In Study 1, Mturk participants were told about a fictional small kitchen appliance company that offered paid repair services or cooking course services (control) for their products. After imagining that they had purchased a toaster from the company, which broke after two years of use, participants reported their likelihood of replacing the toaster. As predicted, participants who were exposed to the repair service condition were less likely to replace their toaster than were those exposed to cooking courses in the control condition. This finding provides initial evidence that the presence of repair services decreases consumers' likelihood to replace broken products.

Study 2 investigates whether the repair service provider moderates the effect of repair services on consumers' replacement likelihood and also tests the mediating role of unused utility. Undergraduate students were randomly assigned to one of four conditions in a 2 (service: repair, music streaming[control]) x 2 (provider: OEM, third-party) between-subjects design. Participants read an article about a fictional headphone company that offered either repair or music streaming services. They imagined their headphones from the OEM had recently broken and indicated their likelihood of replacing their broken headphones as well as how much utility remained in their broken headphones. In the OEM provider condition, participants were less likely to replace their headphones when the OEM offered a repair (vs. music streaming) service. However, in the third-party condition, replacement likelihood was high and did not differ by services offered (repair vs. music streaming). Perceptions of unused utility were greater when the OEM offered a repair service but did not differ based on the service provided by the third party, mediating the effect of repair service on replacement likelihood only in the OEM condition. These findings indicate that OEM-provided repair services increase perceptions of unused utility in broken products, decreasing replacement likelihood.

Study 3 further supports the role of unused utility by manipulating length of use prior to breakage (i.e., unused utility). Undergraduate students imagined that they owned a pair of headphones that had broken after either 9 months (high unused utility) or 4 years (low unused utility) of use and read about a headphone repair service by either their headphone OEM or a third party. When unused utility was low (4 years of use), participants were less likely to replace their headphones when the OEM offered the repair service. However, when unused utility was high (only 9 months of use), participants had low replacement likelihood regardless of repair service provider.

Last, study 4 examines whether the effect of OEM repair services on replacement can occur through OEM-certification of third-party repair services (e.g., Dell-certified repair technicians at BestBuy). Dell laptop owners recruited through Mturk were randomly assigned to one of three conditions (provider: third-party, OEM-certified, OEM). Participants were asked to imagine that their laptop broke after two years of use and then viewed an advertisement for a laptop repair service offered by a third-party repair company, a Dell-certified repair company, or Dell. Replacement likelihood did not differ between the OEM and OEM-certified conditions, with both of these conditions significantly lower than the third-party condition. Unused utility mediated the negative effect of repair provider on replacement likelihood. Thus, OEM-certifications can enable a third-party repair service to signal unused utility and decrease replacement likelihood.

In sum, consumers' tendency to replace a broken product can be overcome when they perceive the broken product to have unused utility, which can be signaled by the OEM or OEM-certified paid repair services. This research has implications for reducing consumer waste, resulting in more sustainable consumption.

When Waste Aversion Overcomes Impatience: The Impact of Product Quality on Consumption Deferral

EXTENDED ABSTRACT

Consumers routinely decide when to consume products they already possess. For example, after purchasing a bottle of wine, consumers may choose to use it immediately or postpone consumption. Understanding how consumers make decisions about consumption timing is critical because of the effect usage has on other important behaviors such as waste, storage, and repurchase. Consumption timing decisions are a central issue in food waste (Block et al. 2016) contribute to the growth of the self-storage industry (Harris 2020) and can affect the timing of product replacement purchases (Bellezza, Ackerman, and Gino 2017). Despite the importance of decisions about consumption timing, they have been studied less extensively than purchase decisions within the marketing literature.

But how does product quality affect consumption timing? Based on the logic that higher-quality is desirable, one might expect higher-quality products to be consumed before lower-quality products. This prediction is consistent with research on temporal discounting, which suggests that consumers are generally impatient and tend to prefer desirable outcomes sooner even if the reward is smaller (Frederick, Loewenstein, and O'Donoghue 2002). In contrast, we argue that consumers often intentionally defer consumption of higher-quality products and instead prefer lower-quality products for more immediate consumption. We posit that higher-quality products may be perceived as overqualified for ordinary usage, and reserved for special occasions when their premium attributes will not be wasted. We define perceived overqualification as the perception that a particular level of product quality is unnecessary for a given consumption occasion.

Study 1 assigned participants (N=926; M_{age}=38.95, SD=12.34; 56.6% female) to consider a recent purchase (bath salts, champagne, dinnerware). Participants were told that this purchase was premium, or standard. Participants reported how many days they would wait to consume the item. The number of days participants would wait before consuming the product was significantly greater for a higher-quality (vs. lower-quality) product, $F(1,917) = 42.19$, $p < .001$. Participants were also asked to write a few sentences explaining their decision. These rationales were coded to identify whether participants spoke to the product being overqualified (i.e., too special, fancy). More participants expressed that the product was overqualified in the higher-quality (40.2%) vs. lower-quality condition (12.9%, $p < .001$), which mediated consumption deferral (95% CI: 1.68, 6.10).

Study 2 manipulated usage occasion (extraordinary vs. ordinary) and consumption timing: proximal vs. distal). Participants (N=401; M_{age}=41.22, SD=13.30; 52.8% female) were asked to select a wine to share with their partner during a homemade dinner that was a typical dinner or an anniversary dinner that was either taking place in 3 or 10 days. The higher-quality wine was described as costing $49.99 while the lower-quality wine was described as costing $19.99. Participants were asked to select their preference of wine, and then were assessed how overqualified the higher-quality wine would be for the usage occasion. Participants were less likely to select the higher-quality wine for a typical versus an anniversary dinner, $F(1,383) = 290.25$; $p < .001$ and no main effect for consumption timing was observed, ($p = .93$). There was also no significant interaction by usage occasion and consumption timing, ($p = .41$), suggesting that the consumption deferral effect is more sensitive to usage occasion than the duration of a delay. Usage decisions was mediated by perceptions that the premium wine was overqualified for a typical dinner (95% CI: 1.54, 2.45).

Study 3 assessed whether consumption deferral of a higher-quality product would be attenuated when the possibility of wasting it through non-use was made salient by bounded consumption (i.e., the product would expire). Participants (N=417; M_{age}=39.29, SD=11.98; 55.8% female) imagined having two gift cards: one card to a high-end restaurant and another to a standard restaurant. In the bounded condition, participants learned that the gift cards would expire in the next seven days, while expiration was not mentioned in the unbounded condition. Participants indicated the likelihood of using each gift card in the next seven days. When consumption was unbounded, the consumption deferral effect was replicated and participants were significantly less likely to use the gift card to the high-end versus standard restaurant; $t(129) = 4.57$, $p <. 001$, but this difference was attenuated when both cards expired in seven-days; $t(185) = .49$, $p = .62$.

Study 4 assessed real consumption behavior nd whether emphasizing quality differences moderated the consumption deferral effect. Students (N=245; M_{age}=20.31, SD=2.13; 52.2% female) completed two tasks: solving long-division math problems and writing a thank you letter to a professor. Two stacks of paper were placed on the student's desk: one stack of lower-quality paper and one stack of higher-quality paper. In the high-emphasis condition labels were present that labeled the paper as low and high quality, whereas in the low-emphasis condition no labels were present. The likelihood of deferring consumption of the premium paper was examined in a binary logistic regression with three independent variables: usage occasion (math vs. letter), quality emphasis (high vs. low) and their interaction. There were significant main effects of usage occasion (Wald = 55.69; $p < .001$) and quality emphasis (Wald = 5.50; $p = .019$) as well as a significant interaction between usage occasion and quality emphasis (Wald = 45.22; $p < .001$). When quality differences were emphasized, the consumption deferral effect observed in earlier studies was replicated such that significantly fewer participants used the higher-quality paper for the math task (16.7%) versus the thank-you letter task (55.0%). In contrast, when quality differences were not emphasized, the consumption deferral effect was attenuated and participants were equally likely to use the higher-quality paper for the math task (46.0%) versus thank-you letter task (50.0%).

This research finds evidence that consumers postpone consumption of higher-quality products because they are perceived to be overqualified for ordinary usage occasions and identifies important boundary conditions (bounded consumption, quality emphasis). While prior work suggests that waste aversion should promote product usage, we identify perceived overqualification as a condition in which waste aversion delays product usage. This distinction highlights the potential for wastefulness to occur during earlier stages of the products life and not only at the time of disposal.

It's Wasteful: When Talking about Product Disposal Hurts Product Evaluations

EXTENDED ABSTRACT

Current research advances the understanding of disposal and waste by investigating how referencing disposal in describing a product influences consumers' product evaluations. Extending past disposal research that focused on consumers' product disposal decisions as outcomes (Trudel and Argo 2013; Trudel, Argo, and Meng 2016), our research examines how talking about product disposal at acquisition influences consumers' willingness to purchase the product by way of affecting product's wastefulness perception.

We propose that consumers associate disposal with waste considerations, and therefore when they consider disposal in evaluating a product, they will perceive the product to be higher on wastefulness. This effect occurs even though descriptions of disposal are irrelevant to the actual wastefulness of the product. We also argue that this heightened wastefulness perception mediates the link between disposal reference and product evaluations. That is, references to product disposal at the time of acquisition will lead to a higher wastefulness perception, which in turn leads to a lower purchase likelihood. We further test how this heightened wasteful perception can be mitigated by examining conditions under which this disposal reference effect is likely to occur and how to mention disposal without hurting product evaluations. Adding to prior research that has examined how an attribute drives consumers' perception of greenness of a product (Gershoff and Frels 2015) or associations eco-friendliness of a product has (Brough et al. 2016; Luchs et al. 2010), we examine whether disposal as it relates to a product influence perceptions of how wasteful a product is.

Study 1 (disposal reference vs. control between-subjects design; N = 400) provided initial support for our prediction that descriptions of disposal lead to higher wastefulness perception. Participants were asked to view descriptions of a product (a computer mouse) and write about their thoughts related to the product. In addition to the product descriptions participants in the control condition saw, those in the disposal condition were reminded to remove the batteries when disposing the mouse, descriptions which do not bear any meaningful implications for sustainability of the focal product. Then participants were asked to rate how wasteful the product is (1 = not at all, 9 = very much). The results indicated a significant effect of condition on wastefulness perception, with those in the disposal condition ($M = 4.50$, SD = 2.36) more likely to perceive the mouse as wasteful compared to those in the control condition ($M = 3.59$, SD = 1.94), $F(1, 398) = 17.52$, $p < .001$.

Study 2 (disposal reference vs. control between-subjects design; N = 398) replicated study 1 findings with a different product category (a backpack) and demonstrated the downstream consequence of wastefulness perception on purchase likelihood (1 = not likely at all, 7 = very likely). Results indicated that compared to those in the control condition, participants in the disposal condition perceived the backpack to be more wasteful, $F(1, 396) = 15.32$, $p < .001$, and indicated a lower likelihood of purchasing the backpack, $F(1, 396) = 14.41$, $p < .001$. Additionally, wastefulness perception mediated the link between disposal and purchase likelihood, $B = -.20$, SE = .07, 95% CI: -.34, -.08 (Hayes 2017, model 4). That is, descriptions of product disposal led individuals to perceive the backpack as more wasteful, which in turn decreased their likelihood of purchasing it.

Study 3 (disposal reference vs. control between-subjects design; N = 400) examined when this association between disposal and wastefulness would likely occur. At the beginning of the study, participants were asked to indicate expected product usage length (i.e., how long they typically use a product) for various product categories including the focal category of the study, backpack. Then they evaluated the backpack in terms of how wasteful and eco-friendly the product is and their purchase likelihood. Results indicated a significant interaction effect of condition and expected usage length on eco-friendliness index, $B = -.01$, SE = .004, $t = -2.10$, $p < .05$. For individuals who expected to use the product for a longer period of time, descriptions of disposal in evaluating a backpack led them to view the product as less eco-friendly, replicating our disposal reference effect. But for individuals who expected to use the product shorter, referencing disposal in product descriptions did not have an effect on eco-friendliness perception of the backpack. Moderated mediation analysis using the condition as IV, expected usage length as moderator, eco-friendliness perception as mediator, and purchase likelihood as DV yielded significant results (Hayes 2017, model 8).

Study 4 (disposal reference vs. control vs. recycle reference between-subjects design; N = 601) demonstrated how to mitigate the negative effect of talking about disposal on product evaluations by increasing the eco-friendliness of the disposal method mentioned. In addition to the two conditions described in study 1, those in the recycle condition were presented with a similar piece of information as those in the disposal condition, but were instead instructed to remove and recycle the batteries. Again, there is no real implications about the actual eco-friendliness of the product, but there was a significant effect of condition on wastefulness perception, $F(1, 598) = 3.02$, $p < .05$. Post hoc analysis revealed that those in the disposal condition rated the product to be higher on wastefulness compared to those in the control condition, as well as those in the recycle condition, Fisher's LSD: both ps $< .05$. However, there was no difference between control and recycle conditions, Fisher's LSD: $p > .05$, indicating that whereas reference to general product disposal led to higher wastefulness perception, mentioning recycling attenuated this effect.

Across four studies, we document a novel effect of how referencing disposal as part of product information hurts product evaluations by increasing wastefulness perception. Our research makes theoretical and practical contributions; we extend the product disposal literature in demonstrating an instance of how disposal thoughts influence consumer decisions before the disposal phase, enrich work on sustainability by showing how consumers draw inferences about wastefulness of products, and sensitize marketers to be careful in talking about disposal due to its potential negative consequences on product evaluations.

Trashing Products to Signal Displeasure

EXTENDED ABSTRACT

When disposing of products, particularly those with market value, consumers often prefer to sell or donate them (Jacoby, Berning, and Dietvorst 1977). In this research, we argue that consumers sometimes deliberately select the disposal method of trashing (e.g., throwing away, burning, shredding) in order to provide an active and emphatic signal to oneself and/or others. Specifically, we argue that trashing symbolically conveys displeasure, particularly when the trashed product could have been sold or donated instead. Because it is costly, trashing products with remaining value (rather than disposing of them in a way that preserves their residual utility) can uniquely express displeasure by representing the symbolic destruction of the people, memories, or ideas associated with the trashed product. As such, we posit that the preference for trashing should be relatively stronger for products with negative (vs. positive or neutral) sentimental value.

We attribute this increased preference for trashing products with negative sentimental value to *symbolic fit*, which we define as a match between a specific disposal method and its ability to express a specific sentiment. We propose that because disposal methods differ in their ability to uniquely express sentimental value, consumers' preferred disposal method will be influenced by a product's sentimental value. To the extent that consumers desire to symbolically make a point to others or send a message to themselves through the disposal of a product with negative sentimental value, the unique ability of trashing to express displeasure provides the greatest symbolic fit, resulting in an active and emphatic signal that alternative disposal methods cannot convey as effectively.

We further argue that one downstream consequence of trashing (rather than selling or donating) an item with market value will be a change in perceived identity. Building on the notion that a particular disposal method is often chosen strategically, our claim is that the use of a particular disposal method may influence the way that one is perceived. We argue that consumers choose specific disposal methods to manage identity, and that perceived identity may be influenced by even a single act of disposal that is intentionally selected for its ability to signal displeasure.

Study 1 examined the extent to which a product's positive versus negative sentimental value affects disposal method preferences. A total of 380 participants were asked to think of a product that they had previously owned but decided to dispose of. Participants were either told that the product should have positive or negative sentimental value. After explaining why the item had positive/negative sentimental value, participants indicated how they disposed of it. As expected, participants were relatively more likely to trash a product with negative rather than positive sentimental value (43.4% vs. 27.6%; $\chi^2(1) = 10.27$; $p = .001$. In contrast, participants were relatively less likely to donate a product with negative rather than positive sentimental value (41.9% vs. 58.0%; $\chi^2(1) = 9.80$; $p = .002$. No significant difference was observed in the likelihood of selling (13.1% vs. 13.3%); $\chi^2(1) = .001$; $p = .97$.

Study 2 tested whether the effect of negative (vs. neutral) sentimental value on disposal method preferences would be mediated by symbolic fit. A total of 402 participants imagined owning a watch that was a gift from a friend whom they had not seen in a while. Those in the negative sentimental value condition learned that their last encounter with the friend involved a "heated argument." Participants indicated their likelihood to trash and to donate the watch. To measure symbolic fit, participants rated the extent that each disposal method served as a signal to themselves and others. To assess relative disposal method preference, we subtracted participants' likelihood to trash the watch from their likelihood to donate the watch. We observed a significant main effect of sentimental value ($F(1, 398) = 4.89$, $p = .028$) on disposal method preference, such that trashing was relatively more likely when the sentimental value of the watch was negative ($M = +1.73$, $SD = 53.31$) versus neutral ($M = +11.69$, $SD = 37.00$). Results of a mediation analysis (Hayes 2017, model 4) showed that the indirect effect of sentimental value (negative vs. neutral) was mediated by the symbolic fit from trashing ($B = -1.99$, $SE = 1.07$; 95% CI: -4.41, -.27) but not donating ($B = -1.61$, $SE = 1.36$; 95% CI: -4.57, .85).

Study 3 examined the consequences of disposal method on perceived identity. A total of 524 participants learned that a baseball player on their friend's favorite team had signed with another team. Participants were informed that their friend had either shredded, donated, or sold this player's baseball card. Subsequently, participants assessed the strength of their friend's perceived identity as a baseball fan. A one-way ANOVA confirmed that perceived identity differed by condition ($F(2, 521) = 5.04$, $p = .007$). Perceived identity as a baseball fan was greater after trashing ($M = 89.60$, $SD = 12.90$) versus selling ($M = 84.58$, $SD = 14.78$; $t(521) = 3.06$, $p = .002$) or donating ($M = 85.89$, $SD = 17.92$; $t(521) = 2.26$, $p = .024$) the card. There was no difference in perceived identity between the sell and donate conditions ($t(521) = .80$, $p = .43$).

This research identifies conditions under which consumers seek to trash identity-relevant possessions that could instead be sold or donated. We show consumers are not only *willing* to trash identity-related products that have market value, but sometimes actively *seek* to do so in order to communicate displeasure. Because trashing (vs. donating or selling) is a disposal method that uniquely expresses displeasure, trashing provides a symbolic fit with negative sentimental value that sends an active and emphatic signal of displeasure more effectively than alternative disposal methods. Additionally, whereas prior research has focused primarily on identity as an antecedent of disposal (Trudel et al. 2016; Trudel 2019; White et al. 2019; Dunn

et al. 2020), we investigate identity as a consequence of disposal and show how preferences for a specific disposal method can affect perceived identity.

SESSION OVERVIEW

People perceive time subjectively. Time perception is nonlinearly scaled with respect to objective time (Read, 2001; Zauberman et al. 2009), and it is vulnerable to certain features of the event (e.g., the peak and the end; Fredrickson and Kahneman, 1993). When judging the continuation of a trend like winning, people are sensitive about the timing of the positive outcome (Gilovich, Vallone, and Tversky, 1985). Although there is much work documenting how time is perceived and how these perceptions affect consumer experiences, there are still many questions regarding how such experiences are adjusted in accordance with lay beliefs about time (e.g., length, speed) and timing (e.g., recency). The four papers in this session explore theoretical and practical questions regarding these lay beliefs about time and timing. For example, what is the role of valence in judging time before and during an event? What about attention? Will paying more attention to time information affect your task commitment? How does the recency of a streak affect people's perception of the self? Do people update their belief about the continuation of success when there is a pause?

The first paper by **Tonietto, VanEpps, Malkoc, and Maglio** demonstrates that event valence affects prospective expectations of how quickly or slowly time will pass during, until the onset, and until the offset of future events. They show that consumers hold the lay belief that time will drag until but fly by during positive future events, and vice versa for negative future events. While this belief about event valence may motivate people to postpone an aversive task, the second paper by **Chun, Lembregts, and Van den Bergh** proposes that explicit attention to duration information can affect procrastination. They show that irrespective of the origin of the information (i.e., externally provided or internally generated), having this numeric information leads people to predict a lower likelihood of procrastination and to increase task completion. The second set of papers then consider lay beliefs on the streak of success. In the third

paper, **Silverman, Barasch, and Small** demonstrate that people make more optimistic predictions about goal adherence following a recent streak of goal-consistent behaviors (versus other patterns with the same overall rate). This occurs because a recent streak signals a greater commitment to the goal. Lastly, **Weingarten and Shen** look to predicting streak continuation of others. They demonstrate that people predict a lower likelihood of streak continuation when an actor takes a break as people believe that the actor's skill does not grow over the break but can grow with continuous actions.

Altogether, this session speaks to the conference theme of self-care by deepening our understanding of how time is perceived or used in judgments and by providing insights on how consumers can better use the time to enrich their lives. The papers are all at an advanced stage of development, having completed at least four or more studies. This session should appeal to researchers and practitioners who are interested in time, intertemporal choice, judgment and decision-making, self-control, and goals.

Time Will Fly During Future Fun (But Drag Until Then)

EXTENDED ABSTRACT

Consumers commonly consider how long the time *during*, until the *onset*, and until the *offset* of future events feel. In the present research, we examine the role of event valence in each of these judgments and propose that consumers tend to perceive positive (vs. negative) future events as particularly short and distant.

Consumers want positive events to last and engage in tactics to prolong enjoyment (Chun, Diehl, and MacInnis, 2017). They also want good things to arrive soon (Balcetis and Dunning, 2010). Consistent with motivated reasoning (Kunda, 1990), these preferences could lead consumers to judge positive events as particularly long and near. However, consumers also hold the lay theory that "time flies when you're having fun" (Gable and Poole, 2012; Sackett et al., 2010), which could color prospective judgments to the extent that consumers expect for the future what they have experienced in the past. Thus, consumers may conclude that time *will* fly throughout future fun. Because lay theories can produce contrast effects when making relevant comparisons (Mukhopadhyay and Johar, 2005), consumers judging that time will fly during future positive events may contrastingly think time will drag during the time beforehand (and vice versa for negative events). Thus, an account based on lay theories predicts that positive future events will feel particularly short and distant.

Appraisals of the distance to the ends of events can be formed via a mental integration of the time prior to and during events. Our lay theory account predicts contrasting perceptions prior to and during future events, which could cancel each other out (based on relative effect sizes) such that the ends of positive and negative events could feel similarly distant. Further, the combination of subjectively distant onset and subjectively short duration could lead the beginnings and ends of positive events to feel equally distant from the present, thus eliminating the duration of future positive events in the mind's eye. Four studies test these propositions.

An initial Pilot Study investigated how long people perceived the duration until and during the Thanksgiving holiday. The more positively participants felt about Thanksgiving, the longer the time

until (r=.128, p=.041), but the shorter the time *during* Thanksgiving felt (r=-.141, p=.016).

Study 1 followed a 3(valence: positive, negative, neutral; between-subjects) x 2(time point: beginning, end; within-subjects) mixed design. Participants considered the upcoming weekend that was either expected to be positive, negative, or neutral and indicated how far away the beginning and the end of the weekend felt (0=very near, 100=very far). We found the predicted interaction. The beginning of the positive event felt significantly farther away than the negative event ($M_{positive}$=74.37, $M_{negative}$=52.31, p<.001). The neutral event fell in-between and significantly differed from both ($M_{neutral}$=66.32, both ps<.01). There were no differences in perceived distance to the ends of events ($M_{positive}$=73.34, $M_{negative}$=68.37, $M_{neutral}$=71.82, all ps>.11). To examine the perceived time *during* the event, we compared how far the end of the event felt to its beginning. As expected, the end of the negative (p<.001) and neutral event (p=.024) felt significantly farther away than its beginning. However, no such difference emerged for the positive event (p=.67). By participants' *own ratings*, the positive event seemed duration-less. Thus, relative to a neutral event, positive events feel farther and shorter, while negative events feel closer and longer.

Study 2 tested the mediating role of expected temporal progression in a 2(valence: positive, negative; between-subjects) x 2(time point: beginning, end; within-subjects) mixed design. Participants considered a scheduled weekend trip that was either expected to be positive or negative and indicated perceived distance to the beginning and to the end of the trip. Then, participants indicated how time would pass until and during the event (1=definitely drag on, 7=definitely fly by). Replicating Study 1, the beginning of the positive versus negative trip felt significantly farther away ($M_{positive}$=68.84, $M_{negative}$=39.60, p<.001), and there was no difference in perceived distance to the trips' ends ($M_{positive}$=63.84, $M_{negative}$=67.58). Once again, the end of the negative event felt significantly farther than its beginning (p<.001), but this was not the case for the positive event (p=.15). Looking next at expected temporal progression, time was expected to pass more slowly *prior to* the positive versus negative event ($M_{positive}$=2.82, $M_{negative}$=4.16, p<.001), but more quickly *during* the positive versus negative event ($M_{positive}$=6.51, $M_{negative}$=3.58, p<.001). Thus, participants expected time to drag before, but fly during positive events (and vice versa for negative events) and these expectations mediated the observed effects on time perception.

In the final study, we tested our process by directly measuring perceived duration and using a moderation approach, whereby our observed effects should be exaggerated for participants who chronically endorse the "time flies when you're having fun" lay theory. The study followed a 2(event valence: positive, negative; between-subjects) x 2(timeframe: until, during; within-subjects) x belief in the lay theory (measured) design. Participants read that they would watch two five-minute-long videos back-to-back. The second video was described as either positive or negative to serve as the valenced event, while the first video served as the preceding interval. Participants indicated how long both the first (until timeframe) and second (during timeframe) videos felt like they would last (0=very short, 100=very long). Lay beliefs were measured via agreement with four statements (e.g., "time flies when you're having fun," α=.73). Conceptually replicating prior studies, participants expected the first video to feel longer when it constituted the time until the beginning of a positive versus negative event ($M_{positive}$=58.27, $M_{negative}$=39.45, p<.001). Conversely, the time during the second video was expected to feel shorter when that event was positive versus negative ($M_{positive}$=39.78, $M_{negative}$=75.50, p<.001). The three-way interaction was also significant (p<.001) such that for both timeframes, greater

chronic endorsement of the lay theory exacerbated the observed effects of valence on perceived duration.

Investigating the role of event valence, we find that the beginning of positive events feels farther away, while the end of positive and negative events can feel similarly distant. Additionally, positive events feel prospectively shorter—so much so that their beginnings and ends can feel similarly distant from the present.

Prospective Duration Neglect - the Effect of Duration Information on Procrastination

EXTENDED ABSTRACT

Procrastination is widely recognized. Think about needing to reply to students' emails or calling a doctor for an appointment: these tasks are often and consistently delayed because the cost of completing them today appears larger than doing them later (Shu and Gneezy, 2010; Zauberman and Lynch Jr, 2005). In this present research, we investigate the role of task duration information (i.e., 5 minutes for a call) and propose that procrastination is, at least in part, caused by inattention to task duration.

It is well-documented that in a retrospective evaluation of an experience (e.g., colonoscopy), people inaccurately factor in the duration of the experience. Instead, the peak, at which one experiences most pain, and the end, when one is released from it, correlate more strongly with the global evaluation of the experience (Fredrickson and Kahneman, 1993; Redelmeier and Kahneman, 1996). While it was shown that increasing duration sensitivity decreases present bias (Read et al., 2005; Zauberman et al., 2009), it has not been documented that making task duration salient decreases procrastination.

To gain initial insight into whether people neglect duration in procrastination decisions, we ran a two-part preliminary study. In Part 1, we collected reasons (e.g., unpleasantness, internal motivation) for procrastinating from 100 Mturkers and had two independent judges (r=.75) rate how much each reason concerned task duration (-3: nothing to do with duration, +3: everything to do with duration). In Part 2, we asked another 100 MTurkers to rate how important task duration is in procrastination (1: not at all important, 7: very important). We found that people considered duration to be an important factor when asked explicitly (M_{dur}=5.22, SD=1.46, t(99)=8.35, p<.001) although naturally generated reasons for procrastination did not concern duration (M_{dur}= -2.36, SD=1.43, t(427)= -34.2, p<.001). This shows that people may not think of task duration when procrastinating despite valuing it highly.

We tested whether making task duration salient decreases procrastination in 5 studies. In Study 1 (N=451), participants were assigned to read one of three vignettes with (v. without) task duration information: writing an email, making a dentist appointment, or submitting a tax form. They were asked to predict procrastination likelihood using 3 items (e.g., "how likely are you to further delay calling the doctor": 1 – not at all, 7 – very much). We found that providing task duration information decreased people's own prediction of procrastination (M_{absent} = 4.10, $M_{present}$=3.51, F(1, 445)=10.22, p=0.001) irrespective of the context.

In Study 2, we tested the effect of duration salience on procrastination in a field study with participation in an online charity event as a behavioral measure. Of the 100 MTurkers who saw the event announcement, 85 committed to participate either on the same day as the registration or a week from the registration. We sent the link to the event on their chosen dates of participation. Those in the duration information (v. control) condition read (did not read) in the invitation email that the event would take about 3 minutes to complete. Running a binary logistic regression on event completion, we found that

those in the duration salient condition (v. control) procrastinated less on the event and completed it on the chosen date (*b*=1.19, *SE*=.55, *z*(83)=2.17, *p*=0.030).

Though Studies 1 and 2 document the effect of duration information on procrastination, we made the duration salient by providing the information. This design can raise a concern that people procrastinate less on a task because the provided estimate is lower than their expectation. Studies 3 to 5 address this concern by asking participants to estimate their own duration. In Study 3 (N=404), we assigned our participants to one of three conditions: control, estimating the duration of a focal task (calling a doctor), and estimating the duration of a similar task (calling a hairdresser). Then, people predicted their likelihood to procrastinate on calling the doctor, using items similar to Study 1. We observed that duration salience had a significant effect on procrastination likelihood (*F*(2,401)=13.23, *p*<0.001)). More importantly, compared to control (*M*$_{control}$=4.99), those in the focal task condition (*M*$_{focal}$=4.27, *t*(401)= -3.21, *p*=0.001) and those in the related task condition (*M*$_{related}$=3.85, *t*(401)= -5.09, *p*<0.001) predicted that they would procrastinate less. The results indicate that making duration salient with the same act but in a different context leads people to believe that they are less likely to procrastinate on a task. Study 3 rules out the alternative explanation of expectancy disconfirmation because it uses self-generated estimates for both the focal and similar tasks.

In Study 4 and 5, we tested whether duration information decreases procrastination when the task is more concrete (Study 4) and when there is an upcoming event (Study 5). Study 4 and 5 used the same experimental paradigm as Study 3. For Study 4, we manipulated task concreteness by asking people to list three actions at the start or end of the task (e.g., hanging up the phone). Results showed that duration salience decreases procrastination (*F*(1,416)=5.79, *p*=0.017) as well as concreteness (*F*(2,416)=3.08, *p*=0.047). However, there was no significant interaction effect (*F*(2,416)=0.85, *p*=0.426). For Study 5, we told our participants that there is an event scheduled to happen in an hour. We counter-balanced the order of the information so that participants learn about the calendar event after (before) learning about the task. We found that duration salience decreases procrastination (*F*(1,417)=9.81, *p*=.002) regardless of the presence of an upcoming event (Event: *F*(2, 417)=0.5, *p*=.473; Interaction: *F*(2,417)=.30, *p*=.745).

We argue that people do not naturally factor in task duration in their procrastination decisions. When attention is drawn to it explicitly, however, people are less likely to procrastinate. We believe this is because duration information leads people to focus less on the relative scarcity of the present temporal resource and more on the costliness of the task itself. Studies 5 hints at the possibility of this explanation as duration salience decreased the likelihood of procrastinating despite having an upcoming event, which can make time appear more bounded and shorter (Tonietto, Malkoc, and Nowlis, 2019).

Hot Streak! Inferences and Predictions about Goal Adherence

EXTENDED ABSTRACT

The rise of behavioral tracking (e.g., Fitbits; meal-logging apps) raises questions about how such data informs consumers' beliefs and future behavior. Specifically, this technology highlights sequences of behavior over time, which could affect inferences of commitment. Moreover, beliefs about the likelihood of staying "on track" with goal pursuit likely inform preferences for restricting choice freedom: If consumers believe they are unlikely to stick to an important goal, they will be more likely to employ restrictive goal pursuit strategies (i.e., commitment devices).

Here, we examine how streakiness of past behavior influences consumers' predictions of future behavior. For example, consider two consumers who have a goal of becoming healthier through regular exercise. Imagine that both of them exercised four days in the past week: Consumer A exercised on Days 1, 2, 5, and 7, whereas Consumer B exercised on Days 1, 5, 6, and 7. While both exercised the same amount, only Consumer B exhibits a *recent streak*: A pattern of behavior with a specific action for three or more recent, consecutive opportunities (Carlson and Shu, 2007). Our key prediction is that a recent streak is a signal of goal commitment, which leads to more optimistic predictions regarding goal adherence. We demonstrate this effect in six studies (four preregistered) comparing a recent streak to several different control conditions, across a variety of goal-directed behaviors.

In Study 1, 461 participants read about an individual with a goal of eating healthy. This individual chose between eating fruit or ice cream every evening. All participants were told that the individual had adhered to the goal on three of the last six days and given in to temptation on the other three days, but saw different patterns: the individual either ate fruit on Days 4, 5, and 6 (*recent streak* condition), on Days 3, 4, and 5 (*old streak* condition), or on Days 1, 4, and 5 (*scattered* condition). Participants then predicted whether the individual would eat fruit or ice cream for dessert tomorrow (*r*=-.87) and reported how committed they perceived the individual to be to their goal of eating healthy (4 items, *α*=.89) on 7-point scales.

Participants predicted the individual with a recent streak was more likely to stick to their goal (*M*=3.84) than an individual with an old streak (*M*=3.31; *p*=.002) or scattered pattern (*M*=3.17; *p*<.001). Participants also perceived the individual with a recent streak as more committed to eating healthy (*M*=3.86) than an individual with an old streak (*M*=3.47; *p*=.005) or scattered pattern (*M*=3.34; *p*<.001). Perceived commitment to the goal mediated the relationship between a recent streak (vs. other patterns) and predicted behavior (*old streak:* Indirect effect=.11, 95% CI [.03, .22]; *scattered:* Indirect effect=.17, 95% CI [.07, .29]).

Study 2 (N=376) replicated these effects when participants forecasted their *own* behaviors regarding a different goal: being productive in the morning by waking up on time (versus sleeping in). Specifically, participants who imagined having a recent streak of waking up on time thought they would be more likely to do so (*M*=4.58) than participants who imagined having an old streak or scattered pattern of waking up on time (*Ms*<3.45, *ps*<.001). Participants with a recent streak also thought they were more committed to their goal than participants with other patterns (*ps*<.02).

Study 3 (N=226) examined this effect using another goal (reducing internet use) and a within-subjects design, and explored an important consequence of inferences of commitment: the willingness to recommend a commitment device. Again, participants predicted that an individual with a recent streak was more likely to avoid online activities and perceived them to be more committed to their goal, relative to an individual with an old streak or a scattered pattern (*ps*<.001). Participants were also less likely to recommend the use of a commitment device for an individual with a recent streak (*M*=4.04), relative to an individual with an old streak (*M*=4.36; *p*<.001) or a scattered pattern (*M*=4.46; *p*<.001).

In Study 4, 602 participants read about an individual choosing to stick to their healthy eating goal or not, and that the individual chose to eat healthy on either the last three days (*recent streak* condition) or yesterday (*no streak* condition). To examine the commitment signal mechanism further, we also varied whether the individual's

rate of choosing to eat healthy over the past several weeks was 20%, 50%, or 80%. We predicted that the less frequently an individual has stuck to their goal in the past, the more a recent streak will signal commitment. That is, we expected the effect of a recent streak on predicted likelihood of sticking to a goal would be strongest in cases where the individual has a low overall rate of goal adherence. As predicted, results showed a significant interaction ($F(2, 596)=27.24$, $p<.001$), such that the effect was strongest when the rate was 20% ($M_{recent\ streak}=3.72$ vs. $M_{no\ streak}=2.47$; $p<.001$), followed by 50% ($M_{recent\ streak}=3.82$ vs. $M_{no\ streak}=3.29$; $p=.007$), and reversed for 80% ($M_{recent\ streak}=4.97$ vs. $M_{no\ streak}=5.64$; $p<.001$). Similar effects were found for perceived commitment ($F(2, 596)=10.36$, $p<.001$).

Two additional studies showed that the effect is strongest for predictions regarding self-control dilemmas than for other behavioral predictions. This suggests that perceived commitment impacts inferences beyond more general beliefs about statistics and streaky patterns (e.g., the hot hand fallacy: Gilovich, Vallone, and Tversky 1985). In Study 5 (N=302), participants again predicted an individual with a recent streak was more likely to eat fruit and more committed to their goal than an individual without a recent streak ($ps<.004$). However, these effects persisted to a lesser degree for inferences about a basketball player shooting free throws (*interactions: Fs>3.50, ps<.03*). In Study 6 (N=402), we found this same attenuation when examining inferences within self-control dilemmas (eating fruit or ice cream) versus choices between leisure activities (watching TV or playing video games; *interactions: Fs>7.75, ps<.001*).

In summary, a recent streak signals commitment to a goal, and thus affects predictions that a person will work harder towards their goal. Together, these results shed new light on the significance of streaky behavior for judgment and prediction.

The Real Momentum Effect

EXTENDED ABSTRACT

When do people predict a streak will continue? That is, when do people believe a basketball player continue to make shots, a hockey pro will continue to score goals, and a bridge champion will continue to win hands, and when do people believe the streak will end? Past research suggests that such factors as streak length (i.e., how many shots; Rabin and Vayanos 2010), agency (i.e., control; Oskarsson et al. 2009), felt momentum (Markman and Guenther, 2007), and whether people are winning or losing influence streak perceptions (Briki et al., 2014).

We examine how people predict the likelihood of streak continuation depending on whether actors increase the interevent times between their actions. That is, if actors take a break in the middle of a streak, do people believe they are more or less likely to continue the streak (for similar ideas for the gambler's fallacy, see Gold 1997)? Contrary to an account in which a break might help refocus, refresh, or relax an actor, we find that people believe breaks have a negative impact on perceived likelihood of streak continuation.

We argue that a break might diminish the perceived likelihood of streak continuation by lowering an actor's perceived skill relative to a control condition. That is, when an actor takes a break, they are perceived to not be as skilled as they were had they continued their actions without a break.

In the first preregistered study (https://aspredicted.org/blind.php?x=8r8uy2, N = 247), we demonstrated the basic phenomenon and suggestive evidence of the process. Participants read about a character named Anuj who had thus far made five shots in a row. Participants also completed practice predictions for shots 3, 4, and 5 in which they guessed whether Anuj continued the streak or not (starting a "streak" around three shots in line with prior literature; Carlson and Shu 2007). On the sixth shot, the key dependent measure, participants were randomly assigned to learn Anuj continued shooting (Control) or first took a break (Break). Relative to participants' estimates of whether Anuj would continue the streak on the sixth shot in the control (67.48%), participants in the break condition thought Anuj was less likely to continue his streak (53.23%; $z = -2.28$, $p = .028$). This result operated through beliefs about Anuj's skill on the final shot (95% CI [-.923, -.295]). An earlier preregistered replication (https://aspredicted.org/blind.php?x=vv77af, N = 320) without the measures for mediation found similar results ($z = -4.75$, $p < .001$).

In a second preregistered study (https://aspredicted.org/blind.php?x=ew7e3x, N = 373), we examined whether this pattern was relative to the actions of others. That is, is a break from an actor harmful if others around him or her also take a break? In this study, participants read about a character named Reid who played Shanghai Mahjong who was on a streak of five wins. Participants were randomly assigned to one of three conditions: Reid continued playing (Control), everyone took a break (Everyone Break), or only Reid took a break (Only Reid); all participants predicted whether Reid would win his sixth hand. Whereas everyone taking a break had a negligible impact on Reid's predicted streak continuation relative to control (63.9% in Control vs. 57.02%), when only Reid took a break (31.09%), he did worse relative to Control ($z = -5.10$, $p < .001$) and when everyone took a break ($z = -3.99$, $p < .001$). This result operated through Reid's perceived skill. Another study without mediation evidence replicated the pattern of results (N = 488).

In a third preregistered study (https://aspredicted.org/blind.php?x=6ga7vs, N = 488), we tested whether, instead of "slowing down" with a break, whether "speeding up" would bolster predictive performance with a more continuous performance measure. In this study, participants read about a character named David who sells rainbow cotton candy every other day. After David's most recent day (Day #7), participants are randomly assigned to read that David returned to run his shop on Day #8 (Speed Up), returned on his usual Day #9 (Control), returned a day later than usual on Day #10 (Slow Down), or returned two days later than usual on Day #11. Participants predicted how much money David would make, in $, instead of the binary measures from the previous studies. We find that people predicted David to do worse when returning later than usual on Days 10 ($t = 2.29$, $p = .023$) or 11 ($t = 2.72$, $p = .0068$), but that David only performed directionally worse when returning a day earlier than usual ($t = 1.49$, $p = .137$). This result operated through David's perceived skill as a function of when he came back to run his shop. Another preregistered replication found the same pattern of results without mediation measures (https://aspredicted.org/blind.php?x=mb6f94, N = 437).

Another study (N = 200) examined whether the aforementioned results applied when an actor was doing poorly instead of winning. In this context, David was described to be paying $100 per day of operation but earning less money (Loss), or to be paying $50 per day of operation but earning more money (Gain). We observed a marginal interaction: the aforementioned break effect was found when David was in the gain domain but not in the loss domain.

Finally, we rule out several other alternatives that could also account for the results. First, we ruled out that the break operates through bracketing. That is, one possibility is that a break segments the actor's efforts into multiple sets and resets their performance for the next set (see Yang and Urminsky 2015). To address this concern, we ran a pilot study (N = 280) in which we observed the usual break effect regardless of how Anuj's shots were bracketed in the descrip-

tion. Second, we addressed whether breaks would help when actors are fatigued. In a pilot study (N = 303), when an actor named Yuval was described as fatigued, whether or not he took a break does not help their performance.

SESSION OVERVIEW

Literature on sequential decision making shows that when consumers make several decisions in a row, an earlier decision can influence the outcome of the following ones (Dhar, Huber, and Khan 2007; Xu and Wyer 2007; Gao and Simonson 2016; Goldsmith, Roux, and Ma 2017). Much of this research applies a mindset perspective and suggests that making a prior decision may activate a cognitive procedure that carries over to influence how consumers make subsequent decisions (for a review, see Xu and Wyer 2010; Xu and Schwarz 2018). The current session brings together four papers that investigate the effects of sequential decision making on spending in contemporary marketing contexts and document novel processes beyond the mindset explanation.

The first paper, by Chen, Xu, and Rodas, presents the novel finding that rating a service professional first reduces the subsequent tip amount. Drawing from the literature on mental accounting and pain of payment, they suggest that when consumers categorize rating and tipping as different types of rewards in the same mental account, rating first may justify tipping a smaller amount. Therefore, even high ratings can surprisingly lead to smaller tips.

The second paper, by Khan and DePaoli, shows that when facing a stockout of the desired product that consumers planned to purchase, they prefer spending more money to buy an expensive substitute from the same brand as the stockout product rather than switching to a different brand. The authors account for this phenomenon by proposing a model of how disruption affects sequential decision making. When an initial decision to purchase an option is disrupted by an unexpected stockout, consumers exhibit greater brand loyalty, even at the cost of spending more, to repair the disruption-induced negative feeling. The studies were conducted in the novel contexts relating to COVID-19 stockouts.

The third paper, by Gao and Zhang, demonstrates that when people allocate resources unit by unit (e.g., spend the first $1,000, then the second $1,000, … the fifth $1,000, etc.) sequentially to acquire products in different categories, they tend to seek variety and invest in a broader variety of product categories. In contrast, when they focus on deciding how much resources to be allocated to each

product category, they tend to invest in a small number of categories and spend more on each category.

The final paper, by Singh and Roux, identifies a novel deferral momentum effect that curbs spending. They find that engaging in one choice deferral prompts greater deferral on subsequent choices in sequential decision-making contexts. It turns out that putting off an initial choice undermines consumer self-confidence, which casts doubt on their decision-making abilities and causes additional deferrals. This tendency is particularly evident among consumers who have low chronic self-confidence.

In addition to documenting novel phenomena and providing compelling explanations, all four papers provide pragmatic and innovative solutions to business practices in the domain of investigation. Given the important role of sequential decision making in people's daily lives and the variety of novel findings uncovered by leading scholars in this research area, we expect this session will be of interest to a broad audience at ACR. Not only should it appeal to researchers working on judgment and decision making, choice, cognition, branding, and service marketing, but also to marketing practitioners and policymakers more broadly.

Rating Service Professionals First Reduces Tip Amount in Sequential Decisions

EXTENDED ABSTRACT

Tips account for a significant portion of the U.S. economy. In restaurants alone, $47 billion are tipped annually (Azar 2011). Tipping is also an important source of income for many service professionals, often representing half the income of those working in the food-service business (PayScale 2015). Given the importance of tipping, a significant amount of research has explored the factors impacting tipping behavior (McCall and Belmont 1996; Lynn and McCall 2000; Lynn 2004; Liu 2008; Lynn 2011; Van Vaerenbergh and Holmqvist 2013). However, new technological advances pose new questions to be answered. For example, requesting ratings of service professionals has become ubiquitous in several contexts, such as ridesharing, restaurants, and delivery apps, yet little is known about the effects of this practice on subsequent behaviors, such as tipping. In this research, we ask: "Can asking for service ratings affect tipping behavior?"

We investigate whether and why the order of rating and tipping impacts consumer psychology and consequently the tip amount. We propose that rating a service professional first decreases the amount that customers subsequently tip. Our prediction is grounded in two assumptions. The first assumption is that tipping is costly, both economically and psychologically. Because tipping means parting with money, it is aversive in nature (Prelec and Loewenstein 1998), even when customers may have the intrinsic desire to reward a service professional or when they are motivated to conform to a social norm and avoid embarrassment (Lynn and Graves 1996; Becker, Bradley, and Zantow 2012). When customers have the opportunity to rate a service, they may perceive their feedback as another, less costly and less painful, way to reward a service professional. The second assumption is grounded in the fungibility characteristic of mental accounting. Although customers generally put ratings and tips into different mental accounts because they are qualitatively different, they may categorize them into the same mental account when there

are economical and psychological benefits. Specifically, customers may be motivated to construe ratings and tips as different formats of rewards given to a service professional, categorizing them into the same mental account of awarding the service professional. When they perceive that providing a rating may partially fulfill the obligation to economically reward the service professional, customers give themselves a legitimate reason to justify a smaller amount of tip. However, because the cost associated with providing a rating is much less, we do not expect that tipping first would decrease the rating that customers subsequently provide.

Five studies, including two field studies and three lab experiments, were conducted to test our Hypothesis. Study 1 was designed as a quasi-experiment, leveraging the design difference between the Uber app (rating first) and the Lyft app (tip first). To conduct the study, we hired a driver who was blind to the study purposes. He was instructed to alternate between the two ridesharing platforms and record the amounts of the ride fare and the tip received from each ride, as well as the duration and distance of each trip. As predicted, we found that after controlling for base fare, customers tipped a smaller amount when the app asked for a rating first before soliciting a tip rather than vice versa ($M_{Tipping\_First}$=$1.35, M_{Rating_First}=$.42; p=.01).

Studies 2a and 2b used a lab scenario design in a more controlled setting to replicate the findings of Study 1 and to provide evidence that tipping does not impact subsequent rating scores. Study 2a manipulated two levels of service quality (high vs. average) within a rideshare app scenario and showed that hypothesized effects occurred regardless of service quality ($M_{Tipping\_First}$=$2.89, M_{Rating_First}=$2.09; p=.05). Study 2b extended the generalizability of the results by changing the context from ridesharing to homestay rentals ($M_{Tipping\_First}$=$17.77, M_{Rating_First}=$12.46; p=.04).

One assumption underlying this proposed effect is that tipping, which involves parting with money, is inherently painful and costly. However, the pain of payment may be reduced if people do not have to part with their own money, in which case the decision order would not affect the tip amount. Study 3 explored this boundary condition with Prolific participants, by adding a factor in which someone else (i.e., an employer) pays for a ride in the scenario. Planned contrasts revealed that rating first led to a smaller amount of tip given ($M_{Tipping\_First\_Self\_Pay}$=$6.47, $M_{Rating\_First\_Self\_Pay}$=$5.45; p=.01). However, when the employer was paying for the trip, the order of rating and tipping did not influence how much people tipped ($M_{Tipping\_First\_Employer\_Pay}$=$8.17, $M_{Rating\_First\_Self\_Pay}$=$8.48; p=.45).

Study 4 was a field experiment with a random assignment of conditions and a consequential measure (i.e., real tipping behavior in a restaurant). It also identified a theoretically and practically important boundary condition. Our proposed mechanism stipulates that rating first can lead to a smaller tip amount because customers perceive providing a good rating as having already benefited the service professional. The results supported this expectation ($M_{Tipping\_First}$=$6.93, $M_{Rating\_Service\_Professional\_First}$=$6.01; p=.02) and also showed that when a rating cannot directly be perceived as beneficial to the service professional, it did not affect the tip amount ($M_{Tipping\_First}$=$6.93, $M_{Irrelevant\_Rating\_First}$=$6.99; p=.88).

Our work also contributes to several literature streams. It enriches tipping literature by identifying whether and how decision sequence can influence the amount people tip. The examination of this effect and its underlying mechanism contributes to the literature on the fungibility of mental accounting. Overall, our work highlights the importance of designing a good consumer decision architecture when both ratings and tips are solicited.

Our research is of value to service-sector firms and managers. Tips are of strategic importance to managers. Higher tips result in

better service, help attract and retain quality workers, and alleviate pressure to increase salaries. We recommend that managers solicit tips before ratings when designing a consumer decision architecture.

Brand Loyalty in Response to Stockouts: Sequential Decision-Making during COIVD-19

EXTENDED ABSTRACT

COVID-19 confronted modern consumers with unprecedented product stockouts. Some data show that consumers demonstrated increased loyalty to trusted brands during this time, while other data show increased brand switching and price sensitivity (Becdach et al. 2020; Klein 2020). We help to predict when product stockouts may promote brand loyalty versus price sensitivity.

When faced with a stockout of a desired product, consumers often choose substitutes that most closely resemble the out-of-stock option (Arens and Hamilton 2016; Huh, Vosgerau, and Morewidge 2016). This is attributed to the negative experience of being denied the desired product, which may engender reactance (Fitzsimons 2000) and emotional jilting (Litt, Khan, and Shiv 2010), thus increasing the appeal of the out-of-stock product and substitutes similar to it.

Shifting from prior research, we propose to model product substitution as a disruption of two sequential decisions: a choice about "what to buy" occurring prior to arrival at the point-of-purchase (e.g., while making a shopping list) and a choice "to buy" occurring at the point-of-purchase (e.g., at the store). In this model, stockouts engender negative reactions through the thwarting of the expected decision sequence rather than through the simple denial of a desired product. This distinction generates new predictions about the importance of the foreseeability of the choice disruption as a driver of consumers' negative reactions. We propose that consumers faced with unexpected (expected) stockouts, and thus faced with stronger (weaker) negative experiences of a disrupted sequential decision-making process, are more likely to exhibit brand loyalty (price sensitivity) in their choice of a substitute. We thus examine substitution decisions in which consumers must allocate additional resources to the purchase to remain brand-loyal by choosing a more expensive upgrade from the same brand over a lower priced substitute from a different brand. Three studies test our prediction.

Study 1 (N=303 MTurk workers): This study tested our prediction that brand loyalty, operationalized as preference for upgrade substitutes, is less (more) likely to arise when consumers anticipate (do not anticipate) a stockout, and was conducted in May 2020 following the initial shortages caused by COVID-19. Participants made choices in three product categories drawn from a pool of categories discussed in media stories about COVID-19 stockouts. For each category, participants imagined a shopping trip in which the product they intended to buy was out of stock. They rated how frustrated such a stockout would be (on a 1–7 scale), then chose from three substitutes: a similarly priced product from a different brand (*D*), a higher priced upgrade from a different brand (*D+*), and a higher priced upgrade from the same brand (*S+*). Participants also indicated whether they had personally experienced a stockout in the category. Results showed that when participants had not (had) experienced shortages, and hence were less (more) likely to expect a stockout, they preferred the *S+* option 23.71% of the time (17.82% of the time). A mixed-model logistic regression controlling for within-participant variance confirmed that lower expectations of stockouts indeed predicted increased choice of *S+* (b=0.70, z(889)=3.35, p<.001). Moreover, participants reported greater frustration when they did not expect a stockout (M=4.88) relative to when they did

(M=3.72, t(904=9.11, p<.0001). A mediation analysis confirmed that stockout expectations impacted upgrade behaviors through frustration (95% CI[0.47, 1.56]). The results support the proposition that consumers faced with an unexpected (expected) stockout have more (less) negative reactions to the disruption of their choices, and are thus more likely to show brand loyalty (price sensitivity).

Study 2 (N=674 MTurk workers): This study replicated the results of study 1 using consumers' predicted likelihoods of stockouts as a direct measure of their expectations. Again, less expected stockouts engendered greater frustration, which drove brand loyalty over price sensitivity (95% CI[-1.72, -0.81]). Moreover, we predicted a managerially important moderator that consumers are more likely to expect shortages in consumable (vs. durable) categories. We propose that demand-side stockouts (arising from increased consumption) are more cognitively available to consumers (e.g., Schwarz et al. 1991) and thus more easily anticipated relative to supply-side stockouts (arising from supply-chain disruptions). Consistent with this notion, during the pandemic, demand-side explanations were commonly accepted causes for consumable stockouts (e.g., toilet paper hoarding narratives) while supply-side explanations were oft-overlooked causes for durable stockouts. As predicted, stockouts in durable (consumable) categories were associated with lower (higher) expectations of a stockout, leading to stronger (weaker) brand loyalty (95% CI[-62.26, -24.15]).

Study 3 (N=298 MTurk workers): Participants purchased a product of their choice from a menu of options by spending points earned via boring tasks. After this choice, participants were confronted with a stockout and given a choice between two substitutes. Substitutes were either the same brand as the original choice (*S*) or different (*D*), and one substitute was the same quality/price level as the original (*S* or *D*) while the other was a more expensive upgrade (*S*+ or *D*+). As participants had no reasons to expect stockouts, we predicted that they would show brand loyalty in their substitute choice, even if this meant selecting a more expensive upgrade option. As predicted, participants in both mixed-brand conditions tended to choose same-brand substitutes: participants in *SD*+ chose *S* over *D*+ 78.38% of the time (significantly greater than chance: z(73)=3.61, p<.001) and participants in *DS*+ chose *S*+ over *D* 75.68% of the time (z(73)=3.23, p<.001). Thus, even when brand loyalty meant paying more, preference for the same brand did not differ (χ^2(1, N=144)=0.15, p=.696). Given there was no overall preference for upgrades (χ^2(1, N=144)=43.27, p<.001), these results suggest that preferences for upgraded options were not driven by preference for quality but by brand loyalty strong enough to overcome price sensitivity.

Our findings contribute to research on sequential decision making, product scarcity, substitution, and brand loyalty. We recommend that when product stockouts loom, managers should use consumer expectations to guide decisions about when to compete on price versus to leverage brand loyalty to upsell. These insights are particularly timely because markets are expected to experience another bout of product shortages as the economy reopens post-pandemic, and our results provide guidance for these impending managerial challenges.

Procedure Dependence: The Effect of Sequential Resource Allocation Procedures on Variety-Seeking Behavior

EXTENDED ABSTRACT

Individuals and organizations often need to allocate resources among multiple target options. For example, an investor may allocate his savings among a list of stocks, a company may assign skilled employees to different tasks, and a government may allocate funding to various infrastructure projects. In many cases, the resource allocation task can be viewed as a sequential task of assigning multiple small units of a resource among a set of individual targets.

Imagine a decision-maker faced with the task of allocating $5,000 to five bonds that are each sold in $1,000 increments. One option is to go down the list of stocks and to determine, for each stock, how much money the stock should receive. An alternative approach is to go down the list of resource units ($1,000) and to determine which stock should receive the first $1,000, the second $1,000, until the fifth $1,000. We refer to the former procedure (focusing on individual targets and deciding how many resource-units each target should receive) as the *allocation-by-target* procedure and the latter (focusing on individual resource-units and deciding which target each unit should be assigned to) as the *allocation-by-unit* procedure.

We propose that an allocation-by-target method leads a decision-maker to focus on the available targets, with the primary task of ensuring that the final distribution of resources reflects her assessment of the relative extent to which the various targets are "deserving" of resources. This process often results in the concentration of resources in the more deserving options. In contrast, under the allocation-by-unit method, the decision-maker's focus is on the individual resource-unit, such that the final distribution of resources across targets is de-emphasized. Since resource units are similar to each other, and humans have inherent tendency to diversify choices (Benartzi and Thaler 2001; Messick 1993; Kahn and Lehmann 1991; Pessemier 1978; Simonson 1990), the decision maker is more likely to assign a given resource-unit to a target that has not received resource allocation in the previous round. As a result, the allocation-by-unit method will lead decision-makers to allocate resources to a broader variety of targets. We demonstrate the procedure dependence effect in four studies.

In the Study 1, we asked participants to allocate an imagined lucky draw prize of $3,000 among six personal expense categories, in units of $500. They followed either the allocation-by-target procedure or the allocation-by-unit procedure. Participants in both conditions were reminded that they could choose any level of variety. On average, participants in the allocation-by-target condition selected fewer categories (M = 3.95) than participants in the allocation-by-unit condition (M = 5.63), t(243) = 12.807, p < .0001, d = 1.636.

Study 2 involved real charitable donations. An experimenter gave each participant $50 and asked them to allocate the money among five charity projects in units of $10. Participants were randomly assigned to one of two allocation procedure conditions. As expected, participants in the allocation-by-unit condition donated to more charity projects (M = 4.25) than did participants in the allocation-by-target condition (M = 3.22), t(92) = 5.07, p < .0001, d = 1.05.

Study 3 tested the mechanism. We held constant the total resources and varied unit size and number of targets. Participants were asked to invest $10,000 in stocks following one of two allocation procedures. Each participant was randomly presented with 2, 5, or 10 stocks. The allocation units were $5,000 in the 2-stock condition, $2,000 in the 5-stock condition, and $1,000 in the 10-stock condition. The study adopted a 2 (allocation procedure: allocation-by-target vs. allocation-by-unit) × 3 (target set size: 2 vs. 5. vs. 10 stocks) between-participants design. We found that when only two stocks were available, participants' preference for variety did not differ between the allocation procedures ($M_{by\text{-}target}$ = 1.69 vs. $M_{by\text{-}unit}$ = 1.53), F(1, 638) = 0.49, p = .482. When the choice set increased to five stocks, the allocation-by-unit lead to greater variety-seeking (M = 3.95) than the allocation-by-target procedure (M = 3.42), F(1, 638) = 4.95, p = .026, η^2 = .01. This difference became even more pronounced when

the choice set increased to 10 stocks. These results suggest that participants in the allocation-by-unit condition were more responsive to the size of choice set, such that they naively diversified resources among available stocks, whereas those in the allocation-by-target condition were less susceptible to the naive diversification bias. This finding is consistent with our conceptualization.

Study 4 manipulated the presence or absence of information pointing to a specific option as deserving more resource than other options. We expected that participants following the allocation-by-target method would show greater sensitivity to the presence of such information. In a 2 (allocation procedure: allocation-by-target vs. allocation-by-unit) × 2 (superior option: present vs. absent) between-participants design, participants were asked to allocate $5,000, in units of $1,000, across the seven stocks. One of the stocks was taken from the semiconductor industry. To manipulate the presence of superior option information, we told half participants that one of the stock was expected to outperform the market. The other half of participants were not shown this information. The allocation results showed that among participants who were not informed of the superior option, the allocation-by-unit procedure led to a greater variety-seeking ($M = 4.13$) than the allocation-by-target procedure ($M = 3.84$), $F(1, 800) = 6.62$, $p = 0.010$, $\eta^2 = .01$. This difference was more pronounced among participants who were informed of the superior option ($M_{by-unit} = 4.01$ vs. $M_{by-target} = 3.34$), $F(1, 800) = 33.75$, $p < .0001$, $\eta^2 = .04$.

In summary, our studies provided converging evidence to a procedure dependence effect in resource allocations. Our research contributes to the literature on sequential decision making, resource allocation, and variety seeking. Practically, organizations and policymakers can strategically choose the allocation procedure to induce more or less variety-seeking. Individual decision-makers should also remind themselves of their allocation criteria, and, if necessary, compare the resource allocation outcomes by following different procedures to avoid the unintended procedure dependence effect in resource allocations.

The Deferral Momentum Effect: Choice Deferral in Sequential Decision Making

EXTENDED ABSTRACT

Imagine you are at the supermarket to buy pasta sauce. You find two brands of pasta sauce that are appealing, but cannot decide between the two, and decide not to choose either of these brands. Would the decision to not choose either pasta brand impact subsequent decisions? Our research aims to answer this question. Choice deferral is a form of decision avoidance that occurs when consumers decide not to choose from the alternatives presented to them, which can also be described as "choosing the no-choice option" (Dhar 1997). Although prior research has examined various antecedents of choice deferral (e.g., Dhar 1997; Dhar and Nowlis 1999; Etkin and Ghosh 2018; Novemsky et al. 2007), the psychological and behavioral consequences of choice deferral remain largely unexplored. To our knowledge, there is limited prior research on the consequences of choice deferral, which examined consumers' likelihood of accepting a less attractive version of an initially deferred opportunity.

Prior research has demonstrated that procrastination can offer short-term benefits (vs. long-term costs), such as a temporary relief from the pressures experienced and reduced stress (e.g., Ferrari 2001; Tice and Baumeister 1997; Van Eerde 2003). Building on these findings, we argue that initial choice deferral (vs. no deferral) will increase consumers' confidence in their decision, as it provides them with a short-term relief from having to make a choice. Building

on this, we further predict a *deferral momentum* effect, whereby initial choice deferral will prompt greater choice deferral on subsequent decisions.

In addition, we build on prior research showing that procrastination and other types of decision avoidance are generally aversive (Anderson 2003) to predict that the relatedness of the sequential decision domains will moderate the deferral momentum effect. When subsequent decisions are in a related (vs. unrelated) domain, consumers who already deferred making a choice will be less (more) likely to defer again, as deferring similar (different) decisions makes one's decision avoidance tendency more (less) salient, thus hindering their decision confidence of deferring subsequent choices in related (vs. unrelated) domains.

Study 1 tested whether initial choice deferral increased subsequent choice deferral. Participants ($N = 275$, 44% male, $M_{age} = 21.6$, $SD = 3.7$) were first asked to choose between two equally attractive digital cameras or choose neither and keep looking for more options (i.e., choice deferral; adapted from Dhar and Nowlis, 1999), as well as to rate their confidence in their decision. Thereafter, participants were sequentially presented with four similar choice tasks (i.e., cars, laptops, apartments, and vacation; adapted from Dhar & Nowlis, 1999) and were again asked to rate their confidence in each decision. The dependent variables were the number of subsequent choices participants deferred (0-4) and average decision confidence. Participants who deferred the first choice (vs. not) also deferred more subsequent choices ($M_{Deferral} = 1.89$, $SD = 1.07$, $M_{NoDeferral} = 1.18$, $SD = 1.07$, $F(1, 274) = 29.57$, $p < 0.001$) and reported higher average decision confidence ($M_{Deferral} = 7.92$, $SD = .74$, $M_{NoDeferral} = 7.44$, $SD = .92$, $F(1, 274) = 8.31$, $p < 0.01$). Decision confidence also moderated the effect of choice deferral on subsequent deferral (95%CI .02; .21]. These results provide preliminary evidence for the predicted deferral momentum and the role of decision confidence in this effect. We acknowledge that participants in this study self-selected into the deferral and no deferral conditions. Study 2 and 3 address this self-selection concern by manipulating deferral.

Study 2 ($N = 115$, 35% male, $M_{age} = 21.34$, $SD = 3.36$) manipulated choice deferral using a scenario about deciding to defer (vs. not) repairing one's cracked smartphone screen. Next, participants were presented with the Consumer Self-Confidence scale (Bearden et al., 2001). Of interest to this research was the Personal Outcomes dimension, which is related to one's confidence in one's decision-making abilities. Results showed that deferral significantly increased participants' decision confidence ($M_{Deferral} = 3.61$, $SD = 0.76$, $M_{NoDeferral} = 3.27$, $SD = 0.82$, $F(1, 114) = 5.38$, $p < 0.05$).

Study 3 ($N = 208$, 45% male, $M_{age} = 21.54$, $SD = 3.45$) explored whether decision domain moderates the deferral momentum effect using a 2 (control vs. deferral) x 2 (related vs. unrelated domain) design. Choice deferral (vs. control) was manipulated using the same scenario as in study 2. Decision domain was manipulated by subsequently presenting participants with a decision involving two pairs of headphones (related domain) or two carry-on luggage (unrelated domain). A binary logistic regression showed a significant interaction between choice deferral and domain relatedness ($\beta = -1.95$, $SE = 0.43$, Wald's $= 6.88$, $p < 0.01$), such that initial deferral reduced subsequent deferral in a related domain ($P_{Control} = 31.9\%$, $P_{Deferral} = 14.8\%$, $\chi^2(1) = 4.18$, $p = 0.04$), but marginally increased subsequent deferral in an unrelated domain ($P_{Control} = 11.3\%$, $P_{Deferral} = 25.0\%$, $\chi^2(1) = 3.11$, $p = 0.08$) thus providing a boundary condition for the deferral momentum effect.

In summary, across three experiments, we provide evidence that initial choice deferral increases consumers' propensity to defer subsequent decisions, and that this effect is moderated by the relat-

edness of the decisions' domains. In addition, we provide evidence that choice deferral increases consumers' decision confidence, which underlies the deferral momentum effect. Although further research is necessary to fully understand the boundaries of these effects, and we are currently conducting follow-up experiments to do so, this research provides an important step toward a better understanding of the psychological and behavioral consequences of choice deferral in a sequential decision-making context, which has important implications for academics, practitioners, and consumers.

SESSION OVERVIEW

Consumers often struggle to reach their long-term goals, such as striving to become healthier or saving money. As a result, consumers often seek out companies with products and services that can help them reach these goals. How can these companies motivate their consumers in goal pursuit? Prior research has found that marketers can effectively motivate consumers by offering rewards for completing goal-consistent actions (e.g., Charness and Gneezy 2009) or sending goal-relevant messages (Goldstein, Cialdini, and Griskevicius 2008). Building on this prior research, this session offers three ways to improve these current strategies for motivating consumers by highlighting: 1) the presence of incentives, 2) the salience of incentives, and 3) the salience of goal-pursuit difficulty.

How can marketers better motivate consumers through incentives? In the first paper, Healey and LeBoeuf demonstrate how incentives affect the order in which consumers complete tasks. The authors find that when incentives are present (vs. absent), consumers are more likely to complete difficult tasks before easier ones because 1) consumers are more motivated by the incentives, and 2) they believe that doing the difficult tasks first will be more likely to lead to overall success.

While incentives may motivate consumers, are they *always* effective? If not, how can marketers make incentives more effective? The second paper by Yoon and Woolley shows that incentive salience has differing effects on prosocial behavior. The authors demonstrate that increasing the salience of a reward can motivate people to donate when initial prosocial motivation is low, or perception of the importance of the charity is low, with no undermining effect on motivation for those who are more prosocially motivated or when the cause is perceived as more important.

Aside from monetary incentives, how else can marketers motivate consumers? The last paper by Park, Gershon, and Sharif examines an intervention for consumers who are struggling to reach their goals. The authors study the effects of highlighting goal pursuit difficulty (vs. ease) within marketing messaging on motivation and goal re-engagement. The authors show that companies that describe the goal pursuit as a difficult process increase consumers' perceived achievability of their goal, which in turn increases 1) consumers' likelihood of re-engaging with the companies' products and 2) motivation to continue their goals.

Taken together, this special session examines novel factors and mechanisms that influence consumer motivation, while also highlighting important practical implications that marketers can adopt.

We believe the session fits well with the conference theme, "Self-care," by emphasizing how marketers and organizations can help consumers accomplish desirable outcomes aligned with their goals. We expect the proposed session to appeal to researchers interested in consumer motivation and well-being, incentives, prosocial behavior, and goal pursuit.

How Incentives Help Us Do Hard Things

EXTENDED ABSTRACT

Imagine that you and your partner are planning a birthday party for your partner's mother. Your partner asks if you can pick up cups for the party (which you consider easier) and also pick out a gift (which you find much harder) by Friday. Which task would you start with? Now imagine that your partner also promises to buy you a fancy dinner if you accomplish both tasks by Friday. Would this change the order in which you approach the tasks?

Previous findings show that when faced with easy and hard tasks, people prefer to start with easier tasks (Habbert & Schroeder, 2020) even though starting with the difficult task is more likely to enhance self-efficacy. Starting with the easier task also results in reduced efficiency (Rusou et al., 2020) and long-term learning (KC et al., 2020). We propose that this preference for the easy task may be attenuated when people have incentives for task completion.

We predict that, when faced with a hard task and an easy task, people may tend to prefer to do the easy task first -- but that an incentive to complete both tasks will increase people's preference to tackle the hard task first. We further predict that this pattern occurs because incentives increase the motivation to complete the tasks successfully and because people have a lay belief that the difficult-first order is more likely to lead to success than the easy-first order. Thus, people's increased motivation when incentivized leads them to choose the difficult-first order because they believe it will help them successfully complete both tasks.

In study 1 (N = 382, pre-registered), participants were assigned to either the *incentive* or the *no-incentive* condition. Participants were asked to imagine that a family member had asked them to complete two tasks: one more difficult (finding a very cheap oil change) and one easier (taking out the trash). Participants in the *no-incentive* condition simply read about the tasks. Participants in the *incentive* condition also read that their family member would give them $50 if they completed both tasks successfully. All participants then indicated which task they would complete first. In the *incentive* condition, 52% of participants chose to complete the difficult task first, compared to only 32% in the *no-incentive* condition (X^2(1, N=382) = 16.37, p = 0.0005).

In study 2 (N = 252, pre-registered), participants were assigned to either the *incentive* or the *no-incentive* condition. Participants were asked to imagine their boss asked them to complete a harder task (renegotiate a contract) and an easier task (compile a list of travel agents). Participants in the *no-incentive* condition simply read about the two tasks. Participants in the *incentive* condition also read that their boss would give them a bonus if they completed both tasks successfully. In the *incentive* condition, 57% of participants chose to complete the difficult task first, compared to only 38% in the *no-incentive* condition (X^2(1, N=252) = 8.94, p = 0.003).

In study 3 (N = 297, pre-registered), we investigated the role of motivation as a mediator, using materials adapted from Study 1. In the *incentive* condition, 58% of participants chose to complete the difficult task first, compared to only 36% in the *no-incentive* condition (X^2(1, N=297) = 16.37, p = 0.0001). Participants also reported, on a 7-point scale, their motivation to complete a) both tasks, b) the difficult task, and c) the easy task. The motivation to complete both tasks (M=6.1>M=5.7, p=.007) and the difficult task (M=5.76>M=4.95, p<.0001) was higher in the *incentive* condition than the *no-incentive* condition. This difference was only marginally reliable for motivation to complete the easy task (M=6.23>M=5.97, p=.07). Further analyses revealed that motivation to complete both tasks and motivation to complete the difficult task each mediated the effect of incentive on task-order choice. Motivation to complete the easy task was not a reliable mediator. Thus, increased motivation may underlie the desire to complete harder tasks first (instead of easier tasks first) when people are incentivized.

Studies 4 and 5 investigate why motivation affects the preferred ordering of tasks. Study 4 (N=200) presented participants with the work situation from Study 2 in a single no-incentive condition. We asked participants to select which task they would start with to a) successfully complete both tasks, b) create the most enjoyable experience, and c) create an overall easier experience. A chi-square analysis revealed that people's choices differed among the three dependent variables (X^2 (1, N=200) = 27.8, p = 0.0001). Most participants (78%) indicated that doing the difficult task first would most likely lead to success, but only 48% indicated that this order would be more enjoyable and 45% viewed it as easier. Thus, participants view the difficult-first path as more likely to lead to success, even though it may not be a very enjoyable path, suggesting why incentivized (motivated) participants select this order.

To complement the results of Study 4, Study 5 used the same scenario and assigned participants (N = 323) to either the *incentive* or the *no-incentive* condition. We asked participants whether prioritizing success or enjoyment seemed more important. Those in the incentive condition were more likely to indicate that prioritizing success was more important (94%) than those in the no-incentive condition (85%, X^2 (1, N=323) = 7.3, p = 0.007). Together, studies 4 and 5 suggest that people are more likely to prioritize success when they are incentivized, and that they feel that doing the difficult task first is the more successful order.

In summary, we find that an incentive causes people to be more likely to choose to do a difficult task before an easier one. This is in part because incentives increase motivation, but it seems to be more specifically due to the fact that doing the difficult task first is seen as the more successful path, and success is prioritized when people are incentivized.

Increasing Prosocial Behavior Through Incentive Salience

EXTENDED ABSTRACT

Consumers are frequently incentivized to engage in prosocial behavior. Organizations provide movie tickets to encourage blood donations (Lacetera and Macis 2010a), cash incentives to encourage recycling (Oskamp, 2000), and thank-you gifts for donating to charity (Newman and Shen 2012). Notably, the provision of incentives to motivate prosocial behavior is in stark contrast to research demonstrating incentives undermine motivation (Deci 1971; Benabou and Tirole 2006; Gneezy and Rustichini 2000a). Indeed, some findings suggest incentivizing prosocial behavior can backfire (Newman and Shen 2012; Schwartz et al. 2015).

Why do charities continue to provide incentives if incentives undermine motivation? Whereas having multiple motives for pursuing an action can be demotivating (Kruglanski et al. 2002, 2018; Zhang et al. 2007; Bélanger et al. 2015), the present research suggests that incentives can motivate prosocial action as a function of their salience. In particular, we predict that when an incentive is more (vs. less) salient, it increases motivation for 1) individuals low on prosocial motivation and 2) charities with causes perceived as less important. Further, manipulating reward salience helps maintain motivation for those high on prosocial motivation or those engaging in a prosocial action for a more important cause, by allowing them to attribute their behavior either to the incentive or to the cause (i.e., to either extrinsic or prosocial motivation). Five studies (three pre-registered) involving real behavior test these predictions.

Studies 1-3a utilized an online fundraiser wherein participants' "clicks" provided both a donation to a charity and an incentive for themselves (adapted from Ariely et al. 2009; Exley 2018; Koo et al. 2020). Participants had 90 seconds to click as many times as they desired to donate to the cause and earn money for themselves. During the click marathon, we displayed a tally tracking the number of clicks as our measure of prosocial engagement, which was log-transformed before analysis.

In Study 1 (N=296), we held the salience of the reward constant and measured participants' extrinsic and prosocial motivation to participate in the click marathon. Regressing extrinsic motivation × prosocial motivation on persistence revealed the predicted interaction, B=-.04, p=.002. When prosocial motivation was low, having higher (vs. lower) extrinsic motivation significantly predicted persistence, B=.07, p =.006, which significantly attenuated when prosocial motivation was high, B=-.04, p=.151. This suggests that extrinsic incentives can motivate prosocial behavior for those less inclined to donate.

We pre-registered Study 2 (N=295) and manipulated the salience of incentives for donating. We expected that when incentives were more (vs. less) salient, people would report greater (vs. lower) extrinsic motivation, which would affect their persistence. In the low (vs. high) salience condition, we framed the click tally as the number of "donated clicks" (vs. "bonus earned"). We also measured perceived importance of the cause as a measure of individual difference in prosocial motivation. Regressing reward salience × prosocial motivation on persistence revealed a significant interaction, B=-.07, p=.007. A more (vs. less) salient reward increased persistence among those low in prosocial motivation, B=.09, p=.040, which attenuated when prosocial motivation was high, B=-.08, p=.101. Moderated mediation analyses demonstrated that the salience of the reward differentially interacted with prosocial motivation by changing people's extrinsic motivation to donate, Bindex=.01, 95% CI=[.001, .021].

In Study 3a (N=512; pre-registered), we manipulated both the salience of the reward and prosocial motivation to donate to provide a causal test of our prediction. We manipulated reward salience as in Study 2. We further manipulated prosocial motivation via charity importance by assigning participants to donate to a particular charity; although both charities were important, one was relatively more important than the other. An ANOVA of reward salience × cause importance revealed a significant effect, F(1, 508)=4.00, p=.047. A more (vs. less) salient reward increased persistence for a charity perceived as less important, p=.037, with no effect when the charity was perceived as more important, p=.462.

Study 3b (N=766; pre-registered) conceptually replicated Study 3a using a new paradigm. Instead of a click marathon, we created a typathon fundraiser wherein participants needed to press keys on the computer keyboard to move an icon across the screen; each key

they pressed counted as an actual donation to the charity and a bonus for themselves. In the low-salience condition, the icon was a heart to symbolize donation to the charity; in the high-salience condition, the icon was a coin to symbolize bonus to the self. We manipulated cause importance as in Study 3a. Consistent with previous results, we found a significant interaction between reward salience and charity importance on persistence, F(1, 762)=5.50, p=.019. A more (vs. less) salient reward increased persistence for a charity perceived as less important, p=.003, which attenuated for a more important charity, p=.744.

Demonstrating a practical implication of this effect, Study 4 (N=207) recruited participants from states offering piecemeal cash-back incentives for recycling bottles. We measured persistence in a prosocial behavior as reported frequency of engaging in cash-in recycling for aluminum, glass, and plastic containers. We further measured two key motivations for recycling: extrinsic (i.e., to gain money) and prosocial (i.e., for environmental concerns). Regressing extrinsic × prosocial motivation on cash-in recycling behavior revealed a significant interaction, B=-.11, p=.015. As predicted, when prosocial motivation was low (-1SD), extrinsic motivation had a greater effect on recycling behavior, B=.96, p<.001, than when prosocial motivation was high (+1SD), B=.66, p<.001.

This research provides insight into the question of when incentives are more (vs. less) effective at motivating prosocial behavior and challenges existing research demonstrating incentives undermine prosociality. We find that increasing the salience of a reward can motivate people to donate when initial prosocial motivation is low, or perception of the importance of the charity is low, with no undermining effect on motivation for those who are more prosocially motivated or when the cause is perceived as more important.

The Struggle is Real: Motivating Goal Pursuit by Highlighting Process Difficulty

EXTENDED ABSTRACT

Whether trying to eat healthier, learn a new language, or lose weight, consumers often struggle to reach their goals. Small setbacks are inevitable. Consumers occasionally splurge on a dessert, procrastinate studying, or gain a few pounds. Unfortunately, when consumers experience setbacks, they may disengage from goals and discontinue using goal-relevant products (e.g., nutrition tracking app or Fitbit). How can marketers help consumers persist after these disappointments?

When consumers stop engaging in goal pursuit, marketers may want to reduce the perceived difficulty of reaching the goal. Consumers are less motivated by goals that appear difficult to achieve (Zhang and Huang 2010), and consequently, marketers often stress that goal pursuit can be an easy process. However, in the current research, we show that highlighting the difficulties of goal pursuit by normalizing struggles and setbacks can significantly influence goal re-engagement.

We hypothesize that when consumers are struggling to reach their goals, companies that describe goal pursuit as a difficult process (vs. easy or no process description), 1) increase consumers' likelihood of re-engaging with the companies' products and, 2) motivate consumers to continue pursuing their goals. We propose that this is driven by the perceived self-achievability of the goal. When companies describe goal pursuit as a difficult (vs. easy) process, consumers believe the goal is more achievable for themselves, increasing their interest in goal re-engagement. We test our Hypothesis across five pre-registered experiments.

Study 1a (N = 903), was a 3-cell between-subjects design: control (no process description), easy, or hard. Participants imagined that they are struggling to reach their health goals and previously used an app called Cronometer that tracks their diet and health; however, they stopped using the app temporarily. Then, they received an email from Cronometer. In the [easy/hard] condition, the email stated that maintaining a healthy diet was an [easy/hard] process; no information about the process was described in the control condition. Participants then answered the following: 1) how likely would you be to start using the Cronometer app again? and 2) how motivated would you be to continue pursuing your health goal? When the process was described as difficult (vs. easy or control), participants were more likely to re-use the app (ps < .001) and more motivated to continue pursuing their goal (p < .001, p = .002, respectively). Study 1b (N = 900) replicated these findings with an easier goal (walking 3,000 steps a day) to test for generalizability (app re-usage: p = .024, p = .015; motivation: p = .002, p < .001, respectively). This provides initial support for our hypothesis: describing goal pursuit as a difficult process improves goal re-engagement.

Study 2 (N = 896) replicated our basic effect and tested the proposed mechanism: perceived self-achievability. Replicating Study 1, describing the goal as a difficult (vs. easy or control) process increased participants' likelihood of re-using the app (ps < .001) and increased reported motivation to continue pursuing their goal (ps < .001). Moreover, participants reported that health goal appeared more achievable for themselves when the process was described as difficult (vs. easy) (p < .001); perceived achievability for others showed no significant difference (p =.61). Mediation results showed an indirect effect of perceived self-achievability (app re-usage: β = .32; 95% CI [.17, .49]; motivation: β = .36; 95% CI [.19, .54]). Describing the goal as a hard process increased participant's belief that they could achieve the goal, increasing the likelihood of re-using the app and motivation to continue pursuing their goal.

Study 3a (N = 1795) tested the proposed mechanism via moderation. When consumers struggle to reach their goals, we find that describing goal pursuit as a difficult process increases their perceived self-achievability. We believe this messaging effectively frames the struggle as part of the goal pursuit process (rather than a personal deficiency), increasing perceived goal achievability. If consumers are instead *succeeding* at reaching their goal, we propose that process descriptions should not affect perceived self-achievability. We tested this prediction with a 2 (goal description: hard vs. easy) X 2 (goal experience: struggling vs. succeeding) between-subjects experiment. Similar to Study 1, participants in the [struggling/succeeding] conditions read that they are currently [struggling/succeeding] in reaching their health goal and have received an email from Cronometer. Results showed an interaction between goal description and goal experience on app re-usage and motivation (p = .004, p = .017, respectively). When struggling to reach their goal, participants were more likely to re-use the app and more motivated to continue pursuing their goal when reading the hard (vs. easy) email (ps < .001). When succeeding in their goal pursuit, however, the effect on app re-usage and motivation was attenuated (p = .018, p = .015, respectively). Study 3a provides additional evidence for the role of perceived self-achievability on goal re-engagement. Study 3b (N = 1812) ruled out an alternative explanation of company effectiveness. If the effect is driven by participants' perceptions of company effectiveness (i.e., the company is more attuned to the participants' struggles), then acknowledging that the customer has stopped using the app might moderate the effect. However, in a 2(goal description: hard vs. easy) X 2(control vs. acknowledge) between-subjects study, we found no interaction between goal description and acknowledgement on app

re-usage (*p* = .78) or motivation (*p* = .64), and only main effects of goal description (*ps* < .001).

We find that when companies describe goal pursuit as a difficult (vs. easy) process, consumers are more likely to re-engage with a company's products and are more motivated to continue pursuing their goals. Mechanism evidence reveals that describing goal pursuit as a difficult process increases perceived self-achievability of the goal, which in turn increases goal re-engagement behaviors. These results are particularly important given that maintaining existing customers is typically more valuable for companies than attracting new customers (Wertz 2018). When re-activating struggling customers, companies must adopt effective messaging. Despite the intuitive appeal of making the goal appear easy to re-engage customers, we show that normalizing the struggle of goal pursuit is more effective.

SESSION OVERVIEW

Every so often we wonder who we are and what makes us "us". Our consumption behaviors are both influenced by, and help shape our answers to these fundamental questions (Belk 1998; Berger and Health 2007). Amidst the chaotic times we are going through with the global pandemic, political turmoil, social unrest and polarization, which have all brought drastic changes to our daily routines and uncertainty about the future, the construction, maintenance, and expression of our identities have become even more relevant.

Identity is a multifaceted and dynamic construct, and individuals claim distinct and overlapping identities at different stages of their lives, which are also impacted by the dynamics of the social context surrounding them. (Ryan and Deci 2012). As we shuffle through multiple identities, we behave in ways that allow us to signal our desired identities (Chan, Berger and van Boven 2012). From wearing masks that reflect our identity to spending with our identity-linked credit cards, we regularly purchase and use self-identifying products. The papers in this special session examine the novel implications of owning, using, and choosing between identity-linked products, and the identity-driven effects of life transitions on our consumption behavior. Together, they provide further evidence of the inherent link between our self-concepts and consumption preferences.

In the first paper, Du and colleagues investigate the downstream consequences of price promotions on identity-linked products. Using diverse social identity groups such as LGBT consumers, black consumers and Asian consumers, they show that when identity-linked products are offered at a discounted price, this can lead to an identity threat, as consumers may infer that their identity is devalued and feel disrespected. In turn, the perceived disrespect results in unfavorable brand attitudes and lowered purchase intentions.

In the second paper, Nenkov and colleagues reveal interesting effects of using identity-relevant credit cards on consumer spending.

Across four experiments and field data from a money management app, they show that even though consumers enjoy using identity-relevant credit cards, they are less willing to charge items and accumulate debt on them.

Reflecting the notion that individuals embrace multiple identities, the third paper by Dommer and Winterich explores what happens when individuals are choosing between multiple identity-congruent products. They show that individuals with high self-variety, whose selves are composed of many (vs. fewer) identities, experience greater decision difficulty and take longer to choose.

Lastly, the fourth paper by Ok and colleagues examines the effects of identity loss experienced after a romantic breakup on consumers' relationships with service providers. In four studies, they show that following the dissolution of a romantic relationship and the ensuing identity loss, consumers become less willing to continue existing subscriptions and more likely to switch to alternative providers, and that this effect is stronger for those with an anxious attachment style in their interpersonal relationships.

Overall, these papers demonstrate the important implications of identity in the consumer behavior domain. We believe this special session appeals to a wide audience, including those who are interested in identity, branding, relationships, and consumer behavior.

Disrespectful Promotions: How Discounts on Identity-Linked Products Hurt Brands

EXTENDED ABSTRACT

Marketers frequently link branded products with consumers' social identities, as this can make the brand more appealing to these consumers (Bolton & Reed, 2004; Forehand & Deshpandé, 2001, Stayman & Deshpandé, 1989). Brands also often offer price promotions (e.g., price discounts) on identity-linked products. Based on prior research on targeted price promotions (Krishna, Keinberg, & Zhang, 2007), one might expect that consumers would react positively when they see a price promotion on a product targeted to them (i.e., linked to their identity). However, we argue that under certain circumstances this popular practice may backfire and hurt the brand. Specifically, when the identity that is linked to a product on sale is from a marginalized group, a reduced price will convey an impression of a devalued identity among members of the targeted group. As judgements that devalue one's social identity are usually construed as a social identity threat (Belmi et al., 2015), we further expect that these consumers will derogate the source of the threat (Petriglieri, 2011). Thus, we expect that targeted price promotions on marginalized identity-linked products will decrease brand attitudes by these targeted consumers, because of perceived disrespect. We test this prediction across four studies that include various marginalized groups and product categories.

Study 1 employed a between subject design (identity-linked product: not on sale vs. on sale) with Asian participants (N=275) residing in the U.S. The study was conducted amidst the Asian Lives Matter movement that has erupted in response to discrimination against Asians during the COVID-19 pandemic. Participants imagined shopping in a store called NIVO, where there were five identity-neutral water bottles and a water bottle with the slogan "Asian Lives Matter." In the on-sale condition, the identity-linked product was

40% off. NIVO brand attitude (α=.98; very negative / very positive, very bad / very good, very unfavorable / very favorable) was lower for participants whose identity-linked product was on sale as compared to not on sale (*M*=4.37 vs. 4.92, *p*=.002, d=.37).

In Study 2, we manipulated the degree to which the price promotion is tied to the identity. A promotion is more strongly tied to an identity when the promotion is only applied to the identity-linked product. When price promotions appear for all of the products, then the promotion is weakly tied to the identity. We expected that the promotion would have a more negative impact on brand attitude when it is strongly (vs. weakly) tied to the identity. The study used a between-subject design (no price promotion vs. weak promotion link vs. strong promotion link). LGBT participants (N=150) imagined shopping at NIVO, an electronics brand, where they were shown a large assortment of cellphone cases, two of which were related to the LGBT identity. In the weak promotion link condition, all NIVO cellphone cases were 50% off; in the strong promotion link condition, only the LGBT cellphone cases were 50% off. Participants in the strong promotion link condition had less favorable brand attitudes compared to those in either the weak promotion (*M*=5.26 vs. 5.65, *p*<.01, d=.59) or the no price promotion (*M*=4.45 vs. 5.65, *p*<.001, d=.89) condition.

In Study 3, we examined the mediating role of perceived disrespect and how it affects consumers' real-world choices. We recruited LGBT participants and employed the same design and scenario as in Study 1, but this time the focal identity-linked product was a LGBT rainbow water bottle. After answering five questions that measured perceived disrespect (α=.90; e.g. "To what extent do you think NIVO would make LGBT consumers feel disrespected?"), participants were told that they could enter a raffle and asked to choose between two prizes: a $55 gift card from NIVO and a $50 gift card from RINAI, a direct competitor of NIVO. Participants in the promotion condition perceived more disrespect (*M*=1.89 vs. 3.03, *p*<.001, d=1.00) and were more likely to forgo five dollars and support NIVO's competitor (2% vs. 14%, *p*=.01). A mediation analysis revealed that disrespect fully mediated the effect of promotion on the choice of gift cards (95% CI = [.39, 2.66]).

Study 4 further explored the role of disrespect. If disrespect drives the effects, then a price promotion on an identity-linked product would not backfire when the brand is an in-group member (i.e., an in-group member's actions would not be perceived as disrespectful towards the group). Black Americans (N=280) participated in a 2 (brand identity: in-group vs. out-group) by 2 (identity-linked product: not on sale vs. on sale) between-subject design. To manipulate brand identity participants saw a photo of the NIVO's employees who were either a group of black employees (in-group) or white employees (out-group). Participants then saw an assortment of nine face masks sold by NIVO, one of which was a Black Lives Matter mask. In the on-sale condition the Black Lives Matter mask was 50% off, in the not on sale condition none of the masks were on sale. Participants indicated their brand attitudes and whether they would purchase a product from NIVO in the future. A two-way ANOVA on brand attitude (Figure 2) revealed significant main effects of price promotion (p<.05, η_p^2=.02) and brand identity (p<.001, η_p^2=.28), and a significant interaction (p<.05, η_p^2=.02). A similar analysis for future purchase intention (Figure 3) revealed a significant main effect of brand identity (p<.001, η_p^2=.22), and a significant interaction (p<.01, η_p^2=.03). Planned contrasts revealed that only when the brand was an out-group member discounting the identity-linked product reduced brand attitudes (M=3.56 vs. 4.32, p<.01, d=.50) and future purchase intentions (M=3.03 vs. 4.22, p<.01, d=.52).

In sum, we show that offering price discounts on products linked to marginalized identities may backfire, reducing brand attitudes and leading to consumer revenge behaviors due to higher perceived disrespect. Accordingly, the effect dissipates when the brand is perceived as an in-group member whose actions presumably would not be perceived as disrespectful. We offer the first academic investigation into the interplay of pricing strategy and social identity and provide implications for marketers on how to better reach out to marginalized consumer groups.

Charging the Self: Consumer Use of Identity-Relevant Credit Cards

EXTENDED ABSTRACT

It is well established that credit cards encourage consumers to spend more, an effect referred to as the credit card premium (Feinberg 1986; Prelec and Simester 2001). The current research shows that all credit cards are not created equal when it comes to the credit card premium effect; specifically, it is weakened when a credit card is relevant to consumers' identity. Credit cards are often linked to consumers' identity in various ways. For example, universities, sports teams, and non-profit organizations issue affinity credit cards carrying the name, logo, and imaging of the organization (e.g., Barclays offers 33 different NFL team and logo choices). Credit cards affiliated with consumers' favorite brands also abound in the marketplace. Most retailers offer branded credit cards, and other brands are starting to do the same: Apple launched their first branded credit card in 2019. Most credit card companies also allow consumers to customize their cards by choosing from a selection of designs or uploading their own images.

Despite the prevalence of such identity-relevant credit cards in the marketplace, research has not considered the effects of consumers using credit cards linked to an aspect of their identity. This is surprising given that prior consumer research has established important effects of identity on decision making and consumption, such that consumers tend to prefer purchasing identity-relevant products (Belk 1988; Reed 2004). Though identity goods are preferred, consumers strategically slow satiation for identity goods (Chugani, Irwin, and Redden 2015) and conserve their usage of nondurable identity products (Sheehan and Dommer 2020). Mandel (2003) found that interdependent (versus independent) consumers seek greater risk in their financial choices. More recently, Han et al. (2019) found that political identity influences individual's financial risk taking. Given consumers prefer identity-relevant goods, but recognizing credit cards pose some financial risk, how will consumers use identity-relevant credit cards relative to traditional credit cards? The current research aims to shed some light on this question. Across four studies and field data from a money management mobile app, we find a paradoxical effect of identity-relevant credit cards on consumers' credit card use: consumers enjoy using identity-relevant credit cards, yet are less willing to charge items and accumulate debt on those cards.

In Study 1, we asked Mturk participants to indicate whether they currently owned credit cards affiliated with: universities, sports organizations, retailers, airlines, or non-profit organizations (identity-relevant); and banks (non-identity-relevant). For each credit card type, we asked participants to indicate: the extent to which their identity overlaps with the identity they associate with each card (Identity Overlap scale; Aron et al. 1992); how often they use each type of credit card; how much they enjoy using each type of card; and whether they use each card primarily for utilitarian purchases, hedonic purchases, or a mix of both. A series of regressions revealed that the more consumers' identity overlapped with a credit card iden-

tity, the more they enjoyed using the card ($p < .001$), the more frequently they used it ($p < .001$), and the more likely they were to use it for hedonic purchases ($p < .001$).

In Study 2, we manipulated credit card identity relevance and examined its effects on a hedonic purchase decision. We recruited Mturk workers living in the New England area who identify as fans of the Patriots and Red Sox sports teams. We randomly assigned participants to an identity-relevant (Patriots/Red Sox) credit card or a control credit card with no affiliation. Participants imagined shopping in a local mall where they see a great looking beach shirt and are trying to decide whether to charge the shirt on their credit card. They indicated how much debt they are willing to incur on their credit card to purchase the shirt, their expected enjoyment of using the card, and the extent to which they expect that using this card will "make a positive impression on others." Results revealed that participants were willing to incur less debt on their identity-relevant card versus the control card ($p < .05$). Participants also expected to enjoy using the identity relevant credit card more and make a more positive impression using it versus the control card (p's $< .001$).

In Study 3, we replicated these results with a utilitarian purchase (work shirt). We presented Boston College students with either a Boston College credit card or a control card. Students were again willing to incur less debt to purchase the work shirt with the Boston College credit card versus the control card ($p = .04$).

Study 4 participants were Penn State students in a mixed design that manipulated payment method between subjects (Penn State credit card, control credit card, cash) and four purchases (headphones, camping chair, backpack, water bottle) within subjects. Compared to charging the items on the control credit card, participants were willing to pay less for the items when charging them on their Penn State card ($p = .05$) or paying cash ($p = .08$),[1] and consumers' willingness to pay with an identity-relevant credit card was similar to that when paying cash.

Finally, we analyzed money management mobile app field data containing nearly 4,000 credit cards. An RA coded whether app users had given each credit card account their own personal name (e.g., Brian's Chase Freedom; identity-linked credit card) or not (generic credit card). In line with prior results, we found that app users carried a significantly lower average credit card balance on the identity-linked than generic credit cards ($p = .06$).

In summary, we identify a robust novel effect of using identity-relevant credit cards on consumer credit card spending: consumers are less willing to charge purchases on an identity-relevant versus a control card. Our results suggest that identity-relevant credit cards might reduce consumer credit card spending and weaken the well-established credit card premium effect (Prelec and Simester 2001). In next steps, we will conduct studies to explicate the process underlying these effects.

The Effect of Self-Variety on Choice Difficulty When Choosing Between Identity-Linked Goods

EXTENDED ABSTRACT

Individuals have a readiness to engage in actions congruent with their identities, a concept known as identity-based motivation (Oyserman 2009). Subsequently, consumers prefer brands and products that express one of their identities to goods that do not (Escalas and Bettman 2005; LeBoeuf, Shafir, and Bayuk 2010; Reed 2004). But these paradigms have traditionally pitted identity goods with

either neutral (no identity) goods or goods congruent with the consumer's outgroup, stemming the question – what happens when an individual must choose between two goods, each of which expresses one of his multiple identities?

We argue that the difficulty of deciding between two identity-congruent products will depend on the individual's self-variety, defined as the extent to which the self is composed of many distinct identities. We theorize that choosing between two identity goods should be difficult for individuals with high self-variety. Because these individuals hold many distinct identities, when asked to choose between identity goods they will feel like the adequacy of information is insufficient (Nagpal et al. 2011), making it more difficult to choose (Hilbig 2008). On the other hand, individuals with low self-variety have fewer distinct identities, making it difficult for them to think of themselves as one identity without also thinking of themselves as another identity. As such, identity goods are seen as very similar to one another and the number of identity options in the set should not impact their perceived information adequacy nor their decision difficulty. In sum, we predict that individuals with high self-variety take longer to make a choice (experience greater difficulty) when the choice set contains two identity goods, compared to when only one identity good is present. This effect does not emerge for individuals with low self-variety.

We assessed self-variety in all of our studies with a task adapted from Linville (1987) that involved sorting traits into identity groups. Participants were given a list of 28 traits (e.g., outgoing, emotional, lazy, assertive). They were instructed to groups traits together based on their various identities by dragging and dropping traits into boxes. Importantly, each trait was listed multiple times for use in multiple boxes.

In the marketing literature, variety is often captured via entropy (Young and Wasserman 2001); entropy has been used to assess both the dispersion of attribute levels across products (Van Herpen and Pieters 2002) as well as assortment variety (Kahn and Wansink 2004). Following this prior work, we assess self-variety as where p_j is the proportion of identities in the self with trait level j. Consistent with entropy as a measure of assortment variety, higher scores indicate greater self-variety.

Study 1 was a real choice task in which we asked participants to either choose between two bags, each of which expressed an identity that they held (gender and American identity), or choose between one of the identity bags and a plain bag. We measured the time they took to make their decision as our measure of decision difficulty (Park and Lessig 1981), as well as their self-variety. In support of our predictions, at high self-variety (Johnson-Neyman point = 3.92; -.57 SD), participants took longer to make their choice when there were two identity options present compared to when there was only one identity option available. There was no significant Johnson-Neyman point at low self-variety. Study 2 replicated this effect using a manipulation of self-variety.

In study 3, we asked participants to choose between two identity candles and a plain candle. By adding the third option of a non-identity good to the choice set, we assessed whether greater decision difficulty would lead those with high self-variety to be more likely to "opt-out" of the decision by choosing this option (Luce 1998), which was indeed the case ($b = .28$, Wald $\chi^2 = 4.81$, $p = .028$).

In study 4 we allowed participants to select two important identities (from a list) and then asked them to choose either between two stress balls consistent with those identities, or between one identity stress ball and a plain stress ball. We measured the time they took to make their decision, their perceptions of information adequacy, and self-variety. Once again at high self-variety (Johnson-Neyman point

---

1   Willingness to pay for the four items was standardized and averaged. We obtained similar results estimating a two-level model with four purchases nested within subjects.

= 4.19; .14 SD), participants took longer to make their choice when there were two identity options present compared to when there was only one identity option available. Moreover, at high levels of self-variety choice time was mediated by perceptions of information adequacy.

Study 5 demonstrates that self-variety only affects decision time and does not affect the length of time it takes participants to evaluate two identity products, suggesting that decision time is not measuring information processing or involvement. Study 6 supports our theoretical framework by examining mindset as a moderator. A satisficing mindset reduced decision difficulty among individuals with high self-variety, suggesting that these individuals have a tendency to engage in greater comparison of identity options because they perceive less information adequacy. Priming a satisficing mindset, which reduces reliance on comparisons in favor of choosing a "good enough" option, therefore reduces decision difficulty among individuals with high self-variety. On the other hand, a maximizing mindset increased decision difficulty among individuals with low self-variety. These individuals see two identity options as similar, and thus have a weaker tendency to compare across options. Priming a maximizing mindset, however, encourages such comparison and thus increases decision difficulty among those with low self-variety.

The identity literature has established that consumers prefer identity goods by studying choice between one identity good and one neutral good. However, with the amount of product customization in the marketplace today, consumers frequently have multiple identity options from which they can choose. The present research examines such choice by being the first paper, to our knowledge, to look at choice between two identity goods without a priori activating one of the identities, which is likely to be more representative of consumer decisions in the marketplace when no one identity is salient at the time of a purchase decision.

When I Lose You, I Lose Me: The Impact of Relationship Dissolution on Switching Behavior

EXTENDED ABSTRACT

Many of us start romantic relationships with the hope that they will last for a lifetime. Yet, such longevity is rarely the outcome. A typical adult in the UK has two serious relationships before getting married (Daily Mail 2014), while half of the marriages in the US result in divorce (APA 2020). Although a romantic breakup is a familiar experience for most, surprisingly, research on the impact of romantic relationship dissolutions on consumer behavior is scant. Romantic breakups can have profound effects on individuals' self-identities, as many consider their relationship an integral part of themselves (Slotter et al. 2010). This research examines one outcome of the change individuals experience in their self-concept following a romantic breakup: willingness to switch service providers.

During romantic relationships, partners' sense of selves become intertwined, as they engage in mutual activities, share social circles, and pursue joint goals (Aron et al. 1995). Upon relationship dissolution, they experience a sense of loss in the aspects of the self that were previously linked to their partner and/or were defined through their role in the relationship (Haber 1990; Mattingly et al. 2020). Given the inherent link between consumers' self-identities and their consumption behaviors (Reed et al. 2012), we propose that the change in one's self-concept ensuing a romantic breakup will also be reflected in their decisions to switch to new providers (vs. stay with the existing ones). We predict that after a romantic breakup, consumers will display higher willingness to discontinue their current subscriptions and greater interest in switching to alternative providers,

and that this effect will be driven by the identity loss experienced after the breakup, as well as the desire to redefine their self-concept and open up a new chapter in life.

We test these predictions in four studies. In Study 1 (n=396) we recruited an equal number of participants who had or had not gone through a breakup within the last three years. Participants who went through a breakup were asked to reflect on their relationship dissolution in a writing task, while those in the control condition wrote about the last book they read. Next, all participants imagined themselves in a scenario depicting a customer who was satisfied with their current cellphone carrier, but had recently seen the ads of two other companies with comparable plans to the incumbent. Participants then answered two questions about their intentions to stay with their current provider and the attractiveness of switching to other providers. We found that participants who reflected on their breakup experience had higher switching intentions compared to those in the control condition ($M_{breakup}$=4.04, $M_{control}$=3.61, p=.022).

In Study 2 (n=380), we manipulated participants' experience of a breakup by using a procedure from Lewandwoski et al. (2006). We recruited participants who were currently involved in a romantic relationship, and they were randomly assigned to imagine either the end of their relationship or their plans for the upcoming weekend (control condition). In the breakup condition, participants listed three attributes they would lose upon relationship dissolution, while control condition participants listed three activities they would do with their partner. Next, participants reported their intentions to switch to new providers across various service categories (e.g., hair salon, restaurant), which were combined into a willingness-to-switch index. Participants in the breakup condition reported higher switching intentions than those in the control condition (p<.001).

Study 3 (n=396) tested the generalizability of the effect in another context and provided preliminary evidence of our hypothesized mechanism. After completing the same writing task as in Study 1, participants imagined that they moved to a new apartment and were deciding between two internet providers—the same provider that they previously used vs. a new one (Jiang, Zhan, and Rucker 2011). In this study, participants in the breakup condition answered three additional questions measuring the level of identity loss experienced after the relationship dissolution (e.g., "*When we broke up, I lost many aspects of my life that were linked to my partner*"). Results reveal that participants in the breakup condition (vs. control) reported higher willingness to switch to the new provider (p=.009), and that the level of identity loss was a positive predictor of switching intentions (p<.001). Also included in this study was a 12-item measure of interpersonal attachment (Wei et al. 2008) assessing individuals' attachment style along the dimensions of anxiety and avoidance. Individuals with an anxious attachment style rely heavily on their partner to confirm their self-worth and experience a greater sense of identity loss after relationship dissolution (Davis et al., 2003). Thus, we predicted that our effect would be stronger for individuals high in anxiety attachment. Indeed, the effect of breakup on switching was significant for participants high in anxiety attachment (+1SD) (β=.65, p=.009), but not for those who were low (-1SD) (p>.90). These results provide additional evidence for our mechanism by showing that individuals who experience a greater loss in their self-identity are more likely to switch providers.

Using the same manipulation from Study 1 and the same DV from Study 3, Study 4 (n=390) showed that the effect of breakup on switching was mediated by lower self-continuity and desire to redefine one's self. Self-continuity was measured by using a modified version of Aron et al.'s (1992) overlapping circles depicting past vs. current self, whereas desire to redefine the self was measured

with 4 items (e.g., "I want to rediscover who I am"). A serial mediation model (PROCESS Model 6, with condition coded as 0=control, 1=breakup) showed that there was a significant indirect effect on switching intentions through self-continuity and desire to redefine one's self (CI$_{95}$ [.03, .13]).

To our knowledge, this is the first work to examine the consumer behavior consequences of the experience of an identity loss resulting from a romantic relationship dissolution, showing that it increases consumers' switching intentions. We also provide evidence that this effect is driven by the desire to redefine one's "self" and open a new life chapter – a process-driven explanation that captures the psychological benefits of switching beyond the outcome utility (Su et al. 2017).

SESSION OVERVIEW

The use of algorithmic consumer assistance has fundamentally changed how humans search, shop, and express their preferences. From receiving product recommendations (Gai and Klesse 2019) to algorithmic decision support by financial robo advisors (Hildebrand and Bergner 2020; Lourenço, Dellaert, and Donkers 2020). Despite the widespread adoption of algorithmic assistance across industries and the emerging research on how algorithmic assistance impacts human decision making (Dietvorst, Simmons, and Massey 2018; Logg, Minson, and Moore 2019), research on both the underlying lay beliefs that consumers possess and how they impact marketing relevant downstream consequences is scarce. The goal of this special session is to shed light on this burgeoning field of algorithmic consumer assistance and how consumers perceive products, services, and also firms that employ such algorithmic assistance. The session will be comprised of four papers that explore two central research streams:

1. Lay Beliefs & Psychological Mechanisms of Algorithmic Consumer Assistance
2. Downstream Consequences of Algorithmic Consumer Assistance for Firms & Consumers

The first two papers in this session explore the first stream. Gai, Leung, and Klesse demonstrate that consumers are less likely to signal diverse preferences when the recommender is algorithmic versus human. They show that this occurs because consumers hold the lay belief that algorithms are less able to understand diverse consumer input than humans and therefore signaling diversity may undermine the accuracy of recommendations. Next, Clegg, Hofstetter, de Bellis, and Schmitt examine how algorithmic transparency affects consumer product adoption. They demonstrate that consumers hold the lay belief that adaptive (vs. pre-programmed) algorithms are more creative

and capable to handle tasks with high variability of outcomes. They further show that enhancing the transparency of adaptive (vs. pre-programmed) algorithms can promote product adoption in high as opposed to low variability contexts (i.e., contexts that require following a narrowly defined procedure, such as a recipe when baking a cake, are considered as low versus high outcome variability settings).

The third and fourth papers explore the second research stream, focusing on the downstream consequences of algorithmic consumer assistance for consumers and firms. Castelo, Boegershausen, Hildebrand, and Henkel show that consumers perceive firms that rely on robotic customer assistance as less customer centric and more cost-cutting oriented, leading to lower service satisfaction and willingness to recommend the firm to others. Finally, Hildebrand and Zehnle show in a financial decision-making context, that the use of conversational bots (i.e., chatbots) leads to lower financial planning stress compared to spreadsheet-like interfaces and that the effectiveness of conversational bots is further amplified for consumers with chronic money management issues.

Taken together, this special session contributes to the conference by showcasing research that addresses fundamental questions about consumers' lay beliefs and attributions toward algorithmic consumer assistance and their downstream effects on consumer choice, firm perception, and financial decision making. The papers in this session span multiple disciplines from diversity signaling in psychology, adaptive user interfaces in human-computer interaction, and explainable AI in computer science. We hope that this session ultimately inspires more interdisciplinary research on the technology-augmented consumer.

Diversity Signaling to Algorithmic Versus Human Recommenders

EXTENDED ABSTRACT

Consumers frequently receive personalized product recommendations from automated algorithms, such as when using Netflix, Spotify, or Amazon. When using such services, consumers typically browse available options and indicate their preferences through the items that they select. The recommender systems then utilize this input about consumers' preferences to generate recommendations of other products that consumers may like. Notably, the recommender systems are built in a way that consumers can receive any recommendation as long as they show interest in diverse products (Datta, Knox, & Bronnenberg, 2018). The question that arises, however, is whether consumers indeed signal diverse preferences to algorithmic recommenders.

While we know that consumers tend to seek variety and signal uniqueness to other humans (Ariely & Levav, 2000; Ratner & Kahn, 2002), it is less clear whether consumers are equally likely to engage in diversity signaling when interacting with algorithmic recommender systems. Thus, in this research, we compare consumers' tendency to engage in diversity signaling (here, defined as selecting items from a diverse set of categories) when consumers indicate their taste to algorithmic versus human recommenders.

In eight studies, we show that consumers are less likely to signal diverse preferences when the recommender is algorithmic versus human. We document that this occurs, because of the lay belief that algorithms are less able to understand diverse input than humans and,

thus, signaling diversity may undermine the accuracy of recommendations. This belief may be driven by two reasons. First, consumers see algorithms as processing product features independently, instead of holistically (Newman, Fast, and Harmon 2020). That is, while humans may find commonality between products with divergent features and understand the tastes of people who like these products, algorithms may be unable to extract a consumer's taste if it is diverse. Second, consumers may see algorithms as prioritizing the accuracy of the output over its diversity, such that it would be futile for them to signal diversity to algorithmic recommenders. Table 1 provides an overview of all our eight studies in different domains (e.g., music, recipes, paintings, tasks) using different approaches (correlational, experimental).

Study 1 measures to what extent consumers hold the lay belief that diverse input would undermine the accuracy of the output (i.e., recommendation). We utilize a 2 (algorithm vs. DJ as the recommender) × 10 (low to high levels of input diversity) between-subject design. Participants (N = 709 on MTurk) read a scenario about music recommendations for a person whose initials are M. F. Participants read that M.F. had to tell the recommender what s/he likes and saw that M. F. selected 1 to 19 (with an interval of 2, thus all odd numbers) music genres out of 20 depending on condition. The more genres selected, the more diverse is M. F.'s input. Participants were asked to rate the accuracy of the output (*"The algorithm [experts] will be able to recommend songs that M. F. likes."*). As the number of selected genres increased, the output was perceived as less accurate, when it is generated by an algorithm ($t(705) = -4.98, p < .001$). However, when participants read that human experts generated recommendations, the relation remained negative but to a lesser extent ($t(705) = -2.75, p = .006$; interaction $t(705) = 1.78, p = .075$). Studies 2 and 3 replicated the finding that an algorithmic (versus human) recommender makes consumers more likely to believe that diverse input would harm the accuracy of the output (e.g., "understanding what I truly like).

Whereas the first studies, explored participants' lay belief, studies 4 to 7 demonstrate that algorithmic versus human recommenders decreases diversity signaling. In study 5, participants (N = 201 from MTurk) were asked to imagine that Amazon's algorithm (versus staff) would recommend HITS based on their topics of interest. They were asked to select their interests from a list of 19 different topics. In line with our prediction, participants in the algorithm (versus staff) condition selected fewer topics (M = 6.84 versus 4.70, t(199) = -3.14, p = .002). Study 6 replicates the effect in the domain of novels. Participants (N = 100 native Chinese) read a scenario about a person named N who has subscribed to a novel recommendation service; depending on condition, the service employed a data-driven algorithm (algorithm condition) or professional editors (human condition) as recommenders. N has favorite novels in three genres (fantasy 99%, adventure 0.9%, and thriller 0.1%) out of eight genres. Participants had to imagine that they were N and indicated which genres they like so that the recommender can understand their tastes. We deliberately made N's primary preference fall within one category (fantasy) to impose a trade-off between accuracy (i.e. fewer categories => more accurate recommendation) and diversity (i.e. more categories => more diverse recommendation). To prevent participants from choosing only the genre "fantasy", we required participants to select at least two genres. We found that participants selected fewer genres when the recommender was algorithmic as compared to human (M = 2.58 vs. 3.10), t(98) = 2.59, p = .008. Study 7 replicates these results in the domain of paintings with European participants. Study 8 uses a causal-chain design and shows that the lay belief that algorithms are worse at understanding diverse tastes underlies the effect that we demonstrate here.

While prior research has investigated the diversity of *output* (Haim, Graefe, & Brosius, 2018) of recommender systems, this research is (to the best of our knowledge), the first to explore whether consumers are less likely to provide diverse *input* when interacting with algorithmic recommender systems (as compared to human recommenders). Our finding that consumers signal less diverse tastes to algorithmic recommenders is important because less diverse input can be self-handicapping when consumers actually desire diverse output. Thus, companies which utilize recommender systems should be aware that consumers hold the lay belief that algorithms cannot understand diverse input; if companies want customers to exploit all that the service has to offer because that increases customer satisfaction (Puntoni, Reczek, Giesler, & Botti, 2020), they need to encourage consumers to provide diverse input.

Algorithm Transparency: How Unveiling Algorithms Influences Product Perception and Adoption

EXTENDED ABSTRACT

Many algorithms are considered "black boxes" that consumers mistrust, view as biased, or as making immoral and harmful predictions or decisions (Awad et al 2018; Davenport and Kirby 2016; Lambrecht and Tucker 2019). However, technically it is increasingly possible to better explain algorithms (Lundberg and Lee 2017; Sundarajan et al. 2017), and public officials increasingly demand that firms provide details about the algorithms steering products and services (Carmon et al. 2019). As a result, algorithm transparency has become a widely-discussed topic in artificial intelligence (AI) and algorithm communication (Rai 2020). Yet, while prior consumer research has compared algorithm to human performance (e.g., Castelo et al. 2019; Longoni et al. 2019), little research has focused on algorithms themselves.

How do consumers perceive information about algorithms? In this research, we investigate how transparency about an algorithm influences product adoption. Specifically, we increase transparency about the type of algorithm of a product and how the algorithm works. Based on computer science literature, we distinguish between two major types of algorithms: adaptive (such as machine learning algorithms; Jordan and Mitchell 2015) and pre-programmed algorithms (i.e., with parameters fixed by a programmer; Schmidhuber 2010).

We base our Hypothesis on prior research on algorithm perception and creative stereotypes (Haslam 2006; Runco 2004). We predict that adaptive (vs. pre-programmed) algorithms are perceived as more creative but less predictable. Consequently, for products performing tasks requiring a high variation in their output (i.e., high output variability, such as providing various answers to user requests from a voice assistant), increasing transparency about adaptive algorithms should increase adoption. Conversely, we hypothesize that increasing transparency about adaptive algorithms reduces adoption of products that perform tasks that require low variation in their output (i.e., tasks with a low output variability), for which predictability may be more valued than creativity. However, this harmful influence of adaptive algorithms can be mitigated by increasing their explainability, which increases how predictable they are perceived. Five experiments test our Hypothesis.

Study 1A and 1B tests the main effect of adaptive algorithms on product adoption in consequential contexts. In study 1A, participants from Prolific ($N=200$, $M_{age}=27.74$, 40.50% female) were randomly assigned to one of two conditions in a two-cell

between-subjects design: They received an advertisement about a real application that generates cooking recipes from scratch (a high output variability task). The ad conveyed information about either the adaptive or the pre-programmed algorithm. Participants could choose between actually using the recipe generator or taking part in a raffle for a monetary reward of £1 (five participants could win). Significantly more participants chose to use the recipe generator in the adaptive (55.56%) versus the pre-programmed condition (38.61%; $\chi^2(1)$=5.76, p=.016).

In study 1B, we measured participants' willingness to pay (WTP) for a beer, whose recipe was generated by an algorithm. Participants received information about either the adaptive or the pre-programmed component of the algorithm (2-cell between-subjects). Participants in the adaptive condition reported higher WTP than in the pre-programmed condition ($M_{adaptive}$=1.96, $M_{pre-programmed}$=1.56; $F(1, 200)$=6.64, p=.011).

Study 2 tests if perceived creativity and predictability mediate how algorithm type influences product adoption. Students of a major US-American University (N=207, M_{age}=24.55, 57.0% female) were informed about the algorithm of a voice assistant (adaptive vs. pre-programmed), and indicated their algorithm perceptions and usage intention. Usage intention significantly increased in the adaptive condition ($M_{adaptive}$=4.70, $M_{pre-programmed}$=4.05; $F(1,205)$=6.50, p=.01). This effect was significantly mediated by an increase in perceived creativity of the algorithm (b=.61, 95%CI=[.34;.94]). There was no mediation via predictability (b=-.02, CI=[-.20;.14]), which we explain with the rather high output variability of voice assistants.

Study 3 tests the moderating effect of output variability. Participants (N=395 US-MTurkers, M_{age}=35.71, 48.61% female) were randomly assigned to one condition in a 2×2 between-subjects design. Participants reported their intention to use a cooking app after being informed about its algorithm (adaptive vs. pre-programmed). Output variability was manipulated by framing the task of the cooking app (i.e., high: baking a completely novel cake vs. low: baking a cake exactly by recipe). We found a significant interaction ($F(1,394)$=14.61, p<.001): When output variability was high, usage intention increased in the adaptive condition ($M_{adaptive}$=5.15, $M_{pre-programmed}$=4.48; $F(1,391)$=8.67, p=.003). When output variability was low, we found the reverse ($M_{adaptive}$=4.37, $M_{pre-programmed}$=5.16; $F(1,391)$=6.11, p=.013). Parallel moderated mediation analysis revealed that the mediation via perceived algorithm creativity was moderated by output variability (index of moderated mediation: .40, CI=[.17;.67]), such that the indirect effect via creativity was stronger in the high output variability condition. The mediation via perceived predictability was moderated in that the indirect effect via perceived predictability was significant only for the low output variability condition (index of moderated mediation: .59, CI=[.30;.93]).

Study 4 tests the moderating effect of explainability of the algorithms. Participants (N=327 car owners from Prolific, M_{age}=41.19, 25.69% female) were randomly assigned to one condition in a 2×2 between-subjects design. They indicated their purchase intention for a driving assistance system after being informed about its algorithm (adaptive vs. pre-programmed), which was either more or less explainable (i.e., details about how the algorithm predicts the driving direction were provided vs. not provided). The interaction between both factors was significant ($F(1,323)$=5.15, p=.024): Purchase intention increased in the adaptive condition, but only if the algorithm was highly explainable ($M_{adaptive}$=3.5, $M_{pre-programmed}$=2.38; $F(1,323)$=7.68, p=.006). No significant difference revealed if the adaptive algorithm was not explainable (M_{adap-}

$_{tive}$=2.79, $M_{pre-programmed}$=3.00; $F(1,323)$=.24, p=.624). Parallel moderated mediation analysis showed that a negative indirect effect of the adaptive algorithm on purchase intention via perceived predictability was significant only in the low but not in the high explainability condition (index of moderated mediation: .20, CI=[.01;.48]). This shows that being transparent about how adaptive algorithms arrive at their predictions can increase purchase intention.

In sum, our findings show that not all algorithms are perceived the same. Making an adaptive algorithm transparent may backfire if the product is expected to provide one specific output. However, increasing explainability of adaptive algorithms makes them less unpredictable, increasing adoption even for products, which consumers feel uncomfortable about, if they lack predictability (e.g., autonomous driving vehicles). Our findings advise managers to carefully consider how to disclose information about algorithms.

Bots at the Frontline: How Consumers Perceive Firms that Employ Service Robots

EXTENDED ABSTRACT

Robots are used to provide customer service online and in stores. However, only 15% of firms that currently use the market-leading Pepper service robot plan to renew their contracts (Whitton 2018). We use real customer-bot interactions to shed light on the challenges facing the use of service robots. We propose that encountering service robots activates a lay theory that automation is motivated by profit maximization at the expense of the customer experience. Since firms have finite resources, consumers rely on a "zero-sum heuristic" (Chernev 2007), such that investments into service robots may be perceived as coming at the expense of a worse customer experience. Firms using service robots should therefore be seen as less customer centric than firms that do not, which should in turn decrease consumers' service satisfaction and willingness to recommend the firm to others. These effects should be attenuated when the firm's perceived motivation for using the automation is to overcome current shortcomings in customer service.

Study 1. In a field study over four days, we varied whether 109 customers in a café placed their order with a Pepper robot or with a human. After ordering, customers rated their agreement with the statements "I would recommend this coffee bar to a friend or colleague" and "I am satisfied with my service experience today" (α = .92). These firm outcomes were worse in the robot condition (M = 5.34) than in the human condition (M = 5.81, $F(1,107)$ = 4.89, p = .029). The difference remained significant controlling for technology affinity, age, gender, and frequency of visiting the café.

Study 2. 238 Prolific participants engaged in an online chat with a chatbot but were told that they were interacting either with a bot or with a human. This keeps the interaction identical across conditions. Participants were told that we were testing new customer service platforms for a telecommunications company and that they interact with one of the company's representatives. After the interaction, we measured participants' service satisfaction and recommendation willingness as in Study 1. We also measured perceived customer centricity of the firm (Habel et al. 2019). The firm was perceived as less customer centric when participants believed they were chatting with a bot than with a human ($M_{Chatbot}$ = 4.75, M_{Human} = 5.28; $t(236)$ = 2.66, p = .008), and consumers had lower satisfaction and willingness to recommend the firm ($M_{Chatbot}$ = 4.87, M_{Human} = 5.38; $t(236)$ = 2.47, p = .014). A mediation model with bootstrapped estimates (5000 iterations) confirmed the positive effect of customer centricity on firm outcomes (β = .79, p < .001), switching off the main effect

of condition (β = -.09, *p* = .49), and an indirect effect excluding zero (-.42, 95% CI = -.71, -.11), indicating full mediation.

Study 3. This study directly tested our proposed customer centricity mechanism by asking half of the participants to read a brief manipulation of customer centricity before interacting with a chatbot. Some companies that introduce automated customer service communicate an explicitly customer-centric motivation behind the automation. We therefore tested whether this approach could be effective at not only boosting the company's perceived customer centricity but also increasing customer satisfaction after interacting with a bot-based service provider. A total of 369 participants (34% female, M_{Age} = 24) from Prolific Academic participated in the experiment. All participants were asked to chat with the same chatbot used in the previous study (a study in which they would evaluate the customer service of a mobile phone company). Half the participants were first asked to read a 210-word "letter from the company's CEO" explaining why they had started using chatbots. This letter was based on a real LinkedIn post from the CEO of a customer service chatbot company and explained that chatbots were intended to improve the customer experience by reducing wait times and increasing personalization. Our findings revealed that reading the customer-centric motivation prior to chatting with the bot made the company seem marginally more customer-centric (M = 3.99, SD = .71) relative to not reading the letter (M = 3.86, SD = .73, t(367) = 1.71, p = .089). Similarly, satisfaction was marginally higher after reading the letter (M = 4.24, SD = .76) relative to not reading it (M = 4.10, SD = .69, t(367) = 1.87, p = .062). Thus, a company introducing automated customer service may be able to slightly improve its customers' perceptions of this change by explicitly communicating a customer-centric motivation behind this change.

Study 4. The COVID-19 pandemic has presented a compelling real-world justification for the use of service bots to benefit customers. We therefore tested whether this justification (i.e., using service bots to protect consumers' health) for the use of service bots in place of human employees would be effective at increasing consumers' satisfaction with bot-provided services. A total of 601 participants were recruited via Prolific and randomly assigned to either a human, robot without, or robot with justification condition. Participants watched a short video of the actual coffee ordering process of Study 1 and the two robot conditions differed in the presence or absence of a justification (using robots during COVID-19 to protect consumers' health). Our findings revealed that satisfaction was highest in the human condition (*M* = 5.48, *SD* = 1.31), significantly reduced in the COVID bot condition (*M* = 5.03, *SD* = 1.72, *t* = 2.64, *Tukey-adjusted p* = .023), and lowest in the regular bot condition (*M* = 4.54, *SD* = 1.84, *t* = 2.79, *Tukey-adjusted p* = .015 vs. the COVID bot condition). Thus, providing a COVID-19-related motivation for the use of service bots results in significantly higher customer satisfaction and perceived customer-centricity than providing no justification, but both outcomes remain worse than human-provided service.

Taken together, the findings of this research help explain why initial rollouts of service robots have been lackluster and have clear implications for how firms can improve outcomes while continuing to pursue the use of this technology.

Conversational Bots Reduce Financial Planning Stress

EXTENDED ABSTRACT

Managing one's personal finances is major source of stress for the majority of American adults and consumers around the world (American Psychological Association 2019; Financial Health Network 2019). Healthy financial planning practices, such as setting a budget and tracking income and expenses, are vital to elevate consumers' long-term financial health. Developing a detailed financial plan is essential to maximize consumer financial well-being in the long-run (Netemeyer et al. 2018), positively affects consumers' FICO credit scores (Lynch et al. 2010), is a major source to drive the creation of long-term wealth (Ameriks, Caplin, and Leahy 2003), and affects the prosperity and economic stability of entire nations (Financial Health Network 2018). Despite the psychological and economic importance of financial planning for consumers, recent survey results reveal that more than 40% of Americans do not agree with the statement "My household plans ahead financially" (Financial Health Network 2019) and over 60% of consumers perceive financial planning as a major source of personal stress in their daily lives (American Psychological Association 2019). To make matters worse, recent research demonstrates that an increase in financial planning stress can cause generalized forms of anxiety and long-term mental health issues (Gamst-Klaussen, Steel, and Svartdal 2019; Harkin 2017; Moschis 2007; Shapiro and Burchell 2012). The primal strategy to improve consumers' financial planning behavior by financial institutions and governmental agencies has been focused on enhancing financial education, from providing educational guides to downloadable spreadsheets to setup a household budget (Consumer Financial Protection Bureau 2020; see also www.consumerfinance.gov). Unfortunately, recent research suggests that these educational approaches are largely ineffective (Fernandes, Lynch, and Netemeyer 2014) and consumers often abandon the use of spreadsheets to engage in a more systematic financial planning (Lusardi and Mitchel 2011; Sardone 2008).

The current work examines a novel intervention using an AI-based conversational interface (or chatbot) to complete a financial planning task, demonstrating substantial reductions in financial planning stress. In three experiments we show that conversational financial planning interfaces reduce financial planning stress compared to traditional, spreadsheet-like financial planning tools and further show that conversational interfaces are most effective for consumers with low levels of current financial well-being. We provide initial evidence on the underlying mechanism, showing that the reduction of financial planning stress is driven by creating a more positive and playful as opposed to negative and arduous financial planning experience. These findings have important implications for the future of consumer financial decision making in technology-augmented environments and the role of conversational interfaces as a novel modality to stimulate positive financial planning experiences.

In Study 1, participants (n=240) were randomly assigned to either a conversational or a non-conversational interface condition to complete a financial planning task. As in typical financial planning tasks, participants had to list a range income and expense categories (e.g., salary, rent, groceries). The non-conversational interface resembled a spreadsheet-like format typically provided by financial institutions whereas the conversational interface condition used a native, interactive chatbot developed for the purpose of this research (to ensure maximum experimental control). We find that using a conversational as opposed to a non-conversational financial planning interface significantly reduced consumers' level of financial planning stress ($M_{NonConv}$ = 2.67, M_{Conv} = 1.82; t(199) = 4.01, p < .001), and these effects were robust across demographics and prior experience with chat technologies. Study 2 (n=258) further explored to which extent the observed effect varies as a function of consumers' chronic money management issues. As shown in Figure 1A and replicating the finding of Study 1, participants experienced significantly lower levels of financial planning stress when using a conversational compared to non-conversational financial planning interface

($M_{NonConv}$ = 3.08, M_{Conv} = 2.69; t(255) = 2.22, p < .05). As shown in Figure 1B, the effect of interface type on financial planning stress was further reduced at higher levels of chronic money management stress ($\beta_{ConvInt \times MoneyMgmt}$ = -.36, t(253) = 2.80, p < .01). Calculating the Johnson-Neyman point revealed a significant interval outside of [.60; 4.08], suggesting that consumers above the mid-point of the scale significantly benefit using a conversational as opposed to non-conversational financial planning interface to reduce financial planning stress. Finally, Study 3 replicated these findings and further found that the reduction in financial planning stress was explained by significantly enhancing consumers' experienced level of playfulness from using the interface. These effects were robust across demographics and consistent across different avatar implementations (from robotic to human-like avatars), and most importantly, enhanced for consumers with lower levels of financial well-being.

Taken together, these findings provide evidence that the type of interface to complete a financial planning task is an unexplored means to reduce consumers' financial planning stress and to create more playful and engaging financial planning experiences.

Paper #4: AI-Supported Physician-Patient Interactions: The Physician's Avatar May Need No Introduction.

Haribabu Ravella, Virginia Tech, USA
Dipankar Chakravarti, Virginia Tech, USA

SESSION OVERVIEW

The rapid evolution of natural language processing and speech recognition technologies has developed AI-driven smart agents that can think on their own, make predictions, adopt humanlike persona, and communicate fluently with humans. Such "smart agents" are rapidly penetrating consumer households and service environments. Smart devices like Amazon Alexa and Google Home can manage household chores, provide information and even make customized purchase recommendations. Deployed in a variety of service contexts, these devices provide intelligent customer support interfaces. In medical contexts, such devices can support physicians in tasks ranging from simple dictation of medical notes to the provision of more advanced healthcare services and patient counseling (IBIS World 2019).

Notwithstanding the enormous potential, our understanding of how to best deploy AI technology in consumer contexts remains fairly rudimentary. Even as we become more familiar with such devices, there are many unknowns and implementation pitfalls. How should the design of such devices reflect appropriate levels of human characteristics (e.g., facial features, voice tones and personalities)? How might such features facilitate or inhibit human-machine communication? If AI devices are to support human professionals, how should their roles be organized and juxtaposed with those of the humans they support? How will their communication styles influence customers given their expectations about the interaction experience and service delivery? To what extent will customers anthropomorphize and respond to AI agents, particularly in medical service contexts where patient compliance is founded on high levels of trust?

This special session brings together four multiple author teams to present four research papers addressing these questions. The first two papers focus on emotionality and customizability of smart agents and how these may influence consumer perceptions and contingent behaviors. First, Hyun and Bond suggest that consumers infer two major personality dimensions from conversations with smart agents: friendliness and reliability. These inferences are based on the service customizability and emotionality embedded in the conversational expressions. Second, Han and Chakravarti present four studies exam-

ining how dynamic versus monotonous vocal tones of smart agents influence consumer persuasion and the moderating role of customer perceptions of the agent's self-relevance.

The remaining two papers provide insights on the deployment of smart agents in medical contexts. Shanks et al. investigate how consumers evaluate human-robot medical teams that are led by a robot or a human. Their results show that behavioral intention ratings are lower towards a team led by a robot versus a human. The effect is mediated by decreased ratings of perceived team leader power and increased consumer anxiety. Finally, Ravella and Chakravarti examine how smart agent avatars can enhance the effectiveness of physician-patient interactions in a healthcare context. They find that a human physician introducing the avatar creates a contrast that lowers the avatar's evaluation. Avoiding such contrasts makes patients more receptive by lowering expectations of empathy from the avatar versus the human physician.

Taken together, these four papers should attract significant interest in the consumer research community. They provide a range of conceptual insights on the mechanisms underlying consumer receptivity to AI agents in service contexts. The findings also shed light on how AI-based smart agents may be designed and deployed more effectively in both general consumer service and medical interaction contexts.

Friendly and Reliable: Antecedents of Interactive Agent Personality

EXTENDED ABSTRACT

Artificially intelligent devices are becoming rapidly established in the lives of ordinary consumers. Our research focuses on a subset of these devices, "interactive agents" (IAs), which we define as "modern technological tools that perform one or more tasks and interface with their users in mutual and dynamic ways" (Gray et al. 2011; Hildebrand et al. 2003). Popular examples include Amazon Alexa, Apple Siri, and Roomba. Although consumers interact with, form relationships with, and often humanize such devices, little is known about how the devices are socially perceived (Schmitt 2019).

Early research on social perception of technology produced social response theory (Reeves and Nass 1996). Its major proposal was that though people recognize machines do not possess feelings, intentions, or motivations, we nonetheless perceive them as "social actors" and interact with them in a reflexive, personal manner (Moon 2000). More recent research explores how consumers endow robots and other advanced machines with humanlike traits including "warmth" and "mindfulness" (Waytz, Heafner, and Epley 2014; Kim, Chen, and Zhang 2016; Kim, Schmitt, and Thalmann 2019). In robotics, a small body of work demonstrates that specific interaction patterns lead to attribution of specific personality traits (e.g., introversion-extraversion; Tapus, Tapus, and Mataric 2007). However, research in this area focuses on a narrow subset of traits adopted from human personality theories, which may or may not be applicable to technological devices.

In prior work (Hyun and Bond 2019), we developed a parsimonious and psychometrically valid instrument to capture perceptions of IA personality. The instrument includes two overarching dimensions ("friendly" and "reliable") with seven underlying facets. In the current research, we examined the nomological validity of a two-

dimensional model. First, we investigated how the two dimensions relate to established constructs in psychology and marketing. Next, we identified theoretical antecedents of each dimension and tested their influence experimentally.

To investigate convergent and discriminant validity of the IA personality constructs, we recruited 243 participants from Mechanical Turk (130 females, *M* Age=35). Participants evaluated one of six popular IA devices (Siri, Alexa, etc., chosen at random). They completed the IA personality measure along with 16 other measures covering anthropomorphism, human and brand personality, product attitudes, and social cognition. Analyses confirmed good fit of the two proposed dimensions ("friendliness" and "reliability") with theoretically overlapping constructs. For example, perceptions of IA friendliness were positively associated with brand sincerity (*r*=.716, *p*< .01) and extraversion (*r*=608, *p* < .01), while perceptions of IA reliability were associated with brand competence (*r*=753, *p* < .01). Analyses also confirmed adequate discriminant validity for all scale comparisons.

Next, we experimentally tested the emotional expressiveness ("emotionality") of an IA device as an antecedent to its perceived friendliness. The expression of emotion provides useful social information about traits of the expresser (Van Kleef 2009), and the mental capacity for refined emotion is considered a uniquely human characteristic (Haslam et al. 2008). To test the prediction that emotionality uniquely influences the friendliness dimension, we recruited 249 US Prolific workers for an experiment involving an audio-based "interactive agent" ("Eva"), in which they interacted with the agent to obtain a restaurant recommendation. Participants were randomly assigned to a *high-emotion* or *low-emotion* condition. We manipulated emotionality by varying the audio script so that the *high-emotion* but not the *low-emotion* script contained positively-valenced, emotionally expressive words (e.g., I am *happy* to assist you…, I am *thrilled* to suggest…, I feel so *proud* to be your assistant; the scripts were otherwise identical.) After interacting with the device, participants completed the 22-item IA personality measure, manipulation check items, and a variety of exploratory attitudinal measures regarding downstream consequences. Analyses supported the role of emotional expressiveness as a unique antecedent to friendliness: compared to participants in the *low-emotion* condition, those in the *high-emotion* condition rated "Eva" substantially more friendly (*M*=3.60, *SD*=1.15 vs. *M*=2.86, *SD*=1.23, *p* < .001; η_p^2=.089), but ratings of reliability did not significantly differ (*M*=5.04, *SD*=1.29 vs. *M*=4.98, *SD*=1.19; *ns;* η_p^2 < .001). Examination of exploratory downstream measures revealed that perceived friendliness was positively and significantly associated with both liking of the device (*b*=.58, *t*=10.65, *p* < .001) and willingness to interact with it (*b*=.45, *t*=7.61, *p* < .001).

Finally, we investigated the ability to customize an IA device ("customization") as an antecedent to perceived reliability. Our logic was based on the principle that customization increases trust and dependability by serving as an implicit reminder of autonomy and control (Ariely and Bitran 2013), and by increasing attention through self-relevant information (Tam and Ho 2005). To test the prediction that customization uniquely influences the reliability dimension, we recruited 195 US Prolific workers for an experiment involving an "interactive assistant," with a procedure similar to the prior study. Participants were randomly assigned to either a *high-customization* or *low-customization* condition. In the *high-customization* condition only, participants were first given the opportunity to select the name, location, and color of the device, and their selections were reflected in the subsequent interaction screens. Otherwise, the two conditions were identical. Analyses supported the role of customization as a unique antecedent to reliability: compared to participants

in the *low-customization* condition, those in the *high-customization* condition rated the device higher in reliability (*M*=5.19, *SD*=1.04 vs. *M*=4.89, *SD*=1.10, *p* < .05; η_p^2=.020), but ratings of friendliness did not significantly differ (*M*=3.03, *SD*=1.34 vs. *M*=2.91, *SD*=1.13; *ns*; η_p^2=.002). Examination of exploratory measures revealed that perceived reliability was positively associated with perceptions of recommendation quality (*b*=.58, *t*=9.90, *p* < .001), and negatively associated with skepticism (*b*=-.55, *t*=-9.33, *p* < .001).

For researchers interested in modern interactive technologies, our work represents a step towards better understanding of personality perception and attribution. For marketers of IA products, our findings suggest that careful construction of product "personalities" may provide a means of differentiation, diversification, and targeting to specific segments. Moving forward, we encourage research that explores how IA personality perceptions influence transactional and relationship variables (performance expectations, willingness to disclose, self-product congruence, etc.).

Smart Recommendation Agents: Voice Tone and Self-Relevance as Keys to Persuasion

EXTENDED ABSTRACT

With recent advances in natural language processing and voice synthesis technologies, voice-controlled artificial intelligence devices are now better able to understand human speech and interact more fluently with human users. Although these so-called "smart agents" can talk and communicate with humans, more research is needed on the role played by the smart agent's voice in human-machine interactions. Our research examines how vocal tone and personalization features designed into such devices influence consumer trust and persuasion in purchase contexts.

As a "carrier of speech" (Belin et al. 2004, p. 129), voice not only delivers semantic content but also transmits feelings and emotions in verbal communications via prosodic cues such as tone, speed, and pause (DeFleur et al. 1993; Nass and Brave 2005). Whereas a modal, or monotonous voice with "overall moderate laryngeal tension" (Gobl and Chasaide 2003, p. 195) does not signal emotion, a dynamic voice pitch communicates emotion (Chasaide and Gobl 2004; Whiteside 1999) and can influence perceptions and evaluations of the speaker's personality and attractiveness (Brown et al. 1973; Tigue et al. 2012).

Recent research (Van Zant and Berger 2020) has shown that "*para*language" (i.e., the acoustic properties of speech such as pitch and volume) influences people's attitudes and choices, and sometimes even more so than linguistic cues. Such modulated speech communicates the speaker's confidence, often without compromising sincerity perceptions. Extrapolating from these *interpersonal* communication contexts, one might expect that a smart agent's recommendation may be more persuasive if delivered in a dynamic versus monotonous (machine-like) tone. Yet, if for a smart agent, such modulation is unexpected, a monotonous voice may be seen as less contrived, cue an inference of objectivity, and raise compliance.

Study 1 manipulated voice of a machine agent to dynamic versus monotonous and tested the effect of voice on persuasion. Participants listened to the agent's voice and responded to the agent by checking answers on a webpage. In Study 1A, 99 UK residents (Prolific panelists) ordered a burger of their choice by interacting with a smart agent (Alexa) speaking in a dynamic or a monotonous tone. At the end of the interaction, Alexa suggested that participants add ice cream for an additional £1. As predicted, participants were more likely to add ice cream when Alexa's recommendation was made

in a dynamic (vs. monotonous) tone ($F(1, 94)$=3.97, p=.049; $M_{Dynamic}$=4.10, SD=2.21; $M_{Monotonous}$=3.21, SD=2.21).

Study 1B replicated the effect with 93 US participants (CloudResearch panelists) who ordered an iPad in similar interactions with a smart agent. Here, the smart agent recommended adding an insurance policy for the iPad at the end of the interaction. Participants were more likely to add the policy when the agent spoke in a dynamic (vs. monotonous) voice tone ($F(1, 91)$=4.19, p=.043; $M_{Dynamic}$=3.67, SD=2.07; $M_{Monotonous}$=2.84, SD=1.83). Moreover, the agent speaking in a dynamic (vs. monotonous) tone evoked more affectively (empathy/sincerity/warmth, α=.94) rooted trust ($F(1, 91)$=4.19, p=.044; $M_{Dynamic}$=3.64, SD=1.79; $M_{Monotonous}$=2.91, SD=1.63). Affective trust mediated the voice tone effect on persuasion (Indirect effect=.23, SE=.13, 95% CI [.0141, .5019]). Interestingly, cognitively rooted (intelligence/competence/efficiency, α=.96) trust measures did not differ across the voice conditions (p=.19).

Study 2 examined how the voice effect is moderated by the extent to which the participant perceives the smart agent as self-relevant. Since self-relevance heightens attachment (Park et al. 2006), smart agents that are perceived as more self-relevant may naturally elicit higher trust. This should attenuate the voice tone effect. We conducted two lab experiments to test this prediction. Each experiment used a 2 (voice: dynamic vs. monotonous) x 2 (self-relevance: high vs. low) between-subjects design.

In Study 2A (N=233), participants purchased an iPad through an interaction with Alexa as in Study 1B. Following the iPad purchase interaction, Alexa recommended the purchase of a product insurance policy. However, prior to the purchase task, Alexa's self-relevance was manipulated. Participants in the high self-relevance condition read an article that described Alexa's functions as highly customizable to their personal preferences. They then interacted with Alexa by talking about their family, friends, and shopping preferences, with Alexa sharing similar self-disclosures. In the low self-relevance condition, participants read an article describing Alexa's functionality in general terms, followed by an audio clip that introduced Alexa's skills and functions. The conversations and the purchase interaction were conducted using Alexa's voice tone, manipulated to be dynamic or monotonous.

As predicted, the data showed a significant interaction between voice and self-relevance on persuasion ($F(1, 229)$=5.12, p=.023). When self-relevance was low, the results were consistent with those in Study 1. Persuasion was higher for the dynamic voice tone ($F(1, 229)$=5.16, p=.024; $M_{Dynamic}$=4.31, SD=1.74; $M_{Monotonous}$=3.57, SD=1.84). However, when participants saw Alexa as self-relevant, voice tone had no significant effect ($F(1, 229)$=.91, p=.34; $M_{Dynamic}$=3.84, SD=1.53; $M_{Monotonous}$=4.15, SD=1.82).

Study 2B (N=185) used a similar procedure, except that Alexa suggested purchasing additional iCloud storage. In this study, we also measured behavioral consequences with a choice measure. Our purchase intention measures showed similar patterns as in Study 2A. There was a significant voice tone x self-relevance interaction ($F(1, 181)$=5.01, p=.026). For low self-relevance, persuasion was higher for the dynamic voice ($F(1, 181)$=7.63, p=.006; $M_{Dynamic}$=3.83, SD=1.75; $M_{Monotonous}$=2.88, SD=1.61). The difference was not significant in the high self-relevance condition ($F(1, 181)$=.14, p=.71; $M_{Dynamic}$=3.21, SD=1.40; $M_{Monotonous}$=3.34, SD=1.76).

Moreover, a binary logistic regression analysis showed a significant interaction of voice and self-relevance on choice (b=-1.38, SE=.67, p=.039). When Alexa was less self-relevant, the proportion of participants who purchased the additional iCloud storage was higher for the dynamic versus monotonous voice tone ($\chi^2(1)$=5.00, p=.025; Dynamic=39.0%, Monotonous=18.0%). There was no sig-

nificant voice effect when Alexa was perceived as more self-relevant ($\chi^2(1)$=.47, p=.49; Dynamic=25.5%; Monotonous=31.9%).

The four studies reported above show a robust pattern of persuasion effects of the voice tone used by a smart agent in purchase interaction contexts. When the smart agent is less self-relevant for the consumer (general skill sets), the dynamic voice is more persuasive than a monotonous (machine-like) voice. However, this voice effect disappears when the smart agent's skills are seen as highly self-relevant. Voice tone plays a smaller role in persuasion when the recommendation agent is more personalized.

Consumer Response to Human-Robot Teams

EXTENDED ABSTRACT

Robots such as the Moxi nurse aide and da Vinci surgical robot work with humans in an assistant capacity in the medical industry. However, advances in technology have changed the possible human-robot team configurations. Robots such as the STAR surgical robot can perform surgeries autonomously, suggesting that we may see robot-led human-robot teams in the near future. Such human-robot team configurations are seen in other industries, namely, the military and manufacturing industries, resulting in increased productivity. We would expect to see similar increases in efficiency when human-robot teams are used in the medical industry, as studies demonstrate that the increased use of technology in healthcare leads to lower hospital stays and lower medical costs (Kalis, Collier, and Fu 2018; Marr 2018).

The possibility for robots to shift from an assistant to a lead role in a human-robot team leads to an important question: How will consumers respond to human-robot teams as a function of the roles shared by the human employees and robots? The literature suggests that consumers will evaluate the robot and human differently, leading to a negative response to the robot leader. Robot exercise coaches are evaluated as less warm and competent (Čaić et al. 2020), while consumers believe that technology is less able than humans to account for their individual characteristics (Longoni, Bonezzi, and Morewedge 2019). We propose that the disparity in human and robot evaluations influences consumers' perceptions of power that the robot-team leader and the human team leader have. This is supported by findings that consumers are more comfortable with robots in less powerful roles and robots that demonstrate lower autonomy levels (Dautenhahn et al. 2005). Consumers hold concerns about robots and artificial intelligence in healthcare (Longoni et al. 2019). Lower ratings of team leader power to a robot leader can intensify these concerns. We hypothesize that the lower ratings of perceived team leader power leading to increase consumer anxiety serially mediate a decrease in behavioral intentions to a robot-led team.

A series of studies examines the effect of a robot (vs. human) led human-robot medical team. The pilot study examines the effectiveness of a human-robot team. Patients at an elderly care facility participated in exercise sessions with either a robot assisted by a human physical therapist or a human physical therapist alone. Participants had an unfavorable reaction to the human-robot team (vs. human), rating the exercises as less favorable ($p < .01$) and reported lower behavioral responses ($p = .04$).

Study 1 examines the effect of a human-robot team on a consumer's response to a robot-led team. Participants received a nutritional counseling session from a live, in-person human-robot team with either the human or the robot as the team leader. The results revealed lower ratings of behavioral intentions ($p < .001$) and team leader power ($p = .002$), and greater consumer anxiety ($p < .001$) when the team was led by a robot (vs. a human). Further, there is

serial mediation (Hayes 2015, Model 6) for the path team leader → power → anxiety → behavioral intentions (a × b = -.1238, 90% CI: [-.2856, -.0060]). A follow-up study, extending these findings to a different robot and human, replicates these results.

Study 2 adds a co-human team as a control condition, providing further support that a robot-led team results in decreased behavioral intentions. There are lower behavioral intentions to the robot-led team as compared to both the human-led and co-human teams. A serial mediation analysis (Hayes 2015, Model 6) is significant when comparing the robot-led and human-led team. However, the serial mediation is non-significant for the human-led as compared to the co-human team.

Studies 3A and 3B examine the role of perceived choice on response to a human-robot team. In Study 3A, participants chose the robot used in the medical team in the choice condition and could not choose the robot used in the control condition. In the control condition, participants had lower behavioral intentions to the robot-led (vs. human-led) team. This was attenuated in the choice condition. Study 3B examined the role of choice on upgrading behavior, finding greater interest in paying to upgrade to a human-human team when the initial team was led by a robot.

The current research adds to our understanding of how consumers respond to robots as they work with humans in new team configurations. Our findings have implications for marketing strategy as we demonstrate that this shift from tool to team leader results in a decrease in behavioral intentions consumer response and strategies to mitigate this negative response.

Ai Supported Physician-Patient Interactions: The Physician's Avatar May Need No Introduction.

EXTENDED ABSTRACT

Physicians are often insufficiently skilled at delivering bad news to patients (Eggly et al. 1997; Monden et al. 2016). Some adopt an impassive communication style to avoid emotional involvement with patients. Others are overly empathetic and may even be perceived as inauthentic (Mast et al. 2005). These deficiencies persist despite an emphasis on developing physician communication skills (Monden et al. 2016).

As in other service domains (Wirtz et al. 2018, Wood and Shulman 2019), a new generation of humanoid service robots (HSRs) offer potential for supporting physician-patient interactions. However, research suggests that patients may display low receptivity to AI-supported healthcare (Longoni et al. 2019) due to concerns such as "uniqueness neglect." However, such resistance may be mitigated when the robot is personalized, plays support versus replacement/ leadership roles (Longoni et al. 2019; Mende et al. 2019; Shanks et al. 2020) or is known to outperform humans (Pezzo and Beckstead 2019).

We argue that an HSR's communication style (CS: empathetic vs. impassive), implemented via facial expression and speech, may drive different patient responses to an HSR (the physician's avatar) versus the physician in-person. A patient interacting with the physician's avatar may have different affective expectations (Tates et al. 2017), assess different cognitive capabilities, and make different motivational and socio-cultural appraisals relative to interactions with the human physician. Our studies are set in the context of treating early-stage breast cancer. Our core physician-patient interaction reflects the first phase of a three-phase procedure used at a leading US breast cancer facility. Here, the oncologist provides the patient with the diagnosis and information about the disease and treatment options.

We developed six videos depicting this physician-patient interaction. A trained male actor played the human physician. The first two videos featured the human physician and embedded the CS manipulation (empathetic vs. impassive) by varying the actor's facial expressions and voice tone, with interaction content held fixed. In two other videos, the human oncologist was replaced by an HSR (the physician's avatar) bearing a superficial resemblance to the human physician. The remaining two videos also featured an HSR, but with less resemblance to the human physician. We created the avatars using commercially available software. To avoid the "uncanny valley" effect, neither avatar was a close likeness to the human. The CS manipulation was embedded in both sets of the avatar videos.

These six videos formed the stimuli in a 2 (CS: impassive vs. empathetic) x 3 (physician: human/similar avatar/dissimilar avatar) between-participants design. The study also included a 2-level manipulation (Hope/Fear) of the prognosis for a breast cancer diagnosis. In Study 1, all three sets of videos included a preamble by the human physician indicating that the diagnosis and the related treatment information would be provided on the next visit (depending on the condition by the human physician or the physician's avatar, and introduced the similar or dissimilar HSR). Participants were 905 women (age range 21-60) recruited from the Prolific web panel. They were randomly assigned to the study conditions, asked to observe the video and then respond to a set of multi-item scales measuring persuasion (likelihood of following the physician's recommendation), trust (overall, cognitive and affective), liking and anthropomorphism (avatars only) in that order.

Whereas the hope/fear manipulation had no main effects on persuasion, trust, and liking, the empathetic (versus impassive) CS produced higher scores on each measure (all p's< .0001). Interestingly, the human physician scored *higher* than either the similar or dissimilar avatar on persuasion, trust, and liking (Means Human: 5.26; 5.08, and 4.14; Similar: 4.09, 4.26, and 3.23; Dissimilar: 4.36, 4.43, and 3.64, respectively all p's<.0001). The dissimilar and similar avatars were rated similarly on trust (4.43 and 4.26; p=.14) and anthropomorphism (3.36 vs. 3.17; p=.14). However, the dissimilar avatar did better on liking and persuasion (p's=.012 and .038, respectively). No two- or three-way omnibus interactions were significant (all p's>.10). Notably, the absence of a physician type by CS interaction suggests that although the human physician was preferred to the avatars, the CS change (empathetic to impassive) lowered evaluations equally for the physician and the avatars.

Study 2 used the same six videos and an identical three-factor design and procedure. The key difference was that the human physician's preamble was replaced by a verbal script stating that the diagnosis and the related treatment information would be provided on the next visit (depending on the condition by the human physician or the physician's avatar—similar or dissimilar HSR). Thus, the avatar was not visually "introduced" by the human physician. The participants were 928 women (age range 21-60) from the Prolific panel. Following random assignment, they observed the videos and completed a set of multi-item scales as in study 1.

The hope/fear manipulation had no main effects and the empathetic (vs. impassive) CS scored higher on each measure (p's< .0001). However, in contrast to Study 1, the dissimilar and similar avatars scored *higher* than the human physician on persuasion, trust, and liking (Means Human: 5.24; 5.00, and 4.00; Similar: 5.81, 5.66, and 4.59; Dissimilar: 5.75, 5.62, and 4.86, respectively, all p's<.0001). The two avatars were rated similarly on each measure. Importantly, the physician by CS interaction was significant for trust (p=.006) and liking (p=.004) and approached significance for persuasion (p=.07). Moreover, the human physician's evaluations dropped significantly

as CS changed from empathetic to impassive (e.g., persuasion: 5.57 vs. 4.90, $p<.0001$). In contrast, persuasion was attenuated less for the dissimilar (5.85 vs. 5.62, $p=.08$) and similar avatars (5.98 vs. 5.62, $p=.007$), with similar effects for liking and trust.

Our results suggest that, if carefully deployed, smart agents acting as physicians' avatars may effectively support physician-patient interactions. The contrast created when the human physician introduces the avatar may have unintended consequences that lower the avatar's evaluation. Without a direct contrast, patients may be more receptive to avatar interactions (particularly as they become common). Indeed, patients may have lower expectations of empathy from an avatar versus the human physician. This could facilitate more effective interactions with positive downstream effects on patient compliance and satisfaction.

SESSION OVERVIEW

People generate and are exposed to vast amounts of text data as they search for information on the Internet, read and share news articles, generate social media posts, chat with friends and family, and write online reviews. The existence of such large amounts of data, along with recent advances in machine learning and natural language processing, have created new opportunities for social and behavioral scientists. Our session explores the use of these data and novel methods (that are different than dictionary-based approaches) for four topics central to the study of consumer behavior.

The first paper of the session examines consumer perceptions for over 700 medical conditions. The authors obtain quantitative representations of online text explanations of these medical conditions through state-of-the-art language models, and use these representations to accurately predict consumer health perception. The authors also use these models to study the psychological correlates of health perception, and understand how language influences health perception.

The second paper examines an important question that consumers constantly face when engaging in everyday conversation: whether to stay on the same topic or switch to a new one. Across multiple studies, the authors demonstrate that while people want to accommodate their partner's topic preferences, they consistently underperform compared to machine learning algorithms that use natural language processing methods for extracting text-based features of the conversations. Thus, this paper presents a novel, text-based approach for topic selection in conversation.

The third paper of the session integrates deep learning-based text analytics methods and structural econometric modeling to construct a real-time, scalable market intelligence tool from freely available online text reviews from websites such as Yelp.com. To accomplish this goal, they overcome two important challenges: computing accurate numerical sentiment scores from free-flowing online reviews and addressing the difficulties with missing attributes in text

data. This novel approach is highly accurate and have the potential to answer additional novel marketing-related questions.

The fourth paper seeks to develop a text analytic approach to perform large-scale inferences of the evolution of consumer knowledge over time. Compared to traditional methods that are costly and limited in scope, the authors demonstrate that this text-based vector semantic algorithm is able to accurately capture and predict many aspects of the evolution of consumer knowledge in the last 25 years, therefore providing a flexible tool for uncovering theoretical and managerial insights into consumer knowledge.

To conclude, the four papers presented in this session will show how different types of text data, combined with various machine learning techniques, can be used to obtain new insights about consumer behavior. The prevalence of text data in everyday life, and the growing power and popularity of machine learning methods, has made easy for researchers to study nuanced behavioral phenomena in naturalistic settings, opening up new avenues for research across diverse areas of Marketing. For this reason, we believe our session will appeal to a broad audience of researchers, as well as practitioners, interested in understanding and influencing consumer behavior.

Machine Learning Models for Predicting, Understanding and Influencing Health Perception

EXTENDED ABSTRACT

Health perception has significant implications for healthcare funding. Unsurprisingly, such funding decisions depend on how consumers, voters, and donors perceive the severity of health states, and changes to media coverage and popular perceptions of a disease can have considerable effects on how much funding is allocated to health programs aimed at combating the disease (Casamayou, 2001).

How can we predict, understand, and influence people's health perceptions for common disease states? One possibility is to use quantitative measures such as "disability adjusted life years" (DALYs) that assess the severity of different medical conditions associated with the disease state (Calvert & Freemantle, 2003). Yet considerable research in psychology and marketing has found that such objective measures are not good predictors of people's health state perceptions (Slovic & Peters, 2006). That is, people are not actually good at evaluating the severity of different health states. Rather, their judgments rely on emotion, memory, linguistic, social, and other psychological cues, which occasionally lead to perceptions that deviate from objective measures such as the mortality rates or DALYs (Chapman, 2019).

More recently, the Internet has become an important information resource, with millions of people using health websites to inform health perceptions and guide health decisions. Our goal, in this paper, is to use information communicated on these websites to model health perceptions for hundreds of common disease states. We use textual information presented on the National Health Service (NHS) website, which is one of the main online sources of health information in the United Kingdom (Powell, Inglis, Ronnie, & Large, 2011). We additionally rely on recent advances in machine learning, known as word and sentence embeddings, which can quantify textual content for use in quantitative analysis (Bhatia et al., 2019; Günther et al., 2019; Jones et al., 2015). By using embedding methods to quantify the informational content of health descriptions on the NHS we

can build a machine learning model that is capable of predicting health perception given a textual description of a health state.

We collected health perceptions for a large set of medical conditions, diseases, and other health states with an online experiment in Prolific. We first scraped online text explanations of 777 different health states such as 'acne' and 'brain aneurysm' on the NHS website. Each of these health states is associated with multiple sentences of summary information ($M = 3.88$, $SD = 2.30$) as well as many pages of additional details. In the experiment, participants ($N = 782$ UK residents) were asked to read NHS summaries for ten randomly selected health states, to imagine that they were diagnosed with each of the health states, and to report their evaluations of the health states by using a standard EQ-5D's visual analogue scale.

We used two state-of-the-art language models called Distil-BERT and Word2Vec (Sanh et al., 2019; Mikolov et al., 2013) to represent our NHS text explanations as high-dimensional vectors. In Study 1, these vector representations were mapped onto aggregate human judgments using a Ridge regression. Our machine learning approach was able to accurately predict how participants perceived different health states (out-of-sample correlation of $r = 0.70$ between predicted and observed health ratings, $p < .0001$). This correlation is close to the split-half reliability correlation of 0.75 which is the theoretical upper-bound in making such predictions. In Figure 1, we also demonstrate the power of our model by comparing its performance to other competing models and measures, including those that rely only on objective statistics like mortality rates, frequency in language, or simpler features extracted from the text data (e.g. text length, concreteness, and sentiment).

A natural next question in our investigation is to interpret the information contained in health state text explanations and discussions that gives rise to these successful predictions. Since the embedding vectors are based on word co-occurrence statistics in natural language, they quantify the extent to which words and concepts are associated with each other in language, and more generally, in the minds of lay people. Thus, in Study 2, we used our embeddings approach to explore which concepts and constructs are most associated with high (and low) health state judgments. Using Linguistic Inquiry and Word Count (LIWC; Tausczik & Pennebaker 2010) and other participant generated keywords as inputs into our model, we found that health states which contained text related to the constructs of "death", "risk", and "money" were more likely to be perceived as bad health states. In contrast, those with text related to other constructs such as "present-focused" (e.g., looks, work), "negation words" (e.g., shouldn't, don't) were more likely to be rated as good health states.

Finally, in Study 3, we used our embedding models to predict how different descriptions of the same disease state can be associated with different health perceptions. Here, our goal was to test the utility of our approach for studying health communication and its effects. In an online study run on Prolific Academic, we asked a separate group of participants ($N = 80$ UK residents) to complete our initial health states ratings survey after reading a health state summary from one of six health states obtained from health-related websites like AmericanBreastCancerFoundation.org. We also obtained a prediction from our model and compared our model predictions with actual participants' average ratings. We found that we were able to correctly predict changes in participants' ratings as a function of disease description. This illustrates one way in which our approach can be used to inform policy-insights and behavioral interventions for better health communication.

In summary, we presented a novel machine learning approach to estimate how people use online summaries of medical conditions, and other health states, to form health perceptions. Our approach uses recent advances in natural language processing, and is able to predict lay health perceptions with very high accuracy. This technique is not only unique in predicting health judgment, but also has significant time and cost efficiencies as it can be easily applied to out-of-sample diseases without participant data. Policymakers, marketers, and researchers can use our method to quantify people's perceptions about different health states as well as to better understand the psychological cues that people use to make health state judgments. We look forward to future applications of textual data and machine learning to the study of lay health perception.

Topic Preference Detection: A Novel Approach to Understand Perspective Taking in Conversation

EXTENDED ABSTRACT

Conversation is one of the most common and important tasks humans do together (Dunbar, Marriott & Duncan, 1997; Pickering & Garrod, 2004). People reveal their preference to converse constantly, and while conversations can serve instrumental or strategic goals (Crawford & Sobel, 1982; Berger, 2014), they can be intrinsically and mutually enjoyable, as well (Mehl, Vazire, Holleran & Clark, 2010; Epley & Schroeder, 2014; Kumar & Gilovich, 2015; Sun, Harris & Vazire, 2019). But even when people share a seemingly simple, cooperative goal such as enjoyment, the decisions necessary for generating conversation can be quite complex. While people may want to talk, they must still mutually decide what to talk about.

Topics are a fundamental structure of conversation, allowing speakers to jointly maintain common ground (Hardin & Higgins, 1996; Passoneau & Litman, 1997; Stalnaker, 2002; Schegloff, 2007). But consider a judgment that everyone confronts during every turn of every conversation: Should we stay on topic, or switch topics?

This decision can be difficult. Although people may have a general sense of their own preferences for different topics, those preferences may vary depending on whom they are talking to. Furthermore, others' preferences can be ambiguous, even after the topic has begun. Formally, we define this task as "topic preference detection": Can people tell whether someone else wants to stay on a topic based on what they have said about it?

Here, we study how well people learn their partners' topic preferences, and whether that affects their own topic choices. We develop this as a naturalistic perspective-taking task, that tests how well people can learn about one another in conversation (Eyal, Steffel, & Epley, 2018). Across three studies we find that (i) people want to accommodate their partner's topic preferences, but (ii) they routinely fail to detect what topics other people prefer. All data, code and preregistrations can be found (anonymized) on OSF at https://goo.gl/gmxyR3.

To define a common set of topics as stimuli, we conducted a pilot study (n=199), using fifty topic-starting questions drawn from previous research (Aron et al., 1997, Huang et al., 2017). Participants wrote a response to each topic question and then rated their preference (-10 to +10) for staying on topic. From that we chose a list of 12 topics (e.g. "what is the strangest thing about where you grew up?"), using topics that had average (but high-variance) ratings. Throughout, we estimate preference detection accuracy as the non-parametric correlation between predicted and actual preferences over the twelve topics.

Study 1A had an asynchronous design, similar to the pilot. We asked mTurk participants (n=392) to read the twelve topic questions one at a time, writing a response, and reporting their preference for staying on-topic. In Study 1B, other mTurkers (n=654) rated their

own preferences for each topic, and then predicted the writer's topic preferences for a set of 24 responses (6 topics each for 4 writers). These human judges were less able to detect writer's preferences (τ = .142, CI_{95} = [.127, .158]), than a simple NLP algorithm (τ = .174, CI_{95} = [.151, .196]) that parsed the same text responses that humans had seen, using ngrams + politeness + word2vec features in a cross-validated LASSO regression (Freidman, Hastie & Tibshirani, 2010; Mikolov et al, 2017; Jurafsky & Martin, 2017; Yeomans, Kantor & Tingley, 2018). The judges also rated their preference for each topic with each of the four writers whose responses they saw. Their responses revealed a strong preference for mutually enjoyable topics – they preferred topics they thought their partner liked (τ = .531, CI_{95} = [.511, .550]). We empirically disentangle this topic accommodation from egocentric projection, which was also common among judges in every study we ran.

In Study 2, we again used the asynchronous topic preference detection paradigm from Study 1, recruited pairs of participants who know each other well (e.g. friends, family) to predict one another's preferences (n=172, preregistered). Again, the machine learning algorithms (τ = .155, CI_{95} = [.121, .189]) outperformed humans (τ = .188, CI_{95} = [.156, .219]). Participants were also overconfident in their prediction accuracy. And when they had more information about their partner - by having known their partner for longer, or by reading their response (vs. only the question) - their confidence increased, but not their accuracy.

In Study 3, we recruited laboratory participants (n=196) to take part in a synchronous paradigm. Participants reported their preference for each topic before meeting their partner, then had 10-minute dyadic conversations. Afterwards, they reported their own topic preferences, and predicted their partner's. Pre-conversation preferences strongly predicted speaking time on each topic (β = .117, SE = .023). And like Study 1, post-conversation preferences revealed a desire for mutually enjoyable topics (β = .557, SE = .031). However, speakers were less accurate predicting topic preferences (τ = .203, CI_{95} = [.166, .240]) than a simple word count of each person's on-topic speech (τ = .247, CI_{95} = [.206, .288]). A separate set of lab participants (N=330) watched videos of the conversations, but were not as accurate as the speakers themselves (τ = .150, CI_{95} = [.128, .171]). Conversely, we applied new a preference detection NLP algorithm to the transcripts, using the same features as before, as well new dialogic cues (e.g. laughter, pauses, follow-up questions), and it again outperformed humans (τ = .338, CI_{95} = [.305, .369]).

This research provides a novel framework for topic selection in co-operative conversation. Our finding show that topic preferences drive conversational behavior, and conversationalists want to find mutually enjoyable topics with one another. However, they are constrained by their ability to listen and reason about other people's conversational behavior. This suggests important limits to perspective taking even in open-ended natural language.

Attribute Sentiment Scoring with Online Text Reviews: Accounting for Language Structure and Missing Attributes

EXTENDED ABSTRACT

Many firms conduct routine tracking surveys on product/service performance on selected attributes chosen by managers that they believe drive overall customer satisfaction (Mittal et al. 1999, Mittal et al. 2001). The summary scores from these surveys are used as dashboard metrics of overall satisfaction and used as performance metrics at firms. However, surveys are costly, suffer from response biases and get outdated quickly (Culotta and Cutler 2016, Bi et al. 2019). Therefore, crowd-sourced online review platforms have emerged as an alternative and less expensive source of scalable, real-time feedback for businesses to listen in on their markets for both performance tracking as well as competitive benchmarking (e.g., Xu 2019, Li et al. 2019).

In this paper, the authors combine deep learning-based text analytics methods with structural econometric modeling to develop a real-time, scalable market intelligence tool from freely available online reviews. While we use restaurant reviews from Yelp.com as an empirical illustration of our method, this tool can be applicable in a range of industries like hotels, education etc. where firms care about monitoring a fixed set of managerially important attributes over time and benchmarking against competitive performance. Even when not used as a replacement for tracking surveys of performance, such quantitative summary metrics are valuable for managers because consumers use review platforms when making choices (e.g., Zhu and Zhang 2010, Luca and Vats 2013). In a study conducted on Amazon Mechanical Turk, we find evidence that providing attribute-level sentiment scores instead of an overall rating and text improves consumer decision-making by reducing the cognitive burden in making a choice. Moreover, with employee compensation and performance being directly linked to online review performance in many firms, the need to develop reliable quantitative metrics that capture attributes and related sentiments from online UGC both for tracking gaps in customer satisfaction as well as managing one's e-reputation has gained critical importance.

Deriving attribute-sentiment scores from text reviews requires addressing two novel and challenging problems: The first challenge lies in coming up with accurate numerical sentiment scores from free-flowing online reviews. For this, they develop a deep learning convolutional-LSTM hybrid model to account for language structure, in contrast to bag-of-words methods that rely on word frequency alone. Bag-of-words based approaches are limited in their ability to adequately score attribute sentiments especially for certain classes of hard sentences. Examples of hard sentences include various types of negations like contrastive (``but", "yet"), long sentences and instances of sarcasm that account for almost 50% of sentences in online reviews. Consider the following examples where sentiment degree is modified, as in (i) "horrible," "not horrible," "not that horrible" and (ii) "delight, "just missed being a delight". When words are just counted as in bag-of-words, making the connections between the key sentiment words "horrible" and "delight" with their degree modifiers will be difficult, without considering how they are grouped adjacently to form phrases—i.e., spatial structure. Likewise, it is difficult to capture the true sentiment in a long or contrastive sentence without accounting for the order in which the words/phrases occur (sequential structure). In our model, the convolutional layer accounts for the spatial structure (adjacent word groups or phrases) and LSTM accounts for the sequential structure of language (sentiment distributed and modified across non-adjacent phrases). Our deep learning model brings about significant accuracy improvements not only in 5-level granular sentiment classification but also in polarity detection (positive and negative) for both "easy" and "hard" sentences.

The second challenge is addressing the problem of missing attributes in text in constructing attribute sentiment scores—as reviewers write only about a subset of attributes and remain silent on others. It is important to understand what causes people to remain silent on certain attributes because assuming ``missing" as "unimportant" can bias attribute-sentiment scores. Further, behavioral science research has long recognized the importance of the right imputation for missing values because people do not ignore missing attributes

in evaluations and often make complex and imperfect inferences from them (Gurney and Loewenstein 2019). For addressing attribute silence, the paper develops and estimates a structural model of reviewer rating behavior that takes into account the data generating process to develop a model-based imputation procedure. This econometric model of rating behavior also helps to identify the different incentives of various groups of reviewers to engage in online WOM. We find three segments of reviewers—the smallest but most active reviewers ("Status Seeking Regulars") who write mainly for being informative to others and maintaining platform status; the largest segment ("Altruistic Mass") who review without reward expectations, and a mid-size segment of "Emotive Irregulars" who review infrequently but write about attributes they are extremely satisfied or dissatisfied with. Our insights around attribute silence in reviews shows that informativeness and need to praise/vent drive more of the writing than the importance of the attribute. Not only does this contribute to the literature on why people engage in online word of mouth (Berger 2014), it also has implications for using reviews as a source of data for needs/benefits identification. In particular, contrary to conventional wisdom, the frequency of mentions of a benefit or a topic may not necessarily be a proxy of its importance. Overall, the paper illustrates the value of combining "engineering" thinking underlying machine learning approaches with "social science" thinking from econometrics to answer novel marketing questions.

Mapping 25 Years of Consumer Knowledge from Text Corpora

EXTENDED ABSTRACT

Consumer knowledge, the set of consumers' acquired understanding of brands, products, and other offerings, is known to be an important driver of consumer responses to brands and product offerings (Alba & Hutchinson, 2000; Hadar et al., 2013; Berger et al., 2020). Notably, consumer knowledge is constantly evolving and can change substantially over time (Smith and Lux, 1993; Polanyi, 1957). Just fifteen years ago, Facebook and MySpace were both rising stars in the social media category. Now, one is nearly synonymous with social media, while the other has fallen out of the mind of many. The ability to understand and predict such changes are thus valuable from both scientific and managerial perspectives.

To our knowledge, however, no method exists that can provide a quantitative, data-driven description of the evolution of consumer knowledge. Although longitudinal databases (especially commercial ones) exist, it is difficult to capture the full trajectory of every brand due to difficulties in keeping up with the constant entry and exit of firms and brands in the marketplace. Short of having a time machine, researchers cannot survey consumers from the past.

This study proposes a novel text analytic technique, Principal Semantic Component Analysis (PSCA), to track the changing meanings of words from time-indexed text corpora and characterize the evolution of consumer knowledge. Specifically, PSCA represents a combination of Principal Component Analysis (PCA) and the Dynamic Word Embedding (DWE) model (Yao et al., 2018), a recently developed diachronic natural language processing (NLP) approach that captures semantic changes.

Compared to static NLP methods such as traditional word embedding models, where the meaning of a word is invariant across time, DWE assigns a distinct meaning to a word per time period. For example, Hamilton et al. (2016) used an early version of DWE to trace the change in meaning of the word "gay" through the past hundred years from emotion to sexuality. Building on this line of literature, we hypothesize that a DWE approach can capture the rapid and

sometimes subtle changes in consumer knowledge. Specifically, in the studies below, we use a DWE model based on New York Times articles from 1996 to 2019, containing 1.3 billion words.

Study 1 presents PSCA findings on changing meanings of brands. Although the method is applicable to any arbitrary brand, only a select set of brands are shown given space constraints. Fig. 2A shows the DWE trajectory of the word "blackberry," which tracks the significant change of the word over the past 25 years, from being associated with the fruit to the smartphone brand and back again. A quantitative account of the above statement therefore should contain two parts: the *vector* of the largest semantic change, and the *timing* of the movements. In the case of "blackberry," a successful model should tell us (a) where "blackberry" was moving to and from, e.g., "smartphone", and (b) when "blackberry" was at the peak or nadir in terms of strength of association, e.g., peaking around 2008 to 2011, which corresponds to the peak years of the brand Blackberry according to its stock prices and revenues.

Specifically, PSCA captures the vector of the largest semantic changes by computing the first principal component of DWE, referred to as Principal Semantic Component (PSC) hereafter. To identify the timing of movements, we then computed the time series of semantic similarities between the brand and the PSC. In Fig. 2B, the PSC of "blackberry" has the meaning of "android, app, smartphone." That is, PSCA identifies that "blackberry" moved most along the direction of "smartphone" from 1996 to 2019. The time series also gives information about the timing of Blackberry's rise and fall along the "smartphone" dimension. In particular, PSCA identifies 2010 as the time when Blackberry reached its peak as a smartphone brand, before dropping sharply after.

To explore the generalizability of PSCA beyond brands, we applied PSCA to detect changes in more intangible concepts, such as fashion trends and fads. For example, PSCA identifies that the word "Atkins" had a sharp but transient rise in association with diets in 2004, likely reflecting the rise and fall of the Atkins diet, and it uncovers how the word "selfie" came to popularity since 2010 and is still going strong (Fig. 2C).

These and other results that match with common impressions provide initial support for the utility of PSCA. In Study 2, we show that PSCA findings correspond with, and can even forecast, commonly used marketing metrics. Specifically, we compare PSCA results with several external metrics related to consumer knowledge. As a benchmark for existing text-based metrics for popularity, we also include word counts of the brand names. Due to space constraints, here we only present comparisons with Interbrand's Best Global Brand ranking, a ranking based on brand equity. Other metrics, including number of users and Brand Asset Valuator scores, lead to similar results.

There are several consistent trends which show that PSCA captures at least part of the consumer knowledge (Fig. 2DE). First, for brands which have peaks in the external metrics, e.g. Blackberry, peaks of PSCA coincide with those of external metrics. Moreover, we found that PSCA acts as a leading indicator of other metrics in the rising stage. This suggests that the semantic information leveraged by PSCA allows the algorithm to detect the rising trends earlier than considering word counts alone. Another notable feature is that external metrics often delay in providing data about brands. For example, Interbrand did not include Facebook until 2011, when the social media platform had already plateaued out according to PSCA. This highlights the important role of textual data in providing information about brands in their early stages, when longitudinal data is scarce.

Collectively, the results demonstrate that (a) textual data indeed contain rich information about consumer knowledge which is other-

wise difficult to obtain, and (b) PSCA offers an accessible solution to extracting such information with similar temporal resolution as survey-based methods, but at much lower costs.

SESSION OVERVIEW

What the world needs now… is a little more conversational understanding. Interpersonal communication is a fundamental part of everyday life. People share word of mouth, customers talk to salespeople, and managers discuss market strategies.

But while a great deal of recent work in marketing has begun to examine why people talk and share, there's been less attention to the broader *conversations* in which interpersonal communication is situated. Why do some conversations last longer than others? In this age of polarization, how can people improve engagement with opposing views? When in conversation are certain linguistic feature more effective? And can conversations help encourage sustainable behavior?

This session addresses these and other questions as it sheds light on the drivers and consequences of consumer conversations. It examines language produced in both experiments and the field, applying text analysis, machine learning, and other techniques to deepen understanding around these important phenomena.

First, **Boghrati and Berger** examine why some consumer conversations last longer than others. Using deep learning to analyze over 26,000 turns in oral conversations reveals the importance of questions and linguistic concreteness in keeping conversations going. That said, not all questions have the same impact, and they distinguish between differential effects of broad and narrow questions.

Second, **Yeomans, Minson, Collins, and Gino** explore how to improve engagement with opposing views. They use machine learning to analyze the language of over 5,000 conversation participants to identify language that communicates thoughtful engagement during disagreement, and show that such language makes writers more persuasive, builds reader trust, and prevents conflict escalation among Wikipedia editors.

Third, **Donnelly, Hurst and Sintov** examine whether conversations can encourage commitment to sustainability. The demonstrate that participants used less electricity, committed to more sustainable foods, and shifted their attitudes more towards a conversational partner's when discussion time was embedded in dyadic decision-making tasks.

Fourth, **Packard, Li, and Berger** study *when* within a conversation particular language features are more impactful. Examining conversational dynamics in over 23,000 turns in call centre conversations from two different firms reveals that using both affective and competent speaking styles can impact customer satisfaction and purchases if one identifies *when* during the interaction each style matters. Results are also replicated in an experiment. The method is further extended to shed light on *when* within conversations using first person singular pronouns and asking questions matters.

Taken together, these papers highlight the causes and consequences of conversations for consumers, as well as employees and organizations. The session should attract a wide audience of researchers with interests in social influence, sustainability, and language across contexts such as word of mouth, negotiation, and customer service. It should also have appeal to those interested in learning about text analysis and machine learning applications. We look forward to a stimulating conversation about conversation among the attendees and presenters.

What Drives Longer Word-of-Mouth Conversations?

EXTENDED ABSTRACT

Consumers have dozens of conversations each day and these conversations have a huge impact on consumer behavior. While there has been great interest in the consequences of everyday consumer conversation, there has been less attention to its drivers. Why do some conversations last longer than others?

Longer conversations can provide more information, reasons, or details, all of which should increase word of mouth's impact (Shafir et al., 1993). A great deal of research demonstrates that longer reviews are more helpful (Liu & Park, 2015; Mudambi & Schuff, 2010; Pan & Zhang, 2011), more persuasive (Zhang et al., 2010), and boost purchase (Ghose et al., 2012; Kim et al., 2018). But why do some consumer conversations, or topics, persist while other don't? In this research, we focus on two main drivers of conversations, questions and concreteness.

Questions. One might imagine that any question encourages conversation. A key function of questions is to solicit information and encourage someone to respond (Dillon, 1982; 1988). Consequently, compared to just making statements, questions can help move a conversation forward.

We suggest that whether or not questions encourage topic persistence depends on the question type (i.e., breadth).

Prior work (Miles, 2013) suggests that questions can be arrayed in terms of their breadth. Broad, or more open questions, broadly seek information and don't constrain the scope of appropriate response. Narrow, or more closed questions, however, tend to suggest a narrower range of responses.

We suggest while narrow questions should encourage topic persistence, broad questions may not have the same effect.

Narrow questions should encourage further progress down a particular direction. Further, to the degree that these questions follow-up an existing line of thought, they suggest that the questioner is interested in that line of thought, and would be happy to continue discussing it.

Broad questions, however, should be less likely to have the same effect. While broad questions give conversation partners more

things to talk about, by calling for more complex or exploratory answers, they also open up other directions for discussion.

Concreteness. In addition to question breadth, we also examine linguistic concreteness. Concrete languages arises from or appeals to immediate sensory experience, while abstract language refers to intangible qualities and concepts (Hansen & Wänke, 2010).

Building on past research, we suggest that concrete language should encourage topic persistence. Consistent with the fact that they tend to refer to real or perceptible entities, concrete things are easier to visualize and require less cognitive resources to process (Friederici et al., 2000). This vividness or ease of imagery, in turn, can impact things like interest and comprehension.

Consequently, we suggest that linguistic concreteness should encourage discussion. Concrete language should facilitate imagery, encourage interest, and make it easier for people to understand the conversation, all of which should encourage continued conversation.

Data. Participants (N=222) completed a conversation study in the laboratory. They were given 10 minutes to talk about whatever they wanted. A professional transcription service converted the recordings to text.

Each ten-minute conversation was then broken down into pieces based on the topic discussed. To break conversations down into these different topics, two research assistants went through each transcribed conversation and marked topic changes. Any instances where participants talked about the conversation itself were removed, resulting in a dataset of 745 conversation topics with over 26,000 conversational turns.

Method. We used NLP to extract key features (i.e., question breadth, linguistic concreteness, and control variables) from each conversational turn.

To determine which turns contained a question, building on prior work (Stolcke et al., 2000) we train a deep learning model. This approach was also used to extract other dialogue acts (e.g., statements) as control variables.

For classification, we use Robustly Optimized Bidirectional Encoder Representation for Transformers (RoBERTa, Liu et al., 2019). We add a neural layer on top of the base model to fine-tune the pre-trained model for our classification task.

Next we identified broad and narrow questions. Research assistants coded each question in the dataset as broad or narrow. We then built a deep learning classifier for question breadth using our manually coded data for future research.

Linguistic concreteness was captured using measures from prior work. We use a boot-strapped extension of the MRC Psycholinguistic Database (Paetzold & Specia, 2016). Averaging concreteness scores across the words in each turn provided a score for that turn.

Given our interest in predicting an event (i.e., topic death) based on a number of time-varying explanatory variables (e.g., linguistic features for a given turn), hazard modeling seems the most appropriate approach. Hazard models relate the time that passes before an event occurs to variables that may be associated with that quantity of time (Allison, 1982).

Results. Topics lasted longer when conversation partners asked questions, but the strength of the effect depended on the type of questions. Topics lasted longer when people asked narrow questions (= -1.23, $p < .001$), and the effect of narrow questions was larger than the effect for broad questions (= 9.78, $p < .01$). This difference consistently persists across all the robustness tests. While broad questions were linked to longer conversations in the most basic specification (= -.44, $p < .05$), this relationship became non-significant once more controls were added.

Topics also lasted longer when people used more concrete language (= -.15, $p < .001$).

Results persist when controlling for factors such as interest, linguistic style matching, other dialogue acts, word count, LIWC content categories, and a variety of modeling approaches.

In conclusion, while a great deal of research has studied the consequences of word of mouth, the drivers of interpersonal communication are less studied. Analyzing hundreds of consumer conversations suggests that even beyond topic interest, linguistic features may drive topic persistence. We demonstrate the important role of question type. Topics last longer when people asked narrow questions, but broad questions did not have the same positive effect. Topics also lasted longer when people spoke more concretely. Hopefully this investigation will encourage more research into this interesting and important topic.

Conversational Receptiveness: Improving Engagement with Opposing Views

EXTENDED ABSTRACT

Disagreement is a fundamental feature of social life, in civic spaces, in professional organizations, and in personal relationships at home. Opposing viewpoints are often inevitable in the pursuit of more important organizational and interpersonal goals. Engagement with diverse perspectives can also help us increase the accuracy of our own belief. However, disagreement can also give rise to biased processing, negative inferences, and conflict. While engagement with opposing viewpoints can be beneficial, its effects will be tempered by the contents of those interactions (see Bail et al., 2019; Paluck, Green & Green, 2018). Here we examine whether "conversational receptiveness" can foster co-operative goals during disagreement and prevent conversational conflict spirals.

In this research we conduct four studies, and all data, analysis code, stimuli, and preregistrations from each study are available (anonymously) at https://bit.ly/2QwyiuL. In Study 1 we instructed 1,102 participants to write responses to statements written by people with whom they disagree, on one of two controversial issues. A separate group of 1,322 participants read responses from people with opposing viewpoints, and evaluated how receptive the writer had been. We parsed the text of the responses into features from the politeness R package (Yeomans, Kantor & Tingley, 2018), and we trained a supervised machine learning algorithm (Friedman, Hastie & Tibshirani, 2010) to build a receptiveness detection model that was generalizable (for datasets from other domains) and interpretable (to design interventions). This model was just as accurate (pairwise accuracy = 66.8%; p<.001), as any one human rater (65.2%; p<.001). The model focuses on the structural, domain-general elements of the language (hedges, acknowledgment, negation, reasoning), and the model's accuracy was unaffected when it was trained and tested on different topics (65.2%; p<.001). In Studies 2 & 3, we apply the model in conversations from organizational contexts where disagreement naturally arises.

In Study 2, we collected conversations between 238 senior local government officials in an executive education program, who were paired up to discuss controversial policy topics (using a negative assortative matching algorithm to ensure they all disagreed with their partner). After the conversation, participants rated their own and their partner's receptiveness. Partner-rated receptiveness was associated with a range of positive interpersonal benefits, like trust in judgment and willingness to work together (r=.289, p<.001). Furthermore, the receptiveness model from Study 1 predicted these positive interpersonal outcomes (r=.232, p<.001), and also showed that partners' re-

ceptiveness converge over time, indicating that one of the benefits of receptiveness is that it is returned in kind (r=.335, p<.001). However, people could not predict how receptive their partner would rate them (r=.048, ns). Our language model held their own speech to a different standard than their partner's speech, focusing more on formality (titles, gratitude, etc.) than demonstrations of listening.

In Study 3 we extend this result to conversations within globally-distributed organizations where disagreement naturally arises, and where people are free talk about many different topics, with many different people. In Study 3A we examine receptiveness among 3,303 students in policy-themed massive open online courses at HarvardX. We collect ideology measures and compare them to the contents of the class discussion forums. We find that on average, students were less receptive to students they disagreed with (r= .099, p < .05). However, the receptiveness of students' posts predicted the receptiveness of the replies they received from other students who disagreed with them (r= .226; p<.001). This suggests that receptiveness is often, and individual choices to be more receptive can foster a more receptive dialogue going forward. In Study 3B, we measure receptiveness during the editorial process of correcting Wikipedia articles. We borrowed a dataset of talk page threads, in which 585 threads ending in personal attacks were each matched to similar thread without an attack (Zhang et al., 2018). We found that editors who were less receptive were more likely to be attacked themselves (59.9%; p<.001).

Study 4 was similar to Study 1 except that some writers were first taught a "recipe for receptiveness", which was developed as a 100-word summary of Figure 1 that can be cheaply deployed as a nudge during conversation. Opponents who read the responses from writer who saw the recipe thought they were more trustworthy and persuasive than writers who responded naturally. However writers did not always predict this effect, and expressed surprising hesitation to be receptive in the future.

Overall, our results suggest that receptiveness is measurable and has meaningful interpersonal consequences, but can be under-utilized in part because speakers can misjudge their own receptiveness. Our results also highlight an under-discussed element of recent efforts to improve civic discourse: The linguistic behavior that people exhibit in conversation can powerfully affect their partners' perceptions, engagement, and willingness to cooperate.

The Influence of Environmentally-Focused Conversations on Pro-Environmental Behavior

EXTENDED ABSTRACT

To address global climate change, action to promote more sustainable use of natural resources is required. Most studies evaluating consumer decision-making rely on paradigms that collect data from a single participant, or examine household-level outcomes. These approaches fail to capture the fact that many consumption decisions are not made independently, but rather in conjunction with others. As a result, these decisions may often involve conversations between two or more actors, during which relevant preferences and beliefs are exchanged and joint commitments are created (Sintov et al., 2019).

Prior work has demonstrated that conversations between two or more people can influence consumer knowledge and beliefs. For example, interpersonal discussions can influence climate change beliefs (Goldberg et al., 2019), and a brief conversation with a political canvasser improved attitudes toward transgender people and intentions of supporting policies in favor of these individuals (Broockman & Kalla, 2016). However, the influence of conversation on behavior is less clear. Two studies evaluating self-reported discussions and energy conservation intentions speak to the promise of conversations in influencing behavior (Sintov et al., 2019; Southwell & Murphy, 2014), but experimental evidence is needed.

In this research we evaluate how conversation content and conversation partners' stances influence subsequent behavior in peer-to-peer sustainability conversations. We achieve this through a set of three experiments with peer dyads that engaged in brief discussions and assessed subsequent behavioral actions supporting environmental policy as well as energy consumption.

Study 1 was a field experiment evaluating the effectiveness of a sustainability-focused conversation on electricity consumption amongst roommate pairs in a college dormitory (*N*=240). The college dormitory had a sustainability-living theme and asked all residents to sign an agreement to conserve resources (including energy and water) and to minimize waste during the semester. After residents signed their agreement, they were asked to have a 10-minute conversation with their roommate and to complete a roommate agreement which required short responses to conversation prompts. In the control condition, roommates conversed and made agreements to quiet hours, sharing of possessions, guests, and cleaning. In the treatment condition, participants were also prompted to converse and make agreements about their sustainability commitment: to conserve electricity, water and reduce waste.

The study team compared average daily electricity use between the treatment and control conditions for the Fall 2019 semester. A significant effect of the intervention was observed such that the treatment condition consumed less energy than control (*b*=-16.23, *SE*=1.89, *p*<.001). We found a positive and significant interaction between intervention and day of treatment (*b*=0.54, *SE*=.06, *p*<.001), suggesting that the effect of the intervention weakened over time. Overall, our effects suggest that a 10-minute conversation that included prompts to discuss energy conservation followed by a commitment resulted in a 22% decrease in energy consumption over the Fall 2019 semester. Our effects weakened after students went home for the Thanksgiving break, suggesting the need for reinforcement after prolonged absence to allow roommate pairs to recommit to resource conservation. Similar effects were observed for water consumption.

Study 2 sought to understand the cumulative benefit of a conversation paired with a commitment by utilizing a between-subjects experimental design. Specifically, participants in a lab setting (*N*=568) were randomly assigned to a conversation-only, commitment-only, or conversation plus commitment condition. We posited that a commitment becomes more impactful following a conversation on the issue at hand. Conversations allow for learning and exchange of pertinent beliefs, thoughts and ideas (Huang et al., 2017), and can serve as an opportunity for conversation partners to develop rapport, trust and psychological safety (Edmondson, 1999).

Participants were informed they would interact with another participant and, following the interaction, they would have the opportunity to click their mouse to support a plant-based foods initiative. Participants were told that if the mouse was clicked collectively 400 times between themselves and their conversation partner a $1 donation would be made to the initiative. Participants were then instructed to have a conversation that was video recorded and the structure of the interaction was varied as a function of treatment. Participants in the conversation-only condition were instructed to spend 2.5 minutes discussing their stances on whether the university should increase plant-based food offerings in on-campus dining areas. Participants in the commitment-only condition were instructed to discuss actor biographies for 2 minutes (as a filler task) and then spend 30 second forming a commitment as to how much effort they

would both contribute to support the plant-based food initiative. Participants in the conversation and commitment condition discussed their stances on plant-based foods for 2 minutes, followed by a 30 second commitment of how much effort they would contribute to the clicking task.

There was a significant effect of condition on clicking ($F(2,281)=5.62$, $p=.004$) such that participants in the conversation and commitment condition clicked significantly more than participants in the conversation-only condition and the commitment-only condition. There were no differences between the conversation-only and commitment-only conditions ($p=.27$). Participants rated policy-relevant conversations as more psychologically safe than conversations about celebrities, and reported greater collaboration in forming a commitment following conversations about the policy. These differences mediated the difference in clicking between the conditions.

In Study 3, participants ($N=302$) had a conversation about plant-based foods with a confederate that either presented three arguments in favor of plant-based foods (supportive of policy) or 3 arguments against plant-based foods (against the policy). We also assessed participants support for the policy before the conversation to assess how policy support was influenced following a conversation with a peer who was either supportive or against the policy. Following the conversation, participants had the same opportunity to click for the policy as Study 2.

Regressing clicking on confederate stance, participant stance, and an interaction of these variables revealed a significant interaction ($b=-.12$, $p=.02$), demonstrating that confederate support (vs. opposition) increased participant clicking among participants who were initially unsupportive of the policy, but did not influence clicking of participants who were initially supportive. These results suggest that conversations can be differently influential depending on pre-support, and suggest that conversations can be more influential to individuals less supportive of environmental policies.

In sum, this research suggests that conversations can be quite effective at motivating increased effort toward sustainable behavior and that the structure and content of dyadic dialogue can influence behavior.

Discovering *When* Language Matters in Service Conversations

EXTENDED ABSTRACT

Consumer conversations are dynamic. People chat with each other online (discussion boards, texting, social media) and debate word of mouth opinions in the "real world." Salespeople try to persuade potential buyers who sometimes push back, while call centre workers talk with customers to help resolve their issues. These important consumer interactions are not monologues, but dynamic dialogues between people.

While conversations are a central feature of consumer life, they can be remarkably difficult to analyze. They entail a messy series of conversational turns with dramatic variation in content and importance. These challenges may be why most prior consumer or marketing language research examines texts or speech acts as singular, static events (e.g., Kronrod et al. 2011; Packard and Berger 2020; Packard, Moore and McFerran 2018).

But a more granular view may be useful. Clearly some parts of conversations may be more important than others, but which parts might those be, and how can researchers identify them? We introduce a novel method allowing researchers to not only examine *what* language matters, but *when* it matters. Specifically, when different linguistic features may play a larger role in a conversation's success.

To demonstrate the approach, we explore the two most important dimensions of person perception—warmth and competence (Abele and Wojciszke 2007; Fiske, Cuddy and Glick 2007). It's difficult to seem both affective (warm) and cognitive (competent). Trying to be more emotionally-concerned impedes perceptions of competence, while acting in a more rational, cognitively-oriented manner makes people seem less warm (the warmth / competence trade off; Godfrey, Jones and Lord 1986; Holoien and Fiske 2013; Wang et al. 2019). As a result, research in customer service contexts suggests employees should use competence-related language, while warm language should be avoided (e.g., Marinova et al. 2018).

Rather than being either competent or warm, we suggest that a better solution may be to think about particular times within customer interactions when each is beneficial. Instead of diving straight into finding a solution, we suggest that affective language may be important at a conversation's beginning. When employees and customers interact for the first time, such as in retail or call center interactions where they usually don't know each other, affective language may help build situated rapport (DeWitt and Brady 2003; Gremler and Gwimmer 2000). But being warm will only go so far. Eventually the employee must address the customer's needs. Here, competence should be important, so shifting to a more analytic, cognitive style should be valuable. Finally, given the work on recency or end effects (Greene 1986), closing with affective language may be key to leaving the customer feeling positive. Our approach uses dynamic modeling and an experiment to test these possibilities.

Data. We obtained nearly 20 hours of audio recordings of 200 customer service calls from a large American retailer. As a dependent measure, the firm provided their end-of-call customer satisfaction measure (1 = not at all helpful, 4 = very helpful). The recordings were transcribed to text. Each conversational turn was treated as a separate record (e.g., turn 1 (agent): "How can I help you?", turn 2 (customer): "I can't find (…)"), resulting in 12,410 turns for analysis.

For our independent measures, we captured affective versus cognitive language using validated linguistic dictionaries (affective processes, cognitive processes; LIWC; Pennebaker et al. 2015) for both the employee and customer previously used as measures of linguistic warmth and competence (Decter-Frain and Frimer, 2016; Berry et al. 1997). Results are also robust to alternative dictionaries (Marinova et al. 2018). We include over 50 controls including customer and employee attributes (e.g., gender, lifetime expenditures, tenure), customer language, and conversation features (e.g., issue, severity, linguistic synchronicity).

Method. We extend methods from functional data analysis (FDA; Ramsay and Silverman 2007) and machine learning (Yang and Zou 2015; Kong et al. 2016) to address the challenges of analyzing conversational language. For any conversation feature(s), this method produces sensitivity (beta) curves that can deviate either positively or negatively from non-significance (zero line) in relation to the outcome of interest.

Results. Results support our theorizing. The importance of cognitive language is limited to the middle of the conversation, as indicated by the area above the zero line and below the 95% confidence interval in Figure 1, panel b. That said, as shown by the negative relationship of cognitive language with customer satisfaction at the beginning of the call, employees who try to quickly and competently solve the customer's problem—see significantly negative customer satisfaction (area below the zero line). Instead, as shown in Figure 1 (panel a), those who use more affective language at the beginning and end of the call see higher customer satisfaction. Using purchases (order count) in the 30 days after the interaction as the dependent measures produces the same results.

Notably, the average employee's use of both affective and cognitive language does not follow the optimal functional forms. Instead, affective language is least used at the start of the call, when it is particularly important, while cognitive language is near its lowest point between 12.5% and 40% into the conversation, which our method reveals is when it offers its most positive impact on customer satisfaction.

These results are replicated in a separate field data set of 204 calls (11,548 turns) from an airline call centre, and in a causal test that experimentally manipulates conversational language.

Discussion. This research begins to shed light on a richer theory of conversational dynamics. While a great deal of work has looked at *what* consumer and employee language matters, *when* linguistic approaches are most useful has received little attention. While prior work suggests speakers should be only warm or competent, our dynamic approach reveals that the warmth/competence trade off may not be so stark. Finally, this work introduces a new method by which consumer and marketing scholars can consider temporal features of language in a range of marketplace dialogues (e.g., social media, live sales interactions). To demonstrate, we offer additional sample applications of the method to previously investigated conversational features like personal pronouns and questions.

Paper #3: "Let's Laugh About it!": Using Humor to Answer Complainers' Online Incivility

Mathieu Béal, Grenoble École de Management, France

Yany Grégoire, HEC Montréal, Canada

SESSION OVERVIEW

Brands often have to deal with negative customer behaviors such as uncivil complaints, social media outrage, or other customer-induced failures. Many of these behaviors are public or can be made public, creating a difficult situation for brands, who are expected to respond to these behaviours (Hogreve, Bilstein, and Hoerner 2019). On the one hand, the customer is king and the expectation is that brands should respond favorably, especially given the public nature to these complaints and failures; on the other hand, the incivility and outrage are on behalf of the customer, and rewarding this outrage and accommodating customer-induced failures may result in negative consequences for the brand.

At present, there is no clear path forward for brands as to how best to minimize backlash and foster positive outcomes for the brand and managing consumer outrage and incivility has been identified as an important research avenues in recent calls (Bacile 2020). Building from this, the aim of this session is to provide timely and critically important insight into how brands should navigate what to do when consumers act uncivil, express highly public outrage toward a brand, or are themselves the cause of a service failure. Specifically, the three papers examine 1) What are the underlying types and motivations underlying consumer outrage, failure, and incivility?; 2) What are the consequences to the brand, employees, and other consumers?; and 3) How should firms respond to these behaviors?

The first two papers explore the first two questions. Specifically, the first paper introduces the concept of *moral peacocking*: the act of condemning perceived offensive behavior via public expression of one's outrage. Results suggest that the motivation stems from personal outrage and is amplified by the desire and ability to signal this outrage to one's ingroup. This results in an unintended 'counter-peacocking' effect, whereby dissociative groups that observe moral peacocking against the brand, not only do not reduce their willingness,

but actually have a strengthened desire to purchase from the brand. The second paper views this question from a service perspective, first categorizing various customer failure types and then demonstrating their negative effect on service worker well-being and the importance of a customer apology to alleviate it.

Finally, all three papers provide some insight into how firms should respond to this outrage and incivility. Specifically, the first paper suggests that due to counter-peacocking, managers may not want to immediately retract marketing messages that enrage a specific segment. The second paper outlines the importance of managerial support when dealing with customer failures. Lastly, the third paper argues that under some circumstances, utilizing humor to address incivility is an effective strategy to generate greater purchase intentions.

In conclusion, the papers in this session aim to provide brands with a path forward when navigating the complex landscape of responding to consumer failure, outrage, and incivility in a way that draws in rather than alienates witnesses and other consumers.

Moral Peacocking: Outrage and Identity Signaling on Social Media

EXTENDED ABSTRACT

Consumer responses to social and moral transgressions are ubiquitous on social media. Donald Trump, the former President of the United States, spent years using Twitter to provoke outrage among Democrats while cementing support among his base (Joseph et al., 2019). Further, reports suggest that Russia utilized social media outrage to sow polarization and division during the 2016 United States election (McCarthy, 2017), with similar campaigns carried out in the UK, France, and Australia (Zappone, 2018).

These online reactions manifest in the marketing world as well. Corporations and brand managers have responded to the acceptance of social media by working to incorporate social media channels into their marketing mix in order to engage consumers (Mousavi, Roper, & Keeling, 2017). However, unlike any previous time in history, these social media channels allow consumers to rapidly respond online to corporate behavior in real time, at times seeking reparations and shaming companies, brands or organizations (Dunn & Dahl, 2012; Joireman et al., 2013; Ward & Ostrom, 2006). Consumers who join in the condemnation see themselves as a group, resulting in increased hostility toward the 'evil' firm as they seek reinforcement from their group members or attempt to align themselves with their group norms (Ward & Ostrom, 2006; Love, Salinas, & Rotman, 2020).

The speed by which these collective responses can spread through social media creates a field full of potential landmines for organizations marketing on social media. For example, when Bud Light advertised the slogan "*The perfect beer for removing 'No' from your vocabulary for the night*" as part of their 'Up For Whatever' campaign, it was immediately condemned for supporting sexual assault, and subsequent independent brand analyses determined it had weakened the Bud Light brand (BrandIndex, 2015). More recently, in late 2018, Nike launched an advertising campaign featuring Colin Kaepernick, the famously polarizing NFL quarterback known for kneeling during the American national anthem in order to bring attention to violence against African Americans at the hands of the police. This resulted in immediate condemnation and a drop in Nike's stock price as consumers took to social media to post pictures of burning

their Nike shoes and apparel. However, the stock subsequently rebounded the following day with an outpouring of consumer support and has continued to significantly exceed market performance at the time of writing.

While examples abound of social media responses targeted at individuals or corporations perceived to break social or moral contracts, there is little extant research that examines consumers' underlying motivation for engaging in these behaviours (Rotman, Khamitov & Connors, 2018). Although these responses may be the result of sincere outrage, another possibility is that these responses are solely the function of identity signaling and impression management, and thus serve simply to elicit recognition and respectability. Ultimately, at present it remains unclear what motivates consumers to take to social media and condemn via public outcry, under what circumstances it becomes likely, and what the consequences of doing so are. For example, would Nike consumers have been motivated to burn their apparel if they knew no one was watching? Similarly, would liberal consumers have marshalled support for Nike if these kinds ofexploring

 public protests did not occur?

The current research explores these questions under the label *moral peacocking*, which we define as the act of condemning perceived offensive behavior via public expression of one's outrage to others. Specifically, we examine why individuals condemn persons, brands, or corporations they deem offensive or outrageous and the downstream psychological consequences of doing so. Across six experiments, we propose and test a model of moral peacocking that includes different social identities and diverse situations to demonstrate that moral peacocking is not necessarily driven solely by personal offense, but also by the perception that one's ingroup would similarly be offended (studies 1a and 1b), thus requiring a public platform (study 1c). We further predict and find that the moral peacocking response can be used to predict offline consumption behavior (study 2). Finally, we provide evidence that moral peacocking can result in greater group polarization causes *counter-peacocking,* whereby a dissociative outgroup is motivated to strengthen their opposing views (study 3) and alter their consumption behavior (study 4).

Study 1a and 1a provide converging evidence for our framework of moral peacocking. Specifically, individuals were more likely to condemn an offensive social media message when they were both personally offended, and they believed their ingroup would be offended by the content of that message. This result builds on traditional identity signaling and moral outrage research by showing that these two motivations act as a multiplicative function leading to an increased intention to peacock. Study 1c demonstrates that that while individuals were more likely to *publicly* condemn a post from an individual representing an opposing group they were not more likely to do so *privately*. This further supports our position that the motivation to morally peacock is a function of not only outrage but also identity signaling.

Study 2 extends the findings from studies 1a-c to the consumption consequences of moral peacocking. In particular, this study highlights that moral peacocking is not simply an act of 'slacktivism' (Kristofferson et al., 2014), but instead can be used to predict real world offline support of a brand.

Study 3 and Study 4 demonstrate the effect of counter-peacocking with real brands and behavior demonstrating that dissociative groups that observe moral peacocking against the brand not only did not reduce their willingness to buy from the brand but actually had a strengthened desire to purchase from the brand. Thus, this "counter-

peacocking" effect highlights that moral peacocking may be counterproductive as a means of punishing an offending brand or company.

The current research suggests that the motivation underlying consumer outrage arises from the interplay of moral outrage alongside the public, ingroup-focused nature of social media platforms. Consequently, in contrast to social media bringing people together, this inadvertently foments backlash as counter-peacocking, further polarizing group identities.

I'm Sorry! Investigating the Influence of Customer Failures and Apologies on Frontline Service Employee Well-being

EXTENDED ABSTRACT

There is a large body of literature on service failure and recovery (Van Vaerenbergh *et al.*, 2019), however surprisingly customer failures (CFs) have not been empirically examined. CFs are characterised by customers failing to effectively fulfil their role expectations. Much of frontline service employees' (FSEs') daily lives are spent co-creating services with customers (Cho, 2019) who frequently generate failures (Tax *et al.*, 2006). CFs can negatively impact that customer's experience, the experience of other customers, and/or the company's productivity (Tax *et al.*, 2006).

Prior research assumes that dealing with such negative customer behaviours is part of the FSE role (Stock and Bednarek, 2014), and the mantra of "the customer is always right" reinforces the inequality of FSEs versus customers (Henkel *et al.*, 2017). Handling CFs requires FSEs to engage in emotional labour by behaving politely and pleasantly even when FSEs do not have these genuine feelings (Cho, 2019), and regardless of the poor performance of customers who hinder their delivery of service quality.

Despite the ubiquity and importance of CFs, the service failure and recovery literature rarely considers them, such as their types, and no prior research contemplates their downstream consequences on FSE well-being. FSE well-being is important, under-researched, and one of eight transformative service research (TSR) themes (Anderson and Ostrom, 2015). FSE well-being can generate positive outcomes, including increased FSE productivity and job satisfaction, enhanced morale and motivation, and reinforced organisational commitment (Robertson and Cooper, 2011). Conversely, stressed and unhappy FSEs are unproductive, demotivated and disengaged (Sawang, 2010).

We argue that the negative impact of CFs extends to FSEs who need to manage them. CFs have a detrimental effect on FSE wellbeing, an important transformative outcome, but we advance that a customer apology can alleviate this by customers taking the blame for their failures. Overall, apologies are a valued reward that redistribute fairness and trust in an exchange relationship (Walster *et al.*, 1973). Apologies enable the victim to make sense of the apologiser and his/her failure (Basford *et al.*, 2014). They can diminish anger, promote forgiveness (Radu *et al.*, 2019) and enhance service evaluations (Hart *et al.*, 1990).

Despite research examining how apologies from FSEs affect customer evaluations following a service failure, there is no literature on the flipped relationship of how customer apologies affect FSEs following a CF. This is surprising given that one in three service failures are customer-caused (Zeithaml and Bitner, 2003). In this paper, we argue that a customer apology, i.e., a customer message containing an acknowledgement of blameworthiness for the CF (Roschk and Kaiser, 2013), can alleviate the negative impact of a CF and improve FSE well-being. We suggest that FSE well-being is negatively affected by a CF due to the extra demand and responsibil-

ity it places on FSEs but can be restored by a customer apology that acknowledges blame and responsibility for CFs.

This paper reports on three studies that investigate this phenomenon. The initial study applies the critical incident technique (CIT) to develop a taxonomy of intentional and unintentional CFs and explores the influence of customer apology on FSE well-being following a CF. Semi-structured telephone interviews were conducted with 103 randomly selected FSEs from a range of business-to-consumer (B2C) service industries. The vast majority of CFs were found to be unintentional and align with the different service consumption stages. Although relatively minor in severity, we confirm that CFs often have harmful implications for FSE well-being. This is particularly in the absence of a customer apology where FSEs frequently experienced negative feelings. In contrast, when describing their emotions following a customer apology, most FSEs felt happiness, delight and relief. This provides initial evidence of the positive influence of customer apology on FSE well-being. An overwhelming proportion of FSEs (79%) felt that there were benefits for themselves, the customer, and/or the organisation emanating from the customer apology. FSEs commonly spoke about the CF and apology incident (multi-coded) to managers (35.1%), co-workers (36%), and family and friends (13%). However, 32% of FSEs kept the incident to themselves.

Studies two and three utilised a full-factorial between-subjects scenario-based experimental design using Mechanical Turk (MTurk). In study two (n=91), we triangulate study one by testing the relationship between customer apology and FSE eudaimonic well-being (interpersonal and intrapersonal dimensions), which is supported. Furthermore, we demonstrate that FSE job satisfaction increases following a customer apology, along with positive affect. These findings extend the service literature by showing that customer apology is a promising approach to foster FSE well-being following CF.

Finally, in study three (n=216), as suggested by the study one findings, we examine the downstream implications of perceived supervisor support following a CF in the presence (versus absence) of a customer apology. Perceived supervisor support is the degree to which an FSE feels that he/she is supported by his/her supervisor in the context of a CF. FSEs feel valued when they perceive supervisor support, and this can buffer stress via emotional regulation (Cho 2019). We argue that FSEs count on managers to relieve job stress and provide emotional support (van Jaarsveld *et al*., 2019) in problematic CF situations. Support helps to relieve the extra demand of CFs so that FSEs are not left feeling to blame or responsible. Our findings suggest that perceived supervisor support nullifies the negative effect of the customer not apologising for their failure, yet when perceived supervisor support is lacking, this washes out the positive effect of a customer apology.

Service organisations need to clearly communicate performance expectations to customers to reduce CFs. We also recommend that signage and other communication be used to emphasise customer responsibilities. FSEs could be trained to garner customer apologies by responding to CFs constructively, drawing customers' attention to their failures without being aggressive or vindictive. Given their prevalence, management should identify intentional and unintentional CF types and develop processes and procedures to minimise them. To promote effective communication between supervisors and FSEs, supervisors could be trained in empathy and emotional intelligence, e.g., via role-playing. High-risk FSEs who chronically experience CFs should be identified and provided intensive ongoing support.

"Let's Laugh About it!": Using Humor to Answer Complainers' Online Incivility

EXTENDED ABSTRACT

[Example A]
@GokeAdebayo: *"Always f***ing up, f**k you and your stupid trains.*
@Virgin_TrainsEC: *Oh I'm soooo sorry, no reaaaaaallly I am – I forgot that we poured gallons and gallons of rain onto the tracks!"*

[Example B]
@DaneMarseille: *"How 'poor' persons can take the high-speed train if a one-ticket costs €179.*
@SNCF: *And how do you do to buy the last-generation smartphone? Same problem and I think it's understandable even for those who don't have a high school diploma"*

The two examples below present two companies' responses—Virgin Trains (Example A) and SNCF (the French railway company; Example B)—to customers' complaints posted on social media. While both companies adopted a form of humorous response with the attempt to amuse, observers' reactions to these replies were diametrically different. In Example A, Virgin Trains receives a large approval from observers, with thousands of likes and retweets. In Example B, SNCF's attempt was a complete fiasco, generating a "bad buzz" that ultimately leads the company to delete the tweet and to present public apologizes.

In this context, managers need to know when humor is appropriate, versus when an accommodative recovery (i.e., apologizing, providing explanations) represents a safer strategy. Unfortunately, academic research does not provide many insights to know when humor is a beneficial tactic for observers (e.g., Béal and Grégoire 2021), versus when humor should be proscribed in favor of an accommodative recovery (e.g., Shin and Larson 2020). In this research, we argue that Virgin Trains' response was amusing because it uses humor to respond to an uncivil complaint. Complaint incivility refers to all forms of rude, disrespectful, condescending, or degrading complaints made by a customer about a firm or an employee (Bacile et al. 2018; Grégoire et al., 2019). The phenomenon of customer incivility is clearly on the rise on social media because of the anonymity associated with such online environments. In a recent survey, 73% of observers reported having witnessed incivility on social media (Pew Research Center 2014). This phenomenon raises the critical question of how companies should manage incivility on social media; this issue has been identified as an important research avenues in recent calls (Bacile et al. 2018). We address such calls and posit that humor is an appropriate and effective tactic to address complainers' incivility on social media.

A recent body of literature has examined the effectiveness of humor on social media (e.g., Béal and Grégoire 2021; Shin and Larson 2020); however, we are not aware of any prior humor research incorporating the notion of complainers' incivility. To examine the effect of humor in the context of online incivility, we rely on benign violation theory, which constitutes an established framework to distinguish successful and failed humorous attempts (McGraw and Warren 2010). Using humor to address online complaints represents a norm violation because the company "makes jokes" rather than resolving the problem. However, if this intervention is perceived as benign, observers would be amused by this norm violation.

In their seminal work on benign violation theory, McGraw and Warren (2010) identify some conditions that make a norm violation benign, including the level of commitment toward the victim of humor. On the one hand, observers tend to have a bad opinion of uncivil complainers, and as result, they feel less committed toward them (Bacile et al. 2018). Accordingly, for uncivil complaints, observers judge the company's humorous response as being benign and amusing, given complainers' prior incivility (e.g., Virgin Trains' example). On the other hand, in the case of civil complaints, observers would feel more committed toward the complainers, and humor will be perceived as a malign violation, translating into little amusement and reduced purchase intentions (e.g., SNCF's example).

Building on this logic, the current research makes three contributions by using three scenario-based experiments conducted in different services contexts (i.e., internet service provider and restaurants). First, the research contributes to the recent literature on customers' incivility in a social media context (Bacile et al. 2018). All things being equal, Study 1 shows that observers are more amused and report higher purchase intentions when companies use humor to address uncivil complaints rather than civil complaints. The more uncivil is a complaint, the more a humorous attempt is effective at generating observers' amusement and purchase intentions.

Second, Study 2 examines if complainers' incivility influences the effects of two types of humor—that is, affiliative humor (e.g., laughing *with* the complainer) and aggressive humor (e.g., laughing *at* the complainer)—on observers' responses. Past research usually finds that people are more amused by interlocutors who favor affiliative humor over the aggressive type (Martin et al. 2003). Building on this, we argue that both types of humor are more amusing in the context of incivility, compared to a civil context. However, we still confirm that affiliative humor keeps its advantages in the eyes of the observers, no matter if the complaint is civil or uncivil.

Third, because affiliative humor is viewed as a more appropriate use of humor (as established in Study 2), we compare, in Study 3, its effectiveness with an accommodative response. The online service recovery literature acknowledges that an accommodative response usually develops the highest observers' positive attitudes and intentions (Johnen and Schnittka 2019). Recent research has recently challenged the overall superiority of accommodative recovery for observers in a social media by highlighting the effectiveness of using humor-based responses. Here, some researchers find that affiliative humor is as effective as an accommodative recovery (Béal and Grégoire 2021), whereas others reconfirm the superiority of accommodative recovery over any humorous attempts (Shin and Larson 2020). Study 3 reconciles such discrepancies about the usage of humor versus accommodative recovery by referring to the incivility of the complaint. When *complainers are civil*, observers respond more favorably to an accommodative recovery compared to affiliative humor. In turn, when *complainers are uncivil*, affiliative humor and accommodative recovery generate similarly high levels of purchase intentions from observers.

SESSION OVERVIEW

Social media platforms have become the main vehicle for firms to communicate information about their products and services to consumers. Some use more direct ways of communicating such as advertisements, while others encourage consumers to share product experiences, post selfies with products, or share specific information with other consumers. Online platforms differ from traditional communication vehicles (e.g., TV or newspapers) in important ways that affect the nature of interaction between consumers and firms. It is therefore timely and critical to understand how consumers react to new forms of communication on social media, so that both firms and consumers benefit from their interactions. The four papers in this session discuss how different types of product communications impact the way consumers think and feel about the target products and the networking platforms.

The first two papers focus on the psychological reactions of consumers after they make a post on social media, specifically, how consumers feel after taking or posting photos about a product or experience. First, Hall, Hyodo, and Barasch demonstrate that consumer satisfaction from an experience is higher when the shared experience (i.e., post) draws more attention. They find that greater attention to a shared post increases self-esteem, which leads to higher satisfaction with the experience. Next, Funk, Hofstetter, and John investigate the effect of taking selfies with a brand. They demonstrate that these brand selfies, compared to simply taking a photo of the brand or a selfie without a brand, elevate both the short-term and long-term brand preference due to heightened self-brand connection. These papers highlight the distinct features of social media, such as the ability to post one's own photos and the visibility of others' reactions, that affect consumer well-being through building consumer-brand relationships and enhancing self-esteem.

The next two papers shed light on the effects of another distinct feature of social media platforms—the presence of others—and examine how this factor affects one's motivations and behavior online.

Kim and Johar investigate the differential impact of social media ads on platform evaluations. They demonstrate that the presence of ads negatively affects evaluations of platforms intended for interaction with close others; this effect is attenuated on platforms intended for interactions with acquaintances or strangers. They posit that consumers feel psychological ownership over their newsfeed when interacting with close others on the platform and this feeling of ownership is threatened when ads intrude in the feed. The fourth paper examines a behavioral consequence of social media interactions, namely the propensity to share information with one's network. Lane and Brucks investigate the specific behavior of sharing untrustworthy news articles. They demonstrate that a "need to belong" motive, readily activated on social media platforms, increases consumer willingness to share these untrustworthy articles because it decreases the sensitivity to source trustworthiness.

Taken together, these four papers contribute to the literature by identifying novel antecedents and consequences of different product communication strategies of firms. They also offer practical implications for firms who desire to develop closer relationships with their consumers online.

Did You See What I Did? How Receiving Attention Enhances Post-Sharing Satisfaction with Shared Experiences

EXTENDED ABSTRACT

Consumer attention is a limited resource that is steadily increasing in value due to an imbalance between the static attention supply each individual and the ever-increasing attention demands faced by consumers (Davenport and Beck 2001; Simon 1971). While marketers recognize the importance of firms attracting and retaining consumer attention, little research has considered the value consumers place on attracting attention from other consumers. This lack of research examining consumer-to-consumer attention exchange is notable given that consumers recognize the relative scarcity of both their own and others' attention (Derber 2000). Specifically, consumers understand that receiving others' limited attention indicates those others are prioritizing that specific signal over competing others (Falkinger 2007). Thus, consumers generally value receiving attention because it is interpreted as a positive social signal.

In order to attract attention, consumers must send some type of signal (Falkinger 2007). In the consumption domain, one such signal is the sharing of consumption experiences. While consumers derive many benefits from consuming experiences (Holbrook 1994; Schmitt 1999), we propose that sharing an experience can provide additional experiential value by helping the consumer attract attention. Because receiving higher levels of attention from others is a positive social signal (i.e., others have prioritized the sharer's signal), we propose the level of attention one receives will predict sharer self-evaluations (i.e., self-esteem). Thus, after sharing an experience, receiving higher levels of attention should enhance sharer self-esteem. This enhanced self-esteem would not have been possible without the experience, meaning this self-esteem value should be partially attributed to the experience, ultimately increasing the sharer's satisfaction with the

experience. We note that many signals of online attention transfer are inherently affirming (likes and favorites). Thus, receiving these signals could simply affirm the desirability of the experience (i.e., social proof). However, we propose our hypothesized effects will be observed when sharers receive even unvalenced attention (e.g., views), because consumers value attention itself.

To test our theory, we leverage a variety of methodologies to establish both internal and ecological validity. Study 1a was a field study in which we partnered with a local jazz concert series to run a social media contest. Concert attendees shared about their concert experience on social media as part of the contest. Two days after sharing, we followed up with those who posted (n=46) and asked them to subjectively indicate the amount of attention their post received (1=very low levels of attention, 100=very high levels of attention) and their satisfaction with the concert (9-point bipolar scale; satisfied/dissatisfied, positive/negative experience). Participants who received higher levels of attention after sharing reported greater satisfaction with the concert experience (B=.027, SE=.009, p =.006). This finding was replicated in Study 1b, in which participants (n=99) logged into their own social media accounts and identified an experience they had shared in the past. Posts that had received higher levels of attention promoted greater satisfaction with the experience itself (B=.288, SE=.093, p=.003).

In Study 2, undergraduate students (n=258) completed a social media simulation in which received attention was manipulated in real time. Participants first viewed a video of a virtual rollercoaster experience and reported their initial satisfaction with the experience (1-7 scale; satisfied/dissatisfied; positive/negative; pleased/displeased). Next, they entered a social media simulation (adapted from Wolf et al. 2015), in which they chose a screen capture from the rollercoaster experience and wrote an accompanying caption. After joining the platform with ten other ostensibly real participants, attention was manipulated by altering the number of "views" participants received (participants could also indicate they had "viewed" other users' posts). Posts received either 9 (high attention) or 1 (low attention) view(s). After the simulation, participants again indicated their satisfaction with the experience and their self-esteem (15 items; 5-point scale; Bagozzi and Heatherton 1994). As a consequential choice measure, they were also offered an opportunity to view another similar rollercoaster. As expected, those who received higher attention reported higher self-esteem (M_{High}=3.95; M_{Low}=3.71; F(1,255)=4.31, p=.039) and satisfaction (M_{High}=5.41; M_{Low}=5.06; F(1,255)=11.21, p=.001; CI_{90}=[.001,.049]). This effect held when controlling for pre-attention satisfaction (F(1,256)=11.83, p=.001). Those receiving high attention were also more likely to view another rollercoaster (χ^2=3.96, p=.047).

Study 3 compares the receipt of explicitly affirming attention (likes) versus neutral attention (views). Undergraduates (n=184) read about sharing a restaurant experience to Instagram. They then saw a screenshot which displayed either 15 or 150 likes (affirming attention) or views (neutral attention). They then reported how satisfied they would be with that restaurant experience. There was no main effect of attention type (F(1,180)=.54, p=.465) or interaction (F(1,180)=.12, p=.732). However, those who received high attention, regardless of type, reported higher satisfaction than those who received low attention (M_{High}=4.42; M_{Low}=4.18; F(1,180)=3.90, p=.050). This effect was again mediated by self-esteem (CI_{95} = [.008, .293]). This suggests attention itself is valued even when it does not explicitly affirm the experience.

Lastly, Study 4 ruled out the possibility that sharers use others' attention to confirm the social desirability of the experience. This was done by manipulating the valence of the experience (sharing a negative experience) and attention recipient (self vs. other). Undergraduates (n=158) read about having a negative hiking experience with a friend, which either they or their friend shared on Instagram Story (which only provides unvalenced attention metrics; i.e., views). Participants learned that their or their friend's post received 9 (low attention) or 96 (high attention) views. Satisfaction was measured before and after the attention manipulation. A significant repeated-measures interaction emerged (F(1,154)=8.12, p=.005). Controlling for initial satisfaction, participants who received high attention reported greater satisfaction with the hiking experience (M_{High}=3.50; M_{Low}=2.08; F(1,153)=23.40, p<.001). However, when attention was received by the friend, the amount of attention did not affect satisfaction (M_{High}=2.72; M_{Low}=2.87; F(1,153)=.17, p=686). Thus, the amount of attention the experience receives does not necessarily signal its quality. Rather, consumers derive value when they *personally* receive attention—value that enhances satisfaction with even negative experiences.

Overall, this research demonstrates the importance of consumer-to-consumer attention exchange for marketers by demonstrating that consumers not only value receiving attention, but also that received attention enhances the value of consumption.

Snapping is Believing: The Effect of Brand Selfies on Brand Preference

EXTENDED ABSTRACT

Many firms actively and conspicuously encourage consumers to take brand selfies, sometimes offering modest incentives to do so, such as a small chance to win a prize (Dunkin' Donuts, 2014; Forever21, 2017). For example, Fisherman's Friends offered consumers the chance to win 24 packs of lozenges for direct messaging a brand selfie to the brand. In doing so, marketers may seek to influence the selfie-taker herself (e.g., when prompting consumers to take a brand selfie, as Fisherman's Friends did), as well as her social networks (e.g., when prompting consumers to share the brand selfie on social media). Here, we focus on the former goal, investigating how and why brand selfie-taking impacts the selfie-taker.

We develop and test a conceptual account for when and why brand selfie-taking can affect the selfie-taker's preference for a given brand. Drawing on self-perception theory (Bem 1972; Festinger and Carlsmith 1959; Shaver 1970), we predict that consumer compliance with a marketer's request to take a brand selfie sparks a self-inferential process that can lead the consumer to feel connected to the brand (e.g., "If I took the brand selfie, I must feel connected to this brand"), increasing brand preference. Specifically, we propose that taking a brand selfie can increase brand preference (H1), and that this effect is mediated by self-inferences of connectedness to the brand (H2). We also test two theoretically-informed moderators. We predict that the effect of brand selfie-taking on self-brand connection is attenuated when consumers are prompted to make external attributions for their behavior (H3). Second, our account is premised on the notion that people sometimes infer their attitudes from their behaviors, and so when they look pleased [dissatisfied] in a photo with a brand, we presume them to infer positive [negative] attitudes (in the form of enhanced [decreased] self-brand connection; Laird 1974, 2007; Strack and Martin 1988). Therefore, we predict that brand selfie-taking will increase [decrease] self-brand connection when the selfie-taker's facial expression is positive [negative] (H4).

Study 1 tests H1 "in the wild" using data from Instagram. Specifically, we assessed the sentiment of a sample of product reviews (N = 120,000) as a function of whether the reviewer (i.e., poster) had taken a brand selfie. As predicted, reviewers' posting of a brand selfie

is positively associated with the sentiment of their review. Although this association persisted after controlling for possible confounders (e.g., brand and user fixed effects, review length), its correlational nature cannot pinpoint causality; therefore, we conducted four randomized experiments, which we describe next.

Study 2 (N = 100) tests H1 using a two condition between-subjects design in which participants chose which of two bottles of water to have as their reward for participating: a bottle from the target brand, or a larger, more valuable, bottle from a different brand. Between-subjects, we randomized participants to either an experimental group, in which they took a brand selfie (i.e., a self-photo with the target brand) or a control group, in which they simply took a selfie (without the brand). Consistent with H1, participants in the brand selfie condition were more likely to choose the bottle from the target brand relative to those in the control group (68% vs. 48%; χ^2 = 4.11, p = .043).

Study 3 (N = 200) tests whether H1 holds over time, as well as offering a partial test of H2. Specifically, participants were randomized to either take a brand selfie or simply a selfie as in Study 1. Then, two days later, we assessed participants' self-brand connection as well as purchase intention. Participants in the brand selfie condition exhibited higher purchase intent relative to the control group (F(1, 366) = 10.49, p < .01); and this effect was mediated by self-brand connection (indirect effect = .69, BootSE = .22, 95% CI = [.27, 1.11]; c' = -.03, SE = .22, p =.91).

Study 4 (N = 594) tests H3. We manipulated the ease of drawing inferences from one's behavior and test whether doing so affects self-brand connection in predicted ways. Specifically, for half of participants, we disrupted the self-inferential process by facilitating external attributions. We did so by prompting participants to attribute their compliance with the photo-taking request to the fact that they had been given an extrinsic, monetary incentive. The study was a 2x2 between-subjects design in which we manipulated photo type (i.e., brand selfie versus brand photo) and attribution prompt (internal versus external). As predicted, the effect of brand selfie taking on self-brand connection was attenuated when participants were prompted to make external attributions for their photo-taking behavior (F(1,590) = 6.96, p < .01, η^2 = .01; *see Figure 1*).

Study 5 tests H4 in a 2x3 between-subjects design. Participants were randomized to either take a brand selfie or a selfie. Critically, we also manipulated participants' facial expressions in their photo, by either instructing them to have a positive expression (e.g., a smile), or a negative expression (e.g., a frown), or giving them no particular instruction on how to appear. As predicted, self-brand connection was reduced in the negative expression condition relative to both the no instruction and positive expression conditions (F(2, 992) = 7.34, p < .001, η^2 = .01; *see Figure 2).*

These results contribute to scholarship by identifying a novel process by which self-brand connections can be constructed: self-inferences generated by taking a selfie with the brand. In doing so, we heed Schmitt's (2013, 2019) calls for more research on how consumers' interactions with brands affect the relationships they form with those brands, particularly when it comes to digital content creation. Second, we contribute to the emerging scholarly literature on consumer engagement by identifying the effects of a novel and increasingly prevalent form of content creation—brand selfies—on the content-creators themselves (including marketing-relevant outcomes, such as purchase interest). With respect to practice, findings imply that marketers ought to prompt consumers to actually smile in their brand selfies, for the positive effect of brand selfie-taking on brand preference emerges when consumers look pleased in the photos.

This is My Space: When and Why Ads on Social Media Cause Negative Platform Evaluation

EXTENDED ABSTRACT

Social media revenue is highly dependent on advertisements. Over 95% of Facebook's 2020 global revenue was solely from advertisements, while platforms such as Twitter, Instagram, and Pinterest all have growing ad revenues every year (Tankovska 2021). Meanwhile, consumer reactions towards social media advertisements are quite negative, ranging from blocking ads on their feeds to deleting the apps altogether. But do ads always decrease evaluations of the platform? The current research investigates when ads hurt platforms and when they do not.

One unique feature of social media ads is that they are shown in a space where you interact with others. We propose that *who* is on the platform with you (e.g., close friends or far acquaintances) will moderate the effect of ads on platform evaluation through feelings of psychological ownership (Pierce et al. 2003; Weiss and Johar 2013). Specifically, the presence of close friends creates the feeling that the platform newsfeed is "my" space, which makes ads feel like an intrusion taking one's ownership away. This decreased sense of ownership causes negative platform evaluation (Jussila et al. 2015; Stoner et al. 2018). If the platform is used for interacting with acquaintances and strangers, this feeling of psychological ownership will not be as high; therefore, ads will not affect platform evaluations as much. We briefly describe four studies that test this theorizing below.

In study 1 (N = 150), we surveyed people's social media usage. For each social networking platform participants said they used, they reported the percentage of the time on the platform they spent interacting with close others and how much psychological ownership they felt over their platform feed (Peck and Shu 2009). Participants further indicated how they would feel about the platform if it showed them advertisements. Across platforms, the higher the percentage of time spent with close others on the platform, the more psychological ownership they felt over the feed (= 2.23, $p < .001$) and the more negativity they had towards platforms showing ads (= 0.34, $p = .007$.

Study 2 (N = 399) was a 2 (tie: close vs. far) 2 (ad: no ads vs. ads) between-subjects experiment. Participants read about a new social networking platform meant for either interacting with close friends or with acquaintances. They wrote down the names of five people that they expected to interact with on this platform, and then saw an example newsfeed with these people. There were either no ads or two ads in between the posts and on the bottom of the page they evaluated the platform. A two-way ANOVA revealed an interaction effect of tie and ad on platform evaluation ($F(1, 388) = 4.29$, $p = 0.039$); for the close-friend platform, the presence of ads significantly lowered evaluation ($M_{noad} = 4.30$ vs. $M_{ad} = 3.77$; $F(1, 388) = 6.98$, $p = 0.009$) while for the far-friend platform, the presence of ads had no effect ($M_{noad} = 3.85$ vs. $M_{ad} = 3.91$; $F(1, 388) = 0.09$, $p = 0.767$).

Study 3 (N = 800) helped pin down the role of psychological ownership. The study was similar to study 2 with the addition of questions where participants indicated the psychological ownership they felt over the newsfeed. Participants who saw ads on the example newsfeed also indicated whether they felt like the two advertisements infringed in their territory. Two-way ANOVAs replicated results from study 2 (interaction: $F(1, 617) = 3.80$, $p = 0.052$). In support of the proposed underlying mechanism, the presence of ads decreased felt ownership over the platform significantly for a close-friend platform ($M_{noad} = 4.51$ vs. $M_{ad} = 3.56$; $F(1,617) = 25.43$, $p < 0.001$) but not for a far-friend platform ($M_{noad} = 3.65$ vs. $M_{ad} = 3.34$; $F(1,617) = 2.76$, $p = 0.097$; interaction: $F(1, 617) = 5.58$, $p = 0.018$). A moderated mediation model revealed that where psycho-

logical ownership mediated the negative effect of ads on the platform evaluation for close-friend platforms but not for far-friend platforms (indirect effect = -0.40, CI95% = [-0.7387, -0.0750]).

What can platforms intended for close interactions do to generate revenues given that advertising can backfire in this case and negatively affect the platform? The psychological ownership literature suggests two possibilities. First, consumers may have higher intentions to purchase customizing features when they feel a higher ownership over the feed (Kirk et al. 2015). Second, consumers may be willing to pay more voluntary donations (Jami et al. 2021; Peck et al. 2020).

Study 4 (N = 400) tested these possibilities using a single factor (no ads vs. ads) between-subjects design. All participants were told that the platform was intended for interacting with close friends. After either seeing no ads or ads, they indicated psychological ownership over the newsfeed. Participants were then asked whether they would pay $1 per month for customizing features and indicated their willingness-to-pay for a donation to the platform (in dollars). As in study 3, ads decreased psychological ownership over the feed (M_{noad} = 4.24 vs. M_{ad} = 3.55; $F_{(1,324)}$ = 17.47, $p < 0.001$). When participants saw no ads, they showed a higher purchase intention for customizing features (M_{noad} = 2.10 vs. M_{ad} = 1.74; $F_{(1,324)}$ = 4.91, p = 0.027) and a greater willingness-to-pay for donations (M_{noad} = 1.13 vs. M_{ad} = 0.80; $F_{(1, 324)}$ = 3.40, p = 0.066). Both effects were mediated by psychological ownership (Indirect effect on customizing = 0.2764, CI95% = [0.1427, 0.4338]; Indirect effect on donation WTP = 0.2112, CI95% = [0.0874, 0.3647]).

In sum, we identify that there is a differential effect of ads on social networking platform evaluations, depending on who is present on these platforms. Specifically, the presence of ads is detrimental to consumer evaluations of social media platforms that are used for interactions with close friends and this effect is driven by feelings of psychological ownership. These findings suggest that it is important for social media platforms to know who their users interact with on the platform and to use advertisements strategically to avoid consumer backlash.

When Friends (Don't) Care About Facts: Belonging Motivation Drives Untrustworthy Information Sharing

EXTENDED ABSTRACT

The explosion of social networking sites has created an online information environment that is inextricably mingled with a social environment (Stafford, Stafford, & Schkade 2004). Although a more social information environment offers the benefit of diverse viewpoints (Dahlberg 2011), it has also been found to reduce fact-checking (Jun, Meng, and Johar 2017) and hinder discernment between true and false information (e.g., Pennycook and Rand 2018, 2021). These inherent susceptibilities and potential for false information to quickly spread online (Vosoughi, Roy, and Aral 2018) represent a pressing challenge for marketers, policymakers, and global citizens.

The current research explores the impact of online socializing spaces on consumers' propensity to share untrustworthy information. As in other social contexts, individuals' online information sharing behavior is largely motivated by a desire to feel a sense of belonging (Nadkarni and Hoffman 2012; Oh and Syn 2015; Syn and Oh 2015). Consumers who are motivated to belong (Baumeister and Leary 1995) tend to prioritize elements of information that connect them to social others (e.g., Higgins 1992). When accuracy is central to group norms, we predict that belonging motivated individuals will pay attention to accuracy cues (e.g., source trustworthiness, McGinnes and Ward 1980). When accuracy is not central to group norms, we

predict that belonging motivated individuals will rely less on accuracy cues, and more on other relationship-promoting elements (e.g., entertainment value of information, Aditya and Darke 2020). As a result, belonging-motivated consumers will be more likely to share untrustworthy information when the recipient members do not (vs. do) have accuracy norms.

We test our predictions in four studies. In each of the studies, we expose participants to social groups that have accuracy norms (trivia night social group) vs. entertainment norms (happy hour social group). We then measure their likelihood of sharing a set of articles paired with either untrustworthy sources (e.g., the National Enquirer) or trustworthy sources (e.g., the Economist) with members of the social group.

In study 1, participants (n = 97; M_{age} = 34.09 years, SD = 13.08; 59.8% female; Prolific) imagined being a member of a trivia night social group with accuracy norms. As predicted, the results revealed a significant main effect of source trustworthiness on article sharing ($F_{(1, 95)}$ = 8.77, p = .004): participants were less likely to share articles associated with untrustworthy sources ($M_{Untrustworthy Sources}$ = 4.07, SD = 1.50) as compared to articles associated with trustworthy sources ($M_{Trustworthy Sources}$ = 4.91, SD = 1.30) among members of a group with accuracy norms.

In study 2, participants (n = 602; M_{age} = 33.88 years; 53.7% female; Prolific) imagined being a member of a trivia night (accuracy norm) or a happy hour (entertainment norm) social group. Results revealed a significant interaction ($F_{(1, 598)}$ = 14.20, p = .000): while participants were less likely to share articles from untrustworthy sources ($M_{Untrustworthy Sources}$ = 3.71, SD = 1.35) vs. trustworthy sources ($M_{Trustworthy Sources}$ = 4.40, SD = 1.46) among members of a group with accuracy norms $F_{(1, 598)}$ = 18.42, p = .000), participants were insensitive to source trustworthiness when sharing information among members of a group with entertainment norms ($M_{Untrustworthy Sources}$ = 4.70, SD = 1.36; $M_{Trustworthy Sources}$ = 4.54, SD = 1.43; $F_{(1, 598)}$ = 1.04, p = .31). As predicted, participants were more likely to share untrustworthy information among members of a group with entertainment vs. accuracy norms ($F_{(1, 598)}$ = 38.03, p = .000)

In study 3, we tested the mediating role of attention. We predicted that participants sharing among groups with accuracy (vs. entertainment) norms would pay closer attention to accuracy cues (i.e., source trustworthiness). After completing the same tasks as in study 2, undergraduates (n = 255; M_{age} = 20.99 years; 55.3% female) completed a memory recognition task for article sources. Memory is an indicator of where attention was directed during a task (e.g., Mandler 1980). Participants sharing among groups with entertainment norms produced lower article source recognition scores (correctly recognized sources – incorrectly recognized sources) as compared to participants sharing among groups with accuracy norms ($M_{Entertainment Norm}$ = .55, SD = 1.16; $M_{Accuracy Norm}$ = 1.36, SD = 1.85; $F_{(1, 253)}$ = 17.78, p = .000). This difference in article recognition explained why participants were less likely to share untrustworthy information among groups with accuracy vs. entertainment norms (IMM = .21 (.10), 95% CI [.03, .43]; Hayes PROCESS Model 14).

Studies 1-3 operationalize belonging by provoking the need for affiliation with groups. Study 4 manipulates another core component of belonging that is distinct from the need for affiliation: the need to feel a sense of connectedness (Lee and Robbins 1995). Individuals who feel disconnected experience difficulty following social cues (e.g., DiTommaso et al. 2003) and are perceived as less interpersonally competent (e.g., Spitzberg & Canary 1985). Thus, we predict that feelings of disconnect will suppress the impact of accuracy norms on untrustworthy information sharing.

In study 4, participants ($n = 689$; $M_{age} = 29.67$ years; 51.7% female; Prolific) imagined being a member of trivia night (accuracy norm) or happy hour (entertainment norm) social group. In a third condition, participants who imagine being a member of a trivia night group were additionally asked to write about their feelings of social disconnect experienced during COVID-19 quarantine. Results revealed a significant interaction ($F(2, 683) = 3.12$, $p = .04$). The patterns for accuracy vs. entertainment norm conditions replicate the findings in the previous studies (figure 1). Most importantly, participants who experienced social disconnect were more likely to share untrustworthy information as compared to participants who were exposed to the same trivia night group but did not experience social disconnect ($M_{Accuracy Norm} = 3.73$, $SD = 1.41$; $M_{Accuracy Norm + Social Disconnect} = 4.21$, $SD = 1.40$; $F(1, 683) = 8.86$, $p = .003$). This finding provides strong support for our theory that the motivation to belong is a key driver of untrustworthy information sharing.

By revealing how belonging needs use shape consumer information sharing decisions, this research advances our understanding of the impact of socializing spaces on the spread of misinformation.

Paper #4: Ethicality-As-Source-Of-Specialness: How and When Ethical Ventures Succeed in Crowdfunding

Carina Thürridl, University of Amsterdam, Netherlands
Bernadette Kamleitner, WU Vienna, Austria

SESSION OVERVIEW

Recent events have raised consumers' awareness of climate change and ethical consumption (Latham 2021). To fulfill their expectations, there has been a notable increase in green and ethical products in the marketplace, giving rise to various marketing campaigns such as crowdfunding and diverse advertising appeals, as well as some consequences such as price increases. While previous research has mostly examined how to promote ethical and sustainable (vs. non-ethical) consumption (e.g., Luchs et al. 2010; White, Habib, and Hardisty 2019), little is known about how consumers respond to different marketing practices and products related to ethical topics. The proposed session brings together four papers offering deeper insights on sustainable and ethical consumption, examining how features of sustainable products affect consumers' decision-making and explore how to facilitate ethical practices more effectively.

The first two papers examine how consumers construe companies' green practices and products based on their features. **Longoni, Tari, and Trudel** (N=1,860) investigate how consumers assess price fairness from companies' green practices, with implications for supporting the company. When the product's price increase is due to the company's willful investment in green manufacturing, consumers perceive it as fairer than price increases due to non-green manufacturing costs. This is because consumers infer that the company has a greater communal orientation. **Hur and Shu** (N=1,515) examine systematic differences in consumers' preference for different types of green products based on the sequence of environmental harm and benefit the product generates. They found that consumers prefer products generating environmental benefits following harm (e.g. conventionally-manufactured electric car) more than products generating benefits followed by harm (e.g. sustainably-manufactured gasoline car). They perceive green products that generate harm first, benefit later (vs. benefit first, harm later) as having greater positive impact on the environment, independent of the actual net effect, especially when they have greater sustainability motivation.

The remaining two papers investigate novel and more effective strategies to promote consumers' ethical practices. **Landekhovska-**

ya, Donnelly, and Reczek** (N=1,306) demonstrate that challenge appeals (e.g., "We Challenge you to Taste the Difference"), compared to informational or ethicality appeals, encourage consumers to try virtuous replacement products such as plant-based meat or lab-made diamonds. They found that the challenge appeals decrease the perceived risk associated with trying the product, which is more successful for more competitive consumers. Lastly, **Thürridl and Kamleitner** (N=816) identified perceived specialness as a key driver, above and beyond creating prosocial impact, in increasing funding behavior for ethical ventures when the ventures seek crowdfunding in exchange for venture-related rewards such as environmentally friendly products. They further found that people's funding behavior is attenuated when they cannot receive products in return for their crowdfunding or when the product is already special.

Together, this session takes a step forward to better understand ethical consumption, with important consequences in supporting ethical companies and sustainable products as well as making the right decisions in evaluating such products. This session should have broad appeals to scholars, marketers, and policymakers who are interested in how different features of ethical products and marketing campaigns shape consumers' decision-making.

Communal Attributions Drive Perceptions of Price Fairness When Recouping Green Manufacturing Costs

EXTENDED ABSTRACT

In recent years, several companies have made strides toward "greening" their manufacturing practices to minimize the negative environmental impact. However, green cost-based reasons for a price increase may lead to perceptions of unfairness. Consumers may view sustainable manufacturing as avoidable (Kahneman et al. 1986), not directly linked to product costs (Bolton et al. 2003; Bolton and Alba 2006), and discount long-term environmental gains compared to short-term losses (Hardisty and Weber 2009). By contrast, we show that consumers view willful adoption of sustainable manufacturing practices as an insight into a firm's communal orientation. Because pro-environmental behaviors signal concern for the welfare of other people and the planet (Stern et al. 1993), consumers attribute a firm that willfully engages in pro-environmental practices with a communal orientation—the perception that the firm acts based on concern for the welfare of others (Clarks and Mills 1993) and is willing to consider other people in the allocation of resources (De Bruin and Van Lange 2000; Fiske et al. 2007).

Across five studies, we show that consumers view price increases due to green manufacturing costs as fairer than price increases due to non-green manufacturing costs of equivalent magnitude (Studies 1A-1B). Green costs boost price fairness perceptions because willful investment in green manufacturing signals that a company is concerned with the welfare of others, a marker of a communal orientation (Study 2). However, the boost in fairness perceptions is eliminated when communal attributions are undermined: if a firm reveals self-interest (Study 3), or is exogenously forced to adopt greener practices (Study 4). Higher price fairness perceptions in case of green costs ultimately affect positive behavior toward the firm (Study 5).

Studies 1A (N=370) and 1B (N=296) showed preliminary evidence of the main phenomenon two different domains and price points. Participants read information about a price increase for a par-

ticular product, and then, in a 3-cell between-subject design, read no information about the source of the price increase (*baseline*); or read information about a non-green source (*non-green costs*); or read information about a green source (*green costs*). Participants rated the fairness of the price increase. In both studies, participants judged a price increase to be fairer when given a reason about the source of a price increase than when given no such cue (*p*s<.001). Most pertinent to our theorizing, participants judged a price increase to be fairer in case of green than non-green costs (*p*s<.001). This effect was robust across domains (i.e., jeans, carpet tiles), and type of cost (energy, raw materials).

Study 2 (N=291) provided further evidence of the effect of green costs on fairness perceptions, and used an analysis of mediation to examine the role of communal attributions. Participants judged the fairness of a price increase due to green or not-green costs and then rated the firm's communal orientation. Perceptions of price fairness replicated prior results (*p*s<.001). Additionally, participants inferred greater communal orientation when a price increase was due to green than non-green costs (*p*s<.001). Higher communal attributions in turn resulted in higher perceptions of price fairness both in the case of direct (0.80, 95% CI = [.51, 1.10]) and indirect costs (1.22, 95% CI =[.89, 1.58]).

Study 3 (N=443) provided further evidence for the role of communal attributions in driving perceptions of price fairness. If communal attributions drive perceptions of price fairness, such effect should be eliminated when consumers believe that a firm's actions are motivated by self-interest rather than goodwill. One such circumstance is when the price increase is higher than the associated cost increase, which violates a firm's entitlement to profit. In this study, a price increase was attributed to non-green costs or to green costs, and ulterior motives were salient or not salient by varying the salience of the firm's profit to cost ratio. When ulterior motives were not salient, participants judged a price increase as fairer when due to green (*M*=4.11) than non-green costs (*M*=3.32, *p*<.001). By contrast, when the firm's ulterior motives were salient, fairness perceptions were the same irrespective of the type of costs (*p*=.99).

Study 4 (N=340) used a different angle to examine the role of communal attributions as mechanism underlying judgments of price fairness We reasoned that perceptions of fairness should decrease when a company's communal orientation is tainted, such as when a company's decision to adopt eco-friendly practices is attributed to external circumstances that the firm had to comply with rather than to the firm's goodwill. Participants were assigned to one condition in a 2 (cost: non-green vs. green) x 2 (attribution: cost attributable to the management team vs. mandated by the local government). Participants judged a price increase to be fairer if determined by increased green (*M*=4.67) than non-green costs (*M*=3.61, *p*<.001). However, this effect only manifested when the eco-friendly practice was attributed internally to the company rather than to external circumstances (*p*=.85; 2-way *F*=12.14, *p*=.001).

To test the generalizability of the results, in study 5 (N=120) we employed a sample from the general population (i.e., passerbys) and measured the proportion of people that would support a new business (i.e., petitioned for the opening of a new restaurant) as a function of whether a price increase was due to an eco-friendly cost-based reason or to a neutral reason. Whereas 79.7% of passersby signed the petition when the price increase was due to green costs, only 60.7% did so in case of non-green costs (χ²=5.2, *p* = .023).

Overall, this research contributes to the literature on dual entitlement and price fairness perceptions (Bolton and Alba 2006; Bolton et al. 2003; Campbell 1999; Kahneman et al. 1986) by showing that green costs are perceived to be fundamentally distinct from costs of equal magnitude but different nature (i.e., non-green), because consumers make moral inferences based on a firm's adoption of greener practices. Our research also has reaching implications for policy makers and contributes to the literature on sustainability (Haws et al. 2014; Luchs et al. 2010) by providing a framework to understand when and why consumers reward companies adopting eco-friendly practices.

Not All Green is Equal: The Sequence of Environmental Harm and Benefit Affects Preferences of Green Products.

EXTENDED ABSTRACT

With rising concerns about climate change, more companies introduce environment-friendly products by making changes to conventionally made products. For example, Ford and BMW have changed manufacturing processes by using recycled plastics for vehicle interiors, while Tesla makes vehicles that operate in an environment-friendly way. However, there is criticism that companies overstate products' environmental benefits, disregarding the hidden cost that are unavoidable at present, and a gap may arise between consumers' perceptions and products' actual impact to the environment. It is thus important to understand how consumers evaluate green products and provide accurate guidelines for their decision-making.

The current research demonstrates that consumers have systematic differences in evaluating green products based on the sequence of environmental harm and benefit generated by products. We show that consumers prefer products that generate environmental benefit following (vs. followed by) harm. This is consistent with Prelec and Loewenstein (1998), where consumers prefer products that generate cost (i.e., environmental harm) up front in order to purely enjoy the product's positive utility (i.e., environmental benefit) afterwards. We predict that this effect arises because consumers perceive products generating environmental benefit following (vs. followed by) harm yield a more positive impact (Chernev 2010; Spreitzer 1995). Further, we propose that this effect is moderated by individuals' sustainability motivation. Consumers with stronger motivation for sustainability would seek products with a greater impact to the environment, and they would prefer products that generate environmental benefit following (vs. followed by) harm even more (Touré-Tillery and Fishbach 2017; Tsiro and Irmak 2020).

Four studies test our theory. Study 1 (N=401) examined the effect of sequence between environmental harm and benefit on perceived environmental impact in a 2(sequence: harm-first-benefit-later vs. benefit-first-harm-later) x 2(information: single-sided vs. double-sided) between-subjects design. Participants in the benefit-first-harm-later condition read descriptions of a gasoline car made with recycled materials that emits gas when driven, and an apartment built with renewable energy but operated with conventional energy in a counterbalanced order. Participants in the harm-first-benefit-later condition read descriptions of an electric car made in a conventional way, but producing no emissions while driven, and an apartment built with conventional energy sources and materials and operated with renewable energy. We also manipulated information by showing either descriptions about benefit only (single-sided) or both harm and benefit (double-sided). We found that people perceived products have greater positive environmental impact when the benefits are generated later (*M*=1.45) than earlier (*M*=.31; *F*(1,397)=91.17, *p*<.001, η_p^2=.19), and this effect attenuated when people read product descriptions about benefits only (*F*(1,397)=13.42, *p*<.001, η_p^2=.03; Figure 1).

In Study 2 (N=302), we used only the double-sided descriptions and examined consequential outcomes of purchase intention.

We also tested whether individual sustainability motivation moderates our effect. We manipulated the sequence of environmental harm and benefit of a car and an apartment as in Study 1. As predicted, participants in the environmental harm-first-benefit-later (vs. benefit-first-harm-later) condition were more interested in purchasing the car and renting the apartment ($M_{harm-benefit}$=4.95 vs. $M_{benefit-harm}$=3.84; $F(1, 300)$=43.98, p<.001, η_p^2=.13), and also felt the products have more positive environmental impacts ($M_{harm-benefit}$=1.38 vs. $M_{benefit-harm}$=-.70; $F(1, 300)$=258.95, p<.001, η_p^2=.46). We measured their individual sustainability motivation, and found a significant interaction between the sequence and their sustainability motivation (β=.47, p<.001). Those with higher motivation (+1SD) were more interested in purchasing products that generate environmental harm first, benefit later (β=1.73, p<.001) than those with lower motivation (-1SD) (β=.38, p=.046; Figure 2). We also found a significant moderated mediation where the perceived environmental impact mediates the effect of sequence on purchase intention, and it is moderated by sustainability motivation ($\beta_{indirect}$=.23, 95% CI=[.13,.33]; PROCESS model 8; Hayes and Preacher 2014).

Study 3 (N=408) demonstrates that our effect holds regardless of when the environmental benefit and harm are generated using a 2(sequence: harm-first-benefit-later vs. benefit-first-harm-later) x 2(manufacturing timing: past vs. future) between-subjects design. Participants in the past condition read the same product descriptions as in Study 2. Participants in the future condition read the products will be manufactured in the future such that both the environmental harm and benefit have not yet been generated. We found that participants in the harm-first-benefit-later (vs. benefit-first-harm-later) condition preferred products more ($M_{harm-benefit}$=1.15 vs. $M_{benefit-harm}$=-.19; $F(1,404)$=128.06, p<.001, η_p^2=.24), and it was not influenced by the manufacturing timing ($F(1,404)$=.32, p=.570), qualified by no interaction ($F(1,404)$=3.04, p=.082). We also found a significant interaction between sequence and sustainability motivation (β=.18, p=.015). Those who had higher motivation (+1SD) perceived the products to have more positive environmental impact than those with lower motivation (-1SD) in the harm-first-benefit-later condition (β=.21, p<.001).

Lastly, Study 4 (N=404) provides additional process evidence using a validated measure of perceived personal impact to the environment. We also demonstrate that our effect is not influenced by perceived causality in generating environmental harm and benefit using a 2(sequence: harm-first-benefit-later vs. benefit-first-harm-later) x 2(causality: low vs. high) between-subjects design. Participants in the low causality condition read a car description as in Studies 2-3; those in the high causality condition read the car is made-to-order and generates environmental harm and benefit only upon personally placing an order. We found that participants in the harm-first-benefit-later (vs. benefit-first-harm-later) condition were more interested in purchasing the car ($M_{harm-benefit}$=4.47 vs. $M_{benefit-harm}$=3.91; $F(1,400)$=12.05, p<.001, η_p^2=.03). Causality did not influence the purchase intention ($F(1,400)$=2.65, p=.104), supported by non-significant interaction ($F(1,400)$=.25, p=.617). Participants in the harm-first-benefit-later (vs. benefit-first-harm-later) condition perceived they have greater environmental impact ($M_{harm-benefit}$=4.13 vs. $M_{benefit-harm}$=3.00; $F(1,400)$=50.46, p<.001, η_p^2=.11), which mediated the effect on purchase intention ($\beta_{indirect}$=.64, 95% CI=[.45,.83]; PROCESS model 4; Hayes and Preacher 2014).

Overall, we find that products that generate environmental benefit following (vs. followed by) harm are perceived to have more positive impacts for the environment and are more preferred. This research contributes to literature on sustainable consumption (White, Habib, and Hardisty 2019) by building forwards from literature on mental accounting (Prelec and Loewenstein 1998), contrast effects (Chernev 2010), and perceived impact (Spreitzer 1995). It offers insights to policymakers and marketers, as not all sustainable products are equally preferred independent of the actual environmental impact, especially among those who care more about sustainability.

Do Challenge Based Advertising Appeals Motivate Consumers to Try Virtuous "Replacement" Products?

EXTENDED ABSTRACT

Consumers increasingly have access to a variety of virtuous "replacement" product options for existing products, such as plant-based meat and dairy (Jiang 2019; Plant Based Foods Association 2020) and lab-made diamonds. We define a virtuous replacement product as a product that is intended to be similar in quality to an existing product, but produced in a more ethical manner (e.g., more sustainability in the case of plant-based meat and without human rights violations in the case of lab-made diamonds; Pimentel and Pimental 2003; Gem Society 2021).

Previous research has demonstrated that it is difficult to encourage consumers to switch to virtuous replacement products, even when informational campaigns highlight the positive impact these choices have on the moral or ethical issue in question (Tobler, Visschers and Siegrist 2011). However, as advances in technology and production of virtuous replacement products have improved, marketers appear to be focusing on the similarity between these more virtuous products and those they are intended to replace. For example, the restaurant Freshii advertises their plant-based chili with the message "We challenge you to taste the difference" (Freshii 2020).

Despite the use of such challenge appeals, no academic research to our knowledge has investigated the efficacy of challenge-based appeals for encouraging trial of virtuous replacement products. We propose that challenging the consumer to discern the difference between the original product and its virtuous replacement will decrease the risk associated with trying the product, promoting trial. Consistent with research documenting consumer reluctance to consider affectively unpleasant ethical issues like environmental harm and human rights violations (Ehrich and Irwin 2005; Reczek et al. 2018; Zane, Irwin, and Reczek 2015), we further predict that challenge appeals can actually be more effective than appeals focused on ethicality. As such, this research contributes to the growing literature documenting effective strategies for increasing consumer interest in virtuous products (e.g., Reczek, White, and Trudel 2018; White, Habib, and Hardisty 2019).

In Study 1 (n = 381; M_{age} = 40.06, SD = 11.82, 49.3% female, all of whom had previously reported never eating plant-based meat) imagined eating in a restaurant and viewing an advertisement for a meatless burger. In the control condition, the burger was advertised as plant-based meat that "tastes just like beef." In the challenge condition, the advertisement further read, "We Challenge you to Taste the Difference." Participants reported their relative preference on a scale ranging from 1 (Definitely Beef Burger) to 7 (Definitely Plant-Based Burger). The challenge appeal significantly increased preference for the plant-based burger ($M_{challenge}$ = 3.38, SD = 1.99, $M_{control}$ = 2.92, SD = 1.93, $t(380)$ = 2.31, p = .02), consistent with our predictions.

In Study 2 (n = 400; M_{age} = 37.04, SD = 10.50, 53.5% female, all of whom had previously reported that they would be purchasing diamond jewelry for Valentine's Day) imagined entering a jeweler and viewing an advertisement for lab created diamonds. In the control condition, the diamonds were advertised as having the same physical and optical properties as traditionally mined diamonds but with no

mining required. In the challenge condition, the advertisement further read, "We Challenge You! Bet You Can't Tell the Difference!" As in study 1, the challenge appeal increased trial, operationalized as interest in asking the jeweler to show them a lab-created diamond jewelry piece from the display case ($M_{challenge}$ = 5.42, SD = 1.63, $M_{control}$ = 5.03, SD = 1.82, $t(398)$ = 2.31, p = .02). We also assessed perceptions of risk associated with lab created diamonds. The challenge condition significantly reduced perceived risk ($M_{challenge}$ = 3.58, SD = 1.52, $M_{control}$ = 3.90, SD = 1.69, $t(398)$ = 1.96, p = .05), which mediated the positive effect of the challenge appeal on interest (95% CI = [.00, .25]).

Study 3 crossed an ethical appeal with a challenge appeal in a 2 x 2 design. Participants (n = 496; M_{age} = 38.54, SD = 16.89; 52.1% female, all of whom had previously indicated they would be purchasing diamond jewelry in the next year) saw the same advertisements as study 2 in the no ethical appeal conditions or an advertisement that stated "Make the Ethical Choice" or "We Challenge you to Make the Ethical Choice" in the ethical appeals conditions. As before, the challenge appeal increased consumer intention to view the lab created diamonds ($M_{challenge}$ = 5.43, SD = 1.70, $M_{control}$ = 4.98, SD = 1.83, $F(1, 495)$ = 8.17, p = .004). There was no main effect for ethical appeal, $F(1, 495)$ =.13, p = .72, but there was a significant interaction, $F(1, 495)$ = 4.43, p = .036, such that a challenge appeal increased trial when no ethical appeal was present, $t(245)$ = 3.69, p < .001, but did not increase trial when an ethical appeal was present, $t(247)$ = .51, p = .61 (see Figure 3).

In sum, this research suggests that a challenge appeal can be effective to increase consumer motivation to try virtuous replacement products, even more so than an ethical appeal. Future studies are planned to explore the impact of challenge-based appeals beyond initial trial.

Ethicality-As-Source-Of-Specialness: How and When Ethical Ventures Succeed in Crowdfunding

EXTENDED ABSTRACT

Crowdfunding offers individuals the opportunity to make small financial contributions to entrepreneurial ventures in exchange for venture-related rewards (Kuppuswamy and Bayus 2018). These often equate to the product of the venture (Thürridl and Kamleitner 2016). Ventures that seek support for products with ethical benefits, i.e., products that positively contribute to social and/or environmental issues, are particularly successful (Simpson et al. 2019). Since crowdfunding decisions are at least partly driven by an opportunity to make an impact (Kuppuswamy and Bayus 2017), the relative advantage of ethical ventures has been suggested to derive from the ideological congruence between their own prosocial goals and the prosocial essence inherent in the reward-based crowdfunding model (André et al. 2017; Simpson et al. 2020).

We argue that beyond creating impact, crowdfunding ethical ventures offers individuals an opportunity for differentiation (Tian, Bearden, and Hunter 2001). Specifically, we propose that funding ethical ventures imbues individuals with specialness, which stimulates funding behavior. In fact, despite possessing a prosocial core, most crowdfunding platforms are primarily positioned around specialness. Indiegogo, for example, describes itself as a platform where "early adopters and innovation seekers find lively, imaginative tech before it hits the mainstream". What thus seems to attract individuals to crowdfunding is the opportunity to obtain special products (Taeuscher, Bouncken, and Pesch 2020; Zvilichovsky, Danziger, and Steinhart 2018). Ethicality can act as a differentiating feature (Defazio, Franzoni, and Rossi-Lamastra 2020). We thus expect that ethi-

cal ventures will be backed because they can satiate funders' need for specialness. This goes beyond current literature suggesting the presence of merely pro-social motivations. Consistent with our ethicality-as-source-of-specialness account, we also propose two practically relevant boundary conditions. We expect our effect to be attenuated when people do not get the specialness-affording ethical product but an alternative reward and when the product is special already.

Study 1 provides initial evidence for our ethicality-as-source-of-specialness account. 100 US mTurkers (39% female, M_{age} = 33 years) evaluated a crowdfunding campaign for a washing bag. In the control condition, participants saw a picture of the bag and read about its functional benefits ("prevents fabric from fading"). In the ethical condition, they saw the same bag but read about its environmental friendliness ("prevents emission of microfibers to keep our waters clean"). We assessed felt specialness (three items from Kamleitner, Thürridl, and Martin 2019, 7-point, α = .91), perceived prosocial impact ("This project would make a positive difference in the world", 7-point), and intended contribution size as a dependent variable (0 = smallest possible, 100 = largest possible). We find main effects on specialness (p < .001), impact (p < .001) and contribution size (p < .01). Mediation analysis shows that specialness [4.73, 22.89] but not impact [-2.01, 12.27] underlies the effect.

Study 2 extends this finding to products with different ethical benefits. 277 European undergraduates (47% female, M_{age} = 21 years) evaluated a campaign for a hammock, which provided a functional benefit ("maximum strength", control group) plus either an environmental ("made from recycled plastic", environmental group) or a social benefit ("made by local artisans in Thailand", social group). We measured felt specialness (α = .84) and prosocial impact as before and assessed funding intentions ("Would you support this project?", 7-point) and monetary contributions (slider scale: €0 - €100). Both the environmental and prosocial venture led to an increase in specialness (environmental: p < .05, social: p < .01), impact (environmental: p < .05, social: p < .001), funding intentions (environmental: p < .001, social: p < .01) and monetary contributions (environmental: p < .01, social: p < .05). Since the environmental and social condition differed on neither variable (all p's > .25), we combined them for mediation. Specialness mediated the effect of venture ethicality on funding intentions [.04, .38] and monetary contributions [.36, 3.95]. Impact also mediated the effect on funding intentions [.08, .41] but not on monetary contributions [-1.35, 1.73]. Regressing funding intentions on both predictors shows a stronger effect of specialness (β = .34, p < 001) than impact (β = .28, p < 001).

In Study 3, we tested the prediction that ethicality loses its advantage when consumers can only back the project but not obtain the special product as a reward. 121 participants (66% female, M_{age} = 27 years) participated in a 2 (venture: ethical vs. non-ethical) x 2 (reward: product vs. goodie bag) between-subjects experiment. Participants saw a travel shoe that was either made of recycled ocean plastic or not and were subsequently informed that they would either receive the shoe or a goodie bag in exchange for a €80 contribution. We then assessed their funding intentions (7-point). When the focal product was offered, the ethical venture was more likely to receive funding (p < .01). When the goodie bag was offered, however, the effect of venture ethicality was attenuated (p = .61, Table 1).

In Study 4, we tested mediation via moderation. 318 nationally representative panelists (51% female, M_{age} = 42 years) participated in a 2 (venture: ethical vs. non-ethical) x 2 (product: special vs. ordinary) between-subjects experiment. We asked them to evaluate a crowdfunding campaign for sunglasses that either provided an ethical ("sponsoring an eye operation per contribution") or functional benefit ("providing clearer views"). In addition, these sunglasses

were either described as special ("innovative sunglasses, patented ultra-flex frame") or ordinary ("classic sunglasses, flexible plastic frame"). We assessed how much participants were willing to contribute (open-ended). The ethical venture yielded a higher funding amount than the non-ethical venture for the ordinary product, ($p <$ .05) but not for the distinctive product ($p = .70$, Table 1).

Our research provides a novel explanation for why many ethical ventures succeed in crowdfunding: specialness. We thereby add to the growing body of research that implicates self-interested rather than prosocial motives behind ethical consumption (Trudel et al. 2019). Insights also contribute to the particular debate about whether crowdfunding is motivated more by altruism or self-interest (André et al. 2017). Finally, we provide clear practical implications for ethical entrepreneurs seeking to realize their ventures through crowdfunding.

Derek D. Rucker, Kellogg School of Management, Northwestern University, USA

SESSION OVERVIEW

Worsening income inequality, protests against racism, and the COVID-19 pandemic have increased attention to the topic of social hierarchy across societies. Researchers have further emphasized the influence that social hierarchies and social rank have on consumption (Dubois and Ordabayeva 2015; Rucker 2020). Adding to this burgeoning body of work, this special session provides new insights and novel findings from three papers on the topic of social hierarchy and consumption. Importantly, this session answers the call of the conference theme, *What the World Needs Now*, by providing insights into an important matter at the forefront of the world today: social hierarchy.

In the first paper, Pyrah and Galoni investigate how individuals on the low ranks of social hierarchy positions express vigilance in their decision-making. They find that low-ranking consumers exhibit a *charisma bias*, in which they overweight social cues relative to other cues in the marketplace. This leads them to be more vigilant at protecting themselves when confronted with social threats, while also increasing their susceptibility to marketers' influences in the face of more positive social cues.

Keeping the focus on low-ranking individuals, Cannon, Goldsmith, and Roux introduce a conceptual work. They propose a new framework for how scarcity and powerlessness – two types of disadvantage that individuals of lower social rank experience – lead to both similar (through one's relative state of disadvantage), and divergent (through one's relative dependence on oneself versus others), consumer behaviors.

While the first two papers examine how an individual's own place in a social hierarchy influences consumption behavior, the third paper rounds out the session by demonstrating how different bases of social hierarchy, dominance versus prestige, impact preferences for positional goods. Specifically, authors Desmichel and Rucker find that dominance (versus prestige) bases of hierarchy increase consumer preferences for higher-positional goods because consumers feel more highly scrutinized in dominance- (vs. prestige-) based hierarchies.

This set of papers opens up new avenues of research in the area of social hierarchy and its consequences for consumers. These papers offer insights into distinct aspects of social hierarchy, including consequences of an individual's own low social rank, the distinction between two types of disadvantage, and divergent effects across different types of hierarchy. As a result, this session is likely to have a broad appeal to the ACR audience, and attract researchers not only curious about social hierarchy broadly, but also interested in specific topics, such as power, trust, consumer disadvantage, and status-signaling. Importantly, we feel that this session is central to the conference theme of *What the World Needs Now*, with social hierarchy at the forefront of many issues across the world. All of the papers are at an advanced stage of completion. Overall, the two empirical papers comprise 10 studies, employing online and lab experiments, with the conceptual paper enhancing the theoretical rigor of the session. We anticipate that this session will provide much-needed insights on the changing world and spark important research questions to be investigated.

The Charisma Bias: How Vigilance Can Help and Hurt Disadvantaged Consumers

EXTENDED ABSTRACT

Disadvantaged and vulnerable populations are among those most targeted and susceptible to manipulative marketing practices. Elderly consumers are asymmetrically victimized and deceived (Benet, Pitts, and LaTour 1993), children are often taken advantage of (Blatt, Spencer, and Ward 1972), and impoverished consumers are disadvantaged in the marketplace, where they are often subject to higher fees, prices, and credit terms (Hill 2002, 2008). Despite evidence that these consumers are often taken advantage of, other work suggests that lower-power consumers should be the most vigilant toward protecting themselves from harmful outcomes. For instance, individuals of lower socioeconomic status and social rank are more vigilant toward threats in the marketplace (Chen, Lee-Chai, and Bargh 2001; Kraus et al. 2011; Kraus et al. 2012). Thus, there seems to be a paradox; on one end, these disadvantaged consumer groups seem to be *more* susceptible to manipulative marketing practices. However, other work also suggests that they should be more vigilant against threats, indicating that they should be *less* susceptible to these practices than their high-powered counterparts.

To resolve this paradox, we propose that low-power consumers exhibit what we call a *charisma bias*. Building on the notion that low-power consumers are communally oriented (Rucker, Galinsky, and Dubois 2012), we propose that low-power consumers overweight social cues when forming opinions about sellers and making purchasing decisions. This overweighting causes them to be less trusting of agents that signal potentially threatening social cues, but also more trusting of agents that signal more positive social cues. Thus, this charisma bias explains why low-power individuals can be both more vigilant toward threats, and also more susceptible to marketers' influences.

We test our Hypothesis across 4 studies. The purpose of studies 1 and 2 was to show that low-power consumers can more successfully identify, and therefore protect themselves from, social cues that signal untrustworthiness. We measured participants' own sense of power in study 1 (Anderson, John, and Keltner 2012) and manipulated power in study 2 (using a recall writing task; Galin-

sky, Gruenfeld, and Magee 2003). To manipulate a potential threat to trustworthiness, we used salesperson compensation method because commissioned (versus salaried) salespeople can be perceived as having ulterior motives, reducing perceptions of trustworthiness (DeCarlo 2005).

In both studies, participants (Ns = 451, 451) were randomly assigned to read a scenario about an interaction with a financial advisor who was either salaried or commissioned. They reported their willingness to invest with the advisor and how much they trusted the advisor's opinion. In both studies, we found the predicted power x seller type interaction on investment willingness (S1 p = .034; S2 p = .057). In both studies, this interaction was such that low-power participants were less likely to invest when the advisor was commissioned (vs. salaried; ps < .001), but there were no significant differences for high-power participants (ps > .11). Finally, a significant index of moderated mediation (95% CI [-.36, -.02]) confirmed that perceptions of trustworthiness mediated this relationship, indicating that low-power (but not high-power) participants successfully identified the untrustworthiness cue, attributing less trustworthiness and lower investment intentions to the commissioned advisor.

The purpose of study 3 was to show that low-power consumers also overweight *positive* social characteristics, potentially leading them to be more susceptible to marketers' influences. We use physical attractiveness, as it has long been associated with positive attributions (Dion, Berscheid, and Walster 1972). We again measured participants' own sense of power. Participants (N = 278) imagined they were shopping for a car and saw a picture of either an unattractive or attractive salesperson (faces previously validated from the Chicago Face Database) (Ma, Correll, and Wittenbrink 2015). After their interaction with the salesperson, participants reported purchase intentions and perceptions of trustworthiness. A significant power x physical attractiveness interaction emerged for both purchase intentions (β = -.127, SE = .060, p = .036) and trustworthiness (β = -.145, SE = .063, p = .022). Low-power participants were more likely to purchase from (and more trusting of) an attractive salesperson. There were no differences for high-power participants. Again, trust mediated the relationship between salesperson attractiveness and purchase intention for low-power, but not high-power, participants (moderated mediation: 95% CI [-.20, -.01]).

The purpose of study 4 was to introduce a non-social cue (product quality) to show that social cues dominate other cues for low-power consumers' decision making. Participants (N = 307) were randomly assigned to a 2 (power: low vs. high) x 2 (physical attractiveness: low vs. high) between-subjects design. After the power manipulation, participants viewed two car options where one car was objectively superior. Participants then viewed the salesperson, who then recommended the *inferior* option. Participants reported their car preference and their perceptions of trustworthiness. Significant power x physical attractiveness interactions were present for both car preference ($F(1, 303)$ = 4.42, p = .036) and perceptions of trustworthiness ($F(1, 302)$ = 9.51, p = .002). Low-power participants were more likely to prefer the inferior car from the attractive salesperson (M = 4.56) than from an unattractive salesperson (M = 4.03; $F(1, 303)$ = 4.12, p = .043). There was no difference for high-power participants ($M_{attractive}$ = 4.11, $M_{unattractive}$ = 4.36; $F(1, 303)$ = .91, p = .341). The same, predicted pattern emerged for trustworthiness. The index of moderated mediation was significant (95% CI [-.425, -.082]). Interestingly, a manipulation check indicated that all participants viewed the objectively superior car as better than the inferior car ($M_{superior}$ = 5.45, $M_{inferior}$ = 4.85, $t(304)$ = 8.33, p < .001; interaction *ns*.), suggesting that low-power participants knowingly

chose an inferior option when they were shopping from an attractive salesperson.

We show that low-power consumers overweight social cues relative to other cues, leading them to be both more vigilant toward potential threats when negative social cues are present (studies 1 and 2), but also more susceptible to marketers' influences when positive social cues are present (studies 3 and 4). This helps resolve the paradox around the vigilance of low-power consumers and shows how this vigilance can both help and hurt low-power consumers' decision making.

Two Pillars of Disadvantage: When and Why Scarcity is Different from Powerlessness
CExtended Abstract

Two prevalent psychological experiences associated with disadvantage in social hierarchies are relative deprivation—i.e., scarcity—and a sense of powerlessness (Andreasen 1975). Scarcity involves a discrepancy between current resource levels and a higher, more desirable reference point (Cannon, Goldsmith, and Roux 2019). A lack of power—or powerlessness—involves a deficit in valued resources in an asymmetric social relationship (Rucker, Galinsky, and Dubois 2012). In the consumer behavior literature, these two constructs are among the most studied topics within the last decade. A literature search reveals that there are 42 academic articles published on either scarcity or power in leading consumer behavior journals (*Journal of Consumer Research*, *Journal of Marketing Research*, and *Journal of Consumer Psychology*) within the past 10 years.

Despite independent interest in scarcity and power, no research to date has investigated the relationship between these two constructs. Perhaps, both scarcity and a lack of power (or powerlessness) are two names for the same psychological experience. First, as evident by how scarcity and powerlessness are defined, both psychological states involve a deficit in valued resources. Many states of disadvantage such as these are viewed as pragmatically interchangeable in their psychological underpinnings (Rucker, Galinsky, and Magee 2018). Second, scarcity and powerlessness can lead to similar behavioral outcomes. For example, both scarcity and powerlessness are associated with a lack of control (Chou, Parmar, and Galinsky 2016); Fast and Chen 2009; Mittal and Griskevicius 2014; Smith and Hofmann 2016) and an increased desire to engage in compensatory consumption by purchasing expensive, luxury goods (Dubois, Rucker, and Galinsky 2012; Hill et al. 2012; Rucker and Galinsky 2008, 2009; Walasek, Bhatia, and Brown 2018; Walasek and Brown 2015).However, other research suggests that scarcity and powerlessness lead to divergent consumer behaviors. For example, scarcity often leads to agentic behaviors such as competitively maximizing one's own financial standing (Roux, Goldsmith, and Bonezzi 2015) and acting aggressively toward inanimate objects, such as a vending machine (Kristofferson et al. 2017). In contrast, powerlessness often leads to communal behaviors such as spending money on others (Rucker, Dubois, and Galinsky 2011) and acting selflessly toward others (Dubois, Rucker, and Galinsky 2015). Therefore, although scarcity and powerlessness can produce similar outcomes, they are not simply interchangeable psychological experiences.

This conceptual review resolves this tension that scarcity and powerlessness produce both similar and different consumer behaviors. To do so, we propose a 2 × 2 theoretical framework to formally situate scarcity and powerlessness in the same model. One dimension captures their similarities through the focus on one's relative state of disadvantage (vs. advantage). A second dimension captures their differences through one's relative dependence on oneself (vs. others). In support of this, Rucker and colleagues observed that par-

ticipants in a low-power state directly reported a greater dependence on others (i.e., dependence on others to get things done, value others' opinions when making a decision) compared with participants who were induced to a high-power state (Rucker et al. 2011). In contrast, scarcity leads consumers to view others not as instrumental to goal pursuit, but instead as competitive threats in their social environment (Kristofferson et al. 2017; Roux et al. 2015).

As a result of this framework, we are able to specify unique consumption consequences for consumers in a state of scarcity versus powerlessness. Because scarcity involves the dual experience of disadvantage and self-dependence, scarcity leads consumers to adopt *self-adjustive* consumer behaviors. That is, consumers experiencing scarcity compensate for their disadvantage by improving themselves on a personally valuable dimension, such as materialism (Chaplin, Hill, and John 2014; Tully, Hershfield, and Meyvis 2015) or caloric intake (Briers and Laporte 2013; Laran and Salerno 2013). In contrast, because powerlessness involves the dual experience of disadvantage and other-dependence, powerlessness leads consumers to adopt *social-adjustive* consumer behaviors. That is, low-power consumers compensate for their disadvantage by strategically improving themselves in the eyes of others, such as showing off via conspicuous consumption (Rucker and Galinsky 2008) and cheating to help others (Dubois et al. 2015).

As a secondary benefit of this framework, we are also able to incorporate power and status as complementary states of advantage. Power is a type of advantage in which one has control over valued resources in a social relationship (Galinsky, Gruenfeld, and Magee 2003; Rucker et al. 2012). In contrast, status is a type of advantage in which one is respected or admired for one's use of skills and expertise (Henrich and Gil-White 2001; Magee and Galinsky 2008). Because power and status are both types of advantage, they lead to the authentic expression of intrinsically-held values (Cheng, Tracy, and Henrich 2010; Kifer et al. 2013; Kraus et al. 2012). However, the active value systems differ between the two types of advantage. Because power is associated with self-dependence and an agentic motivation (Rucker et al. 2012, 2018), power leads consumers to adopt *self-expressive* consumer behaviors, in which one purchases items that align with personally held values, such as high-quality, performance products (Rucker and Galinsky 2009). In contrast, because status is associated with other-dependence and a communal motivation (Blader and Chen 2012; Blader, Shirako, and Chen 2016), status leads consumers to adopt *social-expressive* consumer behaviors, in which one purchases items that align with socially held values, such as eco-friendly products (Griskevicius, Tybur, and Van den Bergh 2010).

Dominant theories on social hierarchy have proposed that advantage leads to agentic responses, whereas disadvantage leads to communal responses (Kraus et al. 2012; Piff et al. 2010; Rucker et al. 2018). However, our conceptual review reveals that two dimensions, rather than just one, is necessary to fully understand how social hierarchy influences consumer behavior. Moreover, our framework explains when advantage and disadvantage *each* produce agentic and communal responses. Practically, this work suggests that not all disadvantaged consumers are interchangeable. Marketers should consider tailoring advertising messages depending on whether the consumer feels scarcity or powerlessness. For example, low-power individuals should be more persuaded by communal messages (Dubois, Rucker, and Galinsky 2016), whereas individuals experiencing scarcity should be more persuaded by agentic messages (Salerno and Escoe 2020).

Dominance- (vs. Prestige-) Based Hierarchies: How Social Hierarchy Base Influences Consumers' Desire for Higher Positional Goods

EXTENDED ABSTRACT

Prior research has established that individuals navigate social hierarchies using two main strategies, namely dominance or prestige (Maner and Case 2016). In dominance-based hierarchies, people in positions of disadvantage navigate and ascend the hierarchy through intimidation and force. In contrast, in prestige-based hierarchies, people navigate and ascend the hierarchy through the support of their peers and skills (Cheng et al. 2013; Henrich and Gil-White 2001). Dominance-based hierarchies are characterized by their steepness (i.e., high inequality) and political manipulations, creating a climate of insecurity and oppression, whereas prestige-based hierarchies are flatter, fostering social harmony and compliance with the hierarchy (Maner and Case 2016).

Both dominance and prestige have been shown to be adaptative and successful bases of social hierarchy, but how they influence consumers' behavior is completely unexplored. For example, what are the consequences for consumption when a consumers' workplace is based more on dominance versus prestige?

The present work provides the first known discussion and exploration of how dominance versus prestige hierarchies fundamentally shape consumption. We examine the relationship between the nature of one's social hierarchy—dominance versus prestige—and consumers' preference for higher positional goods. That is, goods can be higher-positional when the brands or products are viewed as higher in the category (e.g., Armani) than lower in the category (e.g., Old Navy; Walasek et al. 2018). We propose that individuals within dominance-based hierarchies exhibit a stronger desire for higher positional goods (e.g., luxury or premium goods) than individuals within prestige-based hierarchies.

Although some theories suggest that individuals in prestige hierarchies might be more sensitive to status and respect (Plourde 2008), we suggest people might gravitate more towards higher positional goods in dominance hierarchies because consumers may feel more highly scrutinized in dominance- (vs. prestige-) based hierarchies. As such, consumers display status goods as they would show other physical attributes (e.g., height, strength; Stulp et al. 2012) as a means to defend themselves in contexts where their weaknesses could be used against them (Ma et al. 2019). As such, the effect should also be more prone to occur among low-confidence consumers versus high-confidence consumers; the latter tending to follow their personal intuitions even when faced with social scrutiny.

Overall, the present work sheds new light on the protective value of higher positional goods (and for example luxury goods) and show these items are considered as safer options in contexts of high scrutiny.

Methodology and Results. We tested our Hypothesis across six studies. In Study 1, we surveyed workers from two different subject pools (MTurk, N = 196, and a Downtown lab pool of non-student respondents in a major US city, N = 118) to learn what they wear at work based on whether they view their work environment as prestige- versus dominance-oriented. We found that participants reported wearing more positional goods when working in more dominant companies (*ps* < .05); in contrast, consumers' consumption of positional goods was not influenced by the prestige-orientation of their company (*ps* > .22).

In Study 2 (N = 200 students), participants watched the video of a fellow student who prepared himself for a job interview at Google. This student read real quotes extracted from Glassdoor.com

either describing Google in a manner consistent with a dominance- or prestige-based company. Participants then voted on the attire that he should wear for the (supposedly real) interview. Participants were more likely to recommend higher-positional attire in the dominance (M = 3.65) than in the prestige condition (M = 2.29, p < .001). In a Supplemental Study, we replicated these results by asking participants to choose between a 7-Eleven (i.e., lower-position) or Starbucks (i.e., higher-position) coffee for themselves to bring to a described work office.

In Studies 3 and 4, we tested the underlying effect of social scrutiny, by measuring (Study 3, N = 286) and manipulating (Study 4, N = 335) the mediator. We manipulated the hierarchy types in a company description, and measured participants' desire to wear a Rolex watch in the given company (7-point scale). In Study 3, the watch was deemed more attractive in the dominance (M = 5.00) than in the prestige condition (M = 4.58, p = .02). The effect was mediated by a greater feeling of social scrutiny (e.g., "I would be scrutinized by others"; Indirect effect = .16, se = .07, 95%CI = [.039, .313], direct effect = .27, se = .18, 95%CI = [-.090, .622]). In Study 4, this effect was eliminated when we reduced social scrutiny by informing participants would not be judged for what they wore (p = .38 vs. p < .001 in the baseline condition).

In Study 5 we used an incentive-compatible design (N = 396) and tested the moderating role of consumers' self-confidence. Specifically, we assigned participants to read the guidelines of either a prestige or dominance-based instructor. Participants then selected the venue in which a business event should be organized. Participants had to select between a standard pub (lower-positional good, "0") and a Hilton hotel (higher-positional good, "1"). To incentivize their decision, participants learned that the instructor would evaluate their answers and designate a winner ($30 bonus). Participants' measured self-confidence moderated the effect of hierarchy types on product choice (p = .01). Participants with relatively low self-confidence were more likely to choose the Hilton hotel (vs. pub) in the dominance condition than in the prestige condition; however, this effect was not found for participants relatively high in self-confidence.

Conclusion. This work is the first to explore how dominance-versus prestige-based hierarchies affect consumption. Simply being immersed within a hierarchy does not produce unilateral effects on consumption; rather, the base of the hierarchy impacts the value and demand for positional goods. With this research, we hope to contribute to understanding how different forms of social hierarchy influence consumers' behavior in unique ways.

SESSION OVERVIEW

Consumer researchers and marketing managers alike are increasingly confronted with highly unstructured data. Text, images, audio, and video provide valuable sources of information, but this content is often non-numeric, multi-faceted, and difficult to parse (Balducci & Marinova, 2018). How can we better use these exciting resources to test theory and uncover insight?

While some prior work has begun to explore unstructured data, the applicability of these methods in consumer research is still quite novel. How can we use video content to understand what becomes popular and why? Might profile pictures provide insight into personality and thus the brands people prefer? And how do vocal features impact perceptions of warmth and competence? This session addresses these and other questions as it deepens our understanding of these new sources of data, and how researcher can parse them to better understand consumer behavior.

First, Bravin, Clegg, Hofstetter, Pouly, and Berger employ a 3D convolutional neural network trained on a large data set of TikTok videos to investigate the value of originality in social media content. Analysis of hundreds of thousands of posts, combined with controlled experiments reveals that highly original content can backfire, because it evokes cognitive dissonance.

Second, Rajaram and Manchanda use deep learning to analyze unstructured data across multiple modalities (text, audio and images). They provide a novel *interpretable* methodological approach that allows testing causality and theory in various contexts. They demonstrate their approach through examining how the composition of influencers' video content can influence user reactions.

Third, Hartmann, Schönmüller, Zwebner, Goldenberg, and Netzer apply deep learning to automated face analysis, testing rela-tionships between personality factors extracted from profile pictures and consumer brand preferences. Their findings validate a conceptual link between consumer facial features and brand personality dimensions and imply how image analysis can be used to predict consumer behavior.

Fourth, Na Kyong, Lowe, and Krishna measure the timbre similarity between users' and AI voices. Three studies analyze the influence of vocal similarity on perceived warmth and competence of AI agents, and choice. They demonstrate how automated voice analyses can shed light on the impact of subtle perceptual cues.

Given the dramatic growth of unstructured data, the world needs a better understanding of how to use it to build consumer theory. The papers in this special session provide methodological tools that offer innovative and theory-driven solutions for important issues in consumer research. These tools are widely applicable to problems related to high-scale and unstructured data sources, as is the case in many of today's contexts (e.g., social media, online branding, and online behavior). Furthermore, this session motivates researchers to embrace methodological triangulation to solve current consumer research issues.

Does it Help to Be Creative on TikTok?

EXTENDED ABSTRACT

People often suggest that originality should boost success on social media. Particularly in online contexts, people like to talk about and share novel information (Berger & Iyengar, 2013) as it is considered more surprising, entertaining, and useful resulting in greater proliferation (Berger, 2014; Berger & Milkman, 2012). Since creative and original things appeal to our natural curiosity (Silvia, 2008), it is widely assumed that originality is valuable in social and business contexts (Hofstetter, Dahl, Aryobsei, & Herrmann, 2020).

But is that actually true? Psychological theories suggest that less originality may actually increase liking of stimuli in our environment. For instance, seeing the same stimulus several times positively affects our attitudes toward this stimulus—a phenomenon called "mere exposure effect" (Zajonc, 1960). Conversely, there exists a systematic bias against high novelty, as it harms our expectations and questions our existing cognitive patterns (Eidelman, Crandall, & Pattershall, 2009; Toubia & Netzer, 2017). Indeed, on social media platforms, content that is of surprisingly low originality oftentimes becomes viral: On TikTok, trending videos follow the same dancing and lip sync screenplay (e.g., one million for the song "savage love", Aniftos 2020).

Accordingly, we suggest that high originality is indeed not advantageous for social media content. Based on cognitive dissonance theory, we argue that highly original content can trigger uncertainty and psychological discomfort (i.e., cognitive dissonance) among viewers, which is an unpleasant state (Whitson & Galinsky 2008). Three studies provide support for this expectation.

The first study provides empirical evidence for a negative effect of originality on content liking. We collected and analyzed a large dataset of 290,503 videos from the social media platform TikTok. The dataset contains descriptive video information (e.g., hashtags, music played, etc.) and content-related statistics such as the number of views, likes, shares, and comments. Since no labels indicate video

dissimilarities, we implement a self-supervised contrastive learning model inspired by Qian et al. (2020). The model is a 3D convolutional neural network trained by simultaneously maximizing the similarity between transformed views of the same video and minimizing the similarity between transformed views of different videos. It allows to extract semantic video embeddings that were used for further analysis. To estimate the degree of originality of a video, we employ the local outlier factor (LOF) algorithm (Breunig, Kriegel, Ng, & Sander, 2000), which computes the local density deviation of a given data point with respect to its k neighbors. Less original videos are more likely to end up in a cluster with high density and thus have a lower LOF. We then use this originality measure in four statistical models that vary in terms of the included control variables to explain video liking. In our first model, we find a significant negative effect of originality on the number of likes ($\beta_{\text{Originality}}$=-1.07, p<.001). Hence, a 1% increase in originality leads to about a 1% reduction in likes. We control for user and music fixed effects in models 2 and 3, respectively, and find that the coefficient decreases consistently with this assumption. Model 4 includes four additional controls (number of days the video was online, popularity, and originality × popularity). We find that a video's lifespan increases its likes ($\beta_{\text{Nr of days online}}$=.19, p<.001) and that the later a user adopted a song in the sequence of adopters, the more likes the video receives (interpreted as higher popularity, $\beta_{\text{Popularity (Nth song user)}}$=.33, p<.001). We find a significant interaction between popularity and originality ($\beta_{\text{Popularity (Nth user of song)}}$=.04, p<.001), showing that the harmful influence of originality is dampened for later adopters.

These models suggest that more original videos receive fewer likes. The fact that the effect is reduced for later adopters supports a cognitive dissonance explanation. As a screenplay becomes more popular, greater originality is required to stand out and trigger dissonance.

Studies two and three test causality through manipulating content originality and measuring liking. We keep the focal content the same but manipulate the context. Everyone saw the same target video (a particular dance), and rated how much they liked it, but we varied the similarity of some videos they watched beforehand. In the low originality condition, participants watched three videos of the same dance first, while in the high originality condition they saw three videos from the same users that involved a completely different dance. All videos were originally retrieved from TikTok. Participants indicated their likelihood to "like" (i.e., how likely they would click on the like button) the video on a scale from 1 (very unlikely) to 7 (very likely).

In study 2 (N=192 participants recruited via Prolific), we find support for the negative main effect of content originality. One-way ANOVA shows that participants are less likely to "like" the target video if it is more original and less similar to previously seen content ($M_{\text{Low originality}}$=4.17, SD=2.05, $M_{\text{High originality}}$=3.55, SD= .18, $F_{(1, 194)}$=4.04, p=.046, d=-.29).

In study 3 (N=134, MTurk), we used different videos, and included a scale for cognitive dissonance (Jiang, Hoegg, & Dahl, 2013). We find again a negative main effect of originality on liking ($M_{\text{Low originality}}$=4.36, SD=2.14, $M_{\text{High originality}}$=3.42, SD=2.36, $F_{(1, 132)}$=7.58, p=.017, d=-.42), which is mediated by cognitive dissonance (indirect effect=-.26, SE=.13, $CI_{95\%}$=[-.04,-.55]; analysis based on 10,000 bootstrapped resamples, 95% confidence intervals; Hayes, 2013).

Our findings support our conceptual reasoning that higher originality of content on social media does not generally pay out. These findings are in contrast to prior research promoting the high value of originality of user-generated content (Berger & Milkman, 2012;

Hofstetter et al., 2020) and suggest a potential negative mechanism triggered by increased cognitive dissonance when viewing highly original content. Our research contributes to literature on consumer behavior on social media and advises managers to not overestimate the value of highly original content (e.g., for brand-related user-generated content). A methodological contribution of our research comes from the development of a self-supervised learning approach that allows systematic investigations of video-based social media content by quantifying its originality.

Video Influencers: Unboxing the Mystique

EXTENDED ABSTRACT

Influencers have the capacity to shape the opinion of others in their network. They were traditionally celebrities (e.g., movie stars and athletes) who leveraged their expertise, fame and following in their activity domain to other domains. However, 95% of the influencers today, or "social media stars," are individuals who have cultivated an audience over time by making professional content that demonstrates authority and credibility (Creusy, 2016; O'Connor, 2017). The growth in their audience(s) has been in part attributed to the fact that influencer videos are seen as "authentic" based on a perception of high source credibility. The increasing popularity of social media stars has resulted in an exponential growth of the influencer marketing industry which is expected to reach a global valuation of $15B in 2022 from $8B in 2019 (Business Insider, 2021). There are now more than 1100 influencer marketing agencies in the world that allow brands to partner with influencers to promote their products (Influencer Marketing Hub and CreatorIQ, 2020). These influencers primarily reach their audience(s) via custom videos that are available on a variety of social media platforms (e.g., YouTube, Instagram, Twitter and TikTok) (Brooks, 2020). Despite the rapid emergence and growth of influencer videos, there is limited research on their design and effectiveness. Specifically, little is known about the relationship between video content and viewer reactions as well as the evolution of these videos over time.

In this paper, we investigate whether the presence and nature of advertising content in videos is associated with relevant outcomes (views, interaction rates, and sentiment). There are a few challenges in carrying out these tasks. First, most data in influencer videos are unstructured. In addition, these data span different modalities – text, audio and images. This necessitates the use of state-of-the-art machine learning methods commonly referred to as deep learning. The second challenge arises from the fact that past approaches in marketing using such methods have typically made a tradeoff between predictive ability and interpretability. Specifically, such deep learning models traditionally use unstructured data to predict marketing outcomes well out-of-sample but suffer from poor interpretability. On the other hand, deep learning models that use ex-ante handcrafted features obtain high interpretability of the captured relationships but suffer from poor predictive ability. Our "interpretable deep learning" approach uses unstructured data across multiple modalities (text, audio and images) to make predictions out-of-sample and ex-post interprets the machine learning "black-box", thus avoiding the need to make this trade-off. We apply our approach to a random sample of publicly available videos of 33 YouTube influencers who receive brand sponsorship.

Our approach helps us identify statistically significant relationships between marketing (brand) relevant outcomes and video elements. The significance of these relationships is supported by a significant change in attention (importance) paid by the model to these video elements. For the outcomes, we use publicly available

data to develop metrics based on industry practice (Influencer Marketing Hub and CreatorIQ, 2020) and past research on visual and verbal components of conventional advertising (Mitchell, 1986). These metrics are # views, engagement (#comments / # views), popularity (# likes / # views), likeability (# likes / # dislikes) and sentiment. The influencer video elements we consider are text (e.g., brand names in title, captions/transcript and description), audio (e.g., speech, music, etc.), and images (e.g., brand logos, persons, clothes, etc. in thumbnails and video frames). In the ex-post interpretation step, we identify salient word pieces in text, moments in audio and pixels in images.

The focus on interpretation allows us to document some interesting relationships (based on a holdout sample) across all three modalities. First, we find that brand name inclusion, especially in the consumer electronics and video game categories, in the first 30 seconds of captions/transcript is associated with a *significant increase* in attention paid to the brand but a *significant decrease* in predicted sentiment. Second, music (without simultaneous human sound) within the first 30 seconds is associated with a *significant increase* in attention. However, longer music duration is associated with a *significant decrease* in predicted engagement, popularity and likeability but a *significant increase* in predicted sentiment. Third, larger pictures (of persons as well as clothes & accessories) in five equally spaced video frames (within the first 30 seconds) are associated with a *significant increase* in attention and predicted engagement. Finally, we also demonstrate that the focus on interpretability does not compromise the predictive ability of our model.

These results are relevant for multiple audiences. For academics, who may be interested in testing causal effects, our approach is able to identify a smaller subset of relationships for formal causal testing. This is done by filtering out more than 50% of relationships that are affected by confounding factors unassociated with attention (importance) paid to video elements. For practitioners, we provide a general approach to the analysis of videos used in marketing that does not rely on primary data collection. For brands, influencers and agencies, our results provide an understanding of the association between video features and relevant outcomes. Influencers can iteratively refine their videos using our model and results to improve performance on an outcome of interest. Brands, on the other hand, can evaluate influencer videos to determine their impact and effectiveness at various levels of granularity (individual video elements, interactions of elements or holistic influence).

Overall, this paper makes four main contributions. First, to the best of our knowledge, it is the first paper that rigorously documents the association between advertising content in influencer videos and marketing outcomes. Second, it presents an interpretable deep learning approach that avoids making a tradeoff between interpretability and predictive ability. It not only predicts well out-of-sample but also allows interpretation and visualization of salient regions in videos across multiple data modalities – text, audio, and images. Third, it generates novel Hypothesis between advertising content and a change in the outcome of interest for formal causal testing as noted above. Finally, it provides a comprehensive, data-based approach for marketers (and influencers) to assess and evaluate the quality of videos.

Brand Faces: Mining Brand Preferences from Consumer Faces

EXTENDED ABSTRACT

For centuries, philosophers, researchers, and practitioners have been fascinated by the information contained in faces and conveyed by facial expressions. This research investigates the association between brand preferences and faces ("brand faces"). Specifically, we propose a novel multi-method approach to extract brand preferences from consumers' profile pictures on social media. While faces have already been used to successfully predict names (Zwebner et al. 2017), sexual orientation (Wang & Kosinski 2018), and political affiliation (Tkachenko & Jedidi 2019), predicting brand preferences from consumers' digital self-portraits poses a promising and managerially relevant challenge.

Conveying identity and emotion, faces are a cornerstone of human communication. Our research bridges two recent literature streams. First, it links to the automated face analysis literature in marketing, management, and psychology (e.g., Choudhury et al. 2019; McDuff & Berger 2020, Xiao & Ding 2014, Zwebner et al. 2017). Second, it employs automated social media mining to harvest brand-related information (e.g., Culotta & Cutler 2016; Netzer et al. 2012). Building on extant research establishing a link between identities and brands (e.g., Bellazza & Berger 2019; Berger & Heath 2007) as well as between identities and faces (e.g., Ballew & Todorov 2007; Cogsdill, et al., 2014; Kachur et al. 2020), we explore if a direct link between faces and brands also manifests in real-world social media data.

Employing recent deep learning techniques for automated face analysis, we show what brand-related information is conveyed in the face by the way consumers present themselves on social media. Specifically, we obtained a data set containing more than 100,000 single-face profile pictures and each user's followership across 444 brands from more than 20 categories (e.g., apparel, cars, print media). For each consumer we represent his or her face as a low-dimensional embedding with the objective to encode it as efficiently as possible while retaining its distinctive characteristics. For this purpose, we work with both a commercial solution (MS Azure) and validate results with a specialized deep neural network (DNN) pre-trained on 2.6 million faces (i.e., the VGG-Face architecture by Oxford's Visual Geometry Group, Parkhi et al. 2015). The DNN embeds faces as 2,622-dimensional vectors through a sequence of (non-)linear operations (see Wang & Kosinski (2018) for a similar approach). The commercial solution returns predictions for 27 facial features, i.e., demographics (e.g., age, gender), head position (pitch, roll, yaw), emotions (e.g., happiness, sadness, anger), accessories (e.g., sunglasses), image quality (e.g., blur, noise).

Across three complementary analyses, we demonstrate the relationship between consumer faces and brand preferences. First, for more than 7,500 unique within-category brand pairs, including "canonical competitors" such as Apple vs. Microsoft, we predict consumers' brand preferences just from their faces significantly above the random-chance baseline. For all brand pairs users with overlapping brand preferences, i.e., users following both brands, are excluded. Out of these images a balanced sample of 200 images (100 per brand) is drawn (80% training data, 20% test data). Given the limited training data, the accuracy levels can be considered conservative estimates. Specifically, the global distribution of accuracies reveals a mean accuracy level of nearly 60%. Hence, error rates are reduced by about 20% compared to a random-chance baseline. Results from robustness checks that we run on subsets of the data suggest that our models capture predictive signals from consumers' profile pictures beyond socio-demographic information. Second, zooming in on consumer faces, our data reveal insightful associations between 27 specific facial features and 47 established brand personality dimensions from the Young & Rubicam's Brand Asset Valuator (BAV), e.g., wearing reading glasses is predictive of liking "intelligent" brands while wearing lip and eye makeup predict liking "glamor-

ous" brands. Third, we can recover meaningful market maps across brands solely from consumer faces, which we validate with external brand perception data. To preempt possible privacy concerns (see Van Noorden (2020) and Zhou et al. (2020) for recent discussions), we abstract from individual faces across all our analyses and explore the link between consumer faces and brand preferences only from an aggregated perspective.

Overall, our results highlight the power of automated face-based brand audience analytics and reveal important implications not only for marketers but also for policy makers as well as for consumers themselves. There are, of course, limitations to our approach. First, brand followership is only a proxy for brand affiliation. For example, someone may follow brands (or politicians) rather out of curiosity and entertainment purposes rather than honest brand preference (see Schoenmueller et al. 2021 for a similar approach). Second, consumers may disguise their real face on social networks. Their profile pictures are not a representation of who they are, but instead of how they consciously choose to present themselves and want to be perceived by others. Despite these limitations, we hope our results stimulate future research on the opportunities and challenges of automated face analytics.

Measuring Objective Vocal Similarity in Human-AI Agent Interactions

EXTENDED ABSTRACT

AI agents (e.g., Apple Siri, Amazon Alexa, social robots including Pepper) have become increasingly prevalent in our daily lives, our homes, and into our workplaces. Voice recognition technology via machine learning has reached the accuracy level of human speech (Arnold, 2018) and algorithms will eventually recognize all the various aspects in speech including nuances and vocal characteristics (i.e., tonal inflection, mood; Kirby, 2019). Also, the use of voice recognition will be advanced to include personalization features, similar to face ID or PIN, so that the AI agent can respond accordingly to the identified user through the vocal characteristics unique to each person's vocal tract. This research examines vocal similarity between an individual consumer and the AI agent. We ask this question: how will consumers perceive, respond to, and be persuaded by an AI agent contingent on similarities between that agent's voice and their own voice?

In this research, we focus on timbre since it is the most prominent feature allowing humans or machines to distinguish one voice from another. Timbre refers to the unique spectrum of frequencies *within* a sound, including one's voice (here measured by Mel Frequency Cepstral Coefficients [MFCCs; Logan, 2000]) and largely accounts for our ability to distinguish between voices or instruments, and can also affect consumer perception in various ways (Bruner 1990). In this work, we ask how *differences* in timbre between a consumer's voice and an AI voice might influence diverse consumer attitudes toward the AI agent, and further impact consumption choice.

This objective measure of vocal similarity in timbre (MFCCs) introduces a new methodological approach measuring the Euclidian distance between the AI agent and each participant's voice. In order to objectively capture and quantify timbre similarity, we wrote employ an observed machine learning process using MATLAB that enables the machine to learn and calculate a point allowing the total Euclidean distance of all vocal elements to reach a minimum. Then, the similarity points are calculated by using the Euclidean distance between the lower rank matrices of the compared voices (i.e., VocSimilarity = dist(Female1, AI Voice1')). Using this procedure to calculate speech similarity, we test our proposed research question and Hypothesis in three experimental studies.

A prevalent body of research in social psychology advocates for the similarity-attraction effect (Collisson & Howell, 2014; Montoya, Horton, & Kirchner, 2008), which suggests that we are more likely to prefer and be initially attracted to similar others. Although research suggests that we prefer to interact with advanced machines that are more human in nature (Nass et al., 1995; Tapus & Mataric, 2007), the uncanny valley theory (Mori, 1970) suggests that the degree to which these machines are similar may play a role in that we experience an eerie sensation and discomfort when they become too similar to ourselves.

In our series of studies, after listening to a single (study 1 and 2) or three different (study 3) AI agents' recommendation of different products (books, SNL videos, and movies), we measured participant's perception of the AI agent. Then, we later recorded and analyzed each participant's voice to create an objective measure of acoustic similarity to the AI voice.

In study 1, participants (152 undergraduates) listened to a sample of an AI voice (gender matched) making a book recommendation and provided their impressions regarding the AI agent. Each participant also had a sample of their voice recorded upon conclusion of the study. Objective similarity between AI and participant voices was calculated using a computer algorithm created for this research. Overall, greater similarity in timbre (MFCCs) led to perceptions of greater warmth (MFCC: $B = -.402$, $SE = .199$, $p < .05$) and competence (MFCC: $B = -.396$, $SE = .159$, $p < .05$). Study 2 (187 undergraduates), used a similar procedure to Study 1, while also including a choice task based on the AI agent's video recommendation. The results suggested that the more similar the participant's voice was to the AI agent's voice in terms of timbre (MFCCs), the participant was more likely to choose the video recommended by the AI agent (MFCC: $B = -.202$, $SE = .087$, $p < .05$).

In Study 3, we introduce three distinct voices of AI agents recommending three different movies. In this study, we demonstrate the effect of vocal similarity on persuasion and trust (competence, benevolence, integrity), and further show that trust mediates actual choice in the recommended movie. The results again show that similarity in timbre significantly predicts evaluations of warmth (MFCC: $B = -.323$, $SE = .085$, $p < .001$), competence (MFCC: $B = -.289$, $SE = .082$, $p < .001$), liking (MFCC: $B = -.295$, $SE = .082$, $p < .001$), and overall trust in the agent (MFCC: $B = -.155$, $SE = .068$, $p < .05$). We also tested the proposed mediation model using the PROCESS macro model 4 (Hayes, 2013). The data shows a full mediation model (direct effect: b = -.231, $SE = .146$, $p > .05$, 95% CI [-518, .055]; indirect effect: b = -.093, $SE = .046$ 95% CI [-.191, -.009]) where overall timbre similarity impacts trust (b = -.155, $SE = .067$, $p < .05$), which in turn leads to higher likelihood to choose the recommended movie (b = .606, $SE = .102$ $p < .001$).

Present research aims to contribute to literatures in psychoacoustics, similarity-attraction effect, and human-computer interaction. We find that, overall, similar timbre and dissimilar pitch was favored. Furthermore, we believe that our research offers useful implications to marketers regarding new technology devices. Although certain voice-relevant cues (e.g., accent, conversational styles) may be more direct and pronounced to individuals when engaging in an interaction, we explore a very subtle cue that subconsciously influence consumers' mindset. Marketers will be able to better understand the mechanisms and conditions under which we prefer AI agents that are more personalized to sound similar in timbre to individual consumers.

We Need to Go Beyond Demographics: Queering Misguided Consumer Segmentation & [Intersectional] Identity Practices

Laurel Steinfeld, Bentley University, USA
Kevin Thomas, Marquette University, USA
Jack Coffin, University of Manchester, UKL
Carol Kaufman-Scarborough, Rutgers University–Camden, USA

SESSION OVERVIEW

In this session we explore race/ethnicity, gender/sex, sexualities, and dis/abilities as "demographic" constructs, recognizing how these identifications matter, how they are socially constructed, and how consumer research can reimagine their deployment so that research more closely aligns with, and can help improve, consumer experiences.

EXTENDED ABSTRACT

"Demographic" categorizations, often used in research and segmentation practices, have many benefits, but they can belie consumers' complex lives. For instance, (dis)abilities may be overlooked or gender over-simplified in favor of race. We posit this occurs because of the hegemonic order: an "imperialist white-supremacist capitalist patriarchy" marketplace (bell hooks, 2010, p.1) assumes able-bodied, white, heterosexual cis-men are the norm. We seek to sensitize scholars, asking ourselves to think differently about the (mis)use of "demographic" identities; emphasizing how consumer research can perpetuate (in)visibilities and (dis)advantages yet could become more inclusive and/or empowering for consumers.

To question and queer these misunderstandings, we focus on these complex issues in the everyday context of grocery stores. These spaces can mundanely (de)construct (in)visibilities and (dis)advantages, like gender-neutral toilets, racially-segregated neighborhoods, and inaccessible buildings, in market-mediated ways. Crucially, these are spaces where multiple identities co-exist, highlighting the helpful yet sometimes insufficient lens of intersectionality. We consider the dynamics of demographics through concrete issues like servicescape design (e.g., accessibility) and material-symbolic structures (e.g., gendered, white-oriented products).

We invite participants to queer their use of demographics and to understand what might be lost by reflecting and sharing their own experiences of (in)visibility and (dis)advantage in supermarkets. Through discussions we will explore:

- How do multifaceted identities shape consumer experiences?
- How are marketplace identities different or similar to personal/political identities?
- When and where can intersectional thinking re-invigorate or develop your consumer research?
- Are there challenges to intersectional research, and how might they be overcome?
- Could such approaches disempower consumers?

SESSION OVERVIEW

Partisan polarization, which is on the rise in the US and elsewhere (Pew Research Center 2020), contributes to contemporary societal challenges like sharing fake news (Osmundsen et al. in press), climate change beliefs (Jenkins-Smith et al. 2020) and COVID-19 responses (Sides, Tausanovitch, and Vavreck 2020). Even obedience to safety measures during a global pandemic is best explained by political attitudes (Ivory, Leatherby, and Gebeloff 2021). Thus, understanding political attitudes matters more than ever. This session takes an important step in this direction by exploring the unique factors that motivate conservatives (vs. liberals) and devising interventions that improve individual and societal well-being.

Endorsers of conservative political ideology value tradition (Feldman 2003), like stability (Carney et al. 2008), and prefer hierarchical structure (Ordabayeva and Fernandez 2018). Such ideological differences even carry onto non-political decisions like preferences for vertically differentiated products (Ordabayeva and Fernandez 2018), luxury consumption (Kim, Park, and Dubois 2018), and financial risk taking (Han et al. 2019). Building on this emerging literature, the papers in this session use a varied set of theories to examine the influence of political ideology on issues ranging from information sharing and using (papers 1&2), adherence to guidelines (paper 3) and pro-environmental consumption (paper 4).

The first two papers examine conservatives' tendency to share and use information. First, exploring conservatives' beliefs about market-based processes, *Kim and Ordabayeva* demonstrate that conservatives (vs. liberals) view free economic market as legitimate and just, which makes them more likely to share personal information with for-profit (vs. non-profit) companies despite privacy concerns.

Next, focusing on conservative's beliefs about other customers, *Huang, Kim, and Dubois* show that conservatives (vs. liberals) are less likely to rely on product reviews from other customers, because they tend to view other customers as lay people who possess knowledge that is no better than themselves, even when the reviews might be beneficial.

Shifting gears from individual to societal well-being, *Jin, Malkoc, and Fazio* capitalize on conservatives' positive associations with structure to devise an intervention (structure vs. restriction framing) to increase their adherence to restrictive measures that can benefit the society at large (e.g., social distancing rules).

Finally, exploring ways to improve sustainable behavior, *Cakanlar, Cavanaugh, and White* find that inducing conservatives with hope – an emotion liberals traditionally score higher on and is associated with pro-environmental acts – is effective in motivating conservatives to engage in sustainable behavior.

Taken together, the papers in this session inform a more nuanced understanding of how lay beliefs (paper 1&2), automatic associations (paper 3), and emotions (paper 4) influence conservative's attitudes and decisions. In doing so, these papers identify conservative's unique psychological needs, like legitimacy beliefs of market-based processes (paper 1), viewing the world as having hierarchical structure (paper 2), need for order (paper 3) and hopefulness (paper 4), while also offering concrete interventions that can be used to increase prosocial behaviors (paper 3&4). We hope that the session can generate a fruitful and timely discussion regarding the role of ideological differences in consumer behavior.

Political Ideology and Disclosure of Personal Information

EXTENDED ABSTRACT

Consumer personal information is a valuable source of insights for marketers. Consumers, however, are increasingly wary of sharing their personal information with companies due to a growing concern of privacy. It is, therefore, important for marketers to understand factors that influence consumers' decisions to share personal information with companies. While past research has identified various contextual factors that influence the decision to share personal information (Acquisti, Brandimarte, and Loewenstein 2015) such as the system interface (John, Acquisti, and Loewenstein 2011) or the type of platform (Melumad and Meyer 2020), we know little about stable factors that systematically influence the individual's decision to share personal information. The current research identifies political ideology as a novel determinant of self-disclosure and investigates its underlying process.

Past research has shown that political ideology, measured on the continuum varying from liberal to conservative ("political conservatism"), is a fundamental belief system that influences various types of decisions and behaviors (Jost et al. 2003b). Important to our theorizing, political conservatism has been shown to predict fair market ideology which is the perception that free economic market is fair, legitimate, and just (Jost et al. 2003a). That is, conservatives, relative to liberals, tend to view market-based processes and common business practices to be fair (Jost et al. 2003b). Building on this literature, we propose that conservatives, relative to liberals, view a company's request to share personal information as legitimate because of their stronger trust in the fairness of market practices. This, in turn, increases conservatives' decision to share personal information with a company. Three studies demonstrate that political conservatism increases the decision to share personal information with a company

(Studies 1&2) and this effect is specific to companies belonging to the free market system (i.e., for-profit company) but does not generalize to a non-market system (i.e., non-profit company, Study3).

Study 1 asked participants (N=263, MTurk) to imagine browsing a task service platform which connects users to freelance workers to complete various tasks. They were told to imagine that they are trying to find someone to help with house-related matters and that they can choose to proceed as a guest or sign up as a member which would require them to share some personal information. Participants were shown eight kinds of personal information (i.e., profession, favorite brands) and asked to indicate how willing they are to share each kind of personal information listed (1=not at all, 7=very much) which were then averaged to form the overall score for the willingness to share personal information (Cronbach's α = .91). Afterward, they completed Right Wing Authoritarianism (RWA; Altemeyer 1981) scale which has been used to capture political conservatism in past research (Altemeyer 1981, 1988). We regressed participants' willingness to share personal information with the company on political conservatism. As predicted, political conservatism positively predicted participants' willingness to share personal information with the company (β =.25, p = .012). Results remained significant when we controlled for prevention-focus, interpersonal trust and various demographics.

Study 2 replicates the main effect using a real behavioral DV. Participants (N=194, MTurk) first indicated their political ideology on two items (1="extremely liberal", 7 = "extremely conservative"; 1 = "strong Democrat", 7 = "strong Republican") on seven-point scales (Pearson r = .81; Kim, Park, and Dubois 2018). Participants were told that the survey was conducted for a knowledge-based consulting firm which was currently in the process of developing a stratified sample of 20,000 people across the U.S. for an upcoming research project and the nature of this research requires participants to disclose some personal information. They were also told that a monetary compensation slightly above the market rate will be offered in exchange for the disclosure of their private information and that they will be guaranteed anonymity, but that there is a potential danger of disclosing personal information as the information will be retained in the system for next 5 years. Participants were then asked to indicate whether they would like to sign up for this survey. As predicted, a logistic regression modeling the probability of signing up for the survey revealed a significant effect of political conservatism (b =.43, *SE* = .20, Wald = 4.46, p = .035, Odds Ratio = 1.54).

Study 3 aims to provide process evidence. If our effect is driven by fair market ideology as we argue, the effect should be observed only when the request is coming from an entity that belongs to the free market system and operates by free market principles (i.e., for-profit company) and not generalize to an entity that does not operate by free market principles (i.e., non-profit company). However, if the effect is driven by other factors such as the generalized increased trust (i.e., conservatives are more trusting) or lower processing (i.e., conservatives think less about the potential negative consequences of sharing), the effect should be observed regardless of the source of the request. Study 3 (N=218, MTurk) tested this logic by adopting the same procedure used in Study1, except that half the participants were told that the company was a for-profit company, whereas the other half were told that it was a non-profit. Political conservatism was measured using a multi-item scale (Everett 2013). As predicted, political conservatism increased the willingness to share personal information when the request came from a for-profit company (β =.021, p = .011) but not when it came from a non-profit company (*F*<1).

In sum, three studies demonstrate that political conservatism increases consumers' willingness to share personal information with a company because it increases consumers' tendency to view such requests as a legitimate and fair business practice.

The Impact of Political Ideology on Attitudes toward Customer Reviews: When and Why Conservatives Don't Listen to and Act on Other Customers Reviews

EXTENDED ABSTRACT

Consumers' attitudes toward products and services are often shaped by others' opinions (Cialdini and Goldstein 2004; Goldstein, Cialdini, and Griskevicius 2008). Therefore, what consumers say about a product, that is, consumer word-of-mouth (WOM), is important for marketers to manage, and a growing body of research on WOM speaks to this importance (Berger 2014; Lamberton and Stephen 2016). The bulk of related research has mainly focused on the sender side and examined the drivers of WOM creation and sharing (Berger 2014). A nascent stream of research has started to examine the recipient side and explored factors influencing individual's reliance on customer reviews in product decisions (e.g., experiential vs. material purchase; Dai, Chan, and Mogilner 2020), but relatively less is known in this domain. The current research thus contributes to this growing literature by identifying a variable that systematically influences individual's reliance on customer reviews in product decisions. Specifically, we propose that political ideology, a core belief system that impacts various consumer decisions (Jost 2017; Jung et al. 2017; Kim, Park, and Dubios 2018) influences individual's attitude toward and reliance on customer reviews in product decisions.

Past research has shown that political conservatism is linked to the view that the world is inherently vertically stratified. Across various contexts, conservatives (vs. liberals) have been found to be more accepting of inequality and a hierarchical social structure (Jost et al. 2003) Further, conservatives consider vertically signaling information (e.g., social status) to be more primary than horizontally signaling information (e.g., similarity). Since people infer missing primary information (Kardes 1988), we propose that conservatives may infer one's rank and credentials even when no such prompt is given. Specifically, we argue that in the absence of information about reviewers given, conservatives (vs. liberals) are likely to infer that reviewers are lay people whose level of expertise and knowledge is *no* better than themselves. Consequently, conservatives, relative to liberals, judge customer reviews to be less useful, and as a result rely less on them. We find support for our proposition by demonstrating a negative association between political conservatism and perceived usefulness of customer reviews (Study 1) as well as the actual decision to read customer reviews (Studies 2 and 3). We further provide evidence for the proposed process by manipulating the expertise of the reviewers (Study 3).

In Study 1, participants first reported their political conservatism on a 7-point scale (1= extremely liberal, 7 = extremely conservative; Jost 2006). Participants then imagined that they were going to make an online purchase and answered some questions about how their decision might be influenced by customer reviews. Specifically, they reported how useful reading customer reviews would be in making their purchase, how important knowing previous customers' satisfaction with an option would be in their decision process, and how much previous customers' reviews would influence their purchase decision, the average of which served as the main DV (. Supporting our prediction, political conservatism negatively predicted perceived usefulness of customer reviews (r = -.15; t(204) = -2.20, p = .029).

Study 2 examined actual decision to read customer reviews by asking participants to allocate a fixed amount of time between two types of information (information provided by the company vs. customer reviews). We first measured political conservatism categorically by having participants indicate the political party they identify with (Republican, Democratic, neither; Kim et al. 2018; Morris, Carranza, and Fox 2008). Then, participants completed a product evaluation task in which they were asked to consider a massager for purchase. Participants were provided with two types of information to inform their decision about this massager. One was information from the business ("detailed descriptions of the product"), while the other was information from other customers ("customer reviews"). Participants were then asked to allocate a total of 100 seconds to each type of information. Participants were led to believe that they would actually read each type of information for the amount of time indicated in their allocation decision. Replicating Study 1's results, Republicans allocated less time (M = 59.14 seconds; $F(1,387)$ = 7.42) to reading customers reviews (vs. business-provided information) than Democrats (M = 64.2 seconds; p = .007).

Study 3 (pre-registered) provided process evidence by manipulating reviewer expertise (reviewer: expert vs customer). Participants first completed the Right-Wing Authoritarianism scale (RWA; Altemeyer 1981) which has been used in past research to capture political conservatism. They then completed a similar product evaluation task as in Study 2 with the following modifications. Whereas the description of the business-provided information was kept constant across the conditions, that of the customer reviews varied. In the customer condition, we told participants that the information was "from other customers" without specifying any details about the reviewers. In the expert condition, however, the information was described as coming "from knowledgeable customers who provide high quality reviews about massagers," and that "their reviews have more than 200 helpful votes on review websites." Consistent with Study 2's results, political conservatism negatively predicted the amount of time allocated to customer reviews when no expertise information was provided (b = - 2.56, $t(496)$ = -2.78, p = .006). In contrast, the effect of political conservatism was attenuated and non-significant when the reviews were from knowledgeable reviewers (b = -.71, $t(496)$ = -.78, p = .435).

In summary, the findings contribute to both the literature on political ideology and the WOM literature by identifying a negative relationship between political conservatism and customer review use and documenting the underlying process.

he Impact of Framing on Political Conservatives' Attitude toward Boundaries

EXTENDED ABSTRACT

Since its emergence in late 2019, the COVID-19 pandemic has wreaked havoc around the world, killing millions and devastating even more. The mitigation of COVID-19 relies on adherence to guidelines, which predominantly relies on restructuring one's physical and social environment by imposing boundaries (e.g., social distancing rules, masking mandates). Unfortunately, there are significant ideological asymmetries, as converging evidence demonstrates that conservatives (vs. liberals) are less likely to adhere to these prevention measures (Nace 2020). The question then is why conservatives are less likely to comply with boundaries, and how can we devise interventions to improve such attitudes.

We propose that conservatives (vs. liberals) may be less likely to adhere to boundaries because they are more likely to view them as restrictions. This is because conservatives (vs. liberals) put greater importance on individual freedom (Crawford et al. 2017) and exhibit greater reactance against what they see as restrictions (Irmak, Murdok, and Kanuri 2020). Thus, if conservatives view boundaries as inherently restrictive, then we would expect them to be less likely to comply with boundaries. If so, how might we change conservatives' attitude toward boundaries to be less restrictive? We propose that one way to do so is to highlight the structure-providing function of boundaries. Boundaries can provide a sense of structure by clearly outlining where things belong and are contained (Cutright 2012). We posit that, because conservatives have greater need for order and structure (Carney et al. 2008; Jost et al. 2003), framing boundaries as providing structure (vs. restriction) and thus focusing conservatives' attention to structure-providing function of boundaries will be effective in increasing their attitude toward the boundaries. Seven studies provide support for these propositions.

The first three studies empirically tested whether conservatives naturally associate boundaries with restrictions. In Studies 1a, 1b and 1c, participants first indicated their political orientation on a 9-point scale (1 = extremely liberal; 9 = extremely conservative; Jost 2006). Next, in study 1a (n = 614), participants viewed an image of a social distancing sign commonly used in retail stores (i.e., an arrow indicating the 6 feet social distance) and indicated how much they think the sign is restrictive. In study 1b (n = 347) they viewed an image of a three-sectioned plate and indicated the extent to which they think the plate restricts what they eat, and in study 1c (n = 526), they viewed a time slot (provided by a fictitious grocery store) and indicated how much the slot restricts consumers' pick-up schedule. As expected, the more conservative-leaning participants were, the more likely they were to view the social distancing sign (β = .15, p < .001), the three-sectioned plate (β =.10, p = .03), and the time slot (β =.06, p = .07) as more restrictive (each measured on 7-point scales).

Study 2 (n = 760) used a word evaluation task to test whether conservatives' need for order could account for their favorable attitude toward structure. The task was divided into two parts. First, participants indicated their immediate response (-3 = very negative; 3 = very positive) to twelve words (randomly presented), four of which were structure-related words ("structure," "control," "guidelines," "guidance"). Upon completing the task, participants engaged in an unrelated filler task, and then proceeded to a second study, where they indicated their political orientation and responded to the need for order scale (Cornelis and Van Hiel 2006). A regression analysis demonstrated that the more conservative-leaning participants were, the more favorable they were toward the structure-related words (β = .03, p = .02). A mediation analysis using PROCESS Model 4 (Hayes 2017) revealed a significant mediation through need for order (index = .0095, 95%CI [.0040, .0163].)

The last two studies test the proposed intervention based on structure-framing. Study 3 (n = 611) employed a 3 cell (framing: no-framing vs. restriction-framing vs. structure-framing) between-subjects design. All participants first indicated their political orientation on the same scale used in the previous studies. Then, in an ostensibly unrelated task, participants imagined going to a restaurant that put a social distancing sign on the floor. In the no-framing condition, participants simply viewed the image of the social distancing sign used in study 1a. In structure-framing (vs. restriction-framing) condition, participants viewed the image and read an additional description of the sign that it is "placed to structure (vs. restrict) customer flow in the restaurant." All participants then indicated their attitude toward the sign on three items (-3 = unacceptable/bad/unfavorable, 3 = acceptable/good/favorable; .95). We conducted a regression analysis using political orientation and framing type as the independent variables and attitude toward the sign as the dependent variable. Results

revealed that, as participants became more conservative, they became more favorable toward the sign when it is structure-framed, which differed from when it lacked a frame (β = .15, p = .001) or had a restriction-framing (β = .24, $p < .001$).

Study 4 (n = 227) replicates the findings of study 2 using a different operationalization of boundary and a more indirect measure of political orientation. Specifically, we measured political orientation by asking participants to read an article about Justice Barrett's elevation to the Supreme Court (a timely issue at the time of the data collection) and indicate how satisfied they are with the confirmation on three items (.99), where greater satisfaction implied higher conservatism. Then, in an ostensibly unrelated study, participants evaluated the three-sectioned plate from study 1b, which was described as "a plate that helps you structure (vs. restrain) your meals" and indicated how much they like this product on two items (.94). Regression analysis revealed a significant interaction of political orientation and framing types (β =.10, p = .05), such that those who are more satisfied with the confirmation evaluated the plate more favorably when it was described using structure-framing (vs. restriction-framing).

Together, our findings shed light on why conservatives may show less adherence to boundaries and how framing can be used to elicit favorable attitude changes among them.

Hoping for Change: How Emotions and Political Ideology Influence Sustainable Consumption

EXTENDED ABSTRACT

Despite the strong evidence that climate change is accelerating (Ripple et al. 2019), it remains one of the most divisive issues in the US (New York Times 2020). While 88% of liberals consider climate change a threatening issue, there is still resistance among the majority of conservatives (Pew Research Center 2019), which is a significant impediment to behavioral change among conservatives (Hoffarth and Hodson 2016). Therefore, it is crucial to understand how messaging strategies can narrow the gap between these two groups in the context of sustainable consumption (Briley et al. 2019).

Many marketers employ emotional appeals to encourage sustainable consumption (Antonetti, Baines, and Walker 2015). Traditionally, they have used negative emotional appeals, such as guilt or fear, in advertisements (Wang and Wu 2019). More recently, however, the use of positive emotions, such as pride and hope, to encourage sustainable consumption has become more common (Coleman, Royne, and Pounders 2020). For instance, companies such as Bacardi and Lonely Whale have used hope-based appeals to decrease the consumption of single-use plastic straws (White, Hardisty, and Habib 2019). While the previous literature demonstrates how using positive emotions can encourage consumers to engage in sustainable consumption, researchers have not yet examined whether emotional appeals influence conservatives and liberals similarly. Given that specific positive emotions might affect particular behaviors differently (Cavanaugh, Bettman, and Luce 2015), we examine whether specific emotions may also interact with political ideology to impact sustainable consumption.

Even though prior studies do not directly address this question, some findings could be interpreted to suggest that hope would be more motivating for liberals than conservatives. This stream of the literature has associated hope with a leftist ideology and fear with a conservative ideology (Cohen et al. 2014; Septianto et al. 2019). In contrast to these findings, we posit that hope can be used to increase conservatives' sustainable consumption. We derive our predictions based on three unique features of hope. First, collective efficacy, which is an essential ingredient of sustainable consumption (Fritsche

et al. 2018), increases the intention to act only when hope is high (Cohen-Chen and Van Zomeran 2018). Second, hope is negatively associated with the motivation of system justification (Badaan et al. 2020), which significantly impedes conservatives' participation in sustainable consumption (Feygina, Jost, and Goldsmith 2010). Finally, hope is associated with abstract construal (Winterich and Haws 2011), which is positively related to sustainable consumption (Reczek, Trudel, and White 2018). These unique characteristics of hope will influence conservatives more than liberals as framing does not generally affect groups that already support an issue (Feinberg et al. 2019). Therefore, we predict that hope will increase conservatives' sustainable consumption. We do not expect any difference for liberals. Four studies tested our predictions.

Study 1 (n=400) tested our hypothesis by using an incidental emotion task. We randomly assigned participants to one of the three conditions (hope, nostalgia, control) and asked them to write about a situation that made them feel the focal emotion. Next, participants indicated how often they intend to perform various sustainable behaviors (e.g., Go out of your way to seek out green products; Eom, Kim, and Sherman 2018) and completed a multi-item scale of political ideology (Kidwell, Farmer, and Hardesty 2013). In support of our predictions, conservatives were more likely to engage in sustainable consumption in the hope condition relative to the control (b=-.32, p=.01) and nostalgia conditions (b=-.26, p=.03), but there was no significant difference among the emotion conditions for liberals (p>.10).

In study 2 (n=357), we replicated these findings with an integral emotion task. Similar to study 1, we randomly assigned participants to one of three conditions (hope, nostalgia, control) and asked them to write about a situation that made them feel the focal emotion for the natural environment. Participants then completed the same measures for sustainable consumption as in study 1 and a multi-item measure of political ideology (Kidwell et al. 2013). Consistent with the previous study, conservatives were more likely to engage in sustainable consumption in the hope condition relative to the control (b=-.73, p<.01) and nostalgia conditions (b=-.60, p<.01). Simple slope tests further indicated that higher levels of hope about the environment eliminated the baseline difference between conservatives and liberals (b=-.07, p=.17); liberals reported higher intentions than conservatives in the other conditions (p<.01).

Study 3 (n=193) used a 2 (political ideology: conservative, liberal) x 2 (emotion: hope x control) between-subjects design. We manipulated political ideology by using a procedure developed by Ordabayeva and Fernandes (2018). Specifically, participants were asked to recall a time when they held politically more liberal or conservative views relative to their current views. They were then asked to read three stories written by previous participants: either stories related to hope about the environment or neutral stories about regular evening routines. Subsequently, participants completed the same measures for sustainable consumption as in the previous studies. The focal interaction was significant (p=.034). We found a significant difference in the conservative condition (M_{hope} =4.02, $M_{control}$=3.68, p=.01), but no significant difference in the liberal condition (M_{hope} =3.76, $M_{control}$=3.85, p=.51). Moreover, within the hope condition, conservatives were more likely to engage in sustainable consumption than liberals (p=.07).

In study 4 (n=484), we examined whether other positive emotions will have similar effects on conservatives. Similar to studies 2 and 3, participants wrote about a situation that induced the focal emotion about the environment. Next, participants indicated their willingness to donate part of their payment bonus to the World Wildlife Organization, which was our dependent variable. At the end,

they completed the multi-item scale of political ideology (Kidwell et al. 2013). We find that conservatives donated more in the hope condition, relative to the pride (*b*=-3.62, *p*<.01), fear (*b*=-2.18, *p*=.06), and control conditions (*b*=-1.98, *p*=.09). There was no significant difference for liberals (*p*>.10). Simple slope tests further indicated that liberals and conservatives contributed similarly high donations in the hope condition (*p*=.24) while conservatives donate less than liberals in the other conditions (*p*<.05).

Overall, our findings contribute to the growing literature on political ideology, sustainable consumption, and emotions.

Chris Janiszewski, Warrington College of Business, University of Florida, USA

SESSION OVERVIEW

Ten years ago, two papers launched a quiet revolution in behavioral research. Daryl Bem's "Feeling the Future" provided 9 experiments demonstrating an impossible result: People possess pre-cognitive ability, such that they react to stimuli that they have not seen yet. The same year, Simonsohn, Simmons and Nelson's "False-Positive Psychology" (2011) showed that common practices in behavioral research (e.g., not reporting all conditions and measures, or deciding when to stop data collection) allowed researchers to provide significant evidence for impossible results (e.g., that listening to "When I'm 64" by The Beatles can lower people's age by more than a year).

These concerning results prompted soul-searching efforts among behavioral researchers and launched a new stream of methodological research. On the one hand, large-scale data collection efforts have examined the replicability of behavioral research in general (Ebersole et al., 2016; Klein et al., 2014, 2018; Open Science Collaboration, 2015), or of highly-influential findings (IJzerman et al., 2020; Klein et al., 2019).

On the other hand, papers have re-examined the research practices of behavioral researchers, and offered suggestions to increase the rigor and replicability of behavioral science. In psychology, some papers have for instance discussed the value of analyzing the cumulative amount of statistical evidence present in a paper (Simonsohn et al., 2013), or argued for pre-registration as a way to achieve greater replicability (van't Veer & Giner-Sorolla, 2016). In marketing, other papers have for instance discussed how to increase power in experiments (Meyvis & Van Osselaer, 2018), or under which conditions mediation analysis can yield useful inferences about consumer psychology (Pieters, 2017).

The present session continues this research tradition, and discusses a range of methodological issues in behavioral research. In the first paper, **Charlton, Montoya, Price and Hilgard** provide a meta-analysis of mediation results in consumer journals, and discuss how these results can yield insights into the statistical power of the stud-

ies. In the second paper, **André** discusses a common practice in behavioral research: Excluding outliers by condition (rather than across the data). Using a mix of simulations and re-analysis of existing data, he shows that this practice can yield unacceptable increases in false-positive rates, with Type I error as high as 43%. In the third paper, **Evangelidis** discusses under which conditions marketing researchers can infer product choices from product ratings. In the fourth paper finally, **van Osselaer and Janiszewski** present "A Recipe for Honest Consumer Research." They argue that by better separating exploratory from confirmatory analysis, consumer researchers can achieve higher rigor without compromising their ability to discover novel and unexpected patterns in their data.

Together, these four papers provide a broad overview of current methodological issues in marketing, and cover all stages of the research process: Research design (van Osselaer and Janiszewski), measures (Evangelidis), data analysis (André) and interpretation of results (Charlton et al.). As such, we believe that this session would appeal to a large audience, and generate a lively discussion.

Noise in the Process: A Meta-Analysis of Mediation Effects in Marketing Journals

EXTENDED ABSTRACT

Evidence of mediation is critical for publication in top marketing journals (Pieters, 2017) despite calls for more varied approaches (e.g., Lynch et al., 2012). This is true not only in experimental consumer psychology, but also adjacent sub-fields of marketing. The popularity of mediation analysis is tied to availability of easy-to-use free software (Hayes, 2018) and the expectation that it can help open the black box and reveal the process underlying observed effects. Researchers are incentivized to find statistically-significant results, as such results suggest novel discoveries or effective interventions. Significant findings are, therefore, easier to publish in general and to publish at high-prestige journals in particular. Given the career advantages attached to significant results, researchers may apply motivated reasoning to obtain results that are favorable to them at the expense of science and the truth (Lilienfeld, 2017). Evidence of this problem is demonstrated conceptually (e.g., Simmons et al., 2011), through failed replications (e.g., Klein et al., 2014), and through meta-analyses of reported statistics (e.g. p-curve; Simonsohn et al., 2013). More recently, this problem was observed in mediation tests in psychology (Götz et al., 2021).

Like the afore-mentioned meta-analyses, the current research examines the average power of mediation tests through analysis of reported statistics—specifically confidence intervals from mediation tests. For our analysis we chose all 2018-2020 articles from the Journal of Marketing, Journal of Marketing Research, Journal of Consumer Research, and Journal of Consumer Psychology that reported at least one mediation test. We selected the first mediation test of a hypothesis from each paper for inclusion in our dataset. This was typically the first mediation test reported, except in rare cases where the first test was intended to rule out an alternative explanation. Meta-analyses, longitudinal studies, and multilevel models were excluded from our dataset. Trained students completed the coding redundantly in pairs with discrepancies being reconciled by the second author. Our key statistic, relative proximity (RP; Götz et al. 2021) was computed by dividing the reported CI's distance to zero by its width. RP's are negative if the CI overlaps zero and positive other-

wise. In this way, we created a table of statistics from 251 mediation tests roughly following the recommendations of a p-curve disclosure table (Simonsohn et al. 2013).

We next ran a series of simulations to determine how the RP scores ought to be distributed for simple mediation analyses when adequately powered (80-95% power), low-powered (33-79% power) and with no power (5% false positive rate) using the 'simstudy' and 'psych' packages for R (Goldfeld & Wujciak-Jens, 2020; Revelle, 2021). We programmed all three sets of simulations to run until the highest positive point of each of their respective RP histograms was 1,000 units for a bin width of .05. We then scaled down the simulated distributions so that their peaks would be 67, equal to the peak of reported results (see Fig. 1). In our final simulated distributions, mediation tests reached statistical significance in 85.0% of tests (adequate power), 55.4% of tests (low power), and 4.4% of tests (null effects).

To simulate true effects, we created a series of 3-variable datasets with a weak population-level indirect effect (β=.04) that fully mediated the relationship between X and Y. We settled on β=.04 because it allowed us to achieve desired power levels using sample sizes that are similar to those reported in marketing journals. This implies that reported indirect effects are also close to β=.04 on average, assuming they are mostly true effects with power in the range of 33% to 95%. We manipulated power by varying the sample size of each simulation while holding all other parameters constant. Sample sizes were drawn at random, uniformly, from a range based on Monte Carlo estimates (Schoemann et al., 2017) for adequate power (80-95%; N=238 to 356) and for low power (33-79%; N=124 to 234).

For null effects, we simulated a 3-variable model in which the population correlations were set to zero for all paths except the path between mediator and dependent variable (b-path) which varied across 4 levels (r=.1, r=.3, r=.5, r=.7). Simulated sample size was also varied based on 20th, 40th, 60th, and 80th percentile sample sizes reported in the mediation tests we coded (138, 195, 250, and 335 respectively). These different levels of b-path correlation and sample size were used to simulate the heterogeneity in a real-life null distribution and to assess whether there are meaningful differences among null distributions, but were all combined for the present analysis when meaningful differences were not found.

The figure posted on the OSF repository (https://osf.io/25b69/) shows that in aggregate, the distribution of RP scores for mediation tests reported in marketing journals is inconsistent with adequately-powered studies. Indeed, the RP scores from reported tests most closely resemble the simulated null distribution. The right tail of the reported tests is longer, however, indicating some statistical power, but less than the desired 80%. This is consistent with the finding that too many confidence intervals from mediation tests just barely exclude zero in psychology journals (Götz et al. 2021).

Although our analysis does not shed new light on why so many mediation tests might be underpowered or false, it is plausible that disconfirming results are being disregarded. Although we estimate the average mediation test to have poor statistical power, nearly all results were statistically significant. Indeed, the observed distribution of RP scores is highly suggestive of some form of selection bias: Even with good (80-95%) statistical power, some portion of tests should result in Type II errors (5-20%), yielding negative RP scores. We observe that confidence intervals which include zero are exceedingly rare in mediation tests in marketing journals.

Many solutions to this problem already exist, including adjustments for familywise error rates in the context of multiple testing, larger sample sizes, replication studies, preregistration, open data sharing, and publication of non-significant results. We propose that greater adoption of such practices and policies in marketing research will substantially increase the quality of evidence in our field.

Outlier Exclusion Procedures Must be Blind to the Researchers' Hypothesis

EXTENDED ABSTRACT

Data about human behavior is noisy. Participants misread instructions, get distracted during the task, experience computer errors, or simply do not take a study seriously. To reduce noise and increase statistical power, it is common practice to identify and remove such "nasty data" (McClelland, 2014) in people's response to a task.

A common example of such aberrant responses are "outliers": Data points that are "too extreme," compared to the rest of the data, to reflect to genuine responses. Multiple methods have been offered to distinguish between regular responses and outliers, and recent papers have summarized the different techniques available to researchers (Aguinis et al., 2013; Leys et al., 2019). Three metrics are commonly used to detect univariate outliers: The z-score (the response's deviation from the mean, expressed in units of standard deviation), the Median Absolute Distance (MAD; the response's deviation from the median; Leys et al., 2013), and the Inter-Quartile Range (IQR) distance (the response's distance from the upper or lower quartile of the distribution).

However, an important question has rarely been discussed in the literature on outlier exclusions: In an experiment with multiple conditions, should one identify and remove outliers across all the data, or within each condition taken separately? Indeed, recent papers covering the topic of outlier removal (e.g., Aguinis et al., 2013; Leys et al., 2019) and the most-cited books and papers on the topic of univariate outliers (e.g., Barnett & Lewis, 1994; Ghosh & Vogt, 2012; Hawkins, 1980; Miller, 1993; Osborne & Overbay, 2004; Ratcliff, 1993) have not discussed this question. Only Cousineau and Chartier (2010) and Meyvis and van Osselaer (2018) have offered an explicit discussion of this question, and suggested that outliers should be searched for, and excluded, within conditions.

In the present paper, I show that this recommendation is, in fact, incorrect. When researchers exclude outliers by condition (rather than across the data), they implicitly reject the null hypothesis that the conditions are drawn from a common distribution. As a consequence, they can no longer interpret the conclusions of statistical tests (e.g., t-tests or ANOVAs) that seek to compare the conditions. In particular, I show that within-condition exclusions inflate any random difference that was originally present between the conditions, and increase the probability of a false-positive result.

I first demonstrate this result in simulated data. I generated 243 experimental setups, orthogonally considering three possible distribution of responses (a normal distribution, a normal distribution with outliers , and a log-normal distribution), three possible samples sizes (50, 100 or 250 observations per condition), three possible methods (z-score, IQR, and Median Absolute Difference) and three possible cutoffs (1.5, 2 or 3 times the z-score/IQR distance/Median Absolute Difference) for excluding outliers, and three different statistical tests: A parametric test of differences in means (Welsch's t-test), a non-parametric test of differences in central tendencies (Mann-Whitney's U), and a non-parametric test of differences in distribution shapes (the Kolmogorov-Smirnov test) .

I simulated 20,000 experiments in each of those 243 different setups, for a total of 4,860,000 simulated experiments. In each experiment, I draw two samples at random from the same population (such that the null hypothesis is true), and observe the p-value of the difference between the two samples under three different outlier

exclusion strategies: 1. No exclusions, 2. Exclusions across the data, 3. Exclusions within each condition. These simulations reveal nominal false-positive rates (α = .5%) when no outliers are excluded, or when they are excluded across the data. In contrast, I systematically observe higher false-positive rates when outliers are excluded within conditions: They are always higher than 6%, and as high as 28%. The most severe false-positive rates are observed for parametric tests (i.e., t-tests or ANOVAs) applied to skewed data (i.e., a log-normal distribution). It is a concerning result: Outliers are most frequently excluded in the context of over-dispersed data (e.g., reaction times, willingness-to-pay, sum-scores…).

I then replicate this result using the data of an actual paper: Cao, Kong, and Galinsky (2020). This paper presents an interesting case study for multiple reasons. First, the authors have pre-registered their analysis and posted their data online, which makes it possible to measure the false-positive rates that one could observe under different outlier exclusion strategies. Second, they have excluded outliers by condition (rather than across the data). Third, it appears that the outliers were iteratively removed: After excluding outliers from their data a first time, they again applied the same procedure to the cleaned data until no new outliers were found. Such iterative procedure has occasionally been recommended to facilitate the identification of outliers in heterogeneous data (Meyvis & Van Osselaer, 2018; Schwertman & de Silva, 2007; Van Selst & Jolicoeur, 1994).

In the authors' data, I again find nominal false-positive rates when no outliers are excluded, or when they are excluded across the data. In contrast, I again find unacceptably high false-positive rates when outliers are excluded within conditions (always higher than 9%, and as high as 43%), and even higher false-positive rates when iteratively excluding outliers within conditions always higher than 58%).

Finally, the paper demonstrates a more general result: Any outlier exclusion procedure that is not blind to the hypothesis that researchers want to test may result in inflated Type I error rates. To demonstrate this result, I focus on residual-based exclusions, in which outliers are identified based on the residuals (studentized or standardized) of a linear model (Cohen et al., 2002; Judd et al., 2017). With this approach, any data point with a residual greater than some pre-determined threshold is excluded from the data. However, I show that an important subtlety of this procedure is often overlooked: The model from which the residuals are computed must exclude the predictor that researchers want to test. I provide additional simulations showing that when the model includes the predictor of interest, we again observe inflated false-positive rates.

I conclude by providing general recommendations and guidelines for outlier exclusion procedures, and offer alternatives to within-condition exclusions.

A Framework for Imputing Choice Shares from Rating Data

EXTENDED ABSTRACT

Behavioral researchers may measure preference using different elicitation procedures, such as choice and ratings. Rating data contain richer information than choice data because they can capture both the extent to which participants like a given option, as well as the participants' relative preference for one option over the other(s). In fact, researchers can readily impute choice shares from rating data by comparing the ratings of the options. Prior literature provides numerous examples where researchers imputed choice shares from rating data (e.g., Burson et al., 2009; Evangelidis & Levav, 2013; Fischer & Hawkins, 1993; Nowlis & Simonson, 1997; Shiv & Huber, 2000). In this paper, I examine when imputations of choice shares from rating data are more likely to be accurate.

I conjecture that choice shares imputed from rating data tend to deviate from choice shares obtained through a choice task because of differences in the extent to which choice and ratings are sensitive to the relative utility of the options. This can occur even when participants' evaluations (or utilities) of the options are held constant across tasks. My basic proposition is that choice is more sensitive to utility differences than rating. Consequently, choice shares imputed from rating data will underestimate consumers' preference for "advantaged" options (i.e., options that carry a higher amount of utility). In my studies, advantaged options are either alternatives that are strictly dominating or options that are favored by their relative attribute performance (as in Tversky et al., 1988).

I provide evidence for my predictions and for various moderators in 6 well-powered pre-registered experiments. Study 1 (N=400) provides evidence for my basic effect using two sets of actual products from Amazon.com. Participants were randomly assigned to one of four conditions of a 2 (stimuli: hard drives vs. water bottles) by 2 (task: choice vs. rating) between-participants design. Participants in the choice conditions were asked to indicate which hard drive (water bottle) they preferred. There was a no-choice option that stated "I have no preference between these options." Their counterparts in the rating conditions were asked to indicate how much they liked each hard drive (water bottle) (1 = not at all, 7 = very much). My data show that choice shares imputed from rating data underestimate consumers' preference for advantaged (i.e., high-utility) options (combined across products: actual choice share = 70.5% vs. imputed choice share = 55%, p = .001; p < .028 for both products). Study 2 (N=247) is a lab experiment that provides further evidence for the effect using actual purchases (actual choice share = 95.1% vs. imputed choice share = 83.9%, p = .006). Study 3 (N=301) shows that the basic effect is observed even when attribute importance is constant across tasks (actual choice share = 65.6% vs. imputed choice share = 30.7%, p < .001).

In subsequent studies, I test moderators of the basic result. Study 4 (N=778) demonstrates that the discrepancy between choice and rating is smaller in magnitude when the response scale used in the rating task is relatively more granular, such as when it consists of more scale points. Replicating previous findings, the choice share imputed from 7-point ratings represented a sizeable underestimation of the actual choice share of the advantaged option (92.2% vs. 55.1%, p < .001). This result was largely attenuated when the choice share was imputed from ratings on more granular scales (choice vs. 20-point rating: 92.2% vs. 81.8%, p = .008; choice vs. 50-point rating: 92.2% vs. 85.4%, p = .057; choice vs. 100-point rating: 92.2% vs. 79.9%, p = .002). Data of Study 4 show that participants are better able to express a weak relative preference for the advantaged option when the rating scale is relatively more granular. This can lead to better imputations of choice shares from ratings. Interestingly, data of Study 4 suggest that the mere use of 20-point rating scales (vs. 7-point rating scales) can greatly boost the accuracy of imputations. Further increases in the granularity of the rating scale (e.g., through the use of 50-point or 100-point rating scales) do not greatly affect the results.

Study 5 (N=502) tests the accuracy of imputations when rating responses are elicited through a strength-of-preference task. Strength-of-preference are rating tasks that involve an assessment of the degree to which the consumer prefers one option relative to the other. Strength-of-preference tasks elicit judgments of relative preference through a single bipolar rating scale with endpoints that indicate strong preference for one option over the other (e.g., −3 = I

strongly prefer A, 3 = I strongly prefer B). Replicating previous findings, the choice share imputed from independent ratings was a substantial underestimate of the actual choice share of the advantaged option (79% vs. 60.5%, p < .001). Importantly, the choice share imputed from strength-of-preference ratings did not differ significantly from the actual choice of the advantaged option (79% vs. 72.6%, p = .171). Further, the difference between the two rating conditions was statistically significant (72.6% vs. 60.5%, p = .019). Study 5 demonstrates that the basic effect is attenuated when the rating task involves judgments of relative (vs. absolute) preference.

Finally, Study 6 (N=602) shows that the effect is attenuated when the difference in utility between the options is relatively large. In order to manipulate the difference in utility between the two options, I varied the magnitude of the difference in attribute values. In the small difference conditions, the choice share imputed from rating data was an underestimate of the actual choice share of the advantaged option (74.3% vs. 50.3%, p < .001). In contrast, in the large difference conditions, this result was largely attenuated (96.1% vs. 93.3%, p = .291).

My data suggest that researchers should be able to impute choice shares from rating data with relatively high accuracy when (1) they employ independent ratings with highly granular scales (S4), (2), they employ strength-of-preference instead of independent ratings (S5), and (3) the options present substantial differences in utility (S6).

A Recipe for Honest Consumer Research

EXTENDED ABSTRACT

Consumer research has rightfully been criticized for p-hacking, Hypothesizing After the Results are Known (a.k.a. HARKing), and other practices that overestimate the reliability, and replicability, of results. Remedies that have been proposed, and partially implemented, have centered on making consumer research more closely approximate the ideal hypothetico-deductive method. Researchers have been urged to form, and register, one or very few Hypothesis before running experiments, test only those Hypothesis, and test each hypothesis with a single, preplanned analysis.

We argue that perfecting the hypothetico-deductive method is not the solution. P-hacking and HARKing are not the problem per se. The problem is that the research community misrepresents exploratory research as hypothetico-deductive. Authors, reviewers, and editors often force exploratory research into a hypothetico-deductive straightjacket. This leads to bad hypothesis testing. The hypothetico-deductive straightjacket also leads to bad exploration, crowding out essential, good exploration. We propose a two-part recipe for honest consumer research, in which authors first report studies in which they unapologetically lean into exploration to generate Hypothesis, followed by studies that are truly hypothetico-deductive and meant to provide strong, reliable tests of those Hypothesis.

The Recipe Part 1: Exploration and Hypothesis Generation

Authors should unapologetically acknowledge the exploratory nature of the first set of studies in a manuscript, which are meant to generate Hypothesis (or refine hunches or two- or more-sided possibilities into specific, formal, Hypothesis) rather than to test them. If authors no longer need to report exploratory studies as hypothetico-deductive, exploratory studies can be designed to maximize the probability of finding something interesting, to get the best possible view of potential moderators, to optimally uncover potential underlying processes, and to explore boundary conditions. This can be achieved by sampling broadly across multiple paradigms, stimuli, contexts, and participants, using more than one independent variable, and employing several measures of potential mediators and dependent variables.

At this stage, qualitative research can be very insightful. Listening to consumers, marketers, or public-policymakers can provide very powerful insights for the generation of Hypothesis and it is often interesting and enriching to (briefly) report these insights in an article.

We believe that exploratory analysis should be reported differently from confirmatory analysis:

Pre-registration of Purely Exploratory should be Optional. While pre-registrations do not prevent exploration (Simmons et al., 2021), they have little benefits in exploratory research.

Report Statistical Tests, Without Correction for Multiple Testing. P-values and confidence intervals are often dismissed as meaningless in exploratory analyses. One might, indeed, argue that purely exploratory analyses should not make use of statistical tests as these tests are designed to test a priori Hypothesis. The latter may be true, but we believe that traditional statistical tests still provide useful information. A classic statistical test still provides an indication how unlikely the result would be if there was really a null effect. Moreover, reporting these statistics over a series of exploratory studies will provide information about the robustness of an effect, as well as allow a reader to compute effect sizes.

Report Analyses with and without Exclusions and Covariates. It is absolutely fine to p-hack exploratory studies. As long as exploratory studies are clearly identified as such, it is good to search for strong relationships, regardless of whether the authors had an a priori hunch about those relationships. Data exclusions and using individual difference or context variables to hunt for interaction effects are extremely useful. They give us information about the people, contexts, and stimuli in which effects are stronger or weaker. The same is true for covariates. By knowing what other variables influence the dependent variable, we learn when and how an effect of the independent variable may be "crowded out" by other influences on the dependent variable. There are clear benefits to doing analyses with and without different sets of exclusions and covariates.

Report, Briefly, What Didn't Work. Suppose there is a real effect that just happens to occur only under very specific circumstances (i.e., narrow generalizability). If the authors run a hypothetico-deductive replication that employs the same, specific circumstances, the effect will replicate. The danger is in the failure to report all the other situations in which the exploratory research did not yield the effect. Even if the authors report the specific analysis that yielded the significant results, the reader does not know how narrowly the effect applies. The result is that readers overestimate the generality of the finding. This is costly because it may lead practitioners to unsuccessfully try to apply the finding in situations in which it does not apply. It might also lead other researchers to waste resources trying to conceptually replicate the effect. The narrow generalizability problem can be mitigated by briefly reporting all exploratory results in a Web Appendix.

The Recipe Part 2: Hypothesis Testing

Following the exploratory studies used to generate Hypothesis, the second set of studies in a manuscript should then be designed to test those Hypothesis. These studies should be truly hypothetico-deductive and they should minimize the probability of Type I errors through preregistration and other ways to avoid p-hacking and HARKing. These studies are designed to present real evidence for a process or a phenomenon. Thus, in addition to minimizing Type I

error, they should also safeguard against alternative explanations of processes and effects:

Pre-registration of Confirmatory Studies is Crucial. In the hypothetico-deductive section of the article, it is absolutely critical that studies are preregistered. In this stage maximum confidence is needed that the hypothesized effects are reliable.

Hypothesis Need to be Clear on What Authors Are Trying to Prove. Most Hypothesis in consumer research are underspecified. They simply indicate relationships between variables, but they do not indicate the scope of the claim the authors are trying to make. Authors should specify whether they only want to provide an existence proof or to also imply a broader scope of relevance and importance.

Authors should Test and Report the Pre-registered Analysis. If authors preregister a hypothetico-deductive study, reporting is easy. Authors should test and report the Hypothesis as pre-registered, nothing more and nothing less.

SESSION OVERVIEW

Algorithms are increasingly replacing humans in making decisions that impact people's lives in profound ways. Although algorithms are often more accurate than humans (Grove, Zald, Lebow, Snitz, & Nelson, 2000), concerns have been raised about the black-box nature of algorithmic decision-making. In most cases, users don't have access to algorithms' inner-workings, and thus they cannot understand how an algorithm reaches a certain determination. Scholars have long recognized the need to make the inner-workings of algorithms transparent (Buchanan and Shortliffe 1984; Watson & Nations, 2019), as the inability to understand how algorithms work can discourage consumers' from relying on algorithmic determinations (Herlocker, Konstan, and Riedl 2000; Sinha and Swearingen 2002; Ye and Johnson 1995).

The four papers included in this session investigate how transparency influences consumers' acceptance of algorithmic determinations, informing this issue from different theoretical angles and utilizing different methodological approaches. In the first paper, **Tomaino, Abdulhalim, Kireyev,** and **Wertenbroch** examine the role of different explanations in providing transparency for algorithmic decisions. They propose that teleological explanations (i.e., explaining why a decision was made) can be effectively used in lieu of mechanistic explanations (i.e., explaining how a decision was made) to convey algorithmic transparency. When consumers are rejected by an algorithm, offering a teleological explanation can reassure consumers about the fairness of the process and increase acceptance of the decision. In the second paper, **Demirdag** and **Shu** examine moderators of algorithmic transparency. Transparency increases trust in algorithmic determinations more when consumers are familiar with the choice options and when the goal an algorithm optimizes aligns with the goal consumers are trying to achieve. Moreover, increasing transparency by explaining the inputs an algorithm considers increases trust more when consumers have a moderate level of expertise and when the process is demonstrated to be fair. In the third paper, **Bone-**

zzi, **Ostinelli,** and **Lisjak** document an unintended negative consequence of initiatives aimed to increase algorithmic transparency. Merely knowing that an explanation about the inner-workings of an algorithm is accessible—without actually reading it—can foster an illusory sense of understanding that yields unfounded confidence in algorithmic determinations. In the fourth paper, **Linzen, Steinhart,** and **Carmon** broaden the perspective by proposing that understanding AI can play a restorative role when consumers feel threatened. Threatened consumers perceive AI-based products as more helpful in managing their lives and thus as more appealing than comparable non-AI products, whereas users subject to low-perceived-threat prefer non-AI products.

Overall, this session provides timely insight into algorithmic transparency, an important topic given the pervasive influence of algorithmic determinations on consumers' lives. This session addresses ACR's theme of *What the World Needs Now* by providing new knowledge on what affects consumers receptivity to decisions made by artificial intelligence agents. This session should be of interest to a broad audience, spark a rich discussion and fruitful opportunities for future research.

Denied by an (Unexplainable) Algorithm: Teleological Explanations for Algorithmic Decisions Enhance Customer Satisfaction

EXTENDED ABSTRACT

With recent developments in artificial intelligence and automation technologies, firms can make complex decisions about customers at scale with increased speed, efficiency, and accuracy. Despite this potential, a major concern with decision-making algorithms is their "black-box" nature (Goodman & Flaxman 2017). While an algorithm may have been created to achieve a clear decision-making objective or goal, the evolving mechanism through which it attempts that goal is often "unexplainable." That is, the algorithm itself has developed a statistical mechanism to achieve its goal that is beyond reasonable human comprehension, improving its statistical performance at the expense of its ability to transparently account for output decisions. A lack of explainability may also arise because of legal or commercial confidentiality restrictions for otherwise explainable algorithms. We study customer satisfaction with explanations for classification decisions and find that firms can still offer a satisfying explanation in lieu of being able to offer a mechanistic explanation of their decision algorithms.

Philosophers and psychologists have long—since Aristotle—distinguished between mechanistic and teleological explanations. A mechanistic explanation describes how the parts of a system interact to cause an outcome (Craik 1943). Teleological explanations explain an outcome in terms of its purpose, that is, what goal an outcome serves (Lombrozo & Carey 2006; e.g., a consumer is told that they are shown an advertisement because the advertiser wants to maximize the consumer's purchase likelihood). These answer two key questions that consumers may ask to assess the fairness of being denied by an algorithm and how to reverse this outcome or prevent it in the future: "how?" (mechanistic) and "why?" (teleological). However, what is key to the context of unexplainable algorithms is that teleological explanations can be provided independently of understanding the underlying mechanism. Across three experiments, we

find that teleological explanations can mitigate negative consumer responses through implying that firms aim to treat consumers fairly.

Our primary contribution is to extend the management literature on human interactions with algorithms by examining the psychological effects of explaining algorithmic decisions to customers. People often trust algorithmic judgments less than humans (Burton et al. 2019; Dietvorst et al. 2015), despite the long-established greater reliability of algorithms (Dawes et al. 1989). Unlike most related prior research though, we do not compare consumer preferences for algorithmic versus human determinations, but examine consumer reactions to varying explanations for algorithmic decisions.

In Experiment 1, we tested whether providing a teleological explanation, over no explanation, would enhance satisfaction and acceptance among customers who have been denied access to desired opportunities by an algorithm. We partnered with a technology firm that offers e-commerce and other services, and processes a large number of purchases every day. Customers of this firm usually make a customer support inquiry when an algorithm blocks a purchase; we measured customer satisfaction as the absence of such an inquiry. Using a sample of N = 10,295 declined purchases, we gave every seventh rejected consumer a teleological explanation of "(The company) blocks such purchases to ensure the financial well-being of our customers." while the remaining consumers were given no explanation for their rejection. We found that being provided a teleological explanation reduced the likelihood of calling customer service by 7.4%.

We designed Experiment 2 to conceptually replicate the findings of our field experiment and also to compare the effect of teleological and mechanistic explanations on satisfaction depending on whether participants can act on the explanation, that is, whether it has instrumental value. To do this, we had participants answer a series of visual perception questions with a $.10 bonus and reduced workload for the rest of the study being awarded, depending on their responses. We then told all participants that they were rejected for this award after completing the visual perception questions and either told them they would have a second chance, or would not have a second chance. Participants were also either given no explanation for this rejection, a teleological explanation describing our selection criteria's goals, or a mechanistic explanation telling them how they answered "incorrectly." Regardless of whether a participant had a second chance, they were always more satisfied with the study when they received either type of explanation. When there was no second chance, i.e. they could not undo their rejection, participants were equally satisfied with a teleological or mechanistic explanation. When there was a second chance, a mechanistic explanation was more satisfying. These results demonstrate that when a mechanistic explanation is not instrumental, a teleological explanation can be equally satisfying to consumers.

In Experiment 3, we directly tested the psychological process underlying the beneficial effect of teleological explanations. We hypothesized that teleological explanations for negative outcomes enhance satisfaction in algorithmic decision-making settings because they convey that customers are being treated fairly, since they can imply they are being treated consistently (Dawes 1979) and according to a reference standard (Kahneman et al. 1986). Using the same general paradigm as Experiment 2, participants were again rejected for a bonus and reduced workload after a visual perception task. Participants were then either given a fair teleological explanation ("This is because the researchers are interested in data from participants with a certain type of visual perception."), a teleological explanation which conveys an unfair process ("This is because the researchers want to collect more data from certain participants while minimizing

the costs of the study."), or no explanation. We found that while an unfair teleological explanation left participants more satisfied with the study than no explanation, the fair teleological explanation was the most satisfying message. These differences between the fair teleological explanation and the other two messages were mediated by the explanation's fairness.

Overall, we find that when a firm cannot offer a mechanistic explanation for a decision due to their usage of an unexplainable decision algorithm, they can still convey fair-processes and achieve consumer satisfaction through offering a teleological explanation. However, in line with increasing political and consumer pressure to offer transparency in a firm's dealings, appeasing consumers through teleological explanations may not always be the most ethical route.

Moderators of Algorithmic Transparency and Explainability

EXTENDED ABSTRACT

Previous research shows that process transparency (i.e., a decision characteristic whereby a decision process is perceived to be understood) is a novel driver of algorithm aversion, since it predicts trust, and consequently contentment with that technology (Demirdag and Shu 2021). Decision recipients value knowing how an outcome materializes and process transparency is one of the determinants of trust. The lack of transparency of algorithmic (vs. self) decision processes lowers consumers' trust in the algorithmic decision-maker's ability to choose for them, hence lowering their satisfaction levels. Additionally, increasing input explainability (i.e., the consumer's ability to know relevant input information regarding a particular decision) has been demonstrated as an effective intervention to increase process transparency and trust, leading to higher consumer satisfaction with decisions made in the digital world (Demirdag and Shu 2021). Building on previous research and across four studies, the current paper investigates moderators for process transparency and input explainability.

Process transparency's influence on algorithm aversion is likely to be affected by the characteristics of the options in a decision, such as familiarity (i.e., the number of product-related experiences gathered by the consumer; Alba and Hutchinson 1987). Past research has shown that high familiarity leads to quicker and more confident decision-making (Park and Lessig 1981). This might be due to the processes of familiar (vs. unfamiliar) decisions being more transparent to the consumer. Accordingly, in study 1 (N = 599), we tested our hypothesis that familiarity moderates the role of process transparency in algorithm aversion, using real or fictitious drink names in a 2 (Self Choice, Algorithmic Choice) x 2 (Option Familiarity: Familiar, Unfamiliar) between-subjects design. A moderated mediation analysis using 10,000 bootstrapped samples revealed that the indirect effect of choice type on trust through process transparency was more substantial for familiar than for unfamiliar decisions: estimated difference (ACME of Familiar - ACME of Unfamiliar) was .469, 95% CI: [.273, .669]. In other words, process transparency mediated the relationship between choice type and trust more for decisions with familiar than unfamiliar options.

In study 2 (N = 958), we studied the moderating role of goal alignment on transparency. In a decision process, decision-maker's goal may or may not align with the consumer's goal in using a digital platform. For instance, the bank's goal in accepting a loan application could be to provide the consumer with the money they need to pay for their necessary expenses (transparent aligned goal). In contrast, the bank's goal could be to earn interest income (transparent misaligned goal). Accordingly, goal alignment might moderate

whether transparency increases trust and satisfaction. In a 2(Human, Algorithm) x 3(Transparent/Aligned, Transparent/Misaligned, Non-transparent) between-subjects design, in the context of a loan application, we find that goal aligned (vs. misaligned) decisions were more satisfactory (F(1, 956) = 105.30, p < .001) and trustworthy (F(1, 956) = 54.99, p < .001). Additionally, nontransparent (vs. misaligned) decisions were viewed as more satisfactory (F(1, 956) = 101.20, p < .001) and trustworthy (F(1, 956) = 57.28, p < .001). Non-transparent and aligned decisions were not significantly different. Therefore, we find that goal transparency can hurt if the goal is not aligned, but it does not help if the goal is aligned.

Study 3 (N = 387) investigated expertise as a moderator of input explainability. Past research has shown that experts rely less on algorithmic advice than lay people (Logg, Minson, and Moore 2019). Experts might find an algorithm's input explainability less valuable for increasing satisfaction with the product, as they may already know how such algorithms make decisions. We tested this prediction in an algorithmic song selection decision on a music streaming platform, Spotify. Participants were either told why the Spotify algorithm chose the songs on a playlist (explainable condition) or not (unexplainable condition). We conducted a floodlight analysis to test, which revealed two Jonson-Neyman points: 3.92 and 19.62. Input explainability had no effect for those who used Spotify more than 19.62 hours per week and for those who used Spotify less than 3.92 hours per week. The input explainability intervention was effective in increasing satisfaction for the 56.6% of participants who used Spotify more than 3.92 hours but less than 19.62 hours. Surprisingly, the mid-level users appear to benefit from input explainability the most. Nonexperts are (dis)satisfied with and experts are satisfied with the algorithmic choice similarly whether it is explainable or unexplainable: explainability had no effect on experts or nonexperts. In study 4 (N = 1,203), we addressed whether and how input explainability is moderated by procedural fairness, since input explainability increases the perceived understanding of internal processes of a human or an algorithmic decision-maker. We employed a 2(Human, Algorithm) x 2(Explainable, Unexplainable) x 2(Fair, Unfair) between-subjects design in the context of a loan application rejection. We found that input explainability increased trust for procedurally fair decisions, but decreased trust for unfair decisions (interaction: B = .168, SE = .028, t(1199) = 6.10, p < .001). Additionally, input explainability increased dissatisfaction for procedurally unfair, but not fair, decisions (interaction: B = -.132, SE = .045, t(1199) = -2.94, p = .003). Therefore, procedural fairness moderates the positive effect that input explainability has on trust and satisfaction such that if the procedures were explained to be unfair, then input explainability hurts trust and satisfaction. In contrast, if the process is demonstrated to be fair through input explainability, then trust and satisfaction could be boosted.

In conclusion, by providing important moderators, the present paper builds on previous research which shows the key roles of process transparency and input explainability. Due to the perceived insufficiency in understanding algorithmic decision processes, unfamiliarity attenuates, but does not eliminate, algorithm aversion. Furthermore, transparency of the goal can hurt satisfaction if the goal is misaligned with consumer's goal, but it does not help if the goal is aligned. Our results indicate that, companies may choose to focus their explainability interventions on their mid-level users, as those customers may benefit more from such interventions. Nonetheless, companies should ensure procedural fairness in order for explainability interventions to be successful.

The Unintended Effect of Algorithmic Transparency: Mere Access to Explanations Foster Illusionary Understanding

EXTENDED ABSTRACT

The increasing influence of algorithmic determinations on consumers' lives has brought about mounting concerns about the lack of transparency of algorithmic decision-making. The inability to access the inner-workings of algorithms poses a serious threat to consumer welfare (Martin 2019) and can discourage consumers' from relying on algorithmic determinations (Buchanan and Shortliffe 1984; Herlocker, Konstan, and Riedl 2000; Sinha and Swearingen 2002; Ye and Johnson 1995). In response to these concerns, legislators have institutionalized a "right to explanation," that is, a right to know how an algorithm works to reach a certain determination (Goodman and Flaxman 2017). And companies have begun to provide access to explanations of how their algorithms work.

These initiatives are motivated by the implicit assumption that explanations can increase consumers' understanding of how algorithms work by revealing their inner workings. Yet, although companies can make explanations for how their algorithms work accessible, evidence shows that people generally don't read transparency policies (Hart 2019). And if consumers don't read such explanations, their understanding of how algorithms work should remain unimpacted, defeating the very purpose of these initiatives.

In this research, we argue that providing access to explanations of how algorithms work can sometimes have an unintended negative effect. Across three studies, we show that merely knowing that an explanation for how an algorithm works is accessible—without actually reading it—can foster an illusionary sense of understanding. This occurs because having the potential to access an explanation fulfils people's innate desire to feel effective—a fundamental human motive referred to as *effectance motivation* (White 1959)—and this, in turn, yields a false sense of understanding. We further show that the illusory understanding fostered by the mere accessibility of an explanation can yield greater confidence in algorithmic recommendations without providing actual knowledge.

In study 1 (n=200) participants read about an algorithm that provides investment recommendations. Participants were informed that a description of how the algorithm works had been available on the company's website versus not before reporting the likelihood they would use the algorithm (1=very unlikely; 7=very likely), and their understanding of how the algorithm works (1=do not understand at all; 7=understand completely). To rule out the possibility that liking toward the company underlies the focal effect, we measure company liking (1=negative/bad/poor; 7=positive/good/excellent). Participants indicated a greater likelihood to use the algorithm when they read that an explanation for how the algorithm works was accessible (M=4.02, SD=1.66) versus not (M=3.34, SD=1.65; t(198)=2.92, p=.004). Participants also reported a greater sense of understanding when the explanation was accessible (M=3.25, SD = 1.67) versus not (M=2.23, SD=1.60; t(198)=4.40, p<.001). Liking toward the company did not differ between conditions (p=.419). A mediation analysis shows that sense of understanding mediated the effect of explanation accessibility on intentions (b=.29, 95%CI: .11, .51).

In study 2 (n=200), we test the hypothesis that the explanation accessibility effect should be more pronounced among individuals with stronger dispositional effectance motivation. Following past research (Epley, Waytz, and Cacioppo 2007), we captured differences in effectance motivation through the proxy measure of desire for control measured with three items from Burger and Cooper (1979).

Next, we manipulated explanation access for a medical algorithm as in study 2. Finally, we measured perceived understanding of how the algorithm works. The analysis revealed a significant interaction (b=.53, t(196)=2.08, p=.039). A Johnson-Neyman analysis (Spiller et al. 2013) revealed that respondents with dispositional desire for control greater than 5.51 (on the 7-point scale) displayed the explanation access effect, but not those with lower desire for control.

Finally, in study 3 (n=200), we test the entire sequential mediation model via sense of understanding and certainty. We first manipulated explanation access in the context of a medical algorithm. Participants then reported their intentions to use the algorithm, performance certainty (1=not at all certain; 7=extremely certain), accuracy (1= not at all accurate; 7 = very accurate), and sense of understanding. Accuracy was measured to rule out the possibility that perception of accuracy, rather than perception of certainty, drives the explanation accessibility effect. The measures of accuracy and certainty were presented in a randomized order.

Participants in the explanation accessibility condition reported greater intentions to use the algorithm (M=4.33, SD=1.64) than those in the control condition (M=3.51, SD=1.80; t(198) =3.37, p=.001). Explanation accessibility also increased sense of understanding ($t(197) = 3.31$, $p =.001$), and performance certainty ($t(198) = 2.58$, $p =.011$). There was no significant difference in perception of accuracy ($t(198) = 1.46$, $p =.145$). A mediation analysis (explanation accessibility→understanding→certainty→intentions) provided support for the proposed theoretical model (b=.33, 95%CI: .13, .57).

Our work contributes to the broader literature on consumers' receptivity to algorithmic versus human determinations (Dietvorst, Simmons, and Massey 2015; Bonezzi and Ostinelli 2021) and, more specifically, to research on algorithmic transparency (Bonezzi, Ostinelli and Melzner 2020). Past research has examined the effects of transparency policies from a cognitive standpoint by investigating how different types of knowledge might be more or less effective at fostering understanding and reliance on algorithmic recommendations. We depart from that tradition by proposing a motivation account of the effects of transparency policies showing that explanations can also fulfill a need for effectance without providing any knowledge. Our findings have implications for companies and public policies by showing a possible, unintended effect of algorithmic transparency initiatives: While designed to promote consumers' literacy, these initiatives can foster unfounded confidence in algorithmic decision-making.

AI Can Help Counter Self-Threats

EXTENDED ABSTRACT

In spite of the tremendous benefits that AI offers, prior research has shown that consumers tend to have reservations regarding AI-based products and services (e.g., Leung, Paolacci and Puntoni 2018; Lynskey 2019; Samuels 2020). In this research, we identify situations in which users embrace AI interactions. We argue that because AI can play a restorative role when consumers experience threat, people who feel threatened are more likely to prefer engaging with AI as a means to improve managing their everyday lives.

People experiencing threat (e.g., loss of control, loss of power, or threat to self-esteem) often seek ways to counter the threat and restore a sense of security (Campbell and Sedikides 1999; Crocker and Park 2004; Ryan and Deci 2000; Steele 1988; Steinhart and Jiang 2019). Indeed, prior research has established connections between such threats and consumption, showing that threatened individuals seek experiences or products that protect or enhance the self (e.g.,

Baumeister, Tice and Hutton 1989; Rucker, Galinsky and Dubois 2012; Shrum et al. 2014).

We argue AI's rather uncanny capacity to provide remarkably helpful recommendations and actions by leveraging insights it obtains from information that it gathers from users may help users cope with self-threats. We hypothesize that threatened consumers are likely to perceive such products as helpful in managing their everyday lives, and therefore as appealing.

Below we present four studies that support our proposition. Study 1a provides preliminary evidence that participants are more likely to prefer AI-based products if they feel threatened. Study 1b replicates and extends these findings by comparing preferences for an AI with a non-AI-based product. Study 1c replicates and further extends earlier findings using a timely threat manipulation (Covid-19). Study 2 shows that threatened participants' preference for AI-based products is mediated by the perceived capacity to help them manage their lives.

In Study 1a (n = 208) we manipulated perceived self-threat through participants' sense of control over their environment (Munichor and Steinhart 2016). Participants wrote either about an experience in which they experienced a loss of control or full control over the course of events. They then viewed a brief video clip in which an actual AI-based virtual assistant (VA) conducted a human-like phone conversation with a human service provider. Consistent with our predictions, threatened participants reported greater intentions to purchase the AI-based product that was featured in the video compared with participants in the low threat (i.e., full control) condition.

In Study 1b (n = 506) we added a non-AI version of the VA. Participants underwent the same threat manipulation used in Study 1a. They then read one of two versions of a VA description: (a) an AI-based VA that learns the user's preferences and integrates them into practical decisions and actions, and (b) a non-AI-based VA that carries out the user's requests, decisions, and orders. A 2×2 ANOVA yielded a significant interaction. As expected, threatened participants reported higher purchase intentions toward the AI version than toward the non-AI version. In contrast, participants in the low threat (i.e., full control) condition preferred the non-AI over the AI version.

Study 1c (n = 312) further replicated and extended the earlier results by utilizing a different threat manipulation. In the threat condition, participants described how the COVID-19 pandemic disrupted their lives. In the baseline condition, participants described a TV show or a movie they had watched recently (cf. Cutright 2012). A 2×2 ANOVA yielded a significant interaction. Consistent with our predictions, participants in the threat condition reported higher purchase intentions toward the AI version than toward the non-AI version. Participants in the baseline condition reported higher purchase intentions toward the non-AI version, though this preference failed to reach conventional level of significance.

Study 2 sought support for the underlying mechanism. We measured the extent to which participants experience threat by asking them to rate how well they were coping during the COVID-19 pandemic. Participants then read the same AI or non-AI VA descriptions used in Studies 1b and 1c. A regression analysis (n = 192) yielded a significant interaction between self-threat and VA versions. The results of a Johnson-Neyman "floodlight" analysis confirmed that, as predicted, threatened participants (who reported that they were not coping well during the pandemic) reported higher purchase intentions toward the AI compared to the non-AI product version. In contrast, non-threatened participants (who reported that they were coping well during the pandemic) reported higher purchase intentions toward the non-AI product. A moderated mediation analysis further showed that among threatened participants, this effect was

mediated by the product's perceived ability to help users to manage their lives, while among participants who felt they were coping well with COVID-19, the mediation effect was not significant.

Collectively, the findings support our prediction of AI's potentially restorative role for people experiencing threat.

SESSION OVERVIEW

Numbers are central to how consumers interact with products and the marketplace. Consumers sum up prices on a menu and add on tax and tip. They consider how many gallons of gas they can buy given the $20 bill in their wallet, the price of a single gallon, and their uncertainty about both. And when weighing different flight itineraries, they may consider that one option is on time 82% of the time and another only 76% of the time. From the basics of prices and quantities, to the probabilities of expectations about future consumption, numbers are intrinsic to consumer experiences. Two examples of biases are the left digit bias leading people to judge the difference between 6.00 and 4.95 to be greater than 6.05 to 5.00 (Thomas & Morwitz 2005) and increased anchoring effects in unfamiliar currencies (Mussweiler & Englich 2003). These and other heuristics and biases shape the way in which consumers evaluate and conceptualize numbers, with substantial implications for how they evaluate prices (Thomas & Morwitz 2009, Cheng & Monroe 2013). Building off these findings, the papers in this session consider three ways in which people may deviate from current theories of decision making and their ubiquitous consumer choices.

The first two papers consider how consumers deal with distributions of numbers. The first paper looks at how people fail to accurately sum numbers, which is critical for managing income and expenses. **Goswami, Greenberg, & Schley** demonstrate a systematic and substantial undercounting of sequences of positive numbers, which they call undersum bias. This bias is extremely robust and withstands both incentives for accuracy as well as for overestimation. They show that undersum bias is both a sizable and consequential cause of overconsumption and overspending behaviors. The second two papers both examine how numeric representations may shape perceptions of uncertainty. **Zimmerman, Spiller, Reinholtz, & Maglio** examine the impacts of metrics on consumer's estimates of uncertain quantities. They show that simple transformations (e.g., inverse and level shift) of the estimated metric produce predictable inconsistencies. These tendencies are driven by making relatively more symmetric estimates of uncertainty in the metric elicited and more uncertainty when the metrics are more numerous. **Schley, Ferecatu, Chan, & Gunadi** reconsider the nature of how consumers categorize uncertainty us-

ing experimental and model-based approaches. In this paper, they show that both probability sensitivity and the shape of the probability weighting function depend crucially on categorical boundaries that are an emergent property of the particular stimulus context. Just as 0% and 100% are natural and distinct boundaries, they document additional categories of probabilities that impact sensitivity.

Together, these papers highlight how biases impact consumers' interactions with numbers. This session documents a new bias, expands the implications of current biases, and adds a new conceptualization of an established theory. Understanding the ways consumers incorrectly use and understand their wealth of numeric information can greatly assist them. We expect this session to appeal to those with interest in modeling risk, consumer overspending, and consumer confidence.

Undersum Bias

EXTENDED ABSTRACT

People often need to engage in quick mental tasks. One common mental task is to keep a running tally, that is, form an estimate of the sum of positive-number sequences. A budget-conscious grocery shopper may decide about whether to add a new item to the cart based on an intuitive assessment of the total bill; someone watching their weight might decide on whether to order the tempting dessert for dinner based on their impression of calories consumed during the day, or a person may need to keep track of expenses to avoid bank overdraft fees. How well do people estimate such sums intuitively?

This paper demonstrates that people systematically underestimate sums of positive-number sequences, which we call undersum bias. Notably, this bias can lead to suboptimal consumption choices. Our research highlights a novel cognitive antecedent of overconsumption behavior that is distinct from accounts based on self-control (e.g., Muraven & Baumeister, 2000) or perceptual biases of future outcomes (e.g., Ainslie, 1975).

Studies 1a and 1b (N = 251) examine the extent to which real shoppers can estimate their total bill at checkout. Grocery store customers were asked how much they were about to spend at checkout. Study 1b additionally tested whether a $5 accuracy incentive for estimation errors within 10% improved estimates. Using 95% winsorized estimates (used throughout), we found that shoppers significantly underestimated their total bill (Δ = Estimate – Actual = -$12.73, $p<.001$). The results were similar in both high-income and medium-income stores ($p=.267$), and incentives for accuracy did not affect the outcome ($p=.567$). The field study provided initial evidence that people underestimated the sum of a sequence of positive numbers in a highly naturalistic setting (see Van Ittersum et al., 2010; Scheibehenne, 2019).

Whereas Studies 1a and 1b demonstrated undersum bias when decision-makers were explicitly provided an estimate, Study 2 examined whether evidence for the phenomenon persisted in situations in which people's intuitive estimates of the running total are input into their judgment and decisions. Prolific participants (N=585; pre-registered) engaged in a simulated shopping trip study in which they were incentivized (up to $1) to maximize the average quality for the price paid. After making choices between 10 pairs of products, participants either estimated their total bill or decided whether to add a $9.99 item to their cart under one of two different total budget condi-

tions. In the *minimum budget* condition, the budget facing the participants was *below* the sum of the minimum prices of each of the 10 product pairs; in the *low* condition, the budget was computed in real-time as the running total plus $8. In both conditions, the normative decision was not to buy (as doing so would exceed the budget; this was incentivized). The proportion of participants who decided to add the focal item to their cart was 65% and 63% in the minimum and low budget conditions, respectively (difference between conditions: p=.680). Both were significantly higher than 0% as well as 50% (a conservative H_0), suggesting that participants underestimated their running bill. Indeed, in the estimate condition, the totals exhibited significant undersum bias (Δ= -22.73, p<.001).

Studies 3-5 examined the robustness of undersum bias in controlled settings. In Study 3a, undergraduates (N=202) reported their impression of the sum of a sequence of 10 comma-separated, randomly-generated, positive numbers that were shown on the computer screen for six seconds, and participants entered their answer on the next page. Fifteen trials (counter-balanced) varied the sorting order (random, ascending, or descending), variance (low, medium, or high), and number-type (decimal, integer). Overall, the results indicated significant undersum bias both in terms of incidence (70% of the trials) and magnitude (Δ= -14.16, p<.001). Study 3b (N= 83; MBA students) replicated these findings by changing the presentation format such that the screen flashed one number at a time for 600 milliseconds before showing the next in the sequence. The results suggest that undersum bias is not an artifact of people's inability to scan all the numbers in a sequence.

Study 4 examined whether undersum bias arose merely from participants' inability to do effective memory-based processing (Hastie & Park, 1986). Prolific participants (N=400; pre-registered) reported the sum on the *same page* in which the sequences appeared, but did so in either 10 or 20 seconds. Participants completed six trials in the experimental round and were told that one of their estimates would be randomly chosen for additional bonuses (up to $5) based on accuracy. Results indicated significant undersum bias in both time-limit conditions (80% and 76% for 10 and 20 seconds, respectively), although undersum bias was attenuated when the time limit was doubled. The results suggest that the bias is not due to mere limitations of memory-based processing. Study 5 (N=185, MTurk) further replicated the bias when participants were incentivized for *overestimation* (i.e., a bonus of up to $5 for being accurate on the *higher* side of the true sum), suggesting that the results were unlikely to be on account of motivated reasoning to believe that estimates are under-budget (Ditto et al., 2009). That this very strong incentive did not arrest the bias suggests it is highly robust.

The subsequent studies examined whether undersum bias is moderated by having participants estimate the average of the sequence before estimating the sum (Study 6: N=151), choosing one of three categorical options indicating ranges before providing their estimates (Study 7a: N=297; Prolific, pre-registered), and providing a range response (i.e., low, high) or an opportunity to revise estimates (Study 7b: N=393; Prolific, pre-registered). While eliciting average and range response had no effect, an opportunity to revise or prior selection of a categorical-range response reduced (but did not eliminate) undersum bias.

Overall, the results indicate the existence of a novel bias that has implications for judgments and choices related to numerical impression formation. A survey reported that 90% of bank overdrafters did so "by mistake," indicating that decision-makers are not sufficiently able to track running totals of expenses (Pew, 2012). Undersum bias, we report in this paper, can be an important contributor to overconsumption and overspending behaviors.

When Metrics Matter: Elicitation Metric Influences Uncertainty Estimates

EXTENDED ABSTRACT

Metrics matter for a number of consumer judgments and decisions (e.g., De Langhe and Puntoni 2016; Larrick and Soll 2008; Spiller, Reinholtz, and Maglio 2020). People make different decisions and judgments when considering the same quantity in different equivalent metrics, such as a car's fuel efficiency as miles per gallon (MPG) vs. gallons per 1,000 miles (GPkM). When consumers generate prediction intervals for an uncertain quantity and two elicitation metrics are formally equivalent but numerically different, how does the elicitation metric affect prediction intervals? We focus on two properties of such prediction intervals: width (i.e., the difference between the upper and lower bounds of an e.g., 80% prediction interval) and symmetry (i.e., the ratio of (a) the difference between the upper bound and the average, and (b) the difference between the lower bound and the average). Using a standard confidence elicitation task (Soll and Klayman 2004), we find that using different but equivalent metrics can affect both width and symmetry.

We make two key predictions. First, we predict prediction interval width depends on magnitude: larger magnitudes lead to wider intervals. This is derived from two findings. People are often insufficiently sensitive to unit changes, such that $700 per week seems like more money than $100 per day (e.g., Burson, Larrick, and Lynch 2009) People often expect uncertainty scales up with magnitude, conceptualizing risk as the coefficient of variation (SD / M), rather than the standard deviation (Weber, Shafir, and Blias 2004). Together, these suggest people may think uncertainty scales up with magnitude, even if that scaling is irrelevant and the effect on uncertainty is normatively inappropriate.

Second, we predict prediction interval symmetry depends on the form of the rate elicited. People often assume a unimodal and symmetric distribution as the default distribution (Fried and Holyoak 1984). When metrics have an inverse relationship, such as dollars per hour and hours per dollar, confidence judgments that are relatively symmetric become more skewed once they have been transformed into the other metric. Thus, people may report a relatively symmetric distribution, independent of the metric, which would be more skewed in the transformed metric. For example, predicting 50 MPG as the median with a symmetric 80% interval of (20, 80) implies a prediction of 20 GPkM as the median with an asymmetric 80% interval of (12.5, 50).

Experiment 1 (n = 99; all n after preregistered exclusions) tests whether prediction intervals differ in symmetry and width when Mechanical Turk workers estimate their wage rates for the previous 100 HITs they completed in either (a) cents per minute or (b) minutes per dollar. People gave estimates for the 90th, 50th, and 10th percentiles in one of the two metrics. Symmetry in each experiment was operationalized by calculating the ratio of the 90th percentile minus 50th percentile divided by the 50th percentile minus the 10th percentile. Width in each experiment was operationalized by calculating the 90th percentile - 10th percentile estimates. We transformed all estimates into both metrics to make comparisons in equivalent metrics. Transformed estimates were significantly less symmetric than elicited estimates (ps < 0.01), regardless of which outcome metric was analyzed. The prediction interval widths did not differ between metrics. Eliciting the same rate in different metrics affected symmetry of underlying uncertainty but not width when assessed in either metric.

As a conceptual replication of Experiment 1, we used a different inverse relationship, foreign exchange rates, in Experiment 2 (n = 169). People estimated the exchange rate in US cents per Turkish

Lira or Turkish Lira per US dollar in two weeks; people were shown 11 matching rates from the past year for reference. Conceptually replicating Experiment 1, we find that the symmetry is greater in the elicited metric than in the transformed metric (ps < 0.01); the average widths did not differ based on the metric.

Experiment 3 (n = 167) asks people to estimate revenue or profit for a fortune telling carnival booth. Revenue was bounded between $0 and $3,600 with a known, fixed cost of $1,500 and no marginal costs. People estimated the 90th percentile, the average, and the 10th percentile of either profit or revenue; profit was known to be revenue less $1,500. After converting all estimates to revenue, we compared the symmetry and widths between estimation metrics. On average, prediction intervals were significantly wider when people gave (larger magnitude) estimates of revenue than of (smaller magnitude) profit (p < 0.05); symmetry did not differ (p > 0.1). Changing the magnitude affected width but not symmetry.

Experiment 3 varied magnitude while holding real quantity constant by including or excluding a fixed quantity (fixed costs). Experiment 4 varied magnitude while holding real quantity constant by changing the unit: single eggs or dozens of eggs. If people are (a) sensitive to magnitude, but (b) insufficiently sensitive to unit, we expect the implied real uncertainty to be higher for dozens of eggs than single eggs (e.g., insufficiently scaling up 1-2 dozen eggs to 10-20 eggs means greater uncertainty for dozens than singles). Experiment 4 (n = 239) asked people to estimate the sales of eggs in a particular grocery store on a single day in either individual eggs or dozens of eggs. As in Experiment 3, people estimated the 90th percentile, average, and 10th percentile of egg sales. All estimates were transformed to be in terms of individual eggs. Estimating dozens results in significantly wider prediction intervals (p < 0.01). Prediction interval symmetry did not differ by metric (p > 0.10).

Across four experiments we find estimates of uncertainty are systematically shaped by metrics. With metrics that are inversely related, elicited intervals tend to be more symmetric than formally equivalent transformed intervals, no matter which metric is elicited. As the values used in estimating intervals increases, so does the degree of uncertainty. These findings reinforce the importance of choosing metrics carefully when discussing uncertainty with consumers and managers.

How Categorization Shapes the Probability Weighting Function

EXTENDED ABSTRACT

Traditional decision-making theories have long documented that consumers predominantly overweigh low probability events and under-weigh high probability events (Kahneman and Tversky 1979). Original conceptualizations of probability weighting typically assumed that consumers have two reference points: at 0% and 100%. 0% chance is seen as "*not happening*", and 1% is perceived as categorically distinct from this. While 100% chance is akin to "*certainly happening*", 99% chance is perceived to be different. Thus, 0% and 100% are categorically distinct from the rest of the probability spectrum, and they consequently act as reference points. Consumers exhibit diminishing marginal sensitivity away from those reference points, resulting in the traditional inverse S-shaped probability weighting function (PWF) (Tversky and Kahneman 1992; Wu and Gonzalez 1996).

In this paper, while we entirely agree with the proposition that categorical distinctions produce reference points resulting in nonlinear sensitivity to probability, we aim to reconsider the nature of the PWF. We tested the tacit assumption that 0% and 100% are the only reference points, and we document *more* distinct reference points. Importantly, we show that the PWF is inherently endogenous and its form is an emergent property of the stimulus context.

In building our theoretical argumentation, we drew upon seminal work in psychophysics and signal-detection theory, which collectively posit that discriminability amongst stimuli leads to sensitivity. The ability to categorize quantities is related to sensitivity to those quantities, and it has been shown that discretization or splitting up a stimulus facilitates discrimination and is linked with greater sensitivity. If any feature that discretizes a stimulus acts as a categorical boundary, these boundaries (like 0% and 100%) serve as reference points, and sensitivity increases near these reference points. But *where* might these reference points be located? In the domain of decisions under risk, risks are predominantly expressed with the use of numbers. Base-10 system of Arabic numerals exhibits a simple nested property: 0 to 9 are nested under sets of 10, and sets of 10 are nested under sets of 100. Relatedly, left-digit effects have been identified in riskless value-based judgment and choice domains (Thomas and Morwitz 2005). Since numbers are used to express risk, and those numbers serve for efficient categorization of the probability space, the PWF may exhibit greater sensitivity when risks cross these left digits. Though, the left digit need not *always* be a categorical boundary. In fact, the shape of the PWF is rather an emergent property of the particular context.

In most studies, we used a modification of Wu and Gonzalez's (1996) laddering paradigm to demonstrate that consumers represent probabilities just below and above the left digit as categorically distinct. If categorical perceptions drive probability sensitivity, we expect higher sensitivity for probabilities that cross these boundaries, and lower sensitivity for probabilities within categories. For example, if Gamble A presents "*1% chance of winning $20 and 12% chance of winning $5*" and Gamble B presents "*16% chance of winning $5*", the probability of the common outcome does not cross a categorical boundary (12% and 16% are in the same 10-20% category). If Gamble C is "*1% chance of winning $20 and 18% chance of winning $5*" and Gamble D is "*22% chance of winning $5*", the probability of the common outcome for Gamble C resides in a different categorical space (10-20% category) than Gamble D (20-30% category). We expect probability sensitivity for the $5 outcome to be greater between Gamble D and C than between Gambles B and A. This greater probability sensitivity will result in the PWF exhibiting additional reference points. We demonstrate this empirical observation in 5 preregistered experimental studies and in a model-based approach. Study 1 applied a fine-grained approach by examining the probability spectrum from 0% to 100%. We found that preference for the riskier option was significantly lower when the probabilities of the common outcome had different left digits. This suggests increased probability sensitivity when the probability of the common outcome crosses a categorical boundary.

In Study 2, we tested whether these boundaries were fixed within the probability space using two gamble ladders. Because categorization is an emergent property of the stimulus context (Rosch, 1999), we surmise that the boundaries are not necessarily fixed at every left-digit jump. We observed probability sensitivity when crossing categorical boundaries. Importantly, our results indicate that the shape of the PWF changes dramatically based on the where the left-digit jumps occur across the probability shape. This implies that the shape of the PWF is not fixed, rather it can have multiple discontinuities that depend on the particular context.

Studies 3, 4a, and 4b demonstrated the robustness of our previous findings. Study 3 tested this categorical-based account in an incentive-compatible context. Consistent with the previous studies,

we observed a similar dip in preference for riskier options (i.e. increased probability sensitivity) when the common payout probabilities crossed categorical boundary.

Whereas all other studies involve choices between risky gambles, Studies 4a and 4b employed certainty equivalents. Specifically, in Study 4a, the probabilities we used clustered around the 50% range. Importantly, results from this study suggest that 50% was treated as a categorical boundary, and probabilities below 50% would be subjectively perceived to be substantially less likely to occur than those just above the 50% boundary. Further demonstrating the robustness of this finding, we replicated this when the probabilities were clustered in the 30% range in Study 4b.

Supplementing our experiments, we also introduced a novel two-parameter model of the probability weighting function that parsimoniously accounts for our empirical findings.

The shape of the PWF is one of the most well-known empirical observations in judgment and decision-making research, with important implications for a host of topics within consumer research. Our key contribution is that we reconsidered the nature of how consumers categorize uncertainty, our results put forth a simple but powerful point: the PWF is crucially shaped by categorical perceptions, and the function needs not be inverse S-shaped.

SESSION OVERVIEW

Will Bitcoin keep going up? How good is this restaurant with mixed reviews? Will the owner of the house accept my price offer? We frequently face uncertainty and risk in various aspects of our lives. However, not all types of uncertainty are equal – decisions and judgments under uncertainty often diverge in different contexts. The papers in this session offer a nuanced perspective on certainty by investigating and disentangling the effect of different types of uncertainty on consumer judgments, inferences, and decision making. They further look at consumer risk taking tendency in important marketing contexts that involve uncertainty and show how consumer behavior may deviate from the predictions of standard decision-making models.

In the first paper, **Fox, Tannenbaum, Ulkumen, Walters, and Erner** investigate attributions of credit, blame, and luck associated with (in)correct predictions about the outcomes of uncertain events by distinguishing two dimensions of uncertainty, namely, *epistemic* (knowable) and *aleatory* (random). They show that epistemic uncertainty is associated with attributions of credit or blame for correct or incorrect predictions, while aleatory uncertainty is associated with attributions of good or bad luck for correct or incorrect predictions. This difference in attributions has important implications for choice of compensation schemes and how people communicate better or worse than expected outcomes.

In the second paper, **Wang, Shiri, and Janiszewski** differentiate between product outcome uncertainty (e.g., uncertain of what color this hair dye will result in) and preference uncertainty (e.g., uncertain of what hair color I want). Contrary to prior findings that preference uncertainty makes consumers reluctant to commit to a single option, the authors find that when the product option has uncertain outcomes, preference uncertainty inflates the perceived probability of preference match and thus increases purchase intention.

The next two papers examine consumer risk-seeking tendency under uncertainty in important marketing contexts. **Mehr and Lewis** investigate the uncertainty regarding product quality when customer ratings are inconsistent. By disentangling the effect of rating dispersion from the frequency of 1-star ratings, they show that consumers are risk-seeking with respect to attribute ratings and prefer experiences with inconsistent (vs. consistent) ratings across reviewers.

Lastly, **Zeithammer, Stich, Spann, and Häubl** examine another important context that involves uncertainty – participative pricing (i.e., consumers making price offers to sellers). When deciding whether to submit an offer, consumers experience uncertainty regarding the seller's secret threshold price and need to trade off the risk of offer rejection (given the participation cost) and the potential gain of offer acceptance. The authors find that consumers' entry decision not only deviates from the predictions of a risk-neutral model but is also inconsistent with the level of risk aversion implied by their submitted offer amounts. Instead, most participants show prospect-theoretic preferences with downside neglect – the opposite of loss aversion.

Taken together, the four papers in this session present distinct yet synergistic findings that advance our understanding of consumer judgments, inferences, and risk-taking tendency under different types of uncertainty, with implications for marketing strategy, communication, word of mouth, pricing, and policy making.

Attributions of Credit, Blame, and Luck Depend on Perceived Nature of Uncertainty

EXTENDED ABSTRACT

People routinely make predictions concerning the outcomes of uncertain events. For instance, financial analysts predict whether the price of a stock will increase, consumers predict whether a product will perform to their satisfaction, and doctors predict whether a treatment will be successful. The outcomes of these forecasts naturally trigger observers to interpret why the forecast was right or wrong and judge the forecaster accordingly.

In this paper we argue that the perceived nature of uncertainty plays a key role in these attributions. We distinguish between two dimensions of subjective uncertainty: *epistemic* uncertainty in which future events are seen as inherently knowable in advance (e.g., the answer to a trivia question) and *aleatory* uncertainty in which future events are seen as inherently random (e.g., the outcome of a dice roll). In six studies we demonstrate that people distinguish uncertainty along these two distinct dimensions. Epistemic (knowable) uncertainty is associated with attributions of credit for correct predictions and blame for incorrect predictions, whereas aleatory (random) uncertainty is associated with attributions of good luck for correct predictions and bad luck for incorrect predictions.

In Study 1 participants are presented with prediction scenarios involving a chance event, a trivia contest, or a hurricane trajectory. We show that a six-item scale concerning the nature of uncertainty loads reliably on these two distinct dimensions. Higher epistemicness ratings are associated with stronger attributions of credit or blame for correct or incorrect predictions, respectively (but are not associated with luck attributions). Meanwhile, higher aleatoriness ratings are associated with stronger attributions of good or bad luck for correct or incorrect predictions, respectively (but are not associated with credit or blame attributions).

Study 2 replicates this finding in an experimental context where we prompt participants to see predictions of the spread of COVID-19 through an epistemic lens (by asking participants to summarize a news story about contact tracing) or an aleatory lens (by asking participants to summarize a news story about biostatistics). We find that people attribute greater credit or blame to the health minister of a country when they are prompted to see the uncertainty around the spread of COVID-19 in that country as epistemic in nature, and good or bad luck when they were prompted to see it as aleatory in nature.

In Study 3 participants act as managers designing a compensation scheme for others making forecasts for different sporting events. When participants perceive uncertainty to be more epistemic (knowable) they allocate a greater proportion of compensation to performance-based pay (versus base pay), and when participants perceive uncertainty to be more aleatory (random) they choose longer (versus shorter) windows of evaluation.

In Study 4 participants evaluate two forecasters—one who makes a prediction using epistemic language (e.g., "I'm 80% sure that sales will increase") and another who makes the same forecast using aleatory language (e.g., "I'd say there's an 80% chance that sales will increase"). When both forecasters are correct, participants are more likely to promote the forecaster who uses epistemic ("sure") language than aleatory ("chance") language; however, when both forecasters are incorrect, participants are also more likely to lay off the forecaster who uses epistemic language. This finding suggests participants' perceptions of credit/blame are amplified by epistemic language whereas their perceptions of luck are amplified by aleatory language.

Switching from listeners' to speakers' perspective, in Study 5 we ask participants which type of language they would choose to express their own uncertainty—epistemic-related words (e.g. "I'm 80% sure) or aleatory-related words (e.g. "I'd say there's an 80% chance"). We find that participants are more likely to choose epistemic words when they are hoping for a promotion (and therefore presumably seeking an opportunity for more credit) but they are more likely to choose aleatory words when they are were worried about being laid-off (and therefore presumably seeking to avoid greater blame).

Finally, in Study 6 we examined 13,092 quarterly earnings report transcripts spanning almost three fiscal years (11 quarters), including 1,439 firms across different major stock indices. We coded each transcript for the proportion of epistemic and aleatory linguistic markers. We find a higher frequency of epistemic words (e.g., "assess," "predict," "model") when earnings exceed the consensus analyst forecast (and they are therefore presumably looking to claim more credit), and a higher frequency of aleatory words (e.g., "chance," "random," "black swan") when earnings fall short of the consensus analyst forecast (and they are therefore presumably looking to deflect blame and appeal to bad luck).

Taken together our findings suggest that perceived nature of uncertainty critically determines attributions of credit, blame, and luck by managers and consumers observing others' forecasts. Recognizing this, forecasters attempt to influence managers' and consumers' impressions of the nature of uncertainty through the language they choose to express their forecasts. We conclude with discussions of broader implications of our work and promising directions for future research.

When Preference Uncertainty Meets Outcome Uncertainty: InflatedProbability Estimates of Favorable Outcomes

EXTENDED ABSTRACT

Consumers regularly experience uncertainties in product choice and purchases (Duke, Goldsmith, and Amir 2018). Generally speaking, there are two types of uncertainties consumers often experience (Maier, Wilken, and Dost 2015). One is product outcome uncertainty (Grant and Tybout 2008; Rust et al. 1999), referring to the uncertainty associated with product performance or functioning (e.g., what color my hair will look like after using this hair dye) or the uncertainty involved in marketing offerings or promotions (e.g., probabilistic selling, mystery box, uncertain gifts). The other type is preference uncertainty (Payne, Bettman, and Johnson 1992; Salisbury and Feinberg 2008), referring to the uncertainty associated with one's preferences, needs, or desires (e.g., what hair color I want). Note that these two types of uncertainty differ in their sources, where outcome uncertainty comes from the external products while preference uncertainty is more associated with the self (Van den Bos and Lind 2002).

Contrary to prior findings that preference uncertainty makes consumers reluctant to commit to a single option (Dhar 1997), we suggest the opposite happens when the product option involves outcome uncertainty. Specifically, when there is outcome uncertainty (e.g., a coffee pack without a clear intensity indicator), consumers with uncertain (vs. certain) preference (e.g., uncertain about their preferred intensity level), perceive a higher probability that the product outcome would match their preferences (e.g., getting a pack of coffee at their most preferred intensity level). Consequently, a consumer with an uncertain (vs. certain) preference is more likely to purchase a product bearing an uncertain outcome. Building on the sampling model of probability judgment (Sloman et al. 2004; Zhu, Sanborn, and Chater 2020), we suggest this occurs because the subjective probability of preference match (under outcome uncertainty) is a function of the number of unique "samples" of preference match people can mentally simulate. Specifically, when preference is certain, only one unique "sample" could be drawn (e.g., I like low-intensity coffee most→preference match happens only when the coffee turns out to be low-intensity). On the contrary, when one's preference is uncertain, more unique "samples" could be drawn (e.g., if I like low-intensity coffee most and the coffee turns out to be low-intensity => match, if I like moderate-intensity coffee most and the coffee turns out to be moderate-intensity => match). As a result, the subjective probability of preference match is higher when preference is uncertain (vs. certain), although, normatively, this probability should be independent of preference uncertainty.

Study 1 (N=101) tests the association between preference uncertainty and perceived likelihood of preference match for a typical product involving outcome uncertainty – blindbox. Participants saw six styles of Bearbrick figurines from a blindbox series. Each blindbox contains one figurine randomly selected from six styles. Then, participants rated the likelihood of getting a figurine they liked most if they purchased a blindbox, preference uncertainty among the 6 figurines, and overall attractiveness of the figurines. As expected, perceived likelihood of preference match was positively associated

with preference uncertainty (p=.008), controlling for the attractiveness of the figurines.

Studies 2a and 2b manipulate preference uncertainty and outcome uncertainty (between-subjects) and show that preference uncertainty increases (decreases) the perceived likelihood of preference match and purchase intention for products with uncertain (certain) outcomes. In study 2a (N=198), participants imagined that their favorite coffee brand just released a new collection, involving coffees with different intensity levels (from level-5 to level-9). The only buying option available at the time was either a coffee pack randomly selected from the 5 intensity levels (the uncertain outcome condition) or a level-7 coffee (the certain outcome condition). To manipulate preference uncertainty, we either told participants that they felt uncertain which intensity level they would like given that this was a new collection (uncertain preference condition), or that they usually liked level-7 given their prior experience with coffees from this brand (certain preference condition). Results showed that when the intensity level of the coffee (the outcome) was uncertain, participants with uncertain (vs. certain) preference were more likely to purchase the coffee pack (p=.002). Perceived likelihood of preference match mediated this effect (p=.031; 95%CI=[.01,.82]). When the intensity level of the coffee is certain, however, preference uncertainty reduced perceived likelihood of preference match, which in turn reduced purchase intention (95%CI=[-.02,-.73]). Study 2b (N=200) replicated the findings in a different context where participants imagined buying teal hair dye for Halloween. First, they saw different shades of teal color from light to dark and were led to feel either certain or uncertain which shade would look best on them. Then they saw a hair dye product and learned that it was available in one of the shades (certain outcome condition) or that it could result in different shades depending on the hair textures (uncertain outcome condition). As in study 2a, we found preference uncertainty increased (decreased) perceived likelihood of preference match and purchase intention when the outcome was uncertain (certain).

Study 3 (N=320) provides evidence for the underlying mechanism. Specifically, we argue that preference uncertainty inflates perceived probability of preference match by increasing the number of unique "samples" of preference match people could draw. If so, this effect should be more pronounced as the number of possible outcomes a product could result in increases (i.e., the number of unique samples increases). Study 3 used the same product as in study 1 except that we manipulated the number of figurine styles in the blindbox series (3 vs. 9). Participants imagined buying a gift for a friend and feeling either certain or uncertain which style their friend would love most. As expected, in the 9-style condition, preference uncertainty increases the estimated probability of getting the figurine their friend would like most (p<.001) and willingness to purchase the blindbox instead of looking for other stores (p<.001), and these effects were attenuated in the 3-style condition.

In sum, this research investigates the joint effect of preference uncertainty and outcome uncertainty and provides novel insights into probability judgment and consumer decision-making under the two types of uncertainty. In addition, it pinpoints the conditions where marketers can benefit from (creating) consumer preference uncertainty.

When Inconsistency is Good: Consumers' Risk-Seeking Response to Attribute Ratings

EXTENDED ABSTRACT

How do consumers think about consistency in ratings? Previous work is mixed: some work suggests that consumers prefer consistency (He and Bond 2015; Moon, Bergey and Iacobucci 2010; Sun 2012; Zhu and Zhang 2010), while other work suggests that consumers prefer inconsistency (Clemons, Gao and Hitt 2006; Moe and Trusov 2011; West and Broniarczyk 1998). Why are there conflicting results? We suggest that previous literature has confounded rating dispersion with the frequency of 1-star ratings. Because consumers take 1-star ratings most seriously, consumers prefer a product with a given average rating when the ratings are less dispersed (so there are fewer 1-star ratings). In our work, by showing participants *attribute* ratings (e.g., ratings of the service, food, value, and ambiance of a restaurant), we can manipulate the consistency of how each attribute is rated while controlling for the overall frequency of ratings of each star value. We find consumers largely prefer inconsistent ratings. This is because they have high expectations and, consistent with risk-seeking in losses (Kahneman and Tversky 1979; West and Broniarczyk 1998), are risk seeking with respect to low ratings.

Study 1 tested whether consumers prefer experiences with consistent or inconsistent attribute ratings. Participants (N=1,186) saw ratings for two of six experiences, pretested to include both pleasurable (e.g., reading a book) and unpleasurable (e.g., going to the dentist) experiences. For each experience, participants saw ratings from two users and were randomized to either the consistent or inconsistent condition. In the consistent condition, the user reviews were similar; both users rated one attribute particularly negatively, and another attribute particularly positively. In the inconsistent condition, the user reviews differed; one user rated one attribute particularly poorly (and the other attribute particularly positively), and the other user provided the opposite ratings. We counterbalanced which attribute was rated poorly and measured preferences via three 7-point scale questions that were standardized and averaged for analyses. Participants found the consistently rated option less favorable (M = 5.42, SD = 1.78) than the inconsistently rated option (M=5.67, SD=1.43; b=-.13 t(1185)=-3.43, p<.001).

Our proposed explanation is that consumers are risk seeking in losses (Kahneman and Tversky 1979). Inconsistent ratings are less diagnostic of the experience, and thus more uncertain or risky. If consumers have high reference points, then they are in the loss domain when ratings are below 5 stars and prefer the riskier inconsistent ratings. If this were true, then inducing a lower reference point should reduce the preference for inconsistent ratings. In Study 2, participants (N=1,560) were randomly assigned to one condition in this 2(rating consistency: consistent vs. inconsistent) x 2(expectations: low vs. high) between-subjects experiment. To manipulate expectations, all participants read that the average rating of dentists in a town was either low (e.g., 1.33/5 stars) or high (e.g., 4.67/5 stars). Participants then saw one experience, either with consistent or inconsistent ratings (as in Study 1). We found a significant interaction between expectations and ratings type (b=.43, t(1,555)=4.22, p<.001). Participants within the high expectations condition preferred inconsistent (M=4.42, SD=1.56) to consistent ratings (M=3.80, SD=1.65; t(784.69)=-5.10, p<.001, d=-.36), while there was no significant difference by condition within the low expectations condition (consistent: M=3.93, SD=1.63; inconsistent: M=3.86, SD=1.53; t(768.22)=.93, p=.35, d=.07).

Why do our results suggest consumers like inconsistent ratings, while some previous work suggests the opposite? If consumers perceive 1-star ratings as particularly diagnostic and thus aversive, then previous work confounding dispersion and the frequency of 1-star ratings could have mistaken aversion to 1-star ratings for preferences for consistency. Study 3 tests this hypothesis. Participants (N=1,049) were randomly assigned to either a consistent, inconsistent, or consistent-middling condition. The consistent and inconsistent conditions

were as in Study 2. In the consistent-middling condition, both users rated every attribute as 3-stars (so the average attribute rating was 3 stars in all conditions). Participants found the consistent-middling condition (M=4.60, SD=1.36) more favorable than the consistent condition (M=4.06, SD=1.61; t(686.33)=4.10, p<.001, d=.31), supporting the possibility that consumers perceive ratings non-linearly, and 1-star ratings are particularly disliked. Participants also found the inconsistent condition (M=4.92, SD=1.36) more favorable than both consistent conditions (vs. consistent: t(689.66)=7.95, p<.001, d=.60; vs. consistent-middling: t(694.71)=4.15, p<.001, d=.31), consistent with previous risk seeking behavior.

Lastly, Study 4 tests one key facet of our proposed mechanism: that participants are risk-seeking with respect to ratings. To achieve this, we included a pure-risk condition in addition to our usual consistent and inconsistent conditions; participants were randomly assigned to one of these three conditions. We used the stimuli from the dentist experience in Study 1, which showed ratings of staff helpfulness and staff friendliness. In all conditions, participants (N=1,019) viewed ratings from two users. In the inconsistent condition, participants viewed inconsistent ratings for one staff member with whom they would interact if they went to this dentist. In the consistent condition, participants viewed consistent ratings, also for one staff member with whom they would interact if they went to this dentist. The pure-risk condition stimuli showed that one user rated both attributes positively for one staff member, while the other user rated both attributes negatively for a different staff member. Participants in this condition learned that there was a 50% chance that they would interact with each staff member if they went to this dentist. Thus, this condition reflected a 50%-50% lottery between a bad and good experience. Participants preferred the pure-risk (M=4.76, SD=1.51) and inconsistent ratings (M=4.66, SD=1.52) conditions to the consistent condition (M=4.14, SD=1.73; vs. pure-risk: t(671.31)=3.53, p<.001, d=.27; vs. inconsistent: t(669.05)=3.99, p<.001, d=.31); there was no significant difference between the pure-risk and inconsistent conditions (t(678.93)=.64, p=.65, d=.04). These results are consistent with consumers preferring inconsistent ratings due to risk-seeking preferences.

Overall, controlling for the number of 1-star ratings, consumers prefer inconsistent (vs. consistent) ratings due to a high reference point and consequently risk-seeking preferences.

Risky Consumer Decision Making in Costly Participative Pricing

EXTENDED ABSTRACT

Consumers make price offers to sellers in a variety of domains, including buying cars and houses, buying used household goods in physical and virtual garage sales, naming hotel-room prices on Priceline.com, making offers to buy trendy items on StockX.com, and bidding in auctions for art or collectibles. Participative pricing—i.e., consumers making price offers that sellers then either accept or reject—occurs in many markets and has recently expanded in scope due to increased digitalization.

Sellers and intermediary platforms may provide consumers with decision aids to assist them in deciding how much to offer, and whether to make an offer in the first place. One of the reasons why consumers might not submit offers on products that they are interested in buying is that preparing and submitting such offers is associated with mental and physical costs, which are a key source of friction in participative-pricing markets. Indeed, prior research has identified several sources of such participation costs—the cognitive and physical effort associated with offer preparation (e.g., Krasnokutskaya and Seim 2011; Samuelson 1985), the hassle associated with submitting the offer and waiting for the outcome (e.g., Fay 2009; Hann and Terwiesch 2003), and the accounting cost arising from various fees and commissions charged by marketplace intermediaries (e.g., Bernhardt and Spann 2010; Moreno and Wooders 2011; Palfrey and Pevnitskaya 2008).

Price offers represent a key feature of participative pricing whereby consumers actively participate in determining their purchase price (e.g., Haruvy and Popkowski Leszczyc 2018; Spann et al. 2018). An essential yet widely unexplored aspect of this form of pricing is that participation is often costly. In this paper, we examine the impact of participation costs on consumers' entry and offer behavior across four incentive-compatible experiments, each of which used extensive within-subject designs. The behavior of interest consists of two nested consumer decisions—(1) how much to offer (or "bid"), and (2) whether to make an offer at all, a decision that is typically referred to as an "entry decision" in the auction literature (e.g., Ertaç et al. 2011; Levin and Smith 1994; McAfee and McMillan 1987; Palfrey and Pevnitskaya 2008)

In our experiments, participants were buyers of "widgets" (imaginary products) in a market with only one seller. The widget seller was computerized and entertained offers, effectively allowing buyers to name their own price. To decide whether an offer was accepted, the seller drew a secret (to participants) threshold price. Offers that exceeded the threshold price were accepted, whereas offers below it were rejected.

In a (typical) round of one of our experiments, the consumer could submit a binding price offer to the simulated seller, and the seller's threshold price determined whether the bid was accepted. This single-agent decision is an ideally tractable setting for gaining insight into consumer decision making in connection with price offers and costly entry, because the analysis does not need to consider strategic interaction among multiple endogenously determined bidders as it would in a multi-bidder auction with entry costs, as in those analyzed by Samuelson (1985) or Menezes and Monteiro (2000).

Nevertheless, participants in our experiments faced strategic uncertainty because they did not know the threshold price set by the seller. Therefore, they did not know a priori whether their offer would be successful (i.e., accepted by the seller). Consumers could make offers that were too low (resulting in a failure to purchase the product), or they could make offers that exceeded the seller's secret threshold prices (thus spending more than would have been necessary).

The offer amount affects both the probability that an offer is accepted and the consumer surplus. While a higher offer increases the probability that an offer is accepted, it also reduces consumer surplus if it is accepted. Thus, consumers must decide how to trade off their potential surplus and the probability of offer acceptance. Moreover, in the presence of participation costs, deciding whether to submit an offer involves comparing the expected utility of the payoff from bidding to the utility of neither getting nor losing anything.

Overall, evidence from our experiments reveals that consumers not only deviate from the predictions of a risk-neutral model (that is often employed for its tractability), but that their behavior also cannot be explained by the standard risk-averse expected utility model. In particular, entry is excessive given the level of risk aversion implied by consumers' submitted offers. We develop and estimate a heterogeneous flexible utility model to parsimoniously connect the entry and offer-amount decisions. The model estimates suggest the majority of participants exhibited prospect-theoretic preferences with downside neglect—the opposite of loss aversion.

Our experiments also examine the potential of various decision aids and decision architectures to shape consumer behavior in costly-participative-pricing settings, in terms of both decision processes and outcomes (i.e., consumer surplus). We find that decision aids help consumers achieve a higher surplus only when the decision architecture entails two stages—i.e., when the offer-amount and entry decisions are distinct and made sequentially. The most beneficial decision architecture asks the consumer to make the decision following backward induction, starting with the contingent offer amount. However, this theoretically appealing architecture only helps when consumers have access to a decision aid. Overall, decision aids reduce downside neglect. Moreover, they reduce probability misperception and are a substitute for learning from experience. Finally, we show that framing the entry decision as a choice to play a payoff-equivalent lottery aligns consumers' entry decisions with the risk-aversion evident from their offers.

SESSION OVERVIEW

Time is a precious and scarce resource (Mogilner et al., 2018), so understanding how to efficiently manage time is key to building a healthier and happier life, both personally and professionally.

This session brings together four papers that examine different aspects of time and its implications for productivity and well-being using a variety of methods. The first two papers provide insights into how gaining and talking about time affect productivity. The last two papers examine how asking for extensions during work and choosing how to spend time outside of work impact real and perceived productivity, worker evaluations, and well-being.

Tonietto et al. investigate how consumers perceive and consume time windfalls; time gained from cancelled tasks. Gained time could be used as productively as any other time. Yet, the authors show that consumers move at a slower pace during gained time, because they perceive it as longer than equivalent intervals that were always free. Consequently, consumers may fail to maximize the use of gained time.

Abreu et al. examine how consumers talk about time following goal failures. They show that consumers tend to attribute goal failure to lack of time instead of considering that they could have "made time". The authors highlight that self-talk about time in response to failures such as "*I did not make (vs. have) time…*" can induce greater feelings of control and thus increase future goal achievement.

Whillans et al. examine how frequently women (vs. men) *ask* for time can cause gender disparities in work-related success and well-being. Despite women experience greater time stress than men, when working under adjustable deadlines, they are less likely to ask for extensions. This may have implications for gender inequalities in the workplace and for well-being. The authors propose that introducing formal policy requests for extensions can help women to be less fearful of social repercussions when asking for extensions.

Buechel et al. focus on how consumers spend their free time influences worker evaluations. They show that lay people and managers acknowledge the benefits of detachment during non-work time for productivity, yet they penalize workers who detach from work

during non-work time when evaluating them. Workers seem to be aware of this penalty and tend to detach less from work when evaluation is salient, and also signal non-detachment when sharing information about spare time with managers. Like Whillans et al., they test how company policy interventions can a) attenuate this detachment penalty and b) encourage detachment from work during free time.

Taken together, these four papers provide novel, diverse, and complementary insights via a variety of methods. Moreover, the current set of papers session provides an excellent fit for the conference theme "What the World Needs". Our session speaks to work-life balance, gender disparities in the workplace, and how to maximize productivity in our professional and personal lives. We believe that our session would be of interest to consumer researchers from all backgrounds and will produce a fruitful interdisciplinary discussion that will encourage more research in the area.

Gained Time is Expanded

EXTENDED ABSTRACT

Scheduled tasks get cancelled, and even global pandemics can lead quarantined consumers with unexpected windfalls of free time. While prior research has examined how gained money is spent (Arkes et al., 1994; Soman and Cheema 2001), and the subjective value of gained time (Festjens and Janiszewski 2015), we examine the perception and consumption of windfalls of time.

Importantly, having plans and then losing them constitutes a change to the status quo in which the consumer gains free time. Separately, because the Weber-Fechner function attests to diminishing subjective magnitude with greater deviation from the status quo (Fechner, 1966/1860), we propose that because windfalls of time register as a change from a reference point of no free time, gained time intervals feel subjectively expanded compared to intervals that were always free.

Further, because time perception can drive behavior within intervals (Tonietto, Malkoc, and Nowlis 2019), we predict that people will slow down during gained intervals. Just as "work expands to fill the objective time available" (i.e., Parkinson's Law; Parkinson 1957), we propose behavior will expand to fill the *subjective* time available.

As an initial foray into examining whether gained time feels expanded, a pilot study revealed that the time earmarked for a cancelled class felt longer the more that students thought of the time as a gain (r=.17, p=.052).

Building on this, Study 1 utilized a 4-cell (gained, free, scheduled, control) between-subjects design. Participants in the gained condition read that they had plans during the next hour that were cancelled, leading them to unexpectedly gain an hour of free time. Those in the free condition instead read that they had the next our free, and those in the scheduled condition read that they had plans for the next hour. They then indicated how much time the next hour felt like (0=very little time, 100=a lot of time). In the control condition, participants simply indicated how much time an hour feels like. The gained hour (M=57.53) felt significantly longer than an hour that was always free (M=43.91), always scheduled (M=40.06), or an hour in general (M=35.43, all *p*s<.001).

In Study 2, we tested whether the subjective expansion of gained time is robust to consumers' affective reactions toward the windfall in a 3-cell (gained-relieved, gained-disappointed, free) between-subjects design. Participants in the gained conditions imagined that

their scheduled plans for the next hour had been cancelled and that they either felt relieved or disappointed by the cancellation of the task accordingly. Those in the free condition imagined that they had the next hour free. Compared to free time (M=46.91) gained time felt subjectively longer both when participants felt relieved (M=66.05, *p*<.001) and when they felt disappointed at the cancellation of the task (M=60.39, *p*<.001). The two gained conditions did not significantly differ (*p*>.1). Thus, emotions towards the cancellation of the activity cannot account for the full effect.

Study 3 explicitly tested whether the elongation of windfalls of time are due to the salient comparison to no free time with a 2 (gain, free) x 2 (control, zero reference) between-subjects design. Participants imagined either that they gained two hours or that they had the next two hours free. In the control conditions, participants were asked: "How much time does the next two hours feel like?" while those in the zero reference point condition were instead asked "Compared to no free time, how much time does the next two hours feel like?" We found the predicted interaction (*p*<.01). In the absence of a reference point, the gained interval once more felt expanded (M_{Gained}=60.55, M_{Free}=46.62, *p*<.01). However, when zero was given as a reference point, both the free and gained intervals felt expanded, (M_{Gained}=63.09, M_{Free}=59.80, *p*>.10). Thus, explicitly comparing to zero led free time to feel like gained time, supporting our proposed framework.

The final three studies examined whether individuals alter their pace of movement during gained intervals. Participants in Study 4a responded to questions about how they behaved on the Sunday that daylight saving ended (in which Americans gained an hour). They indicated whether they took their time and moved more slowly (0=took my time much less/much faster pace, 100=took my time much more/much slower pace) compared to an average Sunday. Compared to the scale mid-point, participants reported moving more slowly (M=55.64, *p*<.001) on a Sunday they gained time. In Study 4b, we examined another naturally occurring time gain: the CO-VID-19 pandemic in which many people's everyday routines were disrupted, leading them to feel they gained time (as confirmed by a pretest). Participants reported perceived time and pace of action for a "typical Tuesday afternoon" both before and after the U.S. began to shelter-in-place. Overall, a typical Tuesday afternoon felt longer (M_{After}=64.32, M_{Before}=52.66, *p*<.001) and was marked by a slower pace of action (M_{After}=67.51, M_{Before}=53.15, *p*<.001) after compared to before shelter-in-place. Further, these effects were exaggerated the more that participants were adhering to quarantine, and thus the more their routines were disrupted by the pandemic.

Study 5 manipulated gained time by having participants sign up for a 30-minute experimental session that was actually designed to take 20 minutes. Participants were either told at the start of the session that they would end early (free) or were told at the end of the session that they had finished early and thus gained time (gain). All participants were then informed that on their way out, there were boxes from which they could take items (e.g., candy, toys) if they wanted. A research assistant recorded the time it took for each participant to leave the lab and reach the elevator at the end of the hall and whether participants stopped at the box.

Participants took significantly longer to leave the lab in the gained (M=29.99 seconds) than free condition (M=25.20 seconds, *p*=.011). Those in the gained condition (65.79%; 100/152) were also more likely to search the box of items compared to the free condition (54.61%; 77/141; *p*=.051).

Taken together, our results indicate that gained intervals feel subjectively expanded, and consumers' behavior expands to fill the subjective time available.

I Don't Have Time for This: How Self-Talk Following Goal Failure Affects Control and Future Goal Achievement

EXTENDED ABSTRACT

For many consumer goals, spending time is a prerequisite for goal achievement. Goals related to physical health, professional success, and personal wellbeing all require substantial investments of time to achieve. But because time is limited (Etkin, 2019; Spiller, 2011) and prone to mismanagement (Fernbach, Kan, & Lynch, 2015; Memmi & Etkin, 2021), people often fail to spend time on goals as intended. Might the way consumers talk about such goal failures matter? Might the language people use influence their understanding of these lapses and propensity to achieve the goal in the future?

Recent work suggests that self-talk (i.e., a conversation with oneself; Senay, Albarracín, & Noguchi, 2010) has important effects on goal achievement. Self-talk can improve athletic performance (Hatzigeorgiadis et al., 2011), help avoid temptation (Patrick & Hagtvedt, 2012), motivate goal-directed behavior (Senay et al., 2010), and improve self-regulation (Kross et al., 2014). Building on this prior work, we examine self-talk following goal failure (vs. prior to goal pursuit) that references a lack of resource—namely, time. We contrast the phrase "I didn't *have* time to pursue my goal" with the phrase "I didn't *make* time to pursue my goal", exploring effects on what people talk about (i.e., what topics or reasons they cite) and implications for feelings of control and future goal achievement.

We suggest that when confronted with goal failure, consumers naturally attribute the failure to a lack of the resource (not "having" time) rather than a mismanagement of the resource (not "making" time). This occurs because doing so is self-protective: it prevents consumers from negative emotions related to being at fault for the failure.

But importantly, we propose that this attribution has a downside, prompting people to talk about the lapse in a way that undermines subsequent goal achievement. This is because saying they didn't "have" time for the goal encourages consumers to think about what they *did* spend time on—that is, other goals or activities that also require time to pursue. Saying they didn't "make" time for the goal, in contrast, reduces attention to competing uses of time and focuses people on actions that could be changed or improved (e.g., procrastination, being lazy, not using time efficiently). Consequently, compared to saying "I didn't have time", saying "I didn't make time" increases people's sense of control over outcomes and makes them more likely to achieve their goal in the future. Six studies support these ideas.

In studies 1A and 1B, we examine the prevalence of "have time" (vs. "make time") using data from Twitter and a large corpus of text containing over one billion words (Davis, 2008). In Twitter, we scraped all tweets within the last seven days with the phrases "I didn't have time" or "I didn't make time" and counted the number of occurrences. In the large corpus, we searched for all the verbs that appear immediately before the word "time" ("have" was the most prevalent). In both the Twitter, $\chi^2(1) = 3571.4$, *p* <.001, and corpus data, $\chi^2(1) = 11471.1$, *p* <.001, consumers were far more likely to use the phrase "have time" versus "make time."

In study 2, we explored why consumers might prefer "have time" (vs. "make time") framing. We asked participants ($N = 500$) to imagine saying they didn't have or make time for a goal. Then, they reported the negative emotions they anticipated feeling (i.e., guilty, blameworthy, bad, discouraged, nervous, tense). Consistent with the idea that "have-time" (vs. "make-time") is self-protective, compared to saying "I don't have time" ($M = 3.91$, $SD = 1.45$), participants anticipated saying "I don't make time" would be more emotionally aversive ($M = 4.31$, $SD = 1.34$, $t(498) = 3.20$, $p = .001$, $d = .29$.

In studies 3 and 4, we test whether "have time" (vs. "make time") framing affects how people understand a prior failure to spend time as intended and resulting feelings of control. Study 3 is a meta-analysis of 10 studies using similar methods ($N = 3,168$). In all studies, participants described a goal that they currently held but that they had not made progress on last week. Then, they wrote a sentence based on the prompt "I did not make time for my goal because…", or "I did not have time for my goal because…". We text analyzed the responses to this prompt using structural topic modeling. Controlling for study fixed-effects, "make time" (vs. "have time") led to fewer references to competing demands on time (e.g., topics related to home, work, and busyness) and to more references related to procrastination, laziness, and not using time effectively (all $ps < .001$). In study 4 ($N = 301$), we again framed a recent goal failure as not having (vs. making) time and measured perceptions of control over goal outcomes. Participants in the "make time" (vs. "have time") condition perceived significantly more control ($M = 3.90$, $SD = .69$ vs. $M = 3.72$, $SD = .65$), $t(299) = 2.24$, $p = .025$, $d = .30$.

In study 5, we test behavioral consequences of "have time" vs. "make time" self-talk in the field. Participants ($N = 600$) were recruited on a Friday and asked to meditate three times over the weekend. On Monday, we recontacted participants. Participants who failed to meditate on at the least one of the three days ($n = 221$) wrote about why they didn't make or have time to meditate over the weekend. On each of the three days following the manipulation, participants reported whether they had meditated that day or not. 208 participants responded to at least one of the three follow-up surveys. Controlling for behavior before the manipulation, participants in the "make time" (vs. "have time") condition meditated significantly more during the next three days ($M = 2.45$, $SD = .85$ vs. $M = 2.30$, $SD = .99$), $F(1, 160) = 4.81$, $p = .029$, $\omega^2 = .02$.

Together, our findings advance understanding of how self-talk shapes goal achievement and has implications for how managers, coaches, and consumers can overcome prior failures to spend time.

Extension Request Avoidance Increases Time Stress Among Women

EXTENDED ABSTRACT

Women experience greater time stress than men: they are more likely to feel like they have too many things to do and not enough time to do them. Given the association between time stress, burnout, and poor work performance, this difference may have implications for gender disparities in work-relevant success and well-being (see Whillans et al., 2020).

Time stress at work results in part from tight deadlines (Buehler et al., 2002). Some deadlines are strict: once a deadline has passed, taking any action related to the task is impossible or costly. However, many everyday work tasks are subordinate tasks—smaller actions that must be completed to achieve a larger goal (Cropanzano et al., 1993), which are less likely to incur deadline adjustment costs. Initial research suggests that asking for more time on adjustable deadlines at work can reduce feelings of time stress (Yoon et al. under review). Given that women juggle more tasks, requests to extend deadlines could be a particularly beneficial option.

Despite the potential benefits, women could be especially likely to avoid requesting extensions due to heightened interpersonal concerns. Women tend to be more relationally oriented and sensitive to the needs of others as compared to men. Relationally oriented individuals tend to be more attuned to social costs, which can deter such individuals from requesting additional resources, such as monetary compensation (Amanatullah et al., 2013). Due to these concerns, women should be less willing to make extension requests than men.

We further propose a means to alleviate women's discomfort towards making extension requests at work: introducing formal policies for requesting an extension. Removing ambiguity can reduce gender differences in negotiation (Bowles et al., 2005). Building on this research, we propose that reducing ambiguity by establishing a formal policy around extension requests could mitigate the proposed gender differences in asking for more time on adjustable deadlines. To explore these Hypothesis, we conducted eight studies (three pre-registered) using a variety of methods including two field studies and a total of 5,142 working adults and students.

Study 1. We recruited adults who worked at least 21 hours a week outside the home ($N=575$; 42.1% female). As predicted, women felt less comfortable making extension requests on adjustable deadlines at work than men, $\beta = -0.38$, $P < 0.001$, 95% CI (-0.55, -0.21). This gender difference held controlling for covariates including with comfort with delegating tasks, age, tenure, and industry, $\beta = -0.40$, $P < 0.001$, 95% CI (-0.56, -0.23). As expected, women also reported experiencing more burnout than men, $\beta = 0.27$, $P = 0.001$, 95% CI (0.11, 0.44). A serial mediation revealed that gender differences in burnout were partially explained by women's greater experience of time pressure (from $\beta = 0.27$, $P = 0.001$ to $\beta = 0.21$, $P = 0.015$), 95% CI IDE (0.05, 0.30), which in turn was explained by their discomfort with requesting extensions for adjustable deadlines (from $\beta = 0.27$, $P = 0.001$ to $\beta = 0.11$, $P = 0.158$), 95% CI IDE (0.004, 0.14).

Studies 2a-c. Working adults imagined feeling highly pressed for time on a work task and being able to ask for an extension from their direct supervisor. Based on this imagined interaction, participants answered how comfortable they would feel requesting an extension. In Study 2a ($N=651$), women felt less comfortable requesting a deadline extension than men, $d = -0.24$, $P = 0.002$, 95% CI (-0.40, -0.09). Women were more relationally oriented ($p < 0.001$). Thus, they expected that requesting a deadline extension would result in greater impression costs, $d = 0.26$, $P = 0.001$, 95% CI (0.12, 0.43). These findings held regardless of the lower vs. higher work status of the employee (Study 2b; $N=599$) or manager gender (Study 2c; $N=600$).

Study 3. Participants ($N=872$) took on the role of the supervisor and imagined themselves in the scenario from Studies 2a-2c. To enhance the ecological validity of our design, participants imagined being a manager and having this interaction with a direct report that they actually worked with at their current jobs. Supervisors evaluated female and male employees who requested a deadline extension as equally competent and motivated, $d = -0.05$, $P = 0.418$, 95% CI (-0.19, 0.08). These results suggest that, contrary to female employee's expectations, supervisors do not disproportionately judge women more negatively for requesting an extension.

Study 4a-5. First, we conducted Studies 4a&b ($N=103$; $N=467$)—two correlational field studies. In these studies, women were more likely to ask for more time when a formal policy was in place. Building on these results, we experimentally examined whether formal policies could reduce gender differences in extension requests among college students ($N=975$). Depending on condition assignment, participants were given no additional information (Control), reminded that they may ask for more time by sending the instructor an email (Informal Request), or reminded of a school-wide policy that would allow them to ask for more time by sending the instructor an email (Formal Policy Request). We then measured students' willingness to ask for an extension, their predicted impression costs, and their trait relational orientation.

Female students who were assigned to the Informal Request condition were significantly less willing to ask for an extension as compared to male students, $d = -0.47$, $P = 0.002$, 95% CI (-0.69, -0.24). Female students who were assigned to the Control condition also reported being less willing to request an extension than the male students, $d = -0.45$, $P = 0.001$, 95% CI (-0.67, -0.22). Critically, when students were informed of a formal policy, female students were equally likely as male students to make an extension request, $d = 0.10$, $P = 0.959$, 95% CI (-0.13, 0.33). Once again, having a formal policy allowed relationally oriented individuals to be less fearful of social repercussions when asking for extension requests.

These findings shed light on a previously unstudied contributor to women's experience of time stress: their reluctance to ask for more time. Compared to men, women feel less comfortable asking for more time, as they believe it will be more interpersonally costly.

Detachment from Work During Non-Work Time and Its Implications on Workers' Evaluation

EXTENDED ABSTRACT

The ongoing pandemic has further highlighted the importance of employee well-being via work-life balance. Among academics, work-life balance is operationalized as psychological detachment (i.e., the state of mentally disconnecting from work; Etzion et al., 1998).

Research on psychological detachment has documented its various benefits for employee productivity (e.g., higher work engagement and proactivity; Sonnentang et al., 2010; Sonnentang, 2003; Chong et al., 2020) and well-being (e.g., increased life satisfaction, lower burnout; Haun et al., 2018; Kuhnel et al., 2009; Fritz et al., 2010). At the same time, however, ingrained in our culture is the protestant work ethic (Weber, 1905). Western societies idealize long working hours (Bellezza et al., 2017) and labor is highly rewarded (Moreau et al., 2011; Morales, 2005; Schrift et al., 2011). For example, workplace surveys suggest that time spent at work– even not working– is associated with better job-related outcomes (Elsbach et al., 2010). Given these opposing forces, we test how managers perceive and evaluate workers who detach from work during non-work time, along with relevant consequences, in three parts:

A first set of studies suggest that people acknowledge the benefits of detachment during non-work time on productivity, yet those same people also penalize workers who detach in worker evaluations. In a 3(detachment vs. non-detachment vs. control) between-subject design, participants in Study 1 (N=311), evaluated a worker who went on a weekend get-away (control; no further information) and either left their work devices at home (detachment) or brought them along (non-detachment). Participants rated the worker on two dimensions: productivity (how relaxed, energized, motivated and productive the worker would be on Monday) and worker evaluation (likelihood of hiring, promotion, pay-raise, perceived commitment, and hard-work). They also indicated the extent to which they perceived the worker identified with their job (mediator). The detaching worker was rated as more productive than the non-detaching one ($M_{Detached}=5.63$, $M_{Non-deatched}=5.14$, $p=.002$), yet was evaluated more negatively ($M_{Detached}=4.67$, $M_{Non-deatched}=5.45$, $p<.001$). The control condition resembled the detaching condition for both ratings. The penalty on detaching workers was mediated by perceptions of being connected to their job (CI [.109;.389]). A replication with real managers (Study 1B; N=201, no control condition) shows similar awareness of the benefits of detachment for productivity ($M_{Detached}=5.80$, $M_{Non-deatched}=5.50$, $p<.001$), along with the penalty for worker evaluations ($M_{Detached}=5.00$, $M_{Non-deatched}=5.60$, $p<.001$).

Study 2 (N=301) uses the same scenario to test the strength of this effect by comparing a superior detaching worker (8/10 worker rating) to two inferior (7/10) detaching or non-detaching ones. Again, detaching workers were perceived as more productive than the non-detaching one ($M_{Detached\ 8/10}=5.79$, $M_{Detached\ 7/10}=5.59$, $M_{Non-deatched\ 7/10}=5.16$), yet they were both evaluated more negatively than the non-detaching one ($M_{Detached\ 8/10}=4.90$, $M_{Detached\ 7/10}=4.70$, $M_{Non-deatched\ 7/10}=5.50$). That is, a non-detaching, inferior worker received higher evaluations than a superior detaching one ($p<.001$).

A second set of studies examine whether workers are aware of the detachment penalty, and its implication for how they plan and communicate their free time. Study 3A (N=200) and 3B (N=200) manipulated whether participants have an upcoming evaluation or not (between-subject). Study 3A asked participants to select 3 out of 12 available detaching and non-detaching activities they'd like to plan for their weekend. Participants chose fewer detaching activities when the evaluation was imminent/salient ($M_{no-evaluation}=7.82$ $M_{evaluation}=7.07$, $p<.001$). Study 3B asked participants about the number of paid vacations they would request, which was lower when an upcoming evaluation was available ($M_{no-evaluation}=21.9$ $M_{evaluation}=17.6$, $p=.001$). Study 4 (N=200) manipulated whether participants' Instagram followers included their supervisor (yes vs. no; between-subject). Participants were presented with four pictures that depicted either detaching or non-detaching activities. They indicated their likelihood of posting each picture and chose one to post among them. A significant interaction emerged ($p=.002$), such that participants indicated higher (lower) likelihood of posting non-detaching (detaching) pictures when their supervisor was among the followers (Non-detach: $M_{supervisor}=4.00$ $M_{no-supervisor}=3.58$; detach: $M_{supervisor}=4.72$ $M_{no-supervisor}=5.12$). Similarly, more participants chose one of the non-detaching pictures if their followers included their supervisor (33% vs. 17%, $p=.007$). Thus, workers are aware of the detachment penalty and change their behavior accordingly.

These findings have important implications for worker evaluations and signaling behavior of employees. It is therefore critical to know if these effects can be mitigated. A final set of studies tests debiasing strategies. For both studies, we manipulated whether the company requires detachment (strong intervention), encourages detachment (weak intervention) or not (control; between subject). In study 5 (N=305), using the same procedure and evaluation measures as Studies 1-2, we replicate the difference in evaluation as a function of detachment in the control condition ($M_{detachment}=4.53$ $M_{nodetachment}=5.51$ $p<.001$) and in the weak intervention condition ($M_{detachment}=4.77$ $M_{nodetachment}=5.60$ $p<.001$), but not in the strong intervention condition ($M_{detachment}=4.99$ $M_{nodetachment}=5.31$ $p=.131$; interaction with control $p=.033$), suggesting only the latter intervention is successful in attenuating the effect. In study 6 (N=186), we use the same interventions of study 5 and sharing measures of study 4 for the condition that includes the supervisor. We see a significant interaction ($p=.007$), such that the presence of the strong intervention decreases the likelihood to post one of the non-detaching pictures, compared to both the control condition ($M_{nointervention}=4.04$ $M_{strong\_intervention}=3.09$ $p=.004$) and the weak intervention condition ($M_{weak\_intervention}=3.91$ $p=.014$).

Results suggest that both lay people and real managers recognize the benefits of detaching for productivity, yet they penalize workers who detach from work during non-work time when evaluating them. Workers are aware of this detaching penalty and thus tend to detach less and to hide their detaching activities. We advance a potential intervention to attenuate this effect on both sides.

While previous work has pointed out many benefits of psychologically detaching from work, our research highlights potential, and serious, negative consequences for worker evaluations. Our findings

have significant implication for how companies interact with their employees, and suggest concrete and implementable steps to create a better workplace and ensure employees' well-being.

SESSION OVERVIEW

This session offers a multi-method, interdisciplinary perspective on the many facets of ambivalence in the consumption domain, its underlying processes, and its outcomes. Ambivalence, the coexistence of positive and negative attitudes or beliefs towards a target, is common in consumers' lives. The large body of research on substances has long documented the coexistence of positive and negative beliefs about substances, whether legal (e.g., alcohol, cigarettes) or illegal (e.g., drugs). From meat to ugly fruits and vegetables, ambivalence is common across many food choices, which often entail both favorable and unfavorable consequences: great taste but highly caloric; poor taste but great health benefits (Buttlar & Walther, 2018). Further, many of the environmentally-related attitudes towards targets such as plastic, or organic or bio-based products, are laden with ambivalence.

Despite the prevalence of ambivalence across consumption contexts, consumer research related to ambivalence is surprisingly scant (notable exceptions include Nowlis, Kahn, & Dhar, 2002; Otnes et al., 1997; Roster & Richins, 2009). Given ambivalence's relevance to and prevalence across many of the big challenges that we face today, understanding how consumers experience and deal with ambivalence may offer novel solutions to affect positive behavioral change.

This session assembles four research programs focused on the many types of ambivalence that consumers encounter: ambivalence inherent to social dynamics in virtual communities (paper 1), ambivalence that underpins the factors facilitating or inhibiting consumers' decision to adopt new technologies (paper 2), the effect of ambivalence on consumers' interest in using risky products (paper 3), and attitudinal ambivalence in a context of distrust (paper 4). The session emphasizes diversity in the methodological approaches, with qualitative research (paper 1), cross-sectional survey research (papers 1 and 2), and experimental research, including neuroscientific laboratory as well as field studies (papers 3 and 4). We aim to show the value and complementarity of these approaches in enriching our understanding of the antecedents, processes, and outcomes related to ambivalence.

The session brings together scholars at multiple stages of their careers, including doctoral students (papers 2 and 4), recently minted PhDs (paper 1) as well as more seasoned researchers. All projects are at advanced stages but not yet published. Hence, the findings presented at ACR will be fresh and ready for discussion, feedback, and audience engagement.

Because there are four papers, we will dedicate the discussion portion to audience engagement. The session chair will invite questions from the audience and moderate the ensuing discussion.

Ambivalent Social Processes in Virtual Support Communities: A Mixed-Method Inquiry of Facebook Groups

EXTENDED ABSTRACT

Perhaps because support communities are usually defined as places where "one is loved and cared for by others, esteemed and valued, and part of a social network of mutual assistance and obligations" (Taylor, 2011, p. 192), research on Virtual Support Communities (VSCs) has primarily focused on their benefits (Bradford et al., 2017; Seraj, 2012). Yet, consumer research contains hints of negative social dynamics within communities, with reports of toxic, off-putting environments (De Almeida et al., 2014) and tensions that threaten community belonging (Thomas et al., 2013). In online contexts characterized by anonymity, invisibility, and asynchronicity (Niemz et al., 2005), people are disinhibited and less able to read social cues and respond to them appropriately (Wright, 2002). Because VSC members do not necessarily know each other personally and/or can 'hide' behind their online profile, comments and reactions are less filtered (Brown et al., 2007; Kozinets, 1999). Thus, it is no surprise that a recent Forrester survey indicates that as many as 37% of U.S. adults believe social media may be more harmful than beneficial (Forrester, 2020).

Our research intersects with the growing scholarly evidence of the duality of VSCs' social processes and with research on technology-related paradoxes to explore whether and how such processes coexist within VSCs and how they impact relational and engagement outcomes (Mick & Fournier, 1998).

Studies

We report the findings of two interrelated studies in the context of Facebook VSCs geared specifically toward health- and wellness-oriented goals. Goal-oriented VSCs are on the rise as people with similar interests "gather and communicate via digital technologies to support one another" (Bradford et al., 2017, p. 9).

Study 1 is a qualitative exploration of a goal-oriented nutrition-focused VSC made up of netnography and in-depth interviews with eleven members of the VSC (Kozinets, 2020). Supported by tacking back and forth to the relevant literature (Russell & Levy, 2012; Strauss & Corbin 1998), this first study informed a conceptual model of the processes through which members become socialized into a VSC that accounts for both the beneficial and harmful forms of support they may encounter therein. The emerging conceptual model of ambivalent social dynamics in which positive and negative com-

munity perceptions affect the three mediating processes of social empathy, social pressure, and social angst. In turn, these three affect the VSCs' informative value, the relationships members forge and maintain with the community, as well as the degree to which they engage within it. The ambivalent social dynamics experienced are captured via multiple paths from positive and negative perceptions of the community toward the relational and engagement outcomes of VSCs. We identify the multiple roles of the social pressure inherent in social communities. It may increase social empathy and the community's informational value as well as its engagement but also contribute to social angst.

In Study 2, we tested this model of social dynamics with cross-sectional survey data from 287 members of Facebook groups focused on health and wellness. Structural equations modeling of survey data reveals two alternative paths through which social dynamics unfold toward their ultimate outcomes in community engagement and relationships. A positive path driven by positive group perceptions and mediated through social empathy leads to a VSC's greater informational value and to stronger relational and behavioral outcomes. A negative path driven by negative group perceptions and mediated through social angst leads to weaker community relationships and to reduced engagement. However, these paths do not operate independently. A serial mediation path reveals the paradoxical role of social pressure in its association with both greater social empathy and VSC's informational value as well as greater social angst. Peer-to-peer pressure is beneficial when it contributes to a feeling of empathy that all members of a community are striving toward the same goal, but if this pressure contributes to social angst, it can hurt bonds with the community.

Discussion

Collectively, the two studies provided empirical evidence of ambivalent social dynamics within VSCs. The data reveal the especially paradoxical role of social pressure which can generate both distress, a form of negative stress that we capture as social angst, as well as positive stress or eustress which appears to be beneficial in social settings if it increases engagement in the community. However, the very relationships members establish within a community can generate pressure that leads members to transform an otherwise pleasurable experience into a distressful one. In fact, constantly being pushed too hard is more likely to be perceived as overly stressful and may result in community defection (Snodgrass et al., 2016). As organizational studies reflect, monitoring the levels of eustress and distress experienced in a group is crucial to ensure that the climate remains balanced in terms of its stress (Kozusznik et al., 2015).

Given the ambivalent nature of social dynamics within VSCs, perhaps the most surprising finding from this research is that self-disclosure is not necessary for those communities to yield informational and emotional benefits. Study 1 revealed that many members do not want to open their vulnerabilities to the virtual (and often large) group. Whenever individuals disclose their transgressions to a collective, they make themselves vulnerable to potentially harmful social dynamics (Boardley & Grix, 2014; Hutchinson et al., 2018; Merton, 1968). We find that even silent members fill their informational and emotional needs by vicariously relying on the existing exchanges and still genuinely feel a part of the community. Vicarious disclosure allows members to cope with the VSC's ambivalent dynamics as it prevents any angst from surfacing as a result of self-disclosure while still enabling positive community bond outcomes. We discuss these implications of ambivalence for research on consumption communities (Algesheimer et al., 2005; Schau et al., 2009).

Ambivalence and Brand Trust in Consumer Adoption of Artificial Intelligence-Enabled Applications

EXTENDED ABSTRACT

From autonomous vehicles to smart home assistants, Artificial Intelligence enabled (AI-enabled) technologies are increasingly available in the market. Whether considering the adoption of such technologies or living with them, consumers are often saddled between their benefits and risks. On the one hand, AI-enabled technologies provide tangible benefits in the form of convenience, customization, and efficiency. On the other hand, consumers may also worry about the risks of privacy invasion, decision-related uncertainties, and loss of control. This research addresses whether and how do these coexisting inhibitory and facilitatory factors affect consumers' intention to use AI-enabled technology. We also assess whether the dynamics of these factors differ as consumers become users.

Building on extant frameworks of technology adoption, this research adds two new dimensions to the understanding of consumer adoption of AI applications. First, and in line with this session, it accounts for ambivalence, the feeling of conflict experienced toward an attitudinal object (Priester & Petty, 1996). Surprisingly, technology acceptance research has not accounted for ambivalence, despite its likely existence in an often-paradoxical domain of consumption (Mick & Fournier, 1998). Second, the research examines the role of brand trust, and its different facets, on consumer adoption of AI applications. Trust represents "the willingness of a party to be vulnerable to the actions of another party based on the expectations that the other will perform a particular action important to the trustor, irrespective of the ability to monitor or control that other party" (Mayer, Davis, & Schoorman, 1995). Trust is an important construct in the domain of AI technology (Choi & Ji, 2015). A review of 150 empirical studies addressing human trust in AI (Glikson & Woolley, 2020) underscored the important role of AI's tangibility, transparency, reliability, and the dynamic nature of trust. Indeed, many studies have confirmed that trust is a major construct for the adoption of automation (Carter & Belanger, 2005; Gefen et al., 2003; Lee & Moray, 1992,1994; Lee & See, 2004; Parasuraman et al., 2008; Pavlou, 2003). The uncertainty and ambiguity inherent to AI-enabled technology is likely to raise doubts that may constrain the adoption, and trust mitigates such constraints (Brown et al., 2004). Building on this large body of research, we posit that consumers' trust in the brand associated with the AI-application will affect both the adoption related decision-making process as well as the ways in which consumers feel toward AI applications, once they become users.

We conducted four studies to test the relationships between ambivalence and brand trust with facilitators and inhibitors of adoption and intention to use AI-enabled technology. We obtained different samples for each study sampling a population in the US with distinct categories of AI. Studies 1-3 focused on the perceptions of the non-users of Autonomous Vehicles (AVs; n=1,237), Smart Home Virtual Assistants (SHVA; n=894), and Telemedicine (TM; n=903), representing the Robotic AI, Virtual AI, and Embedded AI, respectively. Study 1 focuses uniquely on the adoption of innovation because AVs are not yet available on the market. Studies 4(a) and 4(b) consisted of current users of SHVA and TM, with a sample of n=344 and n=346, respectively, enabling us to examine difference between users (studies 2 and 3) and non-users of Virtual AI and Embedded AI categories.

The models were tested using structural equation modeling. With regards to adoption, the findings based on non-users (studies 1-3) reveal that facilitators of adoption have a strong relationship with intention to use, and they mediate the relationships of inhibitors, ambivalence, and brand trust. Surprisingly, inhibitors of

adoption do not directly affect intention to use; however, they are negatively related to facilitators. As predicted, brand trust is an antecedent of facilitators (positively related) and inhibitors (negatively related). Interestingly, ambivalence is related positively and significantly to both facilitators and inhibitors although its relationship is much stronger with inhibitors than with facilitators (AV=.49 vs .30, SHVA=.45 vs .22, TM=.55, vs .37).

The dynamics of inhibitors, facilitators, ambivalence and trust differ once usage begins. Facilitators remain the only variable associated with consumers' intentions to continue usage. Brand trust becomes an anchoring factor for users: with findings from studies 4a-b showing a greater relationship between brand trust and facilitators than with non-users and brand trust has a non-significant or much weaker relationship to inhibitors. Ambivalence's role is also different amongst users: amongst SHVA users, the relationship between ambivalence and facilitators is stronger (.30 in study 4a; whereas in study 2 it was .22***) and amongst users of TM, the relationship between ambivalence and facilitators is negative (-.30*** in study 4b whereas it was positive and .37*** in study 3). Although across both studies 4a-b, the relationship between ambivalence and inhibitors increases (from [4a].45*** to .80***, and [4b] .55*** to .82***), the inhibiting factors are not related to consumers' intentions to continue usage for TM.

General Findings

The main takeaways from all four studies are that facilitating factors of adoption mediate the relationships between inhibiting factors, brand trust, and ambivalence on consumers' intentions to adopt AI-enabled applications. Once usage begins however, brand trust increases but ambivalence decreases consumers' perceptions of the technology's benefits, which, in turn, affects their intentions to continue usage. We discuss implications of these dynamics for understanding consumers' adoption and retention of novel technologies and offer suggestions for further research to explore the interplay of ambivalence and brand trust.

Hasty or Hesitant? The Interplay between Ambivalence and Social Norms on Consumers' Product Use Intentions

EXTENDED ABSTRACT

Ambivalence (the coexistence of positive and negative attitudes towards a target) is common in consumers' lives, yet past research examining the consequences of ambivalence for consumer behavior yields conflicting findings. Ambivalence has been connected to *approach* behavior (Nowlis, Kahn, & Dhar, 2002; Roster & Richins, 2009; van Harreveld, van der Pligt, & de Liver 2009) and to *avoidance* behavior (Foster et al., 2016; Oser et al., 2010). One important factor overlooked by past research is the nature of the focal product: specifically, are the positive (negative) aspects experienced immediately?

The current work examines the consequences of ambivalence for consumer behavior specifically with respect to products that feature immediate positive benefits (such as energy drinks, electronic cigarettes, and cognitive enhancers) and yet also carry negative health consequences that worry policymakers. Understanding the effects of ambivalence in consumption contexts that may be immediately appealing but have negative lifelong consequences for consumers is particularly relevant and important from a policy and consumer bell-being perspective.

We propose that ambivalence, and the arousal that it triggers, increases approach tendencies behavior in the context of consumption choices that feature immediate positive consequences. We base this prediction on research showing the relationship between ambivalence and arousal and research examining the consequences of arousal for information processing and consumer behavior: Past research suggests that ambivalence is experienced as unpleasant when the positive and negative components are simultaneously accessible, which produces physiological arousal (Van Harreveld et al., 2009). Past research on the experience of arousal, in turn, suggests that it causes people to focus on immediate consequences; particularly those make them feel better (Noseworthy, Di Muro, & Murray, 2014). As previously described, ambivalent attitude targets are characterized by a mix of positive and negative components or consequences; consequences that may manifest immediately, or after a delay. If a consumer experiences ambivalence and arousal in a context in which the immediate consequences associated with consumption are positive, the short-term focus may cause the positive components to loom larger and enhance approach behavior. We propose that consumers' ambivalence towards products that feature immediate positive benefits enhances interest in and intention to approach these products, and that this effect is mediated by arousal.

We provide further evidence for our proposed process by examining the role of social norms—one's perceptions of what other people think and do (Cialdini, Reno, & Kallgren, 1990) – in moderating the relationship between ambivalence and approach behavior. We have proposed that ambivalence influences behavior through arousal, a condition which fosters heuristic (versus deliberative) processing. Normative information is prevalent and serves as a powerful heuristic cue in a number of marketing contexts (Abrams & Hogg 2010; White, Habib, & Hardisty 2019). We propose that norms moderate the relationship between ambivalence and product interest: when perceptions of group usage norms are higher, ambivalence is related positively to interest in and intentions to use the product. Conversely, lower perceptions of usage norms lessen the relationship between ambivalence and interest in and intentions to use the product.

Studies

We tested our Hypothesis across four studies. Study 1a was a controlled experiment in which we used the incentive-compatible Becker Degroot Marschak (BDM) paradigm (Becker, Degroot, & Marschak, 1964; Wertenbroch & Skiera, 2002) to activate ambivalence among current consumers energy drinks to assess the influence of ambivalence on willingness to pay (WTP) for a new brand of energy drink. This first experiment showed that ambivalence is linked to greater risk-seeking behavior among current users of a product category, as indicated by more (vs. less) ambivalent participants' willingness to pay more for a new product in that category.

Study 1b complements 1a by examining a context where individuals did not have preexisting attitudes; cognitive enhancers. Participants viewed statements about a new product that were mixed valence (high ambivalence condition) or positive valence (low ambivalence condition). After a delay, participants were reintroduced to the focal product. Participants in the high ambivalence condition were more aroused (as measured by skin conductance) than participants in the low ambivalence condition. Arousal, in turn, enhanced attention to subsequent positive (but not negative) information about the product, as measured by eye tracking. This study provides indirect support that ambivalence supports approach tendencies in the context of products that feature immediate positive benefits, and that arousal is an underlying mechanism.

Study 2 is cross-sectional study conducted in another population (French teenagers), which replicates the effect of ambivalence on interest in products that provide immediate benefits (e-cigarettes

and cigarettes). The study also documents the moderating role of normative social norms: the positive relationship between ambivalence and intention to use a risky product is enhanced when teens perceive higher usage norms among an associative reference group.

Study 3 assessed whether a public health norms intervention can reduce the influence of ambivalence on risky intentions. Building on the cross-sectional results of Study 2, we manipulated teens' perceptions of the prevalence of e-cigarette usage among their peers to assess whether this changes the relationship between ambivalence and intention to use e-cigarettes. Thus, Study 3 is a two-condition design in which participants received an intervention message (designed to reduce perceptions of associative group vaping norms) or a control message. Results showed that reducing the perceived normativity of substance use among an associative group attenuates the effect of ambivalence toward e-cigarettes on intention to use them.

We have two additional studies planned and can report the results of these studies at ACR. The first is a field study in which we manipulate the immediate positive (negative) consequences of a product towards which consumers are ambivalent. The second is a lab study designed to test our entire model (manipulating ambivalence, arousal mediator, social norms moderator).

Distrust towards Institutions Reduces Attitudinal Ambivalence

EXTENDED ABSTRACT

Trust is fragile. As the year 2020 has illustrated, distrust can pervade our lives in many ways. While the COVID-19 pandemic was unfolding, the levels of trust of citizens around the world fluctuated sharply regarding the capacity of governments to manage the crisis (Edelman, 2020). Another example occurred at the 2020 U.S. presidential election. After the Trump camp issued claims of voting fraud, Trump voters' trust in the government and the media plunged 15%, at half of Biden voters' trust level (Edelman, 2020). Therefore, one important question is about the broader implications of distrust for society. In this research, we propose that a state of distrust entails reduced levels of subjective attitudinal ambivalence about topics unrelated to the context of distrust.

Extensive research shows that distrust elicited in one domain can affect cognitive processes in another domain (e.g, Mayo, 2015). In particular, a repeated finding is that a mental state of distrust spontaneously activates incongruent thoughts (e.g., Mayer & Mussweiler, 2011; Schul, Mayo, & Burnstein, 2004). For example, Schul et al. (2004) showed that distrust led participants to generate semantically opposite words in a free association task (e.g., "dirty" for "clean"). Mayer and Mussweiler (2011) showed that distrust enhances cognitive flexibility and thus creativity. One question that remains unexplored is the impact of distrust on attitudes and more specifically on subjective ambivalence toward topics that can be unrelated to the context of distrust. Although one prediction based on the literature could be that distrust triggers opposite views on a topic thereby increasing ambivalence, we propose that distrust entails reduced levels of subjective attitudinal ambivalence.

Drawing on the Meaning Maintenance Model (Heine, Proulx, & Vohs, 2006), we argue that distrust threatens one's sense of meaning, the need for expected and predictable relations in one's representation of the world. In turn, one might compensate by reducing its subjective ambivalence toward given topics (Heine et al., 2006). We see several reasons why distrust could reduce meaning. First, by triggering incongruent thoughts, distrust creates unexpected links between concepts or ideas, which can disrupt one's existing mental representation on a cognitive level (Mayer & Mussweiler, 2011;

Schul et al., 2004). Second, while trust is associated with a feeling of security (Ainsworth et al., 2014), distrust implies uncertainty regarding the trustworthiness of a target (Weiss et al. 2020), thereby reducing the perception of predictability in one's environment. Finally, trust ties the self with the target of trust (Weiss et al. 2020), a relationship that is compromised under distrust. The resulting threat to the self could reduce the sense of meaning.

We further argue that one way to cope with the meaning threat posed by distrust is by reducing one's attitudinal ambivalence. Research suggests that through its attitudes, one can restore the self-esteem critical to the sense of meaning (McGregor & Marigold, 2003; McGregor et al., 2001; Steele, 1988). Furthermore, a lower level of subjective ambivalence toward a target topic implies the perception of less conflicting reactions. Therefore, reducing one's ambivalence could provide a feeling of reconciliation restoring a sense of meaning on a cognitive and affective level (Priester & Petty, 1996, 2001). Note that in this research we investigate the subjective perception of ambivalence rather than the objective amount of opposite thoughts (Priester & Petty, 1996). We conducted three preregistered studies in the context of distrust in institutions.

Studies

In study 1, we established the relationship between distrust and lower subjective attitudinal ambivalence. Participants (N = 200) indicated their level of trust in a series of institutions. Then, following Priester and Petty (1996, 2001), we asked them for their positive and negative thoughts and feelings about three societal topics (e.g., drinking alcohol, Genetical Modified Organisms). For each topic, we measured subjective ambivalence, that is the extent to which they felt conflicted, indecisive, and one-sided or two-sided about the topic. Consistent with our prediction, there was a significant relationship between distrust and subjective ambivalence ($F(1, 198) = 43.88$, $p < .001$), such that the more participants distrusted institutions, the less they were ambivalent about topics.

In study 2, we provided evidence for causality. We manipulated distrust in institutions through a writing task. Participants (N = 700) were randomly assigned to one of three conditions: distrust, trust or a control condition. They had to recall a time when they distrusted or trusted a governmental institution, or something they did the day before. The manipulation was followed by a measure of affect and the same measure of subjective ambivalence as in study 1 with three different topics (e.g., use of animals in medical research). Results showed that distrust (vs. trust and control conditions collapsed) reduced subjective ambivalence, controlling for negative affect as preregistered ($F(1, 697) = 5.08$, $p = .025$).

Study 3 extended our findings in an ecologically valid setting, the 2020 U.S. presidential elections. In the weeks following the elections, American participants (N = 622) indicated their trust in the U.S. election system and democracy. We then measured subjective ambivalence about nine topics (e.g., nuclear power) as in studies 1 and 2. Finally, we asked participants to report their vote and their political preferences. A mediation analysis revealed a significant indirect effect (indirect effect = -0.41, bootstrapped 95% CI = [−0.57, -0.26]) supporting a relationship between vote (Donald Trump vs. Joe Biden) and subjective ambivalence driven by trust in democratic institutions when controlling for political preferences. Trump voters had less trust in democratic institutions ($b = -1.38$, $t(619) = -7.71$, $p < .001$), which, in turn, was linked to less subjective ambivalence ($b = 0.30$, $t(618) = 6.47$, $p < .001$). When trust was controlled for, the effect of vote on subjective ambivalence was no longer significant. Ancillary analyses showed that the indirect effect was significant for all topics taken separately.

In summary, these studies enhance our understanding of the relationship between distrust and subjective attitudinal ambivalence, with evidence in a real-world setting. This research has implications for marketing as it suggests that exposure to distrust cues (via media for instance) could affect product attitudes and thus consumption.

SESSION OVERVIEW

Normative theories of consumer choice suggest that money should be treated as fungible, regardless of the source of the money or the current account it is in. Yet, beginning with research by Richard Thaler and others (1985, 1999) on "mental accounting," scholars have demonstrated that people do not treat their money from different sources as interchangeable, but deviate from this standard in predictable ways. For example, people are more willing to spend money on fun experiences if this money was obtained because of a happy event rather than a sad event (Levav and McGraw 2009).

The proposed session explores other important implications of mental accounting as well as the precursors that determine whether people group events (or money) into separate mental accounts. Papers in this session investigate how mental accounting influences college choice, well-being, charitable donations, and spending. All four papers share the theme of mental accounting, and three of the four also share an emphasis on patience or timing, whether focused on timing as a precursor of mental accounting or as an outcome.

Mrkva, **Walker**, and **Farrokhnia** study how consumers allocate money into different mental accounts based on the amount of effort exerted to acquire the money. Compared to easily-acquired money, they find that consumers prefer to spend hard-earned money on long-lasting items, such as computers with warranties, durable goods, and donations with long-term impact. They test this using experimental manipulations of effort and with real-world data from financial transactions and lotteries.

Yoon, Yang, and **Morewedge** investigate how mental accounting influences an extremely important consumer decision—college choice. They find that people mentally integrate the costs from each year of college and psychologically experience those costs very early (prior to making their first payment, even if they have loans that delay payments) whereas the benefits of college are not psychologically experienced until after graduation. As a result, present-oriented people are more likely to choose low-cost, low-return colleges.

Evers, **Imas**, and **Kang** develop an elegant theory of the precursors of mental accounting, which explains when and why people group events together rather than separating them into different mental accounts. They suggest that the similarity of two events (along salient dimensions; Tversky 1977) is the primary precursor that determines whether people mentally group two events together or separately. They test and support this model across 5 experiments and also show that it accounts for several seemingly contradictory findings in the prior mental accounting literature.

MacDonald, **Walker**, and **Silverstein** suggest that mental accounting often causes people to delay consumption. They find that consumers mentally categorize expensive products with special occasions and thus wait longer to consume expensive products. This is a new development, because previous sunk costs research suggests people consume expensive products earlier due to the psychology of sunk costs (Arkes and Blumer 1985). All four papers are in the late stages of development.

Effort Accounting: People Prefer to Spend Hard-Earned Money on Long-Lasting Purchases

EXTENDED ABSTRACT

Consumers sometimes earn money through hard work and other times acquire money effortlessly. Previous research suggests that the source of money influences how it is spent, however little is known about how the amount of effort exerted to attain money influences spending. Across 5 studies, we demonstrated that acquiring money through higher effort influences spending. Specifically, consumers prefer to spend hard-earned money on long-lasting items, such as computers with warranties, durable goods, and donations with long-term impact (rather than only short-term impact).

We first examine financial transaction data from 392,564 consumers and 1,547 small-stakes lotteries to show that lotteries increase spending on non-durable goods more than durable goods. In Study 2, we manipulated whether economic stimulus payments were framed as easily-acquired gifts vs. hard-earned money, showing that people are more willing to spend money on computers without warranties and donations with only short-term impact when the stimulus money is framed as easily-acquired. Then, we conceptually replicated these results with money earned in high-effort vs. low-effort laboratory tasks and other effort manipulations. These effects were driven by consumers' subjective perceptions that they had less resource slack after earning money through substantial effort (though participants were aware their objective slack and future earning potential was equivalent).

In Study 1, we analyzed financial transaction data that tracks all bank account transactions from over 390,000 users and conducts small-stakes lotteries ($40 to $1000 per lottery win) among users. We predicted that people would be more likely to spend money attained via these lotteries (easily-acquired) on transitory non-durable goods rather than longer-lasting durable goods. As expected, we observed an increase in spending in the days following a windfall (i.e. lottery win). Critically, this increase in spending was much larger for non-durable goods (e.g., food from restaurants) than for durable goods (e.g., household appliances and electronics). We used the Bureau of Labor Statistics' definition of durable and non-durable good catego-

ries to classify each transaction. Then, we computed a mixed effects model (Mrkva et al., 2021; Westfall et al. 2014) estimating the increase in durable and non-durable purchases after a lottery windfall, while adjusting for variance associated with each user's spending patterns and for seasonal and weekly differences in purchases across users.

In Study 2, we directly manipulated effort framing and isolated the extent to which the dependent variable involved long-lasting vs. short-term outcomes. To do so, we manipulated whether an upcoming economic impact (stimulus) payment was described as easily acquired (similar to a "gift" sent from the U.S. government) or as hard-earned money that was earned through hard work, paid to the federal government via taxes, and then returned to eligible taxpayers ("hard-earned" condition). Following this manipulation of perceived effort, participants completed two dependent variables assessing their willingness to use the money on items with long-lasting vs. short-term outcomes. One dependent variable consisted a choice between donating $20 to a charity focused on long-term impact vs. a charity focused on short-term impact (both would address an ongoing humanitarian crisis in Yemen, but with resources devoted more towards long-term vs. short-term relief). The decisions from a random subset of participants were implemented. The second dependent variable asked participants to choose whether they would prefer to use some of the stimulus money to purchase a $1000 computer with no warranty but premium features (Intel i7 processor; 1 TB storage) or a $1000 computer with a 3 year warranty but two features that were less advanced (Intel i5 processor; 0.5 TB storage). Participants completed both scenarios in random order to increase power in this and all subsequent studies.

Participants were more likely to donate to a charity with long-lasting impact in the "hard-earned condition" than in the "easily-acquired condition," $z=2.79$, $p=.005$. Those in the "hard-earned condition" were also more likely to choose to spend $1000 of their stimulus on a computer with a warranty but less premium features than were participants in the "easily-acquired condition," $z=2.07$, $p=.038$.

In Study 3, we manipulated experienced effort using a "real effort task" commonly used in experimental economics (Gill and Prowse 2013). Participants were randomly assigned to the "high effort" or "low effort" task, which entailed moving sliders as fast as possible to a predetermined location (high effort condition) or fewer sliders at a leisurely pace to a predetermined location for the same amount of time (low effort condition). Following this effort manipulation, participants completed the same long-term vs. short-term impact donation decision as in Study 2. Participants were more likely to donate to a charity with long-lasting impact in the "high effort condition" than in the "low effort condition," $z=4.61$, $p<.001$, conceptually replicating Study 2.

In Study 4, participants were randomly assigned to the "hard-earned" or "easily-acquired" condition. They imagined they worked hard overtime at work. In the "hard-earned condition" they received $1,000 from this hard work. In the "easily-acquired condition", their employer paid the same amount regardless of overtime, but they won a $1,000 lottery. Then, participants completed the computer choice as in Study 2. Participants in the "hard-earned" condition were more likely to choose the computer with a warranty (53%) compared to those in the "easily-acquired" condition (44%), $z=3.66$, $p<.001$.

Study 5 investigated the proposed mediators. It was similar to Study 4, except that both conditions involved money earned at work (through very hard work vs. easy work). Following the effort manipulation and computer choice, we added measures of three potential mediators (perceived slack, wastefulness, and self-connectedness of

the money) and included items to assess alternative explanations of our results (mood, unexpectedness, perceived wealth, future earnings potential).

Participants in the "high effort" condition were more likely to choose the computer with a warranty (50%) compared to those in the "low effort" condition (33%), $t(222)=6.19$, $p<.001$. According to a parallel mediation model testing the three potential mediators, these effects were partially mediated by perceived slack and desires to avoid waste (but not self-connectedness).

Consumers sometimes earn money through hard work and other times acquire money effortlessly. We argue that consumers put hard-earned and easily-acquired money into separate mental accounts and spend hard-earned money differently.

Early Cost Realization and College Choice

EXTENDED ABSTRACT

A college education is an economic ladder that can boost human capital (Becker 1962), but it is an expensive investment that led many students to pay the tuition using student loans. Currently, 43 million Americans have active student loan accounts for federal student loan programs (e.g., Stafford loans and Perkins loans; National Student Loan Data System 2021). We examine how people make college choices based on their financial ramifications when they can make use of student loans.

Student loans change the temporal dynamics of financial costs and benefits of a college education. With a student loan, attendance costs are no longer due while attending college. Loan payments are usually deferred until after graduation, and these payments are spread over many years (National Center for Education Statistics 2018). Student loan repayments are usually 8-11% of income after graduation (Avery and Turner 2012). Suppose students recognize financial costs and benefits when they earn income and pay back the student loans (i.e., after graduation). In this case, students should not worry about the immediate cost of higher education, and thus prefer High-Cost High-Return colleges (HC-HR, hereafter), such as expensive private schools that promise higher income after graduation, over Low-Cost, Low-Return colleges (LC-LR, hereafter), such as state schools or for-profit colleges. In reality, however, students exhibit substantial debt aversion before enrollment, even with student loans, and often choose LC-LR schools that will yield a lower lifetime income (Sallie Mae 2017).

We hypothesize that students psychologically realize the financial costs of college earlier than the financial returns, even though they will actually realize the costs and returns at the same time after graduation. The asymmetric psychological realization of costs and benefits frames college choices as intertemporal tradeoffs between a smaller short-term investment with smaller long-term returns (i.e., LC-LR colleges) and a larger short-term investment with larger long-term returns (i.e., HC-HR colleges), even when there are no actual short-term transactions. Thus, present-oriented students are more likely to choose LC-LR colleges because short-term financial cost is weighted heavily over long-term gain, whereas future-oriented students are more likely to choose HC-HR colleges because long-term financial gain is weighted heavily over short-term financial cost.

Using model simulations, we tested whether the asymmetric psychological realization of costs and benefits indeed leads to intertemporal tradeoffs in college choices. We created two mathematical models, a cash-flow model and a tuition myopia model, that calculate the present value of college education considering financial costs and expected income after graduation. Two models are identical except the cost recognition timings. The cash flow model recog-

nizes costs after graduation when the loan repayment is due, while the tuition myopia model recognizes costs during college when the tuition is due. A simulated decision maker evaluated 123,753 HC-HR and LC-LR college pairs from the College Scorecard database (https://collegescorecard.ed.gov/; Department of Education) using the two models, and listed colleges that yielded higher present values. The results demonstrated very different predictions depending on the cost recognition timing. When the simulated decision maker recognizes costs after graduation (i.e., cash-flow model), HC-HR colleges dominated college choices (85.36%, across all conditions). However, when costs were recognized while attending (i.e., tuition myopia model), most college choices became intertemporal tradeoffs (90.02%, across all conditions) such that the dominant college option was influenced by the individual discount rate of the decision maker (that is, impatient prefers LC-LR colleges, whereas patient prefers HC-HR colleges). The model simulation suggested that the timing of cost recognition may significantly impact how people make choices between HC-HR and LC-LR colleges.

In Study 1, we directly compared when students actually and psychologically realized the costs and returns associated with college. Undergraduate students from a large non-profit state university were asked to imagine that they secured a student loan that can cover all college expenses. Then then indicated when the financial costs and returns of college education would be realized, psychologically and actually. The results demonstrated the misalignment between the psychological and actual realization timings for the financial costs but not for the financial returns. Participants psychologically realized financial costs earlier than actual loan payment dues ($t(387) = 12.01$, $p < .001$; Wilcoxon Signed-Ranks Test: Z = 10.37, $p < .001$). However, we did not find such a misalignment for the financial returns ($t(387) = 1.34$, $p = .18$; Wilcoxon Signed-Ranks Test: Z = 1.07, $p = .28$). The result provides preliminary evidence for the tuition myopia model that recognizes costs ahead of returns, leading to intertemporal tradeoffs for college choice.

Studies 2 and 3 tested whether people make intertemporal tradeoffs when making college choices. Study 2 tested our hypothesis against a simple student debt aversion account, whether people simply avoid expensive schools. Study 3 tested our hypothesis against a Return on Investment account (ROI), whether people use the ROI principle when making college choices. In both studies, we presented a series of college financial information (annual attending costs & expected income after graduation). We analyzed the choice patterns of participants to see if the pattern can be explained by intertemporal tradeoffs or by alternative Hypothesis. Study 2 supported our tuition myopia account (F(2,166) = 130.24, $p < .001$, ηp2 = .61) over the debt aversion account (F(2,166) = 2.28, $p = .11$). Study 3 also supported our tuition myopia account (F(1,96) = 85.98, $p < .001$, ηp2 =.47), over the ROI account, (F(1,96) = .35, $p = .55$).

In Study 4, we tested whether an alternative way of presenting information that can align the psychological cost timing with actual payment timing can increase the preference for HC-HR colleges. Instead of providing college cost information based on annual costs, we presented college costs based on loan payment amount after graduation. This alternative information increased preference for HC-HR colleges, ($t(178) = 5.57$, $p < .001$, d = .83), as predicted by the cash-flow model.

Together, the current investigation provides insights regarding how people make college choices with student loans. We suggest that people asymmetrically recognize the financial cost and benefit timings, which make college choices as intertemporal tradeoffs between LC-LR colleges and HC-HR colleges.

The Role of Similarity in Mental Accounting

EXTENDED ABSTRACT

The evaluation of sequential outcomes—good and bad—is inherent to daily life. A professor teaches a great lecture in the morning, a fine graduate seminar in the afternoon, but a much-anticipated dinner at a fancy restaurant disappoints. A stock trader starts the morning with heavy losses on one asset, sees positive returns on another in the afternoon, and ends the day arguing with her partner. Are these experiences evaluated jointly as a good (or bad) day, or is the pain and pleasure of each outcome evaluated separately, as distinct experiences? And as a result, would the person prefer to combine the experiences on the same day or spread them over time?

We present a categorization based model of mental accounting, in which consumers are more likely to categorize and evaluate similar outcomes as one larger "event," whereas dissimilar outcomes are categorized and evaluated as separate, smaller "events." The professor in the above example would be much more likely to combine the class and the seminar into one event as compared to the dinner and either of the earlier outcomes. Analogously, the trader would be more likely to view the workday as a wash followed by a bad night, compared to viewing the morning as a loss followed by a lukewarm rest of the day. This categorization in turn affects preferences over the timing of outcomes; due to the shape of prospect theory, consumers prefer to experience similar negative outcomes together, while preferring to separate dissimilar negative outcomes over time. For positive outcomes, we predict and find the opposite. Similar positive outcomes are preferred to be spread over time while dissimilar positive outcomes are preferred to be experienced at the same time.

In Study 1 (N = 400), we investigate the premise of our model; how do consumers categorize experiences. We presented participants with a total of 6 different negative outcomes (e.g., breaking a glass, finding out their milk is sour, finding out the cost of internet has increased by $10) that varied in their degree of similarity to other events. Participants then were asked to organize these outcomes into "events" combining outcomes together that they perceived to be part of one larger event. Consistent with our expectations, we found that participants were a lot more likely to combine similar outcomes into the same event as dissimilar ones.

In the next 4 studies (all N > 100 per cell) we turn to our models' main predictions, investigating preferences over the timing of outcomes. For example, in Study 5, participants were informed they had to complete 3 tasks in total; one questionnaire as well as tasks A and B. They were told they had to complete task A right now and would have to complete the questionnaire 1 week from now. Then they could choose whether they also wanted to complete task B right now, or whether they would rather complete it one week later together with the questionnaire. While both task A and B were unpleasant tasks, depending on the condition they were framed as being similar tasks or dissimilar tasks. Consistent with our model's predictions, we found that participants preferred to experience both negative tasks at the same time when they were framed as similar tasks, whereas when the differences between the tasks were emphasized they preferred to spread the experiences over time by opting to complete task B a week later. We also measured perceived similarity and found that perceptions of similarity mediated this effect. Across Studies 2-5 we varied both the valence of the outcomes and the degree of perceived similarity of the outcomes. We consistently find that increasing similarity for negative outcomes increases preferences to experiences those outcomes on the same day while for positive outcomes increased similarity increases preferences to segregate these outcomes over time.

Combining mental accounting with prospect theory, Thaler (1985) derived a logical prediction termed hedonic editing; because of the shape of prospect theory, consumers should integrate negative outcomes and segregate positive outcomes. So far, evidence for hedonic accounting has been mixed, with some work finding preferences consistent with these predictions and other scholars finding consumers behaving differently (e.g., Linville & Fisher, 1991; Thaler, 1999; Thaler & Johnson, 1990). We propose, and find evidence consistent with, the importance of similarity in mental accounting. The degree to which outcomes appear to be similar or dissimilar constrains the degree to which consumers are able to book outcomes to the same or different mental accounts and as such affects preferences over the timing of these outcomes.

Waste Not, Wait a Lot: The Mental Accounting of Sunk Costs Leads to Delayed Consumption

EXTENDED ABSTRACT

Imagine purchasing a high-priced bottle of wine. Would you feel compelled to drink it right away, or would you save it for a later time? Like many people, you might consider saving it for an upcoming anniversary or dinner party (Shu and Sharif 2018), especially if you paid more for it.

These kinds of decisions to delay the consumption of expensive products stand in opposition to previous findings in the sunk cost literature. Prior research has shown that consumers tend to engage in greater, immediate consumption of products as sunk costs increase (Thaler 1980). For example, consumers who pay full price (compared to a discount) for season theater tickets attend more plays early in the season rather than waiting until later in the season (Arkes and Blumer 1985). Why in some instances might higher sunk costs compel consumers to consume more now and in other instances to wait?

We argue that when consumers are free to choose when consumption occurs, higher sunk costs will not lead consumers to consumer more immediately. Instead, consumers who incur high sunk costs will delay consumption until a time that is psychologically commensurate with that cost. We find that this effect emerges because consumers' want to avoid feeling wasteful. By delaying consumption of a high cost product to a moment in the future that feels worthier, consumers can reassign the cost of the product to a more commensurate mental account, thereby reducing feelings of waste.

In 6 studies, we examined how the ability to delay consumption changes how sunk costs influence consumption decisions. In Study 1 (N=162), we examined this effect using a paradigm with real consumption and spending. Participants completed a task in exchange for either a voucher (no sunk cost) or cash ($4; sunk cost), which they could exchange for unlimited chocolates. Unlike previous sunk costs paradigms, participants were allowed to consume both in the moment *and* in the future by taking chocolate home. In contrast to previous findings, immediate consumption did not differ by condition ($t < 1$). However, participants with high sunk costs took more chocolates home ($M = 3.18$) than those with low sunk costs ($M = 1.66$), $p = .003$; d = .49). This effect persists when controlling for perceived quality, income, liking, hunger, and mood.

In Study 2 (N=260), we examined the effect of sunk costs on consumption of a non-durable product. Make-up users imagined purchasing a cosmetic product at either full price (high sunk cost) or a discount (low sunk cost). Consistent with our predictions, those with higher sunk costs preferred to delay their consumption of the more expensive product to a more special occasion ($M_{Higher SC} = 4.88$; $M_{Lower SC} = 3.44$), $p < .001$; $d = .56$.

In Study 3 (N=302), consumers imagined purchasing a bottle of wine at either full price (higher sunk cost) or a discount (lower sunk cost). Participants indicated when they would drink this bottle of wine using a sliding scale with endpoints labeled "Today (now)" to "Many days from now (much later)." Participants also completed a 3-item scale measuring feelings of wastefulness ($\alpha = 0.91$). Consistent with our predictions, consumers indicated that they would wait longer to consume the wine when sunk costs were higher than when sunk costs were lower ($p = .021$; $d = .27$). Critically, feelings of waste mediated this effect (95% CI [10.07, 20.11]).

In Study 4 (N=404), we examined the role of mental accounting in consumers' decisions to delay consumption of products with high sunk costs. Participants chose which of two frozen meals they would eat for lunch and which they would save for either dinner or a late afternoon snack. One meal was said to have cost $8 (higher sunk cost) while a second identical meal was said to have been on sale for $3 (lower sunk cost). Most consumers are more comfortable paying more for dinner than lunch and paying more for lunch than a snack, so we predicted that consumers would prefer the more expensive meal for dinner when choosing which meal to eat for lunch vs dinner, but would prefer the more expensive meal for lunch when choosing which meal to eat for lunch vs a snack. Consistent with our preregistered hypothesis, 59% chose to consume the more expensive meal for dinner than for lunch, and, in the other condition, 31% chose to consume the more expensive meal for lunch than for a snack, χ^2 (1) = 31.27, $p < .001$. Thus, in order to better justify their spending, consumers shifted consumption of the higher sunk cost purchase to the more commensurate mental account.

In Study 5a (N=403), participants imagined visiting a pizza buffet with either high ($21.95) or low ($6.95) sunk costs. In the *bounded* condition, participants could only consume pizza while at the buffet, while in the *unbounded* condition participants could also save pizza for later. We observed a significant interaction between sunk cost and boundedness on immediate consumption ($p = .042$). Participants indicated that they would consume more pizza immediately at the higher cost buffet when they could not take pizza home with them ($M_{Lower SC} = 4.41$; $M_{Higher SC} = 5.92$; $p = .001$). However, there was no difference in the amount consumed immediately when pizza could be saved ($t < 1$). Instead, when unbounded, consumers preferred to save more for later at the higher cost buffet ($M_{Higher SC} = 8.61$; $M_{Lower SC} = 6.35$), $p = .001$. Study 5b (N=495) replicated the results of Study 5a using an all-you-can-eat sushi buffet – a product unlikely to evoke anticipated utility for future consumption.

This research provides new insight into how sunk costs influence consumption. Although prior literature suggests that higher sunk costs cause greater immediate consumption, we demonstrate that when consumers can choose when to consume a product, they prefer to save high-priced products for more commensurate occasions in order to better justify the expense and feel less wasteful.

SESSION OVERVIEW

This session explores the psychological factors influencing how consumers think about and engage in financial resource allocation. The papers come together in three themes. First, we focus on how feelings of optimism, anxiety, and surprise influence the allocation process and spending decisions. Second, we consider whether—and when—consumers consider tradeoffs when allocating between different options. Third, we consider budget strategies that may lead to worse financial outcomes. Using data from government surveys, a financial application, a simulated budgeting game, and many experiments, these studies provide a rich, multi-method exploration into the psychology of financial resource allocation.

How might a consumer's feelings influence their allocation decisions? Starting with the thought processes that precede resource allocation, Herzog and Bartels find that surprising prices influence the likelihood of considering opportunity costs. Using survey data from the US and UK, Gladstone and Pomerance uncover a positive association between optimism and savings. Furthermore, they find manipulated optimism—incidental to finances—increases savings intentions. Relatedly, Goodyear et al. use data from a financial application to identify consumers who are likely to feel anxious exhibit larger 'payday effects' (Gelman et al. 2014; Olafsson and Pagel 2018). In controlled experiments, they show anxiety about financial planning leads consumers to perceive their ordinary paychecks as windfalls, which are more readily spent (Arkes et al. 1994).

Consumers must carefully consider trade-offs to effectively allocate their limited resources. Gladstone and Pomerance discuss how rich and poor consumers experience trade-offs differently. They propose a "boost" of optimism may be especially important for consumers with lower incomes who will need to forgo more competing causes. Herzog and Bartels find that consumers are more likely to spontaneously recall similarly priced options for comparison when a focal option's price is unexpectedly high. Even when alternatives are fully known, do consumers allocate resources properly? Dolifka

and Spiller find that consumers over-allocate to budgets with higher average values at the expense of trade-offs at the margin. Feedback about such trade-offs may improve allocation decisions, highlighting an approach for possible interventions.

Budgeting can be a beneficial strategy when allocation decisions are complicated or consumers lack self-control (Thaler 1985, 1999). However, this session acknowledges some reasons why budgets may lead people astray. Dolifka and Spiller suggest consumers are especially sensitive to the average values of the purchased set, rather than the entire consideration set. A consequence is that past budget allocation decisions can reinforce future errors if people attend to the average value of their prior purchases. Goodyear et al. highlight that budgeting anxiety (having intent without a certain plan) leads to an ironic failure of budgeting, as measured by excessive payday spending. These insights remind us that budgeting alone may not improve consumer welfare; we should be concerned with—and attempt to improve—*how* budgets are used.

Together, these projects offer new insights into the psychological factors that shape how consumers allocate their scarce resources in complex environments.

Chasing Consumer Surplus: Average Value Attracts Budget Allocations

EXTENDED ABSTRACT

Consumers use budgets to allocate resources between competing uses (Zhang and Sussman 2018). Once allocated, funds within budgets are no longer fungible (Hastings and Shapiro 2013; Heath and Soll 1996; Soman and Cheema 2011). Therefore, spending directly reflects prior allocation decisions. What drives budget allocations?

Prior research highlights many key inputs into how budgets are set. Consumers allocate in accordance with anticipated spending, which may lead to misallocations when expenses are mispredicted (Howard, Hardisty, and Sussman 2019), ignored (Sussman and Alter 2012), or uncertain (Ülkümen, Thomas, and Morwitz 2008). Budgets may be set as self-control devices to curb anticipated spending and limit consumption (Krishnamurthy and Prokopec 2010; Thaler 1985, 1999). Incidental factors—such as the arbitrary partitioning of accounts—may guide allocations (Bardolet, Fox, and Lovallo 2011). But how does the value of possible purchases influence budget allocation? That is the question we seek to address.

Normatively, resources should be allocated to equate the marginal value of purchases across budgets. But might consumers also be sensitive to average values? Prior research on melioration (Herrnstein and Prelec 1991) and the matching law (Rachlin and Laibson 1997) suggests people make distributed choices in proportion to the average benefits of those choices. We extend this work to budgeting, in which consumers allocate resources in advance of spending. In two preregistered experiments, we find that holding constant the normative marginal value, consumers allocate more funds to budgets with higher average values.

In experiment 1, $N = 100$ participants repeatedly allocated budgets between two lunch vendors for 10 simulated pay periods. By varying the lunch offerings available while holding the budget fixed (7 vouchers each 10-day pay period), we separately varied the

number of supramarginal options offered by each vendor (number of offerings in the top 7) and the average value across the two vendors. We regressed budget allocated to vendor 1 on (a) number of supramarginal vendor 1 options, (b) number of submarginal vendor 1 options (number of offerings in the bottom 3), and (c) the difference in average value of vendor 1 and vendor 2 options. Controlling for the number of supramarginal and submarginal goods and accounting for clustering, increasing the difference in average value induced a greater allocation to vendor 1 ($b = 0.14$, $se = 0.05$, $t(84) = 2.68$, $p = .009$).

In experiment 2, we used an incentivized budgeting game in which participants repeatedly set and spent from budgets. In this game, participants allocated a token currency between budgets for two kinds of goods: blue and red tiles. Tiles earned known numbers of points, from 5 to 100, and total points determined bonus payments. In each simulated game week, the total number of tiles (80) exceeded the total number of tokens (23). The challenge was to set budgets that would allow for the subsequent purchase of the highest-value tiles.

For all participants in all conditions, there were 40 blue tiles (9 worth at least 60 points) and 40 red tiles (14 worth at least 60 points). Participants faced the same 80 tiles each week, which were equally distributed across five days. Given a weekly budget of 23 tokens, the point-maximizing budget allocation was always 9 tokens for blue tiles and 14 tokens for red tiles, and the point-maximizing spending rule was always to buy every tile worth at least 60 points.

The number of blue or red tiles worth at least 60 points was held constant; but we independently varied the two distributions of supramarginal and submarginal values. In the supramarginal region of the distribution with values of at least 60 points, we manipulated either the 9 blue tiles or the 14 red tiles to have a higher average value. In the submarginal region with values below 60, we manipulated either the 31 blue tiles or the 26 red tiles to have a higher average value. Participants were informed they would see the same distribution of 80 tiles for the entire session and had five practice weeks to become familiar with the game and the distribution of tiles. Following the practice weeks, participants played the incentivized six-week game. We pre-set optimal budget allocations in the sixth week, allowing us to test whether participants maximize their points given an optimal budget allocation.

$N = 402$ participants (391 after preregistered exclusions) were randomly assigned to one cell in a 2 (supramarginal distribution: blue high, red high) x 2 (submarginal distribution: blue high, red high) design. Though the normative marginal value was held constant, participants in the blue-high-supramarginal condition allocated significantly more tokens to blue ($M = 10.8$, $SD = 1.8$) than did those in the red-high-supramarginal condition ($M = 9.9$, $SD = 1.8$; $t(387) = 4.83$, $p < .001$, $d = 0.49$). Neither the effect of submarginal distribution nor the interaction was significant. Follow-up analyses indicated these results were not attributable to asymmetric costs of allocation errors.

Participants earned more points with better budgets. Comparing earned points in the sixth week (with a pre-set optimal budget) to the fifth week (with a self-allocated budget), scores were an average of 23.4 points higher with the optimal allocation ($se = 4.5$, $t(387) = 5.58$, $p < .001$). These results highlight the importance of budget allocation on subsequent spending and demonstrate how allocating based on average values can conflict with maximization goals.

In two rich experiments using distinct paradigms, we document consistent robust evidence that consumers allocate more to budgets with higher average purchase values. Our research contributes to the budgeting literature by demonstrating that budgets are driven by average value in a way that incurs a loss of value at the margin. This research also suggests a potential strategy for budgeting tools aimed at improving consumer welfare: recoup value at the margin. Highlighting the marginal purchase value over the average purchase value could help consumers to both budget and spend better.

Price Expectations and Spontaneous Opportunity Cost Consideration

EXTENDED ABSTRACT

Before deciding how to best allocate their resources, consumers must become aware of their available options. Although this process may often involve contemplating alternatives that are immediately available, it may also require recalling outside options, which can be both difficult and costly due to limitations on attention and memory (Mehta, Rajiv, and Srinivasan 2003; Nedungadi 1990; Posavac, Sanbonmatsu, and Fazio 1997).

Because of these limitations, consumers may not spontaneously consider opportunity costs while deciding whether to purchase a focal option (Frederick et al. 2009; Jones et al. 1998). Among consumers who do not regularly think about a purchase as a choice between alternatives, Spiller (2011) proposed that they are more likely to consider opportunity costs under budget and resource usage constraints. Given that neglecting outside options often implies a narrow focus on the focal option, we investigated whether some salient features of the focal option itself can also prompt opportunity cost consideration. Specifically, we investigated whether unexpectedly high (low) prices make the spontaneous consideration of opportunity costs more (less) likely.

Unexpected prices can influence choices across a variety of purchasing contexts (Mazumdar et al. 2005), but the thought processes triggered by unexpected prices have been understudied. While it is clear from research on transaction disutility that consumers likely recall typical prices or cheaper substitutes when prices seem high (Thaler 1985), they may also be more likely to recall more reasonable alternatives at the same price point.

In Study 1a, we tested if spontaneous opportunity cost consideration is more likely when prices are higher than (vs. similar to) expected. Study 1b served as a direct replication and extension to study unexpectedly low prices. In a hypothetical purchase context, participants from Prolific (Study 1a $N = 577$; Study 1b $N = 879$) observed focal options and completed a thought-listing task. They first observed an image of one of ten possible products from a variety of product categories and estimated its price. These estimates were multiplied by values (determined by a pretest) such that the listed price was either similar to, lower than (Study 1b only), or higher than the expected price. Participants were asked to imagine that they were shopping and considering purchasing the focal product. The price was then revealed along with a textbox and instructions to describe their thoughts about the product and their decision process. Three research assistants coded whether participants considered the possibility of using a similar amount of money for something else instead of the focal product that they were presented with. Participants who observed prices that were higher than expected were slightly more likely to spontaneously consider opportunity costs (higher = 9.72% vs. expected = 6.27%, $p = .130$ in Study 1a; higher = 8.63% vs. expected = 4.48%, $p = .029$ in Study 1b). In addition, participants who observed prices that were lower than expected were slightly less likely to spontaneously consider opportunity costs (lower = 3.11% vs. expected = 4.48%, $p = .215$; lower = 3.11% vs. higher = 8.63%, $p = .003$). The incidence rate of explicitly mentioning opportunity costs is modest, but the observed patterns are consistent with our predictions.

In Study 2, we ran a conceptual replication by using consumer decision scenarios with more context, clearer motivation, and clearer instructions about what should be discussed in the open-ended responses. Participants from Prolific (*N* = 884) were randomly assigned to one condition in a 3 (price: lower than expected, similar to expected, higher than expected) x 2 (scenario: painting vs. data recovery) design. They read a scenario about deciding whether to purchase a painting they liked or a data recovery service to retrieve their lost pictures and videos. We elicited an expected price that was manipulated to be either lower than, similar to, or higher than expected. Participants read that they had plenty of money available for the purchase and wrote down thoughts that came to mind while contemplating spending that amount on the focal option. In this study, participants were asked to self-code their open-ended responses. They were presented with their responses and asked if they mentioned using that amount of money for something else instead of the focal option. Consistent with Studies 1a and 1b, participants who observed prices that were higher than (27.78%), versus similar to (17.16%), expected were more likely to spontaneously consider opportunity costs (*p* < .01). Further, participants who observed prices that were lower than (8.73%) (vs. similar to) expected were less likely to spontaneously consider opportunity costs (*p* < .01).

This project builds on existing behavioral theories (e.g., Nedungadi 1990; Spiller 2011). about when consumers spontaneously consider outside options from memory in purchasing decisions by studying an important aspect of consumer decision-making: price expectations. These findings help further our understanding of when consumers might be more or less likely to appreciate the full scope of their potential costs by considering forgone options in addition to out-of-pocket costs (Becker, Ronen, and Sorter 1974; Frederick et al. 2009; Thaler 1980). It also sheds light on which thoughts come to mind when actual prices deviate from expected prices. In addition to considering typical category prices and cheaper substitutes when faced with unexpectedly high prices, consumers may also be more likely to consider outside options at similar price points for comparison.

The Ironic Effect of Budgeting Anxiety and Increased Spending on Payday

EXTENDED ABSTRACT

In contrast to predictions of standard economic theory (e.g. Carroll 1997), research has documented a "payday effect" whereby consumer spending spikes following the receipt of predictable income like a paycheck (e.g. Olafsson and Pagel 2018). Some suggest that this effect is driven by consumers who are financially illiquid (Kaplan and Violante 2014). However, others demonstrate that the effect also occurs for those with substantial liquid assets (Olafsson and Pagel 2018). A natural question emerges: Why are consumers spending more on paydays?

To gain greater insight into the payday effect, we used real income and spending data (*N*=67,360) provided by a financial application, Money Dashboard, to examine whether certain groups were more prone to this effect. The data allows us to observe the timing and amount of each user's paychecks and spending, *before* they began using the budgeting application. To measure the payday effect, we perform panel regression analysis:

$$Y_{ick} = \sum_{k=-7}^{7} \beta_{kc} I_i (Paid_{t-k}) + X'_{it} + \varepsilon_{it} \quad \textbf{(Eq. 1)}$$

Where is the spending ratio of user *i* on day *t* in category *c*, *Paid* is a dummy equal to 1 if the user receives a paycheck on day *t-k*, and is a vector of control variables. All consumers in our sample display significantly greater spending in response to getting a paycheck. However, we found that this effect is significantly stronger among women (=0.15, =0.08; *p*<.001), younger consumers (=0.13, =0.08; *p*<.001), and lower-income consumers (=0.23, =0.05; *p*<.001). It could be argued that women, younger, and lower-income consumers experience greater financial constraints. However, we suggest that anxiety could be driving this effect. Research shows that anxiety is higher amongst these groups (Armstrong and Khawaja 2002; Mirowsky and Ross 1999; Lindemann 1996). Financial constraint is also associated with anxiety (e.g. Hayhoe et al. 2012). This is consistent with past work that finds financial constraint drives the payday effect. This could also explain why the effect is present for higher income individuals, as experiencing anxiety is not limited to those with low incomes (e.g. FPSC 2018). Finally, past research indicates that anxiety leads individuals to construe money differently, like overestimate the size of money (Zaleskiewicz et al. 2013), which could increase payday spending.

To determine whether anxiety could be driving the payday effect, we conducted three experiments. In Experiment 1 (*N*=744), we examined what types of anxiety are experienced throughout the pay cycle. Participants read a hypothetical scenario about a week in their life where they received a paycheck. We asked participants to indicate their current level of anxiety about several financial concerns. We also asked participants to indicated how much their paycheck felt like a "bonus" to determine if anxiety changed how individuals construed their income. We found that anxiety about planning one's income was higher before and on payday than after payday (M_{PrePay}=4.34; M_{Payday}=4.45; M_{PostPay}=4.08; *p*=.03) and anxiety about making one's paycheck last until the next paycheck was higher before and on payday than after payday (M_{PrePay}=4.30; M_{Payday}=4.45; M_{PostPay}=3.98; *p*=.018). However, anxiety related to money in general did not differ over the pay cycle (*p*=.12). Further, we found that anxiety about planning one's income (*β*=0.23, *p*<.001) and anxiety about making one's paycheck was associated with construing income as a bonus (*β*=0.18, *p*<.001), but not anxiety related to money more generally (*p*>.1).

In Experiment 2 (*N*=246) we manipulated financial constraint. This allowed us to determine if the payday effect is due to financial constraint or anxiety about one's ability to plan income. All participants read a scenario where prior to payday they received a $50 parking ticket. Participants were randomly assigned to one of two conditions that manipulated financial constraint. Participants in the constrained condition were told they cut back on their spending whereas those in the unconstrained condition were told they did not make any changes. Next, participants were told they received their paycheck. We tested payday spending by asking participants to order a meal at a restaurant after receiving their paycheck. We found that though experiencing financial constraint increased anxiety ($M_{\text{Constrained}}$=4.61, $M_{\text{Unconstrained}}$=3.39; *p*<.001) and concerns about planning one's income ($M_{\text{Constrained}}$=5.11, $M_{\text{Unconstrained}}$=3.37; *p*<.001), it did not impact spending (*p*>.1). However, higher anxiety was related to increased spending at the restaurant (*β*=1.48; *p*=.02).

In Experiment 3 (*N*=293), we tested the full model. Using the same manipulation as Experiment 2, we asked participants to indicate their preference for a cheap versus expensive restaurant. We found that experiencing financial constraint increased anxiety ($M_{\text{Constrained}}$=4.88, $M_{\text{Unconstrained}}$=3.32; *p*<.001) and concerns about planning one's income ($M_{\text{Constrained}}$=5.02, $M_{\text{Unconstrained}}$=2.88; *p*<.001). However, experiencing financial constraint did not impact restaurant prefer-

ence (p>.1). Using a path analysis, we found that financial constraint led to higher concern about planning one's income (p<.001), concern over planning one's income led to higher levels of anxiety (p<.001), experiencing higher levels of anxiety led to construing income as a windfall (p<.001), which led to preferring more expensive restaurants (p<.001).

If anxiety about income planning concerns is driving the payday effect, then we should expect a reduction in payday spending when uncertainty about planning one's income is reduced. One way to reduce this uncertainty is to use financial planning applications. To examine if a finance application could reduce uncertainty, we conducted a pilot study (N=99). We asked participants to indicate their level of agreement with statements regarding the purpose of an application. We found that individuals believed that finance applications restore a sense of control (M=5.75), reduce uncertainty (M=5.54), and reduce anxiety (M=4.84). As such, using Equation 1 we examined the difference in payday spending before consumers using the financial application and after they began using the application. We found that there is a significant reduction in the payday effect after using the application. Consistent with our anxiety account, we found that those most likely to experience greater anxiety display the greatest reduction in payday spending after using the application.

In sum, these results demonstrate that, ironically, experiencing anxiety about planning income can lead individuals to increase the amount they spend on payday. Also, this work begins to provide some insight into practical interventions that can be used to curb overspending behaviors on payday.

Believing in a Brighter Future: Optimism Boosts Savings for the Poor but Not the Rich

EXTENDED ABSTRACT

Having money saved fulfils basic psychological and economic needs for consumers (Deaton 1989; Ruberton, Gladstone and Lyubomirsky 2016), yet many people lack sufficient savings to cope with life's ups and downs (Demirgüç-Kunt and Klapper 2012). Past work has focused on factors such as financial literacy and self-control as drivers of savings (Baumeister 2002; Fernandes, Lynch, and Netemeyer 2014; Laibson et al. 1998; Lusardi 2008). We investigate another potentially important influence on saving: whether a person feels optimistic or pessimistic about the future (Scheier, Carver, and Bridges 1994).

How might optimism influence savings? It is plausible that optimism could reduce the desire to save. For example, a generalized belief that the future will be positive may reduce the perceived need to stash money away 'just in case' (Puri and Robinson 2007). However, we argue that optimism increases the perceived efficacy of saving, which will increase the amount people save overall. After all, people are more motivated toward goals that feel attainable and valuable (Wigfield and Eccles 2000).

Furthermore, we predict that the role of optimism on saving will be moderated by a person's current financial state: optimism will have a greater effect on the poor than on the rich. We note that saving among the poor is a discretionary act—there are always needs or wants that compete with saving, meaning people with lower incomes need optimism to boost the perceived efficacy and value of saving. In contrast, because wealthier people have more money to spare, they can save regardless of whether their disposition leads them to see savings as effective. We provide evidence that optimism increases savings, especially among lower income individuals, in 4 studies (3 additional studies are not reported for brevity).

In study 1, we test for an association between optimism, income and savings in cross-sectional survey data from The National Longitudinal Study of Adolescent to Adult Health, a nationally representative study of U.S. adolescents. Our sample includes respondents who completed the Wave 4 interview in 2008 ($N = 4,443$), the only wave to measure optimism. Participants answered four items measuring optimism, and indicated their income, total savings, and demographics. Using an ordinal logistic regression, we predicted saving from optimism, income, and their interaction, while controlling for demographic covariates to increase power (income, education, age and gender). As predicted, we find a positive effect of optimism on savings ($\beta = .265$, $z = .027$, $CI_{95\%} = [.21, .32]$, $p < .001$, OR = 1.30), and that the effect of optimism on savings is lower among wealthier individuals ($\beta_{interaction} = -.002$, $z = -2.12$, $CI_{95\%} = [-.004, -.0001]$, $p = .034$, OR = .998).

In study 2, we test our Hypothesis using survey responses from a nationally representative sample from the United Kingdom ($N = 4,170$). Participants answered four items measuring optimism as in study 1, indicated their total amount of savings (binned), their total income (binned), and demographic characteristics. Participants additionally answered whether they set savings goals, allowing us to probe whether optimism and income interact to predict the perceived efficacy of savings. We first predicted whether participants had a savings goal (binary) from their level of optimism, their income, and the interaction of the two (optimism and income were mean-centered). As predicted, more optimistic participants saved more ($\beta = .20$, $z = 4.13$, $p < .001$), and the effect of optimism decreased at higher income levels ($\beta_{interaction} = -.05$, $z = 2.71$, $p = .007$). Controlling for optimism and income, participants with savings goals saved more than participants without savings goals ($\beta = .70$, $t(3,298) = 3.46$, $p < .001$).

In studies 3 and 4, we replicate these patterns in the lab. In study 3, we randomly assigned 439 participants into one of four conditions in a 2 (optimism, pessimism) x 2 (high income, low income) experiment. To manipulate optimism, participants wrote down things they were looking forward to (optimistic condition) or not looking forward to (pessimistic condition) over the next week, year, and 5–10 years. To manipulate wealth, participants read brief vignettes. Participants indicated what percent of their income they wanted to save over the next year. As predicted, optimistic participants wanted to save a higher percent of their income than pessimistic participants ($M_{optimism} = 31.18$, $M_{pessimism} = 27.71$, $\beta = 3.45$, $t(418) = 1.78$, $p = .077$). Wealth had no influence on savings ($M_{lowWealth} = 30.36$, $M_{highWealth} = 28.55$, $t(418) = .89$, $p = .374$), and we did not observe an interaction between the two manipulations ($\beta_{interaction} = -3.89$, $t(418) = 1.00$, $p = .317$). This suggests the possibility that it is not a *psychological* difference between higher and lower income households that drives the difference in the effect of optimism, but perhaps structural factors (e.g., that higher income households tend to save by default).

Given that lower income households are more in need of saving, in study 4 we recruited only participants with self-reported household income lower than $50,000 ($N = 402$). We manipulated optimism with a short vignette accompanied by a cartoon illustration, measured the perceived efficacy of saving, and measured behavioural intentions to save. As predicted, optimistic participants perceived saving to be more effective ($M_{optimistic} = 8.86$, $M_{pessimistic} = 6.65$; $t(400) = 9.35$, $p < .001$), and intended to save a higher percentage of their next paycheck ($M_{optimistic} = 32.33\%$, $M_{pessimistic} = 26.58$; $t(400) = 2.50$, $p = .013$). The effect of optimism on behavioural intentions to save was mediated by the perceived efficacy of saving ($CI_{95\%} = [6.51, 11.75]$).

Promoting saving is a critical step to helping people improve their lives and compound wealth. Despite a large amount of research into its antecedents and consequences, we are far from a comprehensive understanding of how to increase saving. The present research suggests that manipulating optimism can be one critical way to help people ascend from poverty, and buffer themselves from financial shocks that perpetuate poor life outcome.

SESSION OVERVIEW

Marketing and consumer research have largely overlooked the consumption of housing and neighborhoods, despite their ubiquity and importance in the lives of consumers. The purpose of this session is to redress this curious omission through the ways in which the sociality of place is constructed, experienced, and maintained in conjunction with market forces. To further explore the multifaceted nature of sociality and its connections to consumption and place, this session features four projects that present the construction of the sociality of place at different levels of analysis, from the level of the individual home through neighborhoods to the level of cities. We also feature a presentation by experienced members of a city planning department to complement the research presentations, in order to present a rich perspective on sociality, consumption, and place.

Conceptually, sociality refers to forms of attachments, interactions, and relationships that exist between individuals and groups (Perren and Kozinets 2018; Russell and Schau 2014; Wittel 2001). These social components come together to form a unique form of social life, and significantly contribute to consumer behavior and social change. Marketing and consumer research is increasingly bifurcating studies of sociality into those that explore more dispersed forms, so-called *network sociality* (Wittel 2001), versus those that focus on more communitarian forms (Bradford and Sherry 2015; Cova and Pace 2006; Muñiz and O'Guinn 2001; Schau, Muñiz, and Arnould 2009). More generally, regardless of the form, extant consumer research suggests that sociality: 1) is linked with the marketplace (Muñiz and O'Guinn 2001; Schouten and McAlexander 1995; Thomas, Price, and Schau 2013); 2) is reflected in forms of infrastructure, both digital and physical (Castilhos 2019; Kozinets, Patterson, and Ashman 2017; Perren and Kozinets 2018); 3) is connected with individual self-concept (Russell and Schau 2014); 4) is connected with individual values and beliefs (Arsel and Bean 2013; Kates 2002); and 5) influences opportunities, social mobility, and access to different lifestyles (Grier and Perry 2018). Experiences and meanings of place occur at many different levels (Gieryn 2000), leaving an opportunity

to extend our understanding of sociality while exploring the diversity inherent in consumption of housing and neighborhoods.

In this session, our projects explore sociality of place at the micro (e.g home), the meso (e.g. neighborhood), and macro (e.g. city) in order to develop understanding of the forms sociality intended for a place, and the links to consumption dynamics. The first project discusses the ways the Peloton brand community members create forms of public space to be shared with the group, but within the domestic realm. Project 2 examines evolving restructuring of sociality shaped by consumption of place through a dispersed Chateau community consisting of emplaced members as well as a global audience of loyal fans. Project 3 explores the way neighborhood socialites are created and consumed by resident consumers. Project 4 features insights from city planners who discuss how sociality is considered in the decisions that shape a city's growth, infill, and future planning. Together these projects enrich our understanding of sociality and contribute towards disciplinary explorations of homes and neighborhoods.

Branded Home: Working it Out in Capitalistic Spirituality

EXTENDED ABSTRACT

Spaces within the family home are becoming ever-increasingly reminiscent of public spaces, such as home theatres, gourmet kitchens, man caves (e.g., bars), and work-out rooms. Traditionally, branded spaces reside in the public domain, yet these spaces are moving into domesticated spaces. The home is soundly recognized as a proximal environment for not only individuals' identity but also negotiated familial identities (Epp and Price 2010). Yet space is conceptualized and designed not by the individuals solely living within the space, but as a result of location, wider social groups, and artifacts available to the residents. Consumers' transition of geography and new social groups can change the meaning of home, impacting the design of domestic space (Cruz and Buchanan-Oliver 2020). Materiality and sociality work recursively to impact public spaces, such as coffee houses (Karababa and Ger 2011) and tailgating (Bradford and Sherry 2015). Public spaces also imbibe an attachment that mimics that of a domestic space (Debenedetti, Oppewal, and Arsel 2014). Yet, domestic spaces offer complex environments in which to understand identity work housed within wider social expectations, including the curation of masculinity in man caves (Moisio and Beruchashvili 2016). While prior literature has investigated some of these unique spaces, lesser research has investigated the impact of brand-ecosystems on these newly-defined spaces in the home. As such, we investigate the following research question: *How are brand-ecosystems influencing the design of branded domestic spaces?*

This study leverages assemblage theory (DeLanda 2006; Deleuze and Guattari 1987) to explore the context of home-gyms for consumers within the Peloton-brand ecosystem. Assemblage theory enables exploration of the wider socio-materiality of the Peloton ecosystem, where social actors and artifacts are investigated as ontologically equivalent in the development of home gym aesthetic. Our netnographic approach (Kozinets 2015) recognizes the wider technoculture of Peloton, and data collection is comprised of online exploration within Facebook and Instagram brand communities and interviews with 30 Peloton riders. We also engaged in a photo-elicitation approach where informants were asked to supply images of

their workout spaces. Additionally, we collected images from social media posts and Peloton blogs. The images were analyzed leveraging critical visual content analysis techniques as guided by Rose (2016). The hermeneutic analysis of the interviews, photographs, and netnographic review of the branded communities was analyzed iteratively to reveal the elements within the assemblage that impact the branded domestic space.

Findings reveal that the branded home gym emerges from the wider socio-material assemblage, including not only the rider but also the branded material (e.g., Peloton bike, rider nameplates, accessories), non-branded material (e.g., weights, lighting, plants, art), instructors, and social circle that takes place online and offline. Ultimately, riders craft their domestic spaces with influence from this assemblage, with significant sway from the blended socio-materiality.

Visual analysis revealed that Peloton riders' spaces include dedicated gym spaces or space entanglements, residing within other domestic spaces. The spaces themselves range from modes of productivity to spiritual entanglements, with many residing in a complimentary manner. In spaces focused on productivity, this is demonstrated by riders emulating the studio aesthetic, including fluorescent lighting and prominent placement of commonly instructor quotes: "*Don't stop, get it. get it.*" Bikes are also stitched into existing modes of productivity, next to office desks and enabling multitasking (e.g., working, taking care of dependents). Spirituality is a common occurrence through the sacred display of branded materiality, but others denote a feeling of tranquility. These spaces are used as a temple to give thanks to the body, and services recovery and well-being beyond the physical. Spirituality is highlighted within riders' spaces through the use of serene colors, an interstitial with nature, the traditional spiritual figurines (e.g., Buddha) and deified brand, instructor, and community elements.

We identify four agential groups associated with the rider that influence the nature of the space, including branded and non-branded materiality as well as branded and non-branded sociality. Embedded within the blended materiality, social structures shape common expectations within these branded domestic spaces, or Peloton shrines. While the materiality alone shapes and constrains the base of the space, the affective atmosphere (Anderson 2009) takes shape as a result of branded and non-branded socio-materiality. For instance, Sherry's space comes to life from branded socio-materiality:

> "On the smart TV, you can put a picture on it. We have a picture of Alex Toussaint on there. He's both me and my husband's favorite instructor...but Alex is just really motivating. We like having him on the screen there, it kind of helps you get into your workout more." (Sherry)

In this case, the parasocial relationship (Dibble et al. 2016) shapes the space's aesthetic. Alex's prominent placement is but one example of the embodied nature of the instructor's influence that creates a deified productivity.

The design of the branded domestic space also emerges from blended sociality. The strength of the social connections within the brand ecosystem, including ties in the online communities, can heavily influence the design of the domestic space. Amanda describes the blended sociality influence, despite physical space constraints:

> "I have my Peloton corner; I have all of my, things. I have Peloton things I've collected across the years... I have a milestone board that one of my Peloton friends got me for my birthday up on the wall..." (Amanda)

The study offers insights into the social and material forces that influence space, and more pertinently, the understudied branded domestic space. The dynamics of the technoculture assemblage reinforce symbolic expectations of the brand meanings inherent within this capitalistic spirituality. With the assemblage of the community, we also gain insight into how brands more readily influence dedicated domestic spaces beyond consumption, but desired sacred devotion. Recognizing the sacred artifacts (Belk, Wallendorf, and Sherry 1989), and in this case, co-opted transcendental domestic spaces, social cohesion and brand loyalty are strengthened. Despite post-modern appeals toward transient experience (Arnould and Price 2004) and liquid consumption (Bardhi and Eckhardt 2017), we see this potential dichotomy of virtualized sacred and profane identity work can be mitigated through materialization in domesticated spaces.

Chateau DIY: Consociality and the Consumption of Place

EXTENDED ABSTRACT

Marketing and consumer research have long been attentive to the ways in which technological media play a role in the sociality of consumer collectivities and their dynamics. Studies of brand communities (Muñiz and O'Guinn 2001), tribes (Kozinets, Hemetsberger, and Schau 2008), consumption communities (Thomas et al. 2013), and subcultures (Kates 2002; Schouten and McAlexander 1995) are all sensitive to differences in sociality present in different contexts, especially in terms of emplaced versus virtual modalities. A significant trajectory to this work has been a growing appreciation for the more dispersed forms of sociality that exist in virtual spaces, such as social media (Arvidsson and Caliandro 2016; Cocker and Cronin 2017) and blogging (Kozinets et al. 2017; McQuarrie, Miller, and Phillips 2013).

To account for more dispersed forms of sociality presented by digital technologies and modern life (Wittel 2001), the concept of consociality offers greater utility (Perren and Kozinets 2018). Consociality refers to forms of sociality that emerge when groups of individuals are "copresent in space and time" (Perren and Kozinets 2018, 23). While research leveraging consociality perspectives is attentive to the interplay of emplaced and more dispersed community members, it attends less to the ways the uniqueness of a place informs these community dynamics. For example, Russell and Schau (2014) find evidence that views of diegetic brands alter consumer behaviors in response to the show's viewing schedules, such as engaging in communal viewing with friends. Further, retailers are working to better engage with their customers' journeys and facilitate online connectedness within physical retailing environments (Thomas, Epp, and Price 2020). However, places have unique emplaced qualities, which may include features of the built environment, or specific linkages with their geographical region (Gieryn 2000). We seek to understand the role of consuming place in the dynamics of an evolving consociality.

To explore consociality and its connections to consuming place, we examine a contemporary consumption community (Thomas et al. 2013) based around Chateau de Lalande, a 16th century chateau located in the Indre department of France. Presently, Lalande operates as a full-time residence and seasonal Bed-and-Breakfast. Since 2018, the property has gained publicity through the British television series, "Escape to the Chateau DIY" and, more significantly, through subsequent creation of a YouTube channel, "The Chateau Diaries" which has grown to more than 130,000 subscribers in less than two years. On this channel, Stephanie, one of Lalande's owners, produces two to three weekly "vlogs" involving scenes of daily life, renovation projects, social gatherings, and problem-solving amongst

herself and the current "cast" of residents, which range from permanent residents, semi-permanent residents, short-term guests, and volunteers who work on site in exchange for room and board. As a result of a sharp increase in viewership throughout 2020, Stephanie now manages one of the top 400 Patreon accounts globally, and has a monthly income of more than $29,000, generated from more than 3,100 individual monthly Patreon contributors. These funds are now a central driving force in the ongoing restoration of Lalande. In tandem, Stephanie created a second YouTube Channel in August 2020 which exclusively comprises "gift opening" videos which serve as a way for Lalande residents to appreciate the items that their audience send to the property while also providing a way for Lalande to contribute to charitable causes as all advertising revenue from this channel is donated to charitable causes. Our data set for this project encompasses Digital Methods (Rogers 2013), supplemented with depth interviewing, analyzed using an iterative, constant-comparative model consistent with grounded theoretic approach (Glaser and Strauss 2017; Spiggle 1994).

We find a heterogenous 'Lalande' community (Thomas et al. 2013) that varies by its degree of closeness to the unique location that is Chateau de Lalande. This familial sociality is rooted in notions of friendship as chosen family, as well as a growing professionalism amongst those involved in the chateau's social media efforts. Our findings illustrate several practices undertaken by members of the Lalande community linked with the uniqueness of the physical place. These practices allow community members to leave their mark, in a material sense, on Chateau de Lalande. This connects with the current owner's view that they are stewards of the place, whose role is to enhance the historical and cultural value of Lalande for future generations while also fostering a place that is simple, cozy, and comfortable – i.e. lived in – and not a "museum" for the dispassionate display of objects.

Further, we observe three broad sets of practices by which consumers transform their relationship to Chateau de Lalande through connecting with unique aspects of Lalande's physical location. In turn, each of these attempts at connection alters the physical reality of Chateau de Lalande and its emplaced sociality. Through *gifting*, consumers send material objects either to enhance Lalande's interiors or grounds, or for the emplaced members of the Lalande community (e.g., clothing, jewelry, etc.). Consumers submit letters outlining the heritage of the items sent, as well as an explanation for how the items might 'fit' with Lalande or suit the people who live there. *Laboring* involves consumers exchanging their own labor for the ability to visit the Chateau in-person and contribute to the ongoing development of the property. Here, consumers transform their role within the community from viewers into closer knit familial members. Once consumers have visited, the emplaced members of Lalande refer to them as family members, often with invitations to revisit Chateau de Lalande in the future. Finally, *partnering* is a form of exchange whereby Lalande owners cede some amount of control over the prioritization of ongoing renovation projects to consumers in exchange for financial resources. Through varying degrees of monthly subscription, Patreon members become more active participants in the physical development of Lalande. Overall, our findings contribute to the ongoing development of perspectives on heterogeneous consumption communities through the lens of consociality as a conceptual framework for interpreting the dynamic interplay between dispersed members of a community.

Consuming Neighborhood Sociality

EXTENDED ABSTRACT

Neighborhoods have been a focal point in sociological literature for well over a century. Sociologists have studied neighborhoods to understand how people form collective identities, defend themselves in the face of outside threats, and negotiate collective meaning in the midst of societal change (Gans 1967; Keller 2003; Whyte 1943). However, this literature has paid little attention to the marketing of these neighborhoods and to residents' roles as consumers. In the consumer research domain, the consumption of neighborhoods and housing is understudied as well, despite their ubiquity and importance in consumers' lives (see Grier and Perry 2018; Saatcioglu and Ozanne 2013 as noteable exceptions).

Consumers are increasingly choosing to live in neighborhoods to gain far more than housing style and location (Gwyther 2005; Katz, Scully, and Bressi 1994; Rosenblatt, Cheshire, and Lawrence 2009); socially inspired design matters as well. Preferences and tastes are shifting to neighborhoods offering walkability, sustainable design, and an emphasis on different forms of sociality (Brass 2018; Katz et al. 1994; Montgomery 2013). Consumers are also considering the intended lifestyle of the place and the sociocultural preferences of the people who live (or are going to live) there and are choosing neighborhoods inhabited by others who share similar lifestyles, tastes, political orientations, and ideologies (Crockett and Wallendorf 2004).

In this research, we demonstrate how these intended forms of social interaction shape approaches to building, changing, and maintaining neighborhoods and their unique culture. We explore the creation, maintenance and consumption of neighborhood sociality in four new construction neighborhoods in a medium sized city in the southeastern United States: Celestial Pines, Arboretum, Lenox Hill, and Magnolia Trace. We define neighborhood sociality as the emergent forms of affiliative interactions and relationships within a neighborhood. Each neighborhood in our study is planned and developed by a single developer/builder, and all have unique design styles and respective socialites. We use ethnographic approaches to observe daily social life, supplemented with depth interviewing and participant observation at neighborhood social events, to understand the ways consumers experience and work to contribute to their neighborhood's sociality, as they understand it.

Our findings identify characteristics of neighborhood design and philosophies resident consumers use to interpret sociality. We also examine different ways resident consumers develop and maintain shared practices that establish normative forms of interaction and social life in efforts to preserve or change sociality. In our interviews with neighborhood developers, we find that the idea for the desired or intended sociality comes first, and then the built environment reflects/reifies that. Developers describe their neighborhood in terms of its design, how it compares with other local neighborhoods and their own previous projects, and the experience they envision for the residents who will live there.

Aesthetics and the built environment act to influence how people interact. For example, Celestial Pines was inspired by a cohousing philosophy, and the design is intended to foster sociality through frequent interaction and a focus on communal care and maintenance. Elizabeth is a long-time resident and a founding member who closely worked with the developers. She describes the design and reliance on communal work:

> *We also wanted community. That's why we didn't want our homes to have garages. We wanted kind of the park-*

ing area separate so that when you walked in from the parking area, we would be passing each other's homes and possibly we would have constant connection to each other rather than driving into a garage and then closing the door and not seeing each other. We really wanted that community. And that sense of community-involved responsibility is for the upkeep of everything. It meant that you were hands-on all the time. You know, in the very beginning, there were four of us so we really had to, like, be hands-on all the time.

Elizabeth makes clear her beliefs about the built environment (i.e., location and nature of parking) on social engagement. By contrast, the sociality in Lenox Hill is more about residents being freed from other responsibilities to pursue their social lives. Sarah, who was a realtor, so enjoyed selling Lenox Hill and its sociality that she bought a house there and became a resident:

If you're gonna spend the money on a house like [her previous very large house], you better have enough money to pay people to do all that shit [clean the pool and mow the yard], and that's a lot of money. And at that point it's like what's the trade-off? Where if you could have the same amenities and not have to maintain any of it, and spend your days off doing whatever you want ... rather than feeling guilty because you haven't mowed your yard in two weeks.

For Sarah, the sociality of Lenox Hill offers her therapeutic value (Higgins and Hamilton 2019). By living in Lenox Hill, she is able to free herself from many of the responsibilities of home ownership, such as cleaning a pool or mowing a yard. This allows her to have more time to pursue her own interests, such as connecting with her neighbors. On an emotional level, Lenox Hill offers Sarah freedom from the psychological burden of guilt she would experience in a neighborhood where she was responsible for this sort of maintenance. Contrasting these two examples allows us to see the varying approaches to producing spaces that facilitate an intended form of sociality.

Our findings contribute to an understanding of how neighborhood sociality is planned, developed, interpreted, and maintained in conjunction with consumption practices. Through greater attention to neighborhood sociality as a meso level of social analysis, we can understand how consumers make sense of the place where they spend the majority of their time, as well as how they form relationships there. Our ongoing efforts aim to afford researchers, as well as community advocates and urban planners, a greater understanding of the power of sociality in transforming human lives, positively (Montgomery 2013) and negatively (Grier and Perry 2018).

Sociality and the City: A Model for Consumer-Driven Problem Solving

EXTENDED ABSTRACT

What makes for a great city? A city's physical environment, including buildings, bridges, parks, streets, sidewalks, and transportation provides the infrastructure for people to move and interact. In addition to the physical environment, the connections and transitions within and between infrastructure are equally important, and it is the combination of places and people that make a functional, attractive, comfortable, and safe framework for social life (Amin 2014; Montgomery 2013; Sim and Gehl 2019).

Urban designers strive to balance vision and reality, aesthetics and function, heritage and change, to make people-centered places that are sustainable and enhance the property values of their surroundings. To accomplish this, city planning departments consider the forms of sociality – the interactions and lived experiences – that contribute to the sense of place they would like to create and foster for residents, businesses, and other groups served throughout the city. A sense of place typically includes commercial elements, such as retail shops and places of employment, as well as plenty of ways for people on the move or stopping to chat, a public park or square, and possibly some planned events or activities.

Successful cities require people who are invested and engaged with their environment and the community. However, different constituent groups have varying priorities, further compounded by the complexity of the issues facing cities, which blend economic, social, and cultural concerns (Castilhos 2019; Philips 2020; Sim and Gehl 2019). City planning and growth management departments must weigh priorities and the feasibility of possible interventions, in order to determine whom and what will be served by proposed initiatives.

In this presentation, we will discuss strategies for creating spaces that encourage and foster sociality in all its forms. Drawing on nearly 30 years of combined experience in city planning we will discuss community engagement practices that encourage community involvement and influence in the city's approaches to growth and change. We manage the city planning and growth management departments for the city of Tallahassee, Florida. Our department uses an agency model within the city government structure to streamline our services in working with neighborhoods, property owners, community organizations, and developers in conceptual site planning, and assists architects and engineers to produce their professional work throughout the city.

Through exploring approaches to community engagement and community driven problem solving, cities can more clearly define the priorities of the city as well as acquire buy-in and support from citizens. The goal is to foster community vitality where people feel a strong stake in their communities and a commitment to making things better. We use a model of community engagement that we call community driven problem solving. This process addresses local concerns in ways that respect the particular contingencies and sociality of the communities involved. Further, it works to leverage existing assets, personal inspiration, and larger potential, ultimately creating good public spaces that promote people's health, happiness, and well-being. Our approach revolves around three practices that use community engagement to inform city planning in effort to encourage an intended form of sociality with a particular subregion of the city, namely: Eliciting, Contextualizing, and Guiding.

In the first stage of our community-driven process, Eliciting, we seek out problem identification from the local community members in their respective neighborhoods or areas of interest in the community. This helps to collectively identify the focal issues but comes with a caveat to also offer up solutions. Common issues that arise range from elicitation efforts are beautification initiatives, preservation of historic districts, economic inequality, and affordable housing. Our goal is to ensure articulation of the issues is rooted in the community who identifies the problem, rather than imposing an outside perspective. To gather these insights, we offer platforms for feedback and information sharing that align with the sociality of the particular context, such as holding town hall meetings, or instigating pop-up events in relevant local venues in areas where citizens may be skeptical of electronic surveys.

After identifying the local issues and some possible directions for solutions, we begin Contextualizing. During this phase of the

process, we work to prioritize issues and determine their feasibility. This often involves evaluating the allocation of resources to projects in a region of the city with particular forms of sociality against redistributing those resources for radically different projects in another region with a very different sociality. Working through these kinds of trade-offs often requires very real conversations and honesty with community stakeholders about our prioritization process and our mandate to reduce disparities and inequality across the city. We must consider the totality of socialities throughout the city's regions, and how these socialities are woven together into a cohesive civic society.

Finally, we pursue the practice of Guiding. Through infrastructure development, which is guided by our city's comprehensive plan, as well as goals for the city, we seek to shape the type and amount of development occurring in any give region of the city. In general, development follows infrastructure, and so we work to shape commercial investment and involvement through strategic infrastructure creation, which derives from the forms of sociality we think is ideal for a particular area of the city.

SESSION OVERVIEW

During the past year or so, consumers' personal and professional interactions have increasingly moved online. Consumers spend hours working, shopping, interacting with friends and expressing their opinions virtually. However, according to the popular press, these enhanced sharing opportunities have resulted in opposing outcomes. While some articles caution that consumers are over-sharing (Steinberg, 2020), others highlight consumers' propensity to under-share (Dooley, 2017). The papers in this session focus on consumers' reluctance to share self-relevant information, by exploring its drivers, consequences as well as what happens when consumers do share, but probably should not have. Overall, the session deepens our understanding of impression management strategies that affect when and why consumers hesitate to share, or do not, and the consequences of their choices.

The first two papers focus squarely on consumers' reluctance to share. **Solinas, Valsesia, Nunes, Ordanini** examines how consumers' likelihood to post reviews online evolves over time. They find consumers are reluctant to post negative reviews early in their reviewing history, resulting in a negative trend in reviews at the reviewer level. They present evidence that this reluctance is driven by people's desire to avoid being perceived negatively.

Carbone, Loewenstein, Scopelliti, and Vosgerau explore how gender influences consumers' reluctance to disclose information about the self. They find women are overall more likely to share information than men. More importantly, while they find men and women are equally likely to disclose positive information, men are especially reluctant to disclose negatively-valenced information in order to maintain a desired image.

The next two papers explore the consequences of consumers' decisions regarding sharing. The first focuses on a context where under-sharing impacts impressions negatively, the second explores a situation where over-sharing has negative consequences. **Karabulut, Moore, and Messinger** explore actors' use of more or less revealing backgrounds online. They find people generally avoid personally revealing backgrounds when they want to come across as competent to their audience. Yet, observers evaluate people with revealing backgrounds more positively, both in terms of warmth and competence.

Finally, **Sezer, Affinito, and Staats** focus on whether advisors share the fact they were right in the past, and how advisees react. They find that, while consumers frequently share the phrase "I told you so" when being right about something, advisees dislike this statement and view people who use it as condescending, less empathic, and less trustworthy, compared to someone that simply stays silent.

Taken together, this session expands our understanding of strategic self-presentation with regards to sharing. We identify different drivers of consumers' reluctance to share, while highlighting when being more forthcoming can help, and when instead being too forthcoming hurts. Given the importance of sharing and its impact on impression management, we expect this session to generate interest among researchers studying strategic self-presentation, information disclosure, online consumer behavior, as well as gender effects. In the spirit of the conference theme "Privacy," we believe this set of papers illuminates what influences consumers' decisions of when and why to stay silent, and will provoke a fruitful and engaging discussion at ACR.

I Want You to Like Me, so I'll Wait to Share the Bad - The Influence of Self-Presentation Concerns on Consumer Ratings

EXTENDED ABSTRACT

Previous work has documented a negative trend in reviews on online platform for individual *products across reviewers*. Prior research suggests this is due to social dynamics (Schlosser, 2005), self-selection (Li and Hitt, 2008; Wu and Huberman, 2008; Hu and Li, 2011; Moe and Schweidel, 2012), and macro-level trends (Godes and Silva, 2012). In this work, we identify a different, yet equally important phenomenon: a negative trend in reviews for individual *reviewers across products*.

We propose and test a self-presentation explanation for this phenomenon. One strategic way to avoid negative impressions is limiting what one says publicly (Schütz, 1998). The MUM effect (Rosen and Tesser, 1970) suggests people avoid delivering negative information as a way of not being linked to the negative feelings it engenders. We argue reviewers are concerned about the impression they might make on other online platform users. Further, in order to avoid making a negative impression before having established a reputation in the community, they tend to stay silent rather than share negative experiences early in their review history.

In study 1, we document a negative trend for individual reviewers across products using real-world Yelp data. The data include 8,635,403 reviews made by 2,189,457 reviewers since its inception (2004) until 2021. Having data since Yelp's inception is critical as it includes reviewers' first reviews, and allows us to test for the existence of a negative trend as users begin accumulating reviews. The number of ratings posted by a reviewer before the focal rating serves as the main predictor, while star rating serves as dependent variable. We analyze the data using an ordinal logit model with random effects at the reviewer level. The coefficient of our predictor is negative and significant, suggesting the existence of a negative trend at the reviewer level (OR=.99; $p<.01$). For a reviewer, accumulating 10

reviews increases by 8.3 percentage points the chance the next rating falls into a lower (vs. higher) star category.

In study 2 (N=324) we disentangle whether the negative trend observed is due to people's reluctance to post negative reviews early on, or a change in how experiences are evaluated over time. This study is a 2(Experience: *Positive* vs. *Negative*) x 2 (Review History: *Early* vs. *Late*) between-subjects design. Participants recalled either a positive or negative experience. Next, they read about an online rating platform where they had already posted either 2 or 22 reviews and were asked if and how they would rate the experience they recalled. Respondents were more likely to post a positive than a negative experience (F(1,317)=44.68, *p*<.001). A significant interaction emerged (F(1,317)=5.87, *p*=.016): participants were more likely to post the negative review late (M=3.88) than early (M=3.24, F(1,317)=5.12 *p*=.024), whereas there was no significant difference for positive experiences. While positive experiences had a higher likelihood of receiving a higher star-rating (OR=5.7 p<.001), the number of prior ratings did not impact how respondents evaluated the experience.

These results suggest the negative trend is mainly due to *when* consumers decide to share negative experiences, as opposed to a change in *how* experiences are evaluated. The next studies provide initial evidence for our explanation: reviewers' reluctance to post negative reviews early on is driven by self-presentation concerns.

In study 3a (N=395) we manipulated Review History (*Early* vs. *Late*) between-subjects. We asked respondents how they expected other users would perceive them if they posted a negative review. We find they expect to be perceived more negatively when posting a negative review early (M=4.71) rather than late (M=4.17, t(393)=3.70, *p*<.001). In study 3b (N=301) we find evidence this expectation is accurate. Respondents formed a more negative impression of a reviewer who posted a negative review early (M=4.67) rather than late (M=3.67, t(299)=5.80 *p*<.001).

Study 4 (N=389) is a single-factor (Review History: *Early. vs Late vs. Late/different platform*) between-subjects design aimed at providing evidence of a self-presentation explanation through moderation. Participants recalled a negative experience and imagined having joined a review platform ("Yum") on which they posted either 1 (*Early*) or 18 (*Late*) review(s). In the *Late/different platform* condition, respondents were told they had posted 17 reviews on Yum but had then joined a new platform ("JustEat") on which they only posted 1 review.

Participants were less likely to post the negative review early (M=3.66) than late (M=4.33, F(1,386)=7.20 p=.008). Importantly, participants in the *Late/different platform* condition were also less likely to post the negative review (M=3.80) than those in the *Late* (same platform) condition (F(1,386)=4.66 p=.031). There was no significant difference between *Early* and *Late/different platform* conditions. These results provide evidence that reviewers' reluctance to post negative reviews early on does not depend on the number of prior ratings per se, but rather on the number of prior ratings in front of a certain audience, consistent with self-presentation concerns playing a role.

Study 5 (N=301) identifies a platform feature that can mitigate the negative trend. We test whether bundling a negative review with more positive reviews, and posting them simultaneously, moderates the effect in a 2 (Review History: *2nd* vs. *17th*) x 2 (Reveal: *Sequentially* vs. *Simultaneously*) mixed design. Respondents imagined joining a review platform and were presented with 18 distinct dining experiences, and a brief description of each, sequentially one-by-one. The 2nd and 17th experiences were described as more negative. Participants rated each experience and reported their likelihood to post that

review. In the *Sequentially* condition, likelihood to post was reported for each experience one-by-one; in the *Simultaneously* condition it was reported after providing all 18 ratings and knowing all reviews would be posted simultaneously. Respondents were more likely to post the 17th (vs. 2nd) negative review (F(1,299)=14.68, p<.001). Participants were more likely to post when reviews would appear Simultaneously than Sequentially (F(1,299)=7.46 p=.007). A significant interaction emerged (F(1,299)=8.48, p=.004). When posted Sequentially, participants were more likely to post the 17th (M=5.12) than the 2nd review (M=4.53, F(1,299)=23.12 p<.001). When posted Simultaneously, no significant difference emerged.

Overall, our studies provide evidence that reviewers' reluctance to post negative reviews early on is due, at least in part, to self-presentation concerns.

He Said, She Said: Gender Differences in Disclosure

EXTENDED ABSTRACT

The advent of an increasing array of digital communication channels and social media has enabled unprecedented levels of information sharing and self-disclosure, which can be inherently pleasurable (Tamir & Mitchell, 2012) and engender health, psychological, and social benefits (e.g., Frattaroli, 2006). At the same time, these new opportunities for self-disclosure take on a public and often permanent character, amplifying the potential for material and reputational damage (Brandimarte, Vosgerau, & Acquisti, 2018; Hofstetter, Rüppell, & John, 2017). The present research explores differences in how men and women navigate these trade-offs and contributes to a vast but somewhat inconclusive literature on gender differences in self-disclosure. Although women are generally found to be more disclosing than men, gender differences are sensitive to features of the context and experimental design (Dindia & Allen, 1992). We circumvent several challenges facing the extant literature in three studies that employ novel designs and measures to explore the boundaries of gender differences in self-disclosure.

In particular, we focus on differences not only in actual disclosure but also in the psychological desire to disclose among men and women. A wide range of factors, such as impression management and the anticipation of negative consequences, can inhibit disclosure. At the same time, men and women face different consequences, and thus have a different set of considerations, when translating the desire to disclose into a decision of whether or not to share information with others. Our results present a robust and systematic pattern in which women experience a stronger psychological desire to disclose and are more likely to act on that desire than their male counterparts. However, these results are driven by an interaction between gender and the valence of the information to be disclosed. Specifically, males and females exhibit a similar desire and propensity to disclose positive information, but males have a substantially lower desire and propensity to disclose *negative* information than females, reportedly due to an interest in impression management.

In **Study 1** (N=215), participants were asked to recall a time when they were "dying to tell someone something" and to indicate whether or not they ultimately shared the information with others. This information could be about any topic and concern oneself or someone else. Female participants were significantly more likely to report having had the experience of "dying to share" than their male counterparts, 91% vs. 76%, χ2(1, N=193)=7.88, *p*<.01. Open-ended descriptions of these events revealed a significant interaction between gender and valence, with a substantially greater proportion of male than female responses coding as positive, 63%

vs. 48%, χ2(1, N=235)=5.66, *p*=.02. This can be explained by gender differences in underlying motivation. When asked to select from a list of motives those that might have driven their desire to disclose, males overwhelmingly selected self-presentational motives relative to female participants. Specifically, significantly more female participants reportedly wanted to reveal the information in order to be comforted, t(162)=2.16, *p*=0.02, while significantly more males wanted to disclose in order to: entertain others, t(162)=-2.14, *p*=0.02; influence how others see them, t(162)=-1.90, *p*=0.03; receive validation or praise, t(162)=-1.89, *p*=0.03, t(162)=-1.82, *p*=0.04; and reinforce their own self-image, t(162)=-1.69, *p*=0.05.

Participants in **Study 2** (N=552) saw a random selection of positive and negative "scenarios" that were almost exclusively self-relevant (e.g., feeling proud about a moral decision you made, learning that a close friend said something hurtful about you). For five of the scenarios that they reportedly experienced in the past, participants indicated their desire to disclose the experience to others using a scale from -5 (*Intense, overwhelming desire to <u>withhold</u>*) to 5 (*Intense, overwhelming desire to <u>share</u>*), and subsequently indicated whether or not they ultimately shared the information with others. For both measures, we observe a main effect of gender: Female participants, on average, experienced a stronger desire to disclose than their male counterparts, M=1.53 (SD=2.43) vs. M=1.03 (SD=2.47), t(2658)=5.21, *p*<.01, and women reported disclosing on average more of the scenarios (77%) compared to men (69%), χ2(1, N=2384)=22.78, *p*<.01. Fixed effects OLS and logistic regressions confirmed the presence of a gender-valence interaction for the desire and propensity to disclose, respectively, albeit marginal for the former measure, Desire: $b_{maleXnegative}$=-.31, t(2,540)=-1.74, *p*=0.08; Propensity: $b_{maleXnegative}$ (as odds ratio)=0.78, z(2,282)=-2.37; *p*=0.02. In addition, we captured participants' self-perceptions of their disclosing behavior using a scale from 0 (*I don't share thoughts and feelings when I should*) to 10 (*I share thoughts and feelings when I probably should not*) and found that, on average, men perceive themselves as being too reserved: the average male rating is significantly lower than that of females, M=4.23 (SD=1.79) vs. M=5.01 (SD=1.83), t(546)=5.91, *p*<.01.

The results from the above exploratory studies were then preregistered and tested in **Study 3** (N=407), where we used similar measures for the desire and propensity to disclose as in Study 2 but manipulated valence and self-relevance (i.e., whether the information was about oneself or someone else) both between subjects (within a domain) and within subjects (across domains). As hypothesized, female and male participants experienced a similar desire to disclose positive experiences, t(799)=0.51, *p*=.31, but male participants experienced a significantly lower desire to disclose negative experiences relative to their female counterparts, t(789)=4.55, *p*<.01. This pattern of results holds for reported propensity to disclose, Positive: t(729)=1.29, *p*=.10; Negative: t(760)=4.27, *p*<.01), and regardless of whether the information is about oneself or others.

The experimental paradigms employed in this research departs from the conventional study designs employed in disclosure research in ways that introduce fewer artefactual constraints and, as a result, more closely resembles actual decision-making, providing a better measure of consequential, real-world disclosing behavior. In all three studies, we consistently observe higher levels of the desire to disclose among female, as compared to male, participants when it comes to negative, but not positive, information. Men reportedly shy away from disclosing negative information in the interest of maintaining a desired image. Sharing information is increasingly prevalent in the Internet age, and gender is an important fault line when it comes to patterns both of desire to disclose and of actual disclosure.

Background for Success: The Role of Videoconference Backgrounds in Self-Presentation

EXTENDED ABSTRACT

By enabling virtual "face-to-face" communication anytime and anywhere, videoconferences are changing how people play, work, and shop. In marketing channels, firms are boosting customer satisfaction by emulating in-person experiences through videoconference sales and service activities (Patel, 2020).

While self-presentation motives and strategies are important for online and offline interpersonal communication (Goffman, 1978; Krämer & Winter, 2008; Leavy & Kowalski, 1990; Schau & Gilly, 2003), online channels such as videoconferencing afford new means of self-presentation, and are the focus of the current research.

Revealing personal information is central to self-presentation (Collins & Miller, 1994). People engage in impression management by choosing what—and how much—information to present about themselves to observers (Krämer & Winter, 2008)—and observers need information about actors to form impressions (Kervyn et al., 2009). Online and offline channels both offer self-presentation opportunities in the form of actors' appearance (e.g., clothing; Bellezza et al., 2014), although the amount of such information conveyed in videoconferences is limited to what is visible onscreen. More critically, videoconferences afford a unique—and controllable—self-presentation cue: the onscreen background, which may be real (e.g., bedroom) or virtual (e.g., nature scene). Indeed, 83% of participants in an MTurk survey (N = 283) agreed that controlling their videoconference background could maximize their ability to create a positive impression, and 53% agreed that they form impressions of others in videoconferences based on their background.

Building on these insights, we investigate how actors choose backgrounds and how observers evaluate actors with different backgrounds. We explore how warmth and competence impressions are affected by actors' use of revealing (vs. non-revealing) backgrounds. Revealing backgrounds offer more self-related information about the actor's personality, preferences, or tastes (e.g., a plain wall vs. a Star Trek scene); the use of such backgrounds should convey warmth (Collins & Miller, 1994). However, we anticipate that there will be a gap between actors' and observers' impressions of—and preferences for—warmth and competence.

Prior work suggests that actors perceive a trade-off between warmth and competence in self-presentation. In professional contexts, actors believe appearing competent is more important (Li et al., 2019), and therefore downplay warmth (Fiske et al., 2007; Holoien & Fiske, 2013). Further, the desire to control one's self-image discourages revelation (Arkin, 1981; Berger & Barasch, 2018; Leavy & Kowalski, 1990). Thus, we suggest that actors should anticipate that using non-revealing (vs. revealing) backgrounds will convey competence. In turn, this should lead actors to choose non-revealing backgrounds, whether real (e.g., plain walls) or virtual (e.g., institutional images, single colours).

In contrast, observers should emphasize warmth. This is because warmth is evaluated before competence, accounts for a greater portion of observers' impressions than competence (Cuddy et al., 2011), and is more accessible and diagnostic than competence in impression formation (Scott et al., 2013). Thus, actors' use of revealing (vs. non-revealing) backgrounds should increase observers' impressions of warmth, and should have positive downstream consequences for observers' intentions toward actors.

We test these predictions in three studies. Study 1 examines actors' preferences for non-revealing over revealing videoconference backgrounds. Undergraduates (N=151) imagined themselves as customer service employees who were joining a videoconference with a customer. They were presented with one of four images in a 2 (background: real, virtual) by 2 (type: revealing, non-revealing) design, and imagined the image was their videoconference background. Images in all studies were pre-tested to be equally positive, but to vary in revealingness. After viewing their initial revealing (non-revealing) background, participants were given the opportunity to switch to a non-revealing (revealing) background. Participants in the revealing background condition were more likely to change their background to a non-revealing background (64% vs. 36%; χ^2=8.38, $p < .01$).

Study 2 tests the gap between actors' expectations and observers' evaluations. Undergraduates (N=490) imagined joining a class via videoconferencing. They were presented with a background image in a 2 (background image: real, virtual) by 2 (image type: revealing, non-revealing) by 2 (role: actor, observer) between-subjects design. They imagined the image was their background (actors), or one of their classmate's backgrounds (observers). Participants then reported on the warmth and competence impressions they expected to make on others (actors), or on their warmth and competence impressions of their classmate (observers).

Analysis showed a background type by role interaction on participants' judgments ($F_{competent}(1, 482) = 33.25$, $p < .001$; $F_{warm}(1, 482) = 17.50$, $p < .001$). Actors in the non-revealing condition expected observers to perceive them as more competent ($M = 2.98$) but less warm ($M = 2.42$) than in the revealing condition ($M_{competent} = 2.54$; $M_{warm} = 3.38$; $F_{competent}(1, 482) = 20.45$, $p < .001$); $F_{warm}(1, 482) = 89.44$, $p < .001$). However, observers showed a different pattern: those in the revealing condition perceived actors as more competent ($M = 3.22$) and as warmer ($M = 3.06$) than in the non-revealing condition ($M_{warm} = 2.70$; $M_{competent} = 2.88$; $F_{competent}(1, 482) = 13.16$, $p < .001$; $F_{warm}(1, 482) = 13.18$, $p < .001$). An additional study found a similar pattern of results using a different context, where participants imagined having a work meeting with other employees.

Study 3 tested the actor-observer gap as well as the downstream consequences of this gap. Prolific participants (N=300) imagined joining a virtual consultation session with a nutritionist who was using either a revealing or non-revealing background. They reported on their anticipated satisfaction with the nutritionist and their warmth and competence impressions of the nutritionist. In the revealing condition, participants evaluated the nutritionist as more warm ($M_{revealing} = 3.89$, $M_{non-revealing} = 3.08$; $F(1, 298) = 100.21$, $p < .001$) and anticipated being more satisfied ($M_{revealing} = 5.73$, $M_{non-revealing} = 5.39$; $F(1, 298) = 7.24$, $p < .01$).

In summary, while actors anticipate that they create impressions of competence when they use non-revealing backgrounds, observers do not share these impressions. Instead, observers perceive actors with non-revealing backgrounds as less warm, which negatively impacts their service evaluations and intentions. These findings provide novel evidence for service employees' self-presentation strategies in their interactions with customers on an emerging platform and customers' reactions to these strategies.

I Told You So Effect

EXTENDED ABSTRACT

From solving complex problems to making purchases, people often rely on advice from others. In fact, consumers rarely make critical decisions in isolation. Prior research has identified multiple factors that influence individuals' use of advice. For instance, deci-sion makers weigh advice more heavily when the advice is costly to get (Patt, Bowles & Cash, 2006), or when the task is difficult (Gino & Moore, 2007). When people feel confident or experience anger (Bonaccio & Dalal, 2006; Gino & Schweitzer, 2008), they are less likely to rely on advice. Similarly, advisor characteristics also impact whether people follow their advice. When the advisors are more experienced (Feng & MacGeorge, 2006; Goldsmith & Fitch, 1997; Harvey & Fischer, 1997; Sniezek, Schrah, & Dalal, 2004; Soll & Larrick, 2009; Yaniv, 2004; Yaniv & Milyavsky, 2007) and have greater confidence (Phillips, 1999; Sniezek & Buckley, 1995; Sniezek & Van Swol, 2001; Soll & Larrick, 2009; Van Swol & Sniezek, 2005; Yaniv & Foster, 1997), the advice is weighted more heavily.

At the same time, however, the consequences of expressions that advisors use depend on the psychological and emotional reaction of the targets, and critically on their appraisal of the advisor statements as helpful or not, because interpersonal aspects in advice exchange is as important as the quality of the advice (Blunden, Logg, Brooks, John & Gino, 2019). While previous research has focused on expressions that prompt advisor credibility and confidence (Soll & Larrick, 2009), little is known about the effects of statements that backfire. In the current research, we investigate a common and a universal statement that is of critical importance in advice-giving contexts: "I told you so."

Building on past research on advice-giving and learning, we conceptualize "I told you so" as a statement that stem from the satisfaction of being right. We propose that individuals who hear this statement view the advice giver as more condescending, less empathic, and less trustworthy. We suggest that although it is a very common statement that exist in all languages across the world, and is a universal phenomenon, saying I told you so backfires as it harms trust in advice exchange and hurts learning.

In Study 1 (N = 302), participants estimated an individual's weight from a photograph for three rounds. Out of 302 participants, 133 of them ignored their advisor's estimate in Round 1, and 169 of them took the advice. In Round 2, those who didn't follow the advice in Round 1, got another piece of advice, but half of them heard the new advice with "I told you so" while the other half only heard just the advice. Among the ones who ignored their partner's advice in the first round, those who received Round 2 advice with "I told you so" perceived the advice to be lower quality than those who received the same advice without the I told you so statement, t (131) = 2.64, p = .009, M = 4.11 vs M = 4.75. Similarly, the group that received "I told you so" perceived their advisor to be more condescending, t (131) = 7.69, p = < .001, M = 4.89 vs M = 2.53, and less empathic t (131) = 3.43, p = . 0008, M = 3.54 vs M = 4.24.

In Study 2 (N=500), we employed the same design as Study 1, and randomly assigned participants to one of two between-subjects conditions: "I told you so" vs "You were wrong.". When participants didn't follow their partners' advice, in Round 2, they either received "I told you so" or "You were wrong" as a message in addition to advice for the new round. Out of 500 participants, 276 of them ignored the advice from their partner in Round 1. Among the group who ignored their partner's advice, those who received "I told you so", perceived their partners to be more condescending t (274) = 8.07, p = < 001, M = 5.01 vs M = 3.71, and less empathic t (274) = 4.32, p = .002, M = 1.81 vs M = 2.37, than those who received "You were wrong" from their partners.

In Study 3 (N=102), participants in the lab completed the same weight estimation task, and those who received "I told you so" in Round 2, along with the advice, perceived their partner to be more condescending, t (100) = 9.67, p < 001, M = 5.03 vs M = 2.87, less empathic t (100) = 7.23, p < 001, M = 1.81 vs M = 3.56, and less

trustworthy t (100) = 3.89, p = .004, M = 3.56 vs M = 4.35. than the participants who didn't hear I told you so, but received the same advice. More importantly, those who received "I told you so" were less likely to choose the same partner for the subsequent round, p = .03.

In Study 4 (N=102), participants engaged in 10 rounds of the same task, but as an advisor this time. After each round, they found out they were right, and their partner was wrong, and they could either send "Bummer!" or "Bummer, I told you so!" as a message. 142 out of 200 participants (71%) chose to send the "I told you so" message at least once across 10 rounds, and on average, participants chose to send this message 3.235 times of the possible 10. About 23% of participants chose to say I told you so after only Round 1. In other words, despite not liking this statement (as shown in Studies 1,2 and 3), when given a chance, participants use their chance to say "I told you so."

We contribute to advice literature by focusing on interpersonal effects, as opposed to decision accuracy and quality, which has been the primary focus of previous research (Bonaccio & Dalal, 2006). We introduce and examine the psychology underlying a common advice statement "I told you so" and shed light on the importance of empathy and trust in learning and building an advisor-advisee relationship.

Paper #4: The Addictive Properties of Mobile Applications: How Endless Scrolling and Intermittent Notifications Impact Consumer Perceptions and Behavior

Ana Valenzuela, Baruch College, CUNY & ESADE Business School, USA
Lennay Chapman, Baruch College, CUNY, USA

SESSION OVERVIEW

As of 2019, a total of 2.71 billion people around the world, including 81% of Americans, owned or used smartphones (Montag et al. 2019; Pew Research 2019). Smartphones are portable, personal, and (because of these features) can provide feelings of comfort during times of stress (Melumad and Pham 2020). Yet smartphones also contribute to unsafe behaviors, have been associated with decreased work productivity (Duke and Montag 2017), and their mere presence can decrease available cognitive resources (Ward et al. 2017).

Many everyday decisions and activities are made with electronic devices. However, little is known regarding how various electronic devices shape how consumers construe and process decisions. Accordingly, the shift from stationary to mobile devices presents consumer behavior researchers with an opportunity for academic research that is not only theoretically important, but that is also rife with timely substantive implications.

Our special session addresses this opportunity by exploring consequences stemming from how the use of one's smartphone to perform certain activities, including choice, may affect the extent of self-expression, what becomes believable and shared, the favored type of cognitive processing and the exertion of agency through choice. We demonstrate that these device interactions (1) activate private self-awareness, namely, intimate self-knowledge and attention to personal internal states, which increases consumers' focus on what makes them – and their choices – unique and distinct from those of others (Song and Sela), (2) make consumers become more likely to believe and share fake news than PC users because smartphone users deliberate less (Xu, Liu and Yang), (3) encourages the deployment of fewer cognitive resources, which makes consumers rely less on deliberative processing when using smartphones compared to using stationary devices (Zhu, Wei, Rudd and Hu), and (4) generate a diminished sense of control – a common feature of addiction – which influences consumers' subsequent behaviors, spe-

cifically, the desire to restore personal control by exerting agency (Chapman and Valenzulea).

Importantly, this session highlights that there are several mechanisms through which consumer use of smartphones might influence user responses, including enhanced self-awareness (paper 1), limited deliberation (paper 2), the deployment of fewer cognitive resources (paper 3), and a diminished sense of control (paper 4). All papers are in advanced stages of completion with multiple studies run.

These progressive approaches and novel results are sure to induce a lively discussion and are likely to appeal not only to researchers interested in this kind of communication devices and their influence on consumer behavior and choices, but to a broader audience interested in consumer-product interactions and consumer interactions with technology more generally.

Smartphones and the Self-Expressive Meaning of Choice

EXTENDED ABSTRACT

Choice is often considered self-expressive. Consumers view choice not only as a means for obtaining material benefits but also for expressing their uniqueness, personality, and attitudes. Perceiving choice as self-expressive and reflective of one's individual preferences, in turn, influences product evaluation and consumers' tendency to exchange, defend, and regret their chosen options (Maglio and Reich 2020; Sela, Berger, and Kim 2017; Weiss and Johar 2013). However, the extent to which choice is seen as self-expressive in specific instances varies considerably, as a function of culture (Kim and Drolet 2003), self-construal (Markus and Schwartz 2010), self-control (Sela et al. 2017), emotionality (Maglio and Reich 2018), and the presence of external incentives (Bem 1972).

We argue that making choices using one's smartphone, compared with PC or tablet computer (e.g., iPad), increases people's tendency to view their choices as self-expressive and reflective of their true individual preferences. We argue that because smartphones are extremely private and personal (Clayton, Leshner, and Almond 2015; Hatuka and Toch 2016; Park and Kaye 2019), using them activates private self-awareness, namely, intimate self-knowledge and attention to personal internal states (Carver and Scheier 1981; Gibbons 1990; Song and Sela 2021). This elevated state of private self-awareness, caused by smartphone use, increases consumers' focus on what makes them – and their choices – unique and distinct from those of others (Gibbons 1990; Kircher and David 2003; Song and Sela 2021).

Four studies support this perspective. In study 1A, participants were randomly assigned to use their personal smartphone, PC, or tablet computer ($N = 218$; 41.7% females, $M_{age} = 36.1$). They chose one of five white, mainstream sedan brands and we measured the extent to which they perceived their chosen option as self-expressive (e.g., "The choice of the car brand shows who I am"; scale adapted from Kaiser et al. 2017). Consistent with our prediction, smartphone users rated their choice as more self-expressive ($M = 4.69$) than both PC ($M = 3.71$; $F(1, 215) = 16.54$, $p < .01$) and tablet users ($M = 4.01$; $F(1, 215) = 6.52$, $p = .01$; not different from PC, $p = .28$). Because both smartphones and tables use touch screens, touch cannot explain the results. Across studies, the effect of device on perceived self-expressiveness was not moderated by the specific option chosen (all p's > .12) or device brand (i.e., apple vs. non-apple; p's > .15).

Study 1B rules out an alternative account based on display size. We randomly assigned participants ($N = 311$; 65.9% females, M_{age} = 19.7) to condition in a smartphone vs. PC vs. PC-small-screen between-subjects design. Participants used their personal devices. Those in the PC-small-screen condition used their laptops but saw the entire study in a smaller frame in the middle of their screen, similar in size to a smartphone. Participants chose sunglasses and rated choice self-expressiveness as in Study 1A. Those in the smartphone condition felt their choice was more self-expressive ($M = 4.32$) than in the PC ($M = 3.88$; $F(1, 308) = 6.20$, $p = .01$) and PC-small-screen condition ($M = 3.91$; $F(1, 308) = 5.36$, $p = .02$; not different from PC condition, $p = .87$).

Study 2 uses an incentive-compatible design to test the mediating role of private self-awareness and the consequences of perceived self-expressiveness. We randomly assigned participants ($N = 334$; 60.8% females, $M_{age} = 21.1$) to use their personal smartphone or PC. They chose a poster, which they could receive, and then rated choice self-expressiveness as in the previous studies. We also measured private self-awareness using a scale adapted from prior research (e.g., "I've been very aware of myself, my own perspective and attitudes"; Matheson and Zanna 1988; Joinson 2001). Smartphone users felt their choice was more self-expressive than did PC users (4.05 vs. 3.69; $F(1, 332) = 4.81$, $p = .03$) and reported higher private self-awareness (4.66 vs. 4.28; $F(1, 332) = 10.31$, $p < .01$). The effect of smartphone use on choice self-expressiveness was mediated by private self-awareness ($a \times b = .17$, $SE = .06$, 95% CI [.06,.30]). Furthermore, compared with PCs, smartphones had a downstream effect on increased willingness to pay for the chosen poster, which was serially mediated by private self-awareness and perceived choice self-expressiveness ($a \times b = .04$, $SE = .02$, 95% CI [.01,.07]; Hayes 2013, model 6).

Study 3 uses moderation to bolster the underlying role of private self-awareness. We randomly assigned participants ($N = 207$; 56.8% females, $M_{age} = 21.9$) to use their personal smartphone or PC. We manipulated private self-awareness by instructing participants to "be sensitive to your thoughts and feelings" (elevated condition) or "keep focusing on the survey" (baseline condition; adapted from Ellis and Holmes 1982). Similar to Study 2, participants chose a poster and rated their choice as self-expressive. A 2 (device type) × 2 (private self-awareness) ANOVA on choice perception revealed a significant interaction ($F(1, 203) = 5.37$; $p = .02$). Whereas smartphone users rated choice as more self-expressive than did PC users in the baseline condition (4.47 vs. 3.57; $F(1, 203) = 8.43$, $p < .01$), there was no difference when private self-awareness was experimentally elevated (4.12 vs. 4.22; $p = .75$). This pattern supports our suggestion that the effect of smartphone use on perceived self-expression is driven by differences in private self-awareness.

Taken together, the findings show that making choices using their smartphone leads consumers to view the chosen options as more self-expressive, in consequential settings, with downstream effects on option valuation. The findings underscore the underlying role of private self-awareness. Smartphones have had a dramatic effect on consumers' lives, reshaping relationships, habits, and consumption behaviors. We hope that this research advances understanding of some of these effects.

People Are More Likely to Believe and Share Fake News on Smartphones (vs. PCs)

EXTENDED ABSTRACT

The rise of social media has contributed to the spread of both credible information and misinformation. In 2020, for example, mis-information surrounding the global pandemic flooded the internet to such an extent that WHO eventually called on institutions and organizations to intervene in the "infodemic" (WHO et al. 2020). The spread of fake news can cause myriad severe problems: distrust of media (Lazer et al. 2018), polarization of political views (Bago, Rand, and Pennycook 2020), threats to public health (Poland and Spier 2010), and distrust of brands (Chen and Cheng 2020), among others.

The nascent literature on misinformation has advanced our understanding of how people's belief in and willingness to share fake news are influenced by both news characteristics (Pennycook et al. 2020; Pennycook, Cannon, and Rand 2018) and individual characteristics (Bronstein et al. 2019; Pennycook and Rand 2020). However, no research, to the best of our knowledge, has investigated whether receptivity to misinformation is influenced by the user's device.

Study 1 explored this question by analyzing a dataset provided by Zubiaga, Liakata, and Procter (2017). The dataset, scraped from Twitter, includes 97,765 replies to 5,802 source tweets. The source tweets relate to one of five breaking news topics in 2014–2015 (Table 1) and were labeled by journalist collaborators as either rumors or non-rumors. We parsed the original json file of each reply to these source tweets and extracted users' device information from the "source" data field. A majority of replies were posted via a mobile device (51%) or a PC (35%). Notably, few replies (2%) expressed concern about the authenticity of the source tweet. A user's Twitter replies appear on the user's own Twitter timeline, so we use replies as a proxy for the user's belief in and willingness to share the source tweets.

To estimate the effect of the device type, we analyzed the data using logistic regression with event fixed effects. The DV was whether the reply was in response to a rumor source tweet, and the main predictor was whether the reply was posted via a mobile device or PC. The analysis revealed that the average mobile user was more likely to reply to a rumor source tweet than the average PC user (Table 2). The effect persisted when we controlled for the scraped covariates, including the follower count of the replying user, whether the source tweet contained a URL, the local time at which the user replied, etc.

Why are people more likely to believe and share fake news when they use smartphones (vs. PCs)? There are several possible explanations. The first is about device characteristics. For instance, smartphones have smaller screens, making it more difficult to process information (Ghose, Goldfarb, and Han 2013). Smartphones are also more associated with fun than with work (Shen, Wang, and Zhang 2019), which may contribute to the lack of deliberation (Zhu et al. 2020). The second is user characteristics. When people self-select devices, the difference could be due to individual differences (e.g., age, education). The third is related to environmental distractions. Because smartphones are more portable than PCs (Melumad and Pham 2020), they can be used anywhere at any time, even when environmental distractions are high. Environmental distractions may reduce deliberation and make people more vulnerable to fake news.

We then tested these possible mechanisms in two experiments. Study 2 (N=201, Prolific) examined the role of device characteristics by randomly assigning participants to use their PC or smartphone, which should hold user characteristics and environmental distractions constant. Participants read 12 news headlines (six true, six fake) about COVID-19 in a random order and indicated their belief in and their likelihood of sharing each headline. We conducted a regression with robust SEs, using participants as the cluster variable, and device (1=smartphone, -1=PC), news (1=true, -1=fake), and their interaction as predictors. We found no significant device

× news interaction effect on belief (B=-.002, SE=.04, t(200)=-.06, p=.955): the device had no significant effect on belief in the fake news (2.46 vs. 2.39; B=.03, SE=.06, t(200)=.53, p=.600) or belief in the true news (4.55 vs. 4.50; B=.03, SE=.06, t(200)=.49, p=.628). We also observed no significant interaction effect on the likelihood of sharing. These null results suggested that our effect is not driven by device characteristics.

Study 3 (pre-registered; N=395, Prolific) further tested the roles of environmental distractions and user characteristics by allowing participants to complete the study on either a smartphone or a PC. Participants read four news headlines (two true, two fake) about COVID-19 in a random order and indicated belief in each headline. They also reported environmental distractions and user characteristics (i.e., gender, age, education, and anxiety). A regression analysis with robust SEs yielded a significant device × news interaction effect (B=-.14, SE=.06, t(394)=-2.56, p=.011): smartphone (vs. PC) users reported stronger belief in the fake news (2.55 vs. 2.19; B=.18, SE=.07, t(394)=2.49, p=.013) but similar belief in the true news (4.01 vs. 4.21; B=-.10, SE=.08, t(394)=-1.35, p=.177). Moreover, smartphone users reported more environmental distractions (2.24 vs. 1.77, F(1, 393)=9.12, p=.003), which mediated the above effect (90% CI for moderated mediation =[-.067, -.005]). No individual characteristics varied with the device, and controlling for them did not change the conclusion. Study 3 thus supported environmental distractions rather than user characteristics as a viable mechanism.

Theoretically, this research contributes to the literatures on misinformation and technology by documenting a novel effect of the device type on consumers' beliefs in and intentions to share fake news. Practically, our work underlines the need for news websites and social media to alert smartphone users to fake news.

Devices, Fast and Slow: How Electronic Devices Influence Consumer Decision Making

EXTENDED ABSTRACT

Many everyday decisions are made with electronic devices, ranging from what groceries to buy to where to have a family vacation, from what job to apply to how to invest life savings. However, little is known regarding how various electronic devices shape how consumers construe and process decisions. This research investigates how using mobile versus stationary devices affects consumers' approaches to decisions. In particular, we argue that using mobile devices prompts consumers to rely less on deliberative processing than using stationary devices.

Based on the distinct mental dispositions consumers develop while using mobile versus stationary devices, we propose three key aspects that define these two types of devices. First, consumers use mobile devices primarily to process fragmented information and stationary devices to process an integrated block of information. Second, consumers tend to use mobile devices in time fragments in-between other activities and stationary devices in a reserved block of time. Third, consumers are more mentally prepared for interruptions that prevent them from focusing on the current decision when using mobile devices than stationary devices. Such mental dispositions can be triggered by different devices a consumer use (e.g., smartphone vs. PC) and vary among individuals for the same device (e.g., a consumer who uses a laptop to browse Tweets in a waiting room would consider it as a mobile device, whereas one who uses a laptop to watch a movie would consider it as a stationary device). Ultimately, consumers are inclined to reserve less cognitive resources when using mobile than stationary devices. Knowing that deliberative processing draws on sufficient cognitive resources (Chaiken and Trope 1999; Kahneman 2003; Kahneman and Frederick 2002), we hypothesize that using mobile devices reduces the extent to which consumers rely on deliberative processing, compared to using stationary devices.

Evidence from six studies, including a field dataset, supports our theorizing.

Study 1 demonstrated that mobile-devices-based decisions required less deliberation than stationary-devices-based decisions. Participants recalled the most recent decision they made, using either smartphones (mobile-device condition) or PCs (stationary-device condition). Codings from three independent coders showed that smartphone-based decisions were less deliberative (MSmartphone = 3.87 vs. MPC = 4.35, t(388) = -4.71, p < .001) and less effortful (MSmartphone = 3.42 vs. MPC = 4.15, t(388) = -7.56, p < .001) than PC-based decisions.

In Study 2, participants indicated how they generally use their smartphones or PCs (between-subjects). In line with our theorizing, participants were more inclined to use smartphones for fragmented information and PCs for an integrated block of information (MSmartphone = 3.33 vs. MPC = 4.43, t(111) = -4.01, p < .001). Participants were also more likely to use their smartphones in time fragments in-between other activities and PCs in a reserved block of time (MSmartphone = 3.19 vs. MPC = 4.77, t(111) = -4.89, p < .001). Finally, smartphones prompted participants to be more mentally prepared for interruptions than PCs (MSmartphone = 4.86 vs. MPC = 3.86, t(111) = 3.32, p = .001).

Studies 3 and 4 examined the key hypothesis via two classic heuristics – the anchoring effect and the attraction effect. Since deliberation reduces the likelihood of using heuristics (e.g., Epley and Gilovich 2006; Kahneman 2003; Pocheptsova et al. 2009; Tversky and Kahneman 1974), consumers who use mobile devices should be more prone to anchors and decoys. In Study 3, across four products (hedge trimmer, hot water dispenser, UV sanitizer box, electric grill), we found that participants who used smartphones were more likely to anchor their willingness-to-pays around the last two digits of their IDs (b = 0.28, SE = 0.03, p < .001) than did those who used PCs (b = 0.20, SE = 0.03, p < .001). In Study 4, participants selected a bonus task from a set of three options, in which a dominated decoy was introduced to one of the two core options (a'ab vs. abb'). We observed an attraction effect only when participants used smartphones – they were more likely to choose the focal option (option a) when it was the dominate option (a'ab) than when it was not (abb'; 76.9% vs. 52.9%, χ2 = 7.30, p = .007). No attraction effect was found when participants used PCs (choice share of the focal option: 66.3% vs. 67.1%, χ2 = 0.01, p = .910).

Study 5 examined how devices affect the likelihood of making a purchase, with the moderating role played by set alignability. Using mobile devices should decrease the likelihood to make a purchase only in a nonalignable set, which is cognitively demanding to process; however, devices should not influence the likelihood in an alignable set, as the choice from which is effortless and does not require much cognitive resources (Alter et al., 2007; Gourville and Soman, 2005; Stanovich, 2011; Zhang and Fitzsimons, 1999). Participants used smartphones or PCs to make a consequential purchase from six power banks that varied on a comparable attribute (alignable-set condition) or a non-comparable attribute (nonalignable-set condition). We found an interaction on the likelihood of buying a power bank (b = 0.67, Wald = 3.12, p = .077): in the nonalignable set, using mobile devices reduced the likelihood of buying a power bank (70.9% vs. 57.6%; b = -.59; p = .034); whereas in the alignable set, the device did not influence the likelihood of making a purchase (59% vs. 61.2%; b = -.09; p = .733).

In Study 6, individual-level clickstream data (N = 241,002) from a UK-based online retailer corroborated our theorizing. Compared to using PCs, using smartphones reduced consumers' decision time (b = -0.15, SE = .03, z = -4.78, p < .001) and their likelihood of making a purchase (b = -0.26, SE = 0.13, z = -2.02, p = .043), while controlling for other inspection related variables.

Overall, this research presents that mobile devices prompt consumers to rely less on deliberative processing than stationary devices. These findings advance our understanding of how the electronic devices consumers use can shape the way they approach decisions and, ultimately, influence their product choice, willingness-to-pay, and the likelihood of making a purchase.

The Addictive Properties of Mobile Applications: How Endless Scrolling and Intermittent Notifications Impact Consumer Perceptions and Behavior

EXTENDED ABSTRACT

As of 2019, 2.71 billion people around the world, including 81% of Americans, owned or used smartphones (Montag et al., 2019; Anderson, 2019). While smartphones provide a portal to social connection and a gateway to information, a growing body of evidence suggests they also can create problems, both at the individual and societal level.

In this paper, we investigate how smartphone features might create a diminished sense of control – a common feature of addiction – and influence consumers' subsequent behaviors. Emerging research supports the proposition that digital technologies can become addictive, due at least in part to self-control challenges (Allcott, Gentzkow, & Song, 2021). Technology addiction is often self-diagnosed (Raghubir, Menon, & Ling, 2021); however, self-awareness alone is ineffective in changing technology-related behavior (Zimmerman, 2021).

Neyman (2017) identified specific smartphone features that contribute to technology addiction. One feature, endless scrolling, refers to content that perpetually loads on a single page, rather than on separate pages. Recent literature has identified endless scrolling as a reason for increased smartphone usage. Montag et al. (2019) explained this increased usage by asserting that when consumers engage in endless scrolling, they may experience a flow state, which is characterized by high levels of enjoyment and involvement, and a willingness to continue the activity even at great cost (Csikszentmihalyi, 2002).

Another smartphone feature is intermittent rewards, which are commonly operationalized through notifications. Notifications refer to visual, haptic, or auditory signals that alert consumers to a new event (Pielot, Church, & de Oliviera, 2014). By providing rewards at random intervals, notifications increase dopamine production in a manner similar to slot machines (Neyman, 2017).

Addiction encompasses both subjective feelings and objective outcomes (Sussman & Sussman, 2011). Subjective feelings associated with addiction include a heightened sense of incompleteness and a diminished sense of connection with the outside world (Hirschman, 1992). It also has been widely documented that addiction is associated with a diminished sense of personal control (Sussman & Sussman, 2011; Walters & Gilbert, 2000).

It is well established that people attempt to regain a sense of personal control when it is diminished (Roth & Kubal, 1975). One way to regain a sense of control is by exerting agency. The act of choosing provides one means of exerting agency (Averill, 1973; Lefcourt, 1973) and can be used to regain a sense of control when it has been diminished (Inesi et al., 2011). Thus, we expected that when

smartphone users feel low in control, they might exert agency, operationalized through the act of choosing.

To test if smartphone features can diminish consumers' sense of control, we recruited 123 participants (Mage = 18.88, SD = 0.927, 50.3% female) to complete our survey in exchange for partial course credit. In the survey, we first asked participants to name an application that contained either endless scrolling or useful information (which served as the control condition). After participants named an application, we asked, "When you are using an app that offers [this feature], to what extent do you feel out of control, like the app is making you continue to use it?" (1=Not at all to 5=An extreme amount). Participants reported stronger feelings of being out of control in the endless scrolling versus the control condition (Mendless scrolling = 3.652 versus Mcontrol = 2.565; F(1, 122) = 5.871; p < .05).

In study 2 (n=109, Mechanical Turk, Mage = 40.43, SD = 10.574, 52.8% male), we added the feature "intermittent notifications." Participants read one of four scenarios about a fictional app called "Local Eats." Each scenario featured either scrolling or notifications, which were operationalized as either "addictive" or not. For example, in the "addictive" scrolling condition participants read that "there are always additional restaurants that appear on the page." In the "non-addictive" scrolling condition, they read that "there are at least five pages of restaurants."

After the scenario, we asked participants, "To what extent do you feel connected to the physical world around you?" (1=Not at all to 5=An extreme amount) and found a main effect of addictive features (Maddictive = 4.204 versus Mnon-addictive = 4.853; F(1, 105) = 5.871; p < .05). Next, we asked, "To what extent do you feel out of control, like the app is making you continue to use it?" Again, we found that addictive features made participants feel more out of control (Maddictive = 4.167 versus Mnon-addictive = 1.942; F(1, 105) = 41.198; p < .001). Importantly, both features (endless scrolling and notifications) increased feelings of being out of control (ps < .01).

In Study 3 we used the same operationalization. After reading the scenario about the Local Eats app, participants indicated to what extent they felt connected to the physical world, a sense of incompleteness, and a desire to regain control. Participants (n=295) in the addictive features conditions felt less connected to the physical world (Maddictive = 4.041 versus Mnon-addictive = 4.495; F(1, 293) = 4.138; p = .043), a greater sense of incompleteness (Maddictive = 4.185 versus Mnon-addictive = 3.455; F(1, 292) = 8.531; p = .004), and a greater desire to regain control (Maddictive = 5.072 versus Mnonaddictive = 4.222; F(1, 292) = 17.740; p < .001).

Then, we tested whether addictive properties increase preferences for agentic choice. Participants read a consumption scenario in which they could make a choice or let a company choose. Specifically, they imagined that they already had selected a 4-star hotel on Main Street. However, they could receive a 10% discount if they instead allowed the hotel booking website to select the exact hotel for them. Our key dependent measure was how much participants kept agency in choice: 64.4% in the addictive properties condition chose the hotel on Main Street vs. 51.5% in the control condition (Chi-Square = 4.560; p = .033); using a likelihood scale, Maddictive = 3.860 versus Mnon-addictive = 3.480 (F (1, 289) = 6.908, p = .009).

This paper's findings contribute to our knowledge of how smartphones impact consumer behavior, and the society at large, with important implications for marketers, tech designers, public policy – and consumers themselves.

Ana Valenzuela, Baruch College, CUNY, USA

SESSION OVERVIEW

Digital payment platforms have gained popularity in recent years. Venmo now boasts more than 40 million users (Rudegeair 2019), and cash is fast going down in the list of the preferred payment methods in the U.S. (Szmigiera 2019). Despite the prevalence of these new payment platforms, little is known about the social and behavioral implications of their use.

These new research questions present consumer behavior researchers with an opportunity for solving questions that are not only theoretically important, but also rife with timely substantive implications.

Our special session addresses this opportunity by exploring behavioral consequences stemming from the use of financial vehicles other than cash. We focus on how using alternative payment vehicles, most of them hosted within digital platforms, may affect information processing, judgements and downstream choice. We demonstrate that (1) the differential attachment that consumers have to their financial vehicles (crypto vs. cash) spills over to their experience with the purchase, their reselling price, and the extent of their investments (Bechler and Huang), that (2) individuals using P2P digital lending platforms opt towards a social default, choosing to invest in an option that others have chosen, even when the social default option is riskier and result in a lower payoff rate in the long run (Shah and Li), that (3) when cash is eliminated as a payment option for small dollar transactions, consumer spending and purchase behavior is affected, such that consumers spend more and make more impulse/unhealthy purchases (Santana, Vera, and Chacon), and that (4) the "social" nature of consumer-to-consumer payment platforms facilitates consumer inferences that private (versus public) P2P payers hold stronger moral personality traits and, thus, are more likely to cooperate with them in the future, and allows them to use of privacy settings to signal cooperative nature (Chapman and Valenzuela). Accordingly, while each paper individually focuses on a consequential outcome stemming from the nature of the non-cash digital financial platforms, collectively this session demonstrates that the behavioral

outcomes and contingencies linked to the use of these payment and investment vehicles the can vary widely.

Importantly, this session highlights that there are several mechanisms through which consumer payment and investment choices might influence user responses, including the possession –self link or attachment, in this case, to a financial vehicle (paper 1), the reference value of social defaults even for investment choices (paper 2), the psychological costs to consumers of lower pain of payment, regardless of transaction size (paper 3), and the signaling properties of keeping financial information private (paper 4). All papers are in advanced stages of completion with multiple studies run.

The progressive approaches and novel results in this session are sure to induce a lively discussion and are likely to appeal not only to researchers interested in the consequences of payment and investment choices, and the nature of financial vehicles, but to a broader audience interested in financial decision making and consumer interactions with technology more generally.

Connectedness to Financial Vehicles and Its Effect on Consumer Experience, Reselling, and Investing

EXTENDED ABSTRACT

Ashley is a crypto "nut." She adopted Bitcoin early, detests fiat, and follows the crypto markets. Her crypto is part of her identity—it makes Ashley, *Ashley*.

Now consider Zack. In contrast to Ashley, Zack holds most of his wealth in USD (cash) and sees crypto as his "play money."

Clearly, Ashley and Zack feel differentially attached to financial vehicles (cash and crypto) available to them. However, the consumer identity and attachment literatures—while vast—have largely overlooked this possibility and its potential effects. If Ashley and Zack purchase books with cash, who will feel more connected to these books, Ashley (who detests cash) or Zack (who is strongly attached to cash)? If Ashley and Zack are investing in crypto, who will take more risks, Ashley or Zack? Spoiler alert: it is Zack in both cases.

Modern consumers now use many financial vehicles to pay for goods and invest. Consumers often bring cash and multiple credit cards to physical stores, send virtual payments with Paypal/Venmo, and invest in cryptocurrencies. We explore how the *financial vehicles* consumers use—specifically, the connection they feel to these vehicles—contributes to their purchase experiences, affects subsequent purchase-related decisions (e.g., item use, reselling prices), and influences investments.

We first conduct a Pilot Study to establish that consumers indeed feel differentially connected to financial vehicles. We measured 1,001 participants' felt connection to 11 financial vehicles (e.g., cash, credit cards, Venmo, cryptocurrencies; see Dommer and Swaminathan 2013; Escalas and Bettman 2003, 2005) and factors that may contribute to this felt connection. The data indicated that consumers feel differently connected to their financial vehicles and illuminated factors that may drive financial vehicle connectedness, including greater frequency of past vehicle usage ($ps<.001$) and greater utilization within consumers' social circles/networks ($p<.001$).

Second, we examine how the relative strength of consumers' connection to their financial vehicles affects their purchase experi-

ences and investments. We theorize that this feeling of connection can *spillover*, such that when consumers use a highly-connected (vs. weakly-connected) financial vehicle to make a purchase, they feel more connected to their purchase. Similarly, when they use a highly-connected (vs. weakly-connected) financial vehicle to invest, they are more likely to hold onto that investment and thus make fewer trades. Our proposition is based on the assumption that consumers' associations with individual entities—including people, objects, groups, and characteristics—do not exist in a vacuum. Rather, these associations vary in strength and direction depending on how these entities relate each other (e.g., Wheeler and Bechler 2021). For instance, consumers view themselves as more intelligent when they strongly associate with an MIT pen (Park and John 2010) and perceive themselves as taller when obtaining tall (vs. short) mugs (Weiss and Johar 2016). We build on this conceptualization to hypothesize that the financial vehicles consumers use can serve as another entity for these transfers to occur.

Studies 1A-2 tested this key prediction by examining how consumers feel about their purchases. In Studies 1A-C, we first measured consumers' idiosyncratic differences in the degree to which they felt connected to their payment methods and then (after a filler task) assigned participants to imagine purchasing items from the university bookstore with different payment methods. In Study 1A (*N*=394; Payment Methods: Cash vs. Credit/Debit Card), participants who were more connected to cash reported that they felt more connected to products they were assigned to purchase with cash than with card, whereas participants who were more connected to their credit/debit card reported that they were more connected to products they were assigned to purchase with card than with cash (interaction: *p*<.001). This effect was replicated in Study 1B with electronic payment methods (*N*=447; e.g., Paypal vs. Venmo) and in Study 1C with cards versus cryptocurrencies (*N*=403), *p*s<.001 (Figure 1).

In Study 2 (*N*=148) we replicated these results by directly manipulating how connected consumers' felt to a specific payment method (their credit card) through social comparison (Festinger 1954; Argo, White, and Dahl 2006). Our pilot data suggested that past usage frequency could determine payment method connectedness, so we informed participants that they either used their credit card more frequently (high connectedness condition) or less frequently (low connectedness condition) than their peers (manipulation check of payment method connectedness: *p*<.001). Participants made to feel highly connected to their credit card (vs. less) reported feeling *more* connected to the 10 purchases they subsequently made with their card, *p*<.001.

Studies 3-6 tested consequences of this feeling of connection on selling, food consumption, mask usage intentions during COVID, and investing. In Study 3 (*N*=399), we found that participants requested higher selling prices for products they purchased with the payment method (cash or credit/debit card) they felt more connected to (interaction: *p*=.01). In Study 4 (*N*=597), we collected information about participants' last meal at a restaurant and found that participants felt more connected to their meal and perceived it to have a greater impact on their weight when they purchased it with a payment method (cash or credit/debit card) that they felt more connected to (interaction: *p*<.001 and *p*=.02, respectively). In Study 5 (preregistered; *N*=1,594), participants imagined that they forgot their facemask at home and were required to purchase one at a store. Participants who were more connected to their cash (vs. credit/debit card) reported feeling more connected to the mask and that they were more likely wear the mask in the future when assigned to purchase it with cash (and vice versa; interaction: *p*<.001 and *p*=.001, respectively).

Finally, Study 6 (preregistered; incentive-compatible; *N*=293) explored investment decisions. Crypto users invested their compensation from a study into a simulation that followed a random 150-day period in the market (e.g., BTC-USD; http://stanford.edu/~cbechler/cgi-bin/mkt_sim/1/index.html?Game=id=ACR&crypto=BTC). We found that consumers who were more connected to crypto traded less frequently in this crypto-based simulation (*p*<.001) and held their money in the market for longer (*p*=.003), indicating less risky investing behavior. Replicating past literature, fewer trades led to greater returns to investment (*p*=.01); thus, consumers who were more connected to crypto tended to receive greater compensation from this investment simulation.

Peer-to-Peer Social Defaults: Do Individuals Socially Conform When Making Private Financial Decisions?

EXTENDED ABSTRACT

From small decisions such as what airline meal to choose, to more consequential choices such as what car to buy or what home improvement to make, consumers are affected in a direct and meaningful way by their peers (e.g., Bollinger and Gillingham, 2012; McShane et al. 2012). Most research has documented that this operates via visual salience: public consumption choices are easy to observe and mimic. Yet, over half of consumer spending including many financial choices, are private and inconspicuous. Are these private, consequential investment decisions susceptible to social defaults, with individuals choosing investments based on what others have also chosen? If so, who is most susceptible to social default effects, and when?

Recent innovations in financial technology, and particularly the emergence of Peer-to-Peer (P2P) lending platforms, have made it possible to answer these questions in real-world empirical settings. P2P platforms operate by creating a marketplace directly connecting borrowers and lenders directly, bypassing conventional bank intermediaries. Similar to other investment options, investors have extensive information about their investment—having access to detailed credit information of the borrower and the purpose of the loan request. However, unlike most investment options, investors are also privy to social information as well such as the number of individual investors who have invested, their average investment size, and percent of the loan that is fulfilled.

Building off research in social influence and mimicry, we posit that when preferences are not well formed, people are more likely to opt towards a social default for their investment choices, choosing to invest in an option that others have chosen even despite the level of risk. Finally, we also predict that individuals may still be susceptible to opt towards social defaults even when it may be detrimental to financial performance.

We obtained data from the largest P2P lending platform in the US, Prosper.com. Prosper allows borrowers to set their own interest rates by posting an auction style listing specifying the maximum interest rate (reserve interest rate) she is willing to accept and the loan amount requested. However, borrowers who set their reserve interest rate high are typically more likely to default than those who set rates lower, leaving lenders (investors) to face a significant trade-off between high risk interest rates and higher potential rewards if these loans do not default and are paid in full.

Our data included 5,829,817 different bids submitted by 54,821 lenders, and allowed us to determine to test whether those who were more uncertain and less experienced (i.e., fewer loans invested in previously) were more likely to use a social default, investing in loans that had a higher number of other peer investors. We find that

inexperienced investors are more significantly more likely to invest in loans that have more investors ($B = .121$, SE = .018, $p<.001$). Our data also allowed for various borrower and loan-level controls (e.g., where the borrower is from, loan interest rate, loan amount), as well as firm-level controls (e.g., availability and distribution of loans). Even despite these controls, we find that inexperienced investors are more significantly more likely to socially conform in their investment decisions ($B=.016$, SE=.002, $p=.003$).

Interestingly, we found our results were moderated by the day of the week: Investors were significantly more likely to rely on social defaults—loans with more investors—at the end of the work week on Fridays, a day that has been associated with investor inattention and distraction, $B=.017$, SE=.002, $p<.001$ (DellaVigna & Pollet, 2009). Moreover, inexperienced investors were significantly more likely to show this end-of-week social default tendency, $B=-.007$, SE=.002, $p<.001$. Importantly, though, socially conforming choices did not lead to better decisions. Rather, investors were more likely to choose riskier loans that led to significantly lower returns ($p<.001$).

Despite this initial evidence, field data made it difficult to determine precise causality or the mechanism driving our effects. We conducted two follow-up experiments to more precisely test whether investment decisions are more susceptible to social default effects when expertise/experience and cognitive resources are lower.

In Study 2 and 3, we adapted an experimental design from Huh and colleagues (2014) to test whether social defaults are more likely to engender choice mimicry when preferences were not as clearly formed, i.e., in more or less uncertain/familiar choice settings and in the face of time pressure/less conscious deliberation. In Study 2, participants were asked to make an investment choice between either one of two English tea companies (more familiarity) or two Korean tea companies (less familiar). In both cases, individuals were told that 64% of previous participants chose either one of the two companies, randomly varying which company was presented as the favored option. Participants were significantly more likely to choose to invest in the social default investment option when the choice was between unfamiliar Korean tea companies versus when the choice was between two familiar English tea companies (M_{Korean} = 72.3% social default option, $M_{English}$ = 51.4%; $p<.001$). These results were partially mediated by tea brand familiarity ($p=.012$).

Finally, in Study 3 (N=448), we tested whether increasing time pressure and reduction in conscious deliberation increased the likelihood for choice mimicry and social defaults using a 2 (uncertain product choice between two Korean teas vs. certain product choice between two English teas) X 2 (time pressure: 10 seconds vs. 1 minute) between-subjects design. We found that participants were more likely to choose the social default option under time pressure, specifically when deciding to invest between two unfamiliar Korean tea companies ($p<.001$). However, time pressure did not significantly influence the likelihood of choosing the social default when the investment choice was more familiar ($p=.557$).

Across a large-scale P2P lending dataset and two follow-up laboratory experiments, we find that individuals are more likely to opt towards a social default, choosing to invest in an option that others have chosen as well when their preferences are not well formed. We find these effects occur in financial choices beyond P2P settings, and even when the social default option is riskier and result in a lower the payoff rate in the long run.

The Effect of Going Cashless for Small Value Transactions: Evidence from the Field

EXTENDED ABSTRACT

In 2018, cash was the third most preferred payment method in the U.S., behind debit cards and credit cards (Szmigiera 2019). Yet its popularity to pay for small-value transactions remains surprisingly high (Arango, Huynh, and Sabetti 2011; Klee 2008). Prior research contends that consumers have a threshold transaction size below (above) which they prefer cash (non-cash), and that the amount is less than $50 (Freeman and Kydland 2000; Lucas and Nicolini 2015;Wakamori and Welte 2016; Wang and Wolman 2016; Whitesell 1989). This is curious because digital payments, credit and debit cards offer both financial and psychological benefits to consumers in the form of float and/or lower pain of payment (Prelec and Loewenstein 1998), regardless of transaction size. However, the lower pain of payment associated with cards also results in higher spending by consumers. This research examines the prevalence of cashless payments for small dollar transactions and their potential implications.

Using five years of purchase transaction data, we determine the threshold where 50% of consumers switch from card to cash. We also examine whether the adoption of non-cash payment methods varies by population density. We then turn our attention to the implications of consumers paying for small-value transactions with cards. Using 26 months of transaction data, we observe the effects of eliminating cash as a payment option on consumer purchase and payment behavior.

We obtained a dataset from an international payments processor that included transactions between $.01 - $100 completed between 2015-2019 (n = 43.94 million). We had no a priori prediction regarding the specific magnitude of the threshold amount. Directionally we expected it to be less than $50, to decline over our observation period, and to be higher in major metropolitan markets (vs. smaller markets).

Table 1 shows the results of a logistic regression on the probability of cash payment (cash = 1, non-cash = 0) with transaction amount, year, and geography as predictors (1=top 25 market, 0 = not top 25 market). As expected, consumers were less likely to pay with cash over time (β_{year} = -.136, $p < .0001$), and were more likely to use cash at smaller transaction amounts (β_{amount} = -.048, $p < .0001$) and if they lived outside of a major metro area ($\beta_{top\ 25}$= -.196, $p < .0001$). Importantly, we also observed a decline in consumers' payment threshold. In 2015 the transaction amount where 50% of payments were cash (vs. card) was approximately $6.00, but by 2019 it had dropped 50% to approximately $3.00 (Figure 1a). Furthermore, we found that this threshold varies by geography. For consumers living in a major metropolitan area in 2019, the amount was also $3.00, but for those living outside these markets, the amount was roughly $1.00 higher (Figure 1b).

Based on our observation that consumers are increasingly paying small dollar transactions with cards, we turned our attention to the potential implications of such a shift. Extant research shows that consumers not only spend more when they pay with card (vs. cash), they also make more impulse purchases and buy less healthy food (Feinberg 1986; Hirschman 1979; Prelec and Loewenstein 1998; Prelec and Simester 2001; Raghubir and Srivastava 2008; Soman 2001; Thomas, Desai, and Seenivasan 2001). However, whether these effects replicate at small transaction amounts and when cash is not a payment option is unknown.

We obtained 26 months of transaction data from a food service vendor that managed a kiosk at a large business school where cash was eliminated as a payment option (i.e., it was "cashless"). The data

include 13 months of transactions prior to the change and 13 months of transactions after the change (n = 63,700), thus providing us with a natural field experiment. A regression analysis showed that average transaction amount after the removal of cash was significantly higher than it was before the change (β = 19.28, p < .0001), despite transaction counts remaining unchanged and controlling for price increases. Additionally, a separate regression on food type purchases showed that transaction counts significantly increased for impulse snacks (β= 15.17, p < .03) after the change, consistent with Thomas et al.'s (2011) finding that consumers purchase more unhealthy items when paying with a card.

In summary, this research focuses on two questions: 1) To what extent are U.S. consumers using card payments for small dollar transactions, and 2) What are the potential implications of such a change? Our data show that the transaction threshold where payments switch from cash to card/digital is low and is also declining. This is true in both major metropolitan markets and smaller markets, although the shift is happening faster in larger markets. We then show why this is potentially important by examining how consumer spending and purchase behavior is affected when cash is eliminated as a payment option for small dollar transactions. Our results confirm that consumers spend more and make more impulse/unhealthy purchases.

These findings have theoretical and policy implications. Theoretically we bridge the research from economics on demand for cash and payment choice with that from marketing on how payment types affect consumer behavior. In doing so, we offer new perspective on the implications of decreased cash use. Second, using a natural field experiment, we demonstrate a causal relationship between payment type choice, spending, and purchase behavior. Third, for policy makers, the debate surrounding going cashless rarely mentions the behavioral effects of using cards. Our research shows that this should be part of the dialogue.

Just between you and me: Paying privately signals moral traits and enhances others' willingness to cooperate

EXTENDED ABSTRACT

Online, consumers face decisions about whether to send messages, photos, and even payments privately or publicly. Such decisions can impact one's own privacy – and also the privacy of fellow consumers. We investigated such privacy decisions in financial contexts. Money, as it relates to personal finances, is a taboo topic people tend to keep private and avoid discussing (Goldberg & Lewis, 1978; Sun & Slepian, 2020). Thus, we hypothesized that keeping financial transactions private might provide social benefits.

Given that moral judgments can be formed quickly (Zajonc, 1980) on the basis of little information (Haidt, 2001), we propose that preserving a fellow consumer's privacy in a financial context might signal strong moral traits. Since morality inferences facilitate cooperation (Tomasello & Vaish, 2013), we investigate whether consumers would be more likely to cooperate with private payers due to the perception that they possess relatively stronger moral traits. We tested these ideas across six studies, in the context of peer-to-peer payments.

In study 1a, student participants (n=67) imagined they had paid for a classmate's lunch, and the classmate reimbursed them either privately or publicly on Venmo. To measure cooperation, we asked participants how likely they would be to pay for their classmate again (1=Extremely unlikely; 7=Extremely likely). Participants were more likely to pay again for private payers (Mprivate=6.212, Mpublic=4.824; F(1, 65) = 13.589, p < .001). In study 1b we replicated these findings with students in Spain (n=193). Participants imagined

they had paid for a classmate, who reimbursed them using the Spanish payment app, Bizum. All participants evaluated two payments: one private and one public. A repeated measures ANOVA revealed that participants were more likely to pay for a private payer again (Mprivate =6.228, M$_{public}$=5.655; F(1, 184) = 38.068, p < .001) and more likely to endorse a private payer (M$_{private}$=5.860, M$_{public}$=5.335; F (1, 184) = 25.981, p < .001).

In study 2 (preregistered), we replicated the main effect of payment privacy setting on cooperation and tested for mediation through perception of moral traits. MTurk participants (n=117) imagined they had received a private (vs. public) Venmo payment from a friend. Participants were more likely to endorse private payers (Mprivate=6.220, Mpublic=5.483; F(1, 115) = 9.307, p < .01), and were marginally more likely to pay for them again (Mprivate=6.254, Mpublic=5.828; F(1, 115) = 3.412, p = .067). Participants then evaluated the payer on six moral traits (considerate, sincere, conscientious, generous, agreeable, and trustworthy) which are associated with exemplars of moral character (Walker & Hennig, 2004). These traits loaded on one factor and were averaged to form a composite measure (α = .862). Private payers were inferred to possess stronger moral traits (Mprivate=5.890, Mpublic=5.362; F(1, 115) = 8.676, p < .01), and the perception of moral traits mediated the willingness to endorse the payer (indirect effect = .3916, 95% CI [.1220, .7408]) and pay for them again (indirect effect = .3402, 95% CI [.1100, .6183]).

Study 3 (preregistered) tested willingness to cooperate within an ultimatum game (UG). Participants on Prolific (n=200) read a scenario in which a new friend reimbursed them privately or publicly. Participants were then told that they would be responders in a UG, playing with this friend (proposer), who had between $1.00 and $4.00 to divide. The friend would make an offer, which the participant could accept or reject. Participants indicated how fair they thought the offer would be. Private payers' offers were expected to be more fair (Mprivate=5.940, Mpublic=5.582; F(1, 196) = 4.105, p = .044). All participants then saw an offer of $0.75, and indicated likelihood of accepting. Participants were more likely to accept the offer from private payers (Mprivate=4.630, Mpublic=4.020; F(1, 196) = 3.905, p = .050). Expected offer fairness mediated the relationship between payment privacy setting and likelihood of accepting (indirect effect=.1082, 95% CI [.0008, .3059]).

In study 4 (preregistered), we investigated whether consumers use privacy settings to signal their own moral traits. Participants (n=60) were instructed to send a Venmo payment to a fellow participant who would rate them based on what kind of impression they made. Participants were told that the person who was rated as the most considerate (vs. the most fun) would receive a $5.00 bonus. After sending payment, participants reported what kind of impression they were trying to make (considerate vs. fun) and how they sent payment (private vs. public). Participants paid privately more often when they were trying to make a considerate impression (82.6%) versus a fun impression (52.8%; χ2 = 5.448; p=.020). This indicated consumers may use privacy behaviors to signal moral traits (e.g. considerateness).

In study 5 (preregistered), we again tested our Hypothesis in the context of a UG. Participants imagined they would be making an offer (as proposer) to a new friend, who would either accept or reject. MTurk participants (n=222) were told they had recently paid their friend either privately or publicly. Then, participants rated the likelihood that their friend would accept their offer. Participants also evaluated how fair their friend would perceive the offer to be, and to what extent their friend would agree that they possessed specific moral traits (conscientious, considerate, sincere, agreeable,

generous, and trustworthy). Participants in the private condition thought their friend would agree more strongly that they possessed these moral traits (Mprivate=5.388 vs. Mpublic=4.821; $F_{(1, 219)}$ = 12.429, p = .001), and would perceive their offer as being more fair (Mprivate=6.159 vs. Mpublic=5.459; $F_{(1, 220)}$ = 5.737, p=.017). The perception of moral traits and expected offer fairness sequentially mediated the likelihood of accepting the offer (indirect effect = .1628, 95% CI [.0584, .3051]).

In sum, we found consumers were more likely to cooperate with private payers because they inferred them to possess stronger moral traits, and expected them to behave more fairly. Additionally, our two final studies provided evidence that consumers use transaction privacy settings to signal information about the self. While online platforms offer consumers the ability to broadcast personal information, our results indicate that when it comes to money, it pays to keep personal information private.

    David J. Hardisty, University of British Columbia, Canada
    Dale W. Griffin, University of British Columbia, Canada

SESSION OVERVIEW

Budgeting is a common and consequential consumer behavior, yet it remains understudied. This is especially true given recent technological advances like budgeting apps, and the economic volatility introduced by the Covid-19 pandemic. Taken together, the papers in this session advance our understanding of consumer budgeting by helping elucidate its psychological mechanisms, downstream effects, and ways in which it can be improved.

In the first paper, **Fei and Bartels** examine how consumers represent and categorize their purchases. Although past research has shown that budgeting behavior is closely related to categorization, it remains unclear how consumers treat the categories. Their paper finds that the taxonomical distance between purchases, derived from the groupings, predicts adjustments in spending and saving. Specifically, when consumers overspend on an item, they are more likely to adjust spending for more closely related items.

In the second paper, **Choe, Kan, and Polman** seek to understand how consumers budget for others. They demonstrate that gift-budgets are perceived differently from personal-budgets which has important implications on consumers' spending behavior. When consumers budget for a personal purchase, they aim to spend less than their budget; when they budget for a gift-purchase (i.e., for others), they aim to exhaust their entire budget.

Mishra, Garbinsky, and Shu explore the downstream effects of budgeting by showing how the use of budgeting apps that display joint household situations for couples affects financial communication between them and their preferences for joint (vs. individual) financial products. Across four studies, they find that couples' perception of their financial position impacts their financial communication. When they think that their financial well-being is low (vs. high), they tend to communicate less with their partner and prefer individual (than joint) financial products.

The final paper by **Howard, Hardisty, and Griffin** explores how consumer budgeting has been impacted by the rise of the "gig economy." They find that consumers who work in the gig economy (e.g., Uber drivers) display an *income prediction bias* in which they over-predict their gig income. They also test two interventions de-

signed to improve prediction accuracy by drawing attention to either relevant past experience, or the possibility of atypical future outcomes.

This session will feature Dr. Abigail Sussman, Associate Professor of Marketing at the University of Chicago Booth School of Business, as the discussant. She will be discussing the relevance of budgeting to consumer financial well-being and providing feedback on the four papers in the session. Although this session will be of substantial interest to those who are active in budgeting research, we expect this session to have a broader appeal. As budgeting closely relates to spending, saving, and financial well-being, this session should attract those who study consumer financial decisions and well-being. Additionally, this session will focus on recent technological advances (such as the rise of the gig economy and budgeting apps) and will be relevant to researchers who study the impact of technology and decision-making. Lastly, the session would appeal to anyone who has an interest in self-other decision making.

Beyond "Food" and "Entertainment": The Effect of Budgeting Taxonomy

EXTENDED ABSTRACT

Budgeting is a common practice among consumers (for review, see Zhang, Sussman, Wang-Ly, and Lyu 2020). Past work suggests that budgeting behavior is closely related to categorization (Henderson and Peterson 1992), and consumers would be less willing to spend on the category if they consumed a typical item in the category (Heath and Soll 1996). But it remains unclear what the categories are, and whether all items within a category or outside of a category are treated the same. The current research attempts to address these questions and better understand mental budgeting processes by investigating how consumers mentally represent expenditures.

In order to recover the mental representation of expenditures, we ask participants to hierarchically categorize common purchases, as people appear to represent creatures, natural objects (Murphy 2002), and foods (Ratneshwar and Shocker 1991) in hierarchically-organized categories. Specifically, we elicit hierarchies of a range of expenditures (e.g., rent, dining out, etc.) using a successive pile-sort method (Boster 1994; Medin et al. 1997), where consumers first sort items into however many categories they would like. Then, they further split and merge the categories that they deem appropriate to generate a hierarchy of categories. This method yields the grouping of items that are the most natural to consumers as well as the taxonomic distance between the expenditures. These distances provide a refined measure of cross-item relationships that can be used to predict spending behavior. Specifically, we hypothesize that when consumers overspent on one item, they would be more likely to adjust spending for more closely related items, as revealed by the taxonomy derived from the successive pile sort task. This hypothesis allows us to make predictions about spending adjustments for items of all distances and does not require the researcher to label the categories.

In Study 1 (N = 27, Mturk), participants perform a successive pile-sort task of 64 budget items (determined through a pilot) on a web interface. To translate the hierarchy to a distance metric, an item had distance 0 with itself, while the items grouped in the subordinate level group (i.e., the group after splitting) had a distance of 1; items grouped in the basic level (i.e., first sort) but not in the subordinate

level group had a distance of 2; those shared only superordinate category (i.e., the group after merging) had a distance of 3 while those never grouped together had a distance of 4. The correlation between all participants' distance matrices passed the cultural consensus model (first eigen value is considerably larger than the second eigen value (12.23 vs 1.39); all factor loadings are positive; Romney, Weller, and Batchelder 1986), which indicated that participants achieve consensus in their representation of the expenditure items. This result suggests that individual participants' representations of these purchases are similar, that there is consensus that some items are closer (e.g., shampoo and toilet paper) and others further (e.g., shampoo and airplane tickets), and it provides the basis of stimuli selection in Study 2 and 3.

Using this method for deriving taxonomies, Study 2 investigated how consumers adjust their spending for items of different distances. To allow for clear distinction of items at different distances, Study 2 used two waves of data collection, separated by two days, to allow for individualized stimuli. In wave 1 (N=198), participants did the categorization task from Study 1. We then tailored the stimuli for each participant for wave 2 (N=161), which used a 2 (spending condition: overspend vs underspend on the focal item) by 2 (scenarios with different sets of items) within-subject design. Each set of scenarios consisted of a focal item that they had "spent" on and four comparison items, one of each that has a distance of 1, 2, 3 and 4 to the focal item. The comparison items were selected so as to be maximally comparable to each other on additional norming measures (e.g., hedonic and frivolous spending) that we collected. When consumers overspent on a focal item, they adjusted their spending less for items at greater taxonomic distances ($b = 0.10$, $t(642) = 2.66$, $p < 0.01$). In other words, the more closely related the comparison item was to the focal item, the more people adjusted their spending downward on that item. For underspending, we did not observe differences across levels ($F(3, 640) = 0.31$, $p = 0.82$). We replicated this finding in Study 2b with comparison items selected from aggregate distances.

In Study 3, we investigated spending behavior beyond self-reported adjustments. Participants (N = 356, MTurk) read that they have spent on a focal product that comes with a discount promotion, and they ranked three other comparison items of varying taxonomic distances in terms of how much they wanted to apply the promotion. The study used a 5 (scenario) by 2 (focal typicality: typical, atypical) by 2 (promotion magnitude: 10% off, 40% off) within-subjects design. According to our hypothesis, participants would want to apply the promotion to the item of closest distance the most to save money on the same budgeting category, and the rank would decrease as distance increases. The result was consistent with our hypothesis: as distance increased, the rank for an item decreased ($b = -0.004$, $t = 3.22$, $p < 0.01$), and the pattern was consistent across both the typicality of the focal product and the promotion magnitude. This pattern was replicated in Study 3b, which used choice rather than ranking as its dependent variable and a buy-one-get-one-free promotion.

The current paper develops its theoretical framework from the literature in cognitive science on the mental representation of categories and concepts and applies the investigation methodology to a mental budgeting context. By recovering consumers' representation of expenditures, we hypothesized and tested for specific spending adjustment patterns related to taxonomic distance. This approach for investigating people's categories of expenditures could be extended beyond budgeting to countless other decisions about spending and saving, and potentially illuminate other applications such as brand extensions and recommendation algorithms for items purchased together.

Divergent Effects of Budgeting for Gift- and Personal-Purchases

EXTENDED ABSTRACT

It is common for people to set budgets. From spending on rent, transportation, food, etc., consumers are often budgeting their money. One expense in particular that consumers make is buying gifts. While gift-giving is a prevalent consumer behavior, the intersection between budgeting and gift-giving has thus far received little attention. In our research, we explore how gift-budgets are perceived differently from personal-budgets, and the effect this has on spending on others.

Traditionally, budgets serve as a reference point for a purchase decision (Heath, Larrick and Wu 1999) and are often accompanied by a consumption-reduction goal (Krishnamurthy and Prokopec 2010). For example, when a consumer budgets $100 to buy a bottle of wine for herself, she will focus on getting the best wine within her budget. We predict that consumers with personal-budgets will prefer to spend less than their budgets in an effort to minimize their spending (i.e., *budget-minimizing goal*). In contrast, when a consumer sets aside $100 to buy a bottle of wine for a gift, we predict that she will focus on choosing the best wine that costs as close to her $100 budget as possible. For gift-purchases, we hypothesize that consumers prefer to spend the entirety of their gift budgets (i.e., *budget-maximizing goal*).

We theorize that the divergence between gift- versus personal-budgets stems from how much consumers focus on saving money. For personal-purchases, budgets are typically set for the purpose of controlling spending (Heath and Soll 1996), and are often driven by a savings goal (Peetz and Buehler 2009). However, gift-purchases often function to satisfy other goals, such as celebration, impression management, and relationship maintenance (Sherry 1983), which make people become willing to increase spending on others. Accordingly, research has found that people are less price-sensitive when choosing gifts than when making personal-purchases (Boncinelli et al. 2019; Wang and Van der Lans 2018). We thus hypothesize that consumers will treat gift-budgets in a relative budget-*maximizing* manner, resulting in weaker savings goals for gift-purchases than for personal-purchases.

In study 1, we asked 224 participants to recall both a recent personal- and gift-purchase, and to write down what "budgeting for a single item (vs. a gift)" meant to them. We coded participants' responses according to whether participants aimed to "spend less than their budget" or "spend around their budget." For personal-purchases, more participants indicated a preference to spend less than their budget (74.3%) than to spend around their budget (25.7%). In contrast, when buying gifts, more participants indicated a preference to spend around their budget (70.1%) than to spend less than their budget (29.9%), $p < .001$.

Study 2 tested the downstream consequences of holding different perceptions of personal- and gift-budgets, while providing process evidence of savings goals to explain the difference. We asked 329 participants to imagine that they set a $100 budget to buy a coffee maker for themselves or for a friend's gift, and to indicate their likelihood to choose between two coffee makers, from 1 (*Model A for $85*) to 8 (*Model B for $100*). Next, we measured participants' savings goals (cf. Peetz and Buehler 2013). Gift-purchasing participants showed a greater preference for the $100 (at-budget) coffee maker (han did self-purchasing participants (M_{gift} = 4.25 vs. $M_{personal}$ = 3.51; $p = .003$, $d = 0.33$). In addition, self-purchasing participants focused more on savings goals than gift-purchasing participants ($M_{personal}$ = 4.68 vs. M_{gift} = 4.29; $p = .002$, $d = 0.34$). A mediation analysis

showed that purchasing a gift rendered a stronger preference for the at-budget option because of gift-purchaser's weaker savings goals, *b* = 0.52, 95% CI: [0.19, 0.83].

In study 3 (pre-registered), we manipulated the explicitness of the budget (explicit, implicit, absent), and again measured participants' saving goals. In the explicit-budget condition, participants were told that they "set a budget of $50" to buy a sweatshirt either for themselves or for a friend's birthday gift. In the implicit-budget condition, participants were told that they were "considering spending around $50." In the absent-budget condition, no budget-related information was provided. All participants ($N = 954$) imagined that the price of the sweatshirt they were interested in buying was $40. Then, we asked participants to indicate their willingness-to-pay (WTP) for a 3-pack of fleece socks to add to their sweatshirt purchase. WTP for the socks was higher for gift- than personal-purchases when the budget was explicit (M_{gift} = $8.67 vs. $M_{personal}$ = $7.51; *p* = .017, *d* = 0.29) and when the budget was implicit (M_{gift} = $9.25 vs. $M_{personal}$ = $7.73; *p* = .002, *d* = 0.37). In contrast, WTP for the socks did not differ when the budget was absent (M_{gift} = $7.53 vs. $M_{personal}$ = $7.82; *p* = .579), which shows that the effect was mitigated when there was no clear budget.

In a final study, we conducted a real shopping experiment by giving $10 to 297 participants, and asking them to make purchases for either themselves or for others as a gift. We found that the amount spent in the gift-giving condition was not significantly different from the implicit $10 budget ($M$ = $9.59, *p* = .267), while the amount spent in the personal-purchase condition was significantly lower than the implicit $10 budget ($M$ = $8.80, *p* = .003). These results provided field evidence that consumers preferred to spend all of their budget when buying a gift (evidencing a budget-maximizing goal), whereas for personal-purchases, consumers preferred to spend less than their budget (evidencing a budget-minimizing goal).

While research in mental budgeting has considered mental budgets broadly as a tool to curb spending, we provided a novel perspective that a mental budget could be a goal-amount for either minimizing or maximizing. In addition, while the majority of work on gift-giving has examined asymmetrical giver-receiver disparities in gift-giving preferences, our research broadens the understanding of gift-giving behavior through exploration of a practical factor—how much money consumers spend on gifts. Finally, our research provides support for *why* choices for the self are different from choices for others in a gift-giving context (Polman and Wu 2020).

How Financial Well-being Impacts Financial Communication Between Couples

EXTENDED ABSTRACT

Many consumer decisions, especially financial ones, have the ability to affect not only the decision maker, but also their spouse (Hamilton et al. 2020; Raghunathan and Corfman 2006; Ramanathan and McGill 2007; Ratner and Hamilton 2015). When it comes to managing joint finances, couples often need to discuss financial matters, establish financial goals, and make choices regarding financial products (e.g., savings and loans). This project explores how a couple's perception of their joint financial situation influences their decision to communicate with each other during these decisions.

In **Study 1A**, we explored the data from a survey conducted by the Consumer Financial Protection Bureau (CFPB). In that survey, over 4000 married participants were asked whether they sought advice on matters involving money from their spouse. Moreover, the survey included scores that measured participants' financial well-being. We found a significant positive relationship between financial well-being scores and the likelihood of seeking a partner's financial advice (*exp*(β)=1.002; *p* =.002*)*. This result suggests that when one's perception of their financial situation is bad (i.e., low financial well-being scores), they seek their partner's advice to a lesser extent. In **Study 1B**, we analyzed another publicly available dataset provided by Inter-university Consortium for Political and Social Research (ICPSR #26544) with 1264 married couples. We found that when couples' everyday money management stress was high, and they thought that their financial situation had worsened, they shared and worked significantly less with their partner towards their financial goals (β=0.05; *p* =.048; β=-0.19; *p* <.001*)*. Thus, the findings from both the secondary datasets converge to demonstrate that a couple's financial situation impacts their degree of financial communication, such that the worse off financially they perceive themselves to be, the less they communicate with one another.

Our next two studies provide experimental evidence for this relationship. Past research suggests that when net worth is negative (i.e., debts > assets), people focus on their level of assets. For this reason, people feel wealthier when they have more (vs. fewer) assets, despite net worth being held constant (Sussman and Shafir 2012). Thus, in **Study 2** (N=601), we manipulated a couple's perceived financial well-being by providing them with a series of nine financial portfolios that had various magnitudes of assets and debts (ranging from low levels to high levels). We varied the amount of debt from $26,000 to $134,000 and accordingly the amount of assets from $1000 to $109,000, all the while keeping the net worth of the household constant at negative $25,000. For each financial portfolio, we asked participants to make a choice between an individual (or joint) financial product (i.e., separate vs. joint loans, savings accounts, or investments), such that choosing the joint financial product would facilitate greater financial communication. Results revealed that when magnitudes of assets were smaller (i.e., lower perceived financial well-being), fewer participants opted for the joint financial product (M_{low}= 66% vs. M_{high}= 76%; p <.001), replicating our previous pattern that when financial well-being is low, couple members are less likely to communicate with their spouse.

If couples' members are shying away from communicating with their spouse when their financial well-being is low, will they be more likely to talk to their spouse when financial well-being is high? In **Study 3** (N=799), we used a 2(net worth: positive vs. negative) x 2(asset-debt magnitudes: high vs. low) between-subjects design to test whether positive net worth moderates our effect. Depending on the assigned condition, participants either saw a positive household net worth of $25,000 or a negative household net worth of $25,000. Participants in the high asset-debt magnitudes condition saw asset and debt magnitudes of $109,000 and $134,000. In contrast, participants in low asset-debt magnitudes conditions saw asset and debt magnitudes of $9,000 and $34,000. We subsequently examined participants' preference for either individual or joint products for three types of financial products (separate vs. joint loans, savings accounts, and investments). Replicating Study 2, participants in the negative net worth condition preferred the joint product moderately less when the level of assets (i.e., their perceived financial well-being) was lower (M_{low} = 5.25) than when the level of assets was higher (M_{high}= 5.57; $F(1,727)$ = 3.12, *p* = 0.078). However, when net worth was positive (i.e., couple members can infer that their joint financial situation is good), we found no difference in preferences for the joint (vs. individual) financial products depending on the varying levels of assets and debts ($F(1,727)$ = 1.411, *p* = 0.235).

Overall, we find that when couples financial well-being is low, they communicate less and show a decreased preference for joint (vs. individual) financial products. This consistent pattern of results sug-

gests that couple members shy away from financial communication when they need it most. These findings have important implications for consumer financial well-being, since couples with less than ideal financial situations might manage their money more effectively (Olson and Rick 2018) by discussing their finances more openly.

Income Prediction Bias in the Gig Economy

EXTENDED ABSTRACT

Gig economy employment is defined by temporary, freelance work. Emblematic examples include driving for Uber, delivering food through apps like Door Dash, and participating in academic research on platforms like Amazon Mechanical Turk. An important and previously unstudied aspect of working in the gig economy is that gig income can be hard to predict. In the present research we test the hypothesis that consumers who work in the gig economy display an *income prediction bias* in which they over-predict their gig income. We also test two interventions designed to improve prediction accuracy.

Is there an Income Prediction Bias?

On the one hand, there are reasons to believe that gig income predictions may be reasonably accurate. For example, gig workers could engage in "income targeting" and simply work for as long as it takes to hit their target (Camerer et al., 1997). On the other hand, there is evidence suggesting that predictions tend to be optimistic, even in the face of contradictory information. For example, research on the planning fallacy has demonstrated that people tend to make optimistic predictions regarding project completion times, even when they are equipped with the knowledge that similar projects have taken longer than planned in the past (Buehler, Griffin, and Peetz 2010). Therefore, based on the logic that an optimistic income prediction means earning more money rather than less, we hypothesize that:

> *Hypothesis 1:*   *Gig economy workers display an income prediction bias in which they over-predict their gig income.*

How Can Income Prediction Accuracy Be Improved?

Several streams of research support the proposition that people do not consider the full distribution of possible outcomes when they make predictions. Two solutions to this problem that have improved prediction accuracy in other domains are: 1) explicitly prompting people to take an "outside view" and base their predictions on relevant past behaviour (Buehler, Griffin, and Ross 1994), and 2) prompting people to consider atypical outcomes when formulating their prediction (Howard et al. 2021). One goal of the present research is to systematically compare the effectiveness of these interventions in the context of income prediction. To accomplish this we test the following Hypothesis:

> *Hypothesis 2:*   *Prompting gig workers to base their predicted income on relevant past income reduces the income prediction bias.*

> *Hypothesis 3:*   *Prompting gig workers to consider reasons why their schedule will be different than usual reduces the income prediction bias.*

Studies 1–3: Examining the Bias

The first goal of Studies 1–3 was to test H1 with samples drawn from different types of gig work. The second goal was to test the feasibility of different participant recruitment channels. Participants in Study 1 were Uber drivers recruited through r/uberdrivers, a reddit.com community that Uber drivers use to communicate with each other (N = 38, M_{age} = 36.6, 13.2% female). Participants in Study 2 were MTurkers (N = 129, M_{age} = 34.9, 40.3% female). Participants in Study 3 were food delivery app drivers recruited through paid advertisements on reddit.com communities like r/grubhubdrivers (N = 47, M_{age} = 29.9, 23.4% female).

Participants in Studies 1–3 completed two surveys. The first survey was completed immediately, and it asked participants to predict their gig income and hours for the next week. The second survey was completed one week later, and it asked them to log into their gig's app and report their gig income and hours for the past week. Supporting H1, the Uber drivers in Study 1 overpredicted their gig income by 18.2% (Mean Difference = $63.90, 95% CI = [-.89, 128.69], $t(37)$ = 2.00, p = .053), the MTurkers in Study 2 overpredicted by 11.6% (Mean difference = $13.05, 95% CI = [1.01, 1.23], $t(128)$ = 2.14, p = .034), and the food delivery app drivers in Study 3 overpredicted by 19.9% (Mean difference = $63.52, 95% CI = [13.64, 113.40], $t(46)$ = 2.56, p = .014). Participants in all three studies also over-predicted the number of hours they would work (p's < .01). However, participants' expected hourly wage did not differ significantly from their actual hourly wage (p's > .10).

Study 4: Bias Reduction

The purpose of Study 4 was to test H1, H2, and H3. To do so we randomly assigned 662 food delivery app drivers (M_{age} = 30.03, 35.0% female) to one of three prediction conditions: control, outside-view, or defocalizing. In the control condition participants were asked to predict their gig income for the next week. In the outside-view condition participants were asked to base their income prediction on their average weekly earnings over the past month. In the defocalizing condition participants were asked to consider two reasons why their work schedule for the next week might be different than a typical week before predicting their income. One week later we sent participants a second survey that asked them to report their actual income earned. This study was preregistered on aspredicted. org (https://aspredicted.org/blind.php?x=nu8j4c).

H1 was supported: delivery drivers in the control condition overpredicted their weekly income by $62.38 or 23.2% ($M_{predictedincome}$ = $331.66, $SD_{predictedincome}$ = 238.15; $M_{actualincome}$ = $269.28, $SD_{actualincome}$ = 238.30; $t(209)$ = 5.76, p < .001, d = .40). H2 was also supported: the outside view intervention reduced the size of the bias by $29.31 or 53.0% versus control ($t(449)$ = -1.95, p = .051, d = .21). H3 was not supported: drivers in the defocalizing condition overpredicted their income by $67.39 or 25.7% ($t(210)$ = 3.20, p < .001, d = .40), and the magnitude of the bias did not differ between the defocalizing and control conditions ($t(419)$ = .32, p = .75, d = .03).

Discussion

To the best of our knowledge the present research provides the first evidence that consumers who work in the gig economy systematically over-predict their gig income. Furthermore, we find that this income prediction bias is associated with over-predicting the number of hours one will be able to work rather than one's hourly wage. Finally, we demonstrate that the bias can be reduced by prompting consumers to take an "outside-view" when prediction their income.

SESSION OVERVIEW

Steeped in a Bourdieusian perspective, the taste literature in CCT tends to elaborate on the ways in which consumers reproduce class-based practices in their quest for distinction and identity construction (Holt 1998; Üstüner and Holt 2007, 2010; Üstüner and Thompson 2011). A subcategory of this literature shows how consumers learn to practice taste and gain communal identity in the process (Arsel and Bean 2013; Maciel and Wallendorf 2017; Seregina and Weijo 2018). Both domains highlight the reproduction of tastes and tend to downplay the role of consumer agency. They are seldom able to explain how social actors develop tastes that vary from their habituated dispositions (Thompson 2018) or how changes in social institutions, such as markets. Further, the practice theoretical literature tends to overlook disagreements and contestations within taste communities.

In the first paper, the authors examine taste practices intergenerationally in families to understand how divergences and convergences of taste practices and ideologies from the oversocialized form occur. They unpack the micropolitics to examine what discursive and practical strategies family members employ to critique and challenge each other's tastes and justify their own, and ultimately how they resolve ensuing tensions to stabilize the familial institution.

In the second paper, the authors examine how market-based taste practices become more complex, thus advancing the role of practices in bringing about market evolution. Using data from the coffee market, they propose that the coffee market is governed by competing institutional logics and further show how practice complexification results from interactions between firms that reflect different logics via a series of mechanisms that incorporate in new materials, skills, and meanings.

In the third paper, the authors examine the discursive emergence, rearticulation, and change of taste structures over time. Drawing upon a prolonged engagement with Greenlandic food culture, they show that the precursor to the formation of a taste regime is the discursive organizing and valorizing of cultural differences. This process is based on sociohistorically and politically established glocalized structures of valorization.

Together these papers: 1) Help advance doxic understandings of taste by enlisting both consumer and market perspectives, operating at different levels of analysis, to examine the emergence and operations of taste; 2) They push theorization of taste beyond the currently entrenched Bourdieusian and practice theoretical approaches by employing a diverse set of sociological and consumption theorists; 3) They draw attention to the undeveloped theme of taste transformation by highlighting how divergences in taste emerge at the level of individual and families and are discursively managed. Further they examine how these transformations emerge sociohistorically, undergo institutionalization and shape tastes at the level of markets and even national cuisines.

This session aligns well with the conference theme of 'What the World Needs Now' because it seeks to examine the reconfiguration of society and markets through novel theoretical approaches and multilevel analyses—within the contextual backdrop of sociohistorical, cultural, and political shifts. Social change is hard to achieve without newer ways of perceiving the world and ideological cooperation.

A Post-Bourdieusian Examination of Taste: How Families Justify Divergent Taste Practices

EXTENDED ABSTRACT

Bourdieusian-inspired consumption research repeatedly shows how consumers replicate social distinctions through the expression of naturalized taste (e.g., Holt 1998; Üstüner and Holt. 2007, 2010; Üstüner and Thompson 2012). However, this literature tends to remain silent on disruptive taste performances that diverge from habituated, class-based ideologies (Thompson 2018). Existing literature provides a deep understanding of the processes by which consumers translate taste into practice (Arsel and Bean 2013), but leaves us to wonder whether individuals oppose, contest, or violate the prescriptions of taste communities. Studies in this domain support the Bourdieusian tenets of social reproduction (e.g., Maciel and Wallendorf 2015; Seregina and Weijo 2017) by showing that consumers' participation in taste regimes tends to align with their socialized tastes. Neither of these streams addresses the agentic aspects of consumer taste, or the micropolitics of taste and how consumers navigate differences within groups. Our research goals are threefold, to illuminate how individuals (1) diverge in their taste practices from their socialized tendencies, (2) criticize the practices of others while justifying their own, (3) navigate the micropolitics of taste to achieve social coordination that helps preserve the stability of institutions.

Drawing inspiration from researchers' criticisms that Pierre Bourdieu (1998) undertheorizes the processes of change—both at the level of individual and society (Calhoun, LiPuma and Postone 1993)—we adopt Lahire's (2003) conceptualization on the 'plurality of dispositions' and Boltanski and colleagues' 'sociology of critique' (Boltanski 2011; Boltanski and Thévenot 2006). Lahire (2003) suggests that social agents develop a broad array of dispositions, each of which owe their accessibility, composition, and intensity to the socialization process in which they were acquired. He further draws a distinction between dispositions to act and dispositions to believe and states that the intensity to which these express in behavior depend on the social context in which agents are interacting.

The foundational tenets of the 'sociology of critique' are that social actors possess a capacity for critical reflection on the fairness

and merit of social arrangements and ideological rationales, which seek to shroud their more invidious subjugatory aspects. In situations of controversy, individuals may deploy orders of worth (forms of common good which align with regimes of justification) in practical tests—i.e., civic, market, industrial, domestic, inspiration and fame—to evaluate and critique worth attributed to persons or things based on these orders. Social actors face an imperative (steeped in the micropolitics of social interactions) to assess and criticize competing justificatory regimes and choose the course that best serves their understanding of fairness (Thompson 2018).

We base our study on 19 in-depth interviews with adult members from two and three generations of seven families of Midwestern American origins. We followed the extended case method (Burawoy 1991) according to which we selected anomalous cases specifically for their theoretical relevance. These were family members who diverged from prior generations and/or their siblings in capital endowments, ideologies, and taste practices. We conducted interviews following the phenomenological method (Thompson, Locander and Pollio 1989) and data analysis following the hermeneutic approach (Thompson 1997).

Our findings imply that younger family members acquire many habituated tastes during primary socialization but adopt divergent ideologies and taste practices owing to their secondary socialized dispositions. The plural dispositions express in different ways in different social situations. These acquisitions result in continuities as well as transformations of taste from one generation to the next. Departures in taste can cause conflicts in familial contexts with family members often premising these disputes on the moralization of taste and lifestyles. They criticize each other using justifications based on the different principles of worth. As an illustration, a son's vegetarianism becomes a point of criticism, with the adult child and parent using justificatory principles of civic and domestic worth to support their arguments for and again this consumption choice. Ultimately, we find that family members attain fragile truces—they raise a plurality of principles of worth, which gives way to the paramount principle of domestic worth.

We make several contributions with our investigation of the underexplored area of divergences of habituated taste and conflicting taste ideologies and practices. Firstly, we examine contestations within families, and the discursive and practical strategies family members employ to diffuse ensuing tensions. Secondly, we extend disciplinary understanding of how social coordination is achieved and institutions—in this case the fundamental institution of family—are maintained and stabilized. Thirdly, we draw attention to the role of consumer agency. We unpack the familial micropolitics that emerge over divergences of capital, ideologies, and taste practices to show how social actors may challenge oversocialized taste prescriptions. Lastly, we advance the boundaries of taste theorization by acknowledging the malleability of the habitus. We show how plural dispositions emerge via primary and secondary socialization and are expressed in particular social contexts to varying extents (Thompson 2018).

How Taste Practices Become More Complex

EXTENDED ABSTRACT

How do taste-based practices become more complex? The markets for beer, coffee, and tattooing share a characteristic: They are composed of practices that have increasingly complexified over time, a process that contributed to their evolution. For example, in the beer market, historically, products were differentiated mainly by brands (rather than their aesthetic properties) until the 1990s. Since then, a rapidly growing craft market has emerged (Carroll and Swaminathan 2000), and consumers can now engage in more complex taste-based practices, develop their knowledge, and conversely expand their tastes (Maciel and Wallendorf 2017). Although the complexification of practices seems ubiquitous to production and consumption, and while we know how consumers learn complex practices, we do not know how this complexity comes to be or how it can contribute to market evolution. We address this gap by studying the complexification of taste-based practices in coffee. Coffee is a market that has been recognized as increasingly complex (Pendergrast 2010), which makes it ideal for our research question. To answer how taste-based practices in a market become more complex, we analyze a multi-sited dataset composed of archival data (more than 2000 pages); field notes, pictures, and videos from 10 industry events; and primary (26 participants) and secondary interviews (42 actors) with consumers and producers.

We use a practice theoretical approach (Shove, Pantzar, and Watson 2012) to propose a theory of market evolution that relies on the complexification of the practices that comprise a market as the primary evolutionary theoretical mechanism. To explain this process, we first show how the coffee market is governed by competing institutional logics—craft and commercial—that lead firms to engage in differentiated performances based on the same practice. Institutional logics are "the socially constructed, historical pattern of material practices, assumptions, values, beliefs, and rules" (Thornton and Ocasio 1999, 804). For example, the making of coffee by Dunkin' employees (a commercial firm) is different from the making of coffee by the employees at the coffee shop owned by World Barista Champion Tim Wendelboe (a craft firm). The first set of employees will make coffee by emphasizing efficiency and maximizing profitability, while the latter will make coffee to perfect an aesthetic experience. The symbolic and material differences in these firms' beverages are an outcome of differences in practices governed by different logics.

Next, we show how practice complexification results from interactions between firms that reflect different logics (e.g., craft vs. commercial firms) and have different targets (narrow vs. broad targets). We identify three mechanisms through which this process happens.

In the first mechanism, firms of the same type *elaborate* a practice between themselves. For example, the World Barista Championship is a yearly competition that pitches the best (craft) baristas from each country against one another. To qualify, baristas need to develop a 15-minutes routine and compete regionally and then nationally. Performances, exchanges, experimentation, and innovation at hundreds of competitions at the regional, national, and world level lead to the development of new ways of making coffee, novel use of objects, and so on.

In the second mechanism, firms *translate* practices to fit better their narrower (i.e., niche) or broader (i.e., mainstream) targets. For example, craft specialists have translated the practice of making ready-to-drink cold brew coffee from craft generalists. Craft generalists make cold brew coffee in a way that removes coffee acidity, which creates a sweet and fruity flavor ideal for a broad range of consumers. Yet, this key characteristic of cold brewing by craft generalists, i.e., the removal of acidic flavors, is also the main reason why craft specialists initially shunned the practice: Craft specialists see the lack of acidity as a flaw that prevents the creation of the complex flavors associated with great coffee beans. To adapt cold brewing to their narrow target of coffee enthusiasts, craft specialists translated the brewing process to attain such acidic flavors. In the process, they

complexified the practice of making cold brew coffee by incorporating new doings and objects.

Last, we show how firms that reflect different logics (i.e., craft vs. commercial) *transform* practices to align better with their assumption, goals, and beliefs (i.e., aesthetic experience vs. profitability). For example, craft firms developed specialty coffee pods from commercial ones to align their goal of perfecting the aesthetic experience of coffee. Again, in transforming the making of coffee pods, craft firms developed new doings and objects and relationships in between to develop pods that would fit their taste.

Elaboration, translation, and transformation result in practice complexification. It leads to the inclusion of novel material elements, diversifying competences, and enriched meanings associated with a practice, which results in a richer repertoire of performances for practitioners.

We extend existing work on the replication and adaptation of practices (e.g., Ansari, Fiss, and Zajac 2010) and theorize how practices complexify. We also contribute to work on market evolution (e.g., Ertimur and Coskuner-Balli 2015) by explaining how practice complexification contributes to market evolution. Although we concentrate on the complexification of taste-based practices, our work has applicability to the complexification of practices in any market where competing logics exist.

The Glocalization Of Discursive Structures of a Culinary Taste Regime: Insights from Greenland

EXTENDED ABSTRACT

Taking as our starting point Arsel and Bean's (2013) definition of taste regimes as "[…] a discursively constructed normative system that orchestrates the aesthetics of practice in a culture of consumption" our aim in this presentation is to reveal how such a discursively constructed system may unfold over time. That is, our unit of analysis is not so much how practices are changing over time, but how they are discursively articulated based on historically established glocalized structures of valorization. We do this by drawing on an empirical study of Greenlandic food culture and examine how this process unfolds over time through glocalization. Doing so, we join several voices that seek to conceptualize taste and taste formation beyond Bourdieusian and practice theory-based approaches (e.g., Parmentier and Fischer 2018).

We situate our analysis in theories of glocalization, most centrally Wilk's concept of structures of common difference (Wilk 1995). Wilk highlights that homogenization occurs at the structural level and that those structures determine the lines along which cultural difference can be expressed. The emphasis on cultural and political identity politics – and thereby fragmentation and expansion in the symbols of cultural differences – are hence expressed within increasingly similar structures. One such structure is food culture and its surrounding taste systems. To bolster our analysis, we draw on two theoretical strands: 1) theories of structure, in particular Sewell's work on structural change and systems of valorization; and 2) recent glocalization theory that highlights the multidimensionality of glocalization along vertical, horizontal and temporal dimensions (Drori et al. 2014).

Empirically we rely on a prolonged engagement with Greenlandic food culture. Greenland's history of being initially populated by Inuit from the north, with Norse seafarers settling in the south, becoming re-colonized in the 18th century by the Danish Kingdom leading to a 20th century process of integration and modernization and ultimately in the 21st century to increasing political and cultural independence – this whole trajectory forms a socio-historical process of identity and nation building. Our data is based on interviews with Greenlandic consumers, interviews with intermediaries in the Greenlandic food sector, as well as a systematic historical analysis of Greenlandic cookbooks and household manuals stretching from 1934 to 2012. Our analysis identifies and historicizes shifts in Greenlandic food culture according to shifts in political and cultural economy of our context.

In our study of the historical development of Greenlandic food culture we identify four discursive structures with four general cultural schemas for organizing and valorizing cultural differences: segregating, integrating, separating, and finally relativizing. These wider socio-political discursive structures are re-articulated over time and inflected more specifically in cultural schemas of food and the interpretation and articulation of food cultural resources such as ingredients and preparation methods and traditions. We show how shifting political contexts over time beget shifting structures of common difference. These shifts we theorize as a glocalization of structures temporally, that is historically, as the structures are co-constitutive and intersecting in discourses of contemporary Greenlandic food culture and its gastronomization.

To understand the dynamics (emergence and possible institutionalization) of tastes we need more studies of taste situated in macro contexts of political, ideological, and cultural history and the interaction of locally institutionalized structures of valorization with globalizing structures of valorization (Askegaard and Linnet 2011). Not all taste regimes may be as influenced by glocalization processes as in our context. However, we would argue that for example the 'soft modernism' studied by Arsel and Bean or other taste and style-based 'isms' to a large degree are flowing as both aesthetic, ideology and practice. Artistic movements in visual or musical arts may emerge in a given locality but often travel across geographical boundaries through globalized media, cultural intermediaries and taste maker practices. This is as evident in *Jugend*, the Nordic version of French art nouveau as in contemporary glocalized rap genres (Solomon 2006). We argue in other words, that in order for a taste regime to emerge – for practices to take place – a discursive system is a pre-requisite for the structuring of taste difference, distinctions and practices. Hence the objects, meanings and doings of a taste regime are only valorized through such evolving discursive systems of valorization. In turn the practices of a taste regime may recursively confirm, reproduce or contest said systems. With such a structural discursive perspective, tastes, in other words, are talked into being.

Working Papers

Crossing the Liminal Line – How Interracial Couples in China Experience Marriage

Amandeep Takhar, De Montfort University, UK
Gaye Bebek, De Montfort University, UK
Jiayi Zhong, University of Wales, Saint Trinity David, UK

This research study seeks to understand, just how interracial couples in China, make consumption choices during the liminal and transitional stage of marriage. We contribute to current literature by identifying the fluidity of their identity projects, as a consequence of the liminality that is experienced during this milestone.

Am I Worth It Now? The Social Currency of Fair Skin for Bengali Millenials in the U.K.

Amandeep Takhar, De Montfort University, UK
Gaye Bebek, De Montfort University, UK
Thomas Magede, University of Wolverhampton, UK

This research study seeks to understand the value and social currency of skin lightening products amongst millennials from the Bengali community in the U.K. It emerges that the consumption of these products surrounds the deep rooted ideologies of beauty, that have been transferred across the migrating generations from India.

Facial Alterations in Marketing Products Can Dehumanize Consumers: The Dark Side of Puppy and Eye Filters on Attitudes toward Underrepresented Consumers

Sumitra Auschaitrakul, University of the Thai Chamber of Commerce, Thailand
Dan King, University of Texas Rio Grande Valley, USA

We show that many products and marketing-related behavior increase racism and prejudiced behavior towards minorities. Marketers who manipulate eyes using filters induce dehumanization, an effect underpinned by consumers' ability to see the self of the person. The effect is robust whether people evaluated minorities, or even when minorities evaluated themselves.

Human Enhancement Technologies for the Übermensch Consumer

Vitor M. Lima, Audencia Business School, France
Russell Belk, York University, Canada

Drawing on Nietzsche's ideas about self-overcoming and Transhumanism literature, we conceptualize Human Enhancement Technologies and the *Übermensch* consumer as a novel perspective on consumer-technology relationships. Moreover, we offer insights that can help guide judgments on how to tackle ethical dilemmas surrounding what it means to be human/non-human, consumer/consumed, therapy/enhancement.

Sharing Consumer Biohacking to Tackle Coronavirus

Vitor M. Lima, Audencia Business School, France
Russell Belk, York University, Canada

By following consumer biohackers' self-experiments to tackle COVID-19, we introduce the Sharing Diagram, which encompasses possible sharing motivations. The contribution of this research is, firstly, to expand current studies of the sharing phenomena. Secondly, to provide insights into discussions of public participation in solutions development during public crises.

When and Why Process Imagery Can Increase Donation Intentions

Joshua Lundberg, University of Kentucky, USA
John Peloza, University of Kentucky, USA
Adam Craig, University of Kentucky, USA

In this work, we add to the nascent literature on sequential imagery by demonstrating how it can enhance the perceived efficacy of charities and thus generate greater prosocial intentions. Further, we find that this effect depends on third-party ratings of the charity and emotional decision making by the consumer.

Humor Use in Response to Negative Publicity

Ying Yu, Huazhong Agricultural University, China
Li Huang, Hofstra University, USA
Ping Qing, Huazhong Agricultural University, China
Tong Chen, Huazhong Agricultural University, China

The use of humor in brands' social media communication has become prevalent. This research explores the effectiveness of humor in responding to negative feedback on social media and the underlying mechanism of perceived norm violations. The results provide important implications for the brands managing customer relationships online.

Which Recommendation Label Can Induce Higher Willingness-to-Pay?

Lina Xu, New Mexico State University, USA
Michael Hyman, New Mexico State University, USA

Companies create various product recommendations to improve the online shopping experience. Across three studies, this work demonstrates that ranking-based recommendation labels reinforce e-shoppers' quality-assessment-belief, which in turn elicits a higher willingness-to-pay than the non-ranking-based ones. This effect is moderated by the congruency of consensus attributes and perceived price differences.

Avoiding Minimalist Design in Gift Giving

Dongjin He, Lingnan University, Hong Kong
Linying (Sophie) Fan, Hong Kong University of Science and Technology, Hong Kong
Yuwei Jiang, Hong Kong Polytechnic University, Hong Kong

This research shows that consumers are less likely to choose a product with a minimalist design when it is to be sent as a gift to others (vs. purchased for self-usage). Furthermore, this avoiding-minimalism effect is moderated by the opportunity to personalize a product for intended users.

A Spiritual Journey to Zero-Waste

Jessica Darveau, Laval University, Canada
Khaoula Ellafi, Laval University, Canada
Aïda Faber, Laval University, Canada

This research explores spiritual aspects that are at play in the transition to a zero-waste lifestyle. Drawing from 35 in-depth interviews with customers of zero-waste grocery stores, it uncovers the spiritual journey that characterizes the commitment to a lifestyle that requires considerable efforts but that is precisely valued for it.

Push It Past the Limit: The Slippery Slope of Product Misuse.

Evelynn Devos, Ghent University, Belgium
Mario Pandelaere, Virginia Tech, USA
Anneleen Van Kerckhove, Ghent University, Belgium

How consumers use a product contributes to product longevity, an important leverage in waste reduction. Results show a slippery slope of product misuse: when consumers successfully exceeded product limits in the past, they will misuse the product even further, because they estimate the odds of negative consequences less likely.

Do You Want to Be Creative? Be Stupid First

Tatiana Karpukhina, WU Vienna, Austria
Martin Schreier, WU Vienna, Austria
Ayelet Fishbach, The University of Chicago, USA

In this research, we test a technique allowing to boost creativity. We find that contrary to our common problem-solving intuition, starting an ideation process by generating "stupid" ideas first significantly increases creativity of the final ideas. Being "stupid" first breaks cognitive fixations, allowing to reach more distant and novel ideas.

Thriving or Surviving? The Role of Mindsets in Times of Crises: Evidence from the COVID-19 Pandemic

Ross Murray, University of Texas Rio Grande Valley, USA
Xiaojing Sheng, University of Texas Rio Grande Valley, USA
Forrest Morgeson, Michigan State University, USA

We conducted qualitative interviews to examine differential responses among service business owners/employees to the COVID-19 pandemic, with some seeing the crisis as enhancing, and others viewing it as debilitating. These findings improve our understanding of the role of mindsets in driving responses among businesses and their employees during crises.

The Effectiveness of a Probabilistic Loyalty Reward Program

Adrian Camilleri, University of Technology Sydney, Australia
Liyin Jin, Fudan University, China
Zhang Ying, Peking University, China

Based on lab and field experiments, this paper finds that a probabilistic loyalty reward program (e.g., "buy 9 get 1 free but also a 10% chance to get 1 free after each purchase") can be more motivating than a traditional loyalty reward program (e.g., "buy 6 get 1 free").

Think Like a Robot: How the Interaction with Humanoid Service Robots Affects Consumer Decision Strategy

Jiancai (Johnson) Liao, Aalto University School of Business, Finland

This research examines a novel effect and its mechanism that humanoid service robots cause a higher level of emotion deficit, which in turn increases reason-based consumption. Furthermore, this research offers boundary conditions of the effect such that the effect vanishes for high anthropomorphism tendency; reverses when the consumption is utilitarian.

Can Nostalgic Feelings Affect Sustainable Behaviors?

Ngan Vo, University of Manitoba, Canada
Raj Manchanda, University of Manitoba, Canada

Marketing plays an important role in understanding how to shift consumer behavior toward more sustainable actions. In the context of emotions, it has been suggested that both positive and negative emotions impact sustainable behaviors. We propose and find that nostalgia can drive sustainable choices via the construct of social connectedness.

It's Not Me, It's You: Awareness of Being Nudged Results in Oppositional Changes in Self-Perceptions

Cory Haltman, The Ohio State University, USA
Rebecca Reczek, The Ohio State University, USA
Cait Lamberton, University of Pennsylvania, USA

The growth in use of behavioral interventions, or nudges, has come with a parallel increase in consumer awareness of such tactics. Across four studies we demonstrate that awareness that one's behavior has been nudged causes a backfire effect, wherein individuals' self-perceptions shift in the opposite direction of the desired behavior.

Understanding Self-Presentation, Aesthetic Motives and Brands' Roles in Teenagers' Use of Instagram

Laurence Dubé-Beaudin, École des Sciences de la Gestion, Université du Québec à Montréal, Canada
Amélie Guèvremont, École des Sciences de la Gestion, Université du Québec à Montréal, Canada

This research studies self-presentation and brand identification among teenagers aged 14-17 on Instagram. Thirty individual interviews were conducted and revealed the importance of self-profile consistency among teenagers and the quest for beauty on this social network. Results also question the role of brands in teenagers' self-presentation.

A Look on the Bright Side: Understanding How Consumer Anonymity Fosters Trust and Satisfaction in Privacy-Enhancing Technologies

Maximilian Hartmann, Heinrich Heine University Düsseldorf, Germany
Alena Bermes, Heinrich Heine University Düsseldorf, Germany
Peter Kenning, Heinrich Heine University Düsseldorf, Germany

This research investigates the role of consumers' feelings of anonymity when using Privacy Enhancing Technologies (PET). Grounded in the Social Identity Model of Deindividuation Effects, the results show that consumer anonymity increases social identity and hence group conformity, which in turn positively influences consumers' trust and satisfaction toward PET.

Color Me Aroused while Keeping the Cool

Nadeesha Bandara, University of Massachusetts Amherst, USA
Elizabeth G. Miller, University of Massachusetts Amherst, USA
George R. Milne, University of Massachusetts Amherst, USA
Lauren Labrecque, University of Rhode Island, USA

Arousal drives a variety of consumer behaviors and colors, especially warm colors, can induce arousal. However, limited research explores ways colors can impact arousal beyond wavelength. In this research, we show that using multiple cool colors can increase arousal through visual complexity, leading to increased purchase intentions and brand excitement.

Increased Generosity Under COVID-19 Threat

Ariel Fridman, University of California, San Diego, USA
Rachel Gershon, University of California, San Diego, USA
Ayelet Gneezy, University of California, San Diego, USA

We study how the presence of threat, proxied by COVID-19 deaths in one's geographic location, affects generosity. A large dataset of real-world donations (N = 696,942), and a 6-month longitudinal dictator game study (N = 1,003 participants) show individuals exhibited greater generosity following COVID-19 deaths in their county.

The Impact of Option Presentation on Optimal Choice Identification: The Moderating Effect Of Childhood Ses

Yue Zhang, Peking University HSBC Business School, China
Jooyoung Park, Peking University HSBC Business School, China

We investigated the effects of interaction between childhood socioeconomic status (SES) and sequential versus simultaneous option presentation on consumers' optimal choice. Two studies show that individuals with low (vs. high) childhood SES are better at identifying the optimal option when the options are presented simultaneously rather than sequentially.

Being a Family in a Digital World: How Digitalization Affects Family Identity Negotiation Through Consumption

Mathilde Lapostolle, ESCP Business School, France
Julien Schmitt, ESCP Business School, France

The influence of digitalization on collective identities, particularly on family identity, is still poorly understood. Drawing on individual interviews, this article provides arguments in favor of a disruption, engendered by the digital revolution, of the way in which families construct, negotiate, and enact their identity through consumption.

The More Thoughtful You Are, The More Uncertain You Become: When a Probabilistic Uncertain Advice Leads to a Higher Evaluation.

Minjeong Ko, Seoul National University, Korea, Republic of

This research examines why people prefer probabilistic uncertain advice over certain advice for inherently uncertain decision domains and found perceived consideration of alternative outcomes as an explanation. Furthermore, the positive influence of probabilistic uncertain (vs. certain) advice on credibility holds only when there are few (vs. many) alternative outcomes.

The Status Signaling Function of Wasting Food

Evelynn Devos, Ghent University, Belgium
Daphne Ribbers, Ghent University, Belgium
Mario Pandelaere, Virginia Tech, USA
Anneleen Van Kerckhove, Ghent University, Belgium

While the consequences of wasting food are well-known on a large scale, it remains unclear what the social consequences are for the individual who wastes food. Results show that wasting—both cheap and expensive—food increases one's financial status, yet also decreases one's social status in the eyes of others.

Green Marketing: Are Influencers the Right Choice?

Satadruta Mookherjee, Grenoble Ecole de Management, France
Shabnam Nazari, Binghamton University, USA

In this research we were interested to examine their effectiveness of influencers for green marketing. We find that for the green products, posts featuring product was perceived more believable and was more effective in persuading consumers than the posts featuring a popular influencer who endorses green products.

How Big is That Voice? Vocal Features of Conversational AI Affects Physicality Perceptions and Product Congruency

Fotis Efthymiou, University of St Gallen, Switzerland
William Hampton, University of St. Gallen, Switzerland
Christian Hildebrand, University of St Gallen, Switzerland

This work examines that modifying a conversational agent's vocal tract length (VTL) causes changes in physicality and masculinity perceptions. We demonstrate that humans attribute greater physicality and masculinity to longer VTL agents and vice versa. We further show that longer (shorter) VTL promotes congruency perceptions with masculine (feminine) food products.

Moms and Memes: Using Social Media to Redefine the 'Good Mother'

Kristen Schiele, California State Polytechnic University, Pomona, USA
Steven Chen, California State University, Fullerton, USA
Christine Hu, California Polytechnic State University, USA

This paper explores the coping mechanisms utilized by mothers of young children in response to the challenges of the Covid-19 pandemic. Through analysis of memes shared in this community, we uncover how mothers use online spaces to cope and redefine what it means to be a 'good mother'.

Fluent in Emoji? Consumer Processing of Emojis vs. Text

Jacob Almaguer, University of Texas Rio Grande Valley, USA
Reto Felix, University of Texas Rio Grande Valley, USA

In an attempt to stand out amidst the text on social media, marketers have started using emoji only communication, with emojis as full substitutes for text. This research demonstrates that emoji only communication is harder to process, and this results in lower brand attitude, when compared to a textual translation.

Brands' Love-Hate Relationship with Hedonic Preference: A Meta-analysis and an Experiment

Mehdi Hossain, University of Rhode Island, USA
Adwait Khare, University of Texas at Arlington, USA
Traci Freling, University of Texas at Arlington, USA
Sultan Alkhuzam, King Saud University, Saudi Arabia
Tracy Khan, University of Rhode Island, USA
Ashok Lalwani, Kelley School of Business, Indiana University, USA

Prior research on hedonic consumption has focused on the role of numerous product-related and contextual factors that influence hedonic preference. Our meta-analysis of this literature reveals a new variable that influences hedonic-preference —brand. Specifically, when hedonicity is lacking in a context, brand can compensate for that lacking.

The Psychological Underpinnings of Toilet Paper Stockpiling During The COVID-19 Pandemic

Mehdi Hossain, University of Rhode Island, USA
Tracy Khan, University of Rhode Island, USA

Authors investigated the psychological underpinnings of panic buying of toilet paper and found that consumers' uncertainty avoidance, future anticipated regret, need for structure and lack of self-control impacted their purchase behavior through anxiety and sense of control. In addition, enhanced thoughtfulness and long-term orientation reduces panic buying.

The Effect of Money Priming on Variety Seeking- Activating the Concept of Money Increases Variety Seeking

Mehdi Hossain, University of Rhode Island, USA
Ashok Lalwani, Kelley School of Business, Indiana University, USA
Priscilla Pena, University of Rhode Island, USA

Our findings suggest that money priming increases variety seeking amongst consumers by inducing one's orientation to the long-term. Studies 1 and 2 provide evidence of money's effect on variety seeking and studies 3-8 explicate the underlying psychological process of LTO. These findings carry significant theoretical and practical implications.

Typefaces as Commodities: A Multimethodological Interpretative Phenomenological Approach to Understanding Font Consumption

Ruffin Relja, University of Gloucestershire, UK

Consumers form relationships with typefaces that are shaped by their degree of 'connoisseurship'. This is a new temporally dynamic (valence and strength) and multidimensional concept comprising five facets: Apprehending; involvement; hunting and gathering; knowing; and gatekeeping. Recommendations are made for market development and to support understanding font consumption more fully.

Does Donating Make Us Happy? The Role of Beneficiary Social Distance

Gopal Das, Indian Institute of Management Bangalore, India
Patrick van Esch, Auckland University of Technology, New Zealand
Shailendra Pratap Jain, University of Washington, USA

Extending prior work examining the impact of recognition from others on charitable behavior, our research shows that donating to socially distant (vs. close) beneficiaries makes donors feel happier. This effect occurs because donating to distant others results in an experience of greater benevolence.

Visual Entropy and Consumer Creative Success

Rong Huang, Saint Anselm College, USA
Weiling Ye, Shanghai University of Finance and Economics, China
Darren Dahl, University of British Columbia, Canada
Yuqian Chang, Rutgers University, USA

Our work demonstrates that visual entropy – a measure of information intensity and uncertainty within a closed microsystem – enhances individual creativity with five empirical studies. We apply novel methodologies by incorporating various creative materials, tasks, and evaluations (of visual entropy and creativity) approaches, including machine-learning-based text-mining and computer vision.

Gamification of Advertising: A Meta-analysis

Gunwoo Yoon, University of Northern Iowa, USA
Joonghwa Lee, University of North Dakota, USA
Carter Briggs, University of Northern Iowa, USA

Gamification of advertising has evolved into a digital marketing strategy. In this meta-analysis, we provide a comprehensive overview of this playful and engaging approach and quantify the effects of gamification on psychological and behavioral outcomes (*ds* > .21). Moderator analyses also suggest insight into the variation of the gamification effect.

Temporal Framing in Risk Communication and the Moderating Role of Message Receivers' Optimistic Bias

Sandra Praxmarer-Carus, Universität der Bundeswehr München, Germany
Marina Wieluch, Universität der Bundeswehr München, Germany

This research studies the moderating effect of comparative optimism on the effects of temporal frames included in behavioral recommendations (such as "start exercising this week" versus "this year") on compliance intention. In two studies, proximal temporal framing proved more effective than distal framing among comparative optimists but not among nonoptimists.

Matching A Brand's Appearance with its Description Can Restore Personal Control

M. Deniz Dalman, Graduate School of Management, Saint Petersburg State University, Russian Federation
Subimal Chatterjee, Binghamton University, USA

Consumers often feel the need to restore control through purchases. Across three studies, we show that consumers can restore their lost control by selecting a brand that looks *more (less)* like a human vs. object if we describe the brand in the first (third) person activating a human (object) schema.

How Sustainability Cues in Advertising Affect Consumer's Trust and Purchase Intention: Slow vs. Fast Fashion

Dominyka Venciute, ISM University of Management and Economics, Lithuania
Neringa Lukosiute, ISM University of Management and Economics, Lithuania
Marius Kuslys, ISM University of Management and Economics, Lithuania

As consumers become more aware and concerned about the environmental issues in the fashion industry, they begin to demand sustainable fashion. This study examines the impact sustainability cues in fashion advertising have on consumers' trust and purchase intention, and compares these cues in slow vs. fast fashion advertising.

Engagement in Interactive Social Media Campaigns: Joint Effects of Social Cause and Monetary Reward

Elizabeth Han, Georgia Tech, USA
Samuel Bond, Georgia Tech, USA
Han Zhang, Georgia Tech, USA

We study the effects of social cause and monetary rewards on consumers' participation in interactive social media campaigns, which ask consumers to create user-generated content (UGC) on behalf of a brand. Through two experiments, we unveil joint effects of social cause and monetary rewards and underlying mechanisms for the effects.

Agency of Objects in Shifting Time and Place

Yuko Minowa, Long Island University, USA
Russell Belk, York University, Canada

How do human-object power relationships change as they are enacted over time? What are different forms of human-object relationships at different temporal stages? Underpinned by Alfred Gell's (1988) theory of the art nexus and incorporating sociality, we propose a model, triadic relations of agency, to answer these research questions.

Product Display Fit: The Effect of Product Fit Between Retail Display and Product Positioning at the Time of Product Use on Consumer Preferences and Liking

Jennifer Sun, Columbia University, USA
Michel Pham, Columbia University, USA

The present research explores consumers' preference for product arrangements that reflect a fit between how the products are displayed in retail settings and the products' position at the time of use. A series of studies explore whether consumers naturally prefer certain product displays that exhibit such a fit.

Warm or Cold? The Effect of Visual Temperature on Food Choice

Yining Yu, Zhejiang University, China
Miaolei Jia, University of Warwick, UK
Bingjie Li, University of Warwick, UK
Shichao Wang, Hangzhou Normal University, China
Lei Wang, Zhejiang University, China

This research demonstrates that consumers have built the association between visual warmth (visual coldness) and unhealthy foods (healthy foods). As a result, consumers are more likely to choose healthy foods in restaurants with visually warm designs. The research contributes to the literature on visual temperature effects and food consumption.

Exploring Consumers' Discontinuous Self-Disclosure from a Transactional Stress Perspective – The Case of Social Networking Sites

Alena Bermes, Heinrich Heine University Düsseldorf, Germany
Maximilian Hartmann, Heinrich Heine University Düsseldorf, Germany
Christina Noffke, Heinrich Heine University Düsseldorf, Germany
Peter Kenning, Heinrich Heine University Düsseldorf, Germany

Based upon the stressor-strain-outcome framework, this study examines why consumers stop disclosing personal information by considering the case of social networking sites. The preliminary results show that disclosure-related stressors induce self-disclosure exhaustion, which results in discontinuous self-disclosure intention. An outlook on further research is provided.

Genuine or Performative? When Activism by Advantaged-Group Members Backfires

Edith Shalev, The Open University of Israel, Israel
Sarit Moldovan, The Open University of Israel, Israel

Influencers from advantaged groups (e.g. men, white people) may utilize social-media to support social causes of disadvantaged groups. While such support is usually admirable, sometimes it elicits negative emotions and harms the influencer's reputation. We find that advantaged group members' support backfires when it seems performative rather than authentic.

Keeping Tabs on Myself: Tracking as Self-Regulation in Financial Goal Attainment

Yiling Zhang, UW-Madison, USA
Nancy Wong, UW-Madison, USA

This research explores the role of expense tracking in controlling spending. Analyzing user data from a financial budgeting app shows that (a) tracking leads to better control in spending; (b) concrete goals lead to tracking over longer duration; and (c) budgeting by itself is not sufficient in attaining financial goals.

Anthropomorphism and Virtual Assistants' Mistakes: Who is to Blame?

Bianca Kato, University of Guelph, Canada
Juan Wang, University of Guelph, Canada
Jing Wan, University of Guelph, Canada

This research investigates whether anthropomorphizing a virtual assistant (VA) influences attribution of blame followed by a mistake. Our findings suggest that anthropomorphism decreases the likelihood of consumers blaming the VA as opposed to its developing company. We suggest that anthropomorphism increases empathy towards VAs, leading to the proposed main effect.

The Senses Help You Escape: The Evading Effect of Cross Sensory Products on Upward Social Comparison Under Brand Alliance

Yijun ZShao, Renmin University of China, China

This research defines the cross sensory product (CSP), which refers to the product with sensory attributes provided by co-brands in a brand alliance and suggests that engaging in upward social comparisons makes consumers feel self-threatened and further leads to need for sensory stimulation, which in turn makes them prefer CSP.

How Gamification Can Be Used to Help Consumers Reach Their Saving Goals

Nethal Hashim, City, University of London, UK
Irene Scopelliti, City, University of London, UK
Janina Steinmetz, City University of London, UK

We test the hypothesis that gamification can increase consumer saving behavior. In a field study (N = 331), consumers who logged their savings over a 4-week period in a gamified web app were more likely to reach their saving goal than consumers who used a non-gamified version of the app.

It Should Be Green, So It Should Be Healthy: The Effect of Green-associated Objects on Perceived Healthfulness of Foods

Sining Kou, Renmin University of China, China
Yijun zhao, Renmin University of China, China

This research demonstrates that consumers would perceive a food with green- (vs. non-green-) associated objects as healthier, and are more likely to purchase it under health-seeking motivation. This effect emerges because consumers associate specific objects (e.g., leave) with the color "green", and associate green with the concept "health".

Feeling the Weight of the World in Your Hands: Effect of Material Density on Consumer Recycling Behavior

Lyndsay Loomer, University of Georgia, USA
Sarah C. Whitley, University of Georgia, USA

What if the inputs to sustainable behavior are not just in a consumer's head, but also in their hands? This research explores the role of material density and its haptic qualities on a consumer's decision to recycle an object. Current manufacturer practices of material lightweighting lend urgency to this topic.

Snacking Behavior in Different Stages of the Family Life Cycle

Marina Cozac, Florida State University, USA
Martin Mende, Florida State University, USA
Maura Scott, Florida State University, USA

This research proposes a focus on how caregiving stress and gender influence consumption behavior. Specifically, this research examines the effects of parental status and gender on snack consumption and choices, and how stress drives the effects. Furthermore, we explore how food positioning impacts consumers' perceptions and snacking behavior.

Party Competition: When Democrats and Republicans are Motivated to Post Misinformation on Social Media?

Xiajing Zhu, University of California, Irvine, USA
Connie Pechmann, University of California, Irvine, USA

This paper investigates when people post misinformation online. By conducting two experiments, this research demonstrates that in a competitive (vs. cooperative) context, people especially Republicans have a higher intention to post anti-outgroup (vs. anti-ingroup) misinformation due to an affiliation motive. This research helps to understand the pervasive misinformation phenomenon online.

Does the Gender of Your Siri Really Matter? The Impact of Voice Control Device Gender on Product Evaluation.

Ksenia Sergueeva, Drexel University, USA
Chen Wang, Drexel University, USA

Three studies investigate *whether*, *how*, and *why* the gender of the voice control device influences consumer evaluation when it fails to comprehend. Results show that the male (vs. female) device is rated higher. Such effect is mediated by perceived comprehension ability of the device and moderated by the task expertise.

Consumers Believe that Others Like an Option Less When Those Others Express Indifference

Graham Overton, Bocconi University, Italy
Ioannis Evangelidis, ESADE, Universitat Ramon Llull, Spain

We show that consumers infer that others derive less utility from a preferred option and more utility from a non-preferred option when they express indifference between alternatives compared to when they express a preference.

Discouraging Effects of True Self on Acquisition

Lina Xu, New Mexico State University, USA
Yanfen You, University of Massachusetts Amherst, USA

"Be your true self" is a trendy slogan in today's marketing campaigns. However, this research suggests that promoting consumers' true selves can discourage their acquisition intentions for the advertised products. Three studies demonstrate the effect using vice/virtuous and experiential/material purchases.

The Impact of Social Distancing on Creativity

Kristen Ferguson, University of Connecticut, USA
Kelly B. Herd, University of Connecticut, USA
Stefan J. Hock, University of Connecticut, USA

While social distancing (i.e., spatial distance between individuals) is now being implemented to contain the spread of COVID-19, its impact on individuals' behaviors remains largely unexplored. Across three studies, we identify improved creativity as one beneficial outcome of social distancing.

Assessing the Relationship between Product Scarcity and Consumer Utility

Claudiu Dimofte, San Diego State University, USA

Consumers who are more resourceful are likely to find value (i.e., utility in a conjoint analysis design) associated with product scarcity if it is driven by excess demand, but not if driven by insufficient supply. The latter is universally unattractive, unless the market includes counterfeit products.

The Effect of Power Distance Belief on Consumers' Attitudes Toward Slum Tourism: The Mediating Role of Perceived Morality

Sohyun Bae, National Cheng Kung University, Taiwan
Xiaoyan (Jenny) Liu, Southwestern University of Finance and Economics, China
Piaoran Ren, Southwestern University of Finance and Economics, China

We examined how consumers' power distance belief (PDB) influences their attitudes toward slum tourism. In three studies, we found that consumers with high PDB have more positive attitudes toward slum tourism than ones with low PDB because they regard such tourism as less immoral.

I'll Do It – After One More Scroll: The Effects of Boredom Proneness, Self-Control, and Impulsivity on Online Procrastination

Cansu Sümer, University of Duisburg-Essen, Germany
Oliver Büttner, University of Duisburg-Essen, Germany

This paper aims to investigate whether boredom proneness, self-control, and impulsivity are related to using social media and instant messaging and visiting online stores for procrastinatory purposes. Results indicate that while boredom and age are predictive of all 3 procrastination types, results differ in terms of self-control and impulsivity.

Consumer War Machines: Explicating Dynamics of Resistance and Capture

Hunter Jones, Aalto University School of Business, Finland
Joel Hietanen, Helsinki University, Finland

This conceptual paper uses Deleuze and Guattari's 'War Machine' concept to analyze the recent r/WallStreetBets short squeeze. Pushing against popular depictions of consumer resistance which leverage a Foucauldian rubric of power, it articulates r/WallStreetBets through a rubric of desire.

Not as Mindful as You Think: A Multidisciplinary Review of the Conscious and Non-Conscious Processes of Mindfulness and Consumption

Letícia Vedolin Sebastião, Copenhagen Business School, Denmark
Torsten Ringberg, Copenhagen Business School, Denmark
Jesper Clement, Copenhagen Business School, Denmark

Mindfulness has been defined as an intentional, effortful, conscious practice. More recent literature, however, points to non-conscious processes, that have not been thoroughly considered. We review the mindfulness and consumption literature and provide an overview situating these contradictory assumptions based on conscious versus non-conscious processes and intended versus unintended outcomes.

The Price of Gaming: Currency Biases From Digital Virtual Products

Arthur França Sarcinelli, FGV EAESP, Brazil
Delane Botelho, FGV EAESP, Brazil

Price currency influences price fairness evaluations and the distance of the exchange rate moderates this relationship. Three laboratory experiments demonstrate that digital virtual product prices listed in fictional currency are perceived to be more fair than real currency, especially when the exchange rate do not appear next to the product.

How Explicit and Implicit Reliance on the "Unattractive produce = More Natural" Lay Theory Affects Consumer's Choice of Unattractive Produce

Yixin Niu, Zhongnan University of Economics and Law, Wuhan, China
Yaxuan Ran, Zhongnan University of Economics and Law, China
Jiani Liu, Zhongnan University of Economics and Law, China

We demonstrate that when people's implicit and explicit reliance on unattractive = more natural belief (UMNB) is incongruent, they form the highest choice of unattractive produce. This is because implicit-explicit incongruence spontaneously leads to deliberations, which further corrects for negative and bias of intuitive preference for beautiful and attractive produce.

Love at First Touch: How Swiping vs. Typing Changes Online Dating Decision-Making

Farhana Nusrat, Drexel University, USA
Yanliu Huang, Drexel University, USA
Cait Lamberton, University of Pennsylvania, USA

We examine how the use of different devices (smartphones vs. computers) influences customers' online dating decision-making process. In two studies, we show that when using their smartphones (vs. computers), customers give greater priority to the inner as opposed to external attributes of a potential dating partner.

What is Happiness? Word Embeddings Quantify Concept of Happiness Across 40 Years in China

Zhiqiang Li, Zhongnan University of Economics and Law, China
Yaxuan Ran, Zhongnan University of Economics and Law, China
Jiani Liu, Zhongnan University of Economics and Law, China

Using the news from People's Daily (1979~2020), we utilized the word embeddings technique to demonstrate how the relationship between "happiness" and its five dimensions (e.g., physical need) embeddings helps to quantify the concept of happiness in China and how the temporal dynamics of the embeddings capture societal shifts.

Understanding the role of companions in a circular healthcare

Ana Suárez Vázquez, University of Oviedo, Spain
Leticia Suárez Álvarez, University of Oviedo, Spain
Ana Belén Del Río Lanza, University of Oviedo, Spain
Víctor Iglesias Argüelles, University of Oviedo, Spain

Through a sample of 1,814 informants (companions and chronically-ill elderly patients) this research reinforces the relevance of the communication between companions and health professionals to improve the well-being of the elderly patient. The current health situation, with the absence of companions, has highlighted the vulnerability of these types of patients.

How Far Is Too Far? Consumers' Responses to LGBTQ-Inclusive Ads and the Role of Gender-Based Ad Congruency

Khue (Kylie) Vo, University of North Texas, USA
Priyali Rajagopal, University of North Texas, USA

How would consumers respond to gay women in beer commercials? We explore how gender congruence influences heterosexual versus LGBTQ consumers' responses to LGBTQ-inclusive ads. Two experiments reveal that heterosexual consumers do not dislike LGBTQ-inclusive imagery unless the gender is incongruent, while LGBTQ consumers are not influenced by such gender congruence

We're Not All in This Together: Consumers Dislike Empathy-based Advertisements During the COVID-19 Pandemic

Eric VanEpps, University of Utah, USA
Craig Brimhall, University of Utah, USA
Brad Bitterly, Hong Kong University of Science and Technology, Hong Kong

How should brands advertise during COVID-19? Across multiple studies, we examine consumer attitudes toward advertising during a global pandemic, COVID-19. We find that attempts at empathy ("we're all in this together") perform worse than attempts at humor, and the best strategy can be to not advertise at all.

Retailer Communications During the COVID-19 pandemic: An Analysis of the Localness Dimension

Amélie Guèvremont, École des Sciences de la Gestion, Université du Québec à Montréal, Canada
Fabien Durif, École des Sciences de la Gestion, Université du Québec à Montréal, Canada
Frédérick Joly, École des Sciences de la Gestion, Université du Québec à Montréal, Canada

This research examines the content of retailer communications aiming to promote local products during the pandemic. Three hundred thirty-eight visuals pertaining to 'buying local' were gathered through various communication channels across industries. Following a content analysis, the main dimensions of localness communication strategies during the pandemic were: social influence/information/emotions/habits.

The Crime of Wanting

Tianjiao Yu, Washington University in St. Louis, USA
Cynthia Cryder, Washington University in St. Louis, USA
Sydney Scott, Washington University in St Louis, USA

We find that when consumers strongly (versus weakly) want products, they are admired less. This "Crime of Wanting" occurs because people infer that a consumer who desires products has less willpower. When high willpower is signaled via other means, the effect dissipates.

Culture Comforts: The Cognitive Effects of Political Ideology on Cultural Consumption

Bryan Buechner, Xavier University, USA
Joshua Clarkson, University of Cincinnati, USA
Ashley Otto, Baylor University, USA
Garrett Ainsworth, University of Oxford, UK

Do consumers differ in their preferences to learn about their own versus other cultures via consumption? The present research proposes consumers' preferences for these discrete types of cultural knowledge vary by their political ideology. Evidence across four studies suggests liberals prefer global consumption experiences, whereas conservatives prefer local consumption experiences.

Creativity is in the Mind of the Beholder: The Role of Thinking Style

Ilgım Benoit, Appalachian State University, USA
Elizabeth G. Miller, University of Massachusetts Amherst, USA
Ceren Ekebas-Turedi, Purdue University Northwest, USA
Elika Kordrostami, Rowan University, USA

Creativity is often viewed as a subjective judgment that varies from person-to-person. However, little research has studied the impact of individual differences on creativity perception. Across three studies, we provide evidence that thinking style moderates perceived creativity such that analytic thinking leads to higher ad creativity perceptions than holistic thinking.

The Role of Managed Violence Within a Therapeutic Servicescape

Amanda Garrison, University of Wyoming, USA
Linda Price, University of Wyoming, USA

This study explores managed violence within a servicescape, providing a theoretical understanding of how servicescape elements facilitate extraordinary consumer experiences with therapeutic value. This research provides theoretical implications for how negative emotions are engaged and managed in therapeutic servicescapes, illustrating the unique, productive, therapeutic and transformative releases managed violence provokes.

I Want What You're Having, but Don't Look At Me: Human Presence in Food Images

Ronghan (Michelle) Wang, Cornell University, USA
Kathy LaTour, Cornell, USA
Suzanne Shu, Cornell, USA

How do consumers value food presented with a human presence (i.e., someone at the table)? Studies showed that consumers have higher food preferences, purchase intentions and willingness-to-pay for food items presented with a human presence, however this positive effect diminishes when that human makes direct eye contact with the audience.

Overinflated Expectations from Maximizing with Unreliable Information

Edward Yuhang Lai, Virginia Tech, USA
Mario Pandelaere, Virginia Tech, USA
Daniel Villanova, University of Arkansas, USA

Maximizers use various ways to strive for the best outcome, such as making selections from a larger assortment size. However, when information is unreliable (vs. reliable), a larger (vs. smaller) assortment size brings less satisfaction with one's choice because heightened expectations of outcomes lead to greater expectancy disconfirmations.

Try Together: Joint Consumption Fosters Choice of Unfamiliar Products

Puyue Zhang, Zhongnan University of Economics and Law, China
Yaxuan Ran, Zhongnan University of Economics and Law, Chna

Joint consumptions are pervasive in consumers' lives. Three experiments demonstrate that compared to individual consumption, joint consumption leads to higher choice of unfamiliar products. Based on the risk-shifting theory, we proposed joint context shifts or dilutes consumption risk. Additionally, relationship closeness would moderate this effect.

Did you really say that? An investigation of AIVAs' effects on consumer embarrassment

Laura Pricer, University of North Texas, USA
Priyali Rajagopal, University of North Texas, USA

The use of voice-enabled virtual assistants (e.g., Amazon Alexa) has become popular among consumers raising the question of how these devices affect consumers' emotions and choice. Results of four studies suggest that the human-like characteristics of AIVAs increase consumer embarrassment because of amplified perceptions of social presence.

Downward Mobility and Status Shielding: Tactics to Overcome Financial Struggles

Aya Aboelenien, HEC Montreal, Canada

During economic and political unrest, how do wealthy individuals manage their consumption? Through an investigation of wealthy Egyptians, post the Arab Spring, the paper show that individuals endeavor to protect their conspicuous distinction by any means. Ihighlight such means and the struggles faced to sustain their acquired capital.

Phonological Fluency: How Syllable Markedness of Brand Names Influences Consumers' Brand Attitudes

Ai Nhan Ngo, University of Texas Rio Grande Valley, USA
Reto Felix, University of Texas Rio Grande Valley, USA
Dan King, University of Texas Rio Grande Valley, USA

This research explores how syllable markedness of monosyllabic brand names influences consumers' brand attitudes. In two studies, we find the relationship is mediated through processing fluency and perceived brand globalness, and moderated by consumer's first language. However, these effects vary based on the position and numbers of the consonants.

Artificial Intelligence Powered Diagnosis Applications: Understanding Patients' Reactions to The Use of Artificial Intelligence During Their Patient Journey

Princesse El Ariss, Univ. Grenoble Alpes, Grenoble INP*, 38000 Grenoble France *Institut of Engineering and Management, France
Agnès Helme-Guizon, Univ. Grenoble Alpes, Grenoble INP*, CERAG, 38000 Grenoble France *Institut of Engineering and Management, France
Antoine Lanotte, Univ. Grenoble Alpes, Grenoble INP*, 38000 Grenoble France *Institut of Engineering and Management, France
Marjolaine Rivard, Univ. Grenoble Alpes, Grenoble INP*, 38000 Grenoble France *Institut of Engineering and Management, France
Arnaud Teston, Univ. Grenoble Alpes, Grenoble INP*, 38000 Grenoble France *Institut of Engineering and Management, France

AI-powered applications in medicine are promising but sometimes elicit reluctance. Data from eighteen interviews based on their patient journey showed that self-use scenarii induced a need for human confirmation while practitioner-use scenarii yielded a search for a balance between the app's and the practitioner's role in decision making.

How Common or Scientific Name Works? The Influence of Food Type and Message Framing on the Choice of Ingredient Name

Dickson Tok, Nanjing University, China
Xi Chen, Nanjing University, China
Chun-Tuan Chang, National Sun Yat-sen University, Taiwan
Xing-Yu (Marcos) Chu, Nanjing University, China

This research investigates the impacts of two strategies for presenting an ingredient on product evaluations: a common or a scientific name. Three studies, including lab and field experiments, demonstrate the effect of ingredient name on the boundary conditions of food type and message framing, providing important insights to marketers.

Consumers' Perspectives On AI Ethics and Trust: An Explorative Investigation of Ethical Concerns Towards Autonomous Cars and Chatbots

Giulia Pavone, Toulouse School of Management Research, France

We investigate consumers' ethical concerns and trust towards autonomous cars and chatbots employing topic modeling and SEM. To increase trust, chatbots, perceived as unethical because unable to truly understand individual needs, should guarantee personalized interactions; autonomous cars, perceived as unethical if their algorithms are not standardized, should follow common rules.

Feeling Well Surrounded: How Body Shape Mobility Influences Self-control

Gitta van den Enden, as, Netherlands
Kelly Geyskens, Maastricht University, Netherlands
Caroline Goukens, Maastricht University, Netherlands

This research investigates the impact of body shape mobility (i.e. the belief that available means enable oneself to reach a goal) on the attainment of long-term goals. We show in three studies that body shape mobility perceptions positively influence self-control and that this effect is mediated by goal attainability.

Harder, Better, Faster, Stronger: The Adoption and Use of AI-based mHealth Applications

Vincent Favarin, TSM-Research, Université Toulouse Capitole, CNRS, France
Lars Meyer-Waarden, TSM-Research, Université Toulouse Capitole, CNRS, France
Julien Cloarec, IAE Lyon School of Management, Université de Lyon, France

Although mHealth applications help improve their users' well-being, obstacles still hamper their adoption and use. Based on automated text analysis and structural equation modeling, two mixed-methods studies (nAdoption = 145; nUse = 3,496) highlight the key roles of personalization and quantified-self in consumer experience of mHealth applications.

Can Sad Content Be Viral? A Reinvestigation of The Role of Emotion in the Sharing of Online Content

Julie Schiro, University College Dublin, Ireland
Lauren Min, University of Kansas, USA

Across a field study of over 100,000 Facebook posts and three experiments, we find that sad *prosocial* content can be more viral than other types of emotional content, including humorous content (positively valenced) and angering content (high arousal), in direct opposition to prior work.

Augmenting Self-extension Theory for the Internet of Things: Scale Development and validation

Min Yan, Newcastle University, UK
Raffaele Filieri, Audencia Business School, France
Matthew Gorton, Newcastle University, UK

This study reviews previous self-extension studies and integrates assemblage theory to develop an augmented conceptualization of self-extension. Through an analysis of interview data, self-extension is conceptualized as possessing five dimensions. This informed a scale development process and the paper presents and validates a new multi-dimensional self-extension scale.

Consumer-Artificial Intelligence Regimes of Interactions: A Sociosemiotics Perspective

Vitor M. Lima, Audencia Business School, France
Luís Pessôa, Pontifical Catholic University of Rio de Janeiro, PUC-Rio, Brazil

By drawing on Eric Landowski's sociosemiotics, we present distinct regimes of consumer-AI interactions. For the AI agentic capacity, rather than a position of mastering, serving, and partnering, consumers experience an ongoing symbiotic regime of adjustment in interacting with AI. Borrowing a term from biology, such a relationship is named *Mutualism*.

How to Polarize Items Evaluation With Different Ranking List Display Modes?

Shen Duan, Renmin University of China, China

We find that consumers have a greater evaluation polarization effect on items in the vertical ranking list than horizontal ranking list, the effect was driven by the difference in the perception of items. In addition, we found that attribute evaluability is the boundary condition for this effect.

"Relative Discount" Or "Absolute Discount"? The Effect of Matching Effect Between Discount Type And Purchase Type on Consumer Preference

Shen Duan, Ex Ordo, China

This study explores the relationship between purchase types and discount types. We find that consumers who are in the material purchases, will prefer absolute discount promotion, while in the experiential purchases, they will prefer relative discount promotion. We also demonstrate the boundary condition of this effect is the evaluation modes.

Domestic Currency vs. Foreign Currency? Research on the Influence of Currency Type on Price Quality Judgment

Shen Duan, Renmin University of China, China

We propose that consumers have a higher tendency to judge the quality of individual price under foreign currency cues than under domestic currency cues; Individual structural needs play a mediating role in the above relationships and the conversion task is the boundary condition of the effect.

A Meta-Analysis on the Effects of Anthropomorphism on Consumer Behavior

Zaichen Li, Bayes Business School (formerly Cass), City, University of London, UK
Irene Scopelliti, Bayes Business School (formerly Cass), City, University of London, UK
Janina Steinmetz, Bayes Business School (formerly Cass), City, University of London, UK

Anthropomorphizing products or brands affects consumer responses toward these targets. To manipulate anthropomorphism, researchers use visual cues of humanlike features, verbal cues of a humanlike mind, or a combination of these. In a meta-analysis, we compare these approaches and observe that verbal cues are most effective at influencing consumer behavior.

Privacy Consumer Activists on Reddit: Exploring Discourse, Sentiment, and Advocated Practices

Alec Slepchuk, University of Massachusetts Amherst, USA
Francisco Villarroel Ordenes, LUISS University, Italy
George R. Milne, University of Massachusetts Amherst, USA

New technologies are changing the conversation around privacy, upsetting consumers, and empowering activism. Yet, little is known about privacy consumer activists. In this research, we examine their marketplace culture by analyzing over 100,000 Reddit comments. We contribute to the literature by identifying what they are discussing, feeling, and advocating.

Identifying and Managing Ruminative Expressions in Negative Reviews

Hai-Anh Tran, Aston University, UK
Yuliya Strizhakova, Rutgers University–Camden, USA
Samuel Johnson, University of Warwick, UK
Lanh Nguyen, Illinois Institute of Technology, USA

We use text mining techniques to detect expressions of *rumination*—repeated negative thoughts—in online reviews. Using topic modeling and sentiment analysis, we demonstrate that three independent dimensions of rumination have separate negative impacts on sales. Management responses expressing empathy and offering compensation decrease these negative impacts.

"The Vegan Generation": Investigating Vegan Consumers' Responses Toward False Advertising on Social Media

Yong Whi Greg Song, University of Texas at Austin, USA
Natalie Brown-Devlin, University of Texas at Austin, USA
Won-Ki Moon, University of Texas at Austin, USA

We conducted an experimental study with vegan and vegetarian populations—consumer groups that are becoming more prevalent yet are understudied. We specifically examined how consumers respond differently to false advertising on social media, whether the advertising advocates vegetarianism or meat-eating, as well as the effects of social media's fact-check function.

Exposure to Xenophobic Claims Leads Asians to Prefer Self-identity Products and Non-Asians to Adopt Cybersecurity Products

Trang Mai-McManus, University of Manitoba, Canada
Jessie Du, Baruch College, CUNY, USA
Linh Nguyen, Université de Lille, France
Shweta Jha, Indian Institute of Management, Indore, India
Yu Ding, Columbia University, USA

In this research, we demonstrate that identity threatened group and threat-observing group react differently after exposure to the same xenophobic claim. The threatened group will try to restore their identity, while the threat-observing group will set up higher bars for security. The proposed mechanism is self-protection tendency.

You Want Me to Put That Where? An Intimate Exploration of Consumer Adoption of Reusable Menstrual Products

Mycah Harrold, Washington State University, USA
Aimee Dinnin Huff, Oregon State University, USA
Anabella Donnadieu, Washington State University, USA

We seek to identify consumer and product factors that facilitate or impede adoption of reusable menstrual products, such as menstrual cups and washable pads. Within this intimate consumption context, we contribute a nuanced, embodied understanding of reusable menstrual product consumption, and identify links between product features and social acceptability.

Heal Your Soul: Intimacy Value of Indulgent Foods

Shih-Chun (Daniel) Chin, University of Illinois at Urbana Champaign, USA
Aric Rindfleisch, University of Illinois at Urbana-Champaign, USA

Although indulgent foods are unhealthy, they can bring positive affective values. In two studies, we demonstrate that consumers associate indulgent foods with intimate relationships, thereby drawing intimate feelings from consuming indulgent foods. As such, consumers prefer these foods more when feeling threats to their close relationships.

Transforming Homo Mechanicus into Homo Ludens: Assembling Playfulness for Self-Care

Marat Bakpayev, University of Minnesota Duluth, USA
Anna Margulis, Universite du Quebec en Outaouais, Canada
Olga Podolska, Access Multi-Specialty Medical Clinic, USA

Contextualizing assemblage theory, this study explores how individuals engage in ludic aspects of virtual communities. A netnographic study of a natural online self-care quest reveals transformations within the community, the individuals, and the discourse. Each level goes through a four-stage stabilization process of ignition, connection, discovery, and strength.

Contagious Disease Threat Can Reduce Healthy Behaviors

Felipe M. Affonso, University of Florida, New Zealand
Juliano Laran, University of Basel, Switzerland
Chris Janiszewski, University of Florida, New Zealand

Consumers are often under contagious disease threat. Although healthy behaviors prevent the risk of many diseases, we show that, ironically, the threat of a contagious disease reduces engagement in healthy behaviors. We propose this happens because the risk associated with getting a contagious disease makes other health-related risks less salient.

Whose Values Come Out on Top When Making Decisions for End of Life?

Daniel Lewin, University of Liverpool, UK

Patients' values and beliefs are important in making decisions for their end of life. In care planning discussions, whose values come to the fore and whose are secondary? This study sought to identify how to help patients' values to be acknowledged while still receiving needed guidance in decision making.

Current Preference from Early Life Experience: The Impact of Childhood SES on Variety-Seeking

Jungkeun Kim, Auckland University of Technology, New Zealand
Jooyoung Park, Peking University HSBC Business School, China
Jihoon Jhang, University of Central Arkansas, USA
Jaehoon Lee, Florida International University, USA
Daniel Chaein Lee, Auckland University of Technology, New Zealand

While prior research on variety-seeking focuses on *current* individual or situational factors, little is known about how *past* life experiences influence variety-seeking. Variety-seeking was stronger for higher-SES childhoods. This effect disappeared when the decision was made for others (vs. themselves) and within the same brand (vs. across different brands).

Robo-Journalism: Less Biased, and More Likely to Be Shared

Jimin Nam, Harvard Business School, USA
Michael Norton, Harvard Business School, USA
Adam Waytz, Kellogg School of Management, Northwestern University, USA

"Robot journalism" – AI-generated news stories – is on the rise. Four studies show that Democrats and Republicans view robot-written stories as less biased than stories by columnists of opposing political parties and are more likely to share them with opposing party members. Robot-written articles may reduce selective news exposure.

Self and Socially-Focused Individuals: Intrinsic Motivation and Self-Construal Influence Neural Mechanisms Associated with Persuasion

Arina Tveleneva, University of Washington, USA
Matt Minich, University of Wisconsin-Madison, USA
Chen-Ting Chang, University of Wisconsin-Madison, USA
Christopher Cascio, University of Wisconsin-Madison, USA

The current study explores how different types of self-perceptions (self versus socially-focused individuals) influence neural processes associated with persuasion. Results suggest that individuals with autonomy-based intrinsic motivation, independent, and interdependent self-construal employ different neural regions when processing information. These findings highlight how differences in self-view can alter persuasive information processing.

Discount First or Last?: Discount Framing and Intertemporal Preference for Periodic Payments

Mijin Kwon, Korea University, Korea, Republic of
Song Oh Yoon, Korea University, Korea, Republic of

Should marketers place a discount in the first or last month? Despite the human nature to desire immediate rewards, framing discounts and regular payments as one flow (vs. discrete events) will make consumers prefer improving sequence and hence delayed discounts to immediate ones.

Differences between Consumers' Sense of Community and Brand Attitudes against Different Brand Rejection Types

Mehmet Yanit, University of Manitoba, Canada
Wendy Yan, Futurpreneur, Canada
Fang Wan, University of Manitoba, Canada

When marketers select a target market, they are implicitly rejecting consumers who are not in the target market. Prior research examined individuals' negative reactions to brand rejection. Extending this scope from individual to community perspectives, we examine how brand rejection shapes consumers' sense of community and, in turn brand attitudes.

Construing in Purchases: The Effect of Purchase Type on Level of Construal

Yu Gu, Tsinghua University, China
Rong Chen, Tsinghua University, China

The different cognitive outcomes of thinking about experiential purchases and material purchases received rare attention in extant literature. Through six studies, this research demonstrates that thinking about experiential purchases evokes a higher construal level than thinking about material purchases. Analytical and affective processing modes mediate this effect.

The Role of Perceived Movement in Digital Brand Recovery Efforts

Laura Boman, Mercer University, USA
Lam An, University of Winnipeg, Canada
Ganga Hewage, Bryant University, USA
Jonathan Hasford, University of Tennessee, USA

Across one real choice and two lab studies, the current research shows that brand failure recovery strategies in digital media including low (versus high) perceived movement visual messaging cues lead to more favorable consumer outcomes. This effect is mediated by perceived stability of the firm.

Sensing Privacy: A Consumer Culture Theory Perspective

Johanna Horppu, Tampere University, Finland

This conceptual paper proposes new perspectives for studying privacy within consumer research and highlights the potential in a more interpretive and relational approach to studying the concept. This approach can help reveal the more diverse, fluid, and affective nature of privacy that better corresponds the reality of the always-connected consumers.

Unpackaging for Mac and Packaging for iPhone: The Interactive Effect of Product Presentation and Purchase Device on Food Choice

Meng Lu, Renmin University of China, China
Jun Pang, Renmin University of China, China
Yuwei Jiang, Hong Kong Polytechnic University, Hong Kong

Packaging has been referred to as the "silent salesman". This research suggests that, consumers are more likely to choose the brand presenting packaged cookies when they use direct-interaction devices (e.g., cellphone).than indirect-interaction devices (e.g., PC) , which is continuously driven by perception of contagion.

Your Money or Your Life: The Role of Message Framing in Reducing Smoking Behavior

Nurit Nobel, Stockholm School of Economics, Sweden

This study explores the efficacy of two types of framings of smoking cessation consequences: appeal type (Time/Money) and valence (Gain/Loss). A randomized controlled field experiment with 2,935 participants conducted via a digital therapeutics app found effects for both framings on short-term cigarette reduction but no long-term difference in smoking cessation.

Moral Justifications of Food Waste: Students in a University Cafeteria

Selin Özokcu, Middle East Technical University, Turkey
Eminegül Karababa, Middle East Technical University, Turkey

The topic of waste interlocks the climate crisis and consumption debates, yet understanding food waste is unattended. This study explores how students morally justify their food waste practices at the university cafeteria in Turkey. While it integrates consumption and food waste literature, it provides novel insights by employing pragmatic sociology.

The Effect of Default Design in a Multi-dimensional Rating System

Peiliang Sun, Harbin Institute of Technology, China
Jill Lei, The University of Melbourne, Australia

In a multi-dimensional rating system, a default design enters a consumer's overall rating as the default value of attribute ratings. Using both field and lab data, we found that a default (vs. non-default) design increases rating variance across different attributes but decreases the average volume of attribute ratings being submitted.

The Self Under COVID-19: Social Role Disruptions Undermine Self-Authenticity

Jingshi Liu, City, University of London, UK
Amy Dalton, Hong Kong University of Science & Technology, Hong Kong
Jeremy Lee, Hong Kong University of Science and Technology, Hong Kong

COVID-19 significantly impacts consumers' social roles and routines. We find that changes in important roles undermine consumers' self-authenticity, but this is mitigated when focusing on the present (vs. past/future). This has implications for healthcare messaging, which should encourage present-focused thinking to cope with role changes.

Wonderful or Scary? Consumers' Reactions to More or Less Human-Like Virtual Models

Claudia Franke, Saarland University, Germany
Andrea Groeppel-Klein, Saarland University, Germany
Julian Dincher, Saarland University, Germany
Annika Ecker, Saarland University, Germany

Virtual models, fictive computer-generated personalities found their way into brand communication. Using three studies, we analyze consumers' reactions towards this new phenomenon and find that disclosing about the virtuality of the model, a human-like instead of cartoon-like design and the use of backstories can reduce virtual model uncanniness.

Should I Help You or Should I Not? The Role of Social Comparison on Helping Behavior Among Consumers

Renata Martins, FGV EAESP, Brazil
Lucia Barros, Fun, Brazil
Felipe Zambaldi, FGV EAESP, Brazil

We are the first to investigate the effect of social comparison on helping behavior among consumers. Those who feel better than others help more due to self-enhancement. However, consumers who feel better (worse) off tend to make more (less) effort helping those whom they see (do not see) as similar.

When People Are More Favorable Toward "White-Collar" AI: Self-Protection Motivation Mitigates Consumers' Aversion to Artificial Intelligence in Professional Domains

Haejoo Han, Seoul National University, Korea, Republic of
Sujin Park, Seoul National University, Korea, Republic of
Kyoungmi Lee, Seoul National University, Korea, Republic of

Across two studies, we find that consumers are more averse to artificial intelligence (AI) in professional versus nonprofessional domains. Such aversion to AI can be attenuated when people feel vulnerable and heightened in self-protection motivation, presumably because people rely on competent entities.

Development and Validation of a Multidimensional Product Perceived Newness Scale

Claire-Lise Ackermann, Rennes School of Business, France
Blandine Hetet, IDRAC, France
Imene Belboula, Universite Lounici Ali, Blida 2, Algeria

This research builds on consumption value taxonomies to suggest that there are four dimensions of Product Perceived Newness: functional, emotional, social and epistemic. This working paper details an ongoing research project aiming to develop a scale that incorporates these four dimensions. Initial results provide support for structural and nomological validity.

Location of Color on Package and Benefits Perception: A Regulatory Focus Perspective

Mitsuru Kaneko, Kyoto Women's University, Japan

We examined how the location of color on package affects consumers' benefit perception. Three experiments show that while prevention benefit is perceived more when the color is on the top, promotion benefit is not perceived irrespective of the location.

Psychological Ownership and Control in Virtual Retail Experiences

Ezgi Merdin Uygur, Kadir Has University, Turkey
Gulen Sarial-Abi, Copenhagen Business School, Denmark

During the Covid19-pandemic, the imposed physical distance facilitated the emergence of virtual experiences. In order to resolve the conflicting previous findings suggesting disrupted vs. increased psychological ownership (PO) for digitals or intangibles; we analyze attitude, control, PO, WOM and visit intentions data collected from real and virtual retail store visitors.

The Shape of Crowding: The Impact of Social Crowding on Shape Preference

Ruiqin Li, Renmin Business School, Renmin University of China, China

The present research suggests that social crowding induces need for belongingness, and then increases preference for circular shapes. Moreover, the effect of social crowding on preference for circular shape only occurs when individuals think high of belongingness and when the component of crowding is outer group.

Circular Shapes with Life: The Impact of Nostalgia on Shape Preference

Ruiqin Li, Renmin Business School, Renmin University of China, China

People have the lay belief that circular shapes are associated with vitality. When people feel nostalgic, the need for connectedness and competence can be satisfied, which can improve sense of vitality. According to self-congruence theory, people full of vitality prefer objects full of vigor and vitality, that is circular shapes.

Sectorial Brands as a Legitimation Tool for Emerging Market Firm's Internationalization: The Case of 'Din Inimă' Umbrella Brand in Moldova

Zahra Sharifonnasabi, Queen Mary University of London, UK
Mirela Barbu, University of Sussex, UK

We examine how sectorial brands facilitate legitimation of emerging market firms aiming to internationalise. Using a longitudinal case of '*Din Inimă*', a sectorial fashion brand in Moldova, we identified three brand-mediated legitimation mechanisms: *material* (expanding international networks), *rhetorical* (selective framing to reposition understandings of Moldovan producers), and *symbolic collectivity* (community).

Sexual Orientation Moderates the Relationship between Digit Ratios (a proxy for prenatal testosterone exposure) and Risk-Taking Propensity

Fabiane Cavalcante, State University of Ceará, Brazil
Danielle Gomes, State University of Ceará, Brazil
Samuel Câmara, State University of Ceará, Brazil
Lilian Carvalho, FGV EAESP, Brazil
Delane Botelho, FGV EAESP, Brazil

Exposure to prenatal testosterone might influence consumer risk propensity. However, previous results on the relationship between digit ratios (a proxy for prenatal testosterone exposure) and risk-taking have been mixed. The results suggest that sexual orientation (declared by the participants) moderates that relationship, consequently future research should account for sexual orientation.

Consumers, Short videos, and the Growing "Consumer Sphere" in China

Zizheng Yu, Cardiff University, UK

Bringing together the literature on the public sphere and focusing on how Chinese consumers deploy short video technologies to make appeals, this article elaborates on a "consumer sphere" model in China, which more comprehensively explains the interactions between businesses, media and government departments within the short video activism tactic.

Empowering Victims Through Choice: The Impact of Being Chosen on Consumer Charitable Support

Zuzanna Jurewicz, Ivey Business School, Western University, Canada
Kirk Kristofferson, Ivey Business School, Western University, Canada

We examine responses to an emerging strategic change in charitable marketing: victim empowerment. Across multiple charitable relationship contexts, we find that being chosen by (vs. choosing) a victim has opposing psychological effects on donors: it increases perceived relationship quality but decreases free will, which increases/decreases program support and long-term commitment.

The Impact of Color on Consumer Perceptions of Product Efficacy

Lauren Labrecque, University of Rhode Island, USA
Christy Ashley, University of Rhode Island, USA
Stefanie Sohn, University of Southern Denmark, Denmark
Barbara Seegebarth, Technische Universität Braunschweig, Germany

Color can communicate important marketing elements such as brand personality, healthiness, flavor, scent, and size. But can color communicate efficacy (i.e., how well the product works)? We explore this important question in this research through three experiments and find that color can impact consumers' perceptions of a product's efficacy.

The Influence of Reward Framing on Food Choices

Luxi Chai, Missouri Southern State University, USA
Marija Grishin, University College Dublin, Ireland

The current research examines the impact of gratification-enhancing framing on healthy food-related decision making by demonstrating that after completing a self-control depleting task, framing the healthy (vs. unhealthy) food option as a reward increases the rewarding feeling and purchase intention.

Simulating Self-Improvement: Need for Cognitive Closure Shapes Preference for Process- and Outcome-Focused Products

Alberto Barchetti, University of Cincinnati, USA
Joshua Clarkson, University of Cincinnati, USA
Ashley Otto, Baylor University, USA

Two experiments show that consumers seeking closure prefer self-improvement products with an outcome (vs. process) focus. This effect is driven by a heightened sense of immediacy in goal attainment and reverses when attainment is unlikely. These findings offer insight into antecedents of self-improvement preferences and the strategic nature of closure.

Exploring the Influencing Factors of Consumers' Willingness to Consume Aging Produce with a Focus on Health and Safety Perception

Christina Neubig, Technical University of Munich, Germany
Jutta Roosen, Technical University of Munich, Germany

This study investigates what factors increase or decrease willingness to consume aging produce. Results show that providing information on healthfulness or safety and the resulting health and safety perception increase willingness to consume; while food disgust sensitivity, reliance in expiration dates, and food waste propensity decrease willingness to consume.

Trickle Down Spending: Relative Income Effects on Consumer Spending in Social Relationships

Max Alberhasky, University of Texas at Austin, USA
Andrew Gershoff, University of Texas at Austin, USA

Income disparity is known to influence economic, health, educational, and psychological outcomes. Yet little is known about how it affects consumer decisions. Five studies show that people spend more on purchases for those who earn less, even when controlling for absolute income. This is driven by feelings of situational sympathy.

To Reward or to Cheer Up: Self-Gift Motivations Change Preferred Gift Types Through Construal-Level

Sujin Park, Seoul National University, Korea, Republic of
Kyoungmi Lee, Seoul National University, Korea, Republic of

This research suggests that the self-gift motivation for rewarding one's achievements activates a low-level construal with vivid mental imagery, resulting in preferences for material self-gift. In contrast, the self-gift motivation for cheering the self up from depressing situations activates a high-level construal, leading to the preferences for experiential self-gift.

Perception, Assemblage and Consumption of Light; A Step Through Consumer-Produced Domestic Atmospheres

Eminegül Karababa, Middle East Technical University, Turkey
Utku Ay, University of Arizona, USA

This study explores how consumers perceive, assemble, and implement light, deliberately or unconsciously, that lead a pathway towards consumer-produced atmospheres in domestic environments. Consumers actively utilize light through domestic practices, constituting layered structures based on networks, involving multiple material and immaterial elements; experiences, emotions, aesthetic reflections, people, objects, and spaces.

Consumers Prefer Complex Algorithms

Zarema Khon, University of Bath, UK
Samuel Johnson, University of Warwick, UK
Haiming Hang, University of Bath, UK
Stephanie Chen, London Business School, UK

Two studies (*N*=195) test a novel factor that drives consumers' adoption of algorithms— complexity. The results showed that consumers generally prefer more complex algorithms to simple ones. The effect is especially pronounced when complex algorithms are used for doing inherently complex tasks, or when the tasks are considered more objective.

A Group of Crying Victims Deserve More Money? Effects of Victim Image, Facial Expression and Victim Identifiability in Charity Advertising

Hsiao-Ching Lee, National Kaohsiung University of Science and Technology, Taiwan
Chun-Tuan Chang, National Sun Yat-sen University, Taiwan
Chia-Han Chang, National Sun Yat-sen University, Taiwan
Jia-Ling Li, Liudui Hakka Cultural Park, Taiwan

We examine how victim image and facial expression in charity advertising affect people' giving behavior. Experiments show that multiple happy-faced victims or one single sad- faced victim increases giving behaviors. Entitativity enhances the effects of happy-faced victims. Victim identifiability reduces the interactive effect of victim image and facial expression.

Showing Dual Concern: The World Needs to Learn How to Criticize with Care

Katie Mercurio, California State University, Chico, USA
Nathan B. Warren, BI Norwegian Business School, Norway
Troy H. Campbell, Chief Scientist at On Your Feet, USA
Lauren C. Howe, University of Zurich, Switzerland
Steven Shepherd, Oklahoma State University, USA

This work introduces dual-concern messaging, which communicates that a target group causes harm while expressing concern for the target group. Five studies show that dual concern reduces the inference that a messenger lacks moral concern for the criticized group and improves criticism acceptance and purchase intentions among the target group.

When the Breadwinner is Locked at Home: Interaction of Domesticity and Masculine Identity

Tanvi Gupta, Assistant Professor of Marketing, Indian Institute of Management Udaipur, India
Vidushi Trivedi, Doctoral Student of Marketing, Indian Institute of Management Udaipur, India
Rupali Kapoor, Research Officer, Indian Institute of Management Udaipur, India

Through a qualitative study, this research explores gender performativity of the breadwinner identity among Indian men, forced to experience domesticity during the pandemic. By applying the concepts of emotional labor and dramaturgy, it finds that male consumers cope with domesticity by symbolic means of appropriation and re-interpretation of their home.

Receptive to the Past: Nostalgia Increases Acceptance of Ugly Food

Yi (Fionna) Xie, Xiamen University, China
Yanfen You, University of Massachusetts Amherst, USA

We propose that nostalgia can facilitate consumer acceptance of ugly foods via enhanced consumer tolerance. We show that nostalgic consumers are more likely to purchase ugly vegetables and fruits, buy snacks made from ugly foods, and are more willing to participate in and share information about an ugly food campaign.

The Impact of Childhood Socioeconomic Status on Risk Preferences in Domains of Loss and Gain

Huizhong Li, Peking University, China
Chenhan Ruan, Fujian Agriculture and Forestry University, China

In this paper, we explored the relationship between childhood socioeconomic status on risk preferences based on inconsistent evidence in previous research. By three studies including second-hand data analysis and experiment studies, it is shown that ones from different childhood SES show different risk preferences in domains of loss and gain.

Economic Inequality Increases Education Spending

Jinyan Xiang, Virginia Tech, USA
Mario Pandelaere, Virginia Tech, USA

Across three experiments, we find that economic inequality increases education spending, because consumers perceive a greater income premium of better education in more unequal societies. This research contributes to literature on economic inequality and education and provides insights to education marketers.

Financial Well-Being for Low-Income Populations in Developing Countries

Luiz Cruz Neto, State University of Ceará, Brazil
Caio Victor, State University of Ceará, Brazil
Verónica Peñaloza, State University of Ceará, Brazil

This research seeks to detect the components of financial well-being (FWB) in the low-income consumers of developing countries. An exploratory study was carried out with qualitative and quantitative aspects. The result showed that the FWB dimensions of the low-income consumer with the consumers in developed countries has some differences.

The Transparency Paradox: Asking for Personal Information Increases Consumers' Value of It

Kyle Murray, University of Alberta, Canada
Tim Derksen, University of Alberta, Canada

In this research we explore how consumers value their private information. We find that simply being asked for personal data increases the perceived value of that information. Underlying this effect is a negative emotional response to the request. The impacts of information bundling and the data breaches are also examined.

How Digital Influencers' Techniques Can Improve Direct Selling Performance

Jordan Rizetto, FGV EAESP, Brazil
Benjamin Rosenthal, FGV EAESP, Brazil

This research aims to understand how direct selling representatives (DSR) can use social media to improve sales. Specifically, this research adopts a mixed-methods approach to investigate how DSR in the field of wellness products uses digital influencers' techniques to enhance the relationship with customers, improve sales, and build brand reputation.

Exploring an Incongruence Frame for Online Reviews

Praveen Sugathan, Indian Institute of Management Kozhikode, India
Subin Sudhir, Indian Institute of Management, Indore, India

Online reviews often include a combination of informational cues such as numeric (i.e., star) ratings and qualitative text. In an effort to understand conflicting informational cues, this research conceptualizes and tests an incongruence frame. Across five studies the incongruence effect is shown to undermine review usage.

75 Years of Internal Reference Price Research: A Review, Calibration of Taxonomy and Classification Framework

Isabel Son, Leiden University, Netherlands
Jean Pierre van der Rest, Leiden University, Netherlands

This paper presents a semi-systematic review of 75 years of operationalization in (internal) reference price research. Conceptual problems in terminology are addressed and a taxonomy of the core constructs is developed. Lowengart's (2002) classification framework is expanded to include six categories, covering three time-intervals, discerning 12 different price cue clusters.

Make It Sporty: Conceptualization, Measurement and Consumer- and Brand -Related Effects of Perceived Sportivity

Reynald Brion, Kedge Business School, France
Renaud Lunardo, Kedge Business School, France
Jean-Francois Trinquecoste, Université de Bordeaux, France

Through six qualitative and quantitative studies, we refine the concept and develop a measure of perceived sportivity. Results show that perceived sportivity is a reflexive second order construct composed of three dimensions – physicality, commerciality, and equipment– that has broad effects on consumer engagement and behaviour.

What Goes Around Comes Around: Belief in Karma Predicts Ethical Consumption

Summer Kim, University of Kansas, USA
Jessica Li, University of Kansas, USA

Consumers with higher beliefs in karma are more likely to engage in ethical consumption by supporting ethical brands and rejecting unethical brands. This link is partly explained by a belief that the unethical brand's immorality transfers to consumers who support the unethical brand.

Cashbacks: Buying More or Less?

Shweta Jha, Indian Institute of Management, Indore, India
Sanjeev Tripathi, Indian Institute of Management, Indore, India

While prior research on cashbacks highlighted its benefits, this study investigates the cost of offering cashbacks. We find that in certain conditions, cashbacks can negatively affect retailers as they lead to consumers reducing the ticket size of the transactions.

Impulsively Sustainable: Can an Inhibitory Control Training Help Consumers to Reduce Fast Fashion Consumption?

Oliver Büttner, University of Duisburg-Essen, Germany
Benjamin Serfas, University of Duisburg-Essen, Germany
Julia Wilberg, University of Duisburg-Essen, Germany
Saskia Flachs, University of Duisburg-Essen, Germany

We examined whether an inhibitory control training based on a Go/NoGo task can help consumers to buy less fast fashion items. Results show that for impulsive buyers, the Go/NoGo training reduced urge to buy clothing, intention to buy fast fashion, and liking of shopping for clothes.

Social Distancing & Mask-Wearing in Response to COVID-19: How Conflicting Physical and Social Threats Compete to Influence Behavior

Julie Schiro, University College Dublin, Ireland
Lauren Min, University of Kansas, USA

Mask-wearing and social distancing can mitigate the physical threat of COVID-19 but at a social cost (e.g., social judgment). We investigate how people make this tradeoff across two experiments. Our findings have important theoretical implications for classic models of protective behavior and substantive implications for health-related marketing communications.

Animal-Friendly Consumption: Power Begets Responsibility

Sunyee Yoon, University at Buffalo, USA
Danny J. M. Kim, University at Buffalo, USA
Jeffrey P. Boichuk, University of Virginia, USA

This research introduces the construct of animal-friendly consumption and explores the sense of power as a predictor of consumer demand for animal-friendly consumption. We show that feeling powerful increases one's demand for animal-friendly products via perceived responsibility.

Psychological Ownership Increases Subjective Knowledge and Risk-Taking Behavior

Y. Rin Yoon, Cornell University, USA
Suzanne Shu, Cornell, USA

Does owning a free share of stock increase future investment? Psychological ownership of a product increases subjective knowledge and thus risk-taking behavior in product-relevant domains. This is because the ownership of a product induces consumers to overestimate how much they learn from product information.

Better Repeated? Effect of Repetitive Number Price on Bundling

Jintao Zhang, Drexel University, USA
Hongjun Ye, Drexel University, USA
Siddharth Bhatt, Penn State Harrisburg, USA
Haeyoung Jeong, North Carolina Central University, USA
Raj Suri, Drexel University, USA

Our study examines the effect of repetitive numbers on bundling price (i.e., 2 for $2.22 vs. 2 for $$2.12) that consumers have higher intentions to purchase bundling products with repetitive number prices, the ease of processing would explain the effect rather than unit price calculation.

Self-Tracking: Topics, Approaches, and Paths for Researching and Theorizing Consumption

Marina Viotto, FGV EAESP, Brazil
Eliane Brito, FGV EAESP, Brazil
Carole Zanette, NEOMA Business School, France

This article presents preliminary results of a semi-systematic literature review aiming to map the main topics and approaches of studies on the self-tracking phenomenon. The intended contributions reside in showing how research on consumption can benefit from investigating self-tracking and in tracing paths for future studies.

Don't Eat Me: The Interactive Effect of Anthropomorphic Food Characters and Gender on Food Consumption

Jennifer Stoner, University of North Dakota, USA
Rijana Adhikari, University of North Dakota, USA
Michael Covey, University of Minnesota, USA

Our research aims to explore the impact of anthropomorphism on consumption of the food. We find an interaction effect of gender with anthropomorphism where women eat less when presented with an anthropomorphic food character. This effect is not seen in men.

The Less in Luxury: Luxury Consumption and Word-of-Mouth Inhibition

Denny Huynh, Duke University, USA
Tanya Chartrand, Duke University, USA

Luxury consumption allows people to communicate status, expertise, and mate value to observer without having to directly engage the observers, but how do people communicate their luxuries outside of observation and ultimately directly to others? Our work suggest that people downplay their consumption due to impression management concerns.

Asymmetric Variety Seeking in Hierarchical Choices

Akshina Banerjee, University of Chicago, USA
Yuji Winet, University of Chicago, USA

In this project, we investigate whether people differentially seek variety at different hierarchical levels of consumption. We distinguish hierarchical levels from categorizations and show that people are more variety-seeking at higher levels of consumption (e.g., choice between restaurants) but more choice-concentrated at lower levels (e.g. choice between food items).

Covid-19 Fear and Perceived Knowledge: Transition towards Sustainability through Religious Coping

Aysha Batool, Government College University Faisalabad, Pakistan
Rizwan Shabbir, Government College University Faisalabad, Pakistan

The study aims to investigate the impact of Covid-19 fear and perceived knowledge on sustainable consumption behaviour of Muslims through mediating role of religiosity. 417 responses, collected during first country-wide lockdown in Pakistan, are analysed through SEM-Smart PLS. Muslims cope with crisis by inclining towards religiosity and sustainable consumption behaviour

Is a (money) problem shared, a problem halved?

Matt Meister, University of Colorado Boulder, USA
Joe J. Gladstone, University of Colorado Boulder, USA

Does talking about one's money problems reduce financial anxiety? Analyzing 360,398 posts scraped from a web forum, the authors find that financial anxiety falls with the cumulative number of posts made. Consistent results are found in large-scale survey data and preliminary experiments.

Representations of Older Women in Advertising: How Older Women Make Sense of Their Images

Carla Abdalla, Faculdade Armando Alvares Penteado, Brazil
Flavia Cardoso, Universidad Adolfo Ibanez, Chile
Benjamin Rosenthal, FGV EAESP, Brazil

To understand how advertising campaigns portray older women in an aging society and how older women make sense of advertising campaigns, we analyzed 626 advertisements and interviewed 14 women with self-reported ages between 65 and 77 years old. We found two main themes: social body and quality time.

Source Memory is More Accurate for Subjective Claims than for Objective Claims

Daniel J. Mirny, UCLA Anderson School of Management, USA
Stephen A. Spiller, UCLA Anderson School of Management, USA

Recalling the source from which a claim originated (source memory), is an important aspect of consumer decision making. Across six pre-registered experiments (N=2,807) we investigate the effect of claim objectivity on source memory. We find that source memory is more accurate for subjective opinions than for objective factual statements.

(Un-)Ethical Consumer Behavior and Dehumanization – When Wealthy Consumers are Perceived as Less Human

Meikel Soliman, Leuphana University Lüneburg, Germany
Jurgen Willems, WU Vienna, Austria
David Loschelder, Leuphana University Lüneburg, Germany

This article examines morality judgements when (non-)wealthy consumers behave (un-) ethically. Three studies show that individuals morally judge and dehumanize wealthy (vs. non-wealthy) consumers more. While prosocial jobs (vs. non-prosocial jobs) buffer this moral judgment and dehumanization of wealthy consumers, we find no differences for self-achieved wealth (vs. given wealth).

Optimal Algorithm Explanations for Consumer Empowerment and Firm Benefit

Mehdi Mourali, University of Calgary, Canada
Dallas Novakowski, University of Calgary, Canada
Ruth Pogacar, University of Calgary, Canada
Neil Brigden, Bow Valley College, Canada

Algorithms' lack of transparency is often blamed for algorithm aversion in consumers. Two experiments demonstrate that algorithmic explanations can improve behavioral intentions, in addition to perceptions of transparency and empowerment. In particular, participants responded favorably to explanations that highlight concrete and feasible steps for consumers to change their future outcomes.

Not in My Group: Racial Minorities' Enforce Stricter Ingroup Boundaries to Avoid Stereotype-Confirmation

Jorge Rodrigues Jacob, IESEG School of Management, France
Jacqueline Chen, University of Utah, USA

We identify one mechanism by which minority perceivers manage threats to their in-group's reputation: categorization. Across four studies, we show that when perceivers are able to exclude targets who reinforce negative stereotypes about the ingroup, they will do so to maintain the group's public reputation.

Ten Years of Research on Food Well-Being: A Review and Research Agenda

Rodolfo Rocha, University of São Paulo, Brazil
Andres Veloso, University of São Paulo, Brazil

In 2011, Block et al. proposed the concept of food well-being (FWB). Several studies were inspired by FWB, approaching it with different lenses. This systematic review aims to contribute to both the FWB and consumer behavior literature by identifying the advances in FWB research and indicating directions for future studies.

Racial Discrimination toward AAPIs and their Resilience Building: Online and Offline Discrimination and Social Support

Sanga Song, Indiana University East, USA
Hyejin Kim, DePaul University, USA

Drawing on minority stress theory and the resilience conceptual framework, we tested a model describing the impact of online and offline discrimination, as race-based stress factors, and of social support, as a protective factor, on the psychological distress of individuals in the AAPI community during the COVID-19 pandemic.

The Language of Apologies in Responses to Customer Reviews

Shereen Chaudhry, University of Chicago, USA
Akshina Banerjee, University of Chicago, USA

We use natural language processing to examine the linguistic features of apologies in manager responses to online customer reviews. We ask what features are essential for a response to be perceived as an apology by third-party observers. Further, we examine the relationship between apologies and customer satisfaction with the response.

Organizing Subcultural Lives and Mobilizing them into Social Movements: Through the Lens of Critical Performativity

Emre Ulusoy, Youngstown State University, USA
Handan Vicdan, Emlyon Business School, France

Drawing on critical performativity, we articulate the subcultural organization and mobilization process of alternative music consumers into social movements and transformations towards social change.

You Are What You Use? Perceptions of Consumers Using Digital versus Analog Goods

Han Young Jung, University of Minnesota, USA
Kathleen Vohs, University of Minnesota, USA

The current research investigates a variety of qualities people infer from a person using digital versus analog products. Two studies (*N*=244) showed that participants perceived a person using digital (versus analog) products as lower in patience, tolerance, ethicality, trustworthiness, reliability, and expertise.

Mindful Consumption Mediates Effect of Mindfulness on Life Satisfaction

Sharad Gupta, Delhi School of Business, VIPS-TC, India
Harsh Verma, University of Delhi, India

We establish the mediating role of mindful consumption in the relationship between mindfulness and life satisfaction by analyzing competing models for moderation (three models), moderated mediation (two models), and post-hoc analyses (three models) using Hayes' Process for Path Analysis. Gender, household income, and socioeconomic status do not impact results.

A Primer and Case Study on What EEG Can Do for Marketing Research

Oriana Aragon, Wilbur O. and Ann Powers College of Business, Clemson University, USA

Marketers expend valuable resources studying consumer behavior through neuromarketing. Electroencephalogram (EEG) investigations have thus far gauged consumers' preferences for presented products. However, EEG offers more utility than product choice from preference. Here we provide a tutorial on EEG classifications, capabilities, and provide information into the practical application of this technology.

Do Consumers Want to be Close With all Their Most Preferred Brands?

Luis Abreu, Duke University, USA
Gavan Fitzsimons, Duke University, USA

Marketers want their brands to have close consumer-brand relationships. But, do consumers want to be close with all their brands? Across a wide variety of categories, we find consumers do not always develop close relationships with their most preferred brands. We explore possible reasons using natural language processing techniques.

Do You Have a Reservation? How Consumer Privacy Concerns Jeopardize Online Tourism Agencies Evaluation

Stéphane Bourliataux-Lajoinie, CNAM, France
Julien Cloarec, IAE Lyon School of Management, Université de Lyon, France

The Dutch Data Protection Authority has fined Booking.com 475,000 euros for late notification of a leak of personal data, following a phone scam in December 2018. We show that ease of use strengthens the indirect effect that runs from privacy concerns to the service evaluation, via trust/risk beliefs.

The Effect of Image Color Saturation and Framing on Prosocial Behavior

Yiping Li, University of Massachusetts Lowell, USA

Low saturation signals deprivation and weakness, whereas high saturation signals rigor and power. Accordingly, we find that when prosocial messages are hope-framed, higher image color saturation elicits greater intentions for prosocial behavior. However, prosocial messages framed as need elicit higher prosocial behavior intentions when they use low color saturation.

Consumer Vulnerability to Resilience: Resource Integration by COVID-19 Survivors in India

Sumit Saxena, Indian Institute of Technology Ropar, India
Amritesh Amritesh, Indian Institute of Technology Ropar, India

This research explores the nature of COVID-19 induced vulnerability among healthcare consumers and analyzes their resource integration practices in their process of recovery and well-being by using a 'passive netnography' approach. The study reveals three critical situational factors of consumer vulnerability and the primary operant resources used to address those.

Genderation of LGBTQ+ Identity in the Digital Marketplace

Gillian Oakenfull, Miami University, USA

This research draws from queer theory, social identity theory, and generation theory to explore the construct of *Genderation*, generational differences in sexual and gender identity and expression that exist within the LGBTQ consumer population. A conceptual model is proposed that identifies socio-cultural antecedents of Genderation. Marketplace implications are also considered.

AI is Blamed More Than Humans When it Falters, But Less so When it Discriminates

Tripat Gill, Wilfrid Laurier University, Canada
Sakshi Korde, Wilfrid Laurier University, Canada
Shirley (Shuo) Chen, Wilfrid Laurier University, Canada

While people are reluctant to use AI (artificial intelligence)-based decision agents, little research has examined blame assignment when such agents falter. In two studies, we find that while AI agents are generally blamed more than humans for adverse outcomes, they garner lesser blame and lower moral outrage for discriminatory behaviour.

Fairness in Joint Consumption Decision Making

Nikkita Sarna, University of Texas at Austin, USA
Andrew Gershoff, University of Texas at Austin, USA

We examine how a desire to be perceived as fair can interplay into joint consumption decision making. Four studies (n=~800) show evidence for this concern as consumers purposefully chose to avoid their preferred alternatives when making decisions for shared experiences, even without knowledge of others' preferences.

Toward Financially Accountable Brand Awareness Building: Predicting the Effects of Altering Brand Recall on Choices

Siyana Hristova, University of California, Berkeley, USA
Zhihao Zhang, University of California, Berkeley, USA
Ming Hsu, University of California, Berkeley, USA

We present an ongoing study that aims to quantitatively predict how changes in brand awareness translate into brand choices, based on a newly-developed formal model of memory-based choices. Findings can have significant implications for marketers who face increasing pressure to justify the financial return on marketing investments.

How Bundling Messages Increase the Likelihood of Going Back to Checkout

Lina Xu, New Mexico State University, USA
Mihai Niculescu, New Mexico State University, USA

How do marketers improve the shopping cart abandonment rate? This research offers a novel approach—using the proportionality of the prices to create dynamic product bundles. Two ongoing studies demonstrate that percentage-framed price changes can ease shoppers' pain of paying and increase their likelihood of going back to checkout.

Tracking Comfort with Interpersonal Touch Over Time: The Effect of #MeToo and COVID-19 on Preferences for Touch

Andrea Luangrath, University of Iowa, USA
Suyeon Jung, University of Wisconsin-Madison, USA
Joann Peck, University of Wisconsin-Madison, USA

Compiling data from 30 studies conducted between 2011-2021 (N = 12,391), we track individual's comfort with interpersonal touch (CIT) over time. We observe that comfort with both initiating and receiving touch decrease significantly after #MeToo (more severely for women) but not further after COVID-19.

Critical Discourse Analysis on Public Advertisements on Minoritized Communities in Milwaukee

Francisco Hernandez, Marquette University, USA
Kevin Thomas, Marquette University, USA

Employing a critical discourse analysis this study appraises the level of racial and cultural sensitivity contained in Milwaukee County Transit System advertisements depicting minoritized consumers. These ads represent a pervasive form of social communication and should project consumer racial and cultural acuity; however, our preliminary findings suggest otherwise.

You Look Like a Man: A Look at Prescriptive Notions Regarding Femininity in the Fitness Culture

Javier Contreras, University of Birmingham, UK

This research aims at understanding the consequences of body image promoted by fitness mainstream culture on body self-perception and women's self-appreciation, the notion of the ideal "feminine" body and the potentially negative stereotypes derived from it by analysing the interaction in social media platforms and through in-depth interviews.

Probability or Outcome - The Importance of Emphasis Framing in Healthcare Messages

Arslan Javed, ESSEC Business School, France
Reetika Gupta, ESSEC Business School, France

Our research underscores the importance of emphasis framing in health communication by examining the competing role of two disease attributes (probability, outcome) for diseases associated with uncertainty. We recommend to policymakers that health messages should focus on the probability of contracting a disease to promote preventative health behaviors (e.g., vaccination).

A Political Body without Place: Feminist Experiences in Suspension

Karla Angelkorte, COPPEAD UFRJ, Brazil
Leticia Casotti, UFRJ, Federal University of RIo de Janeiro, Brazil

This ethnographic study explores the process of de-domestication through feminist experiences cycles resulted from a constant search for emancipation until the suspension generated by the virtualization of experiences. This search guided through collective experiences loose meaning in a domestic space with technologies in a social isolation context.

Resource Scarcity Decreases Ethical Behavior

Todd Haderlie, Florida International University, USA
Jaehoon Lee, Florida International University, USA

We identify a novel relationship between scarcity and ethical behavior. When resource scarcity is made salient, consumers engage in less ethical behavior. Furthermore, the effect of resource scarcity on ethical behavior is stronger for consumers with high (vs. low) levels of the inclusion of others in the self (IOS).

Consumers' Perceptions of Corporate Communications

Hyebin Kim, Washington University in St.Louis, USA
Sydney Scott, Washington University in St Louis, USA
Rachel Gershon, San Diego, USA

Sellers regularly communicate with customers to build relationships. For thank you notes and apology notes, we find that notes from an individual seller are evaluated more positively than notes from a company. However, when a gift is included with the note, notes from individual sellers and companies are evaluated similarly.

Social Acceptance Scoring: First Steps Towards a Novel Quantification of Acceptance in Transitive Sectors

Regina Mukhamedzyanova, Faculty of Business Administration and Economics
Heinrich-Heine-Universität, Universitätsstraße 1, 40225 Düsseldorf, Germany
Nadine R. Gier, Faculty of Business Administration and Economics
Heinrich-Heine-Universität, Universitätsstraße 1, 40225 Düsseldorf, Germany

Social acceptance is crucial within transitive sectors to establish a change within society. However, the quantity and quality of social acceptance especially in transitive sectors are only roughly quantifiable. Drawing on acceptance theory, a Social Acceptance Scoring (SAS) is conceptually defined, providing an innovative framework of acceptance across multiple dimensions.

Danger!? The Effect of Color Red on Construal Level.

Xiaolei Su, City University of Hong Kong, Hong Kong
Nakaya Kakuda, City University of Hong Kong, Hong Kong
Hisashi Kawamata, Waseda University, Japan
Yves Dupuis, Concordia Universiy, Canada

This research investigated the effect of color (red vs blue) on construal level. Surprisingly, results were inconsistent with prior research which suggests that red background should lead to concrete construal when answering an online survey. Two studies from different cultures are employed.

Moral Emotion Laden Markets: A Study of Market Participants Seeking Donor-Assisted Conception

Anna Hartman, University of Melbourne, Australia
Eileen Fischer, York University, Canada

This paper illuminates the institutional factors contributing to a market laden with moral emotions by studying the experiences of consumers undertaking donor-assisted conception in the United States. We highlight how consumers in this market engage in *emotion-legitimacy work* to shape evaluations (legitimacy judgments) and associated emotions involved in market participation.

Brief Intervention for Changing Negative Attitudes Toward Opioid Agonist Treatment within Criminal Justice System: Results from a Pilot Study in Ukraine.

Maxim Polonsky, Yale University, USA

Our brief intervention targets attitude change via a perceived ownership of a solution to a problem, where the investment of time in a brief problem-solving task results in psychological ownership of ideas. Our intervention improved attitudes toward evidence-based treatment for substance abuse disorders among criminal justice personnel in Ukraine.

Seeing is Believing: The Impact of Transparency of Electronic Product Design on the Product Evaluation

Keyin Liang, Zhejiang University, China
Lili Wang, Zhejiang University, China

People are interested in how electronic products work. We find that transparency of electronic product design increases consumers' purchase intention and this effect is mediated by perceived product efficacy. We also identify two moderators: type of product and product orientation to provide practical implications.

How to Undo the Beautiful is Good Stereotype: Get Familiar with Ugly Produce

Angela King, University of California, Irvine, USA
Loraine Lau-Gesk, University of California, Irvine, USA

This research examines factors that help consumers undo the 'beautiful is good' stereotype when fresh produce shopping. Findings suggest that high familiarity enables consumers to ignore good looks. In contrast, low familiarity breeds ignorance. Consumers with more (vs. less) cognitive resources believe that pretty (vs. ugly) produce tastes better.

Motivating Consumers to Reduce Their Smartphone Screen Time

Yusu Wang, University of Chicago Booth School of Business, USA
Chuck Howard, Texas A&M, Mays Business School, USA

Consumers underestimate their smartphone screen time. Making this perception-reality gap salient increases motivation to reduce screen time more than only making reality salient. Greater motivation to reduce screen time is associated with lower planned screen time, and lower planned screen time is associated with lower actual screen time.

Self-image on the Line: How Face Payment Fosters Self-regulation in Making Healthier Food Choice

Lifeng Yang, ShanghaiTech University, China
Guangxin Xie, University of Massachusetts Boston, USA
Yuhao Lu, ShanghaiTech University, China

Two field experiments provide preliminary evidence that the current face payment technology could activate one's healthy consumption intention, rendering individuals to choose healthier food options more likely. When a cognitive load is implemented simultaneously in the face payment process, this effect above dissipates, suggesting that self-attentiveness mediates the process above.

Customer Preferences for Face Masks Reveal Trade-offs between COVID-19 Safety and Emotional Communication

W. Craig Williams, Fox School of Business, Temple University, USA
Chelsea Sposit, Fox School of Business, Temple University, USA
Vinod Venkatraman, Fox School of Business, Temple University, USA

Face masks have proven vital for reducing the spread of COVID-19, but little is known about how masks impact consumer interactions. Over two pre-registered studies, participants preferred that employees wear masks when showing neutral versus happy expressions—via increased satisfaction and tipping—revealing trade-offs between safety and emotional communication.

Examining Role of Anthropomorphism in Customer Switching Behavior

Gurbir Singh, Indian Institute of Management Amritsar, India
Archit Vinod Tapar, Indian Institute of Management Rohtak, India

This study investigates the moderating role of anthropomorphism in the relationship between service failure (low vs. high severity) and switching in a post-failure context. The results showcase a dual effect of anthropomorphism, where it reduces the switching behaviour in low-severity condition and enhances the switching behaviour in high-severity condition.

Doing Green or Buying Green? Differential Effects of Pro-Environmental Activities on Self-Signaling

Marie Ozanne, Cornell University, USA
Helen Chun, Cornell University, USA

Both "doing" and "buying" green (recycling or buying recycled materials) are activities helping to protect the environment. Across different green actions and purchases, we find that doing (vs. buying) green leads consumers to take more credit for their green contribution and create positive signals to the self and others.

Pro Equality Behaviors in Marketing, Anti-Racism Matters

Ania Rynarzewska, Mercer University, USA

Consumer hyper exposure to media mid-pandemic drew consumer's attention to most problems with still ever prevalent racism and inequality. This study provides evidence for support of social justice and equality regardless of race in organizational marketing practices to benefit organization and the world.

Effect of Price Change Allocation in Multidimensional Pricing on Consumers' Price Perceptions

Igor Makienko, University of Nevada Reno, USA
James Leonhardt, University of Nevada Reno, USA

In this paper we investigate how allocation of price change among different pricing components affects consumers' perceptions of such changes. We limit our investigation to a situation when a company offers products with shipping and handling fee. We build our conceptual framework based on partitioning pricing and bundling pricing literature.

Film Festival 2021

The Personal Benefits of Seeking Out Wildlife Encounters: Birdwatching

Ai Nhan Ngo, University of Texas Rio Grande Valley, USA
Ross Murray, University of Texas Rio Grande Valley, USA
Michael Minor, University of Texas Rio Grande Valley, USA

This film explains consumers' personal benefits from birdwatching as a hobby or lifestyle and extends biophilia hypothesis (Wilson, 1984) and attention restoration theory (Kaplan & Kaplan, 1989). The 15 interviews reveal several important themes: purpose, joy, exercise and social activities, camaraderie with others, and peace.

Violence Against Doctors: A customer incivility perspective

Rajesh Chandwani, Indian Institute of Management Ahmedabad, India

This videography attempts to understand the phenomenon of customer incivility against employees in healthcare services by providing a processual analysis of violence against doctors based on doctors' perspectives. The study furthers our understanding about prevention of aggressive customer behaviour in the healthcare- an under-researched area.

A Manhattan Spring Chronicle: The untold Maslow story of COVID-19

Iris Mohr, St. John's University, USA

The film, A Manhattan Spring Chronicle: The Untold Maslow Story of Covid-19, takes place in New York City during Spring 2020. As the Maslow hierarchy of needs is reflected on, the film seeks to answer through observation and media footage whether the theory holds up considering the pandemic.

The Intersections of Food, Health, Poverty, and Dignity

Sharon Schembri, Fisk University, USA

This study focuses on food consumption for impoverished consumers and aims to contribute to research on vulnerable consumers. A visual ethnographic research design includes 20 onsite interviews and participant observation. A short film documents the findings demon-stratiing the intersections of food, health, poverty, and dignity.

Cultured Meat in Singapore: The Moral and Practical Paradoxes

Cindy Ho, National University of Singapore, Singapore
Emilea Teo, National University of Singapore, Singapore
Sean Chaidaroon, National Univeristy of Singapore, Singapore

This video presents interviews with prospective consumers, a vegetarian food seller and experts to elicit their receptivity and concerns of cultured meat. As the first country to approve cultured meat for sale, these interviews enliven local Singaporean voices in sharing their genuine perspectives on the consumption of scientifically invented meat.

Luxury in Flux: An Examination of Producer and Consumer Perceptions Amidst COVID-19

Moumita Gyomlai, Ohio University, USA
Jacob Hiler, Ohio University, USA

This film explores the changing definitions and perceptions of luxury amidst the worldwide pandemic from the viewpoint of both consumers and producers through a hermeneutic and phenomenological lens. It aims to uncover shifting consumer mindsets and how these effects will continue to change the luxury industry in a post-pandemic world.

Time Compression: A Rhythmanalysis of a Consumer's Everyday Life

William Walczak, University of British Columbia, Okanagan, Canada
Seger Nelson, University of British Columbia, Okanagan, Canada
Eric Li, University of British Columbia, Okanagan, Canada

This experimental documentary employed Lefebvre's rhythmanalysis approach to showcase a time-compressed consumer's everyday life. While brands and consumer goods have become indispensable components of our work-home-social lives, our film illustrated the vulner-ability and mundanity aspects of our consumer society.

Knowledge Forums

FORUM
Let's Get Digital: A Virtual Knowledge Forum on Marketing in the Age of Digitalization and Artificial Intelligence

Chairs:
Gizem Yalcin, Rotterdam School of Management, Erasmus University, Netherlands
Gil Appel, George Washington University, USA
Andrew Stephen, University of Oxford, UK
Markus Giesler, York University, Canada
Wendy Moe, University of Maryland, USA
Das Dasgupta, University of Southern California, Saatchi & Saatchi, USA
Christ George, Subscription Trade Association
Amanda Mizrahi, Edelman
Pamela Dunaway, Marketing Science Advisors, USA
Emmanuel Frankforter, Contilt, Israel

The digital age has driven an unparalleled expansion of human knowledge, both in academia and the practice. This forum brings together a panel of academics and practitioners to discuss the latest insights on digital marketing and try to identify potential gaps between theory and practice.

FORUM
How to Do Automated Text Analysis

Chairs:
Jonah Berger, Penn, USA
Grant Packard, Schulich School of Business, York University, Canada
Ming Hsu, University of California, Berkeley, USA
Matthew Rocklage, University of Massachusetts Boston, USA
Ashlee Humphreys, Northwestern University, USA
Gideon Nave, The Wharton School of the University of Pennsylvania, USA
Andrea Luangrath, University of Iowa, USA
Sarah Moore, University of Alberta, Canada
Christopher Olivola, Carnegie Mellon University, USA
Michael Yeomans, Imperial College London,UK

More and more consumer research is leveraging automated textual analysis. But doing so correctly requires understanding the available tools, and how they can be applied. This forum provides a helpful how-to, covering some main techniques, how to use them, and how they can be applied to a variety of questions.

Forum
Marketplace Exclusion of Financially Vulnerable Consumers

Chairs:
Anastasiya Pocheptsova Ghosh, University of Arizona, USA
Jenny Olson, Indiana University, USA
Sydni Do, University of Arizona, USA
Kate Barasz, Univ. Ramon Llull, ESADE, Spain
Wendy De La Rosa, University of Pennsylvania, USA
Rebecca W Hamilton, Georgetown University, USA
Ron Hill, American University, USA
Erick Mas, Indiana University, USA
Taylor Nelms, Filene Institute, USA
Mike Palazzolo, University of California, Davis, USA
Vanessa Perry, George Washington University, USA
Maura Scott, Florida State Universi, USA
Eesha Sharma, Dartmouth College, USA
Steven Shepherd, Oklahoma State University, USA
Dilip Soman, University of Toronto, Canada
Broderick Turner, Virginia Tech, USA
Steve Wendel, MorningStar, USA
Kalinda Ukanwa, University of Southern California, USA

This Forum examines the unique consumption barriers that financially vulnerable consumers encounter in the marketplace, and how these barriers affect consumers' financial access and decision-making. Academic and industry researchers will further discuss novel solutions to improve marketplace outcomes for consumers themselves, marketers, and policy makers.

Forum
What the World Needs Now: Better Marketing for a Better World

Chairs:
Gita Johar, Columbia University, USA
Shilpa Madan, Virginia Tech, USA
Jonah Berger, Penn, USA
Pierre Chandon, INSEAD, France
Rebecca W Hamilton, Georgetown University, USA
Leslie John, Harvard Business School, USA
Aparna Labroo, Northwestern University, USA
Peggy Liu,, University of Pittsburgh, USA
John Lynch, University of Colorado, USA
Nina Mazar, Boston University, USA
Nicole Mead, York University, Canada
Vikas Mittal, Rice University, USA
Michael Norton, Harvard Business School, USA
Dilip Soman, University of Toronto, Canada
Madhu Viswanathan, University of Illinois at Urbana-Champaign, USA
Katherine White, University of British Columbia, Canada
Rajesh Chandy, London Business School, UK
Christine Moorman, Duke University, USA
John Roberts, University of New South Wales, Australia

The gap between what marketing has studied and what marketing can do for improving people's lives remains substantial (Chandy et al. 2021). In conversation with senior researchers, this knowledge forum leverages a novel format to identify the anatomy of impactful papers that seek to make the world a better place.

FORUM
Children as Consumers: Past and Future Research Directions

Chairs:
Margaret Echelbarger, University of Chicago Booth School of Business, USA
Michal Maimaran, Kellogg School of Management, Northwestern University, USA
Lan Chaplin, University of Illinois at Chicago, USA
Deborah John, University of Minnesota, USA
Mary McIlrath, University of Illinois, USA
Sophie Nicklaus, Centre for Taste and Feeding Behavior, INRAE, France

Children are consumers, yet, compared to adults, we know relatively little about their consumption experiences. We bring together marketing scholars working with children to discuss the state of child consumer behavior literature, identify opportunities to collaborate and complement each other's work, and highlight best practices for working with children.

FORUM
Mental Health Matters: Making Mental Well-Being a Marketing Research Priority.

Chairs:
Jane Machin, Radford University, USA
Ann Mirabito, Baylor University, USA
Elizabeth Crosby, University of Wisconsin-Lacrosse, USA
Natalie Adkins, Drake University, USA
Justine Farrell, University of San Diego, USA

Millions suffer from mental illness every year and the mental wellness economy is booming, but research from marketing academics on mental health is scarce. In this Knowledge Forum, discover why our field should care about mental well-being in the marketplace and explore techniques to study this important group of consumers.

FORUM
Beyond Beauty: How Can Aesthetics and Design Be Leveraged to Enhance Consumer and Societal Wellbeing?

Chairs:
Freeman Wu, Vanderbilt University, USA
Martin Reimann, University of Arizona, USA
Luca Cian, University of Virginia Darden School of Business, USA
Xiaoyan Deng, The Ohio State University, USA
Linda Hagen, University of Southern California, USA
Henrik Hagtvedt, Boston College, USA
Kelly B. Herd, University of Connecticut, USA
Yuwei Jiang, Hong Kong Polytechnic University, Hong Kong
Page Moreau, University of Wisconsin-Madison, USA
Vanessa M. Patrick, University of Houston, USA
Laura Peracchio, University of Wisconsin-Milwaukee, USA
Adriana Samper, Arizona State University, USA
Maura Scott, Florida State University, USA
Julio Sevilla, University of Georgia, USA
Claudia Townsend, University of Miami, USA

This knowledge forum explores novel ways in which aesthetics and design can be leveraged to improve consumer decision-making, particularly in substantively important domains such as aesthetics-based nudges, consumer-technology interactions, and inclusive design. This forum aims to provide an opportunity to generate new research ideas related to these topics.

Forum
Fields of Gold: Generating Relevant and Credible Insights Via Web Scraping and APIs

Chairs:
Johannes Boegershausen, Erasmus University Rotterdam, Netherlands
Abhishek Borah, INSEAD, France
Hannes Datta, Tilburg Universty, Netherlands
Andrew Stephen, University of Oxford, UK

</div>

Researchers increasingly use publicly available web data to examine consumer research questions. Much of the design decisions involved in collecting web data have remained neglected and undiscussed. This knowledge forum highlights the key design decisions that help to maximize the relevance and credibility of research findings based on web data.

Linda Price, University of Wyoming, USA
Grant Donnelly, The Ohio State University, USA
Silvia Bellezza, Columbia Business School, USA
Karen Fernandez, University of Auckland, New Zealand

</div>

Marketers encourage consumers to buy products to express their identities but think relatively little about how consumers will get rid of these products. Processing excess products place a massive burden on the environment (e.g., decomposition) and on consumers' personal lives (e.g., hoarding, taking up living space). We will host a panel discussion around the topic of how consumers dispose of their used, but still useful material possessions. We will divide the time into a discussion of the research issues, opportunities and challenges in three subtopics.

The first subtopic is: What is product disposition and why is it important?

The majority of extant marketing literature has focused on strategies to help firms attract and persuade consumers to *buy* products and engage in *repeat* purchases. However, very few products get completely consumed such as water and food. The interesting problem that emerges is how to motivate consumers to keep used items out of the landfill.

The second subtopic emphasizes how individual differences (loneliness, social isolation, and age) affect material attachment and disposition decisions. Material attachment varies in intensity and reflects the relationship between an individual and a specific material object. Individual differences such as loneliness and social isolation may explain why some people become more attached to objects than others.

Finally, we'll discuss a third managerial sub-topic about interventions. Interventions, such as encouraging consumers to take pictures or to adopt a fresh start mindset, may work better at influencing disposition decisions than current practice.

Forum
Studying Race in Marketing: Making Race More Than A Variable We Collect

Chairs:
Marcel Rosa-Salas, University of Illinois at Chicago, USA
Broderick Turner, Virginia Tech, USA
Esther Uduehi, University of Washington, USA

</div>

This forum considers new conceptualizations for the study of race, consumer behavior, the structure of markets, and marketing industry practices. Through current research projects and interactive discussion, panelists will showcase race-related research and tools to inform marketers on handling race-focused issues within business.
