) covariates without explicitly controlling for them (Kachur et al. 2020). The mean AUC scores before matching were 0.912 for leaders vs. actors and 0.949 for leaders vs. professors. The scores decreased, on average, by 0.029 and 0.032, respectively, after matching. This finding suggests that when classifying leaders and non-leaders the DNN model did not mitigate covariates; rather, it actively capitalized on them to increase predictability.

Finally, we employed adversarial machine learning on the matched samples (Huang et al. 2011). If adversarial attacks removed morphological features, a model relying on such features should fail. On the other hand, if the model did not fail, then more transient features may exist. Figure 2 provides an example of four types of adversarial attacks. On average, no distortions brought prediction power down to chance level, and some distortions even improved prediction power. For example, Masking Step 1 increased AUC scores to 0.833 for leaders vs. professors, and Masking Step 2 further increased this AUC to 0.852. These findings show that the DNN model performed better without facial information (e.g., after applying masking distortions). Inversely, prediction power decreased when non-facial infor-

mation was blocked (e.g., Bordering Step 1 and 2, the opposite of masking).

Overall, we found evidence of algorithmic bias in the sampling, preprocessing, and model implementation stages in algorithmic FRS. These results suggest FRS algorithms are misusing specific features on the face as the primary determinant of a human's traits and capacities, in ways that are systematically biased and misinterpreted. Just as organizations and researchers are starting to become more aware of how biases related to race, gender, disability, and other characteristics influence human decisions, it is our hope that this research will motivate people to pay closer attention to the biases algorithms can perpetuate, broadly and specifically, in FRS algorithms.

A Persuasive Chatbot for Encouraging COVID-19 Vaccination

EXTENDED ABSTRACT

Computer scientists have been attempting to build chatbots that can persuade humans to change their attitudes and behaviors for at least two decades, with limited success (Andrews, Manandhar, and De Boni 2008; Rosenfeld and Kraus 2016). Only recently have researchers succeeded in creating chatbots that can understand human arguments and present relevant and convincing counter-arguments in real time (Hunter et al. 2019).

We developed a chatbot to persuade people to get a COVID-19 vaccine. The development process involved asking many people to argue *against* vaccines, identifying the common categories of arguments (i.e, unknown long-term effects, fast development, etc.), developing counter-arguments for each of those arguments, presenting those counter-arguments to people opposed or hesitant regarding vaccines, collecting their second-level arguments, categorizing those, developing second-level counter-arguments, and so on, for as many rounds of argumentation as we want the bot to be capable of. For each round, a classifier algorithm is used to let the bot automatically classify individual arguments into one of the common categories identified.

We tested whether a chatbot can persuade people to get a COVID-19 vaccine more effectively than a static list of arguments. We also tested whether the chatbot's effectiveness changes if it includes statistics or emotional anecdotes in its arguments, since human persuaders are often more effective when using the latter (Freling et al. 2020).

We recruited participants from Prolific who were not already extremely likely or extremely unlikely to get a COVID-19 vaccine (answering at the endpoints of our $1 - 7$ scale). Those who are extremely unlikely will be much more difficult to persuade and those who are extremely likely do not need persuading. 396 participants chatted with the bot, which used either statistics or anecdotes to open and close the chat. For example, statistics included the current death toll from COVID-19 and anecdotes included emotional descriptions of losing a loved one to COVID-19. The bot began and ended the conversation with either a statistic OR an anecdote, but in between the bot used the same arguments across the two conditions. In the static argument condition, which we view as a control condition, 193 participants read a list of 10 arguments in favor of vaccinations. We measured participants' likelihood of getting the vaccine on a 7-point scale before (T1) and after (T2) the chatting with the bot or reading the list.

Overall, the static list did not shift likelihood of getting vaccinated (T1 = 4.42, T2 = 4.64, p = .145). The bot, with both anecdote and statistic conditions combined, marginally shifted likelihood (T1 = 4.30, T2 = 4.50, p = .069). The two bot conditions were equally

effective. None of the three conditions were significantly more or less effective from each other overall. Neither chatbot condition interacted with age or gender in shaping effectiveness. However, the effectiveness of both bot conditions and of the static condition varied significantly depending on participants' T1 likelihood, as shown in Table 1. Interestingly, the largest effects overall were observed among the people least likely at T1 to get vaccinated.

Work is ongoing to improve the chatbot, both in the vaccine domain and other domains. For example, the current version of the chatbot is not able to answer specific questions about the vaccine, which likely limits its persuasiveness. A question-answering version of the chatbot is currently being developed.

If accepted, this presentation will introduce the marketing community to the development and use of persuasive chatbots and present the development and testing of this specific bot as a case study. The presentation will include a brief tutorial on the basic steps involved in building such a chatbot which audience members can then try themselves. While the results of this particular case study hold promise regarding the effective use of chatbots to change attitudes in this and other domains, they also highlight the challenges in doing so and suggest that highly sophisticated technologies do not always perform better than much simpler approaches.

Paper #3: Ontology and Circulation: Towards an Eco-economy of Persons
    Eric Arnould, alt, Finland

SESSION OVERVIEW

The theme of ACR 2021 is What the World Needs Now. The Conference organizers state that "There are many ways ideas can change the world" and invite participants to "tell us what matters." The three papers in this session are a direct response to this call, arguing that a reconfiguring of the human relationship to the non-human world is a crucial response to the challenges facing humanity, and that consumer researchers have an as yet untapped role to play in this reconfiguring.

As noted by Descola (2013, 2014), foreshadowed by Guattari (1989), and explored by Harraway (2008), the relationship between humans and the global biome is paradigmatic of the challenges of, and the challenges imposing themselves on humanity in this century. For Descola, a non-exhaustive list of these challenges would include "climate change, the erosion of biodiversity, the multiplication of transgenic organisms, the exhaustion of fossil fuels, the pollution of fragile environments and of large urban centers, the accelerating disappearance of tropical forests and coral reefs, all have become issues of public debate at the global scale and fuel the disquiet of numerous inhabitants." In this special session, we reflect on the relationship between consumer culture and biosociality in the face of these and related challenges.

An acknowledgement of the problematic human role in the contemporary anthropocene era rests on the dethroning of humanity as a species outside and beyond the biological. On a more situated level, an understanding of the bio-social anthropos is a precondition for understanding the modes of human desires, seductions and aberrations. The complexity of life and the complexity of the human condition is the starting point for a consumer research agenda and an approach to consumer culture, that can cope with the obvious global challenges to sustainability we are facing.

Biosociality as ontology and epistemology addresses the challenges imposed on the vision of sustainable consumption by the current tendency to reduce the cultural, psychic and biological consequences of consumer culture to predominantly if not exclusively a human affair. Furthermore, it reformulates the enduring attitude-behavior gap between consumers' oft-stated desire for more sustainable consumption and the reality of their behavior in a new way, as a problem related to the systemic misconstrual of the relationship between human economic behavior and the biome. Finally, a biosocial perspective offers an alternative that recognizes the necessity of resource circulation in any imaginable economic system.

This special session explores simultaneous acknowledgement of the sociality of the biological and the biologicality of the social without recourse to flawed, universalizing genetic reductionisms. We aim to open the way for investigations and conversations addressing the possibility of a biosocial renewal of thought in consumer culture theory and on a more sustainable consumption system against the ecological precarity which consumer capitalism produces. As indicated, biosocial renewal is defined by the contingent extension of the principle of sociality to other living beings, and the recognition that all living beings are in communicative relations with significant others, and between whom resources circulate in value co-creation processes.

We offer three papers sharing a common concern for post-human perspectives on consumption and markets that reflect on these topics. Dr. Lorna Stevens, expert in ecofeminism has agreed to serve as a discussant.

Some key terms: anthropocentrism, biosociality, sustainability, posthumanism, biosemiotics, neo-animism, nature, culture, ecosystem.

Reflections on "The Signs of Life and the Life of Signs

EXTENDED ABSTRACT

The purpose of this research is to propose interdisciplinary arguments for a dialogue between consumer culture theorization and biological anthropology and biology. In this sense, it contributes to the "manifesto" for a future interdisciplinary research program published earlier this year (Askegaard 2021). Here it was underlined that an endeavor to open a discussion between the scientific field of CCT with its roots in hermeneutics and other schools of thought in sociology and cultural anthropology and the disciplines of biological anthropology and biology is sorely needed. So far, it is fair to say, there has been very little such dialogue. CCT researchers are generally "culturalists", and rightfully so. But as Morin (1980 - and before him for example also Marcel Mauss) would point out, any attempt to isolate the phenomenon of "culture" from the fact that it exists in and of a biological world is suffering from the same type of reductionism as the one, CCT originated in opposing, i.e. reducing the consumer to a bounded rational decision maker operating independently of her/his cultural contexts and existential reflections. CCT, so far, has been 'missing the boat', as Rose (2013) warns us not to do. He, instead, invites researchers in the human sciences broadly to acknowledge that "much that is specific about our humanity, our individual existence and collective arrangements can be understood in terms of our characteristics as specific kinds of living beings" (*op.cit.* p.8).

It is thus very fair to say, that a "biological turn" has not appeared within the realm of interpretive consumer research. This is very different from the situation in consumer psychology, where neurological research and not least its intellectual derivative, evolutionary psychology, has produced a highly visible "Darwinization". These attempts to advance a biological / evolutionary psychology perspective in marketing and consumer research generally remain caught in the implied assumption that all behavior is goal-oriented and are consequences of evolutionary psychological optimization processes. It is largely based on a relatively hard-wired modular mode of conceiving the human brain and its ensuing adaptive functionality that has been strongly challenged, even by contemporary

neuroscience (David 2002). It is thus easy to criticize research that builds on reductionist applications of Darwin's notion of natural selection, but that is not the same as denying that biology should play any role at all. The question is how interpretive consumer research can come to terms with a non-reductionist biology that neither jumps on the bandwagon of neuromania nor fall prey to an attack of *Darwinitis Vulgarensis*.

This research provides an exploration of a non-reductionist attempt at a mutual rapprochement between biological science and the sciences of the human in order to reflect on the reach and significance for consumer research of such a rapprochement. Inspired from the classical philosophy of semiosis of C.S. Peirce on the one hand, and biologist von Uexküll's exploration of the biological significance of the *Umwelt* (≈ surroundings, environment) on the other, the theory, indeed the paradigm, of biosemiotics first suggested by American semiotician Thomas Sebeok and developed by Danish biologist Jesper Hoffmeyer (Hoffmeyer 2008) represents one potentially very fertile ground for biosocial theorizing. Biosemiotics allows for the fundamental insight that sign processes, "interpretation" and therefore a certain degree of autonomy is not exclusive to the animal, let alone the human world but is constitutive of life itself. Life processes, in other words, are fundamentally semiotic. This has consequences not only for how biology sees itself, although that may be the biggest inherent revolutionary potential, but also, according to Hoffmeyer, to our thinking in other domains such as ethics, aesthetics, health, cognition and technology. This presentation will critically and constructively evaluate these propositions.

Apart from its concrete influence of such central conceptualization for consumer research, biosemiotics as a paradigmatic point of departure invites to a non-reductionist dialogue between scientific disciplines studying the human from biological as well as socio-cultural perspectives, in other words the constitution of a biosocial theorization. Consumer culture theory can – and should – find inspiration in open systems approaches to human biology and culture, such as biosemiotics, in order to anchor its theorizing of behavior in a framing of the human being that includes a complex interactivity not solely in terms of the classical structure-agency relationship of the individual and its social context but also to the bio-communicative characteristics of the species.

As noted by Descola (2013), the relationship between humans and nature will be paradigmatic for the challenges of, and the questions imposing themselves in this century. An acknowledgment of the human role in the contemporary Anthropocene biosphere rests on the dethroning of humanity as a species outside and beyond the biological. On a more situated level, an understanding of the biosocial *anthropos* is, in my view, a precondition for understanding the modes of human desires, seductions and aberrations. The complexity of life and the complexity of the human condition is the starting point for a consumer research and an approach to consumer culture, that is able to cope with the obvious challenges we are facing.

Ontological Hybridities in Consumption Practices

EXTENDED ABSTRACT

This research examines the mingling of human/non-human relationships in Western consumption practices. Since the Enlightenment, relationships to non-human entities, namely nature (Canniford and Shankar 2013), are shaped by a particular modern "ontology" (Descola 2013), or worldview (Redfield 1952). What Descola (2013) terms "naturalism" grants mankind the unique privilege to stand above and apart from nature, owing to its reflexivity and consciousness (Charbonnier 2015; Descola 2013; Latour 2004; White 1967). However, some scholars alert us to the fact that the dissociation of humans from nature, known as the "Great Divide," is a fiction that has been entertained for centuries through Science, Reason and Technique (Latour 2004; Viveiros De Castro 2004). As a result, such epistemological dualism prevents us from understanding relationships that are not part of this dominant paradigm (Choné et al. 2016).

Anthropologists have long established that magical thinking permeates individual and social practices (Frazer 1890; Hirschman 1985; Mauss 1902; St James, Handelman, and Taylor 2011) and continues to do so in so-called highly educated societies (Rozin et al. 1986). Psychologists as well as CCT researchers provide many instances of how sympathetic magic operates (Argo, Dahl, and Morales 2006, 2008; Morales and Fitzsimons 2007; Fernandez and Lastovicka 2011). These studies demonstrate that Westerners may be affected by non-modern ontologies, thus illuminating the entanglement of categories such as nature/culture and humans/non-humans (Canniford and Shankar 2013).

However, in addition to Askegaard's (2021) call about biosociality, more research is needed on ontological porosity and the way consumers hybridize non-naturalist ontologies in their consumption practices. We draw on Descola's (2013) approach of four "ontologies" – animism, totemism, analogism and naturalism – to explore such ontological hybridization within everyday life. Descola's (2013) four "ontologies" rest on the way human societies conceive of "physicality" (form, substance) and "interiority" (intentionality, mind, consciousness) of other beings, which are then perceived to be similar or different. We next briefly describe each ontology that, according to Descola (2013), is connected to both specific cultural groups/societies and geographical areas.

In analogism, all elements, including beings, are differentiated from each other through a discontinuity of both interiority and physicality. This creates a feeling of disorder that is solved by the search for stable correspondences between heterogeneous components (Descola 2013, 2014). Differently, animism considers that most being (humans, animals, plants and certain objects) possess an interiority similar to those of Man (a continuity of interiorities), while being characterized by a discontinuity in their physicalities. Relationships between humans and non-humans are intersubjective. In totemism, particular sets of humans share physical and moral properties with non-humans in the form of a continuity of both their interiorities and physicalities. In naturalism, human beings are the only ones to have a mind, a consciousness, a reflexivity. While naturalism acknowledges a discontinuity of interiorities, it posits a continuity of physicalities of non-humans and humans along a continuum that relies on physical, chemical and biological laws. Due to their formal and informal education, Westerners operate within a naturalist ontology. However, Descola suggests that non-naturalist ontologies may occasionally "infiltrate" the organization of our representations, actions and fields of habits (Descola 2013). We thus further the author's conjecture that ontological boundaries may be porous so as to create ontological hybridities, i.e., the co-presence of several ontologies within individuals.

In order to explore ontological infiltrations in consumption practices, our research adopts an interpretive, phenomenological perspective (Goulding 2005) with 25 consumers. These were initially recruited in the first author's close circle of acquaintances to find the most favorable conditions possible for intimate conversations that require complete trust. Then, a snowball sampling was used in order to bring more variance in terms of cultural variance and human-nature relationships as known by relatives and friends. Interviews were conducted at home and sought to contextualize various experiences of nature and relationships to animals and plants, but also to objects,

inanimate things and spirits, e.g., having an animal, being vegetarian, placing credence in astrology, believing in powers of gemstones, etc. The sample consists of 17 women and 8 men, aged 24 to 67 (with an average age of 41). We tried to uncover, in our informants' own verbalization, various thematized narrative accounts that were then confronted to Descola's analytical categories to illustrate instances of naturalist as well as animist, totemic or analogic ontologies.

Findings show that informants exhibit analogic and animist infiltrations in naturalistic ontology (and to a lesser extent totemic infiltrations that we will not develop here because of space constraints).

Analogic infiltrations lead informants to link together elements that are supposed to be unrelated within naturalist reasoning. Such infiltrations result in buying, crafting or retrieving (through inheritance or donations) objects (lucky charms, dream catchers ...) for their magical effect or because they (re)present or symbolize a deceased loved one, part of whose being is (in) the object. Analogic infiltrations nurtures forms of consumption that are based on a constant exchange of universal energies in the world, regardless of distance and time. Such fluids lead people to resort to alternative medicine such as lithotherapy, magnetism, reiki, purification, etc., and also to pay particular attention to the origin and traceability of products. This explains why they also favor self-production for food and various ecofriendly household products. Circulation of energies also leads them to attach great importance to nature and to respect plants and animals on the basis that everything is interconnected and energetically linked.

Differently, animist infiltrations result in an anthropomorphization of non-humans, mainly animals but also plants and objects. In animism, non-humans are considered to be similar to humans in terms of interiority, hence leading to protect biodiversity and treating other beings with great care. Though their purchases, informants with animist infiltrations take into account how animals are reared and avoid consuming products of animal origin or containing animal products in food, clothing and cosmetics. Likewise, some do not buy pets from pet stores because animals are not things that can be monetized. Informants exhibit similar orientations towards plants. They for example refuse to use chemicals for weeding and exclude the purchase of cut flowers because this would "kill" them. Overall, animism leads to pro-environmental consumption since many informants engage in self-production of various goods (clothing, cosmetics, hygiene and cleaning products) that respect non-humans and environment. They also frequently buy and give second-hand products to which they offer a second life in order to preserve natural resources.

Findings bring to light ontological infiltrations that permeate naturalist ontology in everyday consumption practices. We show that one individual may accommodate several ontologies which are variously mobilized depending on circumstances or situations. In sum, we demonstrate that Western consumers exhibit a continuum of ontological hybridities that more or less hybridize their naturalist ontology. Our research aims to go beyond the Anthropos to fully consider the active, perceptual and practical relationships that individuals entertain with various beings of the world, what Ingold calls "an ecology of materials" (2012: 435). Our preliminary findings make it possible to consider inflections that are likely to foster a more sustainable future.

Ontology and Circulation: Towards an Eco-economy of Persons

EXTENDED ABSTRACT

The marketing discipline evinces what could properly be termed a Romantic conception of the improvability of humanity and its ability to contribute to this progressive improvement (Doherty, Clark and Brown 1998; Campbell 2018/1987). Strategic initiatives like Corporate Social Responsibility (CSR), sustainability marketing, Base of the Pyramid (BOP) marketing or FairTrade enshrine this Romantic drive to ethical progress (Belz and Peattie 2010, 14), although each inspires well-grounded critiques (Kolk and van Tulder 2010; Huang 2017; Blowfield and Dolan 2010). Set against this is the growing recognition among scientists that whatever its form market capitalism inevitably produces ever greater ecological precarity (DeSabata 1995; increasing GhG emissions, deforestation, loss of biodiversity, ocean acidification, climate change induced migration). Implicit in this recognition, is the limitation of a Romantic marketing paradigm to address these existential threats to humanity. Consequently, this paper investigates an alternative vision of resource circulation via a critique of prevailing ontology.

The paper suggests the possibility of a post-humanist, neo-animistic retooling of resource circulation and offers a glimpse of an eco-economy of persons. A neo-animist ontology helps address the challenges to sustainable human livelihoods and biotic communities imposed by the Dominant Social Paradigm (DSP) as identified in macromarketing, the enduring attitude-behavior gap identified in green consumer research, and the axiological partitioning of behaviors found in consumer practice research. But more fundamentally a neo-animist perspective critiques the social exchange paradigm which anchors the entire marketing episteme (Bagozzi 1978; Brinberg and Wood 1983; Pandya and Dholakia 1992; Safari and Albaum 2019), as well as most approaches to the circular economy (Clark and Bonato 2020; Temesgen, et al. 2019). At a minimum, this neo-animist offers an alternative to the Romantic perspective on resource circulation. It "acknowledges that it is only through an examination of what keeps society and consumption unsustainable that we can understand the ways to transition to a sustainable society" (Kemper and Ballantine 2019, 293). The paper briefly reviews some of the literature on sustainable marketing and consumption. Then, the naturalist and neo-animist ontologies are contrasted. Animism does not imagine a nature-culture dichotomy. Animism asserts that all living beings have similar "souls," or at least selves, even though radically different physical bodies house these selves. Animal and plants are "social beings, endowed with interiority and faculties of understanding similar to those of humans" (Descola 2013, 352). This recognition of an indeterminate, animating force shared among living things leads philosophers to recognize parallels between animism and Renaissance neo-Hermetic philosophy and Schilling's *Naturphilosofie* (McGrath 2019), traditions which lost out to naturalism in Western thought.

Consistent with Guattari's (1989) observation, subjectivity in animisms is destratified, meaning that unlike naturalists, animists may attribute personhood to humans or other beings. However, these attributions are contingent. Not all creatures are other-than-human persons; they, like humans, must display the capacity to "be with others, share a place with them, and responsibly engage with them" (Bird-David 2006, 43). Ascribed selfhood is both relational and situational in animist societies rather than foundational and individual (Descola 2013; Kohn 2003; Strathern 1988; Strathern and Stewart 1988). Social acts define an animate being as a person, for whom social life is emergent (Ingold 2000). What Descola calls transitive

principles of resource circulation, specifically gifting, reciprocal exchange, and predation (symbiosis) are these defining actions.

An contemporary example of the matsutake eco-economy (Tsing 2015) is then offered that provides a glimpse of neo-animist principles of exchange in operation. The paper then returns to a critique of exchange theory in marketing and examples of non-utilitarian resource circulation to illustrate the paradigmatic changes required to move to a more sustainable system of resource circulation while preserving a role for exchange in a future economy.

SESSION OVERVIEW

Culturally-oriented consumer researchers contributed to contemporary branding thought with two interlinked theoretical perspectives—namely, cultural branding and brand as assemblage. While cultural branding attends to how iconic brands draw from socio-historical disruptions and emergent cultural ideologies (Beverland et al. 2020; Brunk, Giesler and Hartmann 2017; Holt 2004; Holt and Cameron 2010); brand as assemblage highlights how interactions between human (e.g., consumers, managers, experts, journalists) and non-human actors (e.g., competing brands, product design, social media discussions) constitute the socio-material amalgams that we call brands (Giesler 2012; Parmentier and Fischer 2015; Preece, Kerrigan and O'Reilly 2019; Rokka and Canniford 2016). At the core of both perspectives lies the idea of relationality: brand meanings are constructed through interrelations between networks of actors, practices, discourses, and occurrences at the intersection of macro, meso, and micro levels of analysis.

In line with the conference theme *What the World Needs Now*, we believe that the contemporary socio-material condition necessitates a relational understanding of branding more than ever. Brands increasingly attain their meanings in relation to disruptive social movements and ideological orientations (e.g., Nike and BLM); alternative experts and conflicting expert systems (e.g., debates on the safety of Pfizer/BioNTech mRNA vaccine); and functionalities of digital platforms (e.g., Tinder's swiping game) and human-AI interfaces (e.g., Alexa as family member). Accordingly, this session brings together three empirical papers focusing on how such interrelationships shape brand trajectories.

The first paper focuses on brand positioning through a conflictual relational process. It examines how denigrating messages about the market leader disseminated by a network of actors become source material for competitors' positioning strategies. Drawing on the mobile dating apps market, the authors reveal how competitors position their brands against the deficiencies of the leader by enrolling an assemblage of cultural ideologies regarding romance and gender equality, person-brands of app executives, and features of app interfaces.

The second paper focuses on brand value generation through relations with alternative experts. It investigates how rebellious brands challenge established expert systems and attain "avant-garde" status. Focusing on French wine, the authors demonstrate that winemakers embracing the disreputable Vin de France designation benefit from their relations with wine merchants, sommeliers, and consumers in creating unconventional brand assemblages with alternative material and expressive elements.

The third paper focuses on how technology brands orchestrate consumer-to-consumer and consumer-to-AI relations. Drawing from the object agency conception, the authors define smart brands as an agentic amalgam of brand, technology and AI. Focusing on Alexa and Google Home, they demonstrate how smart brands infiltrate into family social systems, disrupt existing consumption practices, and (re)skill consumers to new branded consumption constellations.

While we focus on three specific cases of how brands attain and generate meaning in relation to expert systems, technology, consumers, and competitors; our insights can be extended further by examining different actors, processes, and relations in yet other contexts. We hope that our session will spark discussions on the contours of branding and inspire researchers to account for the role of various human and non-human actors—once considered externalities—in co-steering brand trajectories.

Capitalizing on Competitor's Doppelgänger Brand Images: Insights from the Positioning Wars in the Mobile Dating Apps Market

EXTENDED ABSTRACT

When brands are assemblages co-constituted by a multitude of actors, brand images are constructed and negotiated through recursive processes over which managers have limited control (Diamond et al. 2009; Giesler 2012; Thompson, Rindfleisch and Arsel 2006). This could, on the one hand, mean that different market actors (such as consumption communities, institutionally-credited experts, media personalities) can be enrolled as brand co-authors and participate in value-generating activities (Schau, Muñiz, and Arnould 2009). However, it could also prove detrimental as these market actors can reframe brand meanings in value-diminishing ways (Holt 2002; Kozinets and Handelman 2008). Culturally-oriented consumer researchers advanced the doppelgänger brand image (DBI hereafter) conception to analyze risks of this nature and make suggestions for brand managers to identify and assuage resulting threats (Thompson et al. 2006; see also Giesler 2012; Parmentier and Fischer 2015). A DBI is defined as "a family of disparaging images and stories about a brand that are circulated in popular culture by a loosely organized network of consumers, antibrand activists, bloggers, and opinion leaders in the news and entertainment media" (Thompson et al. 2006, 50). According to this conception, a DBI operates as the evil twin of the official branding story by challenging the brand's authenticity and undermining the identity value it generates for consumers. Brand managers, nonetheless, can treat the emergence of these demeaning messages as an early warning sign of the frailties of their branding story and make necessary changes before the DBI threat gets out of hand (Giesler 2012).

This early conception provides important insights regarding the emanation and trajectory of DBIs and pertinent suggestions for

branding professionals to proactively turn DBIs to their advantage. However, it pays scant attention to cases where competitors can also turn the DBIs of their rival brand to their own advantage. According to the original definition, defamatory messages are disseminated by "consumers, antibrand activists, bloggers, and opinion leaders;" however, competitors are also likely to take an active part in brand disparagement by means of their marketing communications. While Thompson and colleagues (2006) identify that Starbucks's vilification as a greedy corporate giant helped create the opposing market niche for locally owned coffee shops, their analysis does not focus on how these local businesses utilize Starbucks' DBI strategically. To tackle this omission, we examine the ways in which the DBI of a popular brand becomes the starting point for competitors' positioning strategies. We specifically ask: How do competitors utilize the DBI of a rival brand to create a distinct market position for their own brands?

In seeking answers to this question, we focus on the positioning wars among mobile dating apps. These digital platforms (as successors of online dating sites such as match.com and eHarmony) initially emerged in the early 2010s and have gained remarkable popularity ever since. Tinder as the most popular dating app is currently used in 190 countries and has registered more than 60 billion matches to date (Tinder 2021). Besides Tinder, there are manifold other apps including Grindr, Bumble, Coffee Meets Bagel, Happn, Hinge, and the League that appeal to individuals with diverse romantic-sexual preferences. Since day one, Tinder has suffered from various DBIs that were instituted by frustrated consumers, journalists, and social media discussions and exacerbated by the marketing communications of competitors. Two most salient DBIs of Tinder have been that (1) the app brings about "the dating apocalypse" by fostering an emotionless hookup culture and (2) it is a hotbed for sexist, sexually objectifying, and misogynistic behavior towards women (Sales 2015). Two rival brands have especially been persistent in making these DBIs central elements of their marketing campaigns and presenting their apps as remedies to Tinder's shortcomings—namely, Hinge and Bumble. Focusing on the positioning wars between these three brands, we assembled an extensive qualitative dataset including ad campaigns and press releases from Tinder, Bumble and Hinge websites; news articles and interviews with app executives in popular media outlets; walkthrough analyses of app interfaces (Light, Burgess and Duguay 2017); and interviews with app users.

Findings of our hermeneutic analysis demonstrate that rival apps derive strategic value from Tinder's DBIs through aligning select cultural ideologies, professional and personal conduct of their app executives, and functionalities of the app interfaces. They first cull from widespread cultural ideologies regarding romance (e.g., traditional ideals of romantic love) and gender equality (e.g., the #MeToo movement) to construct origin myths standing up to Tinder's toxic culture. Then, they cultivate these myths through the person-brands of app CEOs and their emotional and professional styles (e.g., Justin McLeod as hopeless romantic and Whitney Wolfe as driven feminist). Lastly, they inscribe the branding story into the user interface through strategic design elements (e.g., icebreakers instead of swiping and women-send-the-first-message feature).

Based on our findings, we extend previous literature on DBIs in two primary ways. First, we elucidate the specific role of competitors in exacerbating the DBI of a rival brand. We show that on top of casting dispersions toward the targeted brand's authenticity and identity value, competitors' purpose in igniting their rival's DBI may be carving out a unique market position by presenting their brand as a remedy to the deficiencies of the targeted brand. Second, we highlight that the targeted brand itself can capitalize on its own DBIs

in ways that are not identified in previous literature. On top of using DBIs as diagnostic tools to detect and revamp the problematic aspects of their brand image, brand managers can choose to own up to their DBIs and make them part and parcel of their brand image. Our analysis provides additional insights regarding the alignment of executives' person-brands with the brand image of their company and integration of product design features in branding stories (thus linking cultural branding and brand as assemblage insights).

Avant-Garde Brands: Rebels Successfully Challenging the Status Quo

EXTENDED ABSTRACT

Entering a long-established market to challenge the status quo is a daunting venture. Yet challengers succeed. Picasso introduced cubism, Apple redefined mobile phones, (e.g., Carpenter and Nakamoto 2019), and nouvelle cuisine eclipsed classic French cuisine (Rao, Monin and Durand 2003; Bourdieu and Delsaut 1975). The work of Picasso and others inspired the term *avant-garde* (Poggioli 1981), describing artists who are novel, radical, and at least implicitly critical of the status quo. In addition to artists, music, fashion designers, films, and brands are described as avant garde. Although scholars have examined many strategies firms use for later entry, none have examined the potential effectiveness of avant-garde brands.

In this paper, we explore how firms use avant-garde brands to successfully challenge the status quo. We focus on French wine. Although wines from the most prestigious regions of France remain the world's most prized and most expensive, wines bearing the vin de France label are among the least prestigious. A group of winemakers has embraced the Vin De France designation with the audacious goal of making wines that rival or surpass the most respected wines of France. Against the odds, some of these rebels are succeeding. The Vin De France wines have succeeded by becoming avant-garde.

We examine the success of avant-garde brands using ethnographic methods. We interviewed producers, retailers, experts, and consumers (Dion and Borraz 2017). We combined interviews with participant observations in shops, and analysis of press articles (Dion and Borraz 2017, Humphreys and Carpenter 2018). Our analysis offers three new insights into late-entry strategy.

First, our analysis suggests an important, yet overlooked role for status. Existing studies of late entry strategy focus on differences among brands based on product attributes but exclude status (e.g., Carpenter and Nakamoto 1990, Zhang and Markman 1998). Status is recognized as a source of an enduring advantage (e.g., Dion and Borraz 2017, Humphreys and Carpenter 2018). The vin de France producers low status suggests that they will be disadvantaged relative to their more famous rivals. We find, however, that the Vin De France producers use innovation to create competitive advantage based on the greater status of their rivals. Incumbent producers cannot imitate these innovations without forgoing their status. Our analysis, thus, describes how low-status later entrants use strategic innovation to transform the status of their rivals into a competitive disadvantage.

Second, our analysis offers new insight into how late entrants shape consumer tastes. Analyses of late-entry strategy assume that firms compete to maximize profits based on exogenous consumer preferences (Carpenter and Nakamoto 1990). Scholars have proposed that firms' competitive strategies shape consumer tastes (e.g., Jaworski, Kohli, and Sahay 2000), but empirical evidence on how firms influence consumer tastes is limited (e.g., Humphreys and Carpenter 2018). Humphreys and Carpenter (2018) show that high-status brands can define product categories in the long-established U.S. market for wine and set benchmarks in those categories. With less

influence, lower-status firms can struggle. In contrast, the Vin De France cooperate with higher-status actors, such as wine merchants, which enables the Vin De France producers redefine the consumers' tastes for wine. Our analysis, empirically demonstrates how low-status firms can shape consumer preferences, while suggesting new avenues for late entry strategy.

Third, our analysis offers new insight into the role of brand symbolic meaning in late-entry strategy. Studies of late entry identify strategies for brands based on attribute differences (e.g., Carpenter and Nakamoto 1990, Zhang and Markman 1998). Previous analyses, however, exclude the symbolic meaning of brands, despite a long tradition of research on brands as valued symbols (e.g., Levy 1959, Rokka 2021). Our analysis suggests that, in addition to attribute differences, later entrants portray themselves as novel, radical, and implicitly critical of the status quo—or simply avant-garde—in comparison to incumbents who can be cast as old-fashioned, conventional and representing the status quo. By creating symbolic differences, even low-status later entrant can successfully challenge exceptionally formidable incumbents. We explore the implication of this finding along with our other findings for managers.

How Smart Brands Nurture Consumer-AI Entanglement

EXTENDED ABSTRACT

How does new branded technology shape consumption? The technology consumption literature in marketing has extensively documented how individual consumers, families, and groups experience and engage with new technological innovations, as well as navigate their different meanings, ideologies, and related practices (e.g., Belk 2013; Giesler 2008; Kozinets 2008; Kozinets, Patterson and Ashman 2016; Mick and Fournier 1998; Schau and Gilly 2003; Sherry 2000; Tian et al. 2014). A related stream has highlighted how brand managers and marketers can successfully create, legitimize, diffuse, and maintain new markets for technological innovations (e.g., Brown, Kozinets, and Sherry 2003; Epp, Schau and Price 2014; Giesler 2012; Giesler and Fischer 2018; Sood and Tellis 2005). In both conversations, however, marketing and consumer researchers have predominantly awarded agency to human actors, be they consumers, brand managers/marketers, or both. Recently, however, consumer research has shifted its focus away from human agency to understanding non-human agency, including technology, and its influence on consumers and markets (e.g., Epp and Price 2010; Hoffman and Novak 2018; Martin and Schouten 2014). Yet, minimal scholarly attention has been devoted to how brands themselves, in particular those for technological innovations, acquire agency to shape consumption practices, rituals, and activities.

In this paper, we therefore examine how technology brands modulate consumption practices in the home by theorizing and unpacking the concept of *smart brands*. We define *smart brands* as an agentic amalgam of brand, technology, and artificial intelligence. Both within and outside marketing and consumer research, agency is typically understood as the ability to act. A subject or market actor can undertake action through his/her decision-making to choose between available alternatives. Yet, according to Miller's (2005, 11) theory of materiality, objects also possess agency to influence consumers, since "material forms have consequences for people that are autonomous from human agency, they may be said to possess the agency that causes these effects." In the words of Borgerson (2005, 441), "Miller's theory of materiality calls the agency of subjects and objects into question, as agency appears to emerge in relation, not as a quality of either subjects or objects." Building on Miller's (2005) idea of object agency, we argue that *smart brands* have agency to think, shape-shift, interrupt, support, colonize, and overall change current social systems.

Our context of inquiry into *smart brands* is Amazon Alexa and Google Home. We draw from ethnographic participant observation and in-depth interviews along with archival and netnographic data to reveal a novel hierarchy of integrated brand uses from branded information to branded action that families acquire and adopt through *smart brands*. Specifically, we illustrate how these *smart brands* act akin to Trojan Horses by innocently moving into social systems such as homes and families only to disrupt existing consumption practices and (re)skill consumers and their families to new branded consumption constellations. We term this process of brand acculturation, E.M.P.A. (exploring, miming, programming, and adjusting) where the family adjusts to the *smart brand* and vice versa. In the first stage of playful interaction, family members ask silly questions to the newly acquired Alexa or Google Home that is typically placed in a prominent family living space, such as the living room or kitchen. In the next stage of performed interaction, different skills are programmed into the Alexa or Google Home, such as home lighting automation that requires purchasing new technology brands supported by the *smart brand*, like Philips' Hue light bulbs. This is followed by the third stage of normalized interaction, where family members accept and routinely purchase new brands for their home recommended by different Alexa or Google Home updates and functions. The final stage we have identified, naturalized interaction, the family members begin to self-reflect on how the smart brand has changed who they are as a family.

Overall, our findings highlight the agency of branded technological innovations. By demonstrating not just how consumers skill Alexa and Google Home, but also how Alexa and Google Home skill consumers and their families, our paper contributes to the literatures on branding innovations (e.g., Giesler 2012), market system dynamics (e.g., Giesler and Fischer 2016), and family consumption (e.g., Price and Epp 2015 for an overview). Family, according to technology marketers, is a decidedly romantic project in which social relationships are stable and technology operates like the proverbial campfire that nurtures unprecedented levels of community and collective problem-solving. A related narrative profiles the sole individual (young and elderly) for whom devices such as Google Home or Amazon Alexa constitute surrogate family. From a sociological experience design perspective, however, smart consumer technologies interact much more dynamically with what Epp and Price (2008, 50) refer to as identity bundles – fragile and frequently changing assemblages of social actors and smart objects, each with their own interests, agendas, preferences and skill levels. As these *smart brands* raise new questions about who controls (and can control) what, they can provoke not only social instabilities and conflicts but also feelings of imprisonment, exclusion, and loneliness. We therefore encourage future researchers to approach the *smart brand* critically, not as a harmonious unity of individuals but as an inherently unstable and evolving social system in which everything is connected but nothing adds up.

Paper #3: Self-Care: How Consumers Balance Self-Centered Care Consumption with the Needs of Others

Rachel Hochstein, Florida State University, USA
Colleen Harmeling, Florida State University, USA
Ela Veresiu, York University, Canada

SESSION OVERVIEW

Caregiving is an inherently intimate act where individuals, families, and service providers make decisions about how to best enhance individual and communal well-being. Parents care for children, children care for parents, teachers care for students, doctors care for patients, and individuals care for themselves. In the past, caregiving occurred primarily within the home and consisted of mainly unpaid labor. Today however, a greater volume of caregiving services are provided by the market. In fact, providing products to fulfill basic needs of life such as soap, medication, and baby formula is the basis for many consumption markets.

Standards of personal care and caregiving are generally collectively defined. However, some consumers may define self-care and caregiving differently from these collective standards and may face complicated choices about how to balance caring for themselves and for others. This may lead them to make care decisions that conflict with the needs and recommendations of influential actors such as bosses, clients, friends, doctors, and public health officials which can create tensions both within the individual and within communities.

The session includes three papers providing unique perspectives on how individuals make care decisions influenced by important others and communities. Taken together these papers shed light on how consumers navigate tensions between caring for themselves and caring for others. First, Robinson, Epp, and Tomar examine how consumers make decisions related to vaccinations for themselves and their children when decisions not to vaccinate are scrutinized by medical professionals and entire communities. Next, Godfrey, Miller, and Cao utilize the uniquely important context of the COVID-19 pandemic to examine consumer choices regarding mask-wearing as a public safety measure. Finally, Hochstein, Harmeling, and Veresiu discuss how consumers determine their self-care needs and navigate tensions that occur when consumers choose to put their own physical and mental well-being first.

This session includes timely research that is especially important considering current ongoing public health crises in which an individual's choice of how to care for themselves may be at odds with collective standards of care. The session is also important considering the increase in mental health awareness and crises. It provides insight into how consumers care for both their physical and mental well-being through the (lack of) consumption of products and services. The goal of the session then is to inspire theoretical and practical insights about caring for self and others that are useful for public policy officials, public health officials, and marketers of caregiving products and services. We expect the session will offer both conceptual and empirical discussion that will attract public policy, transformative consumer researchers, and service researchers.

The Seesaw of Loss and Hope: How Vaccine-Hesitant Parents Make Sense of and Experience their Choices to Engage in Oppositional Social Practices

EXTENDED ABSTRACT

Vaccinating one's child is not just a consumer choice in today's risk and knowledge society. It is often framed as a moral act, with implications for public health. "The moral dimension of risk is embedded in the underscoring of the child's need for support, safety and protection as a fundamental parental responsibility" (Brusdal and Frønes 2013, 160). Parents generally seek to justify their decisions as aligned with normative prescriptions of moral consumption (Pugh 2009). However, even though a strong formal public code supports the long-term benefits of childhood vaccination with substantial evidence from the medical establishment, the World Health Organization lists vaccine hesitancy among its top ten threats to world health (The Lancet 2019), directly contributing to epidemics of vaccine-preventable diseases (Feikin et al. 2000; Parker et al 2016). Our research question asks, how do vaccine-hesitant parents justify and experience their choice to delay or avoid vaccines for their children within an economy of morals?

Our study joins a broad conversation recognizing that the responsibility for many choices with implications for public well-being has shifted from institutions to individuals (Veresiu and Giesler 2018). These choices are loaded with moral imperatives and subjected to judgments from an array of stakeholders (Eckhardt and Dobscha 2019; Sharmir 2008; Soneryd and Uggla 2015). Certainly, parenting decisions are no exception. Parents often experience harsh moral judgments when departing from normative actions (Epp and Velagaleti 2014; Thomas and Epp 2019). Of particular interest, recent research recognizes the emotionality involved in responsibilization, especially in cases of resistance (Gonzalez-Arcos et al. 2021), but more work is needed to specify the emotion work involved in navigating resistance to fully capture parents' experiences of justification.

We adopt Boltanski and Thévenot's (2006) "economies of worth" as an analytic lens. It draws our attention to the ways individuals justify their choices to others by appealing to what they believe are commonly agreed-upon principles. We know, however, that principles sometimes conflict on moral grounds. In our context, potential conflicts exist between domestic polities rooted in the micro-context of familial bonds and civic polities rooted in the macro- and meso-context of public health that emphasize the common good. Thus, the grounds of moral arguments are differently configured (Hauser and

Benson 1999). Public health officials marshal statistical evidence that assumes a *deficit model* of public understanding of science (Gross 1994), but this model misses the "situated logics" of family, religious, and political beliefs that guide parents' vaccination decisions (Campeau 2019). An economy of worth lens helps us analyze the beliefs, ideologies, and value systems that parents hold and how they are shaped by and expressed through discursive interactions with the medical establishment.

To study parents' moral justifications and emotion work, we partnered with a mid-Michigan county's local health department aimed at developing a customized healthcare intervention to increase pediatric immunization completion rates. The State of Michigan requires parents to attend a one-on-one vaccine education session prior to granting non-medical vaccine waivers for their children. After approaching all parents who requested a non-medical waiver (between 5/25/16 to 9/9/17), we obtained audio recordings of 388 parent-nurse conversations to identify parents' complex vaccine stories (Czarniawska 2004; Thompson 1997). Follow-up depth interviews with a purposeful sample of these parents further develop findings around the emotion work parents undertake as they navigate economies of worth to justify their choices.

As we anticipated, our analysis revealed that vaccine-hesitant parents identify new risks and attempt to justify their choices against the institutional dictum in a relationship of vaccination (that of their child) consumption with the state, medical institutions, and the community. This is accomplished through discourses that are characterized by parents' experiences of emotional forces of loss and hope that we portray through a seesaw metaphor. Three parental discourses of justification emerged from our analysis: 1) reacting to **lived/ empathic health traumas**, 2) believing in the body's superior **native immunity**, and 3) focusing on **institutional distrust** (see Table 1). Across the themes, we observed tensions between domestic and civic polities that parents resolved through emotion work. The seesaw metaphor captures two interconnected ends that summarize parents' emotion work: protection of their child(ren) from communicable diseases (CD) versus protection of their child(ren) from potential negative outcomes they believe may result from immunizations. For example, following a health trauma, parents saw themselves thrown high up on one end of the seesaw with little agency over their children's health ("Thrown High"). They tended to interpret their prior vaccination decision as lowering one end of the seesaw by protecting their child against CD but raising the seesaw's opposite end by increasing the likelihood of experiencing a health trauma (e.g., autism). Other parents could, at first, be morally driven to avoid vaccinating their child altogether due to strong religious reasons bolstering the discourse of native immunity and act as "Bystanders," but they could later "Tiptoe" to the other end of the seesaw and vaccinate their child in a spread-out fashion to gauge the risks and appease their anxieties. In this way, the seesaw metaphor affords a dynamicity to vaccine-hesitant parents' decision-making rather than succumbing to the assumption that they are "oriented towards the static state" (Palomera and Vetta 2016) of adopting a discourse. Thus, the economies of worth framework illuminates how parents execute emotion work while gauging risks and contingencies involved.

In part, parents' feelings of anxiety and loss evidenced in the seesaw metaphor stem from the normative judgments they face when they must accept the moralized responsibility for their choices about childhood immunization (Gonzalez-Arcos et al. 2021; Veresiu and Giesler 2018). Acknowledging these tensions, there is more required than the civic world's "technology of trust" (Hüntelmann 2020) garnered through statistical evidence and scientific jargon. A deeper, "local" contextualization to understand parents' choices (Lawrence

et al. 2014) is paramount toward exploring the roots of vaccine hesitation and how they can be addressed. Ultimately, successful healthcare interventions should move beyond the deficit model of messaging about vaccine hesitancy to instead consider customized interventions based on the emotion work parents undertake to resolve tensions between domestic and civic polities.

Taking Care of Society: Understanding the Disruption and Persistence of Social Norms During the COVID-19 Pandemic

EXTENDED ABSTRACT

COVID-19 brought the importance of care to the foreground in healthcare and frontline market interactions. But the global pandemic also disrupted daily routines and rituals that normally sustain important shared meanings, identities, and relationships. We conduct a multi-method study of how consumers negotiate COVID-19-related social norm disruptions. Our research shows that these negotiations constitute an often-unconscious form of care work, through which consumers and service providers initiate and routinize socially desirable norms of behavior that create and sustain society in everyday interactions.

Despite the presence of goals, motives and ideologies, consumer behavior remains relatively disconnected from consciously articulated attitudes or values (Shove 2010). Actions are often guided intuitively by social, cultural or physiological influences (Allen 2002; Goldstein, Cialdini, and Griskevicius 2008; Williams and Andrew Poehlman 2017). Over a lifetime of practice, consumers settle into familiar, "common sense" rituals and routines that guide much of their behavior (Swidler 1986, 2001). Although not typically conceptualized as care work, the reproduction of shared norms and patterns of activity plays a key role in maintaining cohesive groups and societies.

However, when established norms and practices become disrupted, values and ideologies rise in prominence as people are forced to rely on them more explicitly to guide behavior. During these unsettled times people experiment with "new ways of organizing individual and collective life" (Swidler 2001, 99) without the aid of settled social norms. Previously mundane rituals and routines become "highly charged" (Swidler 2001, 99) symbolic acts, invested with meaning by competing ideological positions. Unsettled times create constant conflict between alternative approaches to care for society, whether through the preservation of familiar social norms or the formation of new ones. The social norm contests the play out during unsettled times remain understudied at the micro level of everyday social and market interaction.

Our research focuses on the use of face masks during the COVID-19 pandemic. Masks have become a prominent feature in consumers' everyday lives. But in the United States, the rapid adoption of masks has been accompanied by a persistent resistance. While this confusion has serious public health implications, it also presents a context for studying consumer responses to social norm disruptions and unsettled lives.

Our research utilizes qualitative and quantitative data that illuminate consumer behavior and experiences with masks at various stages of the COVID-19 pandemic. While our broader research includes data from both the United States and China, this extended abstract includes only results from the United States. These US data include 80 hours of ethnographic participant observation in a range of market places during the pandemic, recorded by researchers and student assistants in over 100 pages (55,000 words) of field notes. Qualitative data also include in-depth Zoom interviews with thirty

US consumers about their customer experiences during the COVID-19 pandemic. Two online studies conducted on MTurk (October 2, 2020; n=388) and Prolific (March 31, 2021; n=500) contained open-ended questions and quantitative measures assessing mask-relevant behaviors, experiences, and attitudes. We summarize the results of our ongoing analysis below.

We find that although COVID-19 masks present a relatively minor disruption, this unfamiliar object makes consumers more reflexively aware of their behavior and disrupts the influence of familiar social norms. In numerous small ways, masks constantly remind consumers that their activities are not normal. By forcing routinized behaviors out of the intuitive realm of common sense, consumers rely more on consciously articulated ideological beliefs to motivate particular actions in specific situations.

In our data, consumers connect mask wearing to several distinct ideological beliefs. In qualitative and quantitative responses, we find that these mask ideologies shape both mask attitudes and mask behaviors. However, our ethnographic and interview data demonstrate that this link is tempered by the presence of new and old social norms.

When consumers perceive mask ideologies as aligned with their own common sense, wearing masks in market spaces and social interactions become normalized relatively easily. In the absence of ideological conflict, new norms stabilize and mask wearing becomes an intuitive "new normal." However, when consumers perceive mask ideologies as disconnected or conflicting with common sense, the new behavior remains ideologically charged. Even when consumers wear masks publicly and regularly, we find that their ideologically conflicted behavior remains resistant to normalization. As Swidler (2001, 105) theorizes, many consumers are reluctant to "abandon established strategies of action… not because they cling to cultural ends, but because they are reluctant to discard familiar strategies for which they already have the cultural equipment."

While some consumers actively protest mask ideologies they perceive as oppressive, we find more often that consumers resist the "new normal" by subtly reasserting old norms where new mask norms remain unsettled. Many consumers keep a mask readily available, but wear it only when social cues indicate that not doing so violates norms adopted by a specific person or location. Others gradually stop wearing masks around friends or businesses who they sense will welcome the gesture. Service providers sometimes pull down their own masks to communicate a heartfelt, smiling "thank you." While unmasked social interactions risk virus contagion, many consumers and service providers implicitly sense that their actions preserve important, familiar social bonds and practices. A common sense oriented toward close, interpersonal community care contradicts with an ideology of public health and welfare.

Initiatives promoting disruptive behaviors succeed primarily among ideologically-aligned groups and communities when they do not address the importance of social norm conflict. During the COVID-19 pandemic, government and market organizations shifted much of the responsibility for containing the virus onto consumers (Aboelenien, Arsel, and Cho 2021). Our research demonstrates that individual public health behaviors always remain embedded in the social fabric of everyday life, which complicates their adoption. Mask wearing succeeds not when people believe strongly in the behavior, but when ideology recedes into the background and actions become socially reinforced as common sense. Market places and interactions provide primary sites where this social learning occurs. Caring for society should include understanding a diverse range of cultural and normative perspectives in order to establish and reinforce beneficial norms from the bottom up.

Self-Care: How Consumers Balance Self-Centered Care Consumption with the Needs of Others

EXTENDED ABSTRACT

Everyday consumers care for themselves by performing activities and consuming products that sustain and restore individual physical and mental well-being. These activities and consumption behaviors are collectively called and marketed as 'self-care.' Though self-care was already emerging as a consumer phenomenon, the prevalence of self-care rhetoric and self-care marketing increased greatly during the COVID-19 pandemic. Today, over 43 million posts on Instagram use the hashtag 'selfcare.' In this research we investigate three primary research questions: (1) how do consumers determine their own self-care needs, (2) how do they navigate tensions that arise when they prioritize themselves, and (3) how does the market interact with consumer enactments of self-care?

We use depth interviews with young adults to investigate perceptions and practices of self-care. We strategically interview both men and women as both may face unique cultural challenges related to caring for themselves (Holt and Thompson 2004; Coskuner-Balli and Thompson 2013). To complement these interviews, we use data from three widely circulated news sources (New York Times, Wall Street Journal, USA Today) to examine and track cultural attitudes towards self-care over time. Through these sources we are also able to follow the evolution of the 'self-care movement' from a medical prescription to a widely discussed consumption phenomenon.

From this initial data several themes are emerging. The data suggests that self-care does not look the same for all consumers as they have varying standards of acceptable (and achievable) physical and mental health. We find that consumers engage in self-care as a response to stress and in an effort to balance internal needs with external demands. Emerging data suggest that consumers engage in indulgent self-care to quickly restore lost internal resources, deep work to increase self-awareness, and maintenance to sustain well-being. Socio-economic factors, cultural expectations, and socialization by parents and teachers also influence how consumers define acceptable levels of self-care (Thompson and Hirschman 1995).

Indulgent self-care occurs as a response to a perceived depletion of internal resources. When engaging in indulgent self-care consumers turn to activities and consumption that quickly release tension and release the brain from external pressures. However, informants realize that indulgent self-care is only a temporary solution. Once this realization is made, informants move into a stage of deep work, often with the help of professional therapists, to not only restore internal resources but also to prevent future resource depletion. In this stage informants become more self-aware and strategically classify activities and consumption as either needs, oughts, or wants.

Tension can occur when consumers define what they need, ought, and want differently than how other important actors categorize an activity or consumption behavior. We identify several strategies consumers employ to defend, reframe, and prioritize their self-care practices. Consumers defend their self-care routines by setting boundaries which clearly delineate behaviors as non-negotiable needs. Reframing occurs when consumers attempt to change their attitude to view generally unpleasant activities as valuable for personal growth. Prioritizing self-care involves consumers engaging in self-talk to give themselves explicit permission to indulge their desires without guilt. Finally, once informants reach a personally acceptable state of wellness, they enter a phase of maintenance to sustain the growth achieved during deep work.

This cycle of indulgence, deep work, and maintenance stands in contrast to market discourse which mostly focuses on encouraging

and enabling consumer indulgence. Self-care marketing often entails messaging that implies a 'treat-yourself' mentality in which consumers are encouraged to indulge their desires and prioritize their own needs without guilt. Through this marketing, consumers are encouraged to re-categorize items as 'needs' for physical and mental well-being instead of as indulgent consumption. It may be for this reason that self-care has been criticized as a selfish excuse for indulgent behavior that comes at the expense of one's responsibilities and obligations to others. Contrary to market portrayals, however, our informants suggest self-care not only enables them to care for themselves but is essential to be able to care for others.

This research holds important implications for research on consumer well-being and how consumers navigate tensions that arise when caring for themselves and for others. Previous research on caregiving has mainly focused on how parents care for others (Thompson 1996; Epp and Velagaleti 2014). We extend this research by focusing on how individuals care for themselves. This research also adds to knowledge on how consumers' think about their physical bodies. Previous research suggests that consumers attempt to control the body by prioritizing mental strength and self-control (Thompson and Hirschman 1995), but our informants suggest that engaging in self-care helps them learn to work with and listen to their physical bodies in order to feel good. Finally, this research contributes to research on indulgent consumption (Mick and DeMoss 1990) and finds that consumers manage guilt related to self-focused consumption by reframing self-care not as selfish, but as allowing them to care well for others in the future.

SESSION OVERVIEW

The rapid growth of the sharing economy and its exciting impact on consumer behavior has attracted growing research interest. This session explores how the sharing economy may create, alter, and redefine social relationships. For instance, the sharing economy has reformed consumers' relationship with providers and turned it to be more egalitarian, which leads to the discussion of bilateral ratings in the first paper. Consumers also tend to have different expectations about providers in the sharing economy (or P2P providers) and providers in the traditional economy, which motivates a better understanding of who would be more supportive of P2P providers in the second paper. The sharing economy has also made previously unaffordable products more accessible. However, the third paper argues that there are potentially negative consequences for consumers' well-being (e.g., feeling inferior in social comparison with friends). In addition, access-based consumption in the sharing economy leads to potential contagion concerns among consumers. Yet, the fourth paper illustrates that consumers' product experience can be positively influenced by previous consumers who accessed the same products.

To be more specific, the first and the second papers look into how the sharing economy has changed consumers' perceived relationship with providers. The first paper investigates the new practice of reverse ratings (i.e., consumers being rated by providers) in the sharing economy. The paper provides two effective strategies for platforms in the sharing economy to effectively employ reverse ratings: adopting a community-focused positioning and emphasizing consumers' interaction with individual providers. The second paper proposes that different segments of consumers may have different perceptions of peer-to-peer (P2P) providers. Specifically, the authors examine how consumers' economic system justification (ESJ) beliefs influence their attitudes toward P2P providers. They find that high (vs. low) ESJ beliefs boost consumers' support for P2P providers.

Taking a slightly different perspective, the third and the fourth papers focus on how the sharing economy has created relationships among consumers as well as influenced consumers' relationships with their friends. The third paper finds that consumers tend to feel inferior in social comparison when they access a certain product

while their friend owns a similar product. This paper also provides several ways to mitigate the perceived inferiority. The fourth paper highlights an inevitable issue in access-based consumption, which is the potential contagion concern. The authors identify the distinctive impact of disclosing information of prior user(s) of a product on a subsequent user's product satisfaction and experiential satisfaction. These results highlight that it is crucial to carefully select the user profile of past users in the sharing economy.

Together, the four papers present a convergent theme of how social relationships emerge and evolve in the sharing economy. We hope this special session will be insightful for audiences who are interested in consumer behavior in the sharing economy. We believe that this special session also speaks to the conference theme ("What the world needs now") by reflecting how new forms of consumption and business models affect consumers' relationships with others in this unsettling time.

From Satisfaction of Consumers to Satisfaction with Consumers: Reverse Rating in Sharing Economy

EXTENDED ABSTRACT

Consumer satisfaction ratings are a well-established indicator of a provider's degree of success (Fournier and Mick 1999). However, as sharing economy take a more dominant position in today's economy, consumers are increasingly being rated by providers in order to assess *satisfaction with consumers*. We term this phenomenon as *reverse rating* (i.e., a practice in which consumers are evaluated by platform providers after a transaction). Recent attempts by sharing platforms indicate the important consequences of reverse ratings, such as Uber claiming it will kick off low-rated riders (Yurieff 2019). Our research questions are: (1) how do consumers perceive reverse ratings and what logic do they follow when interpreting this practice? and (2) when it comes to the implementation of reverse ratings, does the platform positioning and provider type matter?

Research on institutional logic (Kirkpatrick 2007; Koen et al. 2020) suggests there are two distinct logics for platforms: community logic and market logic. The community logic accentuates group membership and affective relations among members on the platform (Habib et al. 2016), while the market logic emphasizes the economic benefits, accessibility and standardized quality of the service (Mair and Reischauer 2017). We argue that these two logics can be manifested by (1) different positioning strategies (i.e., community positioning vs. marketplace positioning) of the platform and (2) different types of provider (i.e., individual provider vs. business provider) available on the platform. We predict that overall, the community logic is more consistent with the employment of reverse rating because this logic encourages consumers to build egalitarian relationships with providers, which should facilitate consumers' adoption of the practice of reverse rating.

Study 1 aimed to examine the effect of positioning strategies on consumers' platform evaluation and future use intention when the platform employs reverse rating. We recruited 401 participants from Prolific. The study employed a 2 (rating: reverse rating, no reverse rating) x 2 (positioning: marketplace, community) between-subjects design. We created a message about a fictitious ride-sharing app called Ridea. The stimuli can be found in Figure 1. After reading the

app introduction, participants were asked about their evaluation of the app (e.g., 1 = *unfavorable, 7 = favorable*) and their future use intention.

Results. When the platform employed reverse rating, the main effect of positioning strategy on both dependent variables were significant: participants had a more positive evaluation of the platform when the platform adopted the community positioning ($M = 5.78$) than marketplace positioning ($M = 4.94$), $p < .001$, $\eta_p^2 = .14$. Participants also had a stronger app use intention in the community condition ($M = 5.06$) than the marketplace positioning ($M = 4.71$), $p = .03$, $\eta_p^2 = .02$. Within the no reverse rating condition, the effects of positioning were not significant.

Study 2 further examined the impact of provider type. We recruited 212 undergraduate students. Participants were randomly assigned to one of two conditions: reading about an app that listed short-term stays offered by either (1) independent hotels or (2) private homeowners. Participants in both conditions were informed that the app employed the reverse rating. The stimuli can be found in Figure 2. Measures were similar to those used in Study 1 except that participants were also asked to indicate their attitudes toward being rated by either homeowners or independent hotels.

Results. We found that participants had (1) more positive attitudes toward being rated ($p = .006$, $\eta_p^2 = .04$), (2) more positive app evaluations ($p = .001$, $\eta_p^2 = 0.49$), and (3) a higher future use intention ($p = .001$, $\eta_p^2 = .05$) in the homeowner condition, as compared to the independent hotel condition.

Study 3 was conducted to understand the underlying mechanism of the findings in Study 2. We recruited 242 undergraduate students. The experimental design and stimuli were the same as those in Study 2. App evaluation and future use intention were included as two dependent measures. Two mediator measures were added after the dependent measures: (1) powerless perception (e.g., "As a consumer, I feel powerless if I am rated by the provider.") and (2) customer entitlement belief (e.g., "If I am paying for the service, I should not be rated or evaluated by the provider.")

Results. The main effect of provider type was successfully replicated. Parallel mediation analyses showed that customer entitlement mediated the main effect of provider type on platform evaluation (CI95%: [.04, .26]) and future use intention (CI95%: [.02, .23]), while powerless perception was not a significant mediator. Being rated by independent hotels triggered a higher level of customer entitlement belief, which led to a more negative app evaluation and a lower future use intention.

Study 4 further examined the differences between providers in practicing reverse rating on platforms using actual bilateral Airbnb reviews. 2,078 guest reviews and 1,605 corresponding host reviews were collected. The number of listings owned by the host served as the proxy for provider type. Hosts who only owned one listing were categorized as private homeowners, whereas hosts who owned more than 100 listings were categorized as rental business.

Results. First, as compared to private homeowners, rental business providers were less likely to leave reviews for guests who left reviews for the listings, $P_{homeowner} = 88\%$, $P_{business} = 66\%$, $\chi^2(1) = 137.42$, $p < .001$, Cramer's V = .26. Second, rental business providers were also more likely to leave identical reviews than private homeowners, which was captured by the comparison of average cosine similarity scores (i.e., a metric that measures how similar two documents are irrespective of their sizes; Ye 2011), $p < .001$, $\eta_p^2 = .29$. The results suggested that it was probably less necessary to allow rental business providers to practice reverse rating than private homeowners.

To conclude, by examining the roles of platform positioning and provider type guided by institutional logics, this paper sheds

lights on our understanding of the reverse rating and how to facilitate consumers' adoption of this practice. The overall results suggest a community-focused positioning and emphasis on the interaction with individual providers are two effective strategies for platforms in sharing economy that employ reverse ratings.

How Economic System Justification Shapes Demand for the Sharing Economy

EXTENDED ABSTRACT

Peer-to-peer (P2P) exchanges which allow consumers to procure products and services from peers (Sundararajan 2017) are increasingly prevalent. The sharing economy has expanded opportunities for individuals and consumers (Nguyen et al. 2020). However, it also has challenges, such as low regulation and entry barriers (Eckhardt et al. 2019), which create uncertainty about the quality of products and services offered by peers (Luo et al. 2021). Hence, demand for P2P exchanges may vary significantly among consumers, highlighting the need to identify consumer segments and characteristics that drive P2P demand.

Emerging research suggests that relational factors such as empathy (Costello and Reczek 2020) and individual traits such as intelligence (Aspara and Wittkowski 2019) influence individuals' support for P2P providers. However, research has not considered the role of consumers' ideological beliefs in the sharing economy. Yet, due to growing public debate about inequality and polarization, ideological views about the fairness of the economic system and outcomes—economic system justification beliefs (ESJ)—are increasingly salient in the marketplace (Jost 2017).

The present research examines how ESJ beliefs influence consumers' support for P2P providers. We propose that high (vs. low) ESJ may boost consumers' support for P2P providers because it may strengthen attribution of entrepreneurial spirit to these providers. Specifically, P2P providers rely on own skills and resources to create, market, and procure products and services. This reliance on self to start and manage an economic operation of P2P providers may be particularly appealing to high- (vs. low-) ESJ consumers who are more likely to believe that economic outcomes are driven by personal factors such as effort and hard work (*Jost and Thompson 2000*). We therefore predict that high- (vs. low-) ESJ consumers may attribute a stronger intrinsic ability and motivation to identify economic opportunities and create something from scratch — i.e., entrepreneurial spirit (Huang et al., 2021) – to P2P providers. Importantly, we expect this effect to attenuate for traditional providers (companies) whose intrinsic qualities are less salient and external infrastructures are more salient. Moreover, the impact of ESJ may attenuate for two types of P2P providers: (1) those who rely on external support; and (2) those who highlight their economic disadvantage (e.g., humble background) which may increase low-ESJ consumers', and lower high-ESJ consumers', P2P support. Six studies and several follow-ups tested the predictions.

Study 1 (N=423) examined how ESJ shapes support for P2P vs. traditional providers. After completing a scale of ESJ (*Jost and Thompson 2000)*, participants read that they were traveling to a different city and considering an accommodation offered by a hotel (traditional) or a resident (P2P). The results showed that ESJ boosted consumer support for the P2P ($p<.001$) but not the traditional provider ($p=1$; ESJ x provider interaction: $p = .013$). A follow-up study showed that the effect of ESJ on support for a P2P provider emerges regardless of the specific online platform (Airbnb vs. Amazon Explore) on which the P2P provider is listed.

Study 2 (N=383) tested the causal effect of ESJ. Participants in the high- (vs. low-) ESJ condition read an article describing the economic system as fueled by hard work and effort (vs. luck and connections). A pre-test confirmed that this manipulation boosted ESJ, but did not move political ideology or power distance beliefs. Participants then read a description of an online course offered by a P2P or a traditional provider (between-subjects). High (vs. low) ESJ boosted interest in the P2P course provider (p=.004), but not the traditional provider (p=.264; ESJ x provider type interaction p=.005). A follow-up study further distinguished ESJ from political ideology and power distance by showing that measured ESJ, but not these two alternatives, predict P2P demand.

Study 3 (N=159) tested the process. After completing the ESJ scale, participants indicated which book about effective leadership they would prefer to receive if they won a lottery: one authored by a self-taught business coach (P2P) vs. one by a business institute (traditional). Participants also indicated which provider possessed stronger entrepreneurial spirit. The results revealed a positive effect of ESJ on preference for a P2P (vs. traditional) provider (p<.001). Perceptions of provider entrepreneurial spirit mediated this effect [.0031, .1194]).

Studies 4A and 4B tested boundary conditions.

Study 4A (N=334) manipulated the P2P provider's reliance on self vs. other people (users) for product design. After completing the ESJ scale, participants saw the description of a book by a P2P author who relied on own ideas vs. collected other people's suggestions to generate ideas for the book (between-subjects). The effect of ESJ on support for the P2P provider was positive and strong when the provider was self-reliant (p<.001), but it was attenuated when the P2P provider relied on user ideas (p=.016; ESJ x provider type interaction p=.037). A follow-up study similarly showed a significant attenuation of the ESJ effect for a traditional provider (company) that relied on user design.

Study 4B (N=301) manipulated the P2P provider's economic disadvantage. After completing the ESJ scale, participants saw a description of a virtual park tour by a P2P provider. In the economic disadvantage condition, the provider description stated that the provider started organizing tours after being forced to quit their day job. In the control condition, this disadvantage information was not provided. The effect of ESJ on P2P provider support was significant and positive in the control condition (p=.043), but it was attenuated and directionally reversed in the economic disadvantage condition (p=.164; ESJ x provider type interaction p=.016).

In Study 5, we obtained and analyzed data on online traffic shares of the most popular P2P (Airbnb, VRBO) vs. traditional (Booking, Hotels.com, Marriott) accommodation platforms across more than 100 countries with different levels of ESJ. We obtained the country-level ESJ scores from the World Values Survey (2008-2020). The results revealed a positive effect of ESJ on the online traffic share of P2P (vs. traditional) accommodation platforms (p<.001). This also held after controlling for country characteristics including political ideology and power distance. A follow-up study documented a positive impact of country ESJ on click-through rates to a Facebook ad of a P2P online course provider.

Signaling Status by Acquiring Ownership (vs. Access)

EXTENDED ABSTRACT

To avoid the pain of low social standing, people may use goods to signal that they are equal or superior to others (e.g., White and Argo 2011; Rucker and Galinsky 2008; Anderson, Hildreth, and Howland 2015). While past work suggests that such signaling pri-marily happens via product ownership, the growing access-based economy allows consumers to temporarily display goods they could not otherwise afford (Bardhi and Eckhardt 2017, 2012). Access-based consumption allows people to use (and display) products by paying a usage fee, normally cheaper than ownership acquisition costs (Lamberton and Rose 2012; Lamberton and Goldsmith 2020). But will accessing goods equalize social status effectively?

We propose that there are reasons to doubt the status-equalizing effect of participation in the access-based economy. Rather, we propose that even when the good in question is identical, acquisition mode (owning vs. accessing) operates as a status signal. Drawing on costly signaling theory (Nelissen and Meijers 2011; Bagwell and Bernheim 1996), we argue that because ownership is perceived to be more costly than access, owners will be perceived to have higher status than those who access similar products. Therefore, those who access may persistently feel socially inferior to those who own. Additionally, we posit that this effect can be mitigated by the payment immediacy of ownership. In cases where the perceived cost difference between owning and accessing similar goods is minimized (e.g., people acquire ownership by paying-over-time or renting-to-own), the difference in status between owners and renters will be mitigated.

We examine the status-signaling effect of acquisition mode by asking participants to imagine themselves in consumption dyads, in which two individuals' acquisition modes are manipulated to be matched (both owned/accessed) or mismatched (one owned, another accessed).

In experiment 1A, 198 females imagined meeting friends for coffee, and were randomly assigned to one of three dyads: participant owned ("I owned while my friend accessed similar Gucci bags"), participant accessed ("I accessed while my friend owned similar Gucci bags"), both owned (i.e., control) and then completed a four-item nine-point subjective social rank scale (Allan and Gilbert 1995), anchored by inferior/superior, incompetent/competent, untalented/more talented, unattractive/more attractive (α = .80). As expected, participants had a higher subjective social rank when they owned but their friend accessed similar bags (M = 5.50, SD = .13) than when acquisition modes were reversed (M = 4.59, SD = .13; p < .001).

Experiment 1B (N = 167 undergrads) included a matched condition in which both participants and their friend accessed similar BWM sedans to use at a social event. No difference was observed between matched and control (i.e., both owned) conditions (p > .99), suggesting it was the mismatched acquisition modes rather than accessing itself that impacted subjective social rank. Experiment 2 (N = 442 Prolific participants; pre-registered) replicated prior findings across brand levels (BMW and Ford).

Experiment 3 tested the moderation role of payment immediacy operationalized as extended payments. Prolific participants (N = 302; pre-registered) imagined getting a new book ($100 to own) for an online reading club. They were randomly assigned to one of four dyads: participant owned ("I bought while my friend rented same books"), participant accessed ("I rented while my friend bought same books"), both owned, participant accessed but friend's ownership is made by extended payments ("I rented while my friend bought same books via 12-month installments"). We also explored a downward consequence: likelihood to share group responsibility. Social compensation theory (Williams and Karau 1991) suggests that decreased social rank will lead individuals to expect their peer to be more capable than themselves, and in turn, that their higher-ranked friend would take more group responsibility. Therefore, before the social rank measure, participants indicated the number of chapters (out of

17) they and their friend were able to lead for the group discussion, respectively.

As expected, participants thought they would lead more chapters when they owned but their friend accessed the book (M = 8.95, SD = 1.28) than when acquisition modes were reversed (M = 7.71, SD = 2.03, *p* = .003), but a similar number of chapters when they owned but friend accessed and when they accessed but friend owned the book via extended payments (M = 8.40, SD = 1.82, *p* = .74). Similarly, participants had a higher subjective social rank when they owned but their friend accessed the book (M = 5.64, SD = 1.05), compared to when they accessed but their friend owned the book (M = 5.15, SD = .92; *p* =.03). However, the effect disappeared when extended payments were applied to own (M = 5.50, SD = .88; *p* >.99; see *Figure* 2). Mediation analyses supported our prediction (participant owned vs. accessed: indirect effect = -.33, 95% CI = [-.66, -.09]; participant owned vs. extended payments: indirect effect = -.10, 95% CI = [-.37, .13]).

Experiment 4 tested the moderating role of payment immediacy, operationalized in a rent-to-own option. Prolific participants (N = 302; pre-registered) were randomly assigned to one of three dyads in a drive-in movie theater scenario: participant owned, participant accessed, participant accessed with the rent-to-own option ("I rented but could own this BMW sedan if I wanted while my friend owned a similar one). Participants' subjective social rank increased when they accessed the vehicle with the rent-to-own option (rent-to-own: M = 5.13, SD = 1.01) compared to without this option (participants accessed: M = 4.74, SD = 1.12; *p* = .042). Though the rent-to-own option enhanced social rank compared to access alone, it did *not* raise social rank to the point that it equaled that conferred by ownership (participants owned: M = 5.79, SD = 1.06; *ps* < .001).

Taken together, this research highlights acquisition mode as a robust status signal, significant in its effect on individuals' subjective social status across brand levels, competitive and neutral contexts, age, gender, and income. Future research will further explore the weight of ownership as a status signal, to see if as the access-based economy grows, this weight may shift – allowing greater, and more accessible, felt equality in the marketplace.

You Get More Than You Bargained For: Contagion Effects in Access-Based Consumption

EXTENDED ABSTRACT

People use products which they do not own to enable or enhance an experience (Bardhi and Eckhardt 2012; Habibi, Kim and LaRoche 2016). Whether consumers are borrowing a tool from a local tool library, or renting an outfit for a wedding, consumers have access to different products they need and choose to access for a specific reason through the process of access-based consumption (Abbey et al. 2015; Benoit et al. 2017).

When consumers choose access-based consumption, the products, more likely than not, have been used by others (Botsman and Rogers 2010; Eckhardt and Bardhi 2016). The potential influence of these prior users, through contagion, is important in these situations. When a product has been touched, the laws of sympathetic magic (i.e. Frazer 1890/1922; Mauss 1902/1972) suggests that some of the essence, or traits, of the toucher passes onto the product itself. Importantly, these essences can transfer from the one person to the next (Kim and Kim 2011; Newman and Dhar 2014). From this we hypothesize that the experience that consumers have with access-based products will be influenced by knowledge of the prior users.

Indeed, access-based consumption firms go to extraordinary lengths to ensure that the products which consumers use are thoroughly cleaned both physically (Argo, Dahl and Morales 2006) and metaphysically of the essence (West and Zhong 2015) of the prior users. Knowing that someone else has used a product leads to a more negative evaluation of said product (Argo, Dahl and Morales 2006; Huang et al. 2017). However, there are specific situations when having knowledge of the prior user may enhance the experience, such as when using a golf club previously used by a professional golfer (Lee et al. 2011). From this, we hypothesize that if the traits of the previous user of an item in an access-based consumption situation are both known and positive, the current user will take those positive traits on themselves and will have a more positive experience overall. However, consistent with prior literature, regardless of the valence, having information about the prior user will decrease satisfaction with the product itself.

2020 led to a rise in public concern for contagion. Consumers are now more aware than ever of the contaminating essence transfer of previous touchers. We hypothesize that any positive experiential satisfaction that existed previously will now be completely overtaken by negative contagion. In other words, because consumers are hyperaware of the negative effects of contagion, any information about prior users will be viewed negatively and lead to a decrease in experiential satisfaction.

We explore these Hypothesis in 4 studies. In study 1 conducted in 2018 (n = 87 students, 100% female) participants were given a purse to use for a week with one factor manipulated between subjects (knowledge of positive traits of the prior user: absent vs. present) in a pseudo-field experiment. A one-way ANOVA revealed that participants with information about the prior user were significantly less satisfied with the purse than participants without information about the prior user ($M_{knowledge\ present}$ = 5.64 vs. $M_{knowledge\ absent}$ = 6.17, F(1,85) = 4.67, p < 0.05). However, because the traits that were given to the participants were positive we expected participants would be more likely to rate themselves higher on those positive traits and have more positive experiential satisfaction. A one-way ANOVA revealed this to be the case ($M_{knowledge\ present}$ = 3.73 vs. $M_{knowledge\ absent}$ = 2.95, F(1,85) = 6.92, p < 0.02). Further, a series of ANOVAs revealed that those who had information on the traits of the prior user rated themselves significantly higher on those traits (all p's < 0.05).

Study 2 (n = 193, 100% female) used the same context as study 1, however all participants received information about the prior user in a 2 (valence of the traits: positive vs. negative) X 2 (connection: association vs. contagion) between-participants design. An ANOVA revealed only a main effect of the connection factor, those in the contagion condition reported significantly lower satisfaction with the purse than those in the association condition ($M_{contagion}$ = 3.97 versus $M_{association}$ = 4.65, F(1,189) = 6.15, p < 0.01). For experiential satisfaction, an ANOVA revealed the predicted interaction between the independent factors (F(1,189) = 12.281, p < 0.01). Participants in the contagion-based condition who received positive information about the prior user reported higher experiential satisfaction than did those who received negative information ($M_{positive\ contagion}$ = 4.61 vs. $M_{negative\ contagion}$ = 3.52, F(1,189) = 38.63, p < 0.01). A moderated mediation analysis revealed that for participants in the contagion condition, trait transfer significantly mediated the relationship between contagion and experiential satisfaction positively when the traits were positive (estimated indirect effect = 0.16; 95% confidence interval [CI], 0.08 to 0.41).

In study 3 (n = 545, 48% female) participants were randomly assigned to use a pen for various tasks in a 3 (valence: positive vs. neutral vs. negative) X 2 (connection: association vs. contagion) study design. A 3X2 ANOVA with experiential satisfaction as the dependent variable revealed the predicted interaction between the vari-

ables (F(2,543) = 3.181, p < 0.05). Planned contrasts revealed that those who had positive information about the prior user of the pen were more satisfied with the experience than those who had neutral information ($M_{positive\ contagion}$ = 3.96 vs. $M_{neutral\ contagion}$ = 3.53, F(1,544) = 4.63, p < 0.04).

In study 4 (n = 122, 100% female), run in the fall of 2020, we replicated the set up of study 2. Participants in the contagion condition reported significantly lower satisfaction with the purse than those in the association condition ($M_{contagion}$ = 3.21 versus $M_{association}$ = 5.05, p < 0.01). This time, however, there was no interaction for experiential satisfaction. Only a main effect of connection was revealed, participants in the association condition were significantly more satisfied with the experience than those in the contagion condition ($M_{contagion}$ = 3.42 versus $M_{association}$ = 4.95, p < 0.01).

SESSION OVERVIEW

Influencers and influencer marketing have been a pervasive area of academic and practitioner interest in the past decade. Past research has uncovered different aspects of influencers, such as how they emerge through capitalizing on taste displays (McQuarrie et al., 2013), which influencer-campaign characteristics are more effective with consumers (Hughes et al., 2019), what the effects of disclosing advertising intent in influencer based campaigns are (Eisend, 2020), and how their appearance and nascent professional activity (Abidin, 2016) disrupted and reshaped fields such as broadening the availability of products (Scaraboto & Fischer, 2013). These processes allowed the emergence of new actors and dispersion of institutional work to ordinary consumers (Dolbec & Fischer, 2015), opening space to activism and embodied resistance towards fashion systems (Veresiu & Parmentier, 2021).

While influencers, albeit sometimes through different, unconventional and disdained forms (Abidin, 2016; Drenten et al., 2020; Smith and Fischer, 2021), generate value for themselves through assuming intermediary roles in marketing communication—social media manager, endorser, and connector of brands and audiences (Campbell & Farrell, 2020)—, new intermediaries and actors have also emerged (Stoldt et al., 2019) as well as a plethora of platforms with different affordances (Kozinets et al., 2021)

We continue this conversation with a special session that looks at this market system which is perpetually evolving. Our goal is not to discuss one particular dyad in the influencer marketing chain, such as influencer-consumers or influencers-brands. Instead, we focus on the emergence of new actors, processes and socio-technical configurations, and practices.

The first paper brings a market system perspective to the discussion on influencers. The authors investigate how influencers disrupted the field of advertising. Through interviews with influencers and influencer agents, the researchers show how new and emergent actors perform boundary work to stake claims to the profession of content creation.

The second paper looks at cross-platform celebrification and how this leverages audience portability through building celebrity capital. By showing how celebrification allows influencers to generate distributed content and how this content is created and evaluated through platform geographies, the authors underline the agility, fragility, and worth of platform content.

The third paper investigates family influencers as a form of digital family entrepreneurship. Highlighting how family influencers build brand biographies and relational narratives, this paper distinguishes family influencers from individuals and discusses the particular ways entrepreneur families build their brands and audience on platforms.

The final paper further elaborates on market work by showing how influencers affect market practices by introducing new materials, competences, and meanings through interaction among influencers themselves (and between influencers and brands), shaping both consumer and practitioner practices.

Taken together, these papers show how influencers' work is not just solely about creating and capitalizing a market but disrupting and shaping systems, including socio-technical systems in which content is created, affecting their audience, consumers, other actors, and practices. Using data from consumers, practitioners, platforms themselves, and mass media, the papers also show that influencer work, while shaping consumers, is a multi-actor market system.

Influencers, Content Markets, and Institutional Work

EXTENDED ABSTRACT

Content is king, as once declared by Bill Gates. Influencers as person brands (Fournier & Eckhardt, 2019) have become essential assets for companies for content creation (Influencer Marketing Hub, 2020; Hollebeek & Macky, 2019; Müller & Christandl, 2019). Their expertise and visibility have disrupted different fields of consumption (Dolbec & Fischer, 2015; Scaraboto & Fischer, 2013), generating a market that operates through monetizing, brokering, and optimizing content for consumer engagement and brand promotion.

In this paper, we theorize the emergence of influencers and discuss how the industry has shifted to operate around one important sociological object: content. We posit that this event has triggered different field-configuration processes of institutional boundary work (Langley et al., 2019; Zietsma & Lawrence, 2010) in content creation, distribution, and monetization.

Our empirical work is built on a database triangulating data from different sources: 10 interviews with influencers, 10 interviews with intermediary agencies, 39 podcasts with professionals in the influencer industry (agents, brokers, and influencers themselves), and 2,104 articles in the specialized press (AdWeek and PR Week). We analyzed the data qualitatively and quantitatively to identify actors, processes, and market devices with careful attention to the tensions and dynamics between different market actors.

Our findings describe the disruption of logics in the field by the emergence of a new actor: the influencer. Influencers themselves struggle to legitimate their work and to manage the tensions of building their own brands versus promoting those of their clients' (also see Parmentier & Fischer, 2021) in creating content. On the side of brands and agencies who hire content creators, many uncertainties remain, such as costs, control of content, alignment with the brand's expectations, and desired outcomes, all of which create contractual problems (Childers et al., 2019). We show that these issues are addressed by different types of boundary work that simultaneously protect the interests of old actors while also reconfiguring the field and opening up spaces for new actors. We discuss the boundary work of both actors that existed before influencers (celebrities, models, opinion leaders, brands, agencies), as well as actors that emerged after the disruption (influencer agents, content farms, influencer platforms).

Competitive boundary work happens when actors engage in actions to protect the function of content creation that they have historically performed (Abbott, 2014) or negotiate their authority inside a field (Gieryn, 1983). As influencers claim the function of creating content for brands, and as different institutions (such as specialized media) recognize them as such, influencers, agencies, and actors previously tasked to create content claim stakes to the jurisdiction of content creation.

Collaborative boundary work consists of the alignment of actors to collaborate inside field boundaries (Cartel et al., 2019; Langley et al., 2019). The actors participating in collaborative boundary work are influencers themselves, agencies, and other intermediaries (Stoldt et al., 2019) that act as brokers between influencers and clients. These actors work together for different ends, which include convincing clients that content work is relevant and that it can bring a return of investment to the brand, assuring influencers that their work is recognizable and compensated, mediating affective labor in talent management, managing content that aligns with clients' interests, and, finally, making sure that the client achieves desirable metrics. Intermediaries act by translating the interests of brands (visibility or engagement) and of influencers themselves (creative and expressive freedom). In that sense, influencer agencies take the role of boundary actors, translating different logics and practices between the two worlds of clients and influencers who enter an exchange relationship around content.

Finally, the third type of boundary work, configurational boundary work, includes new actors (such as influencers and influencer agencies) that reconfigure field boundaries (Langley et al., 2019) to claim space in content work. Our data shows that these configurations emerge from boundary objects that allow new and old actors to work together. Media kits are an example of these objects allowing influencers to display and publicize their services for clients in a language that the clients are accustomed to. Other objects include metrics, which allow quantifying the results of content work for the clients and can be negotiated a priori a campaign. Through these configurations the functions of actors are negotiated, established and realigned.

In conclusion, our work contributes to the previously discussed disruption of fields (Dolbec & Fischer, 2015) and influencer work (Abidin, 2016). We take a market systems approach to look at the actors and dynamics that operate around a valuable object: content. We show that disruption and the emergence of a new actor have cascading effects in a field and result in the emergence of even more actors and continuous and complex boundary work. As the market logic shifts toward selling, brokering and monetizing content, the market also reorients itself around this object.

Becoming Famous: Influencer Marketing and the Cross-platform Acquisition of Celebrity Capital

EXTENDED ABSTRACT

Increasing attention has been given to executing influencer marketing (Campbell & Farrell, 2020), with a focus on understanding disclosure practices (e.g., Evans et al., 2018) and the impact of authenticity (e.g., Audrezet et al., 2020). Influencer marketing arose to prominence when the industry was dominated by only a few platforms, such as YouTube and Facebook. Yet, the modern social media landscape is saturated with both established and emerging platforms—Twitch, Clubhouse, and more—giving rise to new opportunities for social media influencers (SMIs) to seek visibility and attention. Meanwhile, some platforms (e.g., Vine, Musical.ly) have ceased to exist in their original forms. Influencers and marketing professionals must navigate influencer marketing across social media platforms in a complex digital landscape where social media platforms are both abundant and precarious. A starting point is understanding how influencers acquire celebrity capital in an evolving social media landscape. The purpose of this study is to explore how SMIs acquire celebrity capital in the modern social media landscape and the role of marketing professionals in this process. Specifically, we ask: how is celebrity capital acquired among social media influencers, and what role do marketing professionals play in the process? More broadly, how has an increasingly interconnected social media landscape shaped this process and does it matter?

Celebrity capital has been identified as a currency for fame (Driessens, 2013); it is "understood as accumulated media visibility through recurrent media representations (Driessens, 2013, p. 17) and exchanged within the field (Bourdieu, 1986) of marketing promotions. For example, celebrities exchange celebrity capital for endorsement deals (i.e. economic capital) and/or introductions to high-profile individuals (i.e. social capital; Carillat & Ilicic, 2019). Most SMIs exist in a stage of liminality: no longer a 'regular' non-commodified person; not yet a full-fledged celebrity. Similarly, the acquisition stage of the celebrity capital life cycle "refers to a celebrity's limited yet growing media visibility and recognizability" (p. 64). In celebrity and media studies, the acquisition of celebrity capital is known as celebrification (Driessens, 2013). Jerslev and Mortensen (2016) draw upon the 'celebrification process' defined by Rojek (2001) to suggest "celebrification encompasses the mediated interplays and negotiations between celebrities/ their management and various media platforms, media institutions and fans/followers (p. 251). Given influencers' unique position in the celebrity life cycle, Carrillat and Ilicic (2019) call on marketing scholars "to investigate the effectiveness of influencers as endorsers, identify potential stars to leverage, and examine the role of agents in managing and developing celebrity capital" (p. 64). Our study sits squarely in this domain seeking to better understand the influencer celebrification process in a saturated media landscape.

Based on close to 60 hours of in-depth interviews with 40 influencer marketing professionals (e.g., influencers, agents, brand executives), our findings point to the importance of cross-platform celebrification in acquiring celebrity capital among SMIs. We define cross-platform celebrification as the process by which social media influencers acquire celebrity capital within an interconnected social media ecosystem. We identify three types of practices in the cross-platform celebrification process: generative cross-platform celebrification practices; collaborative cross-platform celebrification practices; and evaluative cross-platform celebrification practices.

First, generative cross-platform celebrification practices authentically grow an influencer's celebrity capital across platforms. This represents the first stage in acquiring celebrity capital for SMIs. Influencers work tirelessly to build their following (i.e., fame labor) and develop niche content which can extend beyond a single platform (i.e., platform agnosticism). That is, influencers work to gain a following through content creation beyond a single platform. Influencers and marketing professionals recognize the precarity of social media platforms and thus stay agile, adapting as the social media landscape transforms. Our findings suggest influencers are not churned out of a system of stardom seeking their 'big break' from gatekeepers in the field; rather, they create their own fame through hard work and dedicated content creation. Marketing professionals act as talent scouts in this stage, seeking the 'next big thing' but recognizing that the acquisition of celebrity capital begins with the influencer.

Second, collaborative cross-platform celebrification practices synergistically expand an influencer's celebrity capital across platforms. This second stage in acquiring celebrity capital serves to deepen connections between influencers, fans, and marketing industry professionals. Influencers enrich relationships with their fans across multiple platforms (i.e., audience portability) and collectively conceive of new creative opportunities with marketing industry professionals and clients (i.e.., creative ideation). That is, influencers can transport their audience across platforms (e.g., podcast, television, social media) and across unique brand partnerships (e.g., collaborative and co-branded product lines). Marketing professionals

act as creative concierges in this stage, leveraging unexpected opportunities for the influencer to connect with fans and brands.

Third, evaluative cross-platform celebrification practices assess the value of an influencer's celebrity capital across platforms. This third stage in acquiring celebrity capital places valuation on the worth and potential of an influencer to deliver meaningful promotional value for a brand. Influencers are appraised based on their ability to gain online community buy-in for a brand partner (i.e., community-centric KPIs) and evaluated by the reach of their content across porous social media borders (i.e., content traversal). Traditional social media marketing metrics (e.g., views, engagement rates) focus on quantifying success in terms of individual platforms and individual tactics (e.g., click-throughs on an Instagram story). In contrast, our findings highlight the value of influencer audiences who propel their content through social media spaces. Marketing professionals act as impact analysts in this stage, assessing an influencers' relevance and potential for success, captured by less traditional (i.e., qualitative) measures of marketing effectiveness.

Within an ever-changing new media landscape, influencers and marketers must learn how to stay relevant and adapt across media platforms. The study contributes to the marketing literature by understanding how influencers, marketing professionals, and audiences (fandoms) coalesce to produce celebrity capital through cross-platform celebrification. We also demonstrate a holistic view of influencer marketing--beyond a single platform, and highlight how influencers' celebrity capital is inherently tied to the communities that follow them.

Family Influencers as Digital Family Entrepreneurship: Monetizing a Collective Human Brand

EXTENDED ABSTRACT

A family goes to Costco; once they're there, one parent films the other as she explains why she chose the products which shape their family's consumption habits. Interestingly, this video, composed by the parents, is not solely meant for the eyes of family and friends; the parents are planning on posting the video on their family's public so-

cial media account. These parents created a social media account for themselves and their children to create collective content to be posted on this public account. This online content showcases the family members individually and collectively in their natural routine, special occasions, displaying talents, or making comedic scenarios. This is the life that family influencers lead via their online presence and curated content on social media.

This phenomenon has been discussed and coined by Abidin (2017), who explains that a family influencer exists via a social media account that represents an entire family rather than one individual. Family influencers are a new genre of microcelebrity "following in the celebrity trajectory of mommy bloggers, global micro-microcelebrities, and reality TV families" (ibid, p.1). Through this performance of microcelebrity, family influencers monetize their accounts in the same way that individual influencers do, through brand sponsorship as media entrepreneurs. Through qualitative findings, this study will recognize family influencers as a branded form of digital family entrepreneurship.

The topic of family entrepreneurship has been thoroughly explored by scholars (Beckhard & Dyer, 1983; Faccio & Lang, 2002; Feltham et al., 2005; Holderness, 2009; Kelly et al., 2000; Shanker and Astrachan, 1996). Researchers find that family businesses are built upon a family's engagement in entrepreneurial efforts (Chua et al., 2004). By capitalizing on today's digital realm, entrepreneurship has also taken place in online sites, namely, social media, to accrue social capital through interactions with others (Fischer & Reuber, 2014). This is particularly true for media entrepreneurs, who leverage social media to attract the attention of niche markets, a primary source of profit for businesses investing in mass media (Khajeheian, 2013). A social media influencer is a form of media entrepreneur who capitalizes on social media by transforming their account into an entrepreneurial venture (Abidin, 2018). Influencers monetize their digital presence by providing the service of brand ambassadorship or sponsorship. While individual influencers have been heavily explored by media and marketing scholars (Himelboim and Golan, 2019; Hughes et al., 2019; Martínez-López et al., 2020; Stoldt et al., 2019), the phenomenon of family influencers, a collective influencer, has not been investigated by marketing or entrepreneurship scholars.

This study addresses the gap in the literature by exploring (1) how influencer families establish and brand themselves as a family business via their social media accounts, (2) and how their branded collective identity mobilizes their content's monetization in the form of sponsorship engagements. By collectively employing various lenses that are novel to the field of family business, be it media, marketing, or branding literature, this study extends the extant literature on family entrepreneurial efforts by recognizing a new form of venture which takes place entirely online.

This study's method combines netnography (Kozinets, 2010), journaling, and interviews. The research focuses on couples who live together with their children, 10-18 years old, and manage a family-based social media account. The research focuses on accounts with 1 thousand to 1 million followers. Therefore, the sample will only consist of micro and macro-influencers, categorized as those with followers between 1k and 100k and 100k and 1m, respectively (Ismail, 2018). By doing so, the study disregards nano and mega-influencers, as the former target their brand sponsorship at their tight-knit communities making them an underdeveloped entrepreneurship venture, and the latter is identified as a type of influencer that usually stems from already established mainstream celebrity status (i.e., Beyonce), rather than through social media amplification (ibid).

The netnography and interviews shed light on how influencer families operate and brand themselves as a family business via so-

cial media accounts. They do so through the content they produce and share and the branded identity formed via their account to monetize through sponsorship engagements. This data is abductively analyzed through a branding literature lens that positions the family influencer account as a branded family business. Individual influencers are known to create an online identity in the form of a publicizable personality through self-commodification (Marwick, 2013). This self-commodification can be viewed as a strategy to construct a human brand (Thomson, 2006). Thomson (2006) defines a human brand as a specific operationalization of the brand concept, namely, a "well-known persona who is the subject of marketing communications efforts" (p. 1). This study acknowledges the concept of human brand and extends the literature by investigating the family influencer phenomenon as a form of collective human brand, namely, one which relies on a number of branded individuals as opposed to one. The research studies family influencer's human branding efforts by paying attention to how their brand is demonstrated as distinctive and visible through the depiction of brand biography and family members' market-relevant cues (Parmentier, 2011). The data on the agency, management, stakeholders, and business relationships of the family influencer account will guide the abductive analysis grounded in family business literature (Astrachan et al., 2002; Astrachan & Shanker, 2003) to parallel the family influencer to a family business. As a result, the study will find evidence to the claim that these online accounts are indeed a form of online family business operated via family business management and self-branding techniques that emerge through their content.

This research contributes to the literature on human brands, technologically mediated consumption habits, family entrepreneurship and gives new insights into how these three intersect. My research will also contribute managerially to existing and prospective family influencers, as well as companies that recruit them, by shedding light on what defines a strong family business and brand through social media account management tactics.

Threading through a Field: Makeup Practice in the Age of Influencers

EXTENDED ABSTRACT

"Do you know Amanda Steele? She has **a social media following bigger than the population of Uruguay**. She is also too young to sit at a bar—or vote in the next election. **Sixteen-year-old Steele (a.k.a. MakeupbyMandy24)** is just one of a generation of beauty influencers who are documenting every topknot on Instagram and **dominating the lists of most-searched videos on YouTube** with their makeup tutorials. These new beauty gurus aren't just offering contouring tips. **They're changing the way we shop for, experiment with, and consume beauty…**" (Allure 2015, emphasis added)

Although applying makeup is an age-old practice, social media influencers only entered the market in the last two decades. Over that time, influencers have become ubiquitous in both the cosmetics arena and in other markets like food, travel and fashion: global spending on influencer marketing increased from $2 billion in 2017 to $8 billion in 2019 (Gerdeman, 2019) and may reach $15 billion by 2022 (Schomer, 2019). Scholars from multiple fields have begun to investigate characteristics of influencers as well as some of their impacts (e.g., Dolbec & Fischer 2015; Evans et al. 2017; Hughes et al., 2019; Kozinets et al., 2010; McQuarrie et al., 2013). Consumer researchers, for example, have addressed such questions as how influencers attract followers (McQuarrie et al., 2013), incite desires (Kozinets et al., 2017) and redistribute the institutional work performed in a field (Dolbec & Fischer, 2015). Marketing scholars have investigated the tactics influencers may use to maximize consumer attention and admiration for brands (e.g., Backaler 2018; Brown & Fiorella 2013; Brown & Hayes 2008; Evans et al. 2017; Hughes et al. 2019; Kapitan & Silvera, 2016; Levin, 2020). These studies collectively suggest that the influencers' impact on markets are many and varied. As yet, however, there is no comprehensive understanding of how influencers may collectively be impacting consumption practices in the contexts they frequent. This study aims to fill this gap by asking the question: **how does the influx of influencers into a field affect consumer practices therein?**

The paper employs a practice theory lens (e.g., Shove et al., 2012; Warde, 2005) to conceptualize the emergence, persistence and disappearance of practices in a field. This lens posits that practices consist of three elements: materials, competences and meanings. Building on early work of Bourdieu (1990), practice theorists initially focused on ordinary experiences and the significance of materiality in practices in everyday life (e.g. Schatzki, 2002; Warde, 2005). This body of research collectively explained mechanisms of routinization and stability as well as change (e.g., Reckwitz , 2002; Shove & Pantzar, 2005; Shove et al. 2012). Consumer theorists followed this trend and employed practice theory to study such topics as choice (Allen, 2002), value creation (Schau et al., 2009), and the meanings of materials and their transformation (Türe & Ger, 2016). Consumer researchers also fruitfully studied the stabilization of misaligned or disrupted practice routines (Canniford & Shankar, 2013; Cardoso et al., 2020; Epp et al., 2014; Phipps & Ozanne, 2017; Seregina & Weijo, 2017; Thomas & Epp, 2016; Woerman & Rokka, 2015). Thus, practice theory studies have already shed considerable light on the routinization and disruption of practices, and it's a lens is well-suited to studying field-level changes (see Hui et al., 2018) of the type of interest here.

In the last decade, the cosmetics market has seen growing demand in North America; it is expected to expand even more in the near future as millennials and generation Z consumers attempt to master the latest makeup trends (Euromonitor International 2019a, 2019b). The number of influencers and followers has grown exponentially in the last decade in the cosmetics industry. Estimates suggest that by 2018 there had been over 349B total views of beauty content created by influencers on YouTube, with no signs of growth slowing in the near future (Pixability, 2018). Indeed, commentators suggest that the cosmetics industry has embraced influencer marketing more eagerly than any other (Gilliand, 2018). For instance, in 2015, Bethany Mota was the top beauty content creator on YouTube with 8.2M followers (Pixability, 2015); as of May 2020 she has 10M followers. The current top name in cosmetics on YouTube is Jeffree Star with 18.2M followers, while Huda Kattan leads cosmetics influencers on Instagram with 43.9M followers (May 2020). Taking all these contextual characteristics into account, it would appear that

the cosmetics market is an ideal one in which to examine how influencers may impact field level practices and individual consumers' performances.

To understand this context, we initially collected extensive archival data to understand the historical rise of influencers in the industry. The archival data was downloaded using Factiva to access US and Canadian newspapers, magazines and online blogs with the key words of "makeup" and "influencer". The dataset is a total 479 pages long (single spaced) without pictures. To gain more familiarity with the context, we also engaged in observational netnography by following 25 beauty influencers from North America on YouTube since March 2020. Lastly, the first author conducted 30 interviews in, 15 with consumers and 15 with professionals in the industry including: influencers; brand owners and managers; marketing, talent and influencer agency professionals; makeup artists; and a beauty magazine editor.

Our preliminary findings regarding practice level changes suggest that influencers affect market level practices by introducing new materials, competences, meanings to existing practices; these introductions, collectively, make practices more complex. The infusion of these new elements into practices is abetted by the networked circuits of interaction among influencers, and between influencers and brands. At the practitioner performance level, we find three patterns among consumers: non-reflexive adaptation; reflexive selection; and rejection of new elements of cosmetics practices. Overall, this research sheds new light on market systems dynamics by theorizing the role of influencers of practices, while extending the practice theoretic lens in more institutional directions.

SESSION OVERVIEW

Legitimation is a cultural process that affects consumer identities (Arsel & Thompson, 2011; Coskuner-Balli & Thompson, 2013; Veresiu & Giesler, 2018), products (Coskuner-Balli & Ertimur, 2017; Giesler, 2012; Irwin, 2001; Kates, 2004), and markets (Huff et al., 2021; Humphreys, 2010b, 2010a; Press & Arnould, 2011). Researchers unveiled the role of the media (Humphreys, 2010a), governments (Giesler & Veresiu, 2014), activists (Kozinets & Handelman, 2004), and consumers (Dolbec & Fischer, 2015; Scaraboto & Fischer, 2012) in legitimation processes.

This session aims to shed light on a burgeoning field of research on market legitimacy. The session is comprised of three papers. The first paper explores the role of myriad marketplace actors in the continuous legitimation and de-legitimacy of markets. The second zooms into one of these actors, the marketers, to explore the role of advertisements in the tensions and dynamics of legitimacy. The final paper unpacks institutional work done by influencers and the cultural processes affecting their professionalization.

The first paper provides a multi-actor process theorization of legitimation through the study of three markets. These markets are meat, cryptocurrency, and vaping. These cases were selected for being at various stages of legitimation. Actors ranging from health to financial institutions to trade associations to governments to brand managers to consumers simultaneously anchor and challenge markets' legitimacy. Through this entangled web of motives and actions, the legitimacy of a market remains perpetually volatile with an ongoing need for reaffirmation.

The second paper studies the gun market in the United States to explore the reasons behind its slow cognitive and normative legitimacy despite legalization. The authors unveil the role of not just the materiality but also the practices displayed in advertisements in legitimacy processes. Analyzing the content of the routines and practices displayed in gun advertising, the authors show that tensions regarding the types of practices displayed generate ongoing market tensions. Despite marketers' intentions to legitimate their product, their communication strategies displaying culturally illegitimate practices contributes to the object's delegitimation.

The final paper takes the emerging field of influencers to explore the historical tensions regarding its professionalization. Through looking at media representations addressed to different stakeholders (general public, practitioners, and academics), the authors unpack a process of legitimation and delegitimation of influencer work. Their findings show that due to the fragile cultural expectations regarding the authenticity of influencer work, professionalization efforts have backfired, putting the category in suspended delegitimation.

These three papers show that legitimacy is an ongoing process that is never complete, and sometimes, impossible. The session will contribute to the conference by showcasing research relevant to multiple stakeholders: consumers themselves, practitioners, and the society at large. Building on contexts that are part of the everyday lives, well-being, and concerns of consumers (vaping, cryptocurrency, meat, guns, influencers), the session aims to both contribute to the academic discussions on legitimacy and generate conversation on these substantive areas, including ethical, political, legal and consumer-well-being concerns. It also will likely elicit discussions on how the pandemic has reshaped the legitimacy of masks, social gatherings, and teleworking.

Markets' Survival Between Legitimacy and Delegitimacy

EXTENDED ABSTRACT

Institutions' survival is contingent on their legitimacy. Legitimacy is "a generalized perception or assumption that the actions of an entity are desirable, proper or appropriate within some socially constructed system of norms, values, beliefs, and definitions"(Suchman, 1995, p. 574). It has three main pillars regulative, normative, and cognitive (Humphreys, 2010a; Scott, 1995). Regulative legitimacy is involved with governmental rules and regulations, cognitive legitimacy is the association between a market and the existing cognitive schemas of individuals and finally, normative legitimacy is associated with the social acceptance of a market (Scott, 1995).

Most of the work on institutionalization investigated the process of gaining legitimacy (Humphreys, 2010a, 2010b; Humphreys & Latour, 2013; Kates, 2004; Press & Arnould, 2011). Through a historical analysis, authors identified the narratives that legitimated multiple markets. For example, the market for casino gambling (Humphreys, 2010a), and community-supported agriculture (Press & Arnould, 2011). Consumers, media, and governments mobilize their actions to shape various pillars of legitimacy (see Dolbec & Fischer, 2015; Humphreys, 2010b, 2010a; Humphreys & Thompson, 2014; Scaraboto & Fischer, 2012). Few researchers investigated the interplay between these legitimacy pillars in the market. For example, how cognitive and normative legitimacy is intertwined (Humphreys and Latour 2013) and the role of physical objects in influencing the legitimacy of consumption (Huff et al., 2021). However, most of the literature tackled the process of obtaining legitimacy and investigated the influence of actors in isolation. Little is known about the spillover effect of the work of marketplace actors and how they influence market delegitimacy. Thus, we ask how does the recursive process of legitimacy and delegitimacy unfold?

We analyzed newspaper articles, industry reports, documentaries, and Twitter hashtags associated with three markets. The media includes both mainstream and specialist counting for 16,580 articles and it covers the narratives around these markets, the political forces into action shaping them. Twitter analysis included the most mentioned hashtags within each market counting for 72,432 comments.

The meat market was chosen as it exists as far as humans were around (Zaraska, 2016) and managed to survive multiple battles of delegitimation across its history. The cryptocurrency market was selected as a new emerging market shaking the legitimacy of the hard currency as the sole form of exchange and aiming to flee its tainted black-market history. For example, cryptocurrencies such as Bitcoin were originally used on sites such as Silk Road where individuals bought and sold illicit drugs and weapons. Finally, the vaping market was selected as a market-facing de-legitimacy, however rather than disappearing, it is constantly shifting to absorb the shocks of delegitimation.

Through our analysis, we identify several overlooked marketplace actors that influence market legitimacy. These actors are scientific and financial communities, scientific and financial institutions, specialized media, industry associations, religious institutions, anti-consumers (e.g, parental groups against vaping), and entrepreneurs. These actors tackle different legitimacy pillars guided by their position in the market. For example, parental groups that exist on social media stand in opposition to vaping as a legitimate practice among teenagers. Their role touches on all three legitimacy pillars in various ways. As parents, they influence the normative delegitimacy of vaping through emotional messages of concern towards their kids. Such influence rests on cognitive legitimacy provided through scientific groups who equip them with scientific proofs. In addition, parents lobby governmental and policymakers to de-legitimate the regulative legitimacy of vaping through tightening the regulations.

Actors contest the existing legitimacy of a market, whether it is legitimate or delegitimate, using four different approaches: problematization, demarcation, validation, and affirmation. By problematization, we are referring to actors' efforts in questioning the current legitimacy status of the market. This strategy is implemented by providing information that contradicts the norm. An example of such problematization is attacking the production practices of meat by claiming their unhealthiness and unsustainability. Problematization targets the cognitive pillar of legitimacy.

Actors are also involved in demarcation by drawing boundaries between acceptable and unacceptable practices in the market. Such a process reshapes the norms and aims to establish new realities markets. Demarcation targets cognitive and normative pillars. For instance, within the cryptocurrency markets, the original cryptocurrency supporters of Bitcoin are quick to denounce any new form of cryptocurrency that doesn't follow the same principles set by Bitcoin. Whereas Bitcoin's supply is dictated by the Proof of Work protocol in which the supply is controlled by the mining process whereby new Bitcoin is added to the market when transactions are approved (Nakamoto, 2008), other cryptocurrencies have pre-mined their supply which is denounced by the Bitcoin community.

Third, is validation when actors provide concrete support for their motives. Validation requires regulative support either through scientific and financial institutions and federal agencies. Cryptocurrency proponents aim to gain regulative legitimacy from the United States government through pushing for clear regulations for this new asset class. Vegans are validating the unsustainability of meat production practices through scientific research (e.g., The China Study Campbell & Campbell, 2016).

Finally, actors are involved in affirmation by rallying support and building networks to achieve their desired legitimacy. Affirmation rests on the acquisition of normative legitimacy within the market. Actors, both pro and against the current state of legitimacy, practice affirmation. An example of affirmation in the formation of trade associations within the meat industry to protect meat producers and the formation of animal activists' groups that stand in opposition of the market.

We argue, in our paper, that markets are neither fully legitimate nor fully delegitimate but rather are inherently contested and volatile. Our paper contributes to the literature on institutional theory by providing a theory of market (de)legitimacy. We do that by highlighting the connection between the myriad marketplace actors and their role in influencing the different legitimacy pillars. Finally, we put forward managerial recommendations for brands and companies to ensure their survival along the legitimation process.

Tensions and Dynamics in the (De)Legitimation of the American Consumer Firearms Market

EXTENDED ABSTRACT

We apply an institutional theory perspective to examine shifts in the three "pillars," or types of legitimacy that sustain an acceptable social institution – regulative, normative, and cultural-cognitive legitimacy (Scott 2008; Thornton et al. 2012) – in the American market for consumer firearms from 2000 through 2020.

In many consumer markets, the pillars of legitimacy are relatively interdependent. Consumers, producers, mainstream media, or policy-makers can establish the foundational elements for one pillar, which can provide scaffolding for other pillars to emerge, and for all three to strengthen in a legitimation process that renders the market acceptable (Humphreys, 2010; Suchman, 1995). For example, the markets for casino gambling (Humphreys, 2010) and recreational cannabis (Huff, Humphreys, & Wilner, 2021) experienced legitimation as iterative emergence of and dependencies between the three pillars. Conversely, in other consumer markets, as one pillar begins to collapse, other pillars follow (e.g., cigarettes; Inness, Barling, Rogers, & Turner, 2008) The interdependent nature of the pillars enables the public to understand a particular market as largely acceptable, unacceptable, or in transition (Rosa, Porac, Runser-Spanjol, & Saxon, 1999; Weijo, Martin, & Arnould, 2018).

Using data related to national public policy, public opinion, retail sales, and advertising, we examine a market characterized by tensions between and dynamics among the pillars that have not enabled the market to attain a status of legitimate or illegitimate. Public policy data, including two US Supreme Court decisions related to rights to firearm ownership and armed self-defense (2008, 2010), and the expiration of a ten-year assault weapons ban (in 2004), show that regulative legitimacy has strengthened in the past two decades (Cook & Goss, 2014; Light, 2017). Laws upholding gun rights have expanded at the national level and across the states, and this expansion of consumers' rights to purchase, own, carry, and use guns in civilian life has coincided with a dramatic increase in year-over-year firearm sales (Law Center to Prevent Gun Violence, 2021; NRA-ILA, 2020; National Shooting Sports Federation, 2020).

Puzzling, then, are the continued lack of normative and cultural-cognitive legitimacy in this market. Throughout our study period, consumer firearms lacked widespread alignment with social values and morals, shared logics of action, and cultural support (Cook & Goss, 2014; Haag, 2016; Melzer, 2019). In spite of a constitutional right to consume firearms, public support for more strict gun regulations has remained between 55-60%, and gun ownership remains steady at 30-40% of American households (Gallup, 2020). Further, some key social institutions have enacted regulations that de-legitimize firearms, including bans on advertisements on social media platforms and mainstream television networks, and bans on carrying firearms in sports stadia, airports, etc. (Claflin, 2021).

Prior research has examined the social movements and institutions seeking to legitimize or de-legitimize guns (Huff, Barnhart, McAlexander, & McAlexander, 2017; Lacombe, 2021; Melzer, 2019). Other research has revealed how guns are an identity resource, a material marker of community, a practical tool, and an essential possession for everyday life (Lacombe 2021, Shapira 2018, etc.). We focus on the work of marketers, and examine firearm advertising by manufacturers. Print magazines remain the dominant medium for gun advertising owing to restrictions imposed by other media. Our research question is, how does gun advertising contribute to the tensions and dynamics of legitimacy in the gun market?

We obtained hard copies of monthly issues of *Guns & Ammo* from 2000-2020, the firearms-focused magazine with the largest circulation that is not published by the National Rifle Association. We catalogued ads ¼ page or larger; classified them as for handguns (ie, pistols, revolvers), traditional rifles, modern sporting rifles (ie, 'AR-15 style'), and/or shotguns; and coded them on 22 different attributes, including the activities depicted in the ad.

We found that the volume and nature of gun ads changed in relation to regulatory expansions over the period of study. After the assault weapons ban expired, ads for 'AR-15 style' modern sporting rifles increased in number, and after US Supreme Court decisions were issued, ads for handguns increased.

Further, over time, the ads made more explicit linkages between types of guns and types of routines or activities that are appropriate. Traditional rifles and shotguns were linked, in text and imagery, to specific activities: exerting deadly force on animals or inanimate targets in the course of hunting, rural life, and target-shooting.

Handguns and modern sporting rifles were linked, in text and imagery, to different activities: the practice of and the potential to exert deadly force against another human in the course of self-defense, including of family and/or property; and of self-assertion, including dominance over perceived (and often abstract) forces of evil or oppression. At times, the distinction between self-defense and self-assertion activities was blurred with use of military (i.e., combat, tactical) themes.

Overall, we find that market legitimacy is a function of the legitimacy of the activities performed with the product, and these activities are portrayed in advertising. The activities related to hunting and sport shooting, and the guns themselves, have long been and continue to be regarded as legitimate by Americans (Littlefield & Ozanne, 2011). In contrast, the activities related to self-defense and self-assertion, and the guns portrayed as appropriate for those activities, are not generally accepted as legitimate. The resulting discrepancies in legitimacy of activities contribute to the friction and unusual dynamics in the legitimation of the firearms market.

These findings point to the importance of (1) understanding the legitimacy of the consumer practice in addition to the product itself (Zanette & Scaraboto, 2019); (2) the interplay between the pillars of legitimacy; consumers may not necessarily regard a product that is legal as normative or aligned with cultural beliefs (Luedicke, Thompson, & Giesler, 2010; Wilner & Huff, 2017); (3) and the irony in marketers' success in encouraging illegitimate practices. One consequence of an 'assault style rifle' being used in a mass shooting – an activity indirectly suggested in some advertising – is that the subcategory of firearm becomes less legitimate for many Americans, and more legitimate for others (Browder, 2019). The net result is a lack of generally-agreed-upon direction of (de)legitimation for the firearms market.

The Impossible Profession of Being an Influencer

EXTENDED ABSTRACT

Influencers have become strategic resources for brands, both as creators of content (Nascimento et al., 2020) and as communicators with an avid and engaged audience (McQuarrie et al., 2013). However, despite the increased literature and practice around them, evidence suggests that their role in companies' strategies is still secondary (Influencer Marketing Hub, 2020), that influencer work is still considered frivolous and that compensation for influencer work is not standardized (Abidin, 2016a). In this paper, we explore the historical and emergent tensions surrounding influencer work in the context of their growing importance in marketing communication.

We draw on the literature domains of both the sociology of professions and legitimacy. The first is based on the premise that expert labor can only be considered professionalized when there is a clear definition of a group's work and their exclusive jurisdiction over others for this work (Abbott, 1988). Such exclusivity comes from the institutionalization of professional work. This process entails several changes in a field (Suddaby & Viale, 2011) and is facilitated through institutional work strategies that result in legitimate expertise, autonomy and authority for members of this profession (Noordegraf, 2020). The second informs us on what 'legitimate' for a profession means. Any entity—including a profession—to be legitimate must comply with different criteria of legitimacy (Deephouse et al., 2017; Humphreys, 2010; Huff et al., 2021). Pragmatic legitimacy demonstrates that a specific professional category manages to solve a real and important problem. Regulative legitimacy refers to if, and how, regulatory bodies recognize members of a professional category's expertise, autonomy and authority. Normative legitimacy indicates that the professional activity does not clash with social norms and rules. Cultural-cognitive legitimacy entails that the general public understands that the professionals' expertise, autonomy and authority are paramount for getting a specific work task done.

Previous literature has offered some insights into the dynamics of the professionalization and legitimation of influencers. First, influencers are considered authentic actors that are experts in creating sincere and emotional connections with their audiences (Kozinets et al., 2010; Ashman et al., 2021). Second, they are authorities of taste (McQuarrie et al., 2013), whose activities have redefined consumption fields (Dolbec & Fischer, 2015; Scaraboto & Fischer, 2013). Finally, influencers calibrate their work for the best type of content to thrive in the attention economy (Smith & Fischer, 2021).

Yet, the legitimacy of influencer work is contested on several grounds: for some they are not 'serious' enough (Abidin, 2016b), due to their reliance on aestheticized and conspicuous lifestyle displays (Abidin, 2016a); for others they are not successful enough, since only 'the lucky few' de facto become successful (Ashman et al., 2018); and yet others claim influencers are also non-authentic, once they might 'sell-out' and change their content when engaging with brands (Kozinets et al., 2010; Kozinets et al., 2017). These challenges seem to intersect with more structural ones, such as a lack of explicit rules provided by digital platforms and a still incomprehensive and incomplete set of rules and standards anchored in corresponding regulations and laws that would define how influencer work needs to be conducted and remunerated lawfully and legitimately.

Our empirical work builds on a database of mass and specialty media, as well as academic articles on influencers that includes 2,104 articles in the specialized press, 14,038 articles in the general press, and 111 academic articles. This data is analyzed qualitatively and quantitatively (through custom dictionaries on LIWC to understand

how professional identities of influencers are framed when addressing various types of audiences (consumers and general public, practitioners, academics). We contextualize this content analysis through historical events that mark the ascension (and fall) of influencers as a professional category (such as the Fyre Festival) with changes in the public opinion.

Our findings indicate that the (il)legitimation process of influencers unfolds in three phases.

In phase 1, influencing work is discussed as productive leisure and unpaid, volunteer, status-oriented—but still authentic—work. Corresponding to the academic discussions on the megaphone effect (McQuarrie et al., 2013), this period marks influencers as ordinary celebrities who work to build and leverage cultural capital through trustworthy opinion leadership.

The second phase aligns with the upsurge of various platforms and the rapid marketization and professionalization of influencer work. This period brings about the introduction of metrics as well as the engagement, conversion, and categorization of influencers including for example the micro-influencer or the pet influencer. In this phase, cultural narratives around influencers start to converge around paid work but without exclusive jurisdiction. Formal means of compensation also bring regulative interference to the field (such as mandatory ad disclosures) and clarify the category of work, while distinguishing it from uncompensated voluntary and ostensibly more authentic word-of-mouth.

The third phase is laden with discourses of delegitimation and contestations on the nature of the work and jurisdiction. Being paid for what was expected to be authentic endorsement breaks cultural legitimacy. Normative legitimacy is also disrupted through scandals such as the Fyre Festival, a fraudulent festival promoted by some of the most popular influencers in the world. On the other hand, the attempts to professionalize and clearly define their work and its jurisdiction through the creation of the Influencers Council in 2019, paradoxically hurts the perceptions of authenticity.

Our work shows that a cultural category that relies on authentically connecting and engaging with an audience might fail at professionalization attempts. What allows influencer work to be considered professional also renders it cognitively and normatively illegitimate. When one's job is to endorse products in exchange for financial arrangements, and attention and affect are gained through heavily aestheticized and conspicuous sponsored performances, the authenticity of the content is questioned by the general public and the practitioners.

Paper #4: Predicting Support for Redistributive Policy with Disadvantaged Babies and Lazy Adults: Framing Inequality to Promote Redistribution

Katherine L. Christensen, Indiana University, USA
David Dolifka, UCLA Anderson School of Management, USA
Franklin Shaddy, UCLA Anderson School of Management, USA

SESSION OVERVIEW

The richest 1% of the world's population owns 44% of the world's financial assets. Last year, for the first time in decades, the global middle class shrunk (Pew 2021). This unequal access to economic resources matters. Financial inequality can reduce economic efficiency, increase vulnerability to financial crises, lower educational attainment and health outcomes for the poor, reduce economic efficiency, and lead to lower levels of well-being (Hertel and Samber 2019; UNDESA 2020).

The goal of this session is to gain a greater understanding of the effects of inequality on consumer judgments and choice by asking two key questions: 1) how does high inequality affect consumer attributions of fairness and charitable giving decisions and 2) by reframing inequality can we increase consumers' preference for redistribution? We explore these questions in a series of four papers.

In the first paper, Day and Norton investigate inequality in an educational context. The authors document current educational inequality across universities and assess estimated and ideal levels of inequality. The researchers show that learning about the current level of endowment inequality increases the perceived unfairness of the distribution of university wealth.

Next, Whillans and Macchia ask: are high-earning individuals more or less generous when income inequality is high? To answer this question, the researchers conduct a multiverse analysis with a globally representative sample (N=948,837). Across models, in countries with higher (vs. lower) income inequality, the authors find that wealthier individuals were more likely to donate and volunteer their time.

The last two papers explore the effect of framing on consumers' attitudes about inequality. Walker, Tepper, and Gilovich examine consumer beliefs about the fairness of inequality and find that economic inequality is seen as less fair when a group, rather than an individual, is presented at the top of the distribution. These results suggest that support for inequality, and policies to reduce it, may depend on how the top of the economic distribution is framed. Finally, Christensen, Dolifka, and Shaddy provide evidence that people indicate higher support for resolving financial inequality across generations when the authors present those disparities as a baby's opportunities, rather than an adult's outcomes. Furthermore, individualistic and structural attributions fully mediate the effect of framing inequality on participants' preference for reducing financial inequality.

Together, these four papers point the way to a deeper understanding of the role of inequality in consumer decision-making. The first paper tackles inequity in the education market, the second paper examines the effect of inequality on charitable giving, and the session's final two papers examine how inequality frames affect consumer fairness judgments and consumer support for redistributive policies. The diverse approaches taken by each paper in this session, and the varying aspects of inequality investigated will attract ACR members from diverse backgrounds including researchers interested in inequality, fairness, social justice, public policy, and ethical issues in marketing.

The Perceived and Ideal Inequality of U.S. College Endowments

EXTENDED ABSTRACT

Equal opportunity is a commonly shared value. In practice, people believe that a main vehicle of opportunity is a university education (Bullock and Limbert, 2003). Indeed, university graduates fair better than high school graduates across several indicators, including higher earnings (Hout 2012). Higher quality university education also appears to relate to better post-university outcomes (Eide et al. 2016; Zhang 2005). Across society, how large is the gap among university education experiences, and how unequal should it be?

We focus on one consequential and well-recognized form: inequality in university and college endowment wealth. University endowments are funded from donations, gifts, and investment earnings, and can be a significant source of funding (Sherlock et al. 2015). Universities with relatively higher endowments per student can also provide more funding for a variety of university operations (e.g., more scholarships, professorships, work, and travel opportunities). In other words, they can offer higher quality education and more educational opportunities than universities with smaller endowments per student. This issue is concerning as elite, wealthy universities are overrepresented by children of wealthy parents, while racialized and lower-class students largely attend less wealthy universities (Chetty et al. 2017). Moreover, as the costs of going to university have risen widely, students from typically non-wealthy families are faced with record-setting student debt, which has doubled in the last decade alone (Tanzi 2018).

To investigate these pressing issues further, we first assess the actual level of university endowment inequality in the United States. We then examine people's perceptions, desired levels, and tolerance of endowment inequality. Providing insight into these judgments is critical, given research suggesting that perceptions of inequality–in domains such as wealth and income–serve as independent predictors

of people's attitudes and behaviors beyond objective inequality in their societies (Gimpelson and Treisman 2018; Hauser and Norton 2017).

First, we identified student enrollments for each of the near 800 universities for the 2015/2016 year and ranked them from those with the largest endowment per student to those with the smallest endowment per student. We then arranged these universities into equal-student quintiles (i.e., top 20%, 2nd 20%, middle 20%, 4th 20%, bottom 20%). Our goal was to provide approximate objective data for comparison purposes rather than directly for policy. Our analysis indicates that the distribution of university wealth is extremely unequal. The top 20% of universities have approximately 80% of the total endowment wealth, whereas the bottom 20% of universities have only 0.6% – a tiny fraction of the total wealth. For the top 20%, this means that the average endowment per student is around $209,000. Meanwhile, universities in the bottom 20% have a mere $1,500 average endowment per student.

Three studies demonstrate people's tendency to both underestimate university endowment inequality and to desire more equal distributions. We assessed beliefs about the degree of university endowment inequality by adapting prior measures of inequality beliefs (Norton and Ariely 2011). Participants were informed that the top 800 (or 100) universities were arranged from largest to smallest endowment per student and placed into quintiles (top 20%, 2nd 20%, 3rd 20%, 4th 20%, bottom 20%). Using sliders participants estimated the percentage of the total university endowment wealth owned by each quintile, which was represented by a labeled column (e.g., top 20%) ranging from 0-100%. Totals were required to equal 100%. As explained to participants, restrictions were programmed to prevent logically impossible estimates (e.g., the top 20% could not be greater than the 2nd 20%).

For the top 800 universities (i.e., the full distribution) participants estimated that the top 20% of universities own 47.14% (CI: 45.30, 48.98) of the endowment wealth but ideally would own 24.39% (CI: 23.07, 25.71). Both judgments are far less than the 80.49% owned by the top 20% (t's > 35.726, p's < .001). Participants also estimated that the bottom 20% of universities own 5.98% (CI: 5.44, 6.52) and ideally would own 17.25% (CI: 16.20, 18.31), which is much more than the 0.60% actually owned (t's > 19.562, p's < .001). Within t-test analyses revealed that ideals for the top 20% were significantly lower than estimates, and ideals for the bottom 20% were significantly higher than estimates (t's > 19.116, p's < .001). In other words, the wealth of the top 20% was underestimated, the wealth of the bottom 20% overestimated, and ideals were much more equal than reality and estimates. These estimates and ideals are not well explained by participants' background characteristics (including income and political affiliation). Finally, a fourth study reveals that learning about the current level of endowment inequality increases the perceived unfairness of the distribution of university wealth.

We discuss the implications of increasing public awareness of educational inequality for both citizen's behaviors (e.g., donations to universities) and educational policies (e.g., taxation, redistribution).

Whether Income and Income Inequality Shape Prosocial Behavior Around the World: A Multiverse Approach

EXTENDED ABSTRACT

Are high-income individuals more or less generous? Due to their greater capacity to help, high-income individuals might be more likely to engage in prosocial behavior than their lower-income counterparts. One phenomenon that makes the prosocial behavior of high-income individuals particularly compelling is income inequality—as it creates a hierarchy in which some people have more resources than others. Income inequality has been increasing around the world (Solt, 2016) and is linked to important downstream welfare and behavioral consequences including health and social problems (Pickett and Wilkinson 2015), lower happiness and life satisfaction (Buttrick and Oishi 2017), and greater cooperation (Hauser et al. 2019).

The effect of income on prosocial behavior and whether income inequality moderates this effect have been previously explored. Yet, published studies have used convenience samples from restricted regions, such as the United States and Europe, and varied measures of prosocial behavior, and income (see Côté and Willer 2020; Schmukle and Egloff 2020 for reviews). Here, we use a large and globally representative data set with 948,837 respondents and 133 countries and consistent measures of prosocial behavior, income, and income inequality. We conduct a multiverse analysis with 30 statistical specifications that contain five income measures (absolute income, log of income, income quintiles, income deciles, and income percentiles), three statistical models (random effects multi-level logit models, fixed effects logit models without covariates, and fixed-effects models with covariates), and two dependent variables (whether people donated money to charity and whether people volunteered time to an organization). First, we explore whether high-income individuals are more likely to engage in prosocial behavior than lower-income individuals. Second, we explore whether high-income are more likely to engage in prosocial behavior under high (vs. low) income inequality.

Multiverse Analysis. When examining a research question, researchers have degrees of freedom to choose the data transformation techniques and statistical models that they find appropriate. However, the answer to the same research question may vary based on the statistical choices that researchers make (Silberzahn et al. 2018). One way to overcome this limitation is to perform a multiverse analysis, which involves systematically conducting analyses that differ in data transformation techniques and statistical methods (Steegen et al. 2016). The goal of this approach is to increase transparency by reporting findings across different statistical scenarios. A multiverse analysis clarifies the robustness of reported results and allows for the observation of whether findings change due to various statistical choices available to a researcher. In our multiverse analysis, we examine whether income shapes the likelihood of engaging in prosocial behavior and whether income inequality moderates this effect by employing 30 different analyses including five income measures and three statistical models.

Data Set. In the present research, we use a large, diverse, and globally representative data set—the Gallup World Poll (GWP). This data set includes nationally representative data from 133 countries, ten survey years (2009-2018), and 948,837 respondents. Given the low correlation between likelihood of donating money to charity and likelihood of volunteering time to an organization of 0.27, we treated these measures as separate dependent variables.

Inequality Measure. To account for the level of income inequality in each country and year, we used the Gini Index in our analyses. Scores closer to one denote higher levels of income inequality. This measure has key advantages for cross-country comparisons: the calculations of the Gini Index are independent of the size of the economy and the population of a country.

Results. Across each of our 30 model specifications, higher-income people were more likely to donate money to charity and volunteer their time to an organization than lower-income individuals. In the 15 models that used whether people donated money to charity as the dependent variable, the odds of having donated money to charity

were, on average, 1.472 times greater than the odds for low-income people. In the 15 models that used whether people volunteered time to an organization as the dependent variable, the odds of having volunteered time to an organization among higher-income individuals were, on average, 1.186 times greater than the odds for low-income people. All findings held controlling for demographic factors (i.e., age, gender, education, employment status, marital status, number of children in the household) and macroeconomic indicators (i.e., log of GDP per capita, unemployment, and inflation rates).

Critically, in 12 out of 15 models, high-income individuals were more likely to donate money to charity under higher (vs. lower) income inequality. For high-income people, the odds of having donated money to charity under higher income inequality was, on average, 1.006 times greater than the odds of donating under lower income inequality. Across all 15 statistical models, higher-income individuals were more likely to volunteer time to an organization under higher (vs. lower) income inequality. In these analyses, the odds of having volunteered under higher income inequality were, on average, 1.005 times greater than the odds of having volunteered time to an organization under lower income inequality. These findings held for covariates.

Discussion. In an era where governments are deprioritizing redistribution and anti-poverty programs, the role of prosocial behavior in shaping societal well-being has never been more relevant. Furthering the debate among academics and policymakers, our study contributes to the prosociality-inequality puzzle of whether income inequality shapes prosocial behavior among the affluent by showing a positive effect of income on prosocial behavior—which is even more positive under greater income inequality. The results of our multiverse analysis complement prior research and set the groundwork for future research: suggesting that we should move from examining if income inequality moderates the effect of income on prosocial behavior to exploring when and why.

People are More Tolerant of Inequality When it is Expressed in Terms of Individuals Rather Than Groups at the Top

EXTENDED ABSTRACT

Despite the ever-growing economic gap between the very wealthy and the rest of the population, support for redistributive policies tends to be low. We propose that the visible wealth of successful individuals may reduce support for redistribution, as people are more likely to believe that the wealth of individuals (rather than groups) at the top is well earned. Prior work suggests that people want to see individual dominance continue more than group dominance (Walker and Gilovich 2021), and that people tend to attribute the behavior and outcomes of individuals more to their dispositions than they do to the behavior and outcomes of groups (Critcher and Dunning 2014). We, therefore, propose that inequality may be seen as more fair when it is framed as an individual at the top of the economic ladder rather than a group because individual success is more likely to be attributed to that person's hard work, talent, and ingenuity. This belief that an individual's economic success is more fairly earned than a group's economic success may in turn diminish people's appetite for policies that narrow the economic gap.

Study 1

Participants in all studies were randomly assigned to either the group or individual condition. In Study1, those in the group condition read that the salaries of the CEOs of the largest companies in America had grown to 372 times that of the average worker. Those

in the individual condition read that the salary of an individual company's CEO had grown to 372 times that of the average worker at his company. Participants indicated how many times greater the CEOs' (CEO's) salary should be compared to that of the average worker. Those in the individual condition thought the salary should be significantly higher (M = 122.8) than those in the group condition (M = 92.7), *p* = .04.

Study 2

In a within-subjects test, participants read first about either a Korean conglomerate or an individual Korean businessman who had accumulated greater wealth than any of its/his competitors. Participants then read about a competition to land a large government contract, which had been won by the conglomerate/businessman. They then rated how fair they thought the outcome of the competition was and how fair they thought the resource distribution was between the conglomerate/businessman and the other competitors. Participants thought it was more fair for the businessman to win the competition (M = 4.98) than the conglomerate (M = 4.54), *p* < .001. They also thought that the resource distribution between the individual businessman and his competitors were more fair (M = 4.79) than the resource distribution between the conglomerate and its competitors (M = 4.20), p < .001.

Study 3

Participants in the group condition saw Oxfam's published estimate that the richest 26 people in the world have as much wealth as the poorest 3.5 billion people. Participants in the individual condition read that the richest person in the world has as much wealth as the poorest 500 million people. Participants then rated how fair they thought this distribution of resources is, and also rated the degree to which they thought the success of the person/persons at the top was due to dispositional factors or situational factors. Finally, participants indicated their support for an inheritance tax to close the gap between the wealthy and the poor.

Participants thought that global wealth inequality was more fair when it was expressed as an individual at the top (M = 4.84) rather than as a group at the top (M = 4.14), *p* = .004.

Participants also thought that the richest person's success was due more to personal characteristics (M = 4.73) than was the success of the richest 26 people (M = 4.10), *p* = .008.

Similarly, participants who read about a group at the top were more in favor of an inheritance tax (M = 6.15) than those who read about an individual at the top (M = 5.34), *p* = .009. A structural equation analysis indicated that the indirect path from condition to fairness to attribution to support for the luxury tax was significant, *p* < .01.

Study 4

Some of the most potent symbols of wealth in the United States are the portraits of people who grace the covers of magazines such as Forbes, Fortune, and Money. We examined whether people who are exposed to a single successful individual on such a cover would be more accepting of inequality than those exposed to a group of successful individuals. Half of the participants saw a Forbes magazine cover that featured 7 billionaires on the cover. The other half of the participants saw a cover of Forbes picturing one of these seven billionaires from the group cover, with the cover randomly selected across participants. They then answered the same questions from Study 3.

Participants thought that the wealth attained by the billionaire(s) depicted on the cover was more fair in the individual condition (M

= 5.62) than in the group condition (M = 4.62), p < .001. They also attributed the success of the individual billionaires pictured on seven individual covers more to dispositional characteristics (M = 6.03) than they did when the seven billionaires were pictured together (M = 5.22), p < .001. Participants who saw the group of billionaires were also more in favor of an inheritance tax (M = 5.73) than those who saw only one billionaire M = 5.10), p = .01. A structural equation analysis indicated that the indirect path from condition to fairness to attribution to support for the luxury tax was significant, *p* < .001.

Gaps between the wealthy and the poor appear to be more tolerable when the gap is between an individual at the top and those at the bottom than when it involves a class of people at the top because an individual is seen as more personally responsible for his or her wealth. This view of individuals as more deserving of their success reduces support for policies aimed at redistribution.

Predicting Support for Redistributive Policy with Disadvantaged Babies and Lazy Adults: Framing Inequality to Promote Redistribution

EXTENDED ABSTRACT

Economic inequality in the United States continues to rise (Horowitz, Igielnik, and Kochhar 2020). While addressing the gap between the "haves" and the "have-nots" is an important societal goal that aligns with the core mission of transformative consumer research (Mick 2006), there is only lackluster consumer support for policies to reduce inequality and redistribute wealth (Horowitz et al. 2020). In this project, we develop and test a framing intervention to increase support for financial equality and redistributive policy.

Opportunities early in life can pave the way to positive outcomes later on, while a lack of opportunity can thwart future potential. Where you start in life as a baby overwhelmingly predicts where you finish as an adult (Clark and Cummins 2014). Despite the direct link between inequality of opportunity and inequality of outcome, we suspect people may find it harder to tolerate unequal opportunity. Our prediction builds upon prior findings suggesting inequality is tolerated when it can be attributed to the individual (e.g., "he lacks skill", "she is lazy") (Bullock 1999; Furnham 1982, 1983; Kluegel and Smith 1986; Piff et al. 2020). We expect unequal opportunities will be harder to rationalize, and we design our intervention around the purest manifestation of opportunity: babies. One baby begins life wealthy and the other baby begins life in poverty. Across four experiments, we show people are more motivated to resolve financial inequalities when those disparities are presented as a baby's opportunities, rather than an adult's outcomes.

In experiment 1 (N = 808), participants were randomly assigned to view eight photographs of either babies or adults. Half of the photographs purportedly showed people with a "family income in the bottom 10%", and the other half showed people with a "family income in the top 10%" (all photos were randomized). Subsequently, participants indicated their agreement with the statement "I would support a policy to make these two groups of people more financially equal" (1 = "Strongly disagree", 7 = "Strongly agree"). We find a stronger preference for equality when the financial disparity is presented with photos of babies (M = 5.15, SD = 1.86) compared to adults (M = 4.83, SD = 1.90; t(806) = 2.41, *p* = .016). To address possible concerns about the use of affectively rich photographs experiments 2-4 use text-based manipulations.

In experiment 2 (N = 806), we present inequality through descriptions of two people.

Participants were randomly assigned to read about two 5-month-old boys or two 35-year-old men. For clarity, we named these people "Michael" and "Robert" (names counterbalanced). In both conditions, these two people were unequal on the dimensions of education, income, and location. To create parallel education and income disparities between the two conditions, we equated the outcomes of the adult ("his income is in the top 10%") to the outcomes of the baby's parents ("the family's household income is in the top 10%"). Therefore, the same degree of inequality was described between the baby and adult conditions.

Replicating our prior results, we find a greater preference for equality when we present disparities between babies (M = 4.92, SD = 1.80), rather than adults (M = 4.41, SD = 1.87; t(804) = 3.94, *p* < .001). After reminding participants that redistributive policies could increase taxes—we observed greater policy support in the baby condition (M = 4.92, SD = 1.86), compared to the adult condition (M = 4.61, SD = 1.86; t(804) = 2.37, *p* = .018). These results are encouraging because consumers' tax and redistributive beliefs are notoriously challenging to move (Srna, Zauberman, and Schrift 2019; Sussman and Olivola 2011) .

In experiment 3 (N = 201), we explore process using a design similar to experiment 2.

We set out to determine if attributions of inequality mediate our framing effect. Because babies do not have a personal history of actions to rationalize their poverty (or affluence), we suspect people should prefer to make structural attributions—rather than individualistic attributions—for a baby's opportunities. Using items from Bullock, Williams, and Limbert (2003) we measure the individualistic (α = .76) and structural attributions (α = .81) for the inequality between Michael and Robert. These two attributions simultaneously mediate the effect of framing on preference for financial inequality. Bootstrapping the confidence intervals (Preacher and Hayes 2004), we find a significant indirect effect through individualistic attributions (ab = .448, CI 95% = [.204, .693]) and structural attributions (ab = .646, CI 95% = [.318, .974]) and no direct effect of condition (β = .198, se = .218, t(197) = .900, *p* = .363) in a model with a significant total effect (β = 1.29, se = .277, t(199) = 4.64, *p* < .001) indicating indirect-only mediation (Zhao, Lynch, and Chen 2010) .

In experiment 4 (N = 1,001), we examined the role of political ideology. Prior work suggests ideological conservatives are more likely to make individualistic attributions to tolerate and rationalize unequal outcomes (Bullock et al. 2003; Chow and Galak 2012). Framing inequality in terms of opportunities should limit the extent to which conservatives can rationalize economic disparities. To test this, we surveyed an equal number of self-reported liberals and conservatives on Prolific Academic and presented them with the same stimuli from experiment 2. Though we do not detect a significant interaction between political alignment (binary) and condition, we observe the simple effect of condition on the preference for equality is only significant for conservatives (β = .360, se = .171, t(2.11), *p* = .035), but not for liberals (β = .195, se = .120, t(499) = 1.63, *p* = .104).

The goal of transformative consumer research is to address real-world problems that affect the lives and welfare of real people. Economic inequality is a pressing, far-reaching problem that most consumers acknowledge but few are willing to act upon. In this project, we propose a simple framing intervention that challenges people to confront the structural reasons for economic inequality.

SESSION OVERVIEW

What consumers choose to communicate can have a variety of important effects. Providing product feedback or publishing online reviews can help firms learn what customers think of their offerings and influence whether others choose to buy. Posting on social media about recent purchases can help consumers manage their public image and cultivate desirable impressions. And transmitting articles, facts, or opinions about important social issues can sway public opinion and coalesce movements. Such processes of consumer sharing are integral to consumers' daily lives. To date, one common approach to studying sharing has been to focus on *what* consumers share (e.g., Berger & Milkman 2012; Melumad, Meyer, & Kim, 2021). Less is known, however, about how firms can proactively influence sharing. In this session, we present emerging research illuminating how firm decisions impact what, when, and how consumers share.

The first two papers examine how firms can effectively solicit consumers to share. Paper 1 investigates consumers' reluctance to talk about donations to charity specifically. Silver and Small argue that when deciding whether share about charitable giving, donors often worry about the effect sharing might have on their reputation, but they overlook how sharing can help the cause. In a large, pre-registered field experiment, the authors find that nudging donors to consider the fact that sharing might inspire others to give too can increase word-of-mouth. Paper 2 asks why some strategies to increase sharing may not work as intended. In a large field experiment with a technology company in seven countries, Reiff and colleagues find that messages that appeal to consumers' sense of agency (e.g., "Your voice is important") surprisingly *decrease* consumers' willingness to share feedback, particularly in countries with lower trust in business. The authors show that low-trust consumers typically perceive these appeals as inauthentic.

Although firms typically want to encourage consumer sharing, they sometimes need to monitor or even remove certain kinds of us-

er-generated content. Paper 3 explores how consumers react to firms' censorship decisions. Kim argues that, rather than deciding what to censor based on content alone, consumers think firms should consider the sharer's *intent*. Indeed, six experiments reveal that consumers adhere to norms of conversation when reacting to firm's censorship decisions: They expect firms to take the perspective of the sharer when determining whether potentially offensive content should be censored.

Finally, paper 4 investigates how presenting consumers with information in different formats impacts what they encode and share. Melumad and Meyer posit that when listening to content, as compared to reading it, consumers process information more superficially, which leads them to pick up on the gist of the story while overlooking potentially important details. As a result, when the same information is presented via audio (vs. text), consumers glean the more salient elements of the story, which leads them to share biased, and often more negative, versions of the story.

Taken together, these four projects outline important advances in our understanding of how firm decisions shape consumer sharing. We believe this session will interest researchers studying a range of substantive topics including word-of-mouth, persuasion, information processing, censorship, and prosocial behavior.

Put Your Mouth Where Your Money Is: A Field Experiment Nudging Consumers to Publicize Donations to Charity

EXTENDED ABSTRACT

Donations to charity could go farther if donors were willing to tell others about their generosity. Indeed, sharing about charity on social media or via personal communication can raise awareness about worthy causes and campaigns, and it can serve as social proof that people are giving to them (Agerström et al. 2016). Moreover, talking about charity often entails implicitly or explicitly asking others to give, which can encourage generosity directly and broaden the reach of fundraising efforts (Andreoni and Rao 2011). Recognizing that consumer sharing drives revenue, many firms, both for-profit and non-profit, ask customers to 'refer their friends' or 'spread the word' in order to reap the benefits of word-of-mouth (WOM). In the domain of charity in particular, such benefits accrue both for the firm and for society more broadly.

Despite the good that can come from talking about their donations, consumers often treat charity as a private matter. In fact, many cultures prescribe modesty with respect to charity, and often treat *anonymous* good deeds as especially praiseworthy (De Freitas et al. 2019). Furthermore, consumers who broadcast their donations or post online about their volunteering are sometimes thought to be doing good for the wrong reasons – to *look* good rather than to *be* good – and judged negatively as a result (Berman et al. 2015). Thus, although publicizing one's good deeds can help to advance the cause, talking about charity also entails reputational risk.

In this work, we predict and show that when deciding whether to talk about their charitable giving, consumers attend more closely to the possible consequences for their reputation than to the possible consequences for the charity. That is, donors are hesitant to talk about

their generosity because of what sharing might say about them, and often fail to think about the good that can come from raising awareness and encouraging others to get involved. Moreover, we demonstrate that a simple nudge reorienting donors to the benefits of sharing for the cause increases WOM and aids fundraising in the field. We report three experiments, all pre-registered at AsPredicted.Org.

In Experiment 1, we sought to show that consumers feel relatively more discomfort at the prospect of talking about donations to charity (vs. about other ordinary expenditures). 198 participants were recruited from MTurk and asked to consider 21 different ordinary purchases. For each purchase, participants rated how comfortable/uncomfortable they would be talking about it with others (1 "extremely comfortable" to 7 "extremely uncomfortable"). Purchases spanned a variety of categories, price-points, and frequencies, and they ranged from purchasing a new house, to buying a dozen eggs, to signing up for a new gym membership. Compared to a variety of ordinary expenditures, talking about a donation to charity was rated as most uncomfortable ($M = 3.85$), on par with talking about an investment in the stock market ($M = 3.79$), and significantly more uncomfortable than all 19 other purchases tested (all $ps < .01$).

Narrowing in on the context of charity specifically, Experiment 2 investigated what people ordinarily think about when deciding whether to share. We recruited 377 behavioral lab participants and asked each to describe a charitable cause they cared about and to imagine donating to it. Participants reported how willing they would be to post about their donation to charity on social media on a 7-point scale (1 "Extremely unwilling" to 7 "Extremely willing"). But before indicating willingness-to-share, participants were randomly assigned to one of three writing tasks. In the consider-reputation condition, participants wrote about how posting about their donation might impact their reputation (i.e., what others would think of them). In the consider-cause condition, participants wrote about how posting might impact the charity. In a third baseline condition, participants wrote about "whatever came to mind" when considering whether to post. Results indicated that participants were more willing to share after considering impact for the cause ($M=3.85$) vs. reputation ($M=3.24$, $p=.012$, $d=.32$) and vs. baseline ($M=3.20$, $p=.004$, $d=.37$). Meanwhile, the consider-reputation and baseline conditions were virtually identical. Moreover, coding participants' written entries in the baseline condition specifically revealed that more participants spontaneously mentioned thinking about reputation (65%) than the cause (35%). These results suggest that people think more about their reputation at baseline, but that prompting them to consider impact for the cause may increase sharing.

Experiment 3 put this account to the test with real sharing decisions. We partnered with DonorsChoose.Org, a major education non-profit, and conducted a field experiment with 80,279 donors. Specifically, over the course of four months, all donors to our field partner's online platform were randomly assigned to one of two sharing solicitation messages at check-out (after donating). The control condition utilized the organization's standard sharing solicitation ("Please share about this project with family and friends"). The treatment condition was designed to re-orient donors to the possibility of helping the cause by sharing ("Your donation can start a chain reaction, but only if you tell others about the cause. Multiply your impact by sharing about this project with family and friends"). To measure sharing, we collected a combined click-through rate on icons included in the sharing solicitation (i.e., to facebook, email, etc.), and we also measured whether each donor in our experiment brought in any downstream donations through unique shareable links provided after click-through. Logistic regressions revealed that donors receiving the cause-focused treatment message were 5% more likely to

click-through (14.9% vs. 14.2%; $p=.006$) and 12% more likely to recruit a downstream donation (2.1% vs. 1.9%; $p=.005$). In practical terms, the average donor in the treatment condition brought in 16% more in downstream donations via WOM ($1.40 vs. $1.61 recruited per participant).

Taken together, our data suggest that consumers hesitate to talk about donations to charity in part because they are concerned about how doing so might impact their reputation. Consequently, when organizations ask donors to share, many donors fail to consider how sharing might help the cause. In line with this psychology, we demonstrate that a brief and free nudge to consider the cause can increase WOM and aid fundraising in the field.

Do Agency Appeals Motivate Consumer Feedback? Evidence from Across the World

EXTENDED ABSTRACT

Agentic beliefs influence consumers' motivation to engage in voluntary behaviors (Bandura, 2006). For instance, when people believe that their actions will have an impact (i.e., have high "self-efficacy"), they tend to donate more to charity (Sharma & Morwitz 2016) and participate more in democratic elections (Abramson & Aldrich 1982). When firms want to increase customer engagement, they often deliberately design marketing messages to increase agentic beliefs (Shah 2020). In the current research, we examine whether this widely used strategy of appealing to agency by attempting to persuade consumers that their behavior is consequential–a persuasion tactic that we call an "agency appeal"–is indeed effective at increasing customer engagement. We study one common form of customer engagement–providing voluntary feedback about products and services–which is a key aspect of marketing strategy (Lemon & Verhoef 2016).

We began our investigation with a large-scale pre-registered field experiment with a Fortune 500 technology company (N=430,666). For two months, consumers who recently received customer service help were sent an email inviting them to complete a voluntary survey about their customer service experience. People were randomly assigned to receive one of five subject lines: a simple survey invitation (control), a survey invitation with time indication (time), and three seminal types of agency appeals (voice, prosocial, and status):

1. Control: "[Company] customer experience survey invitation"
2. Time: "[Company] customer experience survey invitation (only takes 2 minutes)"
3. Voice (agency): "Your voice is important: Shape the [Company] customer experience"
4. Prosocial (agency): "Your help is needed; Shape the [Company] customer experience"
5. Status (agency): "Your expert advice is appreciated: Shape the [Company] experience"

As pre-registered, we focus on the combined effect of the three agency appeals.

The experiment ran in seven countries: Brazil, Canada, China, France, Germany, Japan, and the US. The subject lines were professionally translated into the respective native language, and they were pre-tested on Prolific with bi-lingual speakers (N=1,337) who were fluent in English and one of the six languages. These tests confirmed that, across all languages, participants rated that the agency appeals more strongly conveyed that the customer feedback would have an impact, compared to the control subject line (p-values<.01).

In line with previous research in other domains, we hypothesized that agency appeals would increase the likelihood that consumers share feedback. To assess whether marketing experts also expected agency appeals to increase feedback, we ran a pre-registered prediction study with members of the UCLA Anderson Marketing Association (N=69). More marketing experts predicted that one of the agency appeals would result in the highest survey completion rate (41% predicted voice, 19% prosocial, 6% status) compared to only 1% of experts who picked the control subject line (p=.003, p=.01, p=.22).

In contrast to our pre-registered predictions and the predictions of marketing experts, the agency appeals significantly reduced the likelihood of survey completion, by 4.1% compared to the control condition (from 21.2 percentage points to 20.4 percentage points; $p<.001$). The negative main effect masks considerable heterogeneity across countries. Compared to the control, agency appeals reduced survey completion in Japan (-10.6% change; p<.001), France (-8.8%; p=.002), Brazil (-8.2%; p=.001), and the US (-6.6%; p<.001); they had no statistically significant effects in Canada (-3.4%) and Germany (+1%); but the appeals significantly *increased* completion in China (+11.2%; p<.001). The time condition did not significantly impact completion rates (vs. control), and this effect did not vary across countries. So why did agency appeals on average decrease consumer feedback? And what might explain the cross-country heterogeneity?

We theorize that when receiving requests from a firm to take an action, consumers draw inferences about the firm's persuasive intent (Friestad & Wright 1994). Specifically, when delivering an agency appeal, the firm communicates an implicit promise that the consumer's actions will be consequential (Kim et al. 2019). If consumers generally do not trust business, they may feel that the firm's promise is not genuine and that its agency appeal is an inauthentic persuasion tactic; this should reduce their willingness to comply with the firm's request (Campbell, 1995; Silver, Newman, & Small 2020). However, consumers who trust business may not perceive the agency appeal as inauthentic, and would thus be effectively motivated by the agency appeal, as we initially theorized.

Our cross-country field experiment allowed us to test this account by examining whether a country's average level of trust in business (Edelman Trust Barometer 2021) moderated the treatment effects of the agency subject lines. Consistent with our theory, the effect of the agency appeals on survey completion was significantly moderated by trust in business (p<.001), such that agency appeals had more negative effects in countries with lower trust in business (e.g., Japan) and more positive effects in countries with greater trust in business (e.g., China).

As further field evidence that low-trust consumers responded negatively to the agency appeals, consumers in the agency conditions were significantly more likely to unsubscribe from future emails than consumers in the control condition (p=.024), and this effect was stronger in countries with lower trust in business (p=.003).

To test the mechanisms stipulated by our theory, we ran a pre-registered lab experiment where 1506 MTurkers were randomly assigned to read either the control subject line or an agency appeal from our field study. Specifically, we used the voice subject line because it is the cleanest appeal to agency among the three appeals tested in our field study. As predicted, the effect of the agency appeal (vs. control subject line) on perceived inauthenticity and completion intention depended on *individual-level* trust in business (p=.007 and .03, respectively) whereby the agency appeal increased perceived inauthenticity and decreased completion intention to a greater extent for people with lower trust in business.

Taken together, our results caution against using agency appeals without first understanding how they are perceived by consumers. More generally, understanding "fit" between communications and cultural values (like trust in business) will improve firms' abilities to predict where marketing strategies will work best.

When is Censorship Permissible? Intent Sensitivity in Digital Censorship

EXTENDED ABSTRACT

A mother posting a photo of her breastfeeding on social media. A photojournalist posting a video from a war zone. If these user-generated posts include the mother's nipple and dead bodies, respectively, do people believe they should be censored? With the increase in the number of online platforms that allow people to create and share content with family, coworkers, and strangers around the world, online platforms have a daunting task of censoring user-generated content. Here, I investigate the psychology of digital censorship by examining people's beliefs regarding how censorship decisions of user-generated content should be made.

Drawing on the notion that people treat social media platforms as a space to have conversations with others (e.g., Martin & MacDonald, 2020), I suggest that conversation norms—particularly the importance of considering the communicator's intent—may play a significant role in shaping people's beliefs about how censorship decisions should be made on social media. Linguistics and philosophy scholars have long recognized the importance of understanding the communicator's intent in facilitating successful conversations (Anscombe, 2000). Rather than simply unpacking the literal meaning of the communicator's message, the listener is expected to consider the communicator's intention underlying the message even in ambiguous situations (Grice, 1969; Stiles, 1987). Here, I posit that people believe the creator's intent should be considered when censoring user-generated content (i.e., an intent sensitivity hypothesis) and that this is driven by people's belief that conversation norms should guide censorship decisions regarding user-generated content.

Studies 1a–1b investigated whether people are less accepting of censorship decisions when the creator's intent is not considered. Study 1a (*N*=601) was a 2 (censorship decision: allow, ban; between-subjects)x2 (intent: no intent, positive intent; between-subjects)x3 (scenario type: explicit language, bodies, breastfeeding; within-subjects) mixed design. Participants read about a social media platform's decision to allow or ban three different user-generated posts with inappropriate content. For each user-generated post they viewed, participants were given either no information about the creator's intent (e.g., "Pictures including blood and dead bodies") or information that enabled them to infer the creator's positive intent ("Pictures from a war zone, posted by a photojournalist. The pictures include blood and dead bodies"). Supporting the intent sensitivity hypothesis, amongst those in the "no intent" condition, decision acceptance was significantly higher when participants learned that the platform had decided to ban (versus allow) the user-generated posts (M_{ban}=5.71 versus M_{allow}=3.37; *p*<.001). In contrast, amongst those in the "positive intent" condition, decision acceptance was significantly lower when participants learned that the platform had decided to ban (versus allow) the user-generated posts (M_{ban}=4.23 versus M_{allow}=5.26, *p*<.001).

Study 1b (*N*=200) employed a 2 (reasoning: intent, content; within-subjects)x2 (scenario type: dead bodies, explicit language; between-subjects) mixed design. Participants read a user-generated post that contains inappropriate content and was created

with negative intent (e.g., "A user posts a note including explicit language to bully a colleague). Participants indicated their acceptance levels of the decisions of two employees—one who recommends that the post be banned due to the post's content and another who bases their ban recommendation on the creator's intent. Across both scenarios, participants thought that the employee whose censorship decision was based on the creator's intent made a more appropriate decision (M=6.11) than that whose censorship decision was based on the post's content (M=5.17, p<.001). Perceived justification also followed the same pattern (p<.001).

Are people sensitive to intent even when negative consequences may arise? Study 2 (N=400) varied whether the user-generated post that is being censored had a negative (versus positive) intent, and whether it was likely to generate negative (versus positive) consequences. Decision acceptance ratings were significantly lower when the post that was banned had positive intent (M=4.86) rather than negative intent (M=5.89, p<.001) regardless of the post's likelihood of generating negative consequences.

If people believe that platforms should consider the content creator's intent, their acceptance of censorship decisions should be linked to their belief that the company is attempting to perspective-take the creator. In Study 3a (N=687), participants in the baseline condition read about a social media platform that sometimes decides whether or not to ban certain types of content posted by a user. Those in the content condition, in addition, read that the platform solely considers whether or not the post includes adult content; those in the content+intent condition read that the platform considers whether or not the post includes adult content and the intention of the creator. Compared to those in the content condition (M=4.02), acceptance ratings in the baseline condition (M=4.30, p=.039) and the content+intent condition (M=4.49; p=.001) were significantly higher. The latter two conditions did not significantly differ (p=.183). Perspective-taking followed the same pattern, and mediated the relationship between condition (using the content condition as the comparison baseline) and decision acceptance. Study 3b (N=201) was a follow-up study, in which I ruled out perceptions of morality as an alternative mechanism.

As a natural extension, the intent sensitivity hypothesis should not hold in contexts where expectations of perspective-taking are not present—for instance, when the decision-maker is a computer algorithm (versus a human employee). Study 4 (N=200) was a 2 (intent: no intent, positive intent; between-subjects)x2 (decision agent: human, algorithm; within-subjects)x3 (scenario type: explicit language, bodies, breastfeeding; within-subjects) mixed-design. Following Study 1a, participants read about three different user-generated posts that contained either no information about the creator's intent or information that enabled them to infer the creator's positive intent. For each post, participants indicated the extent to which they thought (1) the platform's computer algorithm and (2) an employee at the platform will ban the focal post. Participants in the "no intent" condition thought that the platform's employees (M=5.75) and the platform's computer algorithm (M=5.67; p=.452) would similarly ban the post. However, participants in the positive intent condition thought that the computer algorithm (M=5.10) would be more likely to censor the user-generated posts they viewed than the employees would (M=4.33; p<.001).

These findings further our understanding of the psychology of digital censorship, and contribute to research on fairness, freedom of speech, digital norms, and conversation norms.

How Listening vs. Reading Shapes the Retelling of News

EXTENDED ABSTRACT

In recent years two significant phenomena in news consumption have arisen. First, to garner more clicks and maintain their competitive edge, news outlets have been publishing content that is increasingly negative and sensationalized in tone (e.g., Lengauer et al. 2012; Sacerdote et al. 2021). At the same time, consumers have been increasingly relying on audio programming (e.g., podcasts) for the consumption of such news content (Adgate 2019). For example, in 2020 alone Apple podcasts were downloaded over one billion times worldwide (Binder 2020), and news websites now commonly offer the option to listen to rather than read posted content (Adgate 2019). Perhaps the most compelling explanation for the resurgence in popularity of audio programming is its convenience: information that was once restricted to reading can now be consumed anytime, anywhere—while shopping, exercising, commuting, or working.

As consumers increasingly listen to news rather than just reading it, how might this alter what they comprehend from a story, and, in turn, the interpretations they share with others? Prior research has shown that, while information encoded through listening and reading is cognitively processed in a similar manner (e.g., Deniz et al. 2019), spoken communication is more vulnerable to miscomprehension due to two features: its relative ephemerality, and greater potential for processing interference (e.g., Daniel and Woody 2010). Although podcasts render spoken language less ephemeral than in conversation (since users can rewind and re-listen to sections), doing so requires more effort than simply re-reading a word/sentence in writing; as a result, listening to a story often requires more sustained attention to achieve the same level of comprehension as reading it. Likewise, in the natural settings wherein people listen to streaming content—e.g., driving or walking—listening is more prone to interference from other modalities such as competing sights and sounds (e.g., Chaiken and Eagly 1976; Munz and Morwitz 2019). As such, while listening to a story might seem simpler than reading it, doing so may leave retellers with an impoverished—and possibly biased—understanding of its content that is then relayed to others.

We hypothesize that when listening to (vs. reading) a story, the greater difficulty of processing auditory information causes consumers to selectively encode the more salient features of the story—privileging, for example, gist statements over qualifying details, or negative information over positive (e.g., Baumeister et al. 2001). Thus, if a story contains a mix of positive and negative information, for example, we predict that a listener would walk away with a more negative interpretation than someone who read it. Naturally, this difference will result in substantively different retellings of the same content depending on whether one listened to or read the story.

We tested these ideas across three large-scale (N=2,025) experiments. In Experiment 1, 882 Prolific Academic participants were randomly assigned to either listen to or read the same news story (716 words; 4:35 listening time) about a researcher accused of fabricating data (the protagonist). After reading or listening to the story, participants were asked to write a summary of it as if they were retelling it to a friend. They then answered a series of questions about their experience while consuming the story (e.g., how immersed they felt), their main takeaways from the story, and a set of questions that tested their memory accuracy for the content. To mimic the negativity that often marks real-world news, the headline and gist statements in the story focused on the accusations against the protagonist, while the more nuanced details qualified this negativity (e.g., detailing that the protagonist's accuser was likely deceitful).

The results confirmed that participants assigned to listen reported being less immersed (M_{listen}=5.24 vs. M_{read}=5.48; $F(1,881)$=7.11, p=.008) and less visually focused on the task (M_{listen}=4.91 vs. M_{read}=6.18; $F(1,881)$=149.74, p<.001); they also recalled a lower percentage of facts accurately (M_{listen}=84%% vs. M_{read}=91%; χ^2=126.94, p<.001). More importantly, listeners were more likely to believe the protagonist was guilty of fabricating data (M_{listen}=4.66 vs. M_{read}=4.39; $F(1,881)$= 7.07, p=.008), and were more likely to falsely recall details congruent with his guilt (M_{listen}=20% vs. M_{read}=16%; χ^2=19.02, p<.001).

To further probe this bias, an independent sample of 773 MTurk judges (blind to condition and hypothesis) read 3 randomly chosen summaries, and rated the extent to which they believed the protagonist was guilty based on each summary (1-4 scale). An additional 775 MTurk judges were recruited to rate how likeable the protagonist seemed based on each summary (1-4 scale). As expected, judges were more likely to believe that the protagonist was guilty based on summaries written by listeners (M_{listen}=2.78 vs. M_{read}=2.63; $F(1,2319)$= 20.15, p<.001), and perceived the protagonist as more dislikable (M_{listen}=3.83 vs. M_{read}=3.73; $F(1,2527)$= 5.08, p=.024).

In Experiment 2, 778 Prolific Academic participants were randomly assigned to either read or listen to an article that included a balance of positive and negative information on the risks and benefits of a shampoo ingredient, and then wrote a summary of it as if for a friend. Because negative information tends to be more salient than positive (e.g., Baumeister et al. 2000), we predicted that listeners would privilege information about risks more than benefits, resulting in more pessimism towards the ingredient.

Conceptually replicating the prior results, listeners reported being less willing to use shampoos containing the ingredient than readers (M_{listen}=3.35 vs. M_{read}=3.68; $F(1,777)$= 7.48, p=.006), and their summaries contained proportionately more mentions of the risks than those of readers (M_{listen}=8.6% vs. M_{read}=6.4%; $\chi^2(777)$= 9.10, p=.002). Likewise, listeners recalled the chance of experiencing negative side effects (10%) as higher than it was (M_{listen}=21.3% vs. M_{read}=16.9%; $F(1,777)$=14.16, p<.001). Finally, Experiment 3 demonstrated that when the gist provided in a story is *positive* but its qualifying details are negative, listeners retold the story as more positive than readers.

Taken together, the findings suggest that listeners tend to process news more superficially than readers, resulting in the proliferation of word of mouth that is more distorted or biased. We conclude by discussing implications for how new modalities affect word of mouth.

Paper #3: Brand Community Logics

Adam D. Slobodzian, PhD Student, Queen's University, Canada

Tandy Chalmers Thomas, Associate Professor and Distinguished Faculty Fellow of Marketing, Queen's University, Canada

SESSION OVERVIEW

The recent tumults have revealed the fissures that divide us with the pandemic's alienating effects piquing a renewed interest in community-building. What the world needs now is to find ways to reconnect and forge communities that can redress our collective differences. Evoking Dewey (1954), the Babel of our times "is not one of tongues but of the signs and symbols without which shared experience is impossible." Where can we find sites for shared experiences? This session suggests that consumer research on collective consumption can offer pragmatic insights for the same.

Consumer research has conceptualized different modalities of social connectedness. Communities are collective consumption sites around shared signs (Muniz and O'Guinn 2001) and subcultures are focal points of social cohesion (Schouten and McAlexander 1995). However, studies also have propounded heterogeneity in communities (Chalmers Thomas, Price and Schau 2013), tensions in collectives (Tumbat and Belk 2011). In order to forge pathways to connect, it is crucial to also be mindful of the frictions that can arise in collective experiences. This session illuminates schisms that can hinder communal experiences in communities and subcultures via the exploration of boundary work and multiple logics.

The first paper executes the boundary work of how communities can be facilitated/hindered via the practice of competition. The authors explore the presumed antithetical relationship between 'community' and 'competition'. They posit that competition need not be an antagonistic conquest but can lead to an agonistic contest that generates community. In the context of competitive storytelling, the authors uncover how 'community' is not necessarily a teleological project but that a conducive alignment (misalignment) of the competitive practice's elements can facilitate (hamper) the emergence of communal experiences.

Moving on to exploring the boundary work of how tensions hindering social cohesion in subcultures can be combated as well as reproduced, the second paper explores how female video gamers' response enactments create, heighten, and maintain gendered boundaries in the gaming subculture. The authors show how tokenism drives the social construction of gendered boundaries by which collective identity of gamer girls is weaponized to exemplify pseudo-gender equality, subsequently controlling their social mobility in the male-dominated gaming subculture.

The third paper illuminates the heterogeneity of brand meanings in a community. The authors extend institutional perspectives into the domain of branding and analyse the Star Wars fandom community to posit how different socio-temporal periods socialize consumers differently, resulting in multiple brand logics. While sensemaking of new brand material is a collective phenomenon, consumers utilize distinct legitimation mechanisms to align or reject new ideas with their existing beliefs based on their respective brand logic. Thus, they show how heterogeneity emerges among the brand community members.

The session will conclude with commentary from the discussant—an expert in collective consumer practices. In sum, the session will illuminate the possible tensions, boundary work, and heterogeneity in logics integral to collective consumption contexts of communities and subcultures. Understanding how we can unite and the mechanics of how we can be divided has clear societal implications in terms of what the world needs now.

Community through Competition

EXTENDED ABSTRACT

The social sciences' corpus has generally posited the concepts of community and competition antithetically, namely, Gemeinschaft (community) versus Gesellschaft (society) (Tönnies 1887), mechanical versus organic solidarity (Durkheim 1893/2014), antistructure versus structure (Turner 1969), and communitization versus socialization (Weber 1978). These historical dichotomies have contemporarily manifested in studies of communal (Kozinets 2002; Tumbat and Belk 2011) and ludic consumption experiences (Canniford and Shankar 2013; O'Sullivan and Shankar 2019; Seregina and Weijo 2017) wherein anti-structural, communal experiences are destabilized by structural, competitive forces. However, we do witness and participate in the empirical coexistence of community and competition, e.g., in neighbourhood competitions and sports. This begets the question – how does the principle of individuation, integral to competition, interact with the principle of socialization, integral to communal experiences? Why are the concepts of 'community' and 'competition' sometimes mutually constitutive rather than oppositional?

Our paper attempts to answer these questions. Firstly, we suggest that competition can be conceptualized as a structured form of play (Caillois 2001) that leads to agonistic contest rather than antagonistic conquest. Thus, we direct focus on how individual competitors can possibly end up sharing a social symbolic space. Secondly, we suggest going beyond ontological presumptions of "consciousness of kind" as an "element of community" (Muniz and O'Guinn 2001) to analyse the "combination of processes necessary" (O'Sullivan et al. 2011) for the emergence of communal experience and subsequent enactment of community. Thus, we illuminate how the bundling of

various elements in the practice of competition can possibly lead to the binding effect of "communitas" (Turner 1969) and condition a sense of community. We insist that investigating the process of generation of community is crucial as it helps us to also identify the conditions that can hamper its generation. We make these arguments in the empirical context of 'story slams' which are competitive storytelling events wherein storytellers compete by telling stories in front of an audience. In-depth interviews with competitive storytellers and participant observation in story slams resulted in data and fieldnotes which were qualitatively analysed. We employed practice theory (Reckwitz 2002; Schatzki 2002) as an analytical lens to examine how "community *happens*" (Buber 2003) as well as how it can be hindered in the mise-en-scène of the competitive storytelling practice.

Our analysis reveals that story slams are constituted of the following practice elements: 1) Rules and format, 2) Competence, 3) Teleoaffectivities, and 4) Practicescape. Rules and format create an "echo of complicity" (Caillois 2001) which binds all the practitioners while also conditioning interdependencies that stimulate communitas. Competence in the form of skills and practical understandings results in the active participation of all and also facilitates collaborative learning and skill sharing. Teleoaffectivities are the affective pursuits recruiting competitors. Registering as motivational ends to compete, teleoaffectivities of self-transformation, diversity representation, and self-exhibition demonstrate how 'community' isn't necessarily a teleological project but is conditioned by different proclivities of pursuits embedded in the competitive practice. Practicescape is an amalgam of cultural context, event space, and material elements. The cultural context of a politically liberal environment facilitates a sense of openness encouraging participation of all. The event space is instrumental in conditioning a visceral sense of gathering, and material elements of the competitive practice, like the conspicuous scoreboard on the stage, serve as cynosures for the active participation of all to facilitate a sense of communion. In sum, the competitive format is constituted by an architectural grid of rules and format through which run various teleoaffective orientations and practical understandings that are embedded in a conducive practicescape. We posit that a conducive alignment of these practice elements is crucial to the emergence of communitas. The favourable alignment of these elements integral to the story slam competitive practice establishes interdependencies amongst the competitors that leads to a sense of competing *together*. This helps us question the autonomous dichotomies that attribute separate spheres to 'community' and 'competition' by showcasing how a supposedly centrifugal force of competition can indeed facilitate the emergence of a centripetal force of community. Rather than separate ontological antithetical spheres, this study demonstrates an evolutionary affinity between the two. However, we do add further nuance to our thesis. Our findings also illuminate how misalignments in the configuration of a competitive practice's elements can hamper the emergence of communitas. We show how certain configurations in rules can hinder the seamlessness of the flow of communitas and how differences in levels of competence can thwart the democratization of participation. Thus, our analysis demonstrates how communal experiences and the sense of community need not be volitional teleological projects. They can, instead, be conditioned (hampered) by the favourable (unfavourable) configuration of the elements of a competitive practice.

Our study contributes to the communal consumption and ludic experiences literature by: 1) advancing an agonistic relationship between the concepts of community and competition against the pervasively documented antagonistic relationship, and 2) contesting the assumption of communal experiences as teleological projects by

demonstrating how the sense of community can, instead, be conditioned or hampered by the way a competitive practice's elements are configured. Further, understanding the competitive dynamics of community-building by examining the mechanics that can facilitate/hinder the sense of community entails crucial societal implications.

More Gamer, Less Girl: The Cultural Production of Masculine Dominance

EXTENDED ABSTRACT

In March of 2019, Chiquita Evans became the first woman ever drafted into the NBA 2K League, the premier esports video gaming league co-organized by the National Basketball Association. The NBA 2K League represents the greatest sports video gamers in the world. Despite her status as an elite gamer, Evans experiences harassment from others in the league. "I've had sexual remarks put towards me," Evans said. "I get told I should be back in the kitchen. '2K is not for women,' I've had that. There's no question about that." Not all gamers criticize Evans' gender-barrier-breaking achievement, but compliments come with a qualifier. "She has (high) basketball IQ for a girl," said a fellow professional NBA 2K gamer. "Most people would be like, 'I'm playing with a girl. She's not going to know what to do.' She knows what she's doing. You can tell." (Associated Press 2019)

In the masculine consumption subculture of gaming, it is not Evans' skillset or knowledge that makes her unique among her fellow male players; it is her gendered-position of being a female gamer. Women in the gaming subculture have reached near parity in statistical representation, relative to men (i.e., 41% of gamers; ESA 2020). However, a culture of male dominance persists. Previous work establishes that gendered boundaries exist in consumption subcultures (Martin, Schouten, and McAlexander 2006; Sherry et al., 2004); however, research to date undertheorizes how such boundaries are formed, traversed, and perpetuated despite zealous efforts to eradicate them (Manne 2017; Ridgeway and Correll 2000). The purpose of this paper is to examine how gender inequalities emerge from status competition and how consumers navigate these inequalities, specifically in the consumption context of video gaming.

Prior research examines attributes of a field that attract women to a hyper-masculine subculture and the role of women in such fields. Sherry et al. (2004) highlight the subordinate role of women used as props in masculine consumption spaces (e.g., sport bars), where gender roles and status competition are more rigid. Similarly, in exploring the hyper-masculine Harley-Davidson subculture, Martin, Schouten, and McAlexander (2006) find women riders co-opt masculine behaviors to redefine personal femininities. Women's apparent empowerment is predicated on their subordinate position in the field (e.g., riding against boys, riding for boys), wherein motorcycling is conceptualized as a symbolic transgression of gendered boundaries. These previous works are insightful in demonstrating that gendered boundaries exist in these domains—but less so in articulating how masculine dominance is culturally produced. Questions concerning how gendered boundaries emerge and evolve remain unanswered. Advancing consumer research on gender inequalities lies less in micro-level conceptualizations of how women perform femininity or masculinity in masculine fields and more in meso-level conceptualizations of how the construction of gendered boundaries intersects with consumers' efforts to navigate such boundaries. Specific to the context of video gaming, how are gendered boundaries socially constructed, and why is gaming persistently considered a man's domain, despite increased engagement, representation, and progress among female gamers in the field? To explore such ques-

tions, we turn to tokenism as a novel conceptual lens for delineating the cultural embeddedness of gender inequality.

Tokenism, in this context, is a pattern of activity generated by social systems in which a dominant group is pressured to share resources (e.g., privilege, power, commodities) with a marginalized group (Laws 1975). Tokenism functions to assert negative consequences on subordinate group members and further interacts with context appropriateness within a given subculture (Yoder 1991), mirroring previous work on understanding consumption contexts within contexts (Askegaard and Linnet 2011). Previous research examines limitations to women entering gaming and why they might leave, but few studies address their lived experiences in the interim (Bergstrom 2018). In this study, we employ tokenism as a conceptual lens to explore the cultural production of masculine dominance: how gendered boundaries are socially constructed in a consumption subculture; how marginalized consumers (e.g., women) navigate gendered boundaries; and how gender inequalities persist within a field despite efforts to jettison such biases.

Data collection and analysis for this study follows a phenomenological approach focusing on lived experiences derived from the contextual environment (Pollio 1982). Twenty-three female gamers (ages 19-29) were interviewed to better understand their lived experiences within the context of video gaming. "Female gamer" is defined as a consumer who self-identifies as a 'woman' and as an avid as opposed to a casual gamer.

Extending previous boundary theoretic work and consumption-based gender inequalities, our analysis articulates the process by which masculine dominance is culturally produced in the consumption subculture of video gaming. Our findings demonstrate the process by which tokenism drives the social construction of gendered boundaries through boundary creation, boundary heightening, and boundary maintenance, which function collectively to retain masculine dominance in the field. Within the gaming subculture, boundary creation works to weaponize a collective identity of gamer girls, boundary heightening works to exemplify pseudo-gender equality, and boundary maintenance works to control women's opportunities for social mobility within the masculine field. To navigate socially constructed gendered boundaries, findings suggest women employ five response enactments: self-policing, reprimanding, grandstanding, withdrawing, and acquiescing.

Utilizing tokenism provides novel insight into the social processes related to boundary creation, heightening, and maintenance, and lends explanatory power to the nature of the response enactments that women utilize when navigating the gendered field. To our knowledge, we are the first to define a process, maladaptive enculturation, that connects individual response enactments at the micro-social level, to the boundary work that occurs at the meso-social level that inadvertently maintains the masculine dominance in the field. Maladaptive enculturation offers a theoretical explanation of how response enactments, utilized by women to navigate socially constructed gendered boundaries, produce unintended and/or counterproductive consequences for collective identity work aimed at gender equality.

Brand Community Logics

EXTENDED ABSTRACT

Traditionally, brands have been evaluated as strong when they have a narrowly and consistently defined meaning that is shared among consumers and fortified through marketing activity (Aaker 1996; Keller 1993; Ries and Ries 2002). This view of branding is grounded in associated-network memory models that link a brand's image to certain attributes in peoples' minds (Keller 1993). This perspective assumes that maintaining the "cognitive fit" among brand elements when introducing new brand material over time will result in similar evaluations among loyal consumers (Keller 1993; Parmentier and Fischer 2015; Ries and Ries 2002) This work, however, does not account for the heterogeneities in meaning that emerge among connected consumers, even though consistent brand components have been used by an organization. For example, when Porsche introduced an SUV into their product mix they used consistent brand elements but were met with conflicting responses from their loyal consumers (Avery 2012); likewise fans of J.R.R. Tolkien's literary works debate specific details about the use of narrative details of Peter Jackson's Hobbit trilogy (Crown 2012); and loyal fans of Americas Next Top Model judged new components as inappropriate to the brand and fuel the dissipation of audience members (Parmentier and Fischer 2015). While a recent growth in branding research that has looked at the sociocultural dimensions of brands, has demonstrated the complexity of brand meaning (Diamond et al. 2009; Ertimur and Coskuner-Balli 2015; Giesler 2008; Parmentier and Fischer 2015) movies, software, and the written word, we still do not fully understand how heterogeneous beliefs and interpretations of brand material can emerge among brand community members.

To address this research gap, we adopt an institutional lens to view brands as institutions and the differences in brand meaning as manifestations of different brand logics that emerge among a consumer community. Research that has utilized institutional perspectives in marketing contexts have yielded important insight into the dynamic interactions between individual and collective actors and institutions, (Dolbec and Fischer 2015; Giesler 2012; Humphreys 2010b, 2010a) such as marketplace evolution (Humphreys 2010b, 2010a), doppelgänger brand images (Giesler 2012), and the coexistence of multiple logics in institutional fields (Dolbec and Fischer 2015; Ertimur and Coskuner-Balli 2015; Scaraboto and Fischer 2013). Research has shown that logics can operate at different levels of society and can coexist and compete within different fields (Ertimur and Coskuner-Balli 2015; Ocasio, Thornton and Lounsbury 2017; Scott 2004). By extending institutional perspective into the domain of brands and branding, we can look deeper into if and how a multiplicity of logics among a brand can coexist within a consumer collective and the active roles that consumers play within a collective, utilizing their heterogeneous logics.

In our work, brand logics are conceptualized as a brand specific schema that consumers use to understand, interpret, and categorise the substance and meaning of a brand (Dolbec and Fischer 2015; Ocasio et al. 2017; Parmentier and Fischer 2015; Scott 2004). To explore the plurality of brand logics among a community of consumers a multimethod analysis of the Star Wars brand community and its components was conducted to better understand how new meanings are interpreted and fit into existing meanings. In order to capture dynamics at the group level, a netnographic analysis of the consumer forum, the Star Wars *Subreddit* was conducted, which includes a large number of active fans with varying views, many of whom are active in multiple Star Wars subgroups (Belk, Fischer and Kozinets 2013). To better understand individual perspectives on the brand, brand components, and behavior in fan communities, interviews were conducted with members of the Star Wars community (McCracken 1988). In addition to the netnography and interviews, participant observation was also conducted to observe fan behaviour and discourse *in vivo* at the opening night premier of the *Rise of Skywalker* film (the most recent Star Wars movie) (Myers 2019).

Our analysis reveals several important insights into the emergence of brand heterogeneity within a community. First, we docu-

ment the existence of multiple brand logics among community members which influences how they interpret, make sense of, and engage with the brand. Notably, these logics are historically developed beginning with fans' first engagement with a brand, and they are maintained over time through consumption practices. These logics also correspond to different 'eras' of fans. In other words, for a narrative brand with a long history, like Star Wars, each 'era' of the brand corresponds to a different brand logic such that over time, multiple brand logics emerge and are layered on top of each other. Second, we show that consumers engage in active sensemaking when new brand material is introduced. This is an ongoing phenomenon that occurs as consumers harness existing brand logics to make sense of new material. Consumers make sense of brand material collectively and retrospectively, often relying on others to bring in different views or explanations to aid in individual sensemaking. Third, consumers are active in their sensemaking, and utilize different sensemaking mechanisms, to align or reject new ideas with their existing beliefs based on their brand logic. These mechanisms are aimed at maintaining an individual's narrative continuity, or their own unique beliefs and views about the brand. Here, it's important to note that although marketers treat the narrative brand as one overarching story in the form of a meta-narrative, consumers are active in their engagement with these narratives and actively reject, adapt, accept, and rework the meta-narrative using resources beyond the brand to establish an individual level micro narrative that may differ from the official brand narrative. This highlights that many, often heterogeneous, beliefs about a brand narrative exist at the individual level in what consumers call their "head canon."

Overall, our findings contribute to consumer research by using the concept of brand logics to conceptualize how different views of a brand can emerge and coexist in a community. The emergent brand logics correspond to different 'eras' in fan socialization, which influences their sensemaking. The focus of sensemaking then becomes maintaining their individual micro-narratives—or a "head canon"—through which the brand gets interpreted, rather than the marketer controlled meta-narrative.

Paper #4: Paper #4: When "Burger and Fries" Seem More Appealing Than "Fries and Burger": The Influence of Linguistic Conventions on Aesthetic Preference

Lynn Zhang, University of Southern California, USA
Norbert Schwarz, University of Southern California, USA

SESSION OVERVIEW

Aesthetics play a pivotal role in marketing practice. Beautiful products achieve higher sales, attractive salespeople are more persuasive, and aesthetically pleasing logos boost brand liking (Patrick 2015). This session curates emerging aesthetics research to provide actionable insights for marketers in domains that have—despite their relevance—received limited attention thus far. In particular, the papers cover, on the one hand, the role of aesthetics in videos, language, and web-interface designs, and, on the other hand, they examine novel downstream consequences beyond liking (e.g., visual engagement, post-decision confidence). Accordingly, these papers jointly broaden the field's view of empirical aesthetics and fill important blind spots pertaining to the antecedents and consequences of aesthetics in diverse marketing stimuli.

Borenstein, Townsend and Morgan investigate how visual aesthetics can inform the design of buttons on web interfaces. The authors manipulate the *post-click* visual salience of buttons. Thus, whether selected options are more (vs. less) visually highlighted. Three experiments demonstrate that increasing the visual salience of selected options leads consumers to experience greater decision certainty. Importantly, this effect is stronger for difficult (vs. easy) decisions.

To and Patrick study the use of negative space in brand logo designs. Negative space logos contain "hidden" elements often not readily seen by consumers (e.g., the hidden arrow in the FedEx logo). The authors show that negative space logos boost visual engagement and increase click-through-rates in a real-world ad campaign. Negative space logos work especially well for ordinary (vs. innovative) products and when consumers discover hidden elements in the logo on their own (vs. are prompted to notice them).

Stuppy, Landwehr and McGraw demonstrate that slow motion increases the appeal of moving content (e.g., videos, GIFs). The effect occurs because slowing the stream of visual information makes the content easier to watch (i.e., more fluent). Analyzing the real-world behavior of users on a GIF sharing platform, the authors find

that slow motion is beneficial for videos displaying complex movement. Videos of simple movements, however, become boring in slow motion. This limitation can be overcome by zooming in on the "action" to increase complexity.

Zhang and Schwarz use fluency theory to decode what drives aesthetic preferences for linguistic expressions. By convention, many phrases follow a particular order. English speakers, for instance, typically say "burger and fries" rather than "fries and burger." Due to being more frequently exposed to the former ordering as compared to the latter, the expression "burger and fries" is more fluent and thus more aesthetically pleasing. This effect replicates among non-native English speakers but becomes stronger the longer people live in English-speaking countries.

Together, these papers provide a nuanced understanding of how empirical aesthetics can inform marketing practice by adopting new perspectives and by covering evidence gathered in the lab, field, and using secondary datasets. We expect this session to generate interest among researchers from a broad range of fields, including consumer preference, experiential consumption, taste, design, and aesthetics. Given the presentations' relevance to fundamental assumptions about "what makes things beautiful", we hope to stimulate a fruitful discussion.

Post-Click Visual Salience Effects on Confidence and Decision Follow-Through

EXTENDED ABSTRACT

Everyday consumers click on buttons while performing various online activities (e.g., shopping or saving for retirement). The visual aesthetics of these buttons – both before and after they are clicked – vary across online platforms (Busch 1997; Kramer 1997). Some retailers use buttons that light up when clicked, while others use buttons that fade in color. The effects of *pre-click* visual aesthetics of a set of choice buttons have been shown to affect online product evaluations (Thomas and Kyung 2019). We examine the psychological consequences of varying the *post-click* visual salience of a single button and its effect on subsequent decision-making.

Consumers often seek feedback to compensate for feelings of doubt and indecision (Timmers, Braber-Van Den Broek, and Van Den Berg 2013). Meanwhile, computer-mediated feedback offers intimate, immediate, and perceivably objective information (Karabenick and Knapp 1988; Kluger and Adler 1993) and is typically expressed visually (Azevedo and Bernard 1995). For instance, a plus sign or the color green post-decision can enhance decision accuracy perceptions (Liu and Gehring 2009; Pfabigan, Sailer, and Lamm 2015). When a button is clicked, a computer produces a visual cue signifying that selection (Busch 1997; Kramer 1997). We propose that this visual cue not only designates selection, but can also provide feedback to consumers about their selection.

Visual salience is an important aspect of aesthetic perceptions influenced by varying perceptual properties, such as color, size, or brightness (Fiske and Taylor, 1991; Howard and Holcombe 2010). We suggest that increasing visual selection salience should enhance positive feedback perceptions, thus increasing decision confidence – feeling certain in the appropriateness or optimality for one's decision (Kruglanski 1989). As confidence increases, behavioral intentions

also increase (Wood and Lynch 2002). A confident consumer feels they possess sufficient knowledge to make a final decision (Chaiken, Liberman, and Eagly 1989). However, this perception of subjective knowledge is unstable and can be enhanced or abated through seemingly extraneous information (Petty, Brinol, and DeMarree 2007). We therefore propose that higher post-click selection salience increases consumers' decision follow-through with a selected alternative (H1) and that this effect is mediated by consumers' decision confidence (H2).

Additionally, when a task is hard, feedback is actively sought out to increase perceptions of knowledge and gain decision confidence (Chaiken et al. 1989). However, when a task is easy, feedback may be ignored, since perceptions of knowledge are already high. We therefore propose that, when a task is difficult, higher selection salience increases consumers' decision follow-through; but this effect is attenuated when the task is easy (H3).

Three studies offer support for these Hypothesis. Across studies, we manipulated selection salience for the focal choice(s) by adjusting the visual shading of clicked buttons. All buttons looked identical *pre-click*, but look visually different *post-click*. In study 1, the selected square button either became 2X darker (i.e., low selection salience) versus 9X darker (i.e., high selection salience). In studies 2-3, the selected radio buttons were either no different than normal (i.e., control condition) versus heavily shaded and grew in size by 2.75X (i.e., high selection salience).

Study 1 tests H1 in a financial investment context. Participants (n = 97; MTurk) selected one of three mutual funds (choice response salience varied d high versus low) and then indicated their likelihood to invest money into their selected fund. Supporting H1, high selection salience increased participants' likelihood to invest (M_{High} = 4.70 vs. M_{Low} = 4.04; $F(1, 95)$ = 10.47, p = .044). Importantly, there was no difference in initial fund preferences across selection salience conditions ($X^2(2)$ = 4.62, p = .10).

Study 2 uses a 2 (response salience: high versus control) X 2 (hard versus easy) design in a job recruitment context. Respondents (n = 261; undergraduate) participated in a 'Healthy Option Identification Quiz' to potentially become an ambassador for a new health brand. Participants either took an easier or harder version of the quiz (identifying the healthier option in each of five pairs) and either received a high or normal response salience on their choices (both randomly assigned). Then participants indicated their confidence in their selections. An ANOVA revealed only an interaction effect on confidence ($F(1, 258)$ = 5.57, p = .019). Supporting H2 and H3, in response to hard questions, participants felt more confident in their responses when selection salience was high vs. control (M_{High} = 5.65 vs. $M_{Control}$ = 4.92; $F(1, 258)$ = 5.68, p = .018). In response to easy questions, confidence did not differ (M_{High} = 7.86 vs. $M_{Control}$ = 8.15; $F(1, 258)$ = .90, p = .34).

Study 3 offers support for all Hypothesis in another financial investment context (2 (response salience: high versus control) X 2 (hard versus easy) design). Participants (n = 500; undergraduate) completed a five-question quiz (hard vs. easy) on financial knowledge with varying salience, indicated their selection confidence, and their desire to apply as a financial tutor. As predicted, only selection salience by task difficulty interaction effects emerged on confidence ($F(1, 496)$ = 6.23, p = .013) and the likelihood to apply as a tutor $F(1, 497)$ = 4.49, p = .035), respectively. In response to hard questions, high (vs. control) selection salience increased participants' confidence (M_{High} = 6.48 vs. $M_{Control}$ = 5.80; $F(1, 497)$ = 5.41, p = .020), and likelihood to apply (M_{High} = 4.11 vs. $M_{Control}$ = 3.38; $F(1, 497)$ = 4.39, p = .037). Neither confidence (M_{High} = 5.86 vs. $M_{Control}$ = 6.21; p = .23) nor application likelihood (M_{High} = 3.68 vs. $M_{Control}$ = 3.99;

p = .39) differed in response to easy questions. A significant moderated mediation model emerged (overall index: b = .40, SE = .17, 5000 BS, 95% CI [.0826, .7553]; PROCESS Model 7; Hayes 2013). In response to hard questions, high (vs. control) salience increased confidence, thereby increasing participants' likelihood to apply (b = .26, 95% CI [.0421, .5137]). This effect attenuated in response to easy questions (95% CI [-.3653, .0783]).

Hidden in Creativity: Negative Space Logos Boost Brand Evaluations

EXTENDED ABSTRACT

A negative space logo design is created when the space around (or in between) a focal visual subject/positive space (e.g., a brand name) is creatively utilized to convey a brand-relevant visual message. Most logo designs utilize positive space (i.e., positive space logos), some logos (e.g., Fed Ex with the hidden arrow embedded within the letters e and x) include a hidden visual design element creatively embedded within the logo (i.e., negative space logos).

Our central hypothesis is that negative space (vs. positive space) logos boost brand evaluations via enhanced engagement because they allow viewers to discover the visual brand message concealed in the logo design (Lidwell, Holden, and Butler 2010). We define engagement as the extent to which consumers feel interested in and maintain attention to a specific visual stimulus (Pieters and Wedel 2007).

Drawing on the visual processing literature on subjective contours, we posit that compared to real contours (positive space logos), subjective contours will attract more attention and be more engaging (negative space logos; Pritchard and Warm 1983). When viewing negative space logos, the "hidden" element of the visual design is often not readily seen by consumers. As such, consumers are able to participate in deciphering the negative space design and thus experience greater engagement. Anecdotal evidence supports this hypothesis. Lindon Leader, the designer of the FedEx logo, proposed that what makes the logo particularly captivating to viewers is that the hidden arrow creates that 'aha moment' for people when they discover it (Airey 2014). If FedEx's PR firm had executed their initial idea to make the arrow more obvious by filling it in with another color (i.e., a positive space arrow like that of the Hillary Clinton campaign), consumers would not experience the 'aha' that makes the logo visually engaging.

Visually engaging logos play an important role in shaping brand evaluations. For instance, Wang (2006) found that when consumers are engaged, the effectiveness of message processing and evaluations towards the advertisement are enhanced. Similarly, Kilger and Romer (2007) showed that engagement is positively correlated with product purchase intentions. Aesthetics research has also examined how specific design features can enhance engagement and brand evaluations. The study of branded mobile app design found that apps with more user-centered design style were more likely to enhance engagement and thus improve consumer connections to brands (Bellman et al. 2011) and visually engaging content increases purchase intent on Instagram (Valentini et al. 2018). In the context of logo design, prior research has demonstrated how more dynamic imagery can increase visual engagement, which can lead to more favorable brand evaluations (Cian et al. 2014) as well as more responsive behavioral change (Cian et al. 2015). Drawing on findings from previous research that demonstrates the role that engagement plays to bolster brand evaluations, we propose that negative space logos can boost brand evaluations by enhancing visual engagement.

Eight multi-method studies test our Hypothesis. Study 1 examines the effect of negative space logos on consumer response in a real-world Facebook ad campaign. Results revealed that consumers were more likely to click on a Facebook ad that featured a negative space logo and were also more likely to sign up to volunteer for a campaign. In studies 2a and 2b, we replicate the effect of negative space logos on visual engagement and brand evaluations in a more controlled lab environment. To establish theory specificity, we compare the effects of negative space logos with active white space logos (Study 2a) and high visual contrast positive space logos (Study 2b) on visual engagement, brand evaluation, as well as consequential downstream variables such as website visits (Study 2a) and willingness to pay (Study 2b).

Study 3a manipulated how consumers come to discover the hidden imagery in negative space logos – via explicit presentation by the brand versus via self-discovery. The results showed that the visual engagement elicited by negative space logos hinges on consumers discovering the hidden visual imagery for themselves. If the hidden imagery is explicitly revealed, the effect of negative space logos on engagement and brand evaluations is attenuated. Participants' mouse movements when viewing a website that featured the brand logo served as an additional measure by which to assess visual engagement. Study 3b replicated the effects observed in Study 3a using eye-tracking measures of engagement. Results showed that consumers paid more attention and fixated longer at negative space logos.

Study 4 demonstrated that engaging nature of negative space logos will spill over to enhance product evaluations, particularly for ordinary/uncool products (vs. innovative/cool products). Our Hypothesis are grounded in prior work which demonstrated that visual design that is composed of both typical/ordinary and complex elements may evoke the most liking. For example, Landwehr, Labroo, and Hermann (2011) found that car sales are highest for typical or ordinary car designs but with some element of visual complexity that makes the car more engaging and interesting. Results showed that that ordinary product designs are evaluated more favorably when presented with negative space logos which generate more visual engagement. In other words, negative space logos work harder for ordinary products compared to those that are cool or innovative.

In Studies 5a and 5b, we examined the moderating role of processing style (holistic vs. piecemeal) on the effect of logo design (positive space vs. negative space) on engagement and brand evaluations. Because the perception of negative space design is rooted in how people perceive visual information as a whole rather than its parts (Köhler 1970), we propose that the effect of negative space (vs. positive space) logos on engagement and brand evaluations will be enhanced when consumers utilize a holistic (vs. piecemeal) processing style. Studies 5a and 5b demonstrated that for consumers with holistic processing style, negative space (vs. positive space) logos generated more favorable brand evaluations. In contrast, for consumers with piecemeal processing style, the effect of negative space (vs. positive space) logos on brand evaluations was attenuated.

In sum, this research investigates how negative space logo design can be effectively used to boost brand evaluations via enhanced engagement.

What Looks Better in Slow Motion?

EXTENDED ABSTRACT

Video content is typically shown at the speed a movement was captured at during production. Sometimes, however, creators slow the presentation of visual movement. Films such as *Reservoir Dogs* (1992) contain iconic slow-motion scenes, the slow motion "hair flip" is an ever-present element in shampoo commercials, and, thanks to slomo functions on smartphones, millions of social media posts are tagged with "#slowmotion". We ask whether Dave Chappelle was right when he quipped, "Everything looks better in slow motion."

Research on slow motion effects is scarce because marketing typically studies the consequences of speeding content up. Accelerating radio spots or podcasts, for instance, can produce various benefits (Chattopadhyay et al. 2003; Moore et al. 1986; Pronin and Wegner 2006). Yet, little is known about how slowing content affects the viewing experience. One noteworthy exception is initial evidence suggesting that slow motion can make the onscreen action seem more deliberate because it creates the impression that people had more time to premeditate before acting (Caruso et al. 2016). Rather than examining judgements of intent, we focus on a more immediate marketing outcome by exploring the value of slow motion for aesthetic experiences.

We hypothesize that slow motion improves the aesthetic appeal of movement because slowing the stream of visual information facilitates processing. Essentially, slow motion lowers the amount of visual information that needs to be processed per unit of time which enables viewers to perceive visual information that would be unavailable at regular speed. Research suggests that processing ease is an inherently hedonic experience accompanied by mild positive affect that people attribute to the object being processed (Winkielman and Cacioppo 2001; Winkielman et al. 2003). As such, dynamic content should be more aesthetically pleasing in slow motion (vs. regular speed), when slowing down facilitates processing.

We test our predictions in five studies, using more than 600 videos, and provide process evidence through moderation and mediation. Study 1 manipulated playback speed within-subjects. For each of 14 videos, participants ($n = 199$) were randomly assigned to the slow-motion or regular-speed version. Next, they indicated video liking (1 = not at all; 7 = very much) and subjective processing fluency (Studying this video clip is 1 = difficult; 7 = easy; Graf et al. 2018). Videos were liked significantly more in slow motion (vs. regular speed; $t = 3.081$, $p = .002$). Fluency fully mediated this effect (a*b = .14, 95% CI [.06, .25]).

Study 2a and 2b provide process evidence by examining movement complexity as a moderator of the effect of speed on liking. We predicted that complex movements would be easier to process, and thus liked more, in slow motion (vs. regular speed). Simple movements, however, should be easy to process regardless of speed. To operationalize the complexity of movement objectively, we developed an algorithm that computes the average deviation of pixels in a dynamic scene over time. We then used this algorithm to measure the dynamic complexity of 100 videos.

For the main study (study 2a), we selected the ten least, ten moderate, and the ten most complex videos. Participants ($n = 212$) watched a random subset of 15 videos out of the 30 available stimuli. We again randomly assigned participants to either the slow-motion or regular-speed version of each video. Video liking was measured with the scale from study 1. The results revealed an interaction between speed (slow vs. regular) and complexity (algorithm score) on liking ($b = .936$, $p < .001$). Complex videos were liked more in slow motion (vs. regular speed). Simple videos, in contrast, were liked less in slow motion (vs. regular speed). To provide field evidence for the above findings, we analyzed online ratings of users on a GIF sharing platform (study 2b). Replicating our experimental results, we find that slow motion boosts the appeal (views and likes) of complex GIFs but not simple GIFs.

We suspected that finding a way to make simple movements more complex would improve the effectiveness of slow motion. Our inquiry identified one strategy: zooming in on a simple scene with a close-up of the "action" (study 3). To manipulate zooming, we cropped away the static background surrounding the dynamic part of a video and then enlarged the cropped videos to the size of the original version. Study 3 manipulated complexity (simple vs. complex) between-subjects and speed (slow vs. regular) within-subjects. In response to each video, participants ($n = 296$) indicated liking and subjective fluency with the previously used scales. The model revealed an interaction between complexity and speed ($b = .074$, $p < .01$). For "zoomed-in" (i.e., complex) videos, slow motion was liked more than regular speed ($p < .001$). When videos were "zoomed-out" (i.e., simple), however, this effect was attenuated ($p = .086$). Our moderation pattern was fully mediated by fluency.

Our final experiment (study 4) examined the moderating role of content valence. Recent findings suggest that fluency unfolds hedonic effects on judgments, thus shifting evaluations in a positive direction, *and* amplifying effects on judgements, thus polarizing evaluations (Landwehr and Eckmann 2020). Study 4 thus manipulated content valence (positive vs. negative) between-subjects and manipulated speed (slow vs. regular) within-subjects. The participants ($n = 401$) indicated liking in response to each video. We detect an interaction between valence and speed on liking; $F(1, 399) = 215.545$, $p < .001$. When participants watched pleasant videos, slow motion was liked more than regular speed; $F(1, 399) = 197.769$, $p < .001$. For unpleasant videos, this effect reversed. Aversive videos were liked less in slow motion as compared to regular speed; $F(1, 399) = 45.009$, $p < .001$.

Our findings suggest that slow motion can increase the visual appeal of dynamic content. By using fluency theory as a theoretical lens, we develop moderators and boundary conditions that help marketers and everyday people to use slow motion more effectively. Importantly, the positive effect of slow motion on aesthetic appeal is contingent on the type of underlying content (e.g., simple versus complex, negative vs. positive) and on the application of stylistic tools (e.g., close-ups vs. wide shots).

When "Burger and Fries" Seem More Appealing Than "Fries and Burger": The Influence of Linguistic Conventions on Aesthetic Preference

EXTENDED ABSTRACT

Background. In everyday language, many phrases follow a particular order. For example, English speakers say "burger and fries" instead of "fries and burger", "salt and pepper" instead of "pepper and salt", and "mom and dad" instead of "dad and mom". Linguistic research indicates that such expressions are processed faster when they follow the dominant ordering than when they do not, consistent with the common observation that frequent exposure facilitates processing. For example, Hutchinson and Louwerse (2013) observed that sequential collocation frequency predicted how fast people were able to tell whether words in a pair were related or not. When word pairs were presented in the order of high collocation frequency (e.g., "parent and child"; "doctor and patient"), participants responded faster than when the order was reversed (e.g., "child and parent"; "patient and doctor"). Since ease of processing has been shown to increase liking and aesthetic pleasure (for reviews, see Reber, Schwarz, & Winkielman, 2004; Schwarz, Jalbert, Noah, & Zhang, 2021), visual materials that are consistent with the linguistic convention (which are processed more easily) should be more aesthetically pleasing than materials that are not.

Method. Three pre-registered experiments tested whether this is the case: Does the frequency with which ordered semantic concepts are encountered in natural language influence the aesthetic pleasure derived from visual materials? Pairs of words that appear more frequently in one order than the other were selected based on their frequencies in the *Corpus of Contemporary American English* (COCA). For example, "pots and pans" appeared 167.8 times more frequently than "pans and pots" in COCA; "salt and pepper" appeared 64 times more frequently than "pepper and salt"; and "burger and fries" appeared 21 times more frequently than "fries and burger".

We arranged visual stimuli side by side (e.g., a picture of a "burger" and a picture of "fries") in an order that did (burger-fries) vs. did not (fries-burger) follow the dominant ordering in English, and asked participants to choose the arrangement they liked more. Experiments 1 and 2 tested whether native English speakers prefer arrangements that are consistent with the more frequent orderings in English, and Experiment 3 tested whether nonnative speakers of English living in the U.S. prefer arrangements that are consistent with the orderings in their native language and in English.

Results. Forty-four undergraduates at the University of Southern California (Exp.1) and seventy-seven MTurk workers (Exp. 2) indicated their preference for arrangements that were congruent vs. incongruent with the frequently encountered ordering in English. The proportions of trials where the congruent arrangement was chosen were compared against chance (50%) in a two-tailed one-sample t-test. As predicted, participants preferred arrangements that were consistent with the more frequently encountered ordering in English in both experiments ($M_{Exp1} = 63.63\%$, $p = .001$, and $M_{Exp2} = 58.44\%$, $p < .001$). This pattern was observed for five out of six pairs in Experiment 1, and for all of the ten pairs in Experiment 2.

In Experiment 3 ($n=68$), USC undergraduates who were non-native speakers of English indicated their preference for the same materials used in Experiments 1 and 2. They were subsequently asked to identify the more frequent ordering in their native language for each pair. At the end of the study, participants reported having lived in the U.S. for an average of 4.12 years, and the average self-reported English proficiency was 4.12 on a 1-6 scale. One-sample t-tests revealed that participants preferred the arrangements that were consistent with the more frequent ordering in their native language ($M = 54.87\%$, $p = .008$) as well as in English ($M = 57.56\%$, $p < .001$). The former pattern was observed in the majority of participants for ten out of fourteen pairs, and the latter was observed in the majority of participants for eleven out of fourteen pairs. A follow-up logistic regression using hierarchical linear modeling further revealed that when participants have lived in the US for "zero" years (intercept), preference for arrangements congruent with English orderings was not significantly above 50% ($M_{probability} = 53.86\%$, $p = .115$). However, with each additional year spent in the US, the odds of choosing the congruent arrangement with English increases by 3.82% ($OR = 1.038$, $p = .032$). It is worth noting, however, that although native speakers of fourteen different languages participated in the experiment, an overwhelming majority (forty-three out of sixty-eight) identified Chinese as their native language. Follow-up studies will aim to recruit more participants who are native speakers of other languages.

Discussion. In sum, Experiments 1-3 show that the same visual stimuli are liked more when their spatial arrangement follows the order in which the corresponding semantic concepts appear in natural language. Given that everyday language use is an ecological manipulation of exposure frequency, these findings are compatible with the logic of mere exposure effects (Zajonc, 1968) and their mediation through processing fluency (Reber et al., 1998). Going

beyond earlier research, these findings highlight that remote context variables, like the frequency of the ordered collocation of semantic concepts in the linguistic corpus, can influence aesthetic pleasure across modalities.

SESSION OVERVIEW

Organizations engage in behaviors that improve social welfare, by donating, supporting their communities, and creating value more broadly. Yet, consumers often criticize organizations and individuals, even when their actions are well-intended. While criticism might lead to improvement, 'what the world needs now' is for us to scrutinize our instinct to be critical, and to recognize the good being done. In this session, we explore consumer evaluations of prosocial actions, and the consequences of these evaluations. We ask (1) How do consumers evaluate others in terms of their moral behavior? and (2) What are the downstream consequences of fixating on morality?

The first two papers in this session explore evaluations and their underlying moral standards. De Freitas, Johnson, Khon, and Kim examine people's general tendency to view firms negatively, despite the objective good that firms add to society. Even though consumers ascribe various negative traits to firms in *general*, *individual* firms are viewed as having an underlying, morally good 'essence'. Consequently, when firms morally deteriorate (lose good traits), this is more identity-disrupting than when they morally improve. In the second paper, Segal, Zwebner, and Barasch examine how individuals evaluate their own generosity compared to other interpersonal moral traits. They find that individuals consider generosity to be less desirable than morality and warmth, and are even less likely to exhibit the classic Better-Than-Average effect when evaluating their generosity vs. these other traits. Both papers highlight how individuals view firms and themselves, and that we should recognize good when it is done.

The last two papers highlight how fixating on high moral standards can lead us to leave money on the table, both in prosocial and consumption contexts. Prinsloo, Nam, and Keenan find that consumers negatively evaluate charities for receiving donations from tainted donors, even when the donor engaged in the transgression *after* the donation. Ironically, placing money in the hands of charities arguably creates more good than leaving it in the hands of tainted donors, since charities could use these donations to create welfare (e.g., relieve hunger, promote equal rights, etc.). Finally, Zallot and Paolacci find that buyers' WTP decreases, and sellers' WTA increases, when engaging in a transaction with an immoral agent. The extent to which markets increase welfare depends on whether products are allocated to the consumers who value them most. However, consumers also use market exchanges to sanction those they do not approve of, which interferes with the ability of the market to achieve efficient allocations.

Together, this session exposes the obstacles that organizations and individuals face in our critical world, and suggests that our high moral standards may sometimes be counterproductive, e.g., leading to fewer charitable donations and market inefficiencies. The papers highlight that we should scrutinize when our moral evaluations are useful vs. needlessly critical, and seek ways to maximize overall welfare despite our instincts to be critical.

EXTENDED ABSTRACT

Corporations Are Viewed as Psychopaths with Good True Selves

EXTENDED ABSTRACT

Firms change over time. Just consider *Intel* (memory chips→microprocessors), *Lego* (wooden toys→build-em-yourself blocks) and *Lamborghini* (industrial tractors→luxury racing vehicles). Here we ask which types of changes are so disruptive that consumers believe that the firm's very identity ceases to exist—a dire scenario for brand managers (Aaker 1996; Simões, Dibb, and Fisk 2005). Little work in consumer behavior has examined this question, but psychology literature has found that people are more likely to say that a person ceases to exist if she loses *good* traits than bad or non-moral ones (Strohminger and Nichols 2014), suggesting that they believe in good 'true selves' or 'essences' that are identity-defining (De Freitas et al. 2017). Notably, people even exhibit this bias when they are misanthropes, members of interdependent cultures, or judging outgroup members (De Freitas and Cikara 2018; De Freitas et al. 2018). Might *firms* be positively essentialized? It may seem unlikely, given that consumers appear to vilify big business (Cowen 2019). Even so, we investigate whether consumers believe that the deeper, identity-defining purpose of a firm is to do good.

Study 1 examined whether there is a moral asymmetry in identity judgments about firms. Participants (N=320, 82 excluded) read one of 8 vignettes about firms in different industries (e.g., clothing, technology, tobacco). Between-subjects, a firm was described as either changing from mostly good to mostly bad traits (e.g., making coats from mostly faux fur→mostly real fur by killing coyotes; deterioration) or vice-versa (improvement). Participants indicated how much they agreed, *The [firm name] after the changes is not really the same company as the [firm name] before the changes.* They also indicated whether they agreed more with a Person A, who thinks the company is still the same company, or Person B, who thinks it is not. DVs in all studies were on 0–100 scales.

Participants thought firm identity was disrupted more by deteriorations than improvements (M_{det}=58.97; M_{imp}=45.65; t(236)=3.45, p<.001, averaging across measures), showing this pattern for 7/8 firms.

Studies 2A-2B contrasted moral changes to changes in product *category*, anticipating that moral changes would be at least as disruptive. Participants were assigned between-subjects to the deterioration condition of Study 1, or to a condition in which the product changed to a different product in the same industry (e.g., lipsticks→eye makeup; Study 2A) or an entirely different industry (e.g., lipsticks→jewelry; Study 2B). Participants (total *N*=640, 71 excluded) answered the same DVs as in Study 1, and (on a new page) a manipulation check, *The [firm name] after the changes is mostly selling to customers in a different type of industry than the [firm name] before the changes.*

In Study 2A, participants thought that within-industry changes were at least as likely to sever existing customer ties compared to moral deteriorations (M_{det}=36.71; M_{cat}=44.01; t(280)=-2.12, p=.035), yet viewed moral deteriorations as more identity-disrupting (M_{det}=58.74; M_{cat}=38.78; t(280)=6.13, p<.001).

In Study 2B, participants thought that between-industry changes were much likelier than moral deteriorations to sever existing customer ties (M_{det}= 31.97; M_{cat}= 57.93; t(285)=7.82, p<.001), yet viewed the two types of changes as equally identity-disrupting (M_{det}=56.56; M_{cat}=51.48; t(285)=-1.54, p=.125).

Study 3 tested the proposed essentialism mechanism (Newman, Diesendruck, and Bloom 2011), while ruling out the alternative possibility that deteriorations disrupted the firm's category membership, e.g., clothing or tech (Rhemtulla and Xu 2007). Finally, we asked whether individual differences in negative attitudes about firms—as measured via a psychopathy scale, modified for firms (Hare et al. 1990)<—moderate these effects.

Participants (*N*=320, 47 excluded) read the same vignettes as Study 1. In the prediction condition, they judged whether the firm after the changes would ultimately revert to its previous majority behaviors, *It is likely that the majority of [company name] will intentionally [description of majority behavior before the changes] again.* In the identity condition, participants answered the usual identity question, then (on a new page) an essentialism question (*The [company name] after the changes no longer reflects the true essence of the [company name] before the changes*) and category membership question (*Plainly speaking, if you had to categorize [company name] after the changes, you would say that it is a [type] company (as opposed to another kind of company, such as vegetable store, car company, real estate agency, etc.)*. Finally, participants in both conditions rated 15 statements about the psychopathic traits of "big companies in general" (e.g., *Are big companies conning or manipulative?*).

The moral asymmetry was selectively mediated by intuitions about essentialism (*b*=-7.45,95% CI [-11.42,-4.14]), but not category membership (*b*=-0.23,95% CI [-1.00,.26]). Furthermore, it was *not* moderated by how negatively people viewed firms (*F*(1,135)=0.15, *p*=.70). Negative attitudes (*M*=59.20) were not inconsequential, however, moderating the effect of condition on predictions of whether a firm would revert to its prior behaviors (*F*(1, 130)=4.25, *p*=.041). Those who ascribed higher psychopathic traits were more likely to agree with negative predictions (reverting to bad majority; *b*=0.34, *p*=.042), but agreed no more or less with positive predictions (reverting to good majority; *b*=-0.14, *p*=.39).

Implications. While existing research has focused on the persistence of a consumer's *personal* identity (Bartels and Urminsky 2011), this work focuses on the persistence of *firm* identity. We con-

firm that consumers have stereotypically negative views of firms, and so perhaps what 'the world needs now' is to think of firms in a more positive (or at least more nuanced/critical) manner. After all, many firms objectively improve our lives and engage in social welfare. Encouragingly, we find that consumers still think of individual firms as having positive essences. In ongoing work, we are leveraging this positive bias about *individual* firms as a framing effect to combat negative biases about firms as a *group*—much as intuitions about 'good true selves' have been leveraged to counteract intergroup prejudice (De Freitas and Cikara 2018).

Finally, moral changes may be particularly threatening to perceptions of brand persistence. So, firms should plan for such changes carefully or even avoid them altogether—perhaps especially after publicizing moral traits through efforts like corporate social responsibility (Chernev and Blair 2015) and brand activism (Vredenburg et al. 2020).

"I'm Not Too Generous": Examining the Desirability of Prosocial Traits in the Self

EXTENDED ABSTRACT

Past research has demonstrated that generosity is one of the first and most vital indicators of morality when people form perceptions of others (Hartley et al., 2016; Miller, 2008). This is often translated, both in society and in prosocial literature, to mean that moral traits are important and positive for the self as well (Berman et al., 2015; Brambilla et al., 2011; Flynn, 2003). However, we show that while individuals like to think of themselves as moral and caring, they do not like to think of themselves as equally generous. That is, generosity is perceived as less desirable than these other interpersonal moral traits.

We additionally investigate one important downstream consequence of the decreased desirability of generosity: the better than average effect (BTA; Svenson, 1981). Motivational accounts of the BTA effect (e.g. Alicke, 1985) posit that individuals view themselves as better than average for positive traits due to the *desirability* of these traits. Therefore, to the extent that generosity is less desirable, we would expect people to not rate their generosity as high as traits like morality or caring when engaging in such comparisons. In this case, the BTA effect should be reduced for generosity versus other interpersonal moral traits.

In study 1 (preregistered, N = 197), we investigated the extent to which participants wanted to hold various interpersonal moral traits. Participants indicated their ideal percentile ranking of five interpersonal moral trait constructs (generous, α=.95; ethical, α=.91; trustworthy, α=.85; warm, α=.93; open α=.88) on a scale from 0-100. On average, participants wanted to be in the 66th percentile for generosity, which was significantly lower than their desired percentiles for openness (M = 75.93, *p* < .001), warmth (M = 76.51, *p* < .001), ethicalness (M = 82.10, *p* < .001), and trustworthiness (M = 84.11, *p* < .001). That is, while participants prefer to be in the top quartile for most interpersonal moral traits, they do not want to be "too generous."

Based on the results of Study 1 and established constructs in past literature (e.g., Goodwin, 2015), in all subsequent studies, we compare generosity to the broader interpersonal moral trait constructs of "morality" and "warmth." To establish this conceptualization, Studies 2a and 2b investigate the desirability of generosity, morality, and warmth. In Study 2a (N = 100), we asked participants to select whether they would prefer to think of themselves as a) very moral or very generous and b) very warm or very generous. We found that being generous was less desirable than both other moral traits

(64% preferred to be moral vs. generous, *p*=.005; 80% preferred to be warm vs. generous, *p*<.001). Study 2b (N=100) replicated these effects for whether participants preferred to be *perceived by others* as a) very moral or very generous and b) very warm or very generous. We found similar results, such that being perceived as generous was less desirable than both other moral traits (65% preferred to be perceived as moral vs. generous, *p*<.003; 78% preferred to be perceived as warm vs. generous, *p*<.001).

Building on these findings, Study 3 (N=181) sought to examine whether desirability perceptions of generosity impact BTA ratings. We elicited desirability perceptions and BTA ratings (counterbalanced) from participants for generosity, morality, and warmth. Desirability was measured using three items (e.g., "how important is it to be a generous person," α=.87). Results again revealed a significant difference in desirability (*p*<.001), such that participants rated generosity as less desirable (M=5.30) than morality (M=5.74, *p*<.001) and warmth (M=5.78, *p*<.001). Similar results were observed for BTA ratings, which were measured using comparisons to the average person, from 1 ("I'm much less generous than the average person") to 7 ("I'm much more generous than the average person"). We found a significant effect (*p*<.001), such that generosity reduced the BTA effect (M=4.81) compared to morality (M=5.15, *p*=.003) and warmth (M=5.25, *p*<.001). There was no different between moral and caring for both measures, which suggests that within interpersonal moral traits, generosity is uniquely perceived. We next ran mediation analyses to determine whether desirability mediates the relationship between trait and BTA ratings. We found a significant indirect effect of trait on BTA ratings (95%CI [-.44, -.18]), suggesting that reduced generosity in BTA ratings was at least partially driven by a lower desirability to be generous.

We have additionally replicated these main effects for BTA ratings and desirability ratings across 11 studies (N = 3,161, all *p*'s < .01).

While past literature suggests that generosity is an important moral trait when evaluating others, our results support the notion that individuals do not want to be "too generous" themselves. We additionally show that this effect translates into self-other perceptions such as BTA beliefs, which has important implications: increased BTA beliefs have been shown to improve subjective well-being and increase task performance (Aspinwall & Taylor, 1993; Ehrlinger & Dunning, 2003). This suggests that a lower desirability for generosity might lead to reduced levels of moral behaviors when they are construed as generous.

Tainted Donations

EXTENDED ABSTRACT

Consumers are myopic in their thinking and often exhibit double standards. For example, many institutions, academic institutions included, were scrutinized for accepting donations from Jeffrey Epstein, a convicted sex offender, even though many of these gifts were accepted before his conviction. Ironically, given that charities use money for welfare creation, society is better off when funds are spent by those other than the "tainted donor." In this research, we examine paradoxical expectations, and potentially damaging evaluations that nonprofit institutions face, in the context of tainted donations. We also explore mitigation strategies.

In five preregistered studies, we find that consumers penalize charities who have received donations from tainted donors (i.e., donors who engage in morally corrupt behavior), even when the charity-donor transaction occurred before the transgression. Specifically, we find that consumers evaluate charities to be lower in morality and trustworthiness, and even indicate lower behavioral intentions to volunteer or donate (Study 1A-C). This effect occurs even if the tainted donor's donation is involuntary, i.e., court-ordered (Study 2), and extends to real donation decisions (Study 3). Finally, we explore potential charity response strategies (Study 4A&B).

In study 1A, participants (*N*=599) evaluated a hunger alleviation charity that had received $1,000,000 from a high-profile donor about a year ago. Then, we randomly assigned participants to one of three conditions. In the control condition, participants received no additional information. In the crime before condition, participants read that "*shortly before* his donation, the donor sexually harassed several women". In the crime after condition, the transgression occurred "*shortly after*" the donation. Results show that participants perceived the charity to be less moral relative to a control (*M* = 5.81) when it received a donation from a tainted donor who transgressed before (*M*=5.05, *t*(596)=6.51, *p*<.001) and after (*M*=5.23, *t*(596)=4.94, *p*<.001) the donation. A similar pattern emerged for trust and behavioral intentions (all *p*<.05).

Studies 1B and 1C demonstrate the robustness of the effect across donation amounts and types. In Study 1B, participants (*N*=1498) evaluated charities that received donations between $5,000 and $1,000,000 from tainted vs. non-tainted high-profile donors. In Study 1C, participants (*N*=801) evaluated charities that accepted monetary vs. non-monetary donations from tainted vs. non-tainted high-profile donors. Across all donation amounts and types, participants perceived the charity to be less moral, less trustworthy, and had lower intentions to volunteer and donate when it received a donation from a tainted (vs. non-tainted) donor (all *p*<0.05).

In Study 2, participants (*N*=301) evaluated a charity that received a voluntary vs. involuntary donation from a tainted donor. In a similar paradigm to that of the previous studies, participants read that the tainted donor donated money in the voluntary condition. In the involuntary condition, participants additionally read that the donor was required to donate as part of the court sentence. The results reveal that participants did not differentiate between a voluntary versus involuntary donation from a tainted donor in terms of charity moral credit, trust, and behavioral intentions (all *ps* n.s.).

In Study 3, we extend the findings to a consequential setting. In an incentive-compatible choice paradigm, participants (*N*=401) evaluated two charities: Iodine Global Network and amfAR. Participants read the mission of each charity, and amfAR was described to have received a donation from a tainted donor, sex offender Harvey Weinstein. Participants then chose to give $100 to one of the two charities and were told that the decision of one randomly selected participant would be implemented. The results reveal that participants were significantly less likely to choose amfAR versus the Iodine Global Network in the tainted donor versus control condition (73.6% vs. 82.5%, χ²(1, *N* = 401) = 4.60, *p* < 0.05).

Study 4A explored rebound strategies. Participants (*N*=1054) read about a charity that received a tainted donation. Then, we randomly assigned participants to one of seven reaction conditions: the charity either did not react, condemned the donor's crimes, condemned the donor's crimes and rejected all future donations, condemned the donor's crimes and redirected the unspent funds to another charity, condemned the donor's crimes and redirected the entire donation to another charity, or condemned the donor's crimes and returned the donation. We also administered a control. Results show that relative to the control, the charity was penalized most in the no reaction condition, both in terms of moral credit and behavioral intentions (all *p* < .001).

Finally, in Study 4B, we manipulated whether the charity provided a reason ("to do good") for accepting a tainted donation. In

the reasons condition, the charity explained, "we have accepted the donation. This gives us an opportunity to use the money to do good." Participants assigned significantly more moral credit to the charity when it explained that it wanted to do good ($M = 4.88$) versus provided no reason ($M = 4.46$), $t(594) = 3.23$, $p<.001$. Relative to a non-tainted control ($M = 5.63$), however, penalization still occurred, $t(594) = 3.86$, $p<.001$.

Our results are surprising considering the results of a pilot: Participants indicated that a tainted versus non-tainted individual *should* donate a higher portion (13.56 vs. 6.16/100) of windfall earnings to charity, $t(298) = 3.73$, $p<.001$. Thus, consumers think that tainted individuals *should* donate more, but paradoxically penalize charities for accepting such donations.

In sum, consumers penalize charities for receiving donations from tainted donors, although they think that these individuals *should* donate more money to charity. In addition, consumers penalize charities even when the donor's transgression occurs *after* the donation. On the one hand, the outrage makes intuitive sense. On the other hand, consumers might hurt those in need since the tainted donations could be used for good. Our findings join recent warnings that moral standards often limit the acceptability of solutions that could create social welfare (Bloom 2016).

Morality as Market Friction: Product Valuations Reflect Moral Judgments of Counterparts in Market Exchanges

EXTENDED ABSTRACT

The extent to which markets increase welfare depends on whether products are allocated to the consumers who value them most. Behavioral research has investigated the extent to which product valuations depend on normatively irrelevant features of the product (e.g., how attributes are framed (Levin & Gaeth, 1988) and of the situation (e.g., whether products are being bought or sold, (Knetsch & Thaler, 1991)). It has not, however, looked at market exchanges as instances of social interactions between people with naturally differing characteristics. In this work we show that product valuations, and thus market exchanges, are shaped by people's moral assessment of their counterpart in the transaction.

Morality is fundamental to people's view of themselves and others (Newman et al., 2014; Strohminger et al., 2017); moral character traits have been shown to be central in interpersonal impression formation (Goodwin et al., 2014). These beliefs and values have a broad-ranging influence, affecting among others decisions relating to social ties (Mosleh et al., 2021) opinions of products (Lee & Kwak, 2016; Stavrova et al., 2016) and donations (Capraro & Rand, 2018). Importantly, morally relevant information is increasingly accessible to consumers (e.g., through social media, (Bennett, 2012; Sun et al., 2014)rapidly forming political participation aimed at a variety of targets, ranging from parties and candidates, to corporations, brands, and transnational organizations. The group-based "identity politics" of the "new social movements" that arose after the 1960s still exist, but the recent period has seen more diverse mobilizations in which individuals are mobilized around personal lifestyle values to engage with multiple causes such as economic justice (fair trade, inequality, and development policies, raising the question of how it affects marketplace behavior. Across seven studies, we show that buyers and sellers change their reservation prices in response to information about their counterpart's moral character (i.e., their actions or beliefs); they lower their willingness to pay (WTP) and increase their willingness to accept (WTA) when interacting with people they deem immoral. As WTP and WTA are generally not normally distributed, we performed both non-parametric tests, and parametric tests on logarithmically transformed values. Results are qualitatively identical.

In Study 1 (N = 399), we randomly assigned participants to either state their WTP (buyer role) or WTA (seller role) for a Barnes&Noble voucher in an exchange with another participant. We orthogonally manipulated perceived moral character by asking participants to state their agreement with morally loaded statements (e.g. "it's ok to lie on your CV") and varying whether there was a match or a mismatch between the buyer's and the seller's opinion. We find that median WTA was higher ($65 vs. $47, p<.001) and median WTP was lower ($25 vs. $45, p<.001) in the mismatch condition than in the match condition. In a control group where no information was provided about the counterpart's opinions, participants behaved similarly to the match condition (WTA=$50, WTP=$45), in line with research showing we default to believe others to be generally moral (Newman et al., 2014). Study 2 (N=360) replicated this experiment under incentive-compatible conditions, yielding qualitatively similar results.

The next set of studies investigate whether morality has a unique role in driving people's valuations within exchanges. Study 3 (N=833) used a similar design to the previous two studies, but varied the extent to which differences in agents' opinions across four statements concerned moral or non-moral domains. We found that the degree to which having differing opinions affected valuations depended on the number of moral statements included in the set (WTA $p<.001$; WTP $p=.037$). Contrast analysis confirmed that when opinion differences were entirely non-moral, they did not influence valuation (WTA $p=.998$; WTP $p=.999$); when opinion differences where entirely moral, valuations were significantly different (WTA $p<.001$; WTP $p<.001$). Study 4 (N=1545) put participants in hypothetical market exchanges with people who committed one moral violation sampled from a set spanning the six moral foundations (Graham et. al. 2009, Haidt 2012, Landy and Bartels 2018), and found that individual level ratings of the "wrongness", or egregiousness, of the violation correlated with reservation prices (WTA, $p<.001$; WTP $p=.001$). Study 5 (N=413) built on research showing that moral judgment of an action is conditional on the agent's intent to perform it (Cushman, 2008). We found that, when faced with a market agent who had performed the same negatively valenced action, reservation prices depend on whether these actions were performed intentionally (WTA $p< .001$; WTP $p=.002$).

The final studies investigated whether reservation prices respond to moral character information for self- or other-directed reasons. People may be willing to pay less for a product because the possibility of engaging with an immoral counterpart is unattractive; alternatively, a lowered valuation might reflect a desire to reduce the value that the seller would obtain by selling the product. Study 6 (N=294) manipulated whether participants considered a brand whose owner was accused of an immoral act or praised for a moral act, and whether profit from the sale of their product would accrue to the owner or to a third party. We found that the reduction in WTP for a product sold by an immoral vs. a moral person was smaller when the profit from the sale would not accrue to the owner ($p=.001$); this suggests that the effect of morality on reservation prices is at least partially driven by a desire to actively and negatively influence market outcomes for immoral agents. Study 7 (N=345) tested whether completing a transaction that reduces (vs maximizes) the surplus an immoral counterpart receives suffices in making consumers feel better about the exchange. Participants considered the purchase of a product from a seller that was either moral or immoral, at either market value or below market value. We found that the negative effect

of seller's morality on predicted happiness with the exchange disappeared when the transaction was less favorable to the seller (p<.001).

Whereas participation in a market has been previously described as affecting moral character (c.f. Falk & Szech, 2013), we investigate the reverse relationship, demonstrating how the presence of moral values affect market exchanges. Reservation prices incorporate moral judgment, making transactions more or less likely to occur depending on people's approval of their counterparts; this may exert 'friction' on the market to the extent that it interferes with its ability to achieve efficient allocations. These findings further our understanding of marketplace morality, showing that consumers may use market exchanges not only to satisfy their needs, but also to sanction actions and beliefs they do not approve of.

SESSION OVERVIEW

Authenticity has become a modern marketplace superlative—a pre-eminent value in a post-modern economy rife with seemingly frivolous consumption. Scholars have suggested that "consumers' search for authenticity is one of the cornerstones of contemporary marketing" (Brown, Kozinets, and Sherry 2003, p. 21). As such, authenticity is a powerful path into consumers' minds and wallets. Consumers talk more about (Morhart et al. 2015) and are willing to pay more for (Beverland 2005; Newman and Dhar 2014; Smith, Newman, and Dhar 2016) products that they perceive to be authentic. Consumers gravitate towards authentic public figures, like leaders (Avolio et al. 2004), artists (Moulard et al. 2014), and celebrities (Moulard, Garrity, and Rice 2015), as well. Even children as young as preschoolers place increased value on authentic offerings (Frazier and Gelman 2009; Gelman et al. 2015). Thus, it is increasingly imperative that marketplace entities of all kinds "excel at rendering authenticity" (Gilmore and Pine 2007) if they wish to thrive.

The four papers in this session—one conceptual and three empirical—add to our understanding of this imperative. These works leverage a diverse set of approaches and theoretical frameworks to explore how authenticity is created and perceived—what factors promote (or fail to promote) the perception of authenticity in the marketplace?

The first paper (Beverland and Cankurtaran) presents a qualitative meta-synthesis of authenticity work. Drawing from twenty-nine papers in leading business journals, these authors identify strategies and cues that offer clarity over the nature of "authenticity work," which ultimately provides tools for how authenticity can be created and maintained. In doing so, this work challenges the contrast between being authentic and performing authenticity, suggesting that all authenticity work is performed.

The second paper (Smith, Ton, and Baskin) explores how information about a founder's social class influences perceptions of brand authenticity. They find that the authenticity attributed to a brand becomes "tainted" when consumers become aware that the brand founder comes from an economically-privileged background. This is driven by decreased attributions of founder effort, which subsequently dampens brand evaluations.

The third paper (Rifkin, Du, and Cutright) investigates the relationships between spontaneity, authenticity, and consumption preferences. Specifically, they demonstrate that people seem more authentic when they behave spontaneously, which drives a preference for consuming spontaneous (vs. planned) actions; however, situations involving heightened personal risk can attenuate this preference.

The final paper (Bailey and Levy) examines how accurate people are at detecting authenticity in their world. Their work reveals that authenticity is perceived with limited accuracy and biased by the individual making the judgement, which provides a new and important consideration for entities who wish to be seen as authentic.

Together, this methodologically- and theoretically-diverse session enhances our understanding of factors affecting how authenticity is created and perceived in the post-modern economy. This session will appeal to scholars interested in authenticity, branding, social cognition, and multi-methods approaches. Moreover, the insights derived from this research arm an array of commercial entities with greater knowledge of how they may render authenticity to consumers, leading to more positive outcomes.

We conduct a qualitative meta-synthesis of authenticity work, identifying the need to balance being authentic and doing authenticity performances. We explore the paradoxical nature of this work through a semiotic square. Performing authentically involves character and strategic work, and two paradoxical forms - real strategic work and ideal character work.

Authenticity Work as Performance: A Qualitative Meta-synthesis

EXTENDED ABSTRACT

There are few claims more compelling, and recently, more common, than "being authentic". Authenticity is viewed as the gold standard in public life - spanning politics, leadership, culture, and the marketplace (Umbach and Humphrey 2017). Authenticity is an enduring ideal (Potter 2011), the standard of modern capitalism (Giddens 1991), central to post-modern marketing (Brown 2001), and the core consumer identity-goal (Arnould and Price 2000). Furthermore, authenticity is central to service encounters (Price, Arnauld and Tierney 1995), cultural branding (Holt 2004), consumer identity work (Belk, Wallendorf, and Sherry 1989; Zhang and Patrick 2021), co-creation with consumer communities (Leigh, Peters and Shelton 2006), and the consumption experience (Chronis and Hampton 2008; Grayson and Martinec 2004; Lasaleta and Loveland 2019; Vredeveld and Coulter 2019) (among others). With tensions arising between historic definitions and ideological discourses of authenticity and the profane nature of the marketplace (Belk et al. 1989), many have noted how marketplace authenticity is inherently contradictory or paradoxical (Rose and Wood 2005). Paradox frames how authenticity is rendered in the marketplace (Gilmore and Pine 2007) and drives much of what we identify as "authenticity work" (Plüg and Collins 2020).

Although recent reviews have brought much needed clarity to definitions of authenticity (Lehman, O'Connor, Kovács and Newman 2019; Nunes, Ordanini, and Giambastiani 2021) as well as subcategories such as brand authenticity (Moulard, Raggio, and Folse 2021), research on authenticity work remains beset by fragmenta-

tion, contradiction, and lack of synthesis. Paralleling previous debates on the nature of authenticity, the lack of consensus regarding marketized authenticity work arises due to the highly contextual nature of previous studies, their primarily qualitative nature, and the differing theoretical and research traditions that frame them. Gaining clarity over the nature of authenticity work is critical since rendering authenticity in the marketplace is essential to brand equity including attachment, liking, price premiums, relationship status, and loyalty (among others) (Becker, Wiegand, and Reinartz 2019; Morhart et al. 2015). Furthermore, greater clarity over the nature of authenticity work provides marketers with the tools needed to help consumers make authenticity judgments about brands and supportive programs.

To address this challenge, we undertook a qualitative meta-synthesis of authenticity work, drawing on leading publications within marketing and management (that covered external-, or market- facing aspects of authenticity work). A qualitative meta-synthesis operates much like a meta-analysis in a number of ways: included studies need to focus on the construct of focus (authenticity work), study findings are treated as data, and the outcome of the synthesis should not only summarize existing studies but also offer new insights for theory (Timulak 2009). Our final dataset, drawn from 4*/4 ranked marketing and management journals in the UK Association of Business Schools Academic Journal Guide, consisted of 29 papers. Study findings and supportive contextual information were entered into ATLAS.ti and coded by both authors following standard qualitative research procedures (Spiggle 1994).

The first part of our findings identified that authenticity work involves the deployment of four strategies (downplaying, connecting, immersion and alignment) and five cues (making, status, empathy, membership, and context) that help address authenticity paradoxes (truth vs. imagined, sincere vs. insincere, culture vs. commerce, timelessness vs. relevance, and coherence vs. dilution). Doing this effectively, involves two performances, which we label "character" and "strategy". Engaging in these performances challenges the "being" vs. "doing" dualism that has previously framed many debates in marketplace authenticity (Beverland, Farrelly and Quester 2010). This debate has framed authenticity in terms of what is genuinely real vs. what is put on for effect. As our findings identified that authenticity work was aimed at addressing contradiction and paradox arising from paired concepts, for the second part of our findings we deployed a semiotic square to help "penetrate and enrich apparent binary oppositions" (Kozinets 2008, p.868) and offer new insights for advancing theory and practice.

Our semiotic square begins with our central binary opposition – the tension between the real (indexical or intrinsic to an object) and the ideal (iconic and socially constructed). This tension reflects a contrary of truth, and gives rise to two contradictions: one of being and one of doing. Each also generates complementarities. The real gives rise to complimentary of identity while the ideal gives rise to the complimentary of expectations. To complete our square, the real gives rise to what we called the work of character, while the ideal gives rise to what we label the strategic work. In exploring the tensions and contradictions we identify that authenticity work also gives rise to real strategic work (such as that represented by storytelling) and ideal character work (such as that embodied in emerging notions of brand purpose for example), reinforcing our case that all authenticity work is ultimately performed.

We contribute to theory and practice in a number of ways. Our meta-synthesis of marketplace authenticity work identifies consistencies across a range of studies and theoretical traditions, providing much needed coherence in this area. Our semiotic square enables us to interrogate these findings further, identifying the need for new forms of authenticity work which highlight the essential performed nature of all forms of authenticity in the marketplace. In light of recent clarifications of the construct of authenticity that highlight its formative nature (Nunes et al. 2021), our review of work also identifies how authenticity can be created and maintained in the marketplace. Furthermore, we expand on how managers can use notions of authenticity as consistency, conformity and connection (Lehman et al. 2019) in a dynamic way to ensure the contradictory elements of authenticity remain balanced over time. In terms of practical implications, our results identify connections between particular paradoxes and relevant campaign strategies and cues. Finally, in terms of future research our findings have implications for our understanding of narrative transportation and storytelling (van Laer, de Ruyter, Visconti, and Wetzels 2014), brand purpose and activism (Vrendenburg, Kapitan, Spry, and Kemper 2020), and cultural branding (Holt 2004).

Why Wealth Taints Authenticity: The Influence of Brand Founder's Social Class on Brand Evaluations

EXTENDED ABSTRACT

After her company's success, Kylie Jenner was hailed as the youngest self-made billionaire (Abad-Santos 2018). However, as writer, Roxane Gay, stated, "[Kylie] grew up in a wealthy, famous family. Her success … comes by virtue of her privilege." Although wealth is desirable, being born wealthy often dulls the shine of an individual's achievements. Conversely, being born poor tends to enhance others' appreciation of an individual's success. Here, we examine why a founder's social class influences brand authenticity.

Information about a brand's origin can influence perceived authenticity (e.g., Newman and Dhar 2014). A founder's social class is an aspect of a brand's origin that may influence authenticity via attributional processes (e.g., Malle 2011). Wealth may decrease brand authenticity because it dilutes the causal link between the founder and brand as it is unclear if the brand is the direct result of the founder's effort (internal attribution) or other cause, namely, their wealth (external attribution). By contrast, a brand created by a founder with a poor background enhances authenticity because the brand is more likely to be attributed to the founder's effort rather than external causes. We tested this reasoning across three studies.

Study 1 examined how privilege type influences brand evaluations and authenticity in a 2 (level: low, high) x 3 (privilege: wealth, education, social network) between-subjects design. In the wealth conditions, participants read: John Patton, the founder of the Cosmo company, grew up in a very *poor/wealthy* family. In the education conditions, the founder *did/did not* receive formal education. In the social network conditions, the founder had *few/many* social connections. Participants rated brand evaluations ($\alpha = .93$) on a 7-item scale (e.g., To what extent was your overall impression of the brand positive (vs. negative)?) and perceived authenticity (i.e., I think this bottle company is authentic).

A 2 x 3 between-subjects ANOVA on brand evaluations revealed an interaction ($F(2, 533) = 5.59$, $p = .004$, $\eta_p^2 = .02$). Brand evaluations increased when the founder grew up poor vs. wealthy (4.77 vs. 4.33; $F(1, 533) = 8.21$, $p = .004$, $d = 0.43$). There was no difference in the education conditions ($F(1, 533) = 0.37$, $p = .54$) and a marginal difference in the social network conditions ($F(1, 533) = 2.81$, $p = .094$).

The same 2 x 3 analysis on perceived authenticity showed an interaction ($F(2, 533) = 4.12$, $p = .017$, $\eta_p^2 = .015$). Authenticity increased when the founder grew up poor vs. wealthy (4.71 vs. 4.09; $F(1, 533) = 9.49$, $p = .002$, $d = 0.46$), with no difference in the educa-

tion ($F(1, 533) = 0.04$, $p = .84$) and social network conditions ($F(1, 533) = 0.88$, $p = .35$).

A mediation analysis (Model 4, Hayes 2018) with brand evaluations as the DV, poor/wealth as the IV, and authenticity as the mediator was significant (95% CI = [.07, .38]).

Study 2 examined whether the internal attribution of effort precedes authenticity. Participants read about a founder from a poor (vs. wealthy) background. They rated brand evaluations ($\alpha = .94$) and perceived authenticity. To capture the internal attribution of effort ($\alpha = .85$), they rated a 3-item scale (e.g., I think that this cup of coffee is a true reflection of the effort of John Patton).

Brand evaluations increased in the poor vs. wealthy condition (5.15 vs. 4.79; $t(195) = 2.07$, $p = .04$, $d = 0.30$). The internal attribution of effort was higher in the poor vs. wealthy condition (4.69 vs. 3.96; $t(195) = 3.51$, $p = .001$, $d = 0.50$). Perceived authenticity also increased in the poor vs. wealthy condition (5.64 vs. 4.84; $t(147) = 3.87$, $p < .001$, $d = 0.57$). A serial mediation (Model 6, Hayes 2018) with brand evaluations as the DV, poor/wealth as the IV, and internal attribution of effort and perceived authenticity as sequential mediators was significant (95% CI = [.05, 25]).

Study 3 tested a boundary condition by manipulating both social class and whether the founding involved hardship or prosperity in a 2 (class: poor, wealthy) x 2 (founding: hardship, prosperity) between-subjects design. Participants rated brand evaluations ($\alpha = .96$) and perceived authenticity. For the internal attribution of effort, they rated: To what extent did you see this coffeehouse as a reflection of John Patton's effort (vs. luck)?

A 2 x 2 between-subjects ANOVA on brand evaluations revealed a main effect of class ($M_{poor} = 5.20$ vs. $M_{wealthy} = 4.52$; $F(1, 356) = 24.07$, $p < .001$, $d = 0.52$), a main effect of founding ($M_{hardship} = 5.01$ vs. $M_{prosperity} = 4.71$; $F(1, 356) = 5.15$, $p = .024$, $d = 0.22$), and an interaction ($F(1, 356) = 4.51$, $p = .034$, $\eta_p^2 = .012$). In the poor conditions, brand evaluations increased with hardship vs. prosperity (5.49 vs. 4.89; $F(1, 356) = 9.81$, $p = .002$, $d = 0.50$). In the wealthy conditions, there was no difference ($F(1, 356) = 0.01$, $p = .92$).

The same 2 x 2 analysis on the internal attribution of effort showed a main effect of class ($M_{poor} = 5.47$ vs. $M_{wealthy} = 4.40$; $F(1, 356) = 42.11$, $p < .001$, $d = 0.62$), a main effect of founding ($M_{hardship} = 5.60$ vs. $M_{prosperity} = 4.26$; $F(1, 356) = 65.81$, $p < .001$, $d = 0.79$) and no interaction ($F(1, 356) = 0.24$, $p = .62$).

The same 2 x 2 analysis on perceived authenticity revealed a main effect of class ($M_{poor} = 5.60$ vs. $M_{wealthy} = 4.89$; $F(1, 356) = 22.97$, $p < .001$, $d = 0.50$), a main effect of founding ($M_{hardship} = 5.41$ vs. $M_{prosperity} = 5.07$; $F(1, 356) = 5.52$, $p = .019$, $d = 0.23$), and no interaction ($F(1, 356) = 1.14$, $p = .29$).

Although the wealthy founder's hardship enhanced attributions of effort and authenticity, these assessments neither aligned with those for the poor founder nor boosted brand evaluations. We contribute to authenticity and social class research by showing that a founder's wealth can "taint" brand authenticity. Future studies will identify when a privileged origin can regain its authenticity.

The Preference for Consuming Spontaneity

EXTENDED ABSTRACT

From TV and film characters, to musicians, to political figures, people in public-facing roles are often seen acting spontaneously. However, is this behavior rewarded by consumers? And if so, why? The current research explores when and why consumers prefer to consume others' spontaneous actions.

We find that consumers often prefer to consume others' spontaneity, and that this is because spontaneous actors seem more authentic. In particular, when people act without a previously-made plan, they appear to be acting in accordance with their "true selves" (Kernis and Goldman 2006). That is, a politician who speaks off-the-cuff seems truer to themselves than one who is scripted. We suggest that it is the value consumers place on authenticity (Arnould and Price 2000; Beverland and Farrelly 2010) that drives a preference for spontaneity.

While spontaneity can make actors seem more authentic, it can also lower perceptions of the end-product's quality. That is, while "free-styling" might make a rapper seem more authentic, for instance, the actual rap *per se* might be lower-quality than a pre-written performance. Prior research supports this intuition, since in-advance planning is associated with higher-quality goal-relevant outcomes (Achtziger, Gollwitzer and Sheeran 2008; Gollwitzer 1999). As such, we expect that the preference for spontaneity will be attenuated in situations when personal risk is heightened, such as when consumers expect to receive the end-product (rather than merely observe the process), or when consumers' own outcomes are tied to those of the actor.

Six studies (five pre-registered) support our theory. An initial field pilot leveraged real online articles to explore the preference for spontaneity. We constructed a dataset of Buzzfeed articles about spontaneity (i.e., about improvised scenes in TV and movies) from the last five years ($n = 10$), as well as 'control' articles that were matched to the spontaneity articles on date of publication and Buzzfeed's content category (TV & Movies; $n = 49$), and compared the total instances of social media engagement (sum total of Facebook comments, "shares", "reactions", Pinterest "pins", etc.). Consistent with a preference for spontaneity, the online articles about spontaneity generated significantly more social media engagement ($M = 14482.8$) than the control content ($n = 49$; $M = 7543$, Mann-Whitney $Z = 2.53$, $p = .012$).

Moving to more controlled experiments, in Studies 1A ($N = 150$) and 1B ($N = 147$), consumers were given the opportunity to watch a clip from a several-years-old football game (1A) and an on-going e-sports game (1B). They could choose to watch either a team that leveraged planned plays, or a team that leveraged spontaneous plays. Across both the determinate (i.e., game that already occurred) and indeterminate (i.e., ongoing game) contexts, consumers overwhelmingly preferred to watch the spontaneous teams (1A: 82.0% chose spontaneity; 1B: 80.3% chose spontaneity).

Though supportive of a preference for spontaneity, one might wonder whether participants were imagining fundamentally different actors or experiences—that is, they could be more novel, exciting, or skilled. To control for this, Study 2 participants ($N = 385$) watched a video of a band's performance, and were told afterwards that it was planned versus spontaneous. Holding the performance constant, describing it as spontaneous increased participants' interest in watching another video from the same band ($P_{Spontaneous} = 54.4\%$ vs. $P_{Planned} = 43.2\%$; $X^2 = 4.81$, $p = .028$), over a video of a different band.

Study 3 ($N = 496$) begins to test the proposed underlying process. We suggest that, relative to planned actions, spontaneous actions increase the actor's perceived authenticity, but also lower the end-product's perceived quality. If this is true, the preference for spontaneity should be attenuated when personal risk is heightened. To test this, we introduced a condition where participants imagined being the end-customer of spontaneity, rather than merely observing as in the prior studies. Results supported our predictions: Consistent with prior studies, when participants imagined watching live legal proceedings, they were more interested in a lawyer that relied on spontaneity (vs. planning; $M_{Spontaneous} = 4.71$ vs. $M_{Planned} = 3.94$, $p < .001$) because the lawyer seemed more authentic ($M_{Spontaneous} = 5.29$

vs. $M_{Planned} = 4.00$, $p < .001$; $ab = .91$, 95% CI [.63, 1.20]). When they imagined hiring a lawyer for their *own* legal needs, however, the preference reversed ($M_{Spontaneous} = 2.86$ vs. $M_{Planned} = 5.28$, $p < .001$), driven by concerns about the quality of the lawyer's arguments ($M_{Spontaneous} = 5.62$ vs. $M_{Planned} = 3.34$, $p < .001$; $ab = -1.33$, 95% CI [-1.68, -1.01]).

Study 4 ($N = 200$) further tests process and reveals another boundary condition based on personal risk. All participants had the choice of e-sports game to watch. Consistent with Studies 1A and 1B, most participants chose to watch an e-sports game involving a spontaneous (vs. planned) team ($P = 75.5\%$), as this team seemed more authentic ($r = -.25$, $p = .012$). However, when we tied participants' own outcome (i.e., the size of their actual compensation bonus) to the game's outcome (i.e., how many points the focal team scored), the preference for spontaneity was attenuated ($P_{Spontaneous} = 75.5\%$ vs. $P_{Planned} = 47.1\%$; $X^2 = 17.00$, $p < .001$), given participants' beliefs about quality of gameplay ($r = .29$, $p = .004$).

Across several domains ranging from artistic (music) to cognitive (law), and from individual (lawyer) to group (sports teams) actions, we observe a preference for consuming spontaneity. By exploring the underlying roles of authenticity and quality concerns, we also identify that spontaneity can be a double-edged sword—highly desirable as an audience-member, but less so as a recipient. These results may therefore reveal an interesting divergence in outcomes: spontaneity can increase impressions of the actor, but decrease impressions of the end-product itself. This work advances understanding of consumers' preferences for experiences and entertainment, delves further into the role of authenticity in marketing, and has implications for celebrities, executives, politicians, and others in public-facing roles.

Are you for Real? Perceptions of Authenticity are Inaccurate and Biased

EXTENDED ABSTRACT

Popular press pieces laud authenticity as a key metric for selecting friends, judging potential mates, and electing leaders, implicitly assuming there is a kernel of truth embedded in these judgments: that we can discern an authentic person the way we can discern an authentic product.

Others are deemed authentic when they seem to behave in line with their "true- or core-self" (Kernis & Goldman, 2006, p. 294. Functional perspectives on perceived authenticity assume that individuals can discern "real, true or genuine" people in the same way they can judge an authentic product (Newman 2019). Past research has implicitly assumed that judgments of authenticity are related to the target's authenticity, reflected in research on the antecedents of authenticity. For instance, perceived authenticity is associated with the target's morality (Bai et al., 2019), their perceived self-knowledge, and self-consistency (Peus et al., 2012)hide information, and deceive others, but rather lead with authenticity and integrity. In this article, we empirically investigate the concept of authentic leadership. Specifically, we examine the antecedents and individual as well as group-level outcomes of authentic leadership in business (Study 1; n = 306). These antecedents parallel variables linked to individual expression of authenticity (Gino et al., 2015; Kraus et al., 2011). However, the accuracy of authenticity judgments remains untested.

Our core proposition in the present research is that perceived authenticity is (1) inaccurate, that is other-ratings of authenticity are not related to self-ratings of authenticity, and (2) perceived authenticity is biased by rater-based processes when making authenticity judgments. We propose that authenticity judgments will be inaccurate for a number of reasons.

First, the standards against which to judge authenticity are difficult to discern compared to other individual differences. For example, people are able to accurately predict individual differences in socioeconomic status and personality traits in others (Ambady & Rosenthal, 1992; Kraus et al., 2019)speech, the body, tone of voice. Unlike authenticity, these differences have generalizable standards for comparison, where what is high vs. low extraversion is common across individuals. However, authenticity can appear remarkably different between individuals. Being accurate at recognizing authenticity requires knowing that person's true self, observing their behavior, and comparing the two.

Second, lay people are "intuitive psychologists" who favor simplistic associations between observed behavior and the internal states of others, a tendency referred to as the fundamental attribution error (Ross, 1977), as in classic example, "she eats because she is hungry" (Heider 1958). If individuals tend to attribute the behavior of others to be internally-derived, we propose that they would similarly consider behavior of others to largely be authentic.

Finally, decades of research on deception detection has found that individuals are barely able to accurately detect lies above chance (for review, see Bond & Depaulo, 2006). While inauthenticity and lying are related, lying is an extreme version of inauthenticity. Indeed, there are many ways that individuals can be more or less authentic that do not involve outright lies, such as sharing selective positive features on dating websites, or omitting negative aspects in the recall of an experience. If individuals have poor accuracy at detecting lies compared to truths, this suggests that detecting authenticity should also have low accuracy.

Because the standards by which to judge authenticity are relatively obscure, the process of judging authenticity is prone to bias. Specifically, we hypothesize two biases which yoke authenticity judgments to the rater making the judgment (rather than the target of the judgment). Decades of research have demonstrated that there are predictable asymmetries between self- and other-perception, which occur because people are biased in how they see themselves (Alicke and Govorun 2005) and how they see others (Ross, 1977). We integrate literatures on deception detection, egocentrism, and person perception to propose two biases which will distort authenticity judgments: a positivity bias and an egocentrism bias.

First, we suggest that raters will exhibit a positivity bias in their authenticity judgments of others. Deception research has found that people reliably exhibit a bias towards truth (DePaulo et al., 1997; Zuckerman et al., 1981). When people are not informed about the base rates of lies to truths, they overestimate the amount truths, potentially as a means of maintaining cohesion and reducing social costs (ten Brinke, Vohs, and Carney 2016). In addition, the fundamental attribution error suggests that observed behavior would be attributed to simplistic internal motivations. This is in contrast to the self-knowledge an individual has of their own motivations, ranging from impression management and social desirability to authenticity. Thus, we hypothesize that others will exhibit a positivity bias in their authenticity judgments relative to a self-rated authenticity. That is, they will default to truth in their authenticity judgments of others.

Second, we propose that authenticity judgments are egocentric, whereby authentic raters will assume others are also authentic. Egocentrism suggests that individuals view and judge others in line with how they view themselves (Nickerson, 1999; Ross, 1977). Indeed, when individuals attempt to understand the inner states of others, they begin at the own point of view and adjust only incrementally (Epley et al., 2004; Tamir & Mitchell, 2013). Therefore, we hypothesize that a raters own authenticity will be predictive of their authenticity judgments of others.

Overview of Studies

We first confirm lay beliefs about the ability to detect authenticity, and the importance of authenticity in interpersonal relationships in Studies 1a-1b. In Studies 2-3, we test the accuracy and biases in authenticity ratings, utilizing a unique interpersonal setting: randomly assigned groups of individuals with little to no prior interactions with one another. The random assignment to these groups mitigates issues in selection that typically occur in interpersonal relationships. We follow these groups over a six-week period, surveying them at multiple timepoints. Participants rated their own authenticity, and the authenticity of every other person in their group. This allowed us to directly compare self- and other-ratings of authenticity and test for biases in authenticity judgments. We find no correlation between self- and other-ratings of authenticity. Social Relations Modeling and Bayesian analyses confirm this null relationship. Second, we find support for the positivity bias and egocentrism bias in authenticity ratings.

In Study 3, we add authenticity meta-perceptions (e.g., what do targets assume about the visibility of their authenticity to others?). We find that authentic individuals expect to be perceived as more authentic. Authenticity meta-perceptions were similarly not correlated with authenticity judgements.

SESSION OVERVIEW

We are in what is called the "decade of self-care" (Carraway 2019; Karlis 2019, Silva 2017). This domain of consumption goes by many names—*self-care*, *self-gifting*, *me-time*, *leisure*, *wellness*—and spans a variety of product categories, ranging from small technological purchases like meditation apps (e.g., Headspace), to personal care products like skincare and personalized vitamin services (e.g., Care/Of), to large-scale luxury wellness retreats (e.g., The Ranch Malibu). Despite this variety in nomenclature and consumption opportunities, this domain of consumption is defined by the promise of increasing consumers' well-being.

The self-care market is vast and growing. Consumer interest in self-care has increased dramatically over the last several years, with rising rates of related Google searches (Karlis 2019), over 18 million hash-tags on social media (Carraway 2019), and over three-quarters of consumers reportedly shopping with a "self-care mindset or mission" (Goldschmidt 2019). Apps pertaining to well-being, such as Headspace and Happify, were the most downloaded category of app in 2018 (Pesce 2018), and IRI has valued this market overall at $450 billion, up $50 billion from the year before (IRI 2017, 2018).

Despite these trends in self-care, however, there are many unanswered questions in the realm of consumer behavior: What are consumers' beliefs about self-care and leisure, and how do these beliefs affect their self-care engagement and eventual outcomes? How do we judge others when *they* engage in self-care and leisure, and how does this compare to the way we judge ourselves?

The present session proposes to answer these questions. First, two papers examine consumers' own beliefs about self-care, unearthing a relatively pessimistic view. **Paper 1** (Rifkin, Gullo Wight, and Cutright) finds that consumers believe that they will not be able to derive emotional benefits from self-gifting when they feel resource-constrained, which drives reduced interest and purchase. **Paper 2**

(Tonietto, Malkoc, Reczek, and Norton) reveals a related belief that leisure can be wasteful and unproductive, which drives reduced enjoyment when people engage in leisure.

Next, two papers examine how we judge others' self-care, revealing a far more optimistic perspective. **Paper 3** (Somasundaram and Olson) finds that self-care is seen as more valuable and deserved when others engage in it, relative to one's own engagement. Finally, **Paper 4** (Daniels, Samper, and Morales) finds that seeing others engage in leisure increases how fulfilled they seem, which drives hiring interest.

These four papers reveal an interesting discrepancy in consumers' beliefs about self-care, in which we encourage others to treat themselves but are cynical about our own self-care. In addition to featuring one of ACR's highlighted themes, we believe this session will stimulate fascinating conversations about how to reconcile this discrepancy, and will appeal broadly to scholars interested in well-being, issues of work versus leisure, resource constraints, social cognition, self versus other perspectives, and hedonic consumption.

No Bandwidth to Self-Gift: How Feeling Constrained Discourages Self-Gifting

EXTENDED ABSTRACT

Self-gifting has been called the "philosophical rallying cry" of many of today's consumers (Bereznak 2017; Fottrell 2017; Green 2017; Norton 2017; Olen 2014), and in response, many major companies have started to position their offerings as *self-gifts*, or purchases one can make with the intention to improve one's own emotional well-being (Checkner 2019; Deng 2017; Voight 2015). While products positioned as self-gifts are growing in prevalence, little is known about what drives consumers' interest in self-gifting (c.f., Heath, Tynan, and Ennew 2011; McKeage, Richins, and Debevec 1993; Mick 1996; Mick and Demoss 1990a, b, 1992; Mick and Faure 1998; Olshavsky and Lee 1993). When and why are consumers more or less interested in self-gifting?

The current research proposes that interest in self-gifting depends upon consumers' perceptions of resource constraint. Resource constraint can impact consumer behavior in a variety of ways; most relevantly, resource constraints are cognitively draining (Shah et al. 2012). Moreover, according to an initial pilot, consumers believe that self-gifting is unique in that it requires a capacity for *savoring* (i.e., being able to actively attend to and appreciate positive emotions; Bryant and Veroff 2007) in order to derive benefit. Taken together, we suggest that consumers are aware of the distracting nature of constraint and consequently believe that feeling constrained will hamper their ability to savor and, in turn, diminish self-gifting's benefits. We therefore predict that resource constraints should decrease interest in products when they are framed as self-gifts, but not when those same products are framed neutrally.

Four studies (three pre-registered) test these predictions. In Study 1 ($N = 927$; pre-registered), participants wrote about a recent resource constraint (time or money) either being imposed or lifted, or did not write anything at all (3 between-subjects conditions). After viewing an ad for headphones framed as a self-gift ("Carve out me-time"), they indicated purchase interest. Consistent with our predictions, those recalling an imposed resource constraint were less inter-

ested in self-gifting ($M = 3.43$), relative to both the less-constrained ($M = 3.85$) and neutral conditions ($M = 4.33$, both $ps < .01$). In this and all subsequent studies, the effects generalized to both temporal and financial constraints.

In Study 2 ($N = 571$; pre-registered), we tested the proposed mechanism. After writing about a resource constraint either being imposed or lifted, participants viewed an ad for headphones that was either framed neutrally (no tagline) or as a self-gift ("Reduce your stress"). As predicted, resource-constrained participants thought they would be less able to derive benefit from the self-gift headphones ($M_{\text{more\_constrained}} = 3.60$ vs. $M_{\text{less\_constrained}} = 4.83$, $p < .001$), which drove reduced purchase interest ($M_{\text{more\_constrained}} = 3.84$ vs. $M_{\text{less\_constrained}} = 4.44$, $p < .001$; mediation $ab = .99$, 95% CI [.66, 1.32]). Importantly, these effects did not occur in the neutrally-framed condition (both $ps > .23$; two-way interaction $ps < .050$; significant moderated mediation), supporting our prediction that resource constraint only suppresses interest in self-gifting (and not all consumption).

Study 3 ($N = 820$; pre-registered) further tested process through moderation. If the negative effect of constraint on self-gifting interest is driven by a belief that one will not be sufficiently capable of savoring to derive the emotional benefits, then the effect should be attenuated by challenging this lay belief. To test this, we varied whether a self-gifting product was described as requiring a capacity for savoring in order to benefit (the theorized lay belief), or as a *means to attain* a capacity for savoring (challenging the lay belief). Results supported our reasoning: Resource constraints reduced purchase interest in the lay belief condition ($M_{\text{more\_constrained}} = 3.95$ vs. $M_{\text{less\_constrained}} = 4.49$, $p = .010$), but the effect was completely attenuated when we challenged the lay belief ($M_{\text{more\_constrained}} = 4.25$ vs. $M_{\text{less\_constrained}} = 4.47$, $p = .281$; interaction: $p = .130$).

Study 4 ($N = 136$) tests the accuracy of consumers' lay beliefs about self-gifting. After manipulating current feelings of resource constraint, lab participants were instructed to engage in self-gifting (eating a real biscotti with a self-gifting intention), and we measured well-being before and after. We found that self-gifting can improve emotional well-being, regardless of resource constraint ($M_{\text{pre}} = 4.80$ vs. $M_{\text{post}} = 5.09$, $p < .001$). Perhaps more importantly, we found that consumers have mis-calibrated expectations about their ability to derive emotional benefits from self-gifting: Rather than being less able to derive benefit, those feeling resource-constrained experienced a greater over-time boost to their emotional well-being ($M_{\text{pre}} = 4.58$ vs. $M_{\text{post}} = 4.97$, $p < .001$), relative to feeling less resource-constrained ($M_{\text{pre}} = 5.05$ vs. $M_{\text{post}} = 5.22$, $p = .060$, interaction $p = .092$). This finding is consistent with prior research suggesting that consumers are poor at predicting hedonic outcomes (Lowenstein and Schkade 1999; Mitchell et al. 1997).

Underscoring the ecological validity of these effects, in supplemental studies, we show that resource constraints undermine actual choice of self-gifting experiences, willingness to purchase self-gifts, and engagement with social media ads for self-gifting. We also corroborate the proposed underlying mechanism through qualitative coding of open-ended responses. Throughout our studies, we also cast doubt on alternative explanations such as feelings of deservingness, affordability, having earned it, justifiability, and a general hedonic orientation.

Overall, our studies reveal that resource constraints suppress interest in self-gifting due to consumers' beliefs about their ability to derive benefits. Importantly, though, these beliefs are miscalibrated, suggesting that those who are least likely to engage in self-gifting are the ones who can stand to benefit the most. In addition to having important consumer well-being implications, this research makes theoretical contributions to research on self-gifting and resource constraint.

Viewing Leisure as Wasteful Undermines Enjoyment

EXTENDED ABSTRACT

Consumers often feel that they cannot make time for all of their desired and necessary tasks, leading leisure activities to be routinely jettisoned (Southerton 2003). Although leisure engagement offers a host of psychological (Coleman and Iso-Ahola 1993; Kahneman et al., 2004), and health benefits (Gump and Matthews 2000; Pressman et al., 2009), we propose that not all consumers value leisure, with some believing that using their (limited) time to engage in leisure is wasteful.

We propose that negative beliefs about leisure's value subsequently reduce hedonic utility from leisure pursuits. People's beliefs and expectations can become something of a self-fulfilling prophecy, in the way that, for example, expecting a product to taste better can lead it to actually be perceived as better-tasting (Lee et al., 2006). Thus, believing leisure is a wasteful use of time, lacking meaningful benefits, could diminish the primary benefit of leisure: enjoyment. However, negative beliefs about leisure's value should not undermine enjoyment indiscriminately. Prior research has distinguished between terminal leisure that is immediately rewarding, and instrumental leisure that serves as an instrument to achieving a longer-term goal (Botti and McGill, 2011; Kruglanski et al, 2018). Believing leisure is wasteful should be particularly detrimental for terminal leisure activities whose primary motivation is pleasure and less so for instrumental activities that are more productive because they are performed as a means to another (productive) purpose. Four studies test the effects of chronically held and primed beliefs about leisure on enjoyment of enacted leisure activities.

Study 1 (N=302) followed a 2(terminal, instrumental) x beliefs about leisure (measured) design. Participants who had celebrated Halloween were recruited for this study. They first indicated what they did (e.g., went to a party; took kids trick or treating) from a pretested list of terminal and instrumental leisure activities. They then indicated how much they enjoyed their Halloween experience (0=not at all, 100=extremely). Finally, they indicated agreement with five statements about leisure's wastefulness (e.g., "Time spent on leisure activities is often wasted time," "Leisure activities are not a productive use of time," $\alpha = .84$; 1=strongly disagree, 7=strongly agree). We found a significant interaction. For terminal leisure activities, greater endorsement of the belief that leisure is wasteful was associated with decreased enjoyment (B = -3.58, $p = .012$). However, there was not a significant relationship between beliefs about leisure and enjoyment for relatively instrumental leisure activities (B = 1.32, $p = .32$). Thus, negative beliefs about leisure uniquely undermined enjoyment of relatively terminal leisure activities. For those activities that are more instrumental – serving a purpose beyond (or in addition to) the pursuit of pleasure – we did not observe a detriment to believing leisure is wasteful.

Building on this, Study 2 (N=199) examined enjoyment of a variety of leisure activities and well-being. Participants indicated how much they tend to enjoy various leisure activities (e.g., hanging out with friends, watching TV, exercising) on average (1=not at all, 7=to a great extent). A pretest was used to classify each activity as terminal or instrumental, and a factor analysis further supported these classifications, with terminal and instrumental activities loading onto separate factors. As such, items were averaged together to form two scales corresponding to enjoyment of terminal and instrumental activities, respectively. Participants then completed scales assessing

happiness (Lyubomirsky and Lepper 1997), depression (Radloff 1977), anxiety and stress (Lovibond and Lovibond 1995). Finally, participants completed the same scale assessing beliefs about leisure used in Study 1 ($\alpha = .85$).

As in Study 1, we found that believing leisure is wasteful was associated with significantly reduced enjoyment of terminal ($r = -.16$, $p = .022$) but not instrumental leisure activities ($r = .06$, $p = .43$). Furthermore, in line with the idea that believing leisure is wasteful may harm not only the immediate enjoyment of leisure, but also the long-term well-being benefits of leisure, we found that negative beliefs about leisure were associated with lower reported happiness ($r = -.14$, $p = .049$) and greater reported depression ($r = .33$, $p < .001$), anxiety ($r = .39$, $p < .001$), and stress ($r = .24$, $p = .001$).

The final two studies experimentally tested the detrimental effect of believing leisure is wasteful by manipulating beliefs about leisure.

In Study 3 (N=189), we manipulated leisure beliefs by providing participants with articles that either primed that leisure is wasteful, leisure is productive, or that breakfast is unimportant (control). After the prime, participants played Tetris on the computer for about five minutes, which a pretest confirmed is considered leisure. Those primed to believe leisure is wasteful enjoyed playing the game significantly less ($M = 52.25$) than those primed that leisure is productive ($M = 61.94$, $p = .058$) and the control ($M = 64.62$, $p = .014$), which did not differ ($p = .58$). Thus, priming negative beliefs about leisure undermined enjoyment. Note that we find a detriment from believing leisure is wasteful rather than a boost from believing leisure is productive, establishing the direction of the effect.

Because the term "wasteful" may have a particularly strong negative connotation, in Study 4 (N=458), we added a fourth condition priming the belief that leisure is "unproductive" in order to test robustness. After the prime, participants watched a humorous video, which a pretest confirmed was considered leisure. As expected, the wasteful ($M = 55.11$) and unproductive ($M = 55.11$) conditions did not differ ($p = .80$). More importantly, participants in both the wasteful and unproductive conditions enjoyed watching the video less than those primed that leisure is productive ($M = 61.94$; vs. wasteful: $p = .086$; vs. unproductive: $p = .045$) and those in the control condition ($M = 64.62$; vs. wasteful: $p = .053$; vs. unproductive: $p = .026$). The productive and control conditions did not differ ($p = -.21$). Thus, priming the belief that leisure lacks value decreases enjoyment of leisure.

Although leisure engagement offers a myriad of established benefits, not all consumers deem leisure valuable. We find that believing leisure is wasteful undermines enjoyment of enacted leisure as well as long term well-being.

Great for You but Not for Me: Examining Actor versus Observer Perceptions of Self-Care

From workplace wellness programs and napping rooms, to FitBit challenges and mobile mindfulness apps, consumers and marketers are investing in "self-care." The current research examines these practices, which we define as behaviors consumers voluntarily engage in to improve their well-being. At the individual level, taking care of ourselves predicts greater life satisfaction (Diener, Lucas, and Oishi 2002), prosocial behavior (Lyubomirsky, King, and Diener 2005), and improved relationships (Diener and Seligman 2002). At the organizational level, workplace wellness initiatives predict greater productivity, decreased absenteeism, and lower healthcare expenditures (Baicker, Cutler, and Song 2010; Spector 1997). Despite these tangible benefits, wellness initiatives are often underutilized (Global Wellness Institute 2016). Why?

The current research examines one potential reason: consumers might undervalue *their own* self-care relative to *others'* self-care. Time is a finite resource that requires making trade-offs among various activities. For example, consumers tend to prioritize their own work/productivity over pleasurable experiences (Keinan and Kivetz 2008; Kivetz and Keinan 2006). Time spent on massages, yoga, and therapy sessions may be seen as passive leisure (i.e., "a nonproductive use of time"; Veblen 1899/2007), which is generally aversive (Hsee, Yang, and Wang 2010). Self-care may also be considered selfish and unnecessary, making it difficult to justify. Specifically, consumers may feel undeserving of the "indulgence" of a bubble bath or meditation (cf. Cavanaugh 2014), and ultimately discount the value of their own self-care relative to others. Lastly, prior work on self-compassion demonstrates that consumers often extend greater kindness toward others than themselves during times of distress (Neff 2003). Taken together, self-care may be a specific domain where consumers as "actors" evaluate the same behavior differently than "observers" (Jones and Nisbett 1972).

We examine this possibility across six studies, featuring various domains and operationalizations of self-care's value. Study 1 assessed value via consumers' emotional tone when speaking about self-care. We scraped 10,000 "self-care" tweets from Twitter over a two-day period and ran them through the Linguistic Inquiry and Word Count (LIWC; Pennebaker et al. 2015) software. Our key predictor was a ratio between 2nd/3rd-person pronouns (other-referencing; observer perspective) and 1st-person pronouns (self-referencing; actor perspective). Greater other-referencing (vs. self-referencing) predicted greater positivity ($\beta = .59$, $p < .001$).

Study 2A (AsPredicted #50565) assessed value via time allocation. Specifically, online participants allocated 100 points across three categories (productivity, self-care, and leisure) for either themselves or another person. A 2 (Actor/Observer) $\times$ 3 (Activity) mixed analysis of variance revealed a significant main effect of Activity ($p < .001$), which was qualified by a significant interaction ($p = .015$). Relative to another person, consumers allocated more time toward their own productivity ($p = .033$), less time to their own self-care ($p = .003$), and an equal amount of time to leisure ($p = .813$). Ancillary analyses revealed that the three activities vary in their anticipated well-being benefits. Namely, productivity is seen as more meaningful than pleasurable ($p < .001$), leisure is more pleasurable than meaningful ($p < .001$), but self-care is equally meaningful and pleasurable ($p = .158$). Thus, self-care is not the same as leisure, as it has both "work" and "play" elements.

Study 2B assessed value via webinar choice. Undergraduates read about two classes being offered by the university—one geared toward self-care and one geared toward financial literacy. Participants selected a webinar for themselves (Actor) or one to recommend to other students (Observer). While financial literacy was preferred in both conditions, participants were less likely to choose self-care for themselves than other students (29.4% vs. 42.5%; $p = .033$).

Study 3 assessed value via self-reported importance. Undergraduates were invited to participate in a creative self-care activity (i.e., they completed an online coloring page; Actor) or to evaluate another student's creative self-care activity (i.e., they saw a completed coloring page from a 21-year-old named Alex; Observer). The key dependent variable was the extent to which they perceived this activity to be a valuable use of time and energy (i.e., valuable, necessary, important, beneficial, essential, and productive; $\alpha = .95$). As expected, participants perceived their own self-care to be less valuable than someone else's self-care ($p < .001$). There were no differences when Alex was male or female.

Study 4 (AsPredicted #49327) replicates our proposed perception asymmetry and offers preliminary evidence for the underlying mechanism. Online participants imagined that they (Actor) or someone else (a 36-year-old named Alex; Observer) received a flyer to participate in a free hot yoga class. They then completed the perceived value index used previously ($\alpha = .93$) and evaluated the extent to which they/Alex felt deserving of taking time to practice self-care (e.g., "I/Alex deserve(s) to take this time for self-care"; $\alpha = .80$). The results revealed a significant indirect effect: participants felt less deserving of self-care for themselves versus another person, which ultimately predicted lower value (Model 4, Hayes 2017; $\beta = .61$, 95% CI: .49, .71).

Study 5 (AsPredicted #60016) tests whether individual differences in self-compassion moderate the Actor/Observer asymmetry. Online participants completed two blocks of questions in a counterbalanced order. In one block, they imagined themselves (Actor) or another person (Observer) practicing self-care over the weekend (agnostic to behavioral domain). They then completed the perceived value index used previously ($\alpha = .94$). In another block, they completed the Self-Compassion Scale Short Form, which includes items like "When something painful happens, I try to take a balanced view of the situation" ($\alpha = .92$; Raes et al. 2011). Replicating Studies 3 and 4, participants perceived another person's self-care as having greater value than their own ($p < .001$). Importantly, this effect was qualified by the predicted interaction ($p = .012$) such that the asymmetry was attenuated at higher levels of self-compassion.

Across six studies, we demonstrate that consumers discount their own self-care relative to others' self-care. This perception asymmetry is driven by perceived deservingness and is attenuated at higher levels of self-compassion. Our work contributes to the time consumption literature by focusing on self-care, an understudied use that is conceptually and empirically distinct from work and leisure.

The Signaling Value of Leisure: How Information About Leisure Activities Affects Perceptions of Well-being and Professional Judgments

An increasing number of service providers use personal biographies, websites, and social media to vie for consumers' business. Often, service providers must decide whether to include additional personal information, such as information about their activities outside of work, in these settings. While previous literature indicates that disclosing one's leisure activities in professional settings might serve as a negative social signal (e.g., Bellezza et al. 2017), we propose that disclosing one's leisure activities can have positive implications in professional settings. We hypothesize that as an individual discloses increased participation in leisure activities, they are perceived as having higher eudaimonic well-being (e.g., meaning, fulfillment; Ryan and Deci 2001), which subsequently increase observers' perceptions of their professional standing, as well as their interest in hiring or working with the individual. We broadly refer to these outcomes as professional judgments. We also identify extrinsic motivation and activity type as important boundary conditions of our conceptual model.

In study 1, we aimed to test our proposed direct effect of leisure activities on professional judgments in a direct marketing context using Facebook advertisements. To do so, we created two advertisements for a service to match individuals with virtual interior designers. Both ads featured a designer named Christine (who purportedly worked for a virtual design company) and mentioned why Christine enjoys working as a virtual interior designer. The control ad featured no additional information, while the treatment ad mentioned that when Christine is not working, she enjoys hiking, cooking, and streaming concerts. As hypothesized, Facebook users were significantly more likely to click on the advertisement when Christine disclosed her leisure activities ($p<.001$).

While our first study provides practicable, real-world evidence that sharing leisure activities can be beneficial in professional settings, it is unable to offer support for our full conceptual model or rule out potential alternative explanations. Our next two studies address these issues. In study 2A, 375 Prolific participants completed a three-cell (leisure activities: zero, one, three) between-subjects study. Participants were asked to imagine that they were planning to purchase a house and wanted to work with a realtor. They then viewed information about a local realtor named Brian, including his biography and headshot. In the zero-activity condition, Brian did not mention any leisure activities in his biography, while in the remaining conditions, he disclosed one and three activities, respectively. Participants then rated their interest in hiring Brian, as well as their perceptions of his eudaimonic well-being. As predicted, participants were more interested in hiring Brian in the three-activity ($M=5.35$) condition compared to the zero-activity condition ($M=5.01$; $p=.012$) and marginally more interested compared to the one-activity condition ($M=5.10$; $p=.067$). Similarly, participants perceived Brian as having higher eudaimonic well-being in the three-activity condition ($M=5.45$) compared to either the zero-activity ($M=5.02$; $p=.002$) or one-activity ($M=4.99$; $p=.001$) conditions. The zero- and one-activity conditions did not differ across either variable. Eudaimonic well-being fully mediated the relationship between leisure activities and hiring interest. Of note, this study also measured and ruled out extraversion and likability as alternative mediators to eudaimonic well-being.

The goal of study 2B was to replicate study 2A in a context that was directly relevant to our participants. To do so, 206 undergraduate students were told that their school was considering hosting virtual writing workshops and were interested in their feedback on potential instructors. They read a description of a graduate student, Jamie, who was being considered for a position to instruct a writing workshop. Participants read information about Jamie's background that included either one or three leisure activities in which she participated (between-subjects). They then rated how interested they were in attending a workshop hosted by Jamie, as well as their perceptions of Jamie's eudaimonic well-being. As predicted, participants were significantly more interested in attending Jamie's workshop ($M_{\text{Three}}=4.89$ *vs.* $M_{\text{One}}=4.50$; $p=.026$) and had higher perceptions of her eudaimonic well-being ($M_{\text{Three}}=5.50$ *vs.* $M_{\text{One}}=5.03$; $p=.001$) in the three- versus one-activity condition. Again, eudaimonic well-being fully mediated the relationship between leisure activities and interest in attending Jamie's workshop.

Study 3 examined the role of extrinsic motivation. We predict that extrinsic motivation runs counter to eudaimonic well-being, and thus when leisure activities are solely extrinsically motivated, the positive downstream consequences of leisure activities will be attenuated. 457 TurkPrime participants participated in a 3-cell (leisure activities: zero, three, three with extrinsic motivation) experiment. They first read about a woman named Christine and were provided with non-focal background information about her. The zero and three activity conditions were similar to previous studies. In the extrinsic motivation condition, participants read that Christine only participates in the three leisure activities to look good to others. Participants then rated their professional judgments (e.g., workplace value, performance), and perceptions of her eudaimonic well-being. As in previous studies, when comparing the zero- and three-activity conditions, Christine received significantly higher ratings of professional judgments ($M_{\text{Three}}=5.73$ *vs.* $M_{\text{Zero}}=5.52$; $p=.037$) and eudaimonic

well-being (M_{Three}=5.55 *vs.* M_{Zero}=5.05; *p*=.001). However, this effect was attenuated when Christine participated in the activities for extrinsic reasons, and in fact, she was rated significantly lower on professional judgments ($M_{ThreeExtrin}$=4.87) and lower in eudaimonic well-being ($M_{ThreeExtrin}$=3.19) compared to both the zero- and three-activity conditions (all contrasts *p*<.001). The relationship between leisure activities and eudaimonic well-being was again mediated by eudaimonic well-being. This study also ruled out similarity and warmth as alternative mediators.

Our empirical package also includes experiments that differentiate the role of time spent on leisure from time spent on work, rule out status as an alternative mechanism, and identify the moderating role of activity type. With respect the latter, using both an experiment and Twitter data, we find that activities perceived as impeding eudaimonic well-being (e.g., using social media), do not offer professional benefits.

In sum, the present research reveals the ironic effect that highlighting how one spends time outside work can increase one's professional standing. We further demonstrate that well-being can be a meaningful tool utilized in professional relationships. We believe that this research offers novel theoretical insights related to self-care, leisure, time, and well-being while also providing useful advice for marketing practitioners.

SESSION OVERVIEW

All parents want the best for their children. But how "best" is defined is often based on one's own experiences and metacognitions (Li, Haws and Griskevicius 2019; Pechmann, Catlin and Zheng 2020). The question is, do parents really know best? In our ever-changing world as new forms of technology emerge, meaning of privacy is redefined, and while higher education has become more accessible, college tuition continues to increase, and COVID-19 has led to increased screen time for all. Parents face these changes without clear guidance. It becomes imperative to understand how parents can make better (not best) decisions for their children's wellbeing.

Family decision making has been studied in various consumption contexts, including viewing of media and TV ads (Mikeska, Harrison and Carlson 2017; Gentile et al., 2012), shaping healthy eating habits (Grier et al., 2007), to financial planning for children's education investments (Ermisch and Francesconi 2001; Kornrich 2016). Our session includes four papers that examine these consumption practices, particularly taking into consideration how the changing world (external) influences critical family decisions (internal). We learn from four different but similar contexts, about the impact of sharenting, empowering role of social media, collective TV viewing and investment in youth sports.

The four papers examine varying *parental decisions* on sharenting (paper #1), investing in educational spending (paper #2) or youth sports (paper #3) and TV viewing (paper #4). These decisions are relevant not only to their children's growth and wellbeing, but paren-tal decisions often reflect *parental identity*. We find that children's overall well-being is dependent of parental styles (paper #1), empowerment levels of the mother (paper #2), parents' own aspirations and identity as an athlete (paper #3) and parents' own consumption practices (paper #4).

In three of these papers, we explore how *parental use of media* may directly or indirectly have long-lasting effect on their children's wellbeing. Lee and Laczniak examine how different parenting styles lead to different sharenting behavior (content of sharenting, frequency, motives of sharenting, resolving conflicts of information privacy between parents and children). Next, Vijayalakshmi and Lin examine how mothers use social media as a source of information as well as social connections that will empower their decisions related to their children's education planning and investment. While both papers explore the motives of parental use of social media and its impact on their children, the former examines online privacy and frictions, while the latter focuses on the role of social media use in empowering mothers. Vijayalakshmi, Das and Divya examine how individual and collective TV viewing in Indian households may impact children's BMI.

The parents are the key decision maker in investments and resource allocation, which is critical in *family financial planning* and *decision making*. Vijayalakshmi and Lin focus on the role of mothers and how the sense of empowerment may impact their influence on educational spending for their children; while Posteher and Hansom identify factors and drivers of parents in supporting investing money in youth sports for their children.

The Role of Parental Style in Sharenting

EXTENDED ABSTRACT

Sharenting refers to parents' habitual use of social media to share information (e.g., news, images) about their children with family and friends, acquaintances, professional networks, and the world at large (Collins 2017). Previous research has studied this relatively new phenomenon from different perspectives: 1) From the information security perspective, researchers tried to promote parents' awareness of related privacy issues, from problematic data practices within firms to digital kidnapping and child grooming caused by external hikers and evil people (Jones 2013). 2) From the consumer's perspective, Fox and Hoy (2019) studied mothers' vulnerability and how it may translate into increased children's consumer vulnerability in sharenting. 3) From the legislation perspective, researchers discussed the limitations of current legislation on protecting children's online privacy (Bessant 2018; Steinberg 2016).

Parental style, a theoretical framework which classifies parents by how they differentially raise and socialize their children (Baumrind 1980), has been studied within the consumer domain (Carlson and Grossbart 1988; Carlson, Laczniak and Walsh 2001). A wide range of outcome variables have been attributed to parental style, including children's perception on mothers' views of television (Carlson, Laczniak and Walsh 2001), children violent videogame play

levels (Walker et al. 2016), cybervictimization of youth (Dehue et al. 2012), children's use of the Internet (Valcke et al. 2010), and teen self-concept (McClun and Merrell 1998).

However, it is unclear how parental style impact parents' sharenting practices and its consequences on children. Specifically, we are interested whether types of parental style can help alleviate the potential negative consequences of sharenting on children. Utilizing parental style to frame such an investigation may prove to be useful. Indeed, a meta-analysis on parental style and the consumer socialization of children found that parental style, especially authoritative parental style, can lead children to have positive interactions with the marketplace, particularly among older children (Mikeska et al. 2016). Therefore, we seek to understand the role of parental style in sharenting, especially its impact on 1) parents' sharenting practices (e.g., content, form, frequency); 2) negative outcomes on children (e.g., privacy risk, self-identity confusion, distress in parent-children relationship).

Our work will contribute to the literature of consumer socialization research in the advent of sharenting, a new phenomenon within the social media domain. By identifying the interplay of different parent styles on children's perceptions of sharenting behavior, our findings will offer helpful guidance for parents to reduce potential negative outcomes on their children. In addition, as sharenting has dramatically increased due to the social isolation in the COVID-19 pandemic, this paper will contribute to a better understanding on which subsets of children are at higher risks of perceiving that their individuality and privacy are violated, and therefore more likely to experience high levels of conflicts with their parents.

We propose that parental style plays a moderating role in the relationship among motives of sharenting, parents' sharenting practices and outcomes on children.

Parents' motives of sharenting. We identified four main reasons for sharenting: 1) seeking parental advice (Verswijvel et al. 2019); 2) maintaining social connections for both parents themselves and children (Duggan et al. 2015); 3) archiving information about children's growth (Blum-Ross and Livingstone 2017); 4) impression management (Kumar and Schoenebeck 2015; Davidson-Wall 2018).

Parents' sharenting practices. Our focus on sharenting practices includes but is not limited to the following aspects: parents' choice of content (e.g., positive or negative information, with or without Personal Identifiable Information), form (e.g., text, image, video), frequency, awareness of privacy risk, willingness to listen to the children.

Potential negative impact on children. Prior work suggests that three negative outcomes of sharenting may affect children: 1) privacy loss/privacy crime (Siiback and Tracks 2019); 2) confusion or embarrassment on self-identity/self-image/digital presence (Choi and Lewallen 2018); 3) distress in parent-children relationship (Steinberg 2016).

Parental Style. Based on two dimensions of warmth and restrictiveness (Maccoby and Martin 1983; Carlson, Laczniak and Walsh 2001), there are four types of parental style: 1) Authoritative parents, are high on both warmth and restrictiveness, and as a result are likely to balance children's rights and responsibilities. Authoritatives encourage self-expression from offspring and expect children to act maturely and in accordance with family rules but also allow a certain degree of autonomy. 2) Neglecting parents, who are low on both warmth and restrictiveness, offer little encouragement or guidance for children's development. As a result, communication between neglecting parents and their children is generally strained and minimized. 3) Authoritarian parents, who are low in warmth, but high in restrictiveness, try to control children, by endorsing adult

supremacy, and discouraging verbal interactions with their children. 4) Indulgent parents, who are high in warmth, but low in restrictiveness, tend to be lenient, accepting, affirmative, and nonpunitive in dealings with children. Indulgents give children adult rights without concomitant responsibilities and communicate openly with them.

Based on the above, we propose the following Hypothesis:

Hypothesis 1:   *Compared to authoritarian and neglecting parents, authoritative and indulgent parents are more likely to be concerned about potential privacy risk of sharenting, to listen to children's feelings and feedback, and to adopt their sharenting practices to alleviate negative outcomes on children.*

Hypothesis 2:   *Children of authoritative parents will be least likely of all children to experience negative outcomes of sharenting*

Hypothesis 3:   *Neglecting parents are least likely of all parents to engage in sharenting.*

Hypothesis 4:   *Compared to other parents, authoritarians are more likely to focus on their own needs while ignoring children's feelings and feedback when engaging in sharenting.*

Hypothesis 5:   *Children of Authoritarians will be most likely of all children to experience negative outcomes of sharenting.*

Data will be collected from both parents and children (10 years or older) via self-administered questionnaires through online paid panels. Children 10 years old or older are chosen because of their ability to respond to items presented in an online survey format. Parents will provide information concerning their motives of sharenting, parental style, sharenting practices, while children will report the impacts of sharenting on their relationship with parents and overall well-being.

Social Media Tools to Empower Mothers for their Children's Educational Growth

EXTENDED ABSTRACT

Despite the significant impact that women may have on future generations, a mother's empowerment is not as well-studied as other demographic variables (e.g., income, education), especially in children's education (Roushdy, 2004). Empowerment theory emerged in the social sciences as a "model for responses to problems that disproportionately impact those with less power and fewer resources" (Christens *et al.,* 2011; p.172). Overall, this ideology seeks to create a more inclusive society, especially by paying particular attention to those who are often marginalized; here, mothers. In this paper, we focus on understanding how a psychologically empowered mother may positively impact her child's educational needs. In particular, we consider mothers' social media use as an antecedent of empowerment. We examine the following research questions: (a) how does a mother's social media use influence her children's educational related outcomes? And (b) how does psychological empowerment explain this relationship?

Through social media, women have been able to build their self-confidence and gain access to information, thus helping them make better-informed decisions. Marketing researchers have found that such processes are suggested to result in feelings of empowerment for the consumer. Others have found that empowered consumers demonstrate the agency to be more involved with firm and product decisions (Hanson and Yuan, 2018; Fuchs *et al.,*2010) and tend to spend more. Similarly, research in organizational settings shows that psychological empowerment leads to higher job satisfaction, organizational commitment, job performance, lower turnover intentions, and employee strain (Seibert *et al.,* 2011). At the individual level, empowerment improves subjective well-being, self-esteem, mental health, and reduces risky behaviors (Christens and Lin, 2014).

Therefore, we draw on psychological empowerment theory (Zimmerman, 2000), which offers a comprehensive measure to capture women's status and sense of power. Prior research in marketing has predominantly focused on only one dimension of empowerment— intrapersonal, which deals with an individual's competence, self-efficacy, and control (Zimmerman, 2000). However, empowerment has another significant dimension—interactional empowerment, which focuses on collective action and interpersonal relationships (Zimmerman, 2000). Yet, we have little to no idea about how interactional empowerment affects consumption. Key constructs studied in this paper are active/passive social media use, dimensions of psychological empowerment (intrapersonal and interactional), and educational savings and expenditures. We focused on educational expenditure in all our studies as it is suggested to be an indicator of educational outcomes (Kingdon, 2005), educational attainment, and skill level (Saha, 2013) in children.

In three studies conducted with mothers of adolescent children, we first establish the relationship between social media use and educational decisions via a behavioral experiment (Study 1). A between-subjects ($n = 114$) design with two conditions, passive ($n = 58$) vs. active social media use was constructed. We recruited participants in the US through the Qualtrics panel, who identified themselves as mothers and had at least one child between ages 11 and 17. We focused on this age range because critical educational expenditures are likely to be considered when the child is nearing college. We primed active (vs. passive) condition by asking participants to read educational articles on a FaceBook page and engage by writing status messages and sharing with friends (vs. only read). The results suggest that parents who are more active on social media are likely to invest more in their children's education ($M_{active} = 3.60$ vs. $M_{passive} = 2.98$, $F (1, 103) = 3.61$, $p = .06$) and education-related items ($M_{active} = 3.09$ vs. $M_{passive} = 2.69$, $F (1, 103) = 4.03$, $p = .04$). But why do active users spend more on their children's education? We examine the role of psychological empowerment to explain the same.

In Study 2 we surveyed mothers ($n = 182$) using a Qualtrics panel to develop the relationship between social media use, psychological empowerment, and educational spending. In Study 3 ($n = 126$) using an M-Turk panel we further measured alternative education spending-related behaviors such as saving for college or donating to school. The results of both Studies 2 (presented here) and 3 suggest that active use of social media increases perceived competence (β (CI) = .24 [.03, .44]), leading to increased investment in children's education (β (CI) = .42 [.04, .80]). Passive use leads to higher control (β (CI) = .18 [.03, .34]), collective action (β (CI) = .19 [.05, .33]) and interpersonal relationships (β (CI) = .19 [.07, .32]). However, none of the factors arising from passive use leads to increased investment in children's education. What is even more significant is that how empowerment takes form, whether intrapersonal and interactional, could lead to different behavioral spending responses. Intrapersonal empowerment, influenced by recognition needs (β (CI) = .23 [.04, .42]), appears to increase spending behavior in individuals. Interactional empowerment, influenced by cognitive needs (β (CI) = .22 [.03, .41]), appears to increase saving behavior in individuals (β (CI) = .74 [.34, 1.13]). The results from both the studies seem to highlight a more significant impact of passive use, rather than active use, on psychological empowerment.

We show that women's empowerment is critical to children's educational investments, apart from health investments. By extending the theory of psychological empowerment to examine educational expenditures, we show that psychological empowerment has a critical role in other contexts than previously studied— community welfare (Zimmerman and Rappaport, 1988) and organizational commitment (Seibert *et al.,* 2011). Through this finding, we argue that psychological empowerment is (a) a necessary motivational (not just as an output variable) variable, and (b) should be treated as a multidimensional construct (not just on its intrapersonal component). Second, we also highlight the need to focus on social media use rather than Internet access to better understand consumer behavior. Finally, we shine a light on considering mothers and their educational expenditure as a critical part of consumption and investment decisions. Parents consider education as a long-term investment and an equalizer, which will help prosper and wellbeing of future generations (Hill and Lai, 2016).

Parental Spending on Youth Sports: Motivations and Expected Return on Investment

EXTENDED ABSTRACT

Youth sports in the United States represent a massive industry with nearly 45 million athletes; nationwide, 75% of families with children have at least one child participating in athletics (Merkel, 2013). From 2010 to 2017, the youth sports industry grew by 55%, and it currently represents a 19 billion-dollar market (Bjork & Hoynes, 2021). Projections show that the market could reach a remarkable 77.6 billion dollars by 2026 (Research & Markets, 2019). This study explores the motivations that parents have for investing in youth sports.

Research has highlighted several positive outcomes of youth sports, particularly with regard to social and physical benefits for the child participants (e.g., Marsh & Kleitman, 2003; Melnick, Miller, Sabo, Farrell, & Barnes, 2001). In conjunction with studies on the experiences of young athletes, it is integral that we consider the role of parents in youth sports, as parents not only shape their child's choice of extracurricular activities, but also provide tangible and intangible support. Children influence the consumption activities of families (e.g., Palan & Wilkes, 1997), yet we know relatively little about the ways in which family values are shaped by youth sports consumption (Epp, Price, & Kozinets, 2005).

The financial burden for parents of children participating in youth sports can be immense, often constraining the family budget (Bean et al., 2014). Many parents justify these sacrifices by planning on their child's athletic excellence as a means for paying for their college education. However, in reality, the National Collegiate Athletic Association (NCAA) reports that less than 4% of high school athletes will play for a Division I or II program (Merkel, 2013), with far fewer receiving scholarships that will alleviate the cost of tuition. Ironically, the total cost of the investment that parents make in memberships, equipment, private training, camps, and travel expenses during middle and high school can greatly exceed the value of the potential college scholarship (Hyman, 2012).

The 2019 Harris Poll conducted for financial firm TD Ameritrade offers valuable insight into parent consumption behavior with regard to youth sports. Despite the scarcity of full-ride scholarships (covering the entire cost of college), results indicated that one in 10 sports parents anticipate that their child's scholarship will be a full ride; moreover, one-third of parents expressed a desire for their child to become a professional athlete or Olympian (Harris Poll, 2019). To pay for youth sports expenses, parents reported cutting back on entertainment, taking fewer vacations, and even taking on second jobs – all in hope of winning the lottery of a full-ride scholarship for their child. Yet, nearly 75% of American sports parents report that youth sports have adversely affected their savings and investments for retirement (Global Sport Matters, 2019). Importantly, The Harris Poll also found that one in five sports parents devote over 20 hours per week to their child's sport, indicating that financial spending on youth sport is accompanied by substantial time investment.

Given these considerable costs, our primary research focus was to identify underlying motivations for parents investing in youth sports for their children. Our overarching research question asked: what are parents' end goals for financially supporting their child's participation in athletics? We hypothesized that parents' commitment to sport would be positively correlated with dollars invested in youth sports. Second, we considered the role of parental identity in consumption behavior. For families with one or more parents who had played sport at the collegiate level, we hypothesized that sports lineage would impact the parents' commitment to their child's athletic endeavors, as well as influence how much money they would spend on youth sports.

To investigate these questions, we conducted a survey for quantitative analysis. We recruited participants through Amazon Mechanical Turk (MTurk). A total of 393 parents of athletes completed a survey reporting their motivations for their child participating in sport, their commitment to their child's participation in sport, and their family lineage of sport.

Our analysis revealed three primary motives that parents have for their children when they invest in youth sports: positive health and wellbeing, life lessons, and a college scholarship. It appears many parents believe that investing in youth sports comes with a return-on-investment that will pay out in the form of a college scholarship. We measured parent sport commitment using an adaptation of the Sport Commitment Model (Scanlan, Carpenter, Schmidt, Simons, & Keeler, 1993), a 19-item questionnaire which examines sport commitment, sport enjoyment, personal investments, social constraints, and involvement opportunities. Results indicated a positive relationship between four aspects of the model and dollars spent on youth sport. Therefore, parental commitment to their child's sport influences the amount of their financial investment.

Finally, we found support that parental decisions regarding youth sports are consistent with consumer behavior research, such that personal values and attitudes are heavily intertwined with consumption (e.g., Kahle et al., 2001; Gillespie, Leffler, & Lerner, 2002). Specifically, in families with at least one parent who is a former collegiate athlete, parents reported higher levels of sport commitment and spent nearly twice as much on youth sports as families without this lineage.

With the onset of COVID-19, youth sports programs faced sudden restrictions and closures; parents were forced to consider the ways in which youth sports are embedded within family priorities, patterns, and spending behaviors. The pandemic did not prevent parents who can afford the pay-to-play model from continuing to invest in their children's athletic careers. As just one example, a California family temporarily moved to Oklahoma so their daughter could continue participating in softball (Butler, 2020). However, the pandemic has further exacerbated financial disparities in youth sport (O'Neal, 2020). It can be difficult for parents who are heavily identified with their child's sporting activities, such as those looking for a return-on-investment, to process that they can no longer make the financial sacrifices they have in the past (Sanderson & Brown, 2020). Taken together, these findings have important implications for parent-child interactions regarding the value of investing in sport, particularly in the aftermath of the pandemic.

Relationship between Household TV Viewing and Children's BMI: Findings from India Human Development Survey

EXTENDED ABSTRACT

With the COVID-19 pandemic, one thing that has seen a significant rise across the world is the rise of adults and children's screen time. Researchers have captured the influence of the introduction of mass media (e.g., TV) in various south Asian countries. For instance, TV has been influential in getting women to adopt better health practices (Tidwell et al., 2019). Similarly, TV has helped in creating political and social awareness in the viewers. At the same time, TV has brought about lifestyle changes in the viewers. Several studies have reported that children's TV viewing significantly increases their Body Mass Index (BMI) (Davison, Francis, & Birch, 2005). Even though TV viewing alone cannot increase BMI, it is suggested to have a significant impact in increasing the time spent being sedentary which in turn leads to increased BMI (indicator of obesity/overweight conditions) (LeBlanc et al., 2015). Sedentary behaviour is associated with poor health outcomes like obesity in children and youth (LeBlanc et al., 2015). Obesity, in turn, increases social risks like isolation or chances of being bullied and could lead to lifelong health related concerns such as hypertension and Type 2 diabetes (Katzmarzyk et al., 2015; Center for Diseases Control and Prevention, 2017). Further, researchers have also noted that parents have a significant impact on children's TV viewing habits (Valkenburg et al., 1999), hence BMI. Consequently, academics, policymakers and doctors have repeatedly focused on advising parents to reduce their children's screen time consumption for a healthy life (American Academy of Paediatrics, 2016).

Most of these studies have focused on higher (vs. lower) per-capita income countries as the obesity and overweight rates have been higher (vs. lower) in such countries. However, the rates of obesity and over-weight children are increasing in India (Little et al., 2016; Gulati 2003). While several reasons for increasing obesity rates in India have been speculated and investigated, the influence of TV viewing has not yet been considered.

Therefore, the current research examines (a) whether TV viewing, after controlling for other factors, is a significant predictor of BMI and (b) the role of adults in influencing children's BMI in an Indian context. Furthermore, we understand how these results might change for different income and caste groups. The data for this study was obtained from the India Human Development Survey (IHDS). IHDS comprises a nationally representative sample of 41,554 Indian households from 1503 villages and 971 urban neighbourhoods in India. Such a large-scale analysis of TV's impact on children's BMI has not been conducted before. The following variables were measured at the individual level in the survey — child's anthropometric measures (used to construct BMI), child's gender, TV viewing duration and other variables for robustness checks (viz., distance to school and time spent in non-sedentary activities). The variables measured at the household level include total household income,

caste and highest education of an adult within the household. Using the unique identifier associated with each household, we were able to combine both the individual and household level data variables.

We make three significant contributions. One, we find that higher income and upper caste children view more television and have higher BMI rates. This result is a stark departure from previous findings that higher TV viewing and higher BMI rates are traditionally seen in lower income households (Lee, 2009; LeBlanc et al., 2015). The results suggest that there is a U-shaped relationship between income groups and children's TV viewing duration. While the highest income family children watch the most amount of TV, the least amount of TV is viewed by children of the middle-income group families (there were no differences between income groups 3 and 4). Next, we find that children in the highest caste group (Brahmins) spent significantly more time watching TV as compared to the three other lower caste groups- other backward caste ($M = 2.21$ vs. 2.14, t (27981) = 3.00, $p < .001$), scheduled caste ($M = 2.21$ vs. 2.10, t (15877) = 4.84, $p < .001$) and scheduled tribe ($M = 2.21$ vs. 2.07, t (7444) = 4.79, $p < .001$)

Second, our results show that TV viewing by adults (vs. children) in the household has a far greater influence on children's BMI. This was true for all the age groups. More interestingly, we find that for children in the age groups of 8-12 ($\beta_{5.1} = .14$, $p < .05$) and 13-15 ($\beta_{5.1} = .17$, $p < .05$), adults' TV viewing has a significant impact on children's' BMI. In fact, the impact of TV viewing on BMI continues to be significant even after controlling for other sedentary behaviours. Further, there was significant effect of income (across all age groups), caste (for 8-12 and 13-15 age groups), household school level education (for 5-7 and 13-15 age groups) and household college education (for 13-15 age group).

Three, we find that children between the ages of eight and fifteen (vs. five to eight) are most vulnerable to the influence of TV (13-15: $\beta_1 = .10$, $p < .01$). For the other age groups, there was no significant relationship between children's TV viewing duration and their BMI. Further, control factors such as income, caste (higher) and parents' education had a positive influence on children's BMI.

There are several likely reasons due to which adults' TV viewing could influence children's BMI. It is likely that children are engaging in co-viewing with them and hence the sedentary activity is increasing their BMI levels. Moreover, children might be more exposed to food ads and also more likely to consume snacks during co-viewing. Finally, adults spending more time watching TV would also mean less time for other activities including interactions and engagement with the children on health-related issues. Future research should confirm these speculations.

SESSION OVERVIEW

Understanding the consequences and antecedents of morality-driven judgment and choice is an important goal for consumer research. Moral norms serve, however, not only as guides for decision-making and behavior, but also as the basis for evaluating our own and others' actions. This session showcases research that provides new insights into how consumers form moral judgments in four important marketplace contexts. Questions addressed in this session include how consumers form moral judgements about i) other consumers ii) their own behavior towards companies iii) the behavior of companies towards society, and iiii) public policy makers.

First, Gai and Bhattacharjee explore moral judgements in consumer dyads. People infer other's moral character based on how much self-control they exert. Traditionally, exerting willpower is associated with moral "goodness" and not exerting willpower with moral "badness". Yet, the authors show an asymmetry in inferences of moral character from self-control. That is, self-control successes are more morally diagnostic than failures. Moral goodness thus requires *both* good intentions and the ability to act on them.

Second, Stuppy and colleagues investigate when consumers judge their behavior towards companies as immoral. A phenomenon that has received scarce attention compared to the reverse relationship: companies behaving immorally towards consumers. The authors investigate this process in the setting of brand imitation. Their results show that consumers feel guilty about buying imitations when they feel kinship towards original brands, when original brands have invested heavily into their product, or are relatively small and vulnerable.

Third, Xu and Bolton uncover how consumers form moral judgements about companies that engage in wasteful manufacturing processes. This work distinguishes two prevalent forms of wastefulness—excess resource-use (i.e., inefficient production)—and excess resource-disposal (i.e., byproducts/residuals). Interestingly, consumers judge the wasteful use of resources (vs. equivalent disposal-based waste) as less harmful and thus less immoral. Interventions that make

environmental harm or resource scarcity salient can sensitize consumers to the immoral nature of wasteful production.

Finally, Kim and colleagues examine how consumers form moral judgements about policy makers. More and more consumers hold "conspiracy beliefs" and are thus convinced that politicians/policy makers pursue malicious intent. The authors track the development of such beliefs during two elections. Importantly, conspiracy beliefs decreased (vs. increased) among consumers who supported winning (vs. loosing) candidates. This pattern suggests that consumers' perceived sense of personal control plays a pivotal role in forming moral judgments.

When asked "What does the world need right now?" many people might respond "morality". Indeed, our society needs answers to global moral crises such as rampant environmental destruction, dwindling civic engagement, and growing racism. This session serves to enhance the field's understanding of how moral judgements are formed to provide answers to these pressing issues. For instance, what leads consumers to make "good" choices in the marketplace (e.g., moral products)? Which factors might spur "good" behaviors (e.g., voting) and diminish dangerous societal developments (e.g., conspiracy beliefs)? We expect this session to encourage a broad discussion of how consumers' moral compass can be (re)calibrated to make the world a better place.

When and Why Does Non-Moral Self-Control Signal Moral Character? Willpower as a Moral Ability

EXTENDED ABSTRACT

Self-control refers to the ability to choose options with greater long-term benefits over those that are immediately tempting but costlier in the long term (Inzlicht et al., 2014). While self-control is deemed morally relevant when it affects group welfare (Mooijman et al. 2017), open questions remain about when *personal* self-control dilemmas with no direct social consequences (i.e., those typically considered "non-moral") are ascribed moral relevance. Past research offers two competing Hypothesis. One is the *moral-neutrality hypothesis*, which predicts that self-control and moral character are largely unrelated and judged independently (Blasi, 2005). The other is the *master-virtue hypothesis*, whereby willpower is essential to moral character (Baumeister & Exline, 2000). This account predicts that self-control success is viewed as evidence of moral goodness and failure as evidence of moral badness.

We propose a third possibility, the *moral-ability hypothesis,* whereby self-control is thought to reflect the ability to successfully enact good intentions. Prior research finds that moral badness is defined by evil desires, independent of ability (Inbar, Pizarro, & Cushman, 2012). In contrast, we suggest that moral goodness require *both* good intentions and the ability to act on them (cf. Stellar & Willer, 2018). Therefore, we expect that while self-control failure will not be thought to imply bad intentions (and thus bad moral character), success will be thought to demonstrate the ability to realize good intentions (and thus signal moral goodness). Accordingly, we predict an asymmetry in inferences of moral character from personal self-control, such that successes are regarded as more morally diagnostic than failures. Four main experiments (and dozens of replications) corroborate this asymmetry and support the moral-ability hypothesis.

Experiment 1 (preregistered at bit.ly/3mT2254) provided initial evidence of this asymmetry: self-control success increased perceptions of moral goodness, but failure did not lead to inferences of moral badness. Participants (N = 261) were randomly assigned to read vignettes in which target individuals succeeded or failed at self-control in personal consumption choices across four different domains (health, procrastination, budget, patience). Failure had no direct social consequences, though success sometimes involved a small social cost (e.g., turning down a friend's invitation in order to save money). Participants then rated the targets' moral character on a 9-point scale (-4 = mainly a bad person, 0 = not sure, +4 = mainly a good person). Supporting the asymmetry proposed by the moral-ability hypothesis, self-control success increased perceptions of moral goodness relative to failure ($M_{success}$ = 1.93, 95%CI = [1.71, 2.15] vs. $M_{failure}$ = 1.31 [1.09, 1.53], repeated ANOVA $F(1, 259)$ = 15.25, $p < .001$), but moral character ratings significantly exceeded the zero midpoint in both conditions.

Experiments 2 and 3 demonstrated that moral character inferences were enhanced by evidence of willpower (beyond the choice outcomes themselves) and ruled out various alternative explanations. Specifically, Experiment 2 (N = 156; preregistered at bit.ly/3goqt5F) showed that compared to the moral signal value of exerting willpower while experiencing self-control conflict ($M_{success}$ = 2.38 [2.05, 2.71] vs. $M_{failure}$ = 1.28 [0.94, 1.62], $t(153)$ = 4.60, $p < .001$), choosing a far-sighted "should" option without experiencing conflict (i.e., due to preference alone) was less diagnostic ($M_{preferences}$ = 1.83 [1.47, 2.18] vs. $M_{failure}$ = 1.28 [0.94, 1.62], $t(153)$ = 2.24, $p = .026$). Experiment 3 found that the magnitude of the asymmetry was moderated by individual differences in belief in free will, or the belief that willpower truly exists and determines choices (Paulhus & Carey, 2011). Moral-character evaluations increased with greater belief in free will in the self-control success condition ($b = 0.34$, $SE = 0.06$, $t(422)$ = 5.85, $p < .001$), but did not vary with belief in free will in the failure condition ($b = 0.06$, $SE = 0.06$, $t(422)$ = 1.02, $p = .310$). We also found no evidence that these effects were moderated by participants' belief in Protestant ethics, perceptions of their own self-control capacity, or political ideology (ps > .15), suggesting that these factors cannot explain our findings.

Experiment 4 generalized these effects to a realistic evaluative setting and ruled out the possibility of judgmental halo effects (Nisbett & Wilson, 1977). Participants (N = 201) were randomly assigned to view social-media profiles of anonymous individuals who reported current "obsessions" associated with success or failure in resisting temptations (e.g., saving up despite the temptation to splurge on hobbies). Our dependent measure was modeled on real-world social media apps that allow people in individuals' networks to attach personality labels to them: participants were asked to guess the top 3 labels used to describe the target individuals from a set of moral, immoral, warm, and cold traits, with monetary incentives for accuracy. Supporting the predicted asymmetry, participants in the self-control success condition selected more moral traits than those in the failure condition ($F(1, 199)$ = 89.73, $p < .001$), but moral traits were selected more than immoral traits across both conditions ($F(1, 199)$ = 342.74, $p < .001$). Importantly, self-control success also *decreased* the selection of warm traits relative to failure ($F(1,199)$ = 32.90, $p < .001$), ruling out halo effects and indicating that this inferential asymmetry is specific to moral character.

Navigating the social world entails constantly evaluating the trustworthiness and moral character of strangers. The current research suggests that people readily infer moral character from entirely personal consumption choices during apparently "non-moral" self-control conflicts, but see success as far more morally diagnostic

than failure. Beyond the well-documented centrality of intentions to moral evaluations, our findings suggest that morality also depends on competence. Good intentions may not translate to good outcomes without "moral ability."

Thou Shall Not Steal: When Do Copycats Trigger Moral Concern?

EXTENDED ABSTRACT

Copycats imitate the trade dress of leading brands to take advantage of the latter's brand equity. According to past work, consumers hold ambivalent attitudes about copycats. On the one hand, copycats are liked as, due to their visual similarity to the leader brand, they feel like familiar and high-quality products (Warlop and Alba 2004). On the other hand, consumers dislike copycats when they feel unduly persuaded into buying copycats through similarity tactics (Van Horen and Pieters 2012).

Despite these insights, former research has neglected the possibility that consumers reject copycats due to moral feelings towards the imitated brand. Past work on morality has studied moral concerns related to the behavior of brands towards consumers/workers (e.g., unfair pricing, sweatshop labor; Campbell and Winterich 2018). The reverse relation – moral concerns of consumers towards brands – and the circumstances under which such concerns enter the decision-making process, has received scant attention. Unlike counterfeits, which are illegal and unequivocally immoral forms of imitation (Zaichkowsky 2006), copycats take unfair advantage of the reputation and work of original brands within legal boundaries. Moral concerns towards the original brand might thus be situation-dependent. By examining situational drivers of copycat morality, our work unpacks an underexplored moral process affecting copycat evaluation.

To decode when copycats trigger moral concern, we draw on the theory of moral foundations (Haidt 2007). People hold culturally shaped core moral values that, when being violated, activate moral concern (Hauser 2006). In the present work, we focus on three moral foundations relating to the setting of brand imitation: reciprocity, harm/care and ingroup loyalty (Graham et al. 2011). We posit that when buying copycats violates these moral foundations, consumers feel as they are overstepping moral boundaries. Six preregistered experiments test circumstances that trigger consumers' reciprocity, harm/care, and ingroup loyalty principles and examine effects on moral concern and copycat preference.

According to the reciprocity principle, consumers should consider it wrong to buy copycats when original firms have invested heavily into their product. That is, because increasing the original firms' investment (e.g., in terms of money/time) should accentuate perceptions of unfairly taking advantage (Adams 1963). To test this idea, study 1a created pairs of original fast-moving-consumer-goods that were low (e.g., basic shampoo) versus high (e.g., innovative shampoo) in terms of firm investment. We presented each original product next to its copycat and participants indicated their preference (1 = original to 7 = copycat). As predicted, copycat preference was lower for high-investment (vs. low-investment) products ($t(150)$ = 3.04, $p = .003$). Study 1b replicated Study 1a. In addition, as copycats are typically morally ambiguous products, whereas counterfeits are uniformly considered as morally bad, we examined whether imitation type would moderate the basic effect. As predicted, we detect an interaction between firm investment and imitation type ($F(1, 392)$ = 3.584, $p = .059$). Replicating Study 1a, copycats were less preferred for high-investment (vs. low-investment) products ($F(1, 392)$ = 5.106, $p = .024$). Among counterfeits, investment had no effect on copycat preference ($F < .1$, $p = .663$). Study 1c tested our pre-

diction in a new product category (apparel) and provides process evidence. Besides measuring copycat preference, we also measured moral concern as a mediator (e.g., Buying the copycat would make me feel guilty). Study 1c held quality perceptions constant to rule out such alternative account. Copycat preference was lower for high-investment (vs. low-investment) products (c = -.39, 95% CI [-.41, -.39]). Moral concern fully explained this effect (a*b = -.33, 95% CI [-.47, -.21]).

Next, we examined how activating the moral principle of harm/care shapes copycat preference. People feel morally obliged to protect the weak and vulnerable from harm (Alicke et al. 2008). Therefore, copycats should feel more wrong when they imitate vulnerable/small original firms. Study 2a thus manipulated whether an original lemonade brand was manufactured by a large or small firm (between-subjects). Next, we measured preference for a copycat version of this lemonade and moral concern towards the original as our mediator. As expected, copycat preference was lower when the original firm was small (vs. large; c = .76, 95% CI [-1.03, -.49]). Again, moral concern fully explained this effect (a*b = .63, 95 % CI [-.43, .83]). Study 2b adopted a moderation design to generate additional process evidence. We suggest that consumers feel it is immoral to buy copycats when doing so harms a smaller, vulnerable company. Therefore, the effect of firm size on copycat preference should be stronger among consumers who focus on an action's outcomes (i.e., consequentialists), as compared to an action's moral worth (deontologists), when making moral judgements. Study 2b used the same design as Study 2a including a measure of consumers' moral orientation. As predicted, moral orientation moderated the effect of firm size (β = .072, $t(598)$ = 1.880, p =.061). Among consequentialists (+1SD), the effect of firm size on copycat preference was significant (β = .443, $t(598)$ = 7.228, p <.001). Among deontologists (-1SD), the effect was attenuated (263, $t(598)$ = 4.278, p < .001).

Study 3 explored how activating the moral principle of ingroup loyalty affects copycat preferences. We predicted that copycats that imitate home (vs. foreign)-country brands should trigger moral concerns because, by purchasing knockoffs of "their" brands, consumers betray their own kind. To test this prediction, we varied the country of origin of consumers (Scots vs. Americans; between-subjects) and imitated brands (Scottish vs. American Whiskey; within-subjects) in a 2X2 mixed design. We detected an interaction between these factors on moral concern, $F(296)$ = 36.91, p < .001 and copycat preference, $F(296)$ = 38.34, p < .001. Scots felt that imitating Scottish (American) Whiskey was more unfair (fair) and demonstrated lower (higher) preference for the Scottish (American) copycat. Among Americans, this pattern reversed. Moral concern partially mediated this effect (a*b = -.14, 95% CI [-.23,-.08]).

Our research provides evidence that copycats can trigger a moral process in which consumers perceive that they are morally transgressing against original brands. By identifying several situational drivers of this effect, our findings provide insights as to how brands can combat competition by a copycat.

Consumer Aversion Toward Company Waste: An Environmental Harm-Based Moral Perspective

EXTENDED ABSTRACT

"Waste not, want not" is a well-known adage expressing aversion to waste. Past research echoes this sentiment, finding that consumers are strongly averse to creating waste (e.g., Arkes 1996; Bolton and Alba 2012). However, little is known about how consumers react to others' wastefulness, such as company waste – which is ubiquitous throughout business activities and harms the environment (Cooper 2005). The present research focuses on company waste during product manufacturing, where waste can arise from excess *use* of resources (i.e., inefficient production) and excess *disposal* of resources (i.e., byproducts/ residuals). Consider fashion waste: the production of garments entails the *use* of large amounts of natural resources (e.g., fashion is the second-largest consumer of the world's water) as well as enormous *disposal* of waste (e.g., fashion is also the second-largest producer of water waste) (McFall-Johnsen 2020). How do consumers react to company waste arising from excess use versus disposal of resources?

While prior research has examined aspects of wasteful disposal (Xu, Bolton, and Winterich 2021), less is known about consumer reactions to company's wasteful use of resources – a major contributor to resource depletion and environmental harm (Schandl et al. 2018). We theorize that consumers are relatively insensitive to company's wasteful use of resources compared to equivalent waste in the form of disposal – arising from reduced perceptions of environmental harm and immorality. For example, wasteful use of resources may be less accessible due to the lack of media coverage and government regulations, leading consumers to judge its environmental consequences as less frequent and important (Menon, Raghubir, and Schwarz 1995); it may be less tangible, with its environmental impact less direct and more difficult to visualize, leading consumers to underestimate its severity (Royzman and Baron 2002); and its environmental impact (resource depletion) may seem more future-oriented, leading consumers to discount its harm (Carmi and Bartal 2014; Strathman et al. 1994). Building upon past research on harm-based morality (Schein and Gray 2018), reduced harm perceptions will lead consumers to judge company's wasteful use of resources as less immoral (compared to equivalent waste in disposal), resulting in relative insensitivity to such company waste.

Given this theorizing, we propose two interventions to boost consumer sensitivity to company's wasteful use of resources: educating consumers about the environmental harm of company waste, and making resource scarcity salient. In addition, we examine the flip side of excess company waste, namely waste mitigation or company sustainability initiatives. Given the aforementioned relative insensitivity, we propose that: i) consumers will react less favorably to firm sustainability efforts that focus on reducing resource *use* (compared to equivalent sustainability initiatives focused on reducing *disposal*) and ii) scarcity/harm-based interventions will increase consumer appreciation of such sustainability initiatives.

Study 1 tests our theory in the field. We ran two separate ads as A/B testing on Facebook, featuring water waste in the fast fashion industry. Supporting our theorizing, consumer engagement was significantly lower when the ad featured wasteful use versus disposal (clickthrough rates: 0.38% vs. 0.59%; $\chi^2(1)$ = 5.30, p = .021).

Study 2 uses a controlled lab experiment. Participants read about an apparel manufacturing company with company waste in the form of excess use/disposal of resources; all other aspects of the description were held constant (e.g., type of resource, price and quality of products). Participants then rated their attitudes/intentions toward the company, as well as perceptions of environmental harm and immorality. Supporting our theorizing, consumer attitudes/intentions were less unfavorable when company waste took the form of resource use (M_{use} = 3.58 vs. $M_{disposal}$ = 2.97, $F(1,214)$ = 7.82, p = .006), driven by perceptions of reduced environmental harm (M_{use} = 4.96 vs. $M_{disposal}$ = 5.46, $F(1,214)$ = 4.60, p = .033) and immorality (M_{use} = 3.77 vs. $M_{disposal}$ = 4.46, $F(1,214)$ = 11.04, p = .001), which serially mediated.

As evidence of robustness, we conducted several conceptual replications with i) incentive-compatible scenarios (consequential

DVs), ii) different operationalizations of company waste (e.g., wording and context), and iii) different levels of waste magnitude. We find consistent support for our theorizing and we also rule out alternative explanations based on waste magnitude, price, quality, warmth, and competence perceptions.

Study 3 examines an intervention (educational messaging about how waste harms the environment) in a 2 (use/disposal) × 2 (intervention/control) design using the stimuli of study 2. Analyses revealed a two-way interaction ($F(1,271) = 38.53$, $p < .001$): consumers are less sensitive to company's wasteful use of resources in the control condition ($M_{use} = 3.81$ vs. $M_{disposal} = 2.95$, $t(271) = 5.08$, $p < .001$) but this effect was attenuated after the intervention ($M_{use} = 2.67$ vs. $M_{disposal} = 2.59$, $t(271) = .45$, $p = .650$). Likewise, study 4 examines natural resource scarcity as a moderator in a similar 2 × 2 design and finds a similar two-way interaction ($F(1,312) = 6.10$, $p = .014$): consumers are less sensitive to company's wasteful use of resources in the control condition ($M_{use} = 3.55$ vs. $M_{disposal} = 2.89$, $t(312) = 4.04$, $p < .001$) but this effect was attenuated after the intervention ($M_{use} = 3.19$ vs. $M_{disposal} = 3.10$, $t(271) = .55$, $p = .583$). These results provide support for interventions to boost consumer sensitivity to company's wasteful resource use by educating consumers about the environmental harm of company waste and making resource scarcity salient.

Finally, studies 5A-5C test the flip side of excess company waste, namely company waste mitigation. Consistent with our theorizing, we find that i) consumers react less favorably to company sustainability initiatives that focus on reducing resource use (versus disposal), but ii) a scarcity/harm-based intervention can effectively boost consumer response. We observe these effects in both lab and field studies and with consequential DVs (e.g., Facebook A/B testing).

Together, these studies provide evidence that consumers are relatively insensitive to company's wasteful use of resources (versus equivalent waste in the form of disposal). By shedding light on how, why, and when consumers are differentially averse to company waste, this research contributes to the literatures on consumer waste aversion and waste management, while providing guidance to practitioners and policy makers regarding effective interventions and sustainability initiatives.

Can Voting Reduce Conspiracy Beliefs? Evidence from Two High-Profile U.S. Elections

EXTENDED ABSTRACT

Among the activities that people perform as citizens, voting is arguably the most sacred. Many theorists consider voting to be a moral action, as it is the primary way people influence the government toward the greater good (Brennan 2012). This lens comports with the 2021 ACR conference's theme, "What the World Needs Now," which encouraged research on this societal activity. We studied the potential impact of voting on a mindset with moral implications, conspiracy beliefs. Conspiracy beliefs — thinking that elite groups with immoral intent exert control over important events (Douglas, Sutton, and Chichoka 2017) — offer insights on the current state of consumers' moral concerns (Raab et al. 2013).

We tested whether voting, particularly for the winning candidate, impacts conspiracy beliefs. Voting, election outcomes, conspiracy beliefs share theoretical links. One, embracing conspiracy beliefs can bolster one's sense of control (van Prooijen and Acker 2015), and the act of making choices (i.e., voting) increases perceived control (Botti and McGill 2006). Two, conspiracy beliefs cement on negative, not positive, events (Douglas et al. 2019), suggesting they may abate if one's preferred candidate wins the election.

Two longitudinal studies (Rindfleisch et al. 2008) of highly-contested elections — 2020 U.S. Presidential election and 2021 U.S. Senate runoff election in Georgia — tracked conspiracy beliefs right before the election (Time 1; T1) and after the winners were announced (Time 2; T2). We tested the hypothesis that voting for winning candidates would predict reduced conspiracy beliefs from T1 to T2 compared to those who did not vote or voted for losing candidates.

Study 1 tested our hypothesis with voters in the 2020 U.S. Presidential election, which was highly anticipated and watched around the world. Data collection took place twice; once on November 2, 2020 (T1; one day before the election), and again on November 8-10 (T2). At T1, participants were N=600 U.S. Mechanical Turk adults (44.80% female; $M_{age} = 39.17$, $SD = 11.91$). Among those participants, N=525 (87.50%) returned for T2.

At both T1 and T2, conspiracy beliefs were measured with the Generic Conspiracist Beliefs (Brotherton et al. 2013; T1 α=.96; T2 α=.97) and Conspiracy Mentality Scale (Imhoffs and Bruder 2014; T1 α=.93; T2 α=.94). Scales were standardized and averaged to create a conspiracy beliefs index. At T1, four items measured support for liberal and conservative ideology, and Democratic and Republican candidates (1=not at all; 100=very much so). Liberal/Democrat responses were reversed. Items were standardized and averaged to form a political attitude index (α=.90). Higher scores indicate more conservative attitudes. At T2, participants indicated whether they voted in the election (no versus yes).

Both studies used mixed models, with conspiracy beliefs modeled as the within-subject factor of time (T1 vs T2), political attitudes and voting behavior as between-subjects factors, and random effects for subject-level intercepts. The higher order interaction between time, political attitudes, and voting behavior was significant, $F(1, 521) = 4.05$, $p = .045$, indicating different patterns for voters and non-voters. Among voters, the time x political attitudes interaction was significant, $F(1, 480) = 9.50$, $p = .002$. Slope analyses revealed that conspiracy beliefs dropped significantly from T1 to T2 among liberal voters, $b = -0.118$, 95% CI=[−0.16, −0.075], whereas conservative voters showed no change, $b = -0.023$, 95% CI=[−0.066, 0.02]. Conspiracy beliefs also dropped among non-voters with more liberal attitudes, $b = -0.173$, 95% CI=[−0.342, −0.004]. Non-voters with conservative attitudes showed no significant change, $b = 0.12$, 95% CI=[−0.049, 0.289]. As predicted, liberal voters (supporting the winner, Biden), experienced significant reductions in conspiracy beliefs, whereas conservative voters (supporting the election loser, Trump), were unchanged. Conspiracy beliefs among liberal non-voters also dropped, which was unanticipated. While the gravity of that particular election may have produced that result, Study 2 assessed whether it replicates.

Study 2's Senate election took place just two months after the Presidential election. New research indicates that supporting the winning or losing candidate can have surprisingly long-lasting cognitive and emotional effects (Toshkov and Mazepus 2020), suggesting potential impacts for Study 2's voters. Namely, if Democrats win that means that liberal voters will have experienced two recent election wins; if Republicans lose, their voters have experienced two losses. Accordingly, we predicted that conspiracy beliefs among voters for winners and losers would show decreases and increases, respectively, if the election outcome mirrored the Presidential election.

As before, data collection took place before the election and after results were announced (T1: December 30, 2020 to January 4, 2021; T2: January 7-12). T1 participants were N=314 Prolific workers (57.60% female; $M_{age} = 35.00$, $SD = 13.22$). Of those, N=256 (81.50%) returned for T2. Only residents of Georgia were eligible

for participation. Conspiracy beliefs, political attitudes, and voting behavior were measured as in Study 1.

As in Study 1, we tested whether changes in conspiracy beliefs between T1 and T2 were explained by political attitudes and voting behavior. The interaction of time, political attitudes, and voting behavior was marginally significant, $F(1, 252)=3.60$, $p=.059$. Among voters, the time x political attitudes interaction was significant, $F(1, 200)=8.56$, $p=.004$. The more that voters supported liberal (winning) candidates, the more their conspiracy beliefs dropped, $b=-0.082$, 95% CI=$[-0.158, -0.007]$. By contrast, the more that voters supported the conservative (losing) candidates, the more their conspiracy beliefs increased, $b=0.077$, 95% CI=$[0.001, 0.152]$. Non-voters' conspiracy beliefs did not significantly change, $F(1, 52)<1$, both for those who supported liberal, $b=0.041$, 95% CI=$[-0.100, 0.181]$, and conservative candidates, $b=-0.057$, 95% CI=$[-0.197, 0.082]$.

Two longitudinal studies of high-profile elections showed that voting for winning candidates predicted significant reductions in conspiracy beliefs. Study 1 also documented decreased conspiracy beliefs among non-voters who supported the winning candidate and Study 2 showed stronger conspiracy beliefs among voters supporting losing candidates. The act of making choices and whether one's preferred outcome evinces may be pivotal to understanding what underlies conspiracy beliefs — and how to change them.

SESSION OVERVIEW

Stress is linked to numerous negative health outcomes, including those involving food consumption behaviors. Research has identified stress as a major factor in appetite regulation, addiction relapse, and various maladaptive coping mechanisms (Sinha & Jastreboff 2013). Prior research associates (Cartwright et al. 2003), and experimentally demonstrates (Zellner et al. 2006), that higher levels of stress tend to drive individuals towards more nutrient-deficient, calorie-dense foods. The COVID-19 pandemic represented an unprecedented stressor that significantly impacted well-being and, subsequently, dietary choices and weight gain. In this proposed special session, we start by examining how the COVID-19 situation influenced stress, food choice motives, consumption, and weight gain. We then explore how a practical, cost-effective intervention, mindful eating, may help address some of these issues through reduced consumption of calorie-dense snack foods.

Elevated stress had a negative impact on dietary choices during the pandemic. Not only do these poor dietary decisions put individuals at higher risk for short-term weight, but they also increase their risk of obesity in the long-term, as consumers begin to form unhealthy consumption habits that may persist over time. Mindfulness has been shown to reduce stress and increase subjective well-being (Keng et al. 2011), while also mitigating the impact of stress on behavior (Creswell and Lindsay 2014).

In the first paper, **Falkenstein and co-authors** investigate how stress resulting from the pandemic influenced food choice in the face of temptation through a study on Chinese and French participants a few months after the onset of the pandemic. They found a small negative correlation between stress from the pandemic situation and healthy food choices when faced with tempting alternatives. **Marty and Nicklaus** surveyed a sample of French adults during the first confinement period and recorded food consumption behaviors, along with food choice motives and stress. They found that heightened stress increased the importance of pleasure as a food choice motive in order to self-soothe, leading to poorer diet quality.

In the third paper, **Langlois and Chandon** investigate how perceived socioeconomic status in an American population influenced stress, diet quality, and weight gain during the pandemic. They find that Americans with lower socioeconomic status experienced greater stress, which subsequently reduced exercise, increased food consumption, and reduced diet quality, leading to higher weight gain. Finally, **Tapper and colleagues** show how mindful eating can reduce consumption of calorie-dense snacks by slowing down the rate of eating.

Together, these four papers highlight the importance of studying how stressors such as the Covid-19 pandemic interact with individual differences in eating motives and socioeconomic status to influence food consumption. While all the papers focus on the behavioral components associated with dietary choices, they each provide insights into theoretical and practical means of addressing the overarching issue of overeating.

Does COVID-related stress affect self-control and the ability to make healthy food choices?

EXTENDED ABSTRACT

The Covid-19 pandemic has impacted people's wellbeing, e.g. the demise of close relatives, the lack of social interactions and financial pressures, which has resulted in post-traumatic stress symptoms and depression (Brooks et al., 2020). Such acute stressors lead to the increased release of stress neuromodulators such as noradrenaline and cortisol (Hermans et al. 2014).

In lab experiments, acute stress has been induced by different procedures such as an ice-bucket challenge type cold-pressor task (Schwabe et al., 2008) and a task mimicking a stressful interview situation (Trier Social Stress Test; Kirschbaum et al., 1993). Previous studies found that such acute stress led to less dietary self-control (Maier et al., 2015; Cohen's d=0.6) as well as more impulsive decision-making (Fields et al., 2014, Hedges'g =0.590).

Over time, experienced stress can turn into chronic stress, marked by increased activity of cortisol and an emotional numbing. Chronic stress has been found to induce increased risk-taking be-

havior when using an incentivized lottery paradigm (Ceccato et al., 2016; r=0.18; p=.011).

Here, we investigated whether and how the Covid-19 crisis is an exogenous stressor that impacts healthy food choices, specifically in the eye of temptation.

We preregistered the following Hypothesis for our study:
1. The Covid-19 pandemic leads to increased stress.
2. The Covid-19 induced stress levels correlate with self-control abilities.

Methods

Our study consisted of two parts: (1) An online study was carried out in China and France from June to September 2020, several months after the onset of the COVID-19 pandemic (China onset: December 2019, France onset: January 2020). Participants were asked to make choices between foods and report their stress levels amongst other items. (2) Each participant was also asked to cut and send a hair strain to extract their hair cortisol levels as a biological marker of chronic stress.

Sample:

After applying our pre-registered exclusion criteria, N= 553 participants (77.9% females) were analyzed. Their age ranged from 18 to 65 years (M_{age}= 25.8, SD=6.76). Most (54%) participants earned less than 1000 EUR per month and were students (50.1%). Participants were recruited in China (n = 199) and France (n = 354). Of the Chinese sample, 53 participants were residents in Wuhan, 94 in Beijing, and 52 in Suzhou. Of the French sample, about 44% were from Ile-de-France. The regional distributions were chosen to ensure variance in COVID-19 severity.

Stress Measures:

- Self-report stress level since the beginning of the CO-VID-19
- Self-report stress level at the moment
- Short version of the Trier Inventory for Chronic Stress (TICS) measuring chronic stress (Petrowski et al., 2019)
- Hair cortisol measure as a biological indicator of chronic stress (currently being pre-processed, available at time of conference)

Food choice task:

We used a food choice task adapted from Maier et al., 2015. Participants rated the tastiness and healthiness of different food items. The ratings were used to construct a food choice set for each participant that satisfied the following two characteristics: (1) Half of the trials showed two foods where the tastier item was also perceived as healthier (2) the other half of the trials showed foods where the tastier item was less healthy and thus there was temptation, and self-control was required to make a healthy choice. Each participant made a total of 20 foods choices with the instruction that (1) they should try to make healthy choices and (2) at the end of the experiment one trial could be implemented.

General risk behavior:

We also asked participants about their willingness to engage in risky behaviors using the DOSPERT scale (Blais & Weber, 2006) and specific COVID-19 related risk behaviors (e.g., not wearing masks).

Analysis & Results

1) Did the COVID-19 pandemic lead to increased non-acute stress?

Due to the lack of a "pre-COVID-19 measure" in our study, we compared the self-reported chronic stress-levels of the same short version of the TICS with prior literature conducted in healthy participants (Petrowski et al., 2019). We found that the mean reported TICS in our study was significantly higher than the score in the previous literature ($M_{COVID19\text{-}Study}$=16.55, $SD_{COVID19\text{-}Study}$=5.96 vs. $M_{literature}$=9.42, $SD_{literature}$=6.33, t(3019)=24.11, p<.001). This result indicated an enhanced stress level among our participants.

2) Is the ability to make healthier choices linked to stress?

No associations were found between stress and healthy choices in genera: stress since the pandemic (r(536) = -.07, p = .126), stress at the moment (r(536) = -.02, p = .675), TICS score (r(533) = -.03, p = .484).

3) Is the ability to make healthier choices when self-control is required linked to stress?

When focusing on food choices that require self-control, we find a very low, albeit significant, correlation with pandemic-induced stress (r(539) = -.09, p = .043). This result indicated that stress, induced by the pandemic, negatively influenced individuals' ability to choose healthy foods in the face of temptation. The other two stress measures yielded no significant correlations (stress at the moment: r(539) = -.01, p = .791; TICS score: r(539) = .01, p = .904).

4) Is stress also linked to other risky behaviors?

We found a small yet significant negative correlation between perceived stress since COVID onset and willingness to engage in risky behavior across life domains (r(539) = -.09, p = .035) and risky behavior linked to COVID-19 (r(539) = -.26, p < .001). However, these two measures did not explain our effects of stress on dietary self-control.

Discussion

We found that the higher the COVID-19-induced perceived stress, the lower people's ability to make healthy food choices when self-control is required. However, this negative correlation was very small and did not hold when investigating both countries separately. We found opposite effects for other risky behaviors outside the food domain. Together, our results showed much smaller effect sizes as compared to controlled lab studies. In a next step, we will investigate whether self-control on dietary choice is also linked to biological markers of stress (i.e., hair cortisol levels) and potential underlying psychological mechanisms.

The Impact of Stress Level on Food Choice Motives and Nutritional Quality of Diet During COVID-19 Lockdown in France

EXTENDED ABSTRACT

At the beginning of the COVID-19 pandemic, governmental authorities imposed nationwide lockdowns to avoid fast-growing transmission of the virus. The first lockdown in France took place from March 17th to May 10th, 2020. During this period, most of the population was asked to stay home except for grocery shopping, medical care, legal obligations and physical activity within a 1 km radius. The threat of virus transmission and major disruptions in daily routines caused by the lockdown (e.g., working from home) were likely to lead to negative feelings (stress, loneliness, depression) and to alter food consumption habits. This uncommon situation of drastic changes in the general population gave the unexpected opportunity to study how stress levels may translate into short-term changes in food choice motives and ultimately changes in the nutritional quality of diet.

A sample of 938 French adults (79% women, mean age of 38.7 ± 11.6) completed online questionnaires on Qualtrics at the end of April 2020 (ethical approval delivered by the ethical evaluation committee for research of INSERM, reference: n°20–683, delivered on April 27th, 2020). Participants were asked about their level of stress, loneliness and depression during the lockdown on continuous scales from 0 to 100, and about their perceived level of change in their eating habits: 'yes, a lot' / 'yes, to some extent' / 'yes, a bit' / 'no'. They were also retrospectively asked about their food choice motives and food consumption during the month before and in the first month of the lockdown. The importance of nine food choice motives was assessed during the month before and in the first month of the lockdown: health, convenience, sensory appeal, natural content, ethical concern, weight control, mood management, familiarity, and price, scoring from 1 to 4 (Steptoe et al. 1995; Cottet et al. 2017). Principal component analysis was performed on the difference (during lockdown – before) of the nine subscales scores to define independent motivational components that were likely to change during the lockdown and we identified: 1/ importance of sustainability (+health, +natural content and +ethical concern), 2/ importance of ease (+convenience, +familiarity and +price), and 3/ importance of pleasure (+sensory appeal, +mood management, -weight control). Food intakes were recorded using a food frequency questionnaire including 110 foods, 12 non-alcoholic beverages and 4 alcoholic beverages (Kadawathagedara et al. 2017). Changes in nutritional quality were estimated by comparing the adherence to the French food-based dietary recommendations before and during the lockdown using the simplified PNNS-GS2, scoring from −17 to 11.5 (Chaltiel et al. 2019).

Among the 938 participants, 80% declared having changed their eating habits during the lockdown. A positive association was found between perceived change in eating habits and level of stress ($F_{(3,934)} = 14.17$, $p < 0.001$), loneliness ($F_{(3,934)} = 5.01$, $p = 0.002$) and depression ($F_{(3,934)} = 10.83$, $p < 0.001$). Overall, the nutritional quality of diet significantly decreased during the lockdown compared to the month before (-0.32 PNNS-GS2, 95%CI [-0.47; -0.18]). Despite an increase in fruit and vegetables (+0.59 portion/day, 95%CI [+0.51; +0.68]), pulses (+0.15 portion/week, 95%CI [+0.09; +0.21]), and fish and seafood (+0.14 portion/week, 95%CI [+0.05; +0.22]) consumption, a sharp increase in the consumption of processed meat (+32 g/week, 95%CI [+23; +41]), sweet-tasting beverages (+37 mL/day, 95%CI [+21; +52]) and alcoholic beverages (+8.6 g of alcohol/week, 95%CI [+5.7; +11.6]) negatively affected the overall adherence to the French dietary recommendations.

To explore the relationship between stress, changes in motivational components, and changes in nutritional quality, we conducted a parallel mediation analysis and found a significant indirect effect of a higher level of stress on a decrease in nutritional quality through an increase in the importance of pleasure during the lockdown (-0.0012, 95%CI [-0.0024; -0.0004]). Indirect effects of stress on changes in nutritional quality through changes in the importance of sustainability (0.0005, 95%CI [-0.0002; 0.0014]) or ease (-0.0001, 95%CI [-0.0002; 0.0003]) were not significant. We also conducted parallel mediation analyses with loneliness and depression in the same way, but we did not find any significant association with changes in motivational components or in nutritional quality.

These results highlight the effect of stress in promoting short-term changes in the food decision making process (i.e., redefining the importance of certain food choice criteria) that translate into changes in food consumption and nutritional quality of diet, and ultimately may have an impact on health outcomes. By promoting more pleasure-oriented food choices, a higher level of stress was as-sociated with a decrease in the nutritional quality of diet during the lockdown. Stress, feelings of emptiness, and boredom management by eating were common behaviours in the French population during the lockdown with 63%, 63%, and 57% prevalence in a 1092 sample of French adults, respectively (Cherikh et al. 2020). In the present study, "pleasure" was defined as an enhanced importance of sensory appeal, but also of mood management. Occasional emotion regulation by eating has been associated with the consumption of sweet foods (De Lauzon et al. 2004; Macht 2011) which may explain the negative relationship between changes in importance of pleasure and nutritional quality of diet. In a context where temporary stress due to a specific, time-limited situation seems to negatively impact short-term eating behaviours, the investigation of the role of chronic stress in shaping presumably deleterious long-term eating habits (e.g., in deprived populations) requires major attention.

Explaining the Socioeconomic Gradient of Obesity: A Longitudinal Analysis of the Psychosocial Factors That Led Low Socioeconomic Status (SES) Americans to Gain More Weight During the COVID-19 Crisis

EXTENDED ABSTRACT

Obesity and low socioeconomic status (SES) are two prominent risk factors associated with COVID-19 (Patel et al., 2020; Popkin et al. 2020). If individuals with low SES gained more weight during the early months of the COVID crisis, it would mean that their vulnerability to the virus has further increased. This is particularly concerning given that people with low SES already tend to have a higher body mass than people with high SES (Dinsa et al. 2012; Wang and Beydoun 2007), a phenomenon known as the socioeconomic gradient of obesity.

Although there is strong evidence that SES and obesity are strongly associated in high- and middle-income countries, there is still a lot of uncertainty about why people with low SES are more likely to have obesity. For instance, we do not know whether the socioeconomic gradient is explained by differences in energy expenditures or in energy intake. The literature on the psychosocial explanations for the SES obesity gradient is also inconclusive (Claassen et a. 2019); these authors note that a significant hurdle lies in studies only addressing one or two psychosocial factors, which prevents the comparison of their relative importance in mediating the association between SES and obesity.

To address these concerns, we conducted a longitudinal multi-wave survey measuring subjective SES, weight change and the environmental and psychological factors that may influence their association. We focused on weight change, rather than food choices, to respond to the call for more externally valid studies of obesity in psychology (Holden et al. 2020; Loyka et al. 2020).

Method

We recruited American residents via Prolific in three separate waves from March 2020 to May 2020. A total of 886 respondents (507 Female) participated in all three waves.

The surveys featured self-disclosure questions aimed at understanding changes in health-oriented behaviors, such as diet/eating styles, exercise, social connectedness, and stress, as well as the Three-Factor Eating Questionnaire (Karlsson et al. 2000) and questions about individuals' experiences during the pandemic (e.g., employment status). We measured all the environmental and psychological factors hypothesized to link SES with BMI, as reported in Claassen and colleagues' 2019 review paper. However, we did not measure factors that are not under the control of the participants,

such as the built environment. To rule out reverse causation, SES and psychological factors were measured during the first two waves of the study, whereas weight change was measured in wave 3.

Results

We utilized the MacArthur Scale of Subjective Social Status (Adler et al. 2000) as the independent variable; this scale consists of a 10-point ladder, where the top of the ladder represents those who are the best off (i.e., the most money, education, and respected jobs), while the bottom of the ladder consists of people who are the worst off in American society. Self-reported weight change during the pandemic was the outcome variable. Age and sex were included as covariates in all models. Trichotomized for illustration (but the continuous measure was used in all the analyses).

ows that respondents in the bottom third in terms of SES were more likely to have gained weight and less likely to have lost weight in the six-week interval of the study. We used Hayes' PROCESS (2017) model 4 (bootstrap sample = 10,000, 95% CI) to examine to what extent the link between SES and weight change was mediated by the psychosocial factors mentioned earlier.

Compared to low SES respondents, those with high SES spent more time outdoors, experienced less stress, focused more on the future than on the present, and expected higher future wellbeing. Apart from grocery scarcity, which was not associated with SES, these results are aligned with the literature. Figure 2 further demonstrates that stress was the only mediator to be strongly associated with weight change and, hence, the only factor to mediate the effects of SES on weight change during the pandemic ($M = -.03$, CI = [-.07; -.01]). The residual effects of SES were not statistically significant, indicating full mediation.

To examine whether stress leads to weight gain by reducing energy expenditures or increasing energy intake, we conducted a second mediation analysis using PROCESS model 81 (bootstrap sample = 10,000, 95% CI). Figures 1 and 3 show that stress decreased physical activity ($M = -.04$, $p = .02$), increased portion sizes ($M = .04$, $p = .008$), and led to a decline in the quality of foods consumed ($M = -.06$, $p < .001$). All three indirect effects were statistically significant and fully mediated the effects of stress.

People with lower SES experienced greater stress during the pandemic, which led them to exercise less, eat more and eat less healthily, thus increasing their chances of weight gain. Despite the advantage of the panel structure of the data and the control variables, SES was measured and hence questions about causality and identification remain open. Our more recent work has effectively manipulated subjective SES and is ongoing.

The Effects of Mindful Eating on Snack Intake, Hunger and Eating Rate

EXTENDED ABSTRACT

Background

Mindful eating is often thought to promote healthier eating. A key feature of mindful eating is paying attention to the sensory properties of one's food (such as its sight, smell, taste and texture) and a number of studies have found this reduces subsequent intake of high calorie snacks (Allirot et al. 2018; Arch et al. 2016; Higgs & Donohoe 2011; Robinson et al. 2014; Seguias & Tapper 2018; Tapper et al. 2018). However, the mechanisms underlying this effect are unclear and several other studies have failed to find such effects (Arch et al. 2018; Whitelock et al. 2019; Whitelock et al. 2018; Seguias & Tapper under review; Tapper & Sequias 2020). In this study

we (a) sought to replicate the effects of mindful eating on subsequent snack intake and (b) explored the possibility that effects are brought about by a reduced rate of eating. Previous research has shown that a slower eating rate is associated with lower food intake (Robinson et al. 2014), possibly because of increased orosensory exposure (i.e., food is in the mouth for a longer period of time) which promotes the release of gut hormones that in turn reduce appetite (Hawton et al 2019; Krop et al. 2018). We explored the possibility that mindful eating leads people to eat less of a subsequent snack because (1) they have eaten more slowly so feel less hungry, and/or (2) carryover effects mean they also eat the subsequent snack more slowly.

Methods

A total of 211 females were randomised to one of three conditions: mindful eating (MIND), slow eating (SLOW), normal eating (CONTROL). After completing a filler task, rating their current hunger level and answering questions on demographics, all participants were asked to eat a 30g portion of cookies that had been broken into 12 pieces. Those in the MIND and SLOW groups were asked to eat one cookie piece each time they heard a beep. The beeps were sounded every 15 seconds. For those in the MIND condition, each beep was also followed by an instruction to attend to a specific sensory property of the food (such as its taste or texture). Those in the CONTROL group were simply asked to eat the cookies in the absence of any beeps or instructions. Participants then rated their hunger for a second time and completed additional filler questions, before being presented with 60g of cookie pieces and 30g of crisps for a supposed taste test. They were asked to rate the cookies and crisps on a number of dimensions and told they could eat as many as they liked since the remainder would be thrown away. The researcher then left the room for 5 minutes. On the researcher's return, the participant was asked to rate their hunger for a third time as well as the extent to which they paid attention to the smell, taste and texture of the first cookie snack and to the snacks in the taste test. They also completed a funnelled debrief to check for suspicion. To allow for assessment of eating rate, participants were recorded via a webcam from the start of the study until the point at which the researcher returned to the room following the taste test. Study procedures and analysis were pre-registered at https://osf.io/xbjpt.

Results

One participant withheld consent, 18 guessed their food intake was being measured and there were protocol deviations for a further 25 participants. Video recording errors occurred for an additional 16 participants. Excluding these left a total sample of 167 for the analysis of food intake and 151 for the analysis of eating rate. Mean snack consumption in the taste test was 25g ($SD = 17$) in the MIND condition, 25g ($SD = 20$) in the SLOW condition and 34g ($SD = 21$) in the CONTROL condition. These means were significantly different ($p = 0.014$, $\eta_p^2 = 0.051$) and post-hoc tests confirmed that food intake was lower in the MIND compared to the CONTROL condition ($p = 0.028$, $d = 0.50$) and in the SLOW compared to the CONTROL condition ($p = 0.027$, $d = 0.48$) but that there was no difference between the MIND and SLOW conditions. However, there were no significant group differences in hunger following the first cookie snack. Participants in the MIND condition reported paying significantly more attention to the smell, taste and texture of their first cookie snack compared to participants in the SLOW and CONTROL conditions ($p < 0.001$, $d = 1.13$ and $p < 0.001$, $d = 1.03$ respectively), but there were no group differences during the taste test. Nevertheless, rate of consumption, calculated in bites per minute from first to last bite, showed a trend toward a group difference ($p = 0.055$, $\eta_p^2 = $

0.038) with a slower rate of eating in the MIND compared to the CONTROL condition ($M = 4.75$, $SD = 1.47$ and $M = 5.51$, $SD = 1.83$ respectively, $p = 0.068$, $d = 0.45$).

Discussion

The results support previous studies showing effects of mindful eating on subsequent snack intake. The fact that equivalent reductions in intake occurred when participants simply ate at a slower rate is consistent with the view that effects are brought about by increased orosensory exposure. Although this slowed rate of eating was not associated with greater reductions in reported hunger, it is possible our measure of hunger was not sufficiently sensitive to detect such changes. Whilst eating the subsequent snack, those in the mindfulness group did not report paying more attention to their food but they did show a trend toward eating more slowly. These results suggest that although there may not be cognitive carryover effects from mindful eating (in terms of attention) there may be behavioural ones (in terms of a slowed eating rate). Since mindful eating may also increase the amount of pleasure obtained from food (Seguias & Tapper under review), it could be an effective and sustainable strategy for slowing eating rate, which could in turn help protect against weight gain. Nevertheless, further research is needed to confirm carryover effects on rate of eating and to examine effects outside the laboratory and over longer periods of time.

SESSION OVERVIEW

Consumers make myriad choices daily – how to spend time, whether to save, whether to give, and whether to consume different products. The choice architecture of how these decisions are structured may have substantial influence on the nature of those decisions, nudging certain behaviors. Advocates of choice architecture are now situated broadly, from high levels of government to consulting practices to market managers. As we consider what the world needs now, one potential answer is more deployment of choice architecture to promote the social good. However, the question may arise: how effective is choice architecture?

The proposed session explores this topic across four empirical papers. The first paper from Shah and colleagues examines this question in the domain of retirement savings. Using a large field study (N=126,673), they identify heterogeneity in responses to a nudge designed to promote savings – simplification. Using follow-up laboratory experiments, they find that reducing informational complexity via simplification increases attention and recall of information on the form.

The second paper from Reeck and colleagues examines this question in the context of digital contact tracing apps for COVID-19. Such apps can help stymie the spread of COVID-19, and most people indicate support for such apps. However, their adoption rates are low.

One reason for this may be the choice architecture of the app design, which makes enabling the app properly more difficult. Across four pre-registered experiments (N=2,613), we demonstrate that the choice architecture of the app design has substantial influence on the likelihood that consumers enable the app. Indeed, the effects we find are even larger than some traditional nudges, such as changing defaults.

The third paper from Habib and colleagues examines how choice architecture can be used to promote charitable giving. Charities in the early stages of fundraising often have difficulty attracting donors. Across four studies and one large dataset, the authors demonstrate that jointly as opposed to separately evaluating charities increases donations to those at earlier stages of fundraising. Joint presentation makes it easier to evaluate options and make comparisons, highlighting the relative neediness of the charity with less progress towards its goal.

The fourth paper from Rai and colleagues examines how choice architecture can be used to alter how consumers spend their time and increase volunteering. In a pre-registered field experiment (N=9,108), trained volunteers were assigned to receive either temporally reframed goals (e.g., volunteering 4 hours each week) or a control condition (e.g., volunteer some hours each week). Temporal reframing produced a significant 8% average increase in volunteer hours. The magnitude of this boost was consistent throughout the 12-week intervention period and did not vary by gender, volunteer tenure, or prior volunteering levels.

Together, these papers demonstrate the effectiveness of choice architecture at shaping consumer behavior across a range of domains. At the theoretical level, these papers contribute to basic theories of consumer attention, motivation, and decision making. Practically speaking, this work has broad implications for what the world needs now, from public health to volunteers.

What is the Impact of Simplification of Information on Pension Contributions? It Depends!

EXTENDED ABSTRACT

People regularly fail to save enough for retirement. There are several barriers and obstacles that prevent individuals from forgoing consumption today in order to secure a better financial pathway for the future. For many individuals, the sheer complexity of comparing the rates of various savings options (e.g., a traditional bank savings account versus a retirement savings account), calculating how much a contribution would accrue over time, and determining where and how to make a contribution can all be substantial obstacles that prevent individuals from saving.

In response to these cognitive and procedural barriers, researchers and practitioners have routinely advocated for simplifying basic forms and notices. A recent meta-analysis found that simplification was one of the most common nudges used by policymakers, used as a behavioral lever in a whopping 36% of nudge unit trials (DellaVigna and 2021). Simplifying forms via improving the visual appeal, personalizing the communication, adjusting framing or formatting of existing communication, or including planning prompts that provide clear action steps have motivated action across a broad range of behaviors such as take-up of welfare benefits and submission of financial aid assistance for university (Bhargava and Minoli 2015; Bettinger et al 2012).

While different strands of research have found evidence that simplification is beneficial at a broad-level, there is limited work to determine whether simplification is always effective at improving behavior and whether it will always yield positive effects. This is particularly important as most previous research documenting the effectiveness of simplification have found mainly positive effects and have focused on cultural contexts where there is a social norm to save for, and even have, a retirement. To study this substantive problem, we aimed to test the effectiveness of several behavioral interventions aimed at simplifying information on retirement savings.

Specifically, we collaborated with two different retirement providers (N=126,673)—one that was ranked highly in rate of returns relative to its peers and one that was ranked lower though had very high customer satisfaction ratings relative to peers, and tested whether simplified retirement account statements improved retirement savings contributions relative to the standard, status quo statement typically used. A representative set of account holders from each firm were randomly assigned to receive either a standard retirement account statement, which served as the control group, or one of four simplified retirement account statement forms that included a behavioral nudge intervention (i.e., gain frame, loss frame, future visualization prompt, or a wallet cutout providing an action checklist of steps to make a contribution).

Regardless of firm or treatment group, all statements contained information on their current account balance, projected monthly income at the time of retirement, the firm's absolute rate of return, and how the firm compared relative to other government approved retirement firms, and how individuals could make additional savings contributions if they so choose. The treatment interventions were not significantly different from one another across any the measures (*p's* > .71), thus allowing us to present results by each intervention and collapsed across the four intervention groups.

The effectiveness of simplifying the account statement was highly dependent on the firm. For the higher-ranking firm, all of the simplification interventions increased the likelihood of making a voluntary retirements savings contribution and the amount they contributed. For customers in the high-ranking firm, each of the four simplification treatment interventions significantly improved contribution likelihood and contribution amount relative to the control by 39% (*p's* <.022). Receiving the simplification intervention statements also improved contribution amounts, both in terms of aggregating across conditions (*B*=.026, *SE*=.008, *p*=.001), as well as individually, (*p's* <.036). Relative to the standard account statement, receiving a simplified account statement increased total contribution amounts by 43%.

However, when looking at results from low-ranking firm customers, we found a significant backfire effect of simplification. For low-ranking firm customers, the same interventions significantly decreased the likelihood of making a retirement contribution by just over 30% relative to the standard form (*z*=-2.37, *p*=.018). Simplifying the forms also produced backfire effects on total contribution amounts, significantly lowering savings by roughly 4%, *B*=-.010, *SE*=.005, *p*=.035.

To determine what drove this difference, we conducted further laboratory studies. First, we found (N=299) that not only were simplified retirement account statement perceived as easier to understand than the standard account statement (*p* = .023), but there also changed the attention and recall of information of the forms relative to the control statement. Individuals given the simplified form spent significantly more time reading the form and were more likely to accurately recall information relative to the control statement (Time Spent: $M_{Simplified\ Form}$ = 30.6 seconds, $M_{Standard\ Form}$ = 20.0 seconds,

$t(297)$ = 2.98, p =.003; Recall Accuracy: $M_{Simplified\ Form}$ = 38.7%, $M_{Standard\ Form}$ = 3.4%, $z(297)$ = 7.49, p <.001). Thus, simplification may unintentionally turn individuals' attention to negative information such as the ranking information more easily than those who received standard forms, in turn leading individuals to be less likely to save for retirement than if they had received the more complex form.

Across two field experiments and a follow-up laboratory experiments, we find that reducing informational complexity via simplification increases attention and recall of information on the form. However, this does not always yield positive results. When simplification increases the attention and salience of negative information (e.g., the firm is lower ranked on a particular attribute relative to other firms) then simplification can be detrimental, significantly decreasing retirement savings and motivation to save for the future relative to more complex or obfuscated forms. From a theoretical perspective, our work contributes to research on the importance of informational fluency on decision-making. Although normative models propose that decision-makers weight cues by their objective validity, our work demonstrates that this is not the case. Simplification can increase the probability that decision-makers even engage with and recall information. At a broader theoretical and substantive level, our work shows the importance of scaling interventions and how they interact within the context of the decision environment–in this case, the firm's rank relative to others.

Nudging App Adoption: Choice Architecture Increases Consumer Adoption of COVID-19 Digital Contact Tracing

EXTENDED ABSTRACT

In 2020, a novel coronavirus ravaged the world, causing a global death toll of over 3.1 million. A new technology developed for smartphones, called digital contact tracing (DCT), enables faster detection and treatment by informing people about their exposures to infected individuals. Widespread usage of DCT has had tremendous impact in China and other countries. It has been estimated that DCT apps in China saved over 150,000 lives and reduced economic losses by 2% of GDP (Xiao, 2020). Surveys in many countries showed a substantial willingness to adopt DCT (Altmann et al., 2020; IGHI, 2020). Actual adoption has been much lower in most countries, however. We investigate a key aspect that could partly explain why so few people adopt and enable these apps, namely the way privacy decisions are presented in these apps. Prior research has demonstrated that privacy preferences are largely constructed (Acquisti, Brandimarte, & Loewenstein 2015; Bellman, Lohse, & Johnson, 1999; Lichtenstein & Slovic, 2006), meaning that people do not have a stable privacy preference stored in memory, but rather assemble a preference when making decisions. This implies that changes to the way a decision is presented, termed *choice architecture* (Thaler & Sunstein, 2008), could drastically influence privacy decisions and whether they enable DCT apps. Thus, the design of DCT apps may impact how many people adopt and enable them.

The choice architecture of DCT (and smartphone apps more generally) involves several aspects. One important feature is whether choices about privacy are separated into multiple decisions or integrated into a single decision. We hypothesized that integrating these into a single decision would make people more likely to enable these apps. We also hypothesized that we could facilitate adoption by formatting adoption *as if* it was the default response without actually changing what happens if no choice is made. Unlike previous research, we simply manipulate whether an option is phrased as if it is the default response, without pre-selecting an option.

We examined the influence of the choice architecture of DCT apps across four pre-registered experiments. Participants in Experiment 1 (n=509) were presented with a simulated app installation and asked whether they would enable certain app features. We varied how the options were presented using a 2 (default format: opt-in vs. opt-out format) × 2 (integration: integrated vs. separated) between-subjects experimental design. Analyses revealed the opt-out format more than doubled uptake compared to the opt-in format. About 28% of participants enabled the app in the "opt-in format" condition, whereas 79% enabled the app in the "opt-out format" condition, z=10.86, Exp(B)=9.74, p<.001. Despite not actually changing the default in this experiment, the default formatting manipulation had a large effect. In fact, the effect was larger than the average effect in a meta-analysis of experiments where defaults are actually changed (Jachimowicz et al., 2019). Integrating the disclosures and feature decisions into a single choice also increased adoption. Specifically, 59% of participants fully enabled the app in the integrated condition, compared to 49% in the condition with separated disclosures and privacy decisions, z=2.21, Exp(B)=1.59, p=.027. In Experiment 2 (n=503) we replicated these effects and demonstrated they were robust across political party affiliation, health status, age, race and income.

In Experiment 3 (n=565), we separated two components of the default format manipulation. Specifically, we predicted that the "opt-out format" made people more likely to enable the app partly because of the opt-out wording itself and partly because the color and position align with options that are habitually chosen in smartphone environments. Additionally, we sought a sample in states that had recently launched a DCT app. We added one condition to isolate whether the effects of default formatting were driven by the opt-out wording, the habit cues (color and position) that typically accompany default options on smartphones, or a combination of these. As predicted, there was a large effect of default formatting, consistent with Experiments 1 and 2, z=6.36, Exp(B)=2.22, p < .001. Furthermore, the condition that isolated "opt-out wording" indicated that this wording alone increased the percentage who enabled the app, compared to the "opt-in wording" (from 51% to 67%, z=3.32, Exp(B)=1.41, p<.001). The percentage who enabled the app was even higher in the opt-out frame condition that also used the typical color and position of default options (82% vs. 67%), z=3.56, Exp(B)=1.57, p<.001. This is consistent with our explanation that the percentage of people enabling the app would be highest when opt-out wording is used along with color and positions that are typically chosen in everyday smartphone environments.

In Experiment 4 (n=1036), we manipulated the color and position of buttons that would enable exposure notification app features. This would allow us to isolate two components of the effect and determine whether blue color or right position (or both) influences adoption. Options to enable an app feature are typically presented in blue or on the right side of an app installation screen, which suggests that either the blue color or the right position could activate habits that cause users to quickly select the button. Presenting the enable button in blue rather than grey increased the percentage of participants who enabled the app features (M_{blue}=88% enabled; M_{grey}=83% enabled, z=2.36, Exp(B)=1.53, p=.018). There was not a significant effect of position, contrary to our hypothesis (M_{right}=87% enabled; M_{left}=84%, z=1.57, Exp(B)=1.32, p=.116).

Digital contact tracing has tremendous potential. In almost every industrialized country, the requisite technology has been developed and attitudes towards DCT are positive (Altmann et al., 2020). In the present research, we demonstrate that the design of DCT apps has a substantial influence on their uptake and whether consumers

enable them properly. Importantly, these effects are achieved without altering defaults. These findings have theoretical implications for behavioral interventions, policy relevance, and practical implications for the uptake of other types of apps as well.

Joint vs Separate Evaluation as a Choice Architecture Tool to Support Needy Charities

EXTENDED ABSTRACT

Charities and individuals often struggle to raise funds in initial stages. Without the backing of existing supporters to provide social proof (Cialdini and Goldstein 2004; Cialdini and Trost 1998) and the high levels of progress that lead to beneficial goal gradient effects (Cryder, Loewenstein and Seltman 2013; Kivetz, Urminsky and Zheng 2006) such charities may falter in their efforts to raise money. We introduce a simple intervention to increase donations to a charity with lower levels of goal progress. In four studies (three preregistered) and one large dataset, we show that asking people to evaluate multiple charities jointly (rather than a single charity on its own) shifts giving to the charity further from its goal. This occurs because presenting charities jointly makes it easier to evaluate options and make social comparisons (Hsee 1996; Ordabayeva and Chandon 2011), highlighting the *relative neediness* of the charity with less progress towards its goal.

In study 1 (N = 100, Prolific, preregistered) we demonstrate our main predicted effect - that people give more to a charity further from its goal in joint evaluations. Participants were shown two organizations jointly, one was further from its goal and had raised $300 out of $3000 and another was closer to its goal and had raised $2700 out of $3000. Both the names of the organizations and their position (left vs right) were counterbalanced in all studies. Participants indicated their likelihood of donating and how they would divide $100 between the two organizations. Participants were more likely to donate, (M = 4.60), t(96) = 2.96, p = .004, and donated more, (M = $58.14), t(96) = 2.79, p = .006, to the organization that had raised less money and had lower progress.

Study 2 (N = 500, MTurk) tests which types of comparisons lead to greater donations to the charity with less funds. All participants were shown two charities that had raised the same amounts as in study 1 - $300 and $2700. The charities either had relatively different levels of progress (e.g., 10% vs 90% as in study 1) or consistent levels of progress (e.g., both at 10%) or no goal information was given. Participants were more likely to donate to the charity that had raised less money when its relative level of progress was lower, t(199) = 2.94, p = .004, but not when it had the same levels of progress as the charity with more funds, t(200) = 1.16, p = .25. This study shows that donations shift to the charity with less funds only when it has lower progress than the comparison charity.

Study 3 (N = 300, Prolific, preregistered) compared joint vs separate evaluations in a 3 (Evaluation type: Joint vs Separate far vs Separate close) factor design. In this study the organization close to its goal only needed £70 to reach it and was clearly labelled as having "£70 to go". Participants determined how an actual £100 donation would be distributed and thus could be the donor who completed the goal (consequential DV). A hybrid t-test (Hsee 1996) revealed that respondents were more sensitive in JE than SE to whether an organization was close to vs far from its goal, t(297) = 5.28, p < .001. In JE, respondents donated significantly more to the organization that was further from its goal than close to its goal (M_{far} = £65.05), t(99) = 5.42, p < .001. Mediation analysis revealed that perceptions of need mediated the effect of joint vs separate evaluation on donations to

the organization far from its goal, β = 4.28, 95% CI[1.63, 7.30] but not the organization close to its goal β = -1.48, 95% CI[-4.11, .82].

Study 4 (N = 541, Prolific, Preregistered) tested joint vs separate evaluations with individuals (rather than organizations) in a design similar to study 2. In order to test if our effects were due to our particular design, we used a scenario from a previous study (Cryder et al. 2013). Participants read about student(s) selling candy to raise money for their school sports team fundraiser. In the joint evaluation condition both students were presented, and one student was close to her goal (needs to sell 2 more candy bars) while the other was far from her goal (needs to sell 32 more candy bars). In the separate evaluation conditions only one student was presented, either close to or far from her goal. We then asked participants their likelihood of buying candy from each student. A hybrid t-test revealed that participants were more sensitive in JE than in SE to progress towards the goal, t(483) = 7.33, p < .001. In JE, they were more likely to buy from the student that was further from her goal (M = 5.92) than close to her goal (M = 4.64), t(169) = 7.40, p < .001. In SE, there was no effect of goal progress on purchase likelihood, t(314) = 1.24, p = .22.

These results are supported by real donation data on small donors that we pulled from Kiva.org, a micro-crowdfunding site. A fixed-effects model predicted percentage change in progress levels from current progress levels, search order ranking of each project (which approximates donor's likelihood of encountering it) and project ID as a fixed effects estimator. When controlling for search order in a fixed effects model, current levels of progress negatively predicted progress towards the goal, β = -1.44xe-06, SE = 5.10xe-07, t = 2.82, p < .005, indicating that projects with lower levels of current progress were likely to make greater progress towards their goal.

Overall, our results provide converging evidence that joint presentation of charities can effectively shift donations to the one further from its goal. In doing so, we contribute to work on the goal gradient hypothesis, social influence, charitable giving, and evaluation mode by demonstrating the circumstances in which people are drawn to organizations that demonstrate lower levels of progress. This work provides insight for charities, and crowdfunding sites to nudge funds to where they are needed most using a simple change in presentation format.

Temporal Reframing Boosts Productivity: A Field Experiment

EXTENDED ABSTRACT

Motivating workers to invest sustained effort toward long-term goals is an important challenge for organizations and policymakers. In recent years, behavioral science has succeeded in generating cost-effective nudges to boost performance on "set it and forget it" goals, such as increasing retirement savings and charitable giving (Cronqvist, Thaler, & Yu, 2018; Thaler & Benartzi, 2004; Breman, 2011). However, unlike nudging a one-time choice, productivity requires repeated decisions to allocate effort towards a target while resisting procrastination, avoiding planning errors, and overcoming forgetfulness (Wieber & Gollwitzer, 2010; O'Donoghue & Rabin, 1999; Zauberman & Lynch 2005; Chasteen, Park, & Schwarz, 2001). In the current investigation, we test whether a *temporal reframing* nudge—breaking down large, long-term goals into an equivalent series of smaller, short-term subgoals—can produce sustained increases in productivity.

Prior research has shown that temporal reframing influences one-time financial decisions by reducing the perceived costs of making lump sum payments. For instance, people are more likely to sign up for a savings program framed as setting aside $5 per day than

$150 per month (Hershfield, Shu, & Benartzi, 2020) or to report they would donate $1 per day than $350 per year (Gourville, 1998). We propose that temporal reframing can also durably increase productivity in the field, because smaller subgoals should be seen as more easily achievable, while also making goal progress feel greater, and creating more imminent and frequent deadlines (Bandura & Schunk, 1981; Soman & Shi, 2003; Ariely & Wertenbroch, 2002). On the other hand, temporal reframing of long-term goals might backfire if the immediate reward of achieving a subgoal breeds complacency (Huang, Jin, & Zhang, 2017; Amar, Ariely, Ayal, Cryder, & Rick, 2011). Subgoals also generate more opportunities to fail on any individual goal, and goal violations can lead to degraded performance and even goal abandonment (Soman & Cheema, 2004; Cochran & Tesser, 1996).

To evaluate the potential of temporal framing as a productivity nudge, we conducted a large, pre-registered (https://osf.io/fyhbx/files/) field experiment. We partnered with Crisis Text Line (CTL), a national non-profit organization that provides free crisis counseling via text message. Anyone who sends a text message to CTL's hotline number is connected with a volunteer trained to discuss the issues brought up by the texter, engage in active listening and collaborative problem-solving, and help develop a plan to ensure the texter's safety. Texters use CTL's service for a wide variety of crises, including suicidal ideation, mental health challenges, and abuse. In order to volunteer for CTL, candidates undergo a screening process and 30 hours of web-based crisis counseling and intervention training. They also commit to a goal of completing 200 hours of volunteering within a year. However, as of October 31st, 2019, fewer than 5% of volunteers who had been with the organization for at least a year had met their 200-hour commitment. Our primary aim was to test if temporally reframing the 200-hour annual commitment would durably increase volunteer productivity.

We randomly assigned 9,108 CTL volunteers to three different experimental conditions. In the *4 hours every week* condition (n = 3,037), volunteers received emails encouraging them to reach their 200-hour goal by volunteering "four hours every week." In the *8 hours every two weeks* condition (n = 3,036), volunteers were encouraged to reach their 200-hour goal by volunteering "eight hours every two weeks." Finally, in the *control* condition (n = 3,035), volunteers were encouraged to reach their 200-hour goal by volunteering "some hours every week." Thus, although the two treatment conditions reframed the 200-hour goal into an equivalent series of smaller subgoals, the *control* condition did not temporally reframe the 200-hour goal; it maintained CTL's standard messaging about volunteers' commitment to the organization. Our intervention was delivered through 6 emails, sent over the course of 12 weeks, all via CTL's usual email system for communicating with volunteers.

Our study's primary, pre-registered dependent measure was the average number of minutes a participant volunteered for CTL in a given week during our study period. Compared to the control condition, either version of the temporal reframing treatment produced about an 8% average increase in hours logged on the counseling platform, and this difference was statistically significant. The magnitude of this boost was consistent throughout the 12-week intervention period and did not vary by gender, volunteer tenure, or prior volunteering levels.

This field experiment demonstrates the substantial and durable benefits of temporal reframing on productivity. Our study suggests that temporal reframing is a costless and autonomy-preserving nudge that can be used to substantially increase productivity. Further, our findings contribute to a small but growing literature on the benefits of nudging repeated choices—such as using social comparison in-

formation to reduce energy consumption (Allcott & Rogers, 2014), real-time feedback to promote water conservation (Tiefenbeck et al., 2018), symbolic rewards to boost volunteer engagement (Gallus, 2017), and wage framing effects to increase factory workers' productivity (Hossain & List, 2012). Our field experiment also advances the nascent literature on temporal reframing (Gourville, 1998; Hershfield, Shu, & Benartzi, 2020). Rather than diminishing over time or even backfiring, we document the objective and universal benefits of this simple nudge to boost sustained effort exerted towards goals over a 12-week period.

SESSION OVERVIEW

Gift-giving is an important area of study for consumer psychologists for several reasons: Good gifts bestow consumers with lots of happiness and strengthen their relationships with others, while poorly-chosen ones do the opposite (Goodman and Lim 2014; Ruth, Otnes, and Brunel 1999); billions of dollars are spent on gifts each year; and gift-giving research can inform other vital areas of consumer psychology, such as construal level theory (Baskin et al. 2014) and judgment and decision-making (Steffel and LeBoeuf 2014), among other areas. Thus, there are many good reasons gift-giving has recently received increased attention from consumer psychologists (see Galak, Givi, and Williams 2016). Building on prior work in this domain, the manuscripts in this symposium inform and extend the field's understanding of gift-giving and, collectively, highlight the *multifaceted* nature of gift-giving.

Givi and Williams study gift-giving across *multiple perspectives*; that is, across the giver's and the recipient's perspective. In particular, they explore givers' and recipients' preferences for *personal* gifts—those intended to be enjoyed by only the recipient—versus *shared* gifts—those intended to be enjoyed by the recipient and someone else. They find that givers do not give shared gifts nearly as often as recipients prefer, in part because givers hold exaggerated concerns that shared gifts might make recipients feel less special than personal ones, and in part because givers worry that shared gifts violate gift-giving norms.

Chen, Petersen, and Lowrey investigate givers' emotions across the *multiple motivations* for gift-giving. Specifically, they examine the gifting motives of altruism, egoism, and social-norms-compliance, and they find that altruism leads to both the highest level of positive emotions and the lowest level of negative emotions. In other words, whereas previous work shows that recipients' emotions can vary across different situations, this research demonstrates that the same is true for givers.

Ganesh Pillai and Krishnakumar study consumers' charitable gift-giving tendencies across *multiple levels* of Machiavellianism

and closeness (to the organization). They find that givers higher in Machiavellianism give considerably less but that this is moderated by closeness: when givers feel close to the organization, Machiavellianism severely hinders giving, but when they feel distant from the organization, Machiavellianism has little effect on the amount given. Moreover, for givers higher in Machiavellianism, beliefs about the organization's ability to reciprocate amplifies the inhibitory effect of closeness on the amount given.

Baskin, Gunasti, and Weinberger delineate how gift-giving spans *multiple stages*. Specifically, they extend the classis Sherry (1983) model of gift-giving (which included the stages of Gestation, Prestation, and Reformulation) to create a more nuanced model. This expanded model (also) includes the stages of Gift Realization, Secondary Reformulation, and Storage, and thus paints a more complete picture of the gift-giving endeavor.

In summary, these manuscripts (all of which are in the advanced stages) explore novel aspects of gift-giving and, together, illuminate the multifaceted nature of gift-giving. Given the manuscripts' diverse perspectives, this symposium should appeal to a wide audience, including those interested in gift-giving, self-other decision making, norms, motives, emotions, individual differences, multi-method research, and prosocial behavior.

Gifts That Please Many but Are Given by Few: How and Why Consumers Do Not Give Enough Shared Gifts

EXTENDED ABSTRACT

Most gifts are given to one specific person. But despite having singular recipients, the items that consumers receive as gifts are often enjoyed by multiple people: a mug can be used by anyone who needs a hot drink, a candle makes a room welcoming for everyone, and so on. Our research expands on existing work on giver-recipient asymmetries (Galak, Givi, and Williams 2016) by exploring gift givers' and gift recipients' preferences for *personal* gifts—those intended to be used by only the recipient—versus *shared* gifts—those intended to be used by both the recipient and someone else. Specifically, we show that givers do not give shared gifts nearly as often as recipients prefer. Further, we demonstrate that this occurs because givers hold exaggerated concerns that shared gifts might make recipients feel less special than personal ones, and because givers worry that shared gifts violate gift-giving norms.

Studies 1A-C were initial examinations of givers' and recipients' preferences for personal versus shared gifts. In Study 1A, participants imagined being either the giver or the recipient of a birthday gift between them and a hypothetical friend. They indicated their preference between a *personal* gift of a set of eight "solo" passes for classes at a gym (to be used only by the recipient) and a *shared* gift of a set of four "buddy" passes (to be used by the recipient and a different friend). In Study 1B, participants thought of an actual friend and considered either giving or receiving a birthday gift. They indicated their preference between a *personal* gift of a high-quality cocktail glass that would be customized with the recipient's initials and a *shared* gift of a set of two average-quality cocktail glasses, where one would be customized with the recipient's initials and the other with the recipient's significant other's initials. In Study 1C, participants again thought of an actual friend and considered either giving or receiving a birthday gift; however, their choice of gift was

consequential such that some participants' choices were realized. They chose between a *personal* gift of a set of three glasses (cocktail, stemless wine, beer) that would be customized with the recipient's initials and a *shared* gift of a set of two glasses (both wine), where one would be customized with the recipient's initials and the other with the recipient's significant other's initials. Across the three studies, givers gave the shared gift less often than recipients preferred (Study 1A: Giver = 32% vs. Recipient = 48%, *p* =.007; Study 1B: Giver = 64% vs. Recipient = 80%, *p* =.005; Study 1C: Giver = 37% vs. Recipient = 57%, *p* = .001).

Study 2 examined the reasons for givers' hesitance to give shared gifts and tested whether givers might be more likely to give shared gifts to recipients to whom they feel especially close. Participants considered exchanging either a *personal* cocktail glass or a *shared* cocktail glass set as a birthday gift with a real friend, one they either felt close to, or one they felt less close to. Participants also indicated the extent to which each gift would make the recipient feel special and violate gift-giving norms (*1 = Not at all, 7 = Very much*). We created difference scores for each measure by subtracting ratings for the personal gift from ratings for the shared gift. Givers gave the shared gift less often than recipients preferred (Giver = 54% vs. Recipient = 74%, *p* < .001). The difference scores suggested that this occurred in part because givers overestimated the extent to which the shared gift would make the recipient feel less special compared to the personal gift (M_{giver} = -.79 vs. $M_{recipient}$ = -.26, *p* = .002, mediation CI$_{95\%}$ = [-.97, -.19]), and in part because givers held a stronger opinion than recipients that the shared gift would violate gift-giving norms (M_{giver} = +.49 vs. $M_{recipient}$ = -.12, *p* < .001, mediation CI$_{95\%}$ = [-.52, -.06]). Giver-recipient closeness did not affect the results.

The previous studies used the recipient's birthday as the gifting occasion. When it comes to birthdays—and many other gift-giving occasions, such as Mother's Day, retirements, and so on—the occasion is celebrating one, specific person: the recipient. But certain other gift-giving occasions celebrate both the recipient and someone else, so making the individual recipient feel special is unlikely to be a giver's top priority. For example, a giver contemplating what to give to a married friend as a housewarming gift is likely to have both people in the couple in mind, even if the giver's friend is the only member of the couple who will actually receive the gift. Moreover, for these sorts of occasions, shared gifts are, presumably, more the rule than the exception, so givers' concerns about violating gift-giving norms should not apply. To that end, Study 3 tested whether givers' choices are more aligned with recipients' preferences when the gift-giving occasion celebrates more than just the direct recipient of a gift. Participants again considered exchanging either a *personal* cocktail glass or a *shared* cocktail glass set as a gift; however, some imagined that the gift was a *birthday* gift, whereas others imagined that it was a *housewarming* gift (i.e., the recipient and their significant other moved into a new home; in neither case would the recipient's significant other be present when the gift was given, eliminating this potential confound). In the birthday context, givers gave the shared gift less often than recipients preferred (Giver = 42% vs. Recipient = 59%, *p* = .006), but in the housewarming context, givers and recipients were equally likely to opt for the shared gift (Giver = 82% vs. Recipient = 84%, *p* = .757).

In conclusion, our work adds to the gift-giving literature by identifying a new dimension on which gifts can be categorized, demonstrating a novel giver-recipient asymmetry in preferences for gifts, and shedding light on the psychological mechanisms that contribute to this mismatch.

The Effect of Different Gift-Giving Motives on Givers' Well-Being

EXTENDED ABSTRACT

Gift giving is a positive social exchange between donors and recipients (Sherry 1983) that reinforces relationships (Caplow 1982; Lowrey, Otnes, and Ruth 2004; Otnes, Lowrey, and Kim 1993; Ruth, Otnes, and Brunel 1999). Prior research has focused on factors influencing givers' purchases, as well as the relationship between givers and recipients (Cleveland et al. 2003; Fischer and Arnold 1990; Laroche et al. 2000; Otnes et al. 1993; Saad and Gill 2003; Vanhamme and De Bont 2008). We investigate how giving motivations affect givers' well-being.

An integrative theory of gift-giving motivations (Wolfinbarger 1990; Wolfinbarger and Yale 1993) based on previous work (e.g., Goodwin, Smith, and Spiggle 1990; Sherry 1983) reveals three distinct motives. The **altruistic motive** maximizes the recipient's welfare; it does not aim at gain and voluntarily does good (Batson and Shaw 1991; Leeds 1963). The **egoistic motive** maximizes the giver's own welfare; it aims at garnering social recognition, reinforcing relationships, and establishing status. The **social-norms-compliance** motive maximizes obeying social obligations, including reciprocity and ritual. We will compare these three motives.

Individuals get emotional benefits from spending money on others (Dunn, Aknin, and Norton 2008, 2014). However, we examine the possibility that different motives underlying the same prosocial behavior such as gift giving might produce different implications for givers' well-being.

First, we expect that an altruistic motivation will bring givers happiness. Evidence shows that both gift giving, in particular, and prosocial behavior, more generally, affect happiness (Aknin, Barrington-Leigh, et al. 2013; Aknin, Dunn, et al. 2013; Aknin, Dunn, and Norton 2012; Aknin, Hamlin, and Dunn 2012; Dunn et al. 2008; Dunn, Gilbert, and Wilson 2011; Elliott, Friston, and Dolan 2000)survey data from 136 countries were examined and showed that prosocial spending is associated with greater happiness around the world, in poor and rich countries alike. To test for causality, in Studies 2a and 2b, we used experimental methodology, demonstrating that recalling a past instance of prosocial spending has a causal impact on happiness across countries that differ greatly in terms of wealth (Canada, Uganda, and India. Emotional benefits exist even when giving is anonymous, going beyond social rewards (Frey and Meier 2004).

Second, we expect that a social-norms-compliance motive will not increase happiness to the same extent. When people's helping behaviors emanate from self-imposed or external pressures, the subjective well-being associated with these actions is eliminated (Konrath 2014; Weinstein and Ryan 2010).

Finally, we expect that an egoistic motivation might produce mixed emotions. Given that the motive itself is to obtain personal gain, givers might experience positive emotions. But egoistic givers might be less happy than altruistic givers. Recalling an altruistic (other-focused) helping behavior or prosocial spending led to higher levels of positive affect compared to recalling an egoistic (self-focused) behavior or personal spending (Aknin et al. 2011; Wiwad and Aknin 2017). Moreover, any positive emotion may be tainted by the simultaneous experience of negative emotions related to feelings of lower moral character (Wiwad and Aknin 2017) or other psychological costs associated with egoism (Crocker, Canevello, and Brown 2017)

We present three experiments examining givers' emotions as a consequence of giving with three manipulated motives. We focus on

the aspect of well-being that refers to a balance between positive and negative emotions (Diener 2000; Kahneman, Diener, and Schwarz 1999). This is the emotional component of hedonic well-being (Diener 2000; Kahneman et al. 2004; Kahneman and Deaton 2010)

In study 1, participants ($N = 117$, $M_{age} = 28.29$) read a hypothetical scenario in which they buy a gift for a co-worker's birthday. In a between-subjects design, the giving purpose was described as making the co-worker happy (altruistic and pure altruistic, where giving was anonymous), reinforcing the identity as a "team player" (egoistic), or as expected by officemates (social norm). Then, we measured happiness (i.e., happy, cheerful, thrilled, excited; $\alpha = .92$). Results revealed a significant effect of gift-giving motives on givers' happiness ($F(3, 113) = 3.88$, $p = .011$; $M_{pure\ altruism} = 4.50$, $M_{altruism} = 3.91$, $M_{egoism} = 3.65$, $M_{sn} = 3.31$). Post-hoc tests showed significant differences between pure altruism versus egoism ($t(60) = 2.51$, $p = .015$), and pure altruism versus social norm ($t(60) = 3.71$, $p < .01$). These results suggested that pure altruistic/altruistic motives led to greater happiness than egoistic/obeying-social norms motives.

In study 2, motives were manipulated as in study 1 ($N = 156$, $M_{age} = 30.02$). We measured happiness and self-conscious negative emotions (i.e., guilty, regretful, remorseful, ashamed; $\alpha = .93$). Results revealed that motives significantly influenced givers' happiness ($F(2, 153) = 6.36$, $p < .01$; $M_{altruism} = 4.66$, $M_{egoism} = 4.31$, $M_{sn} = 3.80$) and negative emotions ($F(2, 153) = 4.85$, $p < .01$; $M_{altruism} = 2.60$, $M_{egoism} = 3.44$, $M_{sn} = 3.30$). Post-hoc tests showed significant differences in happiness between altruism versus social norm ($t(105) = -3.65$, $p < .01$), and egoism versus social norm ($t(103) = -1.91$, $p = .059$), suggesting altruistic/egoistic motives had positive effects on happiness. The significant differences in negative emotions were between altruism versus egoism ($t(102) = -2.71$, $p < .01$), and altruism versus social norm ($t(105) = -2.50$, $p = .014$), suggesting that altruism produced the lowest level of negative emotions.

In study 3, participants ($N = 161$, $M_{age} = 22.65$) read the same scenario. We again measured participants' happiness and self-conscious negative emotions. We found a significant main effect of motives on givers' happiness ($F(2, 158) = 7.44$, $p < .01$; $M_{altruism} = 5.09$, $M_{egoism} = 4.54$, $M_{sn} = 4.01$) and negative emotions ($F(2, 158) = 4.93$, $p < .01$; $M_{altruism} = 1.52$, $M_{egoism} = 2.19$, $M_{sn} = 2.05$). Post-hoc tests showed significant differences in happiness between altruism versus egoism ($t(108) = 2.06$, $p = .042$), and altruism versus social norm ($t(104) = 3.98$, $p < .01$). Post-hoc tests also showed significant differences in self-conscious negative emotions between altruism versus egoism ($t(108) = -2.93$, $p < .01$), and altruism versus social norm ($t(104) = -2.72$, $p < .01$), again suggesting that altruism led to the lowest level of negative emotions.

The results suggest that gift-giving motivations affect givers' emotions differently. Altruism produces the highest level of positive emotions, but the difference, especially with egoism, is not so striking, and egoistic giving also makes givers happy. However, altruism is also associated with the lowest level of negative emotions, while egoism produces a high level of negative emotions. Thus, from a broader perspective, altruism has the greatest positive impact on hedonic well-being via positive and negative emotions.

Close, but not Generous: Machiavellians, Reciprocity, and Prosocial Giving

EXTENDED ABSTRACT

Consumers spend money on others in at least two ways, gifts to others and donations (Dunn et al. 2008). In this paper, we investigate consumers' donations to organizations, which is a specific form of prosocial giving. Giving money as donations is often considered altruistic and prosocial (Batson 1998). However, not all prosocial giving is altruistic (Simpson and Willer 2015). Sometimes people give to prosocial causes to increase utility to themselves (e.g. build relationships, increase self-esteem, be recognized for their actions; Hilbert and Horne 1996). We examine how Machiavellianism, defined as a tendency to distrust, engage in manipulative behaviors, and gain control (Dahling, Whitaker, and Levy 2009), influences donations. Machiavellianism has been associated with greater concern for maximizing self-benefits (Sakalaki, Richardson, and Thepaut 2007), lower likelihood of helping others (Wolfson 1981), lower interest in developing closer relationships (Lyons and Aitken 2010), and greater engagement in pretend altruism in the presence of others (Bereczkei, Birkas, and Kerekes 2010). Therefore, we predict that consumers with high Mach tendencies will donate less. High-Machs could use donations as a strategic tool to build relationships and to advance self-interests. Therefore, high-Machs will donate less to organizations that are closer to them because there is less utility that can be derived by donating more when they already share a close relationship.

To use donations as an effective strategy to advance high-Machs' self-interest, they would also need to perceive the receiver's ability to reciprocate. Higher ability of the receiving organization to reciprocate may signal to high-Machs that there is a low need for donations and their generosity would be perceived as less impactful. Therefore, we argue that the giver's beliefs about ability of the receiving organization to reciprocate further interacts with Machiavellianism and relationship closeness to influence donations.

Therefore, we hypothesize:

Hypothesis 1: Consumers with higher Machiavellianism will spend lesser on donations.

Hypothesis 2: Consumers with higher Machiavellianism will spend significantly lesser amounts of money on donations when they have a close relationship with the receiving organizations than they would if they had less close relationships with the receiving organizations.

Hypothesis 3: Hypothesis Consumers with higher Machiavellianism will spend lesser money on donations when they have a closer relationship with the organization, and when they believe that the receiving organization is able to reciprocate their donation than when they have less close relationship, and have lesser belief in its reciprocity ability.

Study 1

73 (54.93% female; 81.43% Caucasian; $M_{age} = 21.07$ years) undergraduate students responded to measures in two study sessions separated by seven days. Participants were offered a chance to win $20 gift card in return for participation. In the first session, participants responded to a 16-item Machiavellian Personality Scale ($\alpha = .86$; MPS; Dahling et al. 2009) and demographics. During the second session, we manipulated respondents' closeness by asking them to think and write about an organization that was close to them (versus not close). To measure giving, we asked them to indicate the amount of money they would be willing to give to this organization.

H1 was tested by conducting a regression analyses with donation-spending as DV, and Machiavellianism as predictor. Results (β_{Mach} = -.35; p = .00) confirmed that Machiavellianism was negatively related to spending on donations.

To test H2, we conducted a moderated regression analyses with donation-spending as the outcome, Machiavellianism as the predictor, and closeness condition as the moderator. Results ($\beta_{Mach*closeness}$ = -.26; p = .02) showed that Machiavellianism inhibited spending on donations more in the high closeness group (β_{Mach} = -.60; p = .00) than in the low closeness group (β_{Mach} = -.08; p = .63). Results held after controlling for household income.

Study 2

To further investigate the effects of Machiavellianism and closeness, and to potentially uncover the reasons behind the contingencies observed in study 1, we recruited 134 non-student consumers (59.7% female; M age = 46.27 years; full time workers). As in study 1, the MPS (α = .89) measured Machiavellianism. Participants named any organization they have interacted with and were then indicated their closeness by using a single item measure that schematically represented the relationship between themselves and the organization as circles 1 = no overlap between circles (minimal closeness) to 7 = complete overlap (extreme closeness; Aron, Aron, and Smollan, 1992). Spending on donations was measured similar to study 1. Finally, to investigate whether the closeness-contingent effects of Machiavellianism on donation-spending was further dependent on the giver's beliefs of the ability of receiving organization to reciprocate, we measured reciprocity ability (2 items; α = .88).

H1 was further replicated in this study because Machiavellianism negatively affected spending on donations (β_{Mach} = -.17; p = .05). H2 was also replicated in this sample as our results ($\beta_{Mach*closeness}$ = -.29; p = .00) showed that Machiavellianism inhibited donation-spending more strongly when closeness was higher (β_{Mach} = -.48; p = .00) than when closeness was lower (β_{Mach} = .11; p = .38).

H3 was tested by a three-way moderated regression analyses with donation-spending as the dependent variable, Machiavellianism as the predictor, and both closeness and reciprocity ability as moderators. Our results ($\beta_{Mach*closeness*reciprocity\ ability}$ = -.20; p = .03) showed that the patterns by which Machiavellianism interacted with the reciprocity ability beliefs of the giver differed between the consumers who experienced lower closeness ($\beta_{Mach*reciprocity\ ability}$ = .18; p = .13) and higher closeness ($\beta_{Mach*reciprocity\ ability}$ = -.21; p = .14). A follow up analyses revealed that especially when consumers experienced higher closeness with the organization they noted, a higher belief in reciprocity ability further amplified the inhibitory effects of Machiavellianism on donation-spending compared to when they had lower reciprocity ability beliefs.

Discussion and Conclusions

In sum, our results show that Machiavellianism has generally inhibitory effect on prosocial giving. While this could be expected, our results also suggest that closeness can further exacerbate the inhibitory effect of Mach on donations. Further, we also showed that consumers belief of the organization's ability to reciprocate also exacerbates the effects of Mach and closeness. This paper highlights prosocial giving of Machiavellian consumers and the not-so altruistic conditions of their giving.

Broadening the Framework of Gift Giving

EXTENDED ABSTRACT

Gifts are tools for symbolic communication. Through gifts, givers try to reconfigure and reinforce their social relationships (Belk 1979; Camerer 1988) and status positions (Caplow 1982; Joy 2001). The foundational Dyadic Gift Giving Model, developed by Sherry (1983) almost four decades ago, details the gift giving process. It describes how givers first think about and select gifts during the Gestation stage. They then present them during Prestation, which is followed by the Reformulation stage where dyads reevaluate their relationships in the context of the gifts. While the Dyadic Gift Giving Model has a catch-all substage of disposal at the end of the process that includes everything from using the gifts to throwing them away, the model does not delve into the details of these essential recipient activities. Recipients' extended engagement with gifts after they receive them is crucial, yet this is not included as a conceptually important and distinct process in existing dyadic gift models.

In this conceptual paper, we argue that while the Dyadic Gift Giving Model established important steps in the gift-giving process, it is not complete. When someone receives a gift, their experience in the gift process often has just begun. Their role as a recipient is activated as they convert the gift into a usable experience -- redeeming the gift card, wearing the sweater, using the toy, or making plans to attend the concert -- which are consequential for the success of the gift and the social relationship that the gift is meant to reinforce. Yet most gifting theory neither conceptualizes these components of the recipient experience nor the important relationship reformulation work that occurs throughout the recipient's engagement with the gift, despite evidence that this is fundamentally important in the gift process. This project introduces the Extended Dyadic Gift Giving Model adding three new multidimensional stages, bringing important conceptual clarity to the dyadic gift process. It contributes to the literature by detailing the important role of recipients, who can be more involved with the gift than givers. In doing so, it opens up new conceptual terrain for future cultural and psychological research.

The Extended Gift Model

While the drama of the giver presenting the gift to the recipient and the initial reaction to the gift is important for reformulating the dyadic relationship (Wooten and Wood 2004), consumer research on dyadic gift process tends to stop around this point, even when the recipient's perspective is analyzed (Ruth, Otnes, and Brunel 1999). However, for the recipient, the journey with the gift has just started. We briefly summarize the new stages added by our model that capture this recipient experience.

Gift Realization

Gift Realization begins where the original Dyadic Gift Giving Model (Sherry 1983) tapers off: after relationship reformulation. It has three components: Secondary Gestation, Phenomenological Experience, and Dispossession. Recipients do not necessarily go through all of these substages, but they all go through at least one. Rather than following a unidirectional path from giver to recipient, the process is more dynamic.

Secondary Gestation. Some gifts such as gift cards, experiential gifts, and gifts needing assembly require transformation, a secondary stage of gestation after the gift is received but before the gift can be used; recipients must put in thought and effort to convert the gift into a usable form. For instance, a gift card recipient accepts a plastic

card in prestation, but the giver intends for it to be converted into a usable item or experience.

Phenomenological Experience. A centerpiece of our model is the phenomenological experience. This is the portion of recipient engagement where the gift is used. During this time, the recipient extracts value from the gift through engagement with it. For instance, a child who receives Legos as a gift builds a village on the table one week and then transforms it to a train station in their bedroom the next, constructing time and time again. Or, the recipient of a cookie making kit gathers their family to bake and then they eat the cookies together, the sweater recipient wears it through several seasons, a gifted painting is placed on the wall to be seen, the recipient of show tickets experiences the show.

Dispossession (with and without use). Gift dispossession occurs when the gift no longer belongs to the intended recipient in its intended form. Prototypically, dispossession occurs either without use and with use. Without use occurs at the beginning of the Gift Realization stage. They might dislike the gift or giver, it might be a duplicate, or it might be broken. The recipient might choose to return, exchange, donate, swap, sell, throw away, destroy, regift, or reject it. Dispossession can also occur with use when some value has been extracted or it is accidentally destroyed.

Storage

Some gifts are neither used immediately nor disposed of, instead they are put in a place where they are not engaged with. Storage can be a transition stage between engagement and dispossession, but an item might also remain in the stage indefinitely.

Secondary Reformulation

Initial reformulation typically occurs based on surface knowledge of the gift - unwrapping it and seeing it in its package, touching the fabric, or imagining how one might use the gift card. However, the secondary reformulation stage occurs after the gift has been experienced in some way. It is through this period that relationship realignment occurs as the affective reaction to the gift shifts or it simply reaffirms the relationship and status roles through use.

Factors Impacting the Process

Consumer research shows tremendous variation in people's enactment of the stages in the original Dyadic Gift Giving Model. How people experience the additional stages will also likely vary based on several variables. We focus on social and gift-related variables that likely influence recipients in each stage . Ultimately, this extended model opens up novel arenas for cultural and psychological research on gift giving.

SESSION OVERVIEW

Culture is an accepted factor in understanding and explaining consumer behaviors. Race, as one cultural component of the lived experience, is understood to be a factor in influencing consumer experiences, yet there remain opportunities to plomb the nuanced experiences of race in the marketplace. Recent scholarship explores some of the nuanced experiences and creates additional opportunities to examine how race influences consumption.

The theme of the conference, 'What the World Needs Now,' is addressed in this session examining Black consumers in the U.S. marketplace and their experiences with racism and discrimination. In the 1960s and 1970s, the examination of Black consumers was typically viewed relative to experiences of whites in the marketplace. More recently, scholars consider a range of positive and negative marketplace experiences had by Black consumers (Cowart, 2018; Foy & Ray, 2019; Green, 1999; Mitchell 2020). Building on prior scholarship, the three papers in this session consider the experience of Black consumers. Collectively, these papers contribute nuance to explanations of race and its impact on consumer experiences. Further, the increasing energy and focus to understand and address racism requires a broader understanding of the various ways that racism may be experienced by Black consumers in the marketplace as well as some mechanisms Black consumers may employ to manage experiences of racism.

Each of the three papers considers consumer interactions with the marketplace where the first two focus on print advertisements and messages within them, and the third considers the transformation of challenges into opportunities to experience joy. The first paper is based on an ethnography that examines colorism in market messages, and in particular print advertisements. In the paper 'Light vs. Dark: Understanding Roles of Colorism through Advertisements in the Marketplace' the phenomenon of 'Blackfishing' is examined. Though colorism is not new, 'Blackfishing' provides opportunities for direct (e.g., advertisements) and indirect (e.g., influencers) forms of racism and discrimination to propagate. In the second paper, 'I Got Beef, But You Don't: Understanding the Difference in Stereotype Perceptions in Media amongst Targeted African Americans,' stereotypical messages centering on single Black parent households is the focus. Through experimental studies examining the relationship between stereotyped Black female (e.g., subservient) or Black male (e.g., athletic) and pur-chase intentions. The third paper titled 'Black 'Joy and Pain': Finding Solace and Resistance in Live Music During COVID-19' is a critical analysis of the 'Verzuz' phenomenon using netnographic techniques. The study considers how in the midst of the global pandemic, an entertainment form was birthed that transformed experiences of denied humanity and associated pains into collective joy and resistance for Black consumers.

Each of these studies has a link to systemic racism that seeps into the lived experiences of Black consumers in the U.S. marketplace, and perhaps the world when considering the African diaspora. While the studies do not necessarily provide answers on how to address systemic racism, they do shed light on its impact. And collectively, these studies offer a bit of what is needed now: an understanding of humanity as experienced by others.

Light vs. Dark: Understanding the Roles of Colorism through Advertisements in the Marketplace

EXTENDED ABSTRACT

Advertisements communicate through symbols represented in images and text (Scott 1994). Those images include individuals, which may be assessed on various dimensions including skin tone. Colorism is a form of discrimination that results in privilege or lack thereof because of one's skin tone and is found in advertisements (Mitchell 2020; Walker 2005). The study examines the role of colorism in the marketplace.

Colorism may be found in advertisements where models of different skin tones are presented as representative product users. Actions that could be viewed as colorism are found in most cultures, and consumption is often found in support of such actions. For example, the preference for lighter skin in other communities has been apparent given the types of products used for skin lightening. Although products such as skin whitening creams have health risks, interest in these products increases due to the pressure of beauty standards (Adbi et al. 2021). The literature provides examples of how consumers depend on products to maintain a favorable status in society that impacts them emotionally.

Lighter skin tones have been favored by members of many ethnicities and cultures and have often been associated with positive connotations in society, while darker skin tones have been portrayed negatively (Cowart 2018; Foy & Ray 2019; Harrison 2005; Mitchell 2020). Conversations surrounding light and dark skin tones in the Black community can be traced to slavery. More specifically, enslaved people assigned work roles based on skin tone (lighter-skinned slaves as house workers and darker-skinned slaves in the fields), and enslaved women were often raped resulting in mixed race enslaved children who may receive preferential treatment based on skin tone (Reece 2018). Such colorism is found in marketing mediums and specifically in print advertisements. Prior research finds that the skin tone of models varies depending on if ads are targeting Black or White consumers, however most models in those ads have lighter complexions (Mitchell 2020). Similarly, the degree of a consumer's ethnic identification also influences receptivity to the skin tone of models. Research finds that the stronger a consumer's ethnic identification, the more positive the evaluations of advertisements featuring darker-skinned individuals (Green 1999, Cowart and Lehnert 2018).

Colorism is evident in advertisements, yet a phenomenon has emerged on social media that reflects colorism. This phenomenon, 'Blackfishing,' is derived from 'blackface' which encompasses a range of temporary visually transformative racist acts that were prevalent during the Jim Crow era (Brundage 2011). 'Blackfishing' is the use of market offerings (from cosmetics such as bronzers and tanning sprays to digital alteration, or even cosmetic surgery) to alter one's appearance to that of a Black or a mixed-race individual (Bell 2019). The preference for darker skin by lighter-skinned individuals has been found in literature (Veras 2016), and 'Blackfishing' encompasses the acts associated with this preference. The prevalence of 'Blackfishing' with models and celebrities in print advertisements and on social media (Kowalczyk & Pounders 2016; Osarogiagbon 2020), is likely to spur consumer outrage.

The present study aims to examine the prevalence of colorism in the form of 'Blackfishing' and how those roles influence consumption. More specifically, this study will examine: 1) How individuals perceive of their skin tone?, 2) How does self-perceptions of skin tone influences consumer behaviors?, 3) How has the existence of 'Blackfishing' influenced consumers' perceptions of print and social media advertisements?; and, 4) To what extent does ethnic identification extent to which 'Blackfishing' influences consumption?

This ethnographic study extends themes found in extant literature on colorism and focuses on understanding how consumers experience 'Blackfishing.' Various sources of data will be employed in this analysis. Data collected through interviews focuses on consumers' experiences of 'Blackfishing' and how those consumers may participate in 'Blackfishing.' As this phenomenon is evident from Asian cultures, American cities, to African villages, individuals from various backgrounds are included in the study. A content analysis of print magazines targeted to Black and White audiences will be included (Mitchell 2020) as will publications targeted across different classes of consumers. Further, to gain a broader range of experiences of 'Blackfishing,' a netnography will be conducted in online communities found on Facebook, Twitter, Tik Tok, and Instagram (Kozinets, 2020).

Preliminary themes emerging from the data suggests an extension on prior research. More specifically the themes include the introduction to colorism during childhood as a part of socialization, emotional impacts of colorism that influence the consumption experience, and how colorism impacts the symbols emerging from print advertisements the importance of the connection between ethnic identity and print advertisements. Prior research identifies roles for colorism in marketing. It is anticipated that the study will extend findings related to 'Blackfishing' in print advertisements and contributes an explanation of how consumers' perceptions and experiences of colorism in the marketplace have evolved over time.

I Got Beef, But You Don't: Understanding the Difference in Stereotype Perceptions in Media amongst Targeted African Americans

EXTENDED ABSTRACT

Fact: A majority of black children lived in single-parent homes (NCES, 1996). However, the stereotypical nature of the depiction of a single black mother and children in an advertisement leads to great debate within the black community. Several print and television advertisement produced in recent years have attempted to depict this phenomenon by utilizing single-parent images in targeted marketing campaigns (KFC, 2007). As a result of this and similarly targeted advertising, thousands of debates among consumers are being produced, with the concern that these images perpetuate stereotypes of minority consumers. While some participants of these debates feel that these depictions are accurate representations of the targeted populations, others feel that these images continue to reinforce negative stereotypes in the minority community.

The key to understanding these disagreements lies in the examination of consumer self-concept. Understanding the multidimensionality of self-concept (Sirgy, 1981, 1982; Heath and Scott, 1998) in the context of minority targeted advertising will increase ad effectiveness for practitioners and reduce the perceived perpetuation of stereotypes among minority consumers. As suggested by Hunt (2007), the discipline of marketing has a responsibility to practitioners, the discipline, society, and its students. A deeper consideration of negatively perceived advertising will not only reduce the separations that exist within society but will allow for an improved image of the discipline.

Several studies have examined the perpetuation of minority stereotypes in both print and television advertising (Paek and Shah, 2003; Donovan and Leivers, 1993; Taylor and Stern, 1997; Colfax and Sternberg, 1972), as well as the general portrayal of minorities in the media (Henderson and Baldasty, 2003; Mastro and Greenberg, 2000; Green, 1999; Mahtani, 2001; Mastro and Stern, 2003). However, none have examined the way in which self-concept can influence the likelihood that advertising is perceived as negative, or stereotypical. Therefore, this study will address the questions: Do some individuals consider an image stereotypical while others do not? Do perceptions of stereotypes vary by racial group? And, do perceptions of stereotypes within advertisements negatively influence consumer purchase intentions? We address these questions and attempt to determine if these perceptions can be used to understand purchase intentions. In addition, this study will utilize the Racial-Ethnic Self-Schema (RES) model (Oyserman, et al., 2003) and provide a quantitative analysis that explains the perceptions and purchase intentions of minority consumers following perceived negative self-relevant activations in advertisements.

An exploratory pilot was completed in order to assess the spokesperson characteristics of race, gender and role of the stereotypical scenarios prior to the creation of ads. The first vignette is female-specific and takes place at a cosmetic counter of a department store. The second is male-specific and takes place on a basketball court. The purpose of the scenarios was to describe an advertisement in which the characters are positioned in situations to prime for either high or low stereotypical profiles. We have developed the following pretest Hypothesis:

Hypothesis 1: *Blacks will view the female-specific ad in which the black woman is in a servitude position as more stereotypical than the ad in which she is being served.*

Hypothesis 2: *Blacks will view the male-specific ad in which the black man is dunking the basketball as more stereotypical than the other two ads.*

One-way ANOVAs were computed comparing the level of perceived stereotype of blacks in gender specific advertisements among African-American respondents. A significant difference was found in the ads ($F(5,26) = 3.85$, $p < 0.05$) when comparing the perceptions of stereotype among African-American females in advertisements featuring women. A significant difference was also found in the ads ($F(5,26) = 10.71$, $p < 0.05$) when comparing the perceptions of stereotype among African-American males in advertisements featuring men.

This analysis will contribute to the advertising and marketing literature by demonstrating that a multi-level approach is necessary to prevent the occurrence of perceived stereotypes and to predict product purchase intentions among targeted consumers. Additional-

ly, we examine how development of a Racial-Ethnic Self Schema is used to moderate the effects of stereotypes displayed in the marketplace, specifically advertising. RES Schema (developed in 4 structures) allow some consumers to reduce the anxiety associated with negative stereotype portrayals in advertising, thus allowing them to cope with the stresses of a marketplace inundated by colonially regurgitated tropes.

Black 'Joy and Pain': Finding Solace and Resistance in Live Music During COVID-19

EXTENDED ABSTRACT

In the African American community, the novel coronavirus and enduring racial discrimination has spawned a double pandemic (Blake 2020; Addo 2020). Statistics recently released by the Centers for Disease Control (CDC 2020) underscore how COVID-19 and racism are intersecting and further exacerbating the corporeal well-being of Black people in the United States. The CDC reports that the odds of a Black person contracting and dying from COVID-19 are more than double that of a White person, and their chance of hospitalization is nearly five times higher. The CDC links these significant discrepancies in health outcomes to discrimination and systemic racism. Explicitly discussing how the health of African Americans and other marginalized ethno-racial groups is adversely impacted by structural forms of racism found in healthcare, education, criminal justice, housing, and banking. Additionally, more than eighty municipalities across the United States, have officially declared racism a public health crisis, and many local hospital systems and school districts are starting to follow suit (Mock 2020). As such, society appears to be ready to acknowledge that while viruses (like SARS-CoV-2) may not discriminate based on race, they circulate within a culture that does, resulting in greater impacts on communities of color.

However, rather than focus on the despair that African Americans must contend with while living within a double pandemic, this study critically examines the ways in which Black joy materializes within the confines of a racialized global health crisis. We do so, because as Johnson (2015) notes, "… [B]lack joy allows us the space to stretch our imaginations beyond what we previously thought possible and allows us to theorize a world in which white supremacy does not dictate our everyday lives" (p. 180). Black joy has also been characterized as a site of resistance and self-care. Both Brooks (2020) and Packnett (2017) evince the way in which choosing joy while navigating the perils of racial oppression is a powerful form of self-preservation and resistance.

The myriad manifestations of denied humanity Black people endure daily is often conceptualized as all-consuming – leaving zero space for joy to manifest, but perhaps the framing of pain and joy requires an ontological shift when considering the lived Black experience. Perhaps, as West (2010) suggests, the two should be situated as coexisting rather than contradictory constructs. Such a reframing may allow us to (re)conceptualize Black joy as more than momentary reprieves from racial oppression to an ongoing and conscious practice of self-care and embodied resistance that emerges in the company of Black pain.

We attempt to develop such a conceptualization by directing our attention to what was once largely characterized as a quotidian aspect of social life – the consumption of live music. The global onset of COVID-19 in early 2020 and the extensive mitigation procedures that followed led to a near complete shutdown of the live music industry. In the U.S., lockdowns prohibited live music performances, leaving the industry decimated and millions of music lovers stuck at home without a key outlet of self-care and stress release (Blistein and Millman 2020). In response, Swizz Beatz and Timbaland, two veteran African American music producers launched Verzuz live battle sessions on Instagram Live in late March 2020. Verzuz battles consist of two comparable music artists from Black music traditions, primarily hip hop and R&B, who play approximately 90-seconds of 20 songs from their music catalog in an alternating fashion during a three-hour live virtual session. Each battle is streamed on Instagram TV, with Apple Music/TV simulcasting the events from July 2020 to March 2021. The start-up social media platform Triller replaced Apple Music/TV as a simulcast partner after Verzuz was acquired by the platform in March 2021.

Although the live digital series is referred to as a battle, Verzuz leans more toward a "friendly competition" largely rooted in nostalgia. Most artists eschew playing new material in favor of long-loved classics. A virtual space of shared intimacy emerges as artists play and offer behind-the-scenes accounts associated with cherished songs from their music catalog as viewers openly recollect and share fond memories that accompany each song. Timbaland identifies the series as a celebration (Leight 2020). While not explicitly stated as such, the fact that the series has only featured Black artists thus far and most viewers (which often reaches into the millions) appear to also be Black, indicates that the series is a celebration by and for Black people. Neither artists nor Verzuz producers are paid for participating and organizing the battles, choosing a more altruistic purpose for the digital franchise -- Timbaland states "the money is the love that we get from the people" (Cochrane, 2020).

In this study, we examine how the Verzuz series offers a virtual space wherein Black joy is collectively constructed. We conduct a netnographic inquiry, an ethnographic approach to gaining consumer insights when studying online communities (Kozinets 2002, 2010). We employ the technique of "lurking", which is an unobtrusive observation technique where researchers gather data without making themselves known to the community members (Kozinets 2010), potentially rendering richer and more authentic data. To date, the researchers have recorded several Verzuz live performances and collected Twitter and Instagram posts using relevant hashtags or replies to the performance posts on Instagram. Utilizing a critical visual reading and discourse analysis framework, data is currently being coded and interpreted using Dedoose, a web-based data analysis platform. While our analysis remains ongoing, preliminary findings suggest Verzuz's may indeed be viewed and utilized by its viewers as a trusted source of Black joy. During the height of the coronavirus, this notion was encapsulated in a viewer's posting to Instagram after the Teddy Riley versus Babyface event:

> *"Whether you're grooving with DJ DNice on #ClubQuarantine, jamming to a Teddy Riley #verzuz Babyface battle, expressing yourself on Tik Tok with #DontRushChallenge videos, or binge watching #BlackAF and #InsecureHBO, do what you gotta do to protect your peace and find your #Blackjoy during these uncertain times. Laughter is good for the soul, and self-care fuels the movement. ♡ ❤ ✋"* – *theequityalliance*

Variations in Consumer Responses to Waste and Disposal

Paper #1: Waste Not: Paid Repair Services Decrease Product Replacement by Signaling Unused Utility
    Nathan Brent Allred, Penn State University, USA
    Karen Page Winterich, Penn State University, USA

Paper #2: When Waste Aversion Overcomes Impatience: The Impact of Product Quality on Consumption Deferral
    Grant E. Donnelly, The Ohio State University, USA
    Aaron R. Brough, Utah State University, USA

Paper #3: It's Wasteful: When Talking about Product Disposal Hurts Product Evaluations
    Sylvia Seo Eun Chang, University of Washington, USA
    Nidhi Agrawal, University of Washington, USA

Paper #4: Trashing Products to Signal Displeasure
    Aaron R. Brough, Utah State University, USA
    Mathew S. Isaac, Seattle University, USA

SESSION OVERVIEW

Waste and disposal have generated much interest across consumers, marketers, and public policy makers. Various brands are promoting ways in which consumers can dispose of their products with reduced environmental impact, and several countries have launched initiatives and campaigns on how to throw away products more responsibly and reduce waste (Allen 2020; Carrington 2020). Scholars have also found that consumers' waste aversion influences their purchase, usage, and disposal decisions (Alba and Bolton 2012; Bellezza, Ackerman, and Gino 2017; Sun and Trudel 2017). This session addresses this important topic by examining various meanings consumers derive from waste and disposal at different stages of the consumption cycle.

Allred and Winterich will start the session by examining how consumers' wasteful tendency to replace rather than repair their broken products can be mitigated. The authors find that paid repair services (especially when offered by the original equipment manufacturer vs. a third-party repair provider) lead consumers to repair their product as the service signals that there are unused utility left in the broken product. Therefore, sensitizing consumers to potential waste influences their decisions to dispose of their products.

Next, Donnelly and Brough demonstrate how waste aversion influences consumers' usage decisions in terms of consumption timing. They show that consumers are willing to wait longer to consume higher (vs. lower) quality products because higher-quality products are perceived to be overqualified for ordinary usage occasions. In doing so, this paper identifies perceived overqualification as a condition in which waste aversion delays product usage.

Chang and Agrawal then examine how people draw waste inferences from thinking about product disposal at the acquisition stage. Due to consumers' association between disposal and wastefulness, consumers evaluate a product to be more wasteful when they consider disposal in evaluating a product, and this wastefulness perception decreases their purchase likelihood. This occurs even though the disposal reference is irrelevant to the actual sustainability of the product, and the paper shows how the disposal-waste association can be mitigated.

Extending the discussion of how consumers derive meaning from disposal, Brough and Isaac explore how disposal can be used to signal displeasure. They find that when disposing of products with negative (vs. positive or neutral) sentimental value, consumers prefer trashing (vs. donating or selling) their products even for those with market value, and this is due to symbolic fit (the ability of a disposal

method to uniquely express sentimental value). Given that trashing products with remaining value is wasteful, this paper has implications for waste reduction.

Overall, the four papers provide insights on how consumers conceptualize waste and disposal, which influences their decision-making at various consumption stages. The first three papers tackle how meaning of waste and waste aversion impact consumers' disposal, consumption, and acquisition decisions, and the last paper addresses what disposal decisions signal to consumers. These findings not only contribute to the consumer literature by expanding our understanding of what waste and disposal mean to the consumers but also provide important implications for businesses, society, and the environment in reducing waste and promoting sustainability.

Waste Not: Paid Repair Services Decrease Product Replacement by Signaling Unused Utility

EXTENDED ABSTRACT

When a product breaks, consumers must decide whether to repair or replace the broken product. While repairing broken products is a better option for the environment, given it takes fewer resources than producing a new product, consumers tend to replace broken products (confirmed in a pilot study for headphones, shoes, toasters, and jackets). Such replacement tendencies likely increase consumption and thus resource use. Indeed, examining Google search data, we found states that have higher search on repair keywords (e.g., "repair", "repair shop") have lower consumption (per the US Bureau of Economic Analysis). Thus, initial evidence suggests promoting product repairs may lead to more sustainable consumption by decreasing product replacement.

The prominence of disposal over repair seemingly contradicts the notion that consumers are generally averse to waste (Bolton and Alba 2012). Past research suggests that some consumers are reluctant to replace products through upgrading because of the remaining utility in the products they own (Cripps and Meyer 1994; Okada 2001). In these cases, consumers seem to be aware of the unused utility in the possession, which makes it wasteful to replace. However, given consumers' perceptions of planned obsolescence in product design (Guiltinan 2009), consumers may no longer tend to infer that utility remains when a product is broken. As such, consumers may not perceive the decision to replace their product as wasteful, thereby allowing consumers to replace rather than repair products without experiencing any aversion to being wasteful. Yet, today, there a growing number of companies offering paid repair services for their products (Suntinger 2019). For example, Apple has paid repair services for their electronics, as does Patagonia for their clothing.

We suggest that when companies offer paid repair services, they signal that their broken products have unused utility in a similar manner that warranties have been shown to signal product quality (Boulding and Kirmani 1993). We hypothesize that company repair services decrease consumers' likelihood to replace broken products due to an increased perception of unused utility signaled by the original equipment manufacturer's (OEM) repair service. However, we theorize that the ability to signal unused utility in broken products is specific to the OEM's paid repair service; the local tailor or third-party computer repair shop does not indicate to customers that their specific product has remaining utility when it breaks. Thus, we predict that the provider of the repair service will moderate the effect such that OEM repair services will decrease replacement likelihood to a greater extent than third-party repair services.
